Land Acknowledgment

This border around what is colonially known as Pennsylvania represents a tragic and unjust history. We acknowledge the Lenape, Munsee, Susquehannock, Osage, Erie, Massawomeck and Haudenosaunee Tribes, among others, on whose ancient and sacred land we hold this conference. As a PME-NA community we recognize the ever-present systemic inequities that stem directly from past wrongdoings, and we commit ourselves indefinitely to respecting and reconciling this long history of injustice.

PME-NA History and Goals

PME came into existence at the Third International Congress on Mathematical Education (ICME-3) in Karlsrühe, Germany, in 1976. It is affiliated with the International Commission for Mathematical Instruction. PME-NA is the North American Chapter of PME. The first PME-NA conference was held in Evanston, Illinois in 1979. Since their origins, PME and PME-NA have expanded and continue to expand beyond their psychologically-oriented foundations.
The major goals of the International Group and the North American Chapter are:

1. To promote international contacts and the exchange of scientific information in the psychology of mathematics education;
2. To promote and stimulate interdisciplinary research in the aforesaid area, with the cooperation of psychologists, mathematicians, and mathematics teachers; and
3. To further a deeper and better understanding of the psychological aspects of teaching and learning mathematics and the implications thereof.

PME-NA Membership

Membership is open to people who are involved in active research consistent with PME-NA's aims or who are professionally interested in the results of such research. Membership is open on an annual basis and depends on payment of dues for the current year. Membership fees for PME-NA (but not PME International) are included in the conference fee each year. If you are unable to attend the conference but want to join or renew your membership, go to the PME-NA website at http://pmena.org. For information about membership in PME, go to http://www.igpme.org and visit the "Membership" page.

PME-NA Steering Committee

Elected Members
Julie Amador (chair), *University of Idaho,* jamador@uidaho.edu
José Martínez Hinestroza, *Texas State University*
Alyson E. Lischka, *Middle Tennessee State University*
Jennifer Holm, *Wilfrid Laurier University*
Oyemolade (Molade) Osibodu, *York University*
Ana Isabel Sacristán, *Center for Research and Advanced Studies (Cinvestav)*
María S. García González, *Universidad Autónoma de Guerrero*
Karl Kosko, *Kent State University*
Jessica Hunt, *North Carolina State University*

Appointed Members
Aaron Brakoniecki (webmaster), *Boston University*, brak@bu.edu
Ji-Yeong I (treasurer), *Iowa State University*, jiyeongi@iastate.edu

Conference Chairs

Past Conference Co-Chairs (2018–2021)

Ana Isabel Sacristán
Center for Research and Advanced Studies (Cinvestav), Mexico
asacrist@cinvestav.mx

José Carlos Cortés-Zavala
AMIUTEM / Universidad Michoacana de San Nicolaìs de Hidalgo, Mexico
jcortes@umich.mx

Current Conference Co-Chairs (2019–2022)

Sandy Spitzer
Towson University
sspitzer@towson.edu

Dana Olanoff
Widener University
dolanoff@widener.edu

Kim Johnson
West Chester University of Pennsylvania
Kjohnson2@wcupa.edu

Future Conference Co-Chairs (2020–2023)

Alyson Lischka
Middle Tennessee State University
Alyson.Lischka@mtsu.edu

Jeremy Strayer
Middle Tennessee State University
jeremy.strayer@mtsu.edu

Elizabeth Dyer
University of Tennessee Knoxville
edyer8@utk.edu

Jennifer Lovett
Middle Tennessee State University
Jennifer.Lovett@mtsu.edu

Ryan Seth Jones

Ryan.Jones@mtsu.edu

Olanoff, D., Johnson, K., & Spitzer, S.M. (2021). *Proceedings of the forty-third annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Philadelphia, PA.

2021 PME-NA Local Organizing Committee

Sandy Spitzer, Towson University (Chair)
Dana Olanoff, Widener University (Co-Chair)
Kim Johnson, West Chester University (Co-Chair)

Kimberly Corum, Towson University (Technology Coordinator)

Graduate Assistants:
Rachael Talbert, Towson University
Kayla Begen, Towson University
Sarah Gill, West Chester University

Volunteers

The Local Organizing Committee is very grateful to the team of volunteers who helped make the conference possible and facilitated interactions between in-person and virtual participants.

Conference Volunteers

Ruby Ellis, *North Carolina State University*
Allison Gantt, *University of Delaware*
Beth MacDonald, *Utah State University*
Matthew Melville, *University of Delaware*
Rachael Talbert, *Towson University*
Karen Zwanch, *Oklahoma State University*

Discussion Session Leaders

Ayman Aljarrah, *Acadia University*
Kimberly Corum & Rachael Talbert, *Towson University*
Carlos Nicolas Gomez Marchant & Stacy R. Jones, *University of Texas*
Crystal Kalinec-Craig, *University of Texas-San Antonio*
Alexa W.C. Lee-Hassan, *University of Illinois Chicago*
Samuel Otten, *University of Missouri*
Sam Prough, *University of Delaware*
Amanda Reinsburrow, *Drexel University*
Rachel Tremaine, *Colorado State University*
Bima Sapkota, *Purdue University*
Caro Williams-Pierce, *University of Maryland*

Session Facilitators

Denish Akuom, *Montclair State University*
Nigar Altindis, *University of New Hampshire*
Carrie Bala, *Utah State University*
Erin Baldinger, *University of Minnesota*
Mona Baniahmadi, *Duquesne University*
Brianna Bentley, *North Carolina State University*
Steven Boyce, *Portland State University*
Lori Burch, *Indiana University*
Rob Ely, *University of Idaho*
Nicole M. Wessman-Enzinger, *George Fox University*
Ben Freeburn, *Western Michigan University*
Julia St. Goar, *Merrimack College*
Steven Greenstein, *Montclair State University*
Lisa Hawley, *Michigan State University*
Jose Martinez Hinestroza, *Texas State University*
Jenifer Hummer, *West Chester University of Pennsylvania*
Michelle Morgan King, *Western Colorado University*
Keith Leatham, *Brigham Young University*
Beth MacDonald, *Utah State University*
Allison McCulloch, *University of North Carolina at Charlotte*
Alesia Mickle Moldavan, *Fordham University*
Chelsea Muhs, *Portland State University*
Nirmala Naresh, *University of North Texas*
Olanrewaju Oriowo, *University of North Carolina at Charlotte*
Blake Peterson, *Brigham Young University*
Luke Reinke, *University of North Carolina at Charlotte*
Gizem Solmaz, *Florida State University*
Megan Staples, *University of Connecticut*
Irma Stevens, *University of Michigan*
Shari Stockero, *Michigan Technological Universit*y
Travis Weiland, *University of Houston*
Xiangquan Yao, *The Pennsylvania State University*
Karen Zwanch, *Oklahoma State University*

Strand Leaders

The Local Organizing Committee is extremely appreciative of the following people for serving as Strand Leaders. They managed the reviewing process for their strand and made recommendations to the Local Organizing Committee. The conference would not have been possible without their efforts.

Neet Priya Bajwa, *Illinois State University*
Pavneet Kaur Bharaj, *Indiana University Bloomington*
Brian Bowen, *West Chester University of Pennsylvania*
Charity Cayton, *East Carolina University*
Lara Dick, *Bucknell University*
Heather Gallivan, *Northern Iowa University*
María S. García González, *Universidad Autónoma de Guerrero*
Maureen Grady, *East Carolina University*
Duane Graysay, *Syracuse University*
José Martínez Hinestroza, *Texas State University*
Charles Hohensee, *University of Delaware*
Melike Kara, *Towson University*
Shiv Karunakaran, *Michigan State University*
Monica Karunakaran¸ *Michigan State University*
Signe Kastberg, *Purdue University*
Erika Litke, *University of Delaware*
Valerie Long, *Indiana University of Pennsylvania*
Jennifer Lovett, *Middle Tennessee State University*
Sararose Lynch, *Westminster College*
Marta Magiera, *Marquette University*
Allison McCulloch, *University of North Carolina at Charlotte*
Susanna Molitoris Miller, *Kennesaw State University*
Emily Miller, *West Chester University of Pennsylvania*
Cody Patterson, *Texas State University*
Christine Phelps-Gregory, *Central Michigan University*
Priya Prasad, *University of Texas – San Antonio*
Patrick Sullivan, *Missouri State University*
Barbara Swartz, *West Chester University of Pennsylvania*
Jennifer Ward, *Kennesaw State University*
Robert Wieman, *Rowan University*
Xiangquan Yao, *Pennsylvania State University*

Reviewers

Likewise, the Local Organizing Committee is also very appreciative of the following colleagues for peer-reviewing submissions to the conference:

Abbaspour Tazehkand, Shahabeddin

Preface

Dear Colleagues,

On behalf of the 2021 PME-NA Steering Committee, the PME-NA 43 Local Organizing Committee, Towson University, Widener University, and the West Chester University of Pennsylvania, we welcome you to Philadelphia, Pennsylvania, USA, for the Forty-Third Annual Meeting of the International Group for the Psychology of Mathematics Education – North American Chapter, held at the Sheraton Philadelphia Downton and virtually.

This year's conference theme is **Productive Struggle: Persevering through Challenges**. The years of 2020-2021 brought a global pandemic and with it, many challenges for mathematics education research. Public schools faced a sudden and prolonged transition to distance education, while higher education experienced a budget crisis as well as the loss of in-person classes and traditional field experiences for teacher education. Many researchers and their communities have encountered unforeseen difficulties including personal or family illness, employment loss, and dramatically increased caregiving responsibilities, all of which fell disproportionately onto already-vulnerable populations. Meanwhile, demonstrations for racial justice highlighted the insidious effects of racism throughout our society. All these challenges reflect long-term issues, while highlighting and uncovering the effects of centuries of unjust structures and systems.

By choosing the theme of *persevering through challenges*, and in Philadelphia, a city which has historically represented an optimistic spirit and a belief in a better tomorrow, we aim to encapsulate an idea of hope towards the future: that through struggle, and through scholarly work, engagement in our community, and sustained effort towards improvement, we can truly make a difference in the lives of teachers and students, and in mathematics education broadly in continent of North America.

We hope this conference serves to provoke learning through productive struggle and to support our field in persevering through these continuing challenges in mathematics education. In particular, we hope that this conference can serve as a model and precedent for implementing a hybrid research conference. Early in the process of planning PME-NA43, we committed to the idea of a fully hybrid conference with the guiding principle that all opportunities should be equally available to both in-person and virtual participants. Each of the 3 plenary talks, 15 working groups or research colloquia, 160 research sessions (presenting a total of 239 papers), and 121 poster presentations are available for live participation and interaction between in-person and virtual participants.

This year's conference will be attended (either in-person or virtually) by more than 640 researchers, faculty members, and graduate students from around the world including Canada, Mexico, Australia, Israel, Cameroon, and across the USA. Each paper was reviewed by multiple referees in an anonymous review process. The result was an overall acceptance rate of 79% of papers accepted in some form (not necessarily in the form in which they were submitted), with 37% of research report submissions accepted as research reports, 48% of brief research report submissions accepted as brief research reports, 83% of poster submission accepted as posters, and 94% of working group submissions accepted. The papers eventually accepted comprised 81 research reports, 158 brief research reports, 121 Posters, and 15 Working Groups or Research Colloquia.

For this conference we created new strands and reframed others. Most notably, we reconfigured the mathematics content strands from being organized by content area (e.g. Geometry, Algebra, Number Concepts) to being organized by grade band (Elementary/Middle Years, comprising early childhood, elementary, and middle-grades mathematics topics; and Later Years, comprising secondary and post-secondary topics.)

We thank the many people who generously volunteered their time over the past year in preparation for this conference. In particular, we thank the three graduate assistants who contributed to these proceedings: Rachael Talbert (Towson University), Kayla Begen (Towson University), and Sarah Gill (West Chester University). Thanks to Carly Sullivan for her invaluable support in planning the in-person events. We would specifically like to highlight the herculean efforts of Kimberly Corum (Towson University) in developing the online conference hub.

We hope that the papers presented within these Proceedings will give you engaging, inspiring, and challenging ideas to transform your practice. And, as we continue to endure a time of challenge and struggle across North America, we hope that this conference can be a learning opportunity for the field to think about what it means to be an active and engaged professional, and how the structure of conferences can support faculty and students across many stages of their lives and careers in *persevering through challenges*.

Thank you,

The PME-NA43 Local Organizing Committee

Plenaries

THURSDAY PLENARY
FROM PRACTICE TO THEORY: LISTENING TO AND LEARNING WITH BLACK MATHEMATICS TEACHERS

Toya J. Frank
George Mason University
tfrank4@gmu.edu

Research on race and racism with respect to Black teachers' experiences is undertheorized in mathematics education. Due to social, historical, political, and cultural forces, Black mathematics teachers at particular social intersections (e.g., racial, socioeconomic, linguistic) experience teaching mathematics in ways that are unique from those in dominant communities. Without a critical and racialized analysis of issues that could potentially influence the attrition of Black mathematics teachers and how they experience mathematics teaching, conversations about the Black mathematics teacher pipeline, and teacher diversity broadly, run the risk of commodifying teachers and reducing their presence to ahistorical notions of diversity solely for the purposes of race matching. In this presentation, I will use data from an NSF-funded mixed-methods research project*, Examining the Trajectories of Black Mathematics Teachers,* to share what our research team has learned from centering Black mathematics teachers' racialized experiences to theorize about race and racism in mathematics teacher education. Additionally, I will share how this work informs research methodology in mathematics education by integrating untapped, yet appropriate, methodologies suitable for challenging issues of recruitment, retention, and praxis of other underrepresented racial and ethnic groups across time periods and school contexts.

FRIDAY PLENARY
PRODUCTIVE PROVOCATIONS

Crystal Kalinec-Craig, *University of Texas - San Antonio*
Pandemics, Scholarship, and Rethinking What Counts

Sam Prough, *University of Delaware*
Parents are Not a Scapegoat for Math Learning Loss

Caro Williams-Pierce, *University of Maryland*
Failure is Not an F-word: If You're Not Failing, You're Not Learning

Rachel Tremaine, *Colorado State University*

Carlos Nicolas Gomez Marchant & Stacy R. Jones, *University of Texas*
Let Us Be the Healing of the Wound/Seamos la Curación de la Herida

PANDEMICS, SCHOLARSHIP, AND RETHINKING WHAT COUNTS

Crystal Kalinec-Craig
The University of Texas at San Antonio
Crystal.Kalinec-Craig@utsa.edu

By now, many of us have readjusted to a new and sadly, a more painful normal. The pandemic left all of us with various scars and lingering emotions. We long hours working in less-than-ideal circumstances at home (especially those working parents who did remote learning while also supporting their children during Zoom classes). We celebrated the first day of kindergarten, graduation, and ceremonies online. We also lost friends and family to the disease. We had socially distanced funerals where we sobbed through masks, unable to grieve and comfort each other. We watched healthcare workers tirelessly go into extreme conditions and beg the world to act with more caution and care towards each other with a highly transmissible disease, only to see so many not take this advice and eventually end up in their hospitals. Many of us had delayed surgeries or medical care. Thousands of workers in the service industry lost their jobs only to find the *same industry* complain that they cannot find enough workers who will come back for less than a living wage and no health benefits. How is any of this humane? We as teachers and teacher educators are not here unscathed as well.

Nearly all of us had to learn quickly about remote learning, even though this went against the core of our teaching philosophies that learning happens in community and in person. For caregivers, they conducted classes on Zoom while helping their children learn remotely, even when learning online was foreign and impersonal. For those who do not have kids, we also faced a crush of increasing workload behind the scenes and added responsibilities as everyone else did. Universities responded by giving early career, tenure-track scholars a pause on their tenure clock to account for the delay in their research and productivity. #ThanksIGuess? Holding each other with grace and humility was a constant battle, even during stressful times, to remember both for ourselves and each other.

But what happens when the university or college calls the "pandemic over" and things should go back to "normal?" Do these struggles and constraints go away just because we can go back to in-person learning? No. The pandemic just illuminated them and made them bigger, more upfront, and more pressing to address. #TheMythOfLearningLoss is creeping into the common language we hear from districts and administration in K-12. Does it mean that schools and districts will welcome researchers back with open arms to engage in scholarship with teachers, children, and families? No. Our work is not the center of their universe (nor should be). Does it mean that suddenly tenure expectations will become more reasonable given a universities' resources, infrastructure, and mission to support and sustain high-intensive research organization? No. What incentive does the university have in doing this?

My provocation begins with a simple question reminiscent of Ball and Forzani's 2007 lecture "What makes educational research "educational"? What does research look like from here on out? How can we reimagine what "counts" as educational research based on our experiences during the pandemic? What can be said of scholarship in the time of caregiving that values our work and does not dismiss it because it is not "a solo author journal article in a top tier journal?" Is that the ONLY work we want to value?

When *Democracy and Education* journal published my interpretation of how I used the Torres' Rights of the Learner with teacher candidates at UTSA, I had mixed feelings because I was not sure if it would have counted for my tenure dossier as a "quality publication." The journal was not JRME. Or JMTE. *Democracy and Education* did not have impact factors or acceptance rates that I could cite in my dossier. But since 2017, I have heard from so many teachers who have been moved by Torres' ideas and how I framed them as a form of divergent formative assessment, that it has been overwhelming. On Twitter, I can see how teachers and other teacher educators can push through their assumptions and elevate children's ideas, voices, and thoughts, without children having to first defend their legitimacy. If I were at another institution, my tenure committee likely would have dismissed that publication and others, without ever considering the content or impact of the work.

Can the work of our colleagues who organize communities also be a part of the valued scholarship field? Can the work of our colleagues who lead protests and create legislative change be valued and elevated as worthy scholarship? Can the work of colleagues who draft ethnic studies standards (especially in states and districts that fear the phrases "Critical race theory" and "colonialism" in Pk-20 classrooms) be a source of valued scholarship? Cathery Yeh, Melissa Corral, Nicole Joseph, and many others should remind us as to how we can create and enact our scholarship in ways that show demonstrable change, especially work that moves and lives beyond our echo chambers in the academe. How can we as a collective begin to advocate for and with each other to reimagine what educational scholarship looks like?

The pandemic is not over and nor can we completely erase the scars left from its impact. But we do have a choice. We can decide to **pivot** as a community to a new vision for what is valued by returning to the humanity of our field, our communities, and our passions. We can also learn to operate in a "new number system for scholarship": reimagine "what counts" as scholarship without simply relying and reifying on traditional models that advanced the careers of some (primarily white scholars), but not nearly all.

For example, we can emphasize and value more teacher-researcher lines of inquiry. Highlight the work of self-study and how this can push us to a more normalized conversation of "what can I do better in my practice through praxis to examine aspects of it?" Emphasize more work that explicitly integrates teaching, research, and service, especially labor that does more than bolster a first author's CV. Find ways to involved full-time faculty like adjuncts and clinical professors of practice and students at all levels (undergrad, grad, doctoral) in research activities… and pay them to do this work. Name and dismantle systems and structures that marginalize, push, and stereotype the scholarship of BIPOC, LGBTQIA, and caregiver scholars… so much that they leave the profession altogether. It is up to the collective to decide what our new normal is going to look like. We shouldn't leave it up to a rubric, committee, or administration.

I invite each of us to take up this question: What do we want the new normal for what "counts" as mathematics educational research to look like? How can we make it more humane and more inclusive for the next generation of mathematics education researchers?

EXPLICIT AND EXPANSIVE: THE IMPORTANCE OF (RE)DEFINING STUDENT SUCCESS IN MATHEMATICS

Rachel Tremaine
Colorado State University- Fort Collins, Colorado
rachel.tremaine@colostate.edu

The work of mathematics education often seeks to increase student success, but rarely explicitly defines this concept. When it is, it commonly corresponds with quantitative measures that enable the positioning of students as economic resources within a school or university's institutional structure, providing an incomplete portrait of student success and reinforcing deficit perspectives on student achievement. Fostering critical analysis of how we conceptualize student success within mathematics requires aligning how we define such success with the perspectives of mathematics students. I advocate for centering student voice in the (re)defining of student success, and issue a call to the mathematics education community to (1) make definitions of student success explicit in mathematics education research and policy, and (2) acknowledge and value the expansive nature of students' definitions of their own mathematical success.

Keywords: Systemic Change, Measurement, Equity, Inclusion, and Diversity, Affect, Emotion, Beliefs, and Attitudes

As mathematics educators and mathematics education researchers, we are given a substantive amount of power in determining what is, and thus what isn't, student success within mathematics. Increasing student success is often put forth as a goal and a justification for our work, but rarely is "student success" explicitly defined. When it is, it often corresponds with quantitative measures such as Grade Point Average (GPA), rates at which students receive D's or F's or withdraw from a course (DFW rates), and persistence rates- measures that enable the positioning of students as economic resources within a school or university's institutional structure (Apple, 2006). While these kinds of measures therefore may be useful in arguing for funding and easing student-to-student comparisons, these notions of "student success" do little to serve the student themselves outside of their connection to and status within the university. Further, these definitions are constructed from a top-down perspective (Martin, 2003); those who have already been traditionally successful within the mathematical academic system have the opportunity to maintain their power by defining what is considered successful within that system. This results in entrenched viewpoints regarding what student success can look like in mathematics and fosters an inequitable system in which the values of the system don't align with the values of all of its participants.

As Weatherton and Schlusser (2020) note, the power present in these definitions may be "unknowingly upheld by researchers, faculty, and other institutional-level stakeholders who consider these dominant ideas of success to be 'common sense' or standard" (p. 10). It takes conscious effort by individuals who are considered traditionally successful within a system to critically examine that system. In order to fundamentally shift how we view student success within mathematics, there exists a need to listen to and place value upon the definitions constructed by key stakeholders in student success: the students themselves. We cannot claim, in any context, to be actively involving students in conversations about their own success when we do not allow them a seat at the table to speak on what they believe success embodies. Evidence points to the idea that students define success in multifaceted and complex ways that go beyond traditional quantitative definitions (see O'Shea & Delahunty, 2018; Quiles-Wasserman, 2019; Weatheron & Schlusser, 2020; Yazedijan et al., 2008), and thus if we continue to define student success in traditional quantitative ways, we neglect elements that are crucial to how students themselves are perceiving their own academic experiences.

Attending to student voice in discussions of student success in mathematical contexts provides a valuable perspective to qualify or counter the dominant ideology of those who are considered successful by traditional definitions. Student voice is already utilized in higher education for means of gathering valuable feedback for program evaluation and reorientation (Campbell et al., 2007; Brooman, Darwent, & Pimor, 2015). However, it has been critiqued for providing a one-dimensional view of students in which those students express views without compelling those within power to take action in response to those views (Seale, 2009). To combat this viewpoint of a one-dimensional student, not only does student voice need to be attended to when considering the concept of student success, student voice must also be given weight when determining how student success is conceptualized within the field.

Particular weight must be attributed to the voices of students for whom mathematics education has not been historically oriented to serve. Traditional quantitative definitions of mathematical success do not serve all students equitably, and often serve to reinforce deficit perspectives on who is successful in mathematical spaces (Baldridge, 2014; Jaremus, 2020). Gutiérrez (2017) potently notes that "we cannot claim as our goal to decolonize mathematics for students who are Black, Latinx, and Aboriginal while also seeking to measure their 'achievement' with the very tools that colonized them in the first place" (p. 12). These 'tools' are widespread at all levels of our educational system, and are particularly manifested in national standardized testing as a gatekeeper for funding and student opportunity (Baldridge, 2014; Gasoi, 2009). Such standards were not designed for the achievement of marginalized students, and thus do not necessarily highlight the ways in which they *are* achieving, instead focusing on and easing the process of deficit-oriented gap-gazing (Gutiérrez, 2008).

One way in which such gap-gazing is present in contemporary societal discourse is as "learning loss," a concept highlighting the quantitative effects of the ongoing COVID-19 pandemic in the context of standardized testing and learning. In this context, when we limit student success to quantitative measures, we ignore the myriad of ways in which our students may have experienced success over the past year and a half of mathematical instruction. For many, that included "persevering through challenges"- the theme of this conference! If we consider "persevering through challenges" an important component of student success, then it is crucial that our definitions of student success acknowledge that facet. However, calls to regain "learning loss" experienced during this time have been oriented towards ensuring that quantitative test scores are matched with those of what prior years would call "successful." This does not recognize the inherent mathematical success of persevering - intellectually and emotionally - through mathematics learning during a pandemic, regardless of quantitative outcome.

To take an anti-deficit approach to student success during this time is to shift the focus from quantitative deficits to the ways in which students *have* experienced success in mathematics. My own research and conversations with undergraduate First-Generation, Pell-grant eligible, and/or racially minoritized women students have revealed that students are thinking about success in intricate ways that both build on and extend beyond traditional quantitative definitions. When asked how they would define success within mathematics, these women provided nuanced perspectives, and I highlight several quotes from four of their interviews, attributed to their pseudonyms, in *Table 1*.

Ada	Taylor	Kenzie	Isabel
"I think [success in mathematics] is about learning something and getting something out of it…even if it's not necessarily the content, I need to get something out of the experience, whether that was learning critical thinking or just something positive."	"I think grades are important, of course, but I think more important than that is actually understanding what you're learning… I think success in a college setting is being able to understand what you're learning, especially with math, because it can be really hard."	"I think [success means] being a level ahead, feeling proud after all that work, you know? Every summer I took a math course, so finally being where I wanted to be… that's what I was reaching for."	"For math in general, I would define success as you actually being able to practically apply your math skills… there's being able to do well in school and then there's being able to actually use what you've learned in school."

Table 1: Quotes from four undergraduate women students speaking on their views of what it means to be successful in mathematics.

The direct quotes from these women students are but a fraction of richer conversations in which they expanded on their definitions of success in mathematics, as well as moments in which they themselves had felt successful within mathematics. By presenting their quotes here, I intend to engage the reader reflectively: in what ways are these quotes aligned and/or unaligned with the ways in which student success is traditionally defined in mathematics education? Student perceptions of their own success in mathematics exist beyond the constraints of quantitative systems that were designed to measure their success. Without acknowledging the expansive nature by which individual students define their own success in mathematics, we risk overlooking dimensions of mathematical success that are immensely impactful and influential to how students discuss and experience their own mathematical journey.

Scholars in other disciplines have put forth research regarding how definitions of student success might be expanded on (i.e. Atwood & Childress, 2018, in School Social and Emotional Learning; Beilin, 2016, in Library Science; Ulrich & Strong, 2019, in Engineering; Weatherton & Schlusser, 2020, in Biology Education). Because mathematics often is often perceived as an indicator of student intelligence (Adiredja, 2019; Gutiérrez, 2018; Roth et al., 2015) and holds a privileged place within capitalistic systems (Andrade-Melina, 2017; Valero, 2018; Woodrow, 2003), ensuring that student success within mathematics is critically examined can have broader implications for ways in which student success is conceptualized within STEM. **With this in mind, I challenge the mathematics education community to move toward centering students in the discussion of "student success" through two actionable items: (1) make definitions of student success explicit in mathematics education research and policy and (2) acknowledge and value the expansive nature of students' definitions of their own mathematical success.**

Make Definitions of Student Success Explicit in Mathematics Education Research and Policy

Using the term "student success" without definition creates an assumption of the term as having universal meaning, which establishes success as a "privileged ideal, partially reliant on the possession of certain cultural or academic capitals" (O'Shea & Delahunty, 2018, p. 1069). Assuming universality of perceptions of success restricts who has an entry point into the conversation about student success. In addition, making explicit definitions of student success "before beginning their projects will allow researchers to clearly ground their work and accurately describe what they intend to study" (Weatherton & Schlusser, 2020, p. 6), fostering clarity for all involved in the project- researchers, participants, and eventual readers. Regardless of how student success is defined, making its definition explicit counters the idea of student success within mathematics as a privileged ideal known only to a select few, and allows for more diverse entry points into the conversation surrounding work that focuses on increasing a specifically-defined component of student success.

Acknowledge and Value the Expansive Nature of Students' Definitions of Their Own Mathematical Success

Students, as key stakeholders in their own success, are and ought to be treated as the authority concerning how they experience success in mathematics. Reconceptualizing what we consider student success in mathematics necessitates seeking out and intentionally placing weight on the perspectives of students with identities that are traditionally marginalized in mathematical spaces. Doing so can counter the ways in which traditional quantitative definitions of student success have reinforced deficit perspectives and systemically minimized the achievements of individuals who hold these identities. Acknowledging the varied way in which student success can be defined also enables better alignment among student-level, faculty-level, and university-level priorities, and reduces the cognitive dissonance felt by students whose definitions of their own success contradict that which they see messaged by their institutions and instructors (Ulrich & Strong, 2019).

In Conclusion

As a concept that underlies so much of what the mathematics education community works toward as a field, the notion of student success deserves our attention and intentionality in assuring that we are framing it in a way that is reflective of how our students see their own success within mathematics. Moving beyond deficit-oriented quantitative measures of student success necessitates exploring and valuing student voice regarding what it means to be successful in mathematics, and that we apply those definitions in our work to critically shift how student success is conceptualized and measured in this field. I implore the mathematics education community to both make definitions of student success explicit in our work and acknowledge that traditional quantitative definitions of success are only a fragment of the expansive ways in which students frame their own success. Students are a key stakeholder in their own mathematical success; their perspectives deserve to be heard, and we are privileged with the opportunity to listen and foster change.

FAILURE IS NOT AN F-WORD: IF YOU'RE NOT FAILING, YOU'RE NOT LEARNING

Caro Williams-Pierce
University of Maryland
carowp@umd.edu

I often use the word 'failure' in my work, and the audience I'm talking to dictates their response to my use of that word. I remember back in grad school, saying the word 'failure' in a mathematics education class, and everyone gasped in horror at the f-word! But just down the hall, where I studied games and learning with other folks, we talked about our experiences of failure in games all the time – no gasping required. Because good games always have useful feedback paired directly with any moment of dramatic failure – that is not always (maybe even *not often*) true in classrooms (or indeed, academia in general).

My provocation is: we need to normalize joyful failure at every step in the mathematics learning process. And to do that, we need to make sure that our feedback is consistent and useful – and provokes reflection on the mathematics and our learning, instead of frustration or rote memorization. There are many ways to design such failure and feedback experiences, and I present one such approach here.

Provocative Objects

In examining failure and learning, I've pretty much become obsessed with mathematical play in all sorts of different contexts. In particular, I think of mathematical play as being particularly likely to emerge when failure paired with feedback are regularly present for the player/learner. I developed the idea of a *provocative object* as a particular tool to designing to support mathematical play and learning (e.g., Williams-Pierce, 2019; Williams-Pierce & Thevenow-Harrison, 2021). Initially, provocative objects emerged as a way of thinking about and designing for mathematical play in videogames; however, we recently extended this construct to *provocative environments* in order to better examine and understand mathematical play in informal makerspaces (Shokeen et al., 2020). Consequently, while I focus primarily on provocative *objects* below, I also describe some of the more recent insights we have developed.

Provocative objects are digital environments that provoke mathematical play and learning by using five key characteristics that can be used for both design and analysis purposes.

#1: Consistent and Useful Feedback

First, provocative objects have consistent and useful feedback. Often, we engage with mathematics in environments that do not provide immediate feedback. For example, if I hand you an expression on a piece of paper (Figure 1), you can simplify it any number of ways, both correct and incorrect.

$$44+56+a+72+28$$

Figure 1: an expression written on paper.

If you decide that you can add 56 and *a* together and you write down 56*a*, the paper will not revolt. You can write it down, hand it in, and wander off to recess – and if you're lucky, you'll get feedback on your failure the following day or week. But with a digital context, like Ottmar and team's *From Here to There* (FH2T; Figure 2), you get feedback about that impossibility immediately.

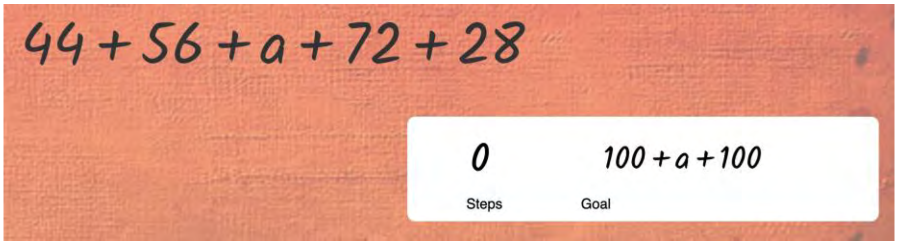

Figure 2: World 1, Puzzle 6. In FH2T, the goal is to modify the top expression to duplicate the target expression in white.

If you tap the + symbol between the 44 and 56, the game will enact the addition, giving you a total of 100 – and feedback that you are engaging in a mathematically possible action. But if you tap the + symbol between the 56 and *a*, the + will shake back and forth – feedback that indicates a mathematically impossible action. In other words, unlike paper, FH2T gives immediate and useful feedback to learners.

#2: Failure Paired with Feedback

The full name of this second characteristic is *high enough levels of difficulty and ambiguity that players experience frequent failure that is closely paired with the feedback.* Failure is so important that when I was designing my dissertation game, *Rolly's Adventure* (RA), one of my first design decisions was how to indicate failure, and how to closely pair that failure directly to feedback without just *telling* the player what they did wrong. That is, how do you tell someone playfully that they are failing, and pair it with feedback that – instead of telling them the answer - helps them reflect upon what they did, so they can learn from it?

This often contrasts with traditional learning contexts – where failure *is* an F-word - and I rely upon game scholars who study failure to understand how wonderful failure can be (e.g., Juul, 2009; Ramirez, 2017). In particular, because the feedback is consistent and useful, every instance of failure comes immediately in the moment: players can see the results of their actions, reflect upon the relationship between their action and the failure/feedback their action evoked, and learn (Williams-Pierce, Dogan, & Ellis, 2021, in revision). For example, in RA, one player was surprised and excited when he experienced failure for the first time (Figure 3).

Figure 3: Emmett (left) experiences fiery death as an indicator of failure in RA (right).

Immediately after this moment of fiery failure, a huge slow grin spread across Emmett's face: "Wh- wh- what?! What the— heck? I don't even know—what just happened?"

So, the first point is that he did not mind failing – shocked surprise was followed immediately by curiosity and interest. And that curiosity and interest led Emmett to discover the feedback that he had not noticed during this first failure: he had not achieved the puzzle goal of perfectly filling the hole (Figure 4).

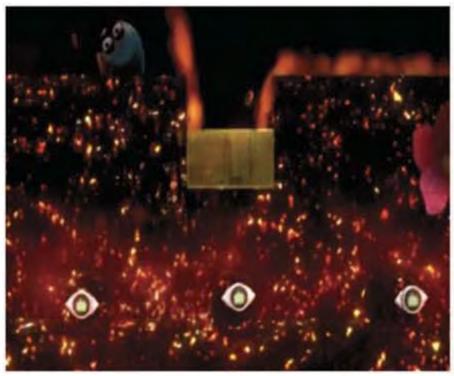

Figure 4: Visual feedback in RA, paired with the fiery failure. (A different puzzle than the previous Figure, as this puzzle is lighter and easier to see in screenshots.)

Note that the fiery death of his adorable avatar (see the rainbow faced minion in Figure 3, right) was the failure indicator, and the feedback indicator (the golden block in Figure 4 that only partially fills the whole) is *not* on fire. The eye of the player is drawn to that golden block, as one of the very few objects not on fire, which helps emphasize the feedback indicator in an otherwise novel (and thus bewildering) context.

However, failure and feedback can be more complex, especially in provocative environments. For example, in ongoing research with Amber Simpson in our mmPlay lab, we've been identifying indicators of failure and feedback in collaborative non-formal robotics makerspaces in elementary school. In this context, failure and feedback are often social in nature, as the students negotiate together to achieve their common goal (Shokeen et al., this volume), rather than a reaction from a designed object.

#3: Non-Standard Mathematical Representations and Interactions

Somehow, our field often seems to settle for ossified representations of and interactions with mathematics for our learners. We point at an expression like $56 + a$, and are deeply confused by our learners trying to add two unlike terms. Much like Emmett not yet seeing the feedback paired with the failure indicator, our learners don't look at a and think that it could be 17, or the color blue, or 80 degrees Fahrenheit – in other words, a does not yet represent *unlike-ness* to them. These learners may instead memorize the rule against adding unlike terms, and try to apply it whenever it seems appropriate. As a consequence, when learners encounter standard representations or interactions, they may immediately try to unthinkingly use a plethora of inappropriate memorized rules. This third characteristic is about avoiding evoking such rules (or a player's mathophobia!), in order to better support learners in joyfully engaging in the mathematics that undergirds both standard and non-standard representations and interactions.

However, this leads to another issue: mathematics learning contexts often over-rely upon written and spoken language as feedback and evidence of learning, instead of letting the mathematics speak directly to the player as happens in RA, or letting the learner use complex modalities to share their understanding (such as gesture; e.g., Williams-Pierce et al., 2017; see also Ng, 2016, for an excellent example of learners using gesture to supplement their mathematics communication in their non-primary langauge). As a result, we struggle as a field to *see* mathematics learning in action because we rely upon written or spoken versions of our ossified school-based field. In our mmPlay lab research, we have found that there are multiple layers of mathematical activity occurring that do not directly manifest in written or spoken language, or manifest as a trivial change in such forms. For the former, as mentioned above, there are gestures that act to uniquely complement spoken language. For the latter, for example, when programming the robot Dash to traverse a path, a student may program in a distance in specific units, only to see Dash go too far. The student then must perceptually compare Dash's location with the desired distance, estimate how much *too far* is, and revise their input to test out their new hypothesis. Here, there is failure (Dash did not stop where the student wanted it to), feedback (the student can visually perceive that Dash went too far), and mathematical activity that involves mentally simulating the distance between the lengths (Williams-Pierce et al., this volume). This mathematical activity may manifest simply in a student revising the code in the application that controls Dash, but that small change represents considerable (and easily missed) mathematical activity on the part of the student.

#4: Mathematical Notation Introduced Late or Not at All

This fourth characteristic is one of my favorites, but it also may be very wrong! Essentially, a provocative object does not start with notation, and only introduces it when – or if – it becomes a deeply useful tool to the learner in their gameplay. Earlier, I used FH2T as an example of the first characteristic because I believe it is a provocative object, but FH2T very clearly violates *this* characteristic as formal notation is the primary representation type in FH2T! Consequently, I'm really psyched that one of my doctoral students, Nihal Katirci, is examining FH2T, mathematical play, and learning for her dissertation. So she'll be the one to tell me if this characteristic is less important than I originally believed, and that I need to dial it down to allow for games like FH2T. But I want to emphasize this crucial fact: I am not *anti-notation*, but I am anti-*notation being mistaken as the math itself*. We have the unfortunate habit of taking representations and teaching learners that those representations *are* the mathematics, instead of merely another *representation* of the mathematics. Stay tuned for Nihal's findings!

#5: The Legitimate Possibility of Alternative Conceptual Paths

Last but certainly not least! RA is a linear puzzle game: you complete one puzzle, then you get to go to the next, and so on – you cannot go from puzzle 1 to puzzle 7 and back to puzzle 2. From one perspective, this can be seen as a violation of this fifth characteristic, but as long as your provocative object is ambiguous and challenging (and rife with failure and feedback), a linear product does *not* dictate a linear conceptual path. In the case of RA, players develop their own conceptual understanding of the mathematics underlying the game, using the non-standard representations and interactions in order to craft their own unique mathematical narrative, and emerge from their gameplay with different experiences. I suspect that FH2T is the same – as I said above, stay tuned for more about that!

Conclusion

In summary, I believe that in mathematics education, with ourselves AND with our students or learners, we need to embrace failure as a beautiful thing – an incredibly wonderful opportunity to learn more about the math or the tool or the people. The five characteristics of provocative objects can help us understand how to *design* such lovely failure, as well as how to *understand* the amazing failure that happens within tools or in our lives.

SATURDAY PLENARY
CRITICAL RACE THEORY AND MATHEMATICS EDUCATION

Panelists
Cathery Yeh*, Chapman University*
Robert Berry*, University of Virginia*
Christopher Jett*, University of West Georgia*
Maria Zavala*, San Francisco State University*
Moderator: Linda Fulmore*, TODOS: Mathematics for ALL*

Critical Race Theory has made headlines with proponents and opponents grappling about its place in education. Many states, school boards, and localities are passing or proposing legislation banning or limiting the teaching of principles attributed to CRT in public schools. Much of what is being passed or proposed under the guise of CRT is not, in reality, CRT. The panel will discuss: What is Critical Race Theory? What is the significance and potential of Critical Race Theory in mathematics education research? How do we navigate through the noise? And, what can we do from an action standpoint?

Chapter 2:

Curriculum & Assessment

IMPACT OF TEACHERS' IDENTIFICATION OF WRITTEN MATHEMATICAL POINTS ON STUDENTS' LEARNING

Napthalin A. Atanga
University of Bamenda, Cameroon/CBC Education Department, Bamenda, Cameroon
naatanga2008@yahoo.com

I examined the relationship between teachers' identification of mathematical points in written lessons and students' mathematical learning opportunities. Lessons in teachers' guides and classroom instruction were analyzed for written mathematical points and those articulated by teachers during instruction. Teachers who appropriately identified written mathematical points together with suggested curricular resources to realize them had a positive impact on students' mathematical learning opportunities. Positive impact was influenced by the teacher's ability to appropriately identify the role of available curricular resources in supporting the achievements of written mathematical points, recognize relationships between suggested activities and curricular resources toward written mathematical points, and develop a productive mathematical storyline.

Keywords: Elementary School Education, Curriculum, Assessment

Quality teaching begins with teachers clearly identifying what students need to learn from their teacher's guide and then designing activities or tasks to support them to reach the intended learning goal. Many research studies (e.g., Morris et al., 2009) have investigated teachers' abilities to clearly identify learning goals from students' written work. For example, Morris et al. (2009) investigated the ability of preservice teachers to identify subconcepts in mathematical ideas students are to learn and found that they could accurately identify at least one subconcept of a learning goal but not all when correct student work was presented to them. This result suggests that unpacking learning goals from resources available to teachers or additional resources they may want to include in their lessons might be a challenging skill to develop.

Hiebert et al. (2007) emphasized the need for teachers to clearly state what students should learn from a lesson. According to Hiebert et al., learning goals help teachers determine whether or not students have arrived at the intended learning. Hiebert et al. further argued that breaking general learning goals into sub-goals provides better guidance to examine the link between teaching and learning. This implies that teachers should carefully evaluate and interpret written lessons together with suggested resources to identify what mathematics students ought to learn. After identification of the lesson goals, teachers look forward to planning moves that will enable them have student learning reach these goals.

Sleep (2009) unpacked ways teachers steer lessons toward mathematical points. Sleep defined mathematical point (MP) as "the mathematical learning goal for an activity as well as the connection between an activity and its goal" (p. 13). Sleep's definition focused on the learning goals of an activity and describes the work involved in steering the lesson towards these goals. Van Zoest et al. (2016) defined MP with respect to student thinking in-the-moment during whole class discussion. According to them, "an MP is a mathematical statement of what could be gained from considering a particular instance of student thinking" (p. 323). From these, we see that Sleep (2009) focused on the activities students are to engage in while Van Zoest et al. (2016) focused on student thinking in-the-moment. Despite this interest in MPs, however, little is known about teachers' ability to identify MPs embedded in suggested curricular resources (CRs)—"valuable support provided to teachers within each lesson in the teacher's guide" (Atanga, 2014, p. 3). By mathematical point (MP), I mean important mathematical ideas students ought to learn for each lesson as communicated in a teacher's guide, which may be different from, or the same as, lesson goals. My definition of MP is similar to those of Sleep (2009) and Van Zoest et al. (2016) in that the emphasis is on the mathematical idea students are to learn, but different in that while Sleep looks at activities students are to engage with and Van Zoest et al. (2016) looks at student thinking, I focus on CRs embedded in teachers' guides.

Specifically, this study examined teachers' ability to identify stated MPs for written lessons in teachers' guides and the impact on the mathematics students ought to learn. I also investigated whether the MPs teachers seem to pursue during instruction as they make use of suggested CRs are the same or different from those communicated in the teacher's guide. This study focused on the impact of teachers' identification of MPs embedded in suggested CRs on the mathematical content students have the opportunity to learn. As such, I asked the research question, *How does teachers' identification of written MPs impact students' mathematical learning?*

Theoretical Perspectives

Sleep (2012) defined the work of steering instruction as involving three mutually dependent actions: "(a) articulating the mathematical point, (b) orienting the instructional activity, and (c) steering the instruction" (p. 937). She described the first two as "mathematical purposing" (p. 938) to involve stating learning goals for students. Morris et al. (2009) found that some preservice teachers either correctly (exactly) or partially identified learning subgoals when presented with student work. Steering instruction towards identified learning goals involves teacher moves deployed during planning or enactment of lessons to support students in achieving the mathematics of the lesson.

Sleep (2012) identified such moves and elaborated on them. The moves shown in Figure 1 are relevant for this study as they have direct impact on reaching the MPs. These moves provide a framework for the analysis in my study.

Work of Steering Instruction	Teacher Moves
1. Making sure students are doing the mathematical work	*a. Asking questions that engage students in mathematical reasoning* *b. Getting students into the work without doing it for them* *c. Distributing the mathematical talk and the kinds of mathematical talk*
2. Developing and maintaining a mathematical storyline	*a. Developing a coherent within-lesson storyline by making mathematical connections across a lesson's activities* *b. Progressing the mathematical storyline by engaging with new ideas/practices or engaging with ideas/practices in new (more challenging) ways* *c. Developing an across-lesson mathematical storyline by looking for mathematical coherence across students' prior and future work* *d. Conveying the mathematical storyline to students by framing, narrating, and summarizing the mathematical work*
3. Opening up and emphasizing key mathematical ideas	*a. Using intentional redundancy* *b. Pointing out the use of a focal concept or skill* *c. Providing definitions* *d. Spending more time on key ideas* *e. Using a combination of teacher and student talk*

4. Keeping a focus on meaning	*a. Deploying representations in ways that highlight intended meaning* *b. Explicitly connecting the activity to the intended mathematics*

Figure 1: Work of Steering Instruction and Corresponding Teacher Moves (Sleep, 2012)

Method

Curriculum programs and teacher participants. Data were gathered from teachers in grades 3-5 using two different curriculum programs: *Investigations in Number, Data, and Space* (*Investigations*) and *Scott Foresman Addison Wesley-Mathematics* (*SFAW-Mathematics*), both published in 2008. The former is an NSF-funded program, while the latter was commercially developed. Six teachers participated in this study; Lisa, Maria, and Jennifer used *Investigations*, while Caroline, Dan, and John used *SFAW-Mathematics*. These teachers have teaching experience ranging from 8 to 11 years, from Head Start to grade 8. They have also taught a variety of subjects for the different grades and have been exposed to both NSF-funded and commercially developed CMs.

Data sources. Data used in this study included classroom observations and post-observation teacher interviews. Each teacher was observed teaching three consecutive lessons in spring 2012 and all enacted lessons were videotaped and transcribed. Each of these six teachers was interviewed to determine whether or not they identified MPs of the written lessons embedded in recommended CRs in their teacher's guide.

Data analysis. I determined written or implied MPs by identifying important mathematical ideas students ought to learn for each written lesson based on the suggested activities in each teacher's guide. Suggested CRs used in written lessons were also analyzed to identify what MPs, written or implied, they are intended to foster. As classroom videos and transcripts were analyzed, issues about teachers' identification of MPs in suggested CRs emerged. I then observed each classroom video to identify the MPs each teacher articulated to students. I compared the MPs articulated by teachers to those written or implied in the teacher's guide using the codes (1) *exactly* (*when the articulated MP is exactly the same as that written or implied*), (2) *differently* (*when the articulated MP is exactly different as that written or implied*), (3) *partially* (*when part of the articulated MP is partially the same as that written or implied and part is different*). This enabled me to determine whether MPs articulated by teachers were similar or different from those written in the teacher's guide or implied by the researcher. In addition, from the classroom videos, I coded teacher moves using Figure 1. This enabled me to determine which MPs are pursued in the lesson to determine which MPs students are effectively exposed to and the kind of learning each teacher likely promoted, by the opportunities available to students. I compared what students effectively learned to intended learning to determine whether teachers' identification of MPs impacted student learning fully positively (*when students actually learned what was intended for them by the opportunities to learn available and are able to demonstrate that with accurate execution of assigned task*), partially positively (*when students partially learned what was intended for them and the other part not encountered and are only partially able to execute assigned task*), or fully negatively (*when students actually did not encounter or learn what was intended for them and are not able to execute assigned task*). Also, I looked at all lessons by teacher to determine the overall impact on student learning and categorize each teacher based on the MPs they articulated as measured by the mathematical content students had the opportunity to learn. Lastly, I searched for patterns across all teachers in each category to describe possible reasons for such impact on student learning.

Results

Because the written or implied MPs I identified and those articulated by the teacher are highly related to the possible impact on student learning, I present the results together in order to illustrate their connectedness. Lisa's and Maria's identification of written MPs was classified as negatively impacting student learning, while Caroline's, Dan's, Jennifer's, and John's identification of written MPs was classified as positively impacting student learning. The difference between these two impacts on student learning can be attributed to the MPs teachers articulated and the way teachers in the different categories emphasized key mathematical ideas, developed meaning, and developed and maintained a mathematical storyline—"following a deliberate progression and making connections among mathematical ideas toward the mathematical points over a course of lessons" (Atanga, 2014, p. 154). Teachers' identification of written MPs is explained below with examples from Maria's and John's lessons to illustrate possible impact on student learning.

Negative Impact on Student Learning

The MPs in the CRs for the three lessons Maria taught are "(1) using the inverse relationship between multiplication and division to solve problems, (2) identifying characteristics of these problems, and (3) write multiplication and division story problems" (Wittenberg et al., 2008, Grade 3, Unit 5, pp. 122-136). The MPs Maria articulated to the students and pursued for the three lessons were "to identify key words to determine whether a problem is multiplication or division, to solve problems, and then to write story problems." The MPs identified and stated by Maria are similar to those written in the curriculum in that students ought to solve problems and write their own story problems. Maria's articulated MPs are different from those written in the teacher's guide in two ways. First, Maria did not specify the suggested methods in the teacher's guide students ought to learn to solve the problems, while written MPs indicated solution strategies students should learn. Second, Maria introduced the identification of "key words" to provide a clue for students to determine whether assigned problems use multiplication or division. Maria hoped that these "key words" would support students in writing their own story problems.

Investigations provides a set of six problems (three pairs) for students to solve. Each pair of problems uses the same numbers, one of them being a multiplication problem and the other division. The curriculum particularly suggests that teachers highlight problems 2 and 3 for discussion with students to achieve the written MPs mentioned above. After this discussion, it is expected that students notice the other pairs of problems, use the inverse relationship between these operations to solve them, and subsequently write their own division and multiplication story problems.

During enactment, Maria led a classroom discussion of each of the six problems. She began by reading each problem and consistently asked, "What's my key word on this problem?" Maria underlined the key word and asked the students what notation could be used, and she wrote either or beside the problem as appropriately determined. Afterwards, Maria asked students for the number sentence, which she wrote when correctly provided. In addition, Maria always asked, "How do I solve this one?" and together with students, a correct solution was provided.

As Maria led students through the solution of the six problems one after another, she focused students on problems 2 and 3 as recommended and orchestrated the following interaction.

Maria**:** …look at question number 2 and question number 3...Do you notice anything special about question number 2 and question number 3? …What do you notice?

Student**:** The top one's 5 and the bottom one's 20 because 20 divided by 4 is 5 and then 5 times 4 is 20.

Maria**:** Good. Adding and subtracting are exact opposites, right? So are multiplication and division so these have the same set of numbers in them it's just that this one is the inverse or opposite of the one right above it. Kind of cool. So if you solve this one and you solve the same numbers you automatically know the answer without having to even solve them. They're part of the same…?

Student**:** Fact family.

Maria**:** Fact family, absolutely.

In this interaction, Maria ended up using problems 2 and 3 to get students to see those numbers as members of a "fact family," an MP not intended for this lesson, which neither highlighted attributes of multiplication and division problems nor the potential of using the inverse relationship between these operations to solve the problems. Although the idea of inverse relationships surfaced in the above excerpt, Maria did not pursue it beyond making a comparison with addition and subtraction. Maria also did not push her students to see how the inverse relationship between multiplication and division could be used to solve problems 2 and 3. Figure 2 shows a suggested representation in the teacher's guide, which Maria did not use.

Number of Groups	Number in Each group	Product	Equation
?	4 muffins	20	20 4 = or ____ 4 = 20
5 packs	4 yogurt cups	?	5 4 = 20

Figure 2. Visual to Illustrate Inverse Relationship Between Multiplication and Division and their Attributes (Wittenberg et al., 2008, Grade 3, Unit 5, p. 124)

This suggested representation is to support teachers in accomplishing the written MPs, but when asked during the post-observation interview about what this representation communicated, Maria said, "I don't always use that table…so we talk about the differences in those notations, rather than relying so much on this chart. I don't know that I feel like the chart aids a whole lot." According to Maria, the chart is basically focused on differentiating the notations for both operations and hence is not particularly helpful.

After solving all six problems, Maria and her students identified and created a list of key words list for each operation; those for multiplication problems included *in all, altogether, how many, total* and those for division problems included *how many equally, share equally, how many groups, how many in each group, divide, put in each*. Following this summary of key words for each operation, Maria asked students to create their own multiplication and division story problems as required by the CM. After three days of teaching, students in Maria's class neither wrote correct multiplication and division story problems nor used the inverse relationship between multiplication and division to solve problems. Hence, it can be concluded that Maria's articulated MPs had a negative impact on students' opportunities for mathematical learning.

Positive Impact on Student Learning

Written MPs for a lesson John taught are "(1) a plane figure has two dimensions: length and width; (2) a solid figure has three dimensions: length, width, and height; (3) there is a unique relationship between solid figures and flat shapes; (4) definitions of mathematical terms" (Charles et al., 2008, Gr. 4, Vol. 3, p. 434). John articulated what students ought to learn during enactment as "today we're going to relate two different types of figures together. What we call plane figures and what we call solid figures." John's MP is the same as the third MP in the teacher's guide, but he did not explicitly articulate to students the first two and the fourth MPs.

In the lesson John taught, *SFAW-Mathematics* suggests that teachers distribute copies of the net of a cube to students, cut out the net, and construct a cube. The teacher's guide for this lesson suggests teachers introduce and illustrate the terms *face, edge,* and *vertex* to students and ask questions to determine the number of each. During enactment, John led students through the construction of the net of a cube, using graph paper. He asked questions such as, "The lines that you have on your graph paper are all making what type of shape?" and students answered, "Squares." John added and illustrated that, "A square is an example of a plane figure. Meaning it's flat. It's one surface. It has basically what we call two-dimensions. It has length and it has width, now the square."

In addition, John asked, "How many squares make up this shape [the net of a cube]?" This question focused students on the constructed net and students could see that there are six squares, to answer correctly. John continued to direct students on what has to be done to create a cube from the net. Students followed John's guidance and experienced the transformation from a net to a cube. John explained, "Now, you have six squares that made up the cube. So we have turned six plane figures, in other words flat figures, into a solid figure that has now three dimensions. We have length, width and height," pointing at each dimension to concretize it. Two things about John's actions are noteworthy here. First, a relationship between plane and solid figures was established using a cube. Second, John established a one-to-one correspondence between a solid figure and its dimensions. Therefore, John used suggested representations and guidance provided in the teacher's guide to develop and maintain a storyline from the net of a cube to the cube together with its dimensions and established a relationship between plane and solid figures.

John used the constructed cube to define the other terms—a *face*, an *edge*, and a *vertex*—students were to learn. He held the cube and said,

> Squares. So it's 6, the 6 faces of your cube are all squares. So a flat...so in flat surfaced figures, which is what we're going to be talking about today for the most part, flat surface is a face. Your cubes have six faces those six faces are all squares. Yes?

John called the six squares of the cube faces. He emphasized that because this solid figure is formed from a plane figure, the faces must be flat. Furthermore, John defined an edge and a vertex as below:

> Ok, so an edge, look at the next highlighted part, it says: An edge is a line segment where two faces meet. Everyone hold up your cube. Run your finger along an edge. Very good, that is an edge. Notice where two faces come together is an edge. Any place where you folded them and those faces came together you created an edge. The last one is a vertex, a vertex is where three or more edges meet, the plural is vertices. So, point on your cube to a vertex.

John accurately defined a face, an edge, and a vertex, mapping the terms to a surface, line, and point, respectively, to illustrate what they represent. Also, John asked for the number of faces, edges, and vertices of the constructed cube. As students provided the correct number, John counted the distinct faces, edges, and vertices to concretely justify students' responses. Students in John's class proceeded with assigned problems from the text with minor difficulties, suggesting that his actions had provided them the opportunity to learn the mathematics.

When John was asked during the post-observation interview about the mathematical significance of the activity from the net of a cube to constructing a cube, he said,

> Well, what it's showing us is the faces of a cube are made up of six squares, and it, and it teaches us that, it teaches students that the faces of solid figures are plane figures, …knowing what the definitions are, knowing that, what a face is, what a vertex is, what an edge is…

This revealed that John had an understanding of the mathematical ideas of the lesson students ought to learn. Hence, I concluded that John's identification of MPs likely has a positive impact on students' mathematical learning.

Discussion/Implications

The findings indicate that a big responsibility in teaching is to accurately identify MPs for the lesson as well as how suggested CRs support their realizations. This study revealed three interdependent aspects of teaching that teachers need to attend to with care in order to expose their students to intended mathematical concepts they ought to learn.

First, teachers must appropriately identify MPs that suggested problems are intended to communicate. Understanding the rich mathematical concepts embedded in suggested problems together with solution strategies is a key in supporting students in reaching the intended learning target of the lesson. Second, teachers should be able to identify written MPs that suggested representations are designed to foster. Kilpatrick, Swafford, and Findell (2001) found that use of representations have significant positive influence on student understanding of the mathematics they ought to learn. Maria failed to make use of Figure 2 that could have helped her communicate to her students the attributes of multiplication and division problems as well as the use of inverse relationship between the operations to solve problems. In contrast, John used the representations available in the teacher's guide to communicate and establish a relationship between plane and solid figures. Third, teachers should identify relationships among CRs toward written MPs of the lesson. Understanding and identifying these relationships require deep knowledge of the representations (Castro Superfine, Canty, & Marshall, 2009) and knowledge about how to translate between the different representations while preserving the structural information presented in each of them (Novick, 2004). Maria seemed not to understand the information conveyed by problems 2 and 3 and Figure 2, making it hard for her to make meaningful connections between them. This resulted in her omitting the use of Figure 2 and attempting to use the suggested problems in isolation, and opportunities to learn important mathematical ideas and solution strategies were missed. In contrast, John seemed to understand each representation suggested in the teacher's guide and translated between the net of a cube and the constructed cube, calling the faces of the cube squares and preserving their structural information.

These aspects of teaching extend our understanding of "mathematical purposing" (Sleep, 2012, p. 938). Identifying written MPs of the lesson and those embedded in CRs, identifying and establishing relationships among CRs toward written MPs, and mapping out and developing a productive mathematical storyline from one MP to another provide us with additional fine-grain details of the work of mathematical purposing in classrooms. Mathematics educators might include into their methods and content courses for preservice teachers activities such as identifying MPs of written lessons and CRs, and discussing relationships among CRs in achieving the stated learning goals. This might help improve teachers' mathematical knowledge for teaching and can ultimately add value to teacher training programs. In addition, results of this study has potential of being used by educators to develop teachers' specialized content knowledge (SCK). Morris et al. (2009) argued that an aspect of SCK is focused on what type of representations teachers might use to effectively communicate a particular mathematical idea to students. So, focusing on teachers' ability to identify MPs in suggested CRs might support the development of needed SCK and hence teachers' subject matter knowledge, because the former is a subset of the latter (see Ball et al.'s 2008 model).

Although this study suggested important skills teachers need in order to promote student learning, the absence of student data to substantiate further the benefits of identifying MPs and developing a "productive" storyline and the small number of teachers and lessons involved limit its wide applicability. Therefore, further studies involving student data and a greater number of lessons and teachers over an extended period of time are needed to investigate what it means for teachers to identify written MPs and develop a potentially productive mathematical storyline toward them.

This paper's purpose is to discuss validity evidence related to a third-grade problem-solving measure (PSM3). PSM3 is connected to a series of tests designed to measure students' problem-solving performance aligned with the Common Core State Standards for Mathematics. Multiple validity sources are drawn together to support the PSM3's interpretations and uses.

Keywords: Assessment; Elementary School Education, Problem Solving

Problem solving is central to mathematical work (National Council of Teachers of Mathematics [NCTM], 2000, 2014) and is a core part of the Common Core State Standards, which were adopted by 42 of 50 states (Common Core State Standards Initiative [CCSSI], 2010). Problem solving is found in every grade-level across the Standards for Mathematics Content (SMCs) and is described in the first Standard for Mathematical Practice (SMP; CCSSI, 2010). The notions of problem and problem solving are pervasive across the Standards for Mathematical Practice (e.g., "Make sense of problems and persevere in solving them, CCSSI, 2010, p. 6) as well as the Standards for Mathematics Content (e.g., "Solve two-step word problems using the four operations", CCSSI, 2010, p. 23) and therefore should be a part of mathematics assessments. Bostic and colleagues (2015; 2017) reported that problem-solving tests used in scholarly studies tend to fall into three categories: large-scale assessments, measures of mathematical problem-solving distinct from curricular standards, and problem-solving assessments focusing on nonmathematical elements. Unfortunately, few mathematical quantitative instruments used with elementary students have reported validity evidence supporting their uses (Bostic et al., 2019). This study fills a gap in the literature by providing validity evidence for a problem-solving measure connected to curricular standards within elementary settings.

Related Literature

Multiple definitions and frames for mathematical problem solving exist. This study is guided by Lesh and Zawojewski's (2007) modeling-influenced perspective on problem solving: "several iterative cycles of expressing, testing and revising mathematical interpretations – and of sorting out, integrating, modifying, revising, or refining clusters of mathematical concepts from various topics within and beyond mathematics" (p. 782). Such a problem-solving perspective requires tasks that encourage students to engage in productive, reflective, goal-oriented problem solving. While there are multiple frames and definitions for what counts as a problem, this study draws upon Schoenfeld's (2011) features of a problem: (a) it is unknown whether a solution exists, (b) a solution pathway is not readily determined, and (c) there exists more than one way to answer the task. Problem solving happens when a task is a problem, not an exercise, for an individual (Polya, 1945/2004; Schoenfeld, 2011); hence a key component to problem solving is a problem.

The PSMs contain word problems and were designed using Verschaffel et al.'s (1999) characterization of word problems: *Open* word problems can be solved in different ways and offer learners multiple entry points. *Realistic* word problems draw on a problem solver's experiential knowledge and engage the student in a real-world task. *Complex* word problems require an individual to employ sustained reasoning. Communicating definitions is important to this study because developing summary (aka purpose) statements within validation work is derived from purposeful choices and in turn, informs users what the instrument can and cannot do (Carney et al., accepted). These statements are like an abstract for an assessment in that they convey essential information for potential measure users and administrators.

This study draws upon the Standards (AERA et al., 2014) to communicate evidence and connect it to interpretations and use. Aspects of a test's interpretation and use include articulating a construct, describing test administration, and scoring (Carney et al., accepted). The research question for this study is: What validity evidence exists for the PSM3? This examination of the PSM3 builds upon work on past PSMs for grades 4-8 (see Bostic et al., 2015; 2017; 2020).

Method

A design science framework (see Middleton, et al., 2008) guides this study to explore five sources of validity (see AERA et al., 2014): test content, response process, relations to other variables, internal structure, and consequences from testing. Only test content, response processes, and internal structure will be highlighted in this paper due to page limitations. Test content evidence provides a connection between content described in items on a test and the intended construct (AERA et al., 2014; Sireci & Faulkner-Bond, 2014). Reviews from an expert panel are a common and appropriate approach for discerning the degree to which there is a match (AERA et al., 2014). Response process evidence explores if respondents behave in ways that are intended or desirable (Padilla & Benitez, 2014). Think alouds are typical approaches to gather response process evidence for problem-solving tests (Leighton, 2017). Internal structure evidence suggests the degree to which items conform to a desired construct (AERA et al., 2014). Rasch techniques as well as classical test theory approaches are both adequate, yet each approach is beholden to differing assumptions (Rios & Wells, 2014). Qualitative data and analyses were used with test content and response process evidence. Quantitative data and analyses were employed to explore internal structure evidence.

Measure

The PSM3 is composed of 15 word problems with three items coming from each of the five SMC content domains: Operations and Algebraic Thinking, Numbers in Base Ten, Number and Fractions, Measurement and Data analysis, and Geometry. A sample PSM3 item reads "Beth is coloring a picture using crayons. The box of crayons has 6 blue crayons, 4 yellow crayons, 8 green crayons, and 6 red crayons. What fraction of the box of crayons is green?" The PSM3 is designed to measure mathematical problem-solving in relation to third-grade mathematics standards.

Data Collection

To address test content, expert panels were conducted with three grade-level mathematics teachers, two terminally-degreed mathematics educators with expertise in elementary mathematics (grades K-6), and one terminally-degree mathematician. Mathematics teachers were current grade three mathematics teachers who had at least four years teaching experience and at least two years teaching third grade. The mathematics educators have elementary teaching experience and have published and presented peer-reviewed work on elementary mathematics teaching. The mathematicians has experience working with elementary teachers and communicated having read and discussed the Common Core State Standards with their university students. Mathematics teachers and teacher educators responded to the following questions: (1) Is the task a problem? (2) Is the task open? (3) Is the task realistic? (4) What Standard(s) for Mathematics Content are primarily addressed by this task? (5) What Standard(s) for Mathematical Content are primarily addressed by this task? The mathematician responded to questions #1-3 as well and additionally, (6) Describe the mathematics addressed by this task. What are two appropriate, grade-level problem-solving strategies? (7) Is the mathematics in the problem correct? (8) Is there a well-defined solution for the task? Items were reviewed once by the expert panel, revised, and then subjected to a second review when necessary. Each expert panel member submitted responses to these questions.

To address response processes, both 1-1 think alouds and whole-class think alouds were used. 1-1 think alouds were performed with a purposeful sample of 12 students consisting of varying mathematical abilities as report by their mathematics teachers (i.e., above average, average, and below average ability), male and female students, as well as white and non-white students. Ability-level judgments were gathered from teachers' views about students' classwork and prior assessment data. Whole-class think alouds (see Bostic et al., 2021) were conducted one year later with two unique sets of students (n=32). Think alouds were videotaped and student work was collected. Combining think-aloud formats allowed for greater and more diverse information about students' responses.

To address internal structure, third-grade students (n=290) across four Midwest districts completed the PSM3 in the last month of the academic year. Districts represent urban, suburban, and rural schools and each has unique populations consisting of different ethnic backgrounds, socio-economic status, and locations. Students with and without an identified disability completed the PSM3 per any Individualized Education Plan requirements. Based upon prior pilot administrations, teachers gave students approximately 90 minutes to answer the questions.

Data analysis

Expert panel reports and student think aloud data were analyzed using inductive analysis (Creswell, 2012) across three researchers, which maintains a parallel structure from previous peer-reviewed work (Bostic et al., 2015; 2017; 2020). The inductive analysis started with re-reading (or re-watching) to materials (e.g., written work and recorded statements from the conference). Next, we made memos consisting of initial ideas stemming from this examination of the data and later reflected on those memos to synthesize them into support (or not). Then, we sought evidence and counter evidence within the data sets to support our burgeoning themes. Impressions with a paucity of counter evidence and a large set of evidence were retained. Finally, we crafted a thematic statement representing the supporting data. Related to test content evidence, an intended goal was to discern the degree to which items were connected to the intended standards and addressed our selected framework for word problems. Related to response process evidence, an intended goal was to explore ways that students' responses aligned with our a priori conjectures in students' problem solving. Psychometric data analysis for internal structure used Rasch modeling (Rasch 1960/1980). PSM3 items were scored dichotomously by three scorers using a scoring key. Generally, it is important to look multiple components from Rasch analysis. First, separation and reliability values of 2.0 and 0.8 are considered good while 3.0 and 0.9 are excellent (Duncan et al., 2003). Rasch infit and outfit statistics (mean square values between 0.5 and 2.0) are considered acceptable and there should be no negative point-biserial statistics (Linacre, 2002).

Findings

Themes for test content evidence were tasks were: complex enough to be considered problems for third-grade students, open, and solvable in multiple ways using grade-level strategies, and based upon realistic contexts that led to realistic solutions. Mathematicians confirmed three and sometimes four developmentally appropriate strategies that students might use to solve the word problems. Expert panel feedback consistently conveyed that tasks aligned with third grade content standards. One teacher shared a sentiment that others echoed: "These are appropriately difficult word problems that will make students think about the math they learn. These problems require more than just using a procedure." Finally, the expert panel conveyed that word problems met developmentally appropriate reading levels. A Flesch-Kincaid reading analysis confirmed (3.4 grade level). In sum, there was majority agreement between expert panel members and researchers' hypothesized content standards.

A theme about response process evidence was that students responded in anticipated ways. Average- and above-average performing students tended to provide more correct answers than below-average students. It was common for lower-performing students to combine numbers using symbolic notation without making sense of the quantities. In the crayon problem described earlier, there were many students who wrote a fraction that did not answer the question. When pressed to explain their thinking, we heard comments like Natasha's: "I made a fraction with the numbers like it says in the problem." All students were able to read the problems, which supported our finding that the PSM3 met grade-level reading expectations.

Psychometric findings support robust internal structure evidence. All items had acceptable infit (MNSQ Range 0.82-1.29) and outfit (MNSQ Range 0.68-2.00) measures, and no items had negative point biserial values. Rasch item reliability (0.93) and separation (6.43) were strong. Collectively, psychometric data suggest a unidimensional variable of problem solving has been created from items on the PSM3.

Discussion & Limitations

The central aim for this study was to report test content, response process, and internal structure validity evidence for the *PSM3*. Synthesized findings suggest the validity evidence as being supportive of the following claims: (a) Mathematics content found on *PSM3* tasks addresses mathematics content described in grade-level standards; (b) Respondents solved *PSM3* tasks in anticipated ways; and (c) The *PSM3* appears to fit a unidimensional construct, which we characterize as mathematical problem solving. These findings connect back to three desired sources of validity: test content, response process, and internal structure (see AERA et al., 2014). Taken collectively, the *PSM3* is an instrument that may be useful for scholars interested in studying third-grade students' mathematical problem solving within instructional contexts using the Common Core State Standards for mathematics. Evidence for relations to other variables as well as consequences of testing/bias will be further investigated. The findings for this study are limited to native English speakers, which should be explored in subsequent studies.

ASSESSING THE QUALITY OF MATHEMATICS IN CAMEROON PRIMARY SCHOOL TEXTBOOKS AND ITS IMPLICATIONS TO LEARNING

Napthalin A. Atanga
University of Bamenda, Cameroon/CBC Education Department, Bamenda, Cameroon
naatanga2008@yahoo.com

Mathematics textbooks for upper primary classes in the English Subsystem of Education in Cameroon were examined to determine the quality of mathematics in them and possible teacher knowledge fostered. The quality of mathematics in these textbooks is classified as medium and the dominant teacher knowledge fostered is common content knowledge. This is because the textbooks are full of accurate standard algorithms and mathematical definitions, yet lack the use of multiple strategies and representations. They also contain high proportion of mathematical explanations that are either partially accurate or accurate but incomplete. Textbooks with medium mathematical quality have high potentials of causing learners and teachers to be mathematically malnourished.

Keywords: Assessment, Mathematical Representations, Curriculum

In 2018, the Ministry of Basic Education in Cameroon introduced reforms in the Primary School curriculum for the English Subsystem of Education. Following this curriculum reform, Cameroon promulgated into law, for the first time, the one textbook policy, meaning only one textbook would be approved by the National Council for the Approval of Textbooks and Didactic Materials (NCATDM) for use in each class for each subject for a period of six years before the selection is reviewed. Following this policy, publishers of textbooks went into writing to submit materials for approval by the NCATDM so that primary school learners and teachers throughout Cameroon would use them for teaching and learning. A goal of the NCATDM is to select the textbook that covers the curriculum in the best possible way to ensure that learners learn appropriate content. This paper focuses on mathematics textbooks only.

Shulman (1986) argued that teachers need more than facts to adequately teach mathematics. A possible point where teachers could obtain knowledge for teaching is during pre-service teacher training programs. Ball, Thames and Phelps (2008) noted that subject matter courses in many teacher preparation programs fail to provide the much needed mathematics content for teaching as the emphasis seems to be on higher mathematics. Therefore, my hypothesis is that in such a case teachers, after being trained, actually encounter the mathematics they are to teach when exposed to textbooks designed for learners. Hence, mathematical knowledge for teaching seems to be encountered and developed as teachers use textbooks to teach.

A number of studies have investigated teachers' mathematical knowledge and its impact on student achievement as well as the quality of mathematics in classroom instruction. Hill, Rowan and Ball (2005) found that the stronger a teacher's knowledge of mathematics, the greater the learning exhibited by learners. Ball, Thames and Phelps (2008) identified the components of mathematical knowledge that the work of teaching demands on teachers. Hill, Blunk, Charalambous, Lewis, Phelps, Sleep and Ball (2008) investigated the quality of mathematics that teachers display in classrooms during instruction and found that there is a strong positive correlation between teacher knowledge and quality of mathematics exhibited in instruction. However, little has been investigated about the quality of mathematics provided in textbooks for

Cameroon schools. This study investigates the quality of mathematics provided in primary school textbooks selected by NCATDM and attempts to answer two research questions. *What is the quality of mathematics in primary school textbooks approved for use by the English Subsystem of Education in Cameroon from 2020-2026? What types of mathematical knowledge for teaching might be promoted for teachers using these textbooks?*

This study has potentials to influence policy on textbook selection, focusing on the high quality of mathematics and the type of mathematical knowledge for teaching promoted. It may also be helpful to mathematics educators to examine the gap between what training of teachers offers and what teachers encounter in textbooks and fill in the space so as to adequately prepare teachers for teaching. In addition, this study can inform professional development on areas to focus so as to strengthen teacher learning.

Theoretical Perspective

Hill, Blunk, Charalambous, Lewis, Phelps, Sleep and Ball (2008) identified key aspects of high quality mathematics in classrooms including accurate mathematical explanations, mathematically accurate and intelligible definitions, accurate summary of mathematical ideas, reflection on explanations, conceptual discussion of procedures, accurate mathematical language, careful use of real world contexts, knowledge and use of multiple solution strategies, use of multiple representations and sequential construction of mathematics from one topic to another. Marshall, Superfine and Canty (2010) argued that multiple representations improve on the quality of mathematics taught in classrooms. Marshall, Superfine and Canty (2010) further argue that just using multiple representations is not enough but called for connections between or among the representations to ensure greater visibility to learners and therefore raise the quality of mathematics in instruction through reflection of the representations, create opportunities for learners to translate among representations. Connections should also be fostered between or among units in a textbook (Ball & Cohen, 1996) as this can help learners see mathematics as a connected subject and be able to pull learning from one unit to another to boost their understanding and sense making in the subject. Teacher's knowledge can also be supported as they use curriculum materials to teach. Ball, Thames and Phelps (2008) identified Common Content Knowledge (CCK), Specialized Content knowledge (SCK), Knowledge of Content and Teaching (KCT) and Knowledge of Content and Students (KCS) as knowledge teachers need to teach.

Methodology

This study is part of a larger study investigating the quality of mathematics in textbooks approved by NCATDM for use in Primary Schools (classes one to six) of the English Subsystem of Education in Cameroon. Learners' textbooks for classes five and six were analyzed for this particular study.

Textbooks for this study. Textbooks approved by NCATDM for classes five and six are published by ASVA Education with titles *Foundation Primary Mathematics 5* and *Foundation Primary Mathematics 6*. Throughout these textbooks, each unit has sections for *let's observe, let's find out, let's retain* and *let's practice. Let's observe* contains demonstration of some methods pupils are expected to learn, *let's find out* contains questions that are presented for learners to reflect on the methods just observed, *let's retain* contains mathematical explanations or definitions of concepts learners are expected to understand as well as examples used to illustrate mathematical concepts learners are to learn and *let's practice* contains problems learners are supposed to engage with in order to reinforce the concepts learned.

Data sources. Data for this study were drawn from the *let's observe* and *let's retain* sections of each unit. This is because these are the sections where representations and mathematical explanations or definitions for concepts learners are expected to learn are provided. Simple random sampling was done and fifty percent of the units in each textbook was selected for analysis. This was to ensure greater coverage to adequately represent each of the textbooks. The following six units out of twelve were selected for analysis in *Foundation Primary Mathematics 5*: Unit 2-basic number operations, Unit 4-number and numeration, Unit 6-modulo arithmetic and number bases, Unit 8-money and shopping, Unit 10-speed, distance and time and Unit 12-graphs and statistics. For *Foundation Primary Mathematics 6*, six units out of twelve selected were: Unit 2-numbers and numeration, Unit 3-basic number operations, Unit 4-base system, Unit 5-fractions and decimals, Unit 6-modular arithmetic, and Unit 7-Rate, ratio and proportion.

Data analysis. In this analysis, mathematical explanations, solutions to examples, representations and definitions were coded. Mathematical sentence were coded using Figure 1.

Codes		**Descriptions**
1A	Accuracy	When all parts of the explanation are correct.
1B	Partially accurate	When some parts of the explanation are correct and other parts are not correct.
1C	Inaccurate	When all parts of the explanation are not correct.
1D	No explanation	When no explanation is provided.
1E	Incomplete explanation	When an incomplete accurate explanation is provided.
2A	Single method	Just one method is used in solving an example.
2B	Multiple methods	In more than one methods used in solving an example.
3A	Connections	Connections made between or among the methods.
3B	No connections	No connections made between or among multiple methods.
3C	Reference made in text	Reference is made about the solution in the text.
3D	No reference	No reference about the solution in the text.
4A	Single representation	Whether a single representation is used employed.
4B	Multiple representation	The use of more than one representation to explain a concept.
5A	Accurate representation	When all parts of the representations are correct, conveying conceptual aspects of the key mathematical ideas to be learned.
5B	Partially accurate representation	When some parts of the representations are correct, conveying conceptual aspects of the key mathematical ideas to be learned while other parts are not correct.
5C	Inaccurate representation	When all parts of the representations are not correct, conveying incorrect conceptual aspects of the key mathematical ideas to be learned.
5D	Reference to representation in the text	When explicit reference is made in the text to explain the representation used.
5E	No reference to representation in the text	When no reference is made in the text to explain the representation used.
5F	Connections between or among representations used	When explicit connections are made in the text to show relationships between or among representations used.
6A	Mathematically accurate and intelligible definitions	All components of the definitions are accurate with no limitations or ambiguity.
6B	Mathematically partially accurate definitions	Some parts of the definitions are accurate while others have limitations or ambiguity.
6C	Mathematically inaccurate definitions	All parts of the definition are not correct.
6D	Accurate but incomplete definitions	Definitions are accurate but incomplete.

Figure 1: Codes and Descriptions

Lastly, I deduced the quality of mathematics learners are likely to learn from using these textbooks as high (*accurate mathematics and representations used and connections among the representations*), medium (*mostly partially accurate mathematics and representations and sometimes connections among them*) and low (*mostly inaccurate mathematics and representations used and no connections among them*). Finally, from the mathematics embedded in these two textbooks, I inferred the dominant kind of mathematical knowledge teachers using them might possibly acquire over time. I coded the knowledge type as CCK (*mathematical knowledge common to other users of mathematics*), SCK (*mathematical knowledge specific to the teaching of mathematics*), KCS (*anticipating what students might think, the confusion/difficulties they might have*) and KCT (*knowledge of teaching and about the mathematics they are to teach, understanding the sequencing of topics, the design rationale of tasks or representations used*).

Figure 2: Coding results

Figure 2 shows that of the 685 mathematical explanations provided, 77.8% of them were accurate in all its parts. The accurate mathematical explanations were all standard procedures including steps that have to be executed by learners. For example, in the unit for *Base System*, conversion from one base to another is required. This textbook explains the procedure as follows "to convert numbers from one base to another other than base 10, we first change them to base 10, then, we change to the indicated base" (class 6 textbook, p. 39). Some of these mathematical explanations were simply facts that are to be learned, memorized and reproduced such as "not all prime numbers are odd" (class 5 textbook, p. 15) and "2 is a prime number but is also an even number" (class 5 textbook, p. 15).

Also, of all the 685 sentences providing mathematical explanations, 9.5% of them are partially accurate. In the class 6 textbook, it is explained that "to look for the cube root, first divide the number by all possible factors" (p. 25). This explanation is partially accurate in that we find the cube root of any number by dividing it by possible prime factors only not "all possible factors." The absence of "prime factors" in the textbook's explanation makes it partially accurate.

Of the mathematical explanations provided, 4.5% are inaccurate in all of its parts. For example, in expressing fractions as decimals, $\frac{1}{2}$ is used in the textbook and written as

$$\begin{array}{r|l} & 0.5 \\ \hline 2 & 10 \\ - & \underline{10} \\ & 0 \end{array}$$

together with the following explanation "1 cannot divide 2 so, we put a point above 1 and affix a zero behind 1 to make it 10, 10 divided by 2 is 5" (class 6 textbook, p. 66). This explanation is not correct in all its parts as the point is not put on 1. Note that every whole number has a decimal point after it. So, 1 can be written as 1.0. Now, since 2 cannot go into 1, we put a 0 above 1 and then put the decimal point above the decimal point and insert a zero (0) after the decimal point. Now 5 tenth multiplied by 2 gives 1.0 as shown to the right.

$$\begin{array}{r|l} & 0.5 \\ \hline 2 & 1.0 \\ - & \underline{1.0} \\ & 0 \end{array}$$

In the textbook's explanation, one wonders how we started with the dividend as 1 and ended up with it as being 10. Of the 685 mathematical sentences, 3.4% had no explanations.

In subtracting fractions, the textbook provides a problem as $\frac{3}{3}-\frac{2}{9}$. Then goes ahead to solve the problem as follows $\frac{3}{3}-\frac{2}{9}=\frac{3\times3}{3\times3}-\frac{2\times1}{9\times1}$, then $\frac{3}{3}-\frac{2}{9}=\frac{9}{9}-\frac{2}{9}$ and finally $\frac{3}{3}-\frac{2}{9}=\frac{7}{9}$ (class 5 textbook, p. 44). In this solution, the authors did not explain why the numerator and denominator of the fraction $\frac{3}{3}$ are multiplied by 3 and why that of $\frac{2}{9}$ is multiplied by 1. Without explaining why the multiplications were done, the learners and teachers are left with a thinking that the numbers were chosen arbitrarily, making their understanding flawed. Of the 685 mathematical sentences, 4.8% had incomplete accurate explanations. In explaining a mixed fraction, the textbook said "a mixed fraction is a fraction which has a whole number attached to it to the left side" (class 5 textbook, p. 41). This explanation is accurate but incomplete as the whole number is the quotient when a number is divided by another number. So, the complete accurate explanation could have been, "a fraction represented with its quotient and remainder is called a mixed fraction." In addition, learners are often confused about the operation between the whole number and the fractional part of the mixed fraction. Learners often see that operation as multiplication because ab means $a\ '\ b$. Therefore, emphasis could have been laid by the authors that the mixed fraction $a\frac{b}{c} = a + \frac{b}{c}$ to dispel this confusion and curb misconceptions that learners often have. This accurate complete explanation provided might cause a smooth transition between improper fractions and mixed numbers and fully explain the idea of mixed fractions.

Of the 123 solutions provided, 111 of them have just one strategy while 12 of them have at least two strategies. When solved using more than one method, no connections are made between or among the methods. This is a missed opportunity to have learners decide which approach or strategy they understand best and will be able to use. In 50% of the time, when more than one solution strategies are used, these are referenced in the text while in another 50% there is no reference about the solution in the text. When no reference is made about the solution in the text, learners are left with the option of struggling to understand what they actually mean. In 76.8% of the time, the authors used single representation to solve problems or demonstrate a concept while in 23.2% of the time, multiple representations are used.

The representations revealed that 32.9% of them were accurate in all parts, conveying conceptual aspects of the key mathematical ideas to be learned.

$$
\begin{array}{rrcrrr}
 & 6 & . & 3 & 4 & 6 \\
 & 0 & . & 0 & 3 & 5 \\
+ & 8 & . & 5 & & \\
 & 0 & . & 7 & & \\
\hline
1 & 5 & . & 5 & 8 & 1 \\
\hline
\end{array}
$$

In adding decimals, the authors accurately lined up all the decimal numbers using the place value table to the left and then calculating the sum (class 5 textbook, p. 53).

Of the representations used, 16.4 % are partially accurate, some parts of the representations are correct, conveying conceptual aspects of the key mathematical ideas to be learned while other parts are not correct.

Fractions	**Decimals**	**Percentages**
$\frac{1}{2}$	0.5	50%
$\frac{1}{4}$	0.25	25%
$\frac{1}{3}$	0.33	33%

In changing fractions to decimals and then percentages, the authors presented the table to the left which is not accurate in all its parts (class 5 textbook, p. 52).

The first two rows are both correct and accurate but the third row is not correct as $\frac{1}{3}$ is not exactly 0.33 as a decimal and $\frac{1}{3}$ is not exactly 33% as a percentage. This inaccurate representation of the third row can be very misleading to teachers and learners.

Of the representations, 13.7% are inaccurate in all parts, conveying incorrect conceptual aspects of the key mathematical ideas to be learned. The representation of equivalent fractions is incorrect, conveying misconceptions of the key mathematical idea. For example, $\frac{1}{2}$ is represented as equivalent to $\frac{2}{4}$ and also $\frac{3}{6}$ on two separate diagrams (class 6 textbook, p. 46). The emphasis in this textbook is on the generation and not on the understanding/meaning of equivalent fractions.

As such the multiplication of numerator and denominator by the same whole number to generate equivalent fractions is emphasized and reinforced. Of the representations used, 21.9% of them are referenced in the text explicitly to explain teachers and learners the concept embedded in them, 15.1% of the representations are not referenced in the text and this has the potential of teachers and learners ignoring them for lack of understanding and none (0%) of the representations are connected explicitly or implicitly to show relationships between or among them and rationale for why they were used.

For mathematical definitions provided throughout the textbooks, 92.6% of them were accurate and having no ambiguity. For example, "proper fractions are fractions whose numerators are smaller than the denominators" (class 6 textbook, p. 45). Of the definitions provided, 7.4% are partially accurate. For example, "when an object is divided into equal parts, each part is a fraction of that object" (class 6 textbook, p. 44). This definition offered by the textbook is partially correct as it is not only when the parts are equal that it is a fraction of the whole. A part of a whole is a fraction whether they are equal or unequal. Also, fractions are formed by dividing *n* units into *m* equal parts $\left(\frac{n}{m}\right)$ and then collecting *n* of those equal parts. In addition, the book defines the calculation of speed or average speed as $\frac{\text{Distance}}{\text{Time Taken}}$ (class 5 textbook, p. 101). This definition is true and accurate for speed but not always for average speed. Average speed is calculated using $\frac{\text{Distance covered in an interval of time}}{\text{interval of time}}$ or $\frac{\text{increase in displacement in that interval of time}}{\text{interval of time}}$. Although speed and average speed might be the same at some point, this is usually not the case and should be clearly distinguished to the teacher and learner. Furthermore, none of the definitions are completely inaccurate or completely accurate; they are incomplete.

The results of this study revealed that the dominant kind of teacher knowledge that might be highly promoted is *Common Content knowledge* (CCK). Figure 2 indicate that majority of the mathematical explanations provided are accurate (77.8%). These explanations are mainly those that could be offered by mathematicians as well as other users of mathematics. Also, in the examples provided inside the textbooks, 90.2% of them were solved using a single method and when representations were used, only a single representation is used to explain a mathematical idea. The single solution methods provided are mainly standard algorithms. In addition, when definitions are provided, 92.6% of them are accurate and often these are standard mathematical definitions.

Discussion/Significance

Overall, the quality of mathematics presented in official textbooks for primary 5 and 6 of the English Subsystem of Education in Cameroon can be classified as medium. This is because in these textbooks, the proportion of partially accurate mathematics is significantly high; multiple solution strategies/representations are rarely used; when multiple solution strategies / representations are used, connections between or among them are rarely established; proportion of mathematical definitions that are inaccurate is significantly high. As such, these textbooks fall short of research recommendations for curriculum materials from which teachers can learn.

Davis and Krajcik (2005) recommended that curriculum materials should contain features to support teacher learning. These features include multiple ways learners might respond to a task or problem and together provide mathematical explanations embedded in these responses and representations that might be employed. In addition, connections between and among the strategies/representations used can be helpful in providing multiple access into the mathematical ideas learners are to learn. Marshall, Superfine and Canty (2010) have argued that when multiple representations are used, connections between or among them should be established in order to raise the quality of mathematics being taught. Ball and Cohen (1996) emphasized that these connections should be fostered by textbook authors. Therefore, establishing connections between or among multiple solution strategies/representations used can help to improve on the quality of mathematics learners learn. In addition to improving the quality of mathematics in textbooks, intentionally making connections in the mathematics textbook might enable learners to see the subject as connected and might be induced into making such connections so as to improve on the quality of their learning. The absence of these features in official textbooks selected for use in the English Subsystem in Cameroon seems to project these curriculum materials as creating very little opportunities for teachers and learners to learn appropriate mathematics and hence being mathematically malnourished.

Teachers are often mathematically malnourished when their learning is limited to a unique form of mathematical knowledge for teaching. The dominant teacher knowledge propagated in these textbooks is common content knowledge (CCK). This is because the percentage of mathematical explanations, single solution methods, single representation and mathematical definitions used in these textbooks are very high. In addition, their focus is laid on standard algorithms. The absence of other forms of teacher knowledge in these textbooks is a clear indication that the teachers using them might be limited in their mathematical knowledge for teaching as a whole and as such limited in teaching this subject to learners.

These findings reveal that mathematics textbooks approved for use in class 5 and 6 in the English Subsystem of Education in Cameroon are not fully providing and developing the needed mathematical proficiency in teachers and learners. The National Research Council (NRC, 2001) characterized mathematical proficiency as having five strands namely *conceptual understanding*, *procedural fluency*, *strategic competence, adaptive reasoning* and *productive disposition*. From the emphasis in these textbooks, one could deduce that only one strand, procedural fluency is promoted because of the heavy emphasis on standard methods and definitions. This study identified that mathematics textbooks selected for use by our learners and teachers fall short of the standard to support and develop their mathematical proficiency. Therefore, textbook authors can use the results of this study to develop materials that will support and develop the needed mathematical proficiency for both teachers and learners in Cameroon. The results will also help the NCATDM review their selection criteria for textbooks and focus on aspects that promote learning of both teachers and learners. The outcome of this study will also help professional development experts and teacher educators in Cameroon to focus on building teachers' capacities in areas identified as limited in these textbooks.

Although this study investigated textbooks in Cameroon, the quality of mathematics in many textbooks around the globe might not be promoting desired mathematical proficiency because the features to support improve this quality are highly limited. As such, the following question need further investigation: What combination of the features to develop mathematical proficiency in both teachers and learners is needed in textbooks to yield optimum learning outcomes? Answers to this question will enable textbook developers focus on using only those features whose interactions produce greatest learning outcomes rather than attempt to include all features that might be overwhelming to teachers.

SLOPE ACROSS THE CURRICULUM: A TEXTBOOK CASE ANALYSIS

Thomas Fisher

This study reviews how slope is developed in expository materials across a seven-textbook series. Slope development is analyzed using a framework of five slope components to describe which components are used and connected, and by investigating accompanying levels of covariational reasoning. Findings suggest that the series describes slope from multiple components, and this development is grounded in various levels of covariational reasoning. While many connections were found between components, occurrences of both visual and nonvisual approaches within components were not prevalent. Suggestions include building connections between Behavior Indicator and Determining Property components through descriptions of covariation as well as more connections to the Steepness component.

Keywords: Algebra and Algebraic Thinking, Curriculum, High School Education, Middle School Education

Slope describes the constant rate of change of a linear function, a notion that can be understood using a variety of representations and applied for different purposes. Even though it is a “universal topic in every country’s mathematics curricula,” slope has been called *elusive* (Lingefjärd & Farahani, 2018, p. 1188) because a deep understanding of slope is difficult to acquire (Hoban, 2021). Not only does slope involve deeply understanding ratios (Lobato, Ellis & Muñoz, 2003; Walter & Gerson, 2007), students must also develop an understanding of a “function as a process” (Wilkie, 2020, p. 317) that involves covariation (Thompson & Carlson 2017). Students need multiple ways to view situations involving slope (Thacker, 2020); yet research (Styers, Nagle, & Moore-Russo, 2020) suggests that teachers themselves need more experiences with tasks that allow them to build rich, flexible, robust notions of slope.

Slope spans the mathematics curriculum. In algebra, slope is used when considering the covariational contrasts between basic linear and more advanced nonlinear functions (Carlson, Jacobs, Coe, Larsen & Hsu, 2002; Ellis, Ely, Singleton & Tasova, 2018). In statistics, slope impacts linear regression and lines of best fit (Nagle, Casey & Moore-Russo, 2017). In single variable calculus, slope is involved in understanding both average and instantaneous rates of change, as well as working with other key ideas, such as relative extrema and the Mean Value Theorem (Bateman, LaForest & Moore-Russo, 2021). Without a solid understanding of slope, it is difficult to make meaning of derivatives in either single or multivariable calculus (McGee & Moore-Russo, 2015; Zandieh & Knapp, 2006). However, students often struggle to grasp more than rote procedures or mnemonics, such as “rise over run” (Walter & Gerson, 2007). Therefore, it is important to understand how slope is developed in curricular materials.

Framework

This study seeks to describe how slope is developed across a textbook series. The study is informed by past work on textbooks, slope, and covariational reasoning.

Textbooks

Textbooks reflect "significant views of what mathematics is…and the ways that mathematics can be taught and learnt" (Pepin & Haggerty, 2001, p. 166). Textbooks play an influential role in mathematics education (Fan, Zhu, & Miao, 2013; Pepin, Gueudet & Trouche, 2013), especially in how teachers shape and sequence their instruction (Davis, 2009). Fan and Kaeley (2000) suggest that textbooks send "pedagogical messages" to teachers, since teachers using different textbooks display differences in their teaching strategies. While teachers may have access to a variety of resources, the textbook is typically the only common resource for students (Lepik, Grevholm, & Viholainen, 2015). Textbooks influence how students learn and how they consider and solve problems (Massey & Riley, 2013).

Slope

Stump's (1999, 2001a, 2001b) seminal work brought to light that slope is a multifaceted notion that can be conceptualized in many ways. Moore-Russo, Connor and Rugg (2011) introduced conceptualizations of slope as the ways that people think about and make meaning of the topic. Their 2011 conceptualization categorization has been used in studies of curriculum and standards conducted in Mexico, South Africa, and the U.S. (Nagle & Moore-Russo, 2014b; Stanton & Moore-Russo, 2012; Dolores Flores, Rivera López, & Moore-Russo, 2020). Since then, the 11 categories have been revisited and revised in research that bridges secondary to postsecondary mathematics (Nagle, Martinez-Planell, Moore-Russo, 2019; Nagle & Moore-Russo, 2014a; Nagle, Moore-Russo, Viglietti & Martin, 2013) resulting in a more nuanced conceptual framework using five connected components, each with visual and nonvisual approaches (Nagle & Moore-Russo, 2013b). In Table 1, we adopt a revised framework omitting the *Calculus* component since our study focuses on the development of slope in a precalculus context. Furthermore, we include both the *Ratio* and *Constant Parameter* components of slope to more completely delineate the nuances of slope development around these two closely connected components.

Table 1: Slope Component Coding (adapted from Nagle and Moore-Russo, 2013b)

Slope Code	Approach	Description
Constant Parameter	Visual (CP-V)	Defining parameter of linear graph (with a *y*-intercept) that indicates a uniform "straightness" of the line's entire graph; no matter which segment of the line is considered the "straightness" is constant due to similar triangles
	Nonvisual (CP-N)	Defining parameter of linear relationship (with a *y*-intercept) indicating constant rate of change between two covarying quantities; slope calculations remain constant between any two points or on any increment of change in independent variable
Ratio	Visual (R-V)	Ratio calculated by rise/run or vertical change divided by the horizontal change between any two graphed points
	Nonvisual (R-N)	Ratio calculated for any two ordered pair points (x_1, y_1) and (x_2, y_2) using the difference quotient $(y_2 - y_1)/(x_2 - x_1)$
Behavior Indicator of line or linear relationship	Visual (BI-V)	Indicator of (increasing, decreasing, horizontal, or vertical) behavior of linear graph; correlates sign of slope to directions of rise and run to determine graphical behavior
	Nonvisual (BI-N)	Indicator of increasing, decreasing, or constant behavior of linear relationship; correlates sign of slope to relationships between *change in y* and *change in x*
Steepness	Visual (S-V)	Measure of steepness of linear graph (how inclined, tilted, slanted, or pitched a line is seen as being); relates slope to angle of elevation of linear graph

of line's angle of inclination with horizontal	Nonvisual (S-N)	Measure of how extreme a linear rate of change is calculated as being (e.g., relates magnitude of $\lvert y_2 - y_1 \rvert$ with corresponding magnitude of $\lvert x_2 - x_1 \rvert$); relates slope to calculation of tan q
Determining Property between lines	Visual (DP-V)	Property that determines if linear graphs will intersect and how (e.g., if slopes are negative reciprocals, the lines intersect at right angles)
	Nonvisual (DP-N)	Property that determines whether two linear relationships that form a system of equations will have solutions and how many solutions will result

Covariational Reasoning

Covariational reasoning relates to the "mental coordination of two varying quantities while attending to the ways in which they change in relation to one another" (Carlson et al., 2002, p. 354). Slope is a topic that describes the covariational relationship between the dependent and independent variables in a linear relationship. To understand the development of slope reasoning across the curriculum, it is vital to consider how these components are built from an underlying conception of covariational reasoning. Carlson and colleagues (2002) describe five hierarchical levels of covariational reasoning, outlined in Table 2. Within the context of this study, which focuses on the development of slope prior to calculus, we do not code for L5 reasoning.

Table 2: Levels of Covariational Reasoning (Carlson et al., 2002)

Level	Description
L1: Coordination	Coordinate change in one variable with change in second variable
L2: Direction	Coordinate direction of change in one variable with change in second variable
L3: Quantitative Coordination	Coordinate amount of change in one variable with change in second variable
L4: Average Rate	Coordinate average rate of change of function uniform changes in input variable
L5: Instantaneous Rate	Coordinate instantaneous rate of change of function with continuous changes in independent variable

Methods

Data Source

The textbook series for this study was developed by the University of Chicago School Mathematics Project (UCSMP, 2021). This series of textbooks was written to correlate with the Common Core State Standards by emphasizing applications, digital resources, and mastery learning. The seven textbooks that comprise the grade 6-12 series were analyzed. In sequential order, they include: Pre-Transition Mathematics (PTM); Transition Mathematics (TM); Algebra (A); Geometry (G); Advanced Algebra (AA); Functions, Statistics, and Trigonometry (FST); and Precalculus and Discrete Mathematics (PC). The parenthetical letters denote the textbooks abbreviations used in the tables and figures below. Since this study specifically focused on slope of a line or linear function, all textbook coding excluded examples of variable or instantaneous slope, unless explicit connections to linear slope were also made.

Research Questions

This study seeks to answer the following questions:

1) Which components of slope are emphasized within each textbook and across the series?
2) What connections are made between components of slope across the series?

3) How is covariational reasoning developed in relation to slope?

Data Coding and Analysis

Data for this study included all the expository material (i.e., the components of the textbook that conveyed information through explanations and descriptions) within the textbook series. The different types of expository material analyzed included: chapter overviews, explanatory dialogue, examples, and activities. Each chapter began with a two-page overview intended to motivate the topics that followed. Within chapters, each section typically followed a similar format of explanatory dialogue punctuated with examples. The explanatory dialogue was text that introduced new terminology and definitions, reviewed foundational ideas, and provided general explanations. The examples were used to illustrate, clarify, and extend the ideas and relationships provided in the explanatory dialogue. They were either fully complete or mostly complete with a few missing details to prompt student thinking. Some sections included activities, often utilizing digital resources, which guided students through a series of steps with embedded explanations and guided questions. The unit of analysis was easily defined for examples and activities, with each example or activity being a single unit of analysis. For the chapter overview and the explanatory dialogue, a unit of analysis was distinguished as all the content included within a single heading or separated by examples or activities. While most units of analysis included one to two paragraphs of mathematical expository content, some were as short as two sentences and others extended to three or more paragraphs.

Two categories were used to code the data: a) slope conceptualization components (distinguishing between visual and nonvisual approaches) and b) covariational reasoning level. Details for the two coding categories are in Tables 1 and 2, respectively. Each unit of analysis was coded for all slope components noted and for the highest level of covariational reasoning present. Therefore, each unit was coded for up to ten possible slope conceptualization-approach pairs and at most one covariational reasoning level. The lead author was the primary coder, meeting weekly for eight weeks with the second author to review coding. Each section of every textbook was coded for all expository material related to slope. Once coding was complete, the data were sorted and prepared for analysis. The sorting was used to study each of the seven textbooks individually as well as to consider longitudinal trends across the entire series.

Results

Across the entire series, 201 units were identified and coded as addressing slope (see Table 3). All seven textbooks in the series addressed slope, even if not explicitly using the term when first introduced. As anticipated by the research team, the number of slope occurrences was highest in the Algebra and Advanced Algebra textbooks.

Table 3: Relative Frequency of Slope Occurrences across the Textbook Series (n = 201)

Percentage of All Slope Occurrences Across Entire Series	Textbook						
	PT	TM	A	G	AA	FST	PC
	5%	14%	35%	10%	20%	7%	8%

Slope Components

Table 4 displays data related to the slope components identified in each textbook, including the number of occurrences with only visual, only nonvisual, or both visual and nonvisual approaches. Across the series, more than two-thirds of all slope occurrences included the

Constant Parameter or *Ratio* component. Moreover, one of these two was the most prominent component identified for each textbook. Table 4 indicates that at least one of these two components was assigned to 50% of the slope occurrences in each textbook, with both components assigned to 50% or more of the slope occurrences in four of the seven textbooks. All other components were assigned to less than 50% of the occurrences in each textbook. Even though textbooks provided a consistent, heavy emphasis on nonvisual approaches of the *Constant Parameter* and *Ratio* components, there were relatively few occurrences linking the visual and nonvisual approaches within either component.

Overall, visual (V) and nonvisual (N) approaches of the slope conceptualization components tended to vary greatly with strikingly few occurrences incorporating both aspects of a slope component. Occurrences linking visual and nonvisual approaches of the *Behavior Indicator* (BI) component were more prevalent than the other components. Connections between BI-V and BI-N were often facilitated by explanations that incorporated multiple representations of linear functions (e.g., the equation $y = 3x+5$ and the corresponding linear graph) when analyzing what the slope indicates both about the rate of change of y with respect to x (i.e., as x increases by 1, y increases by 3) and about the graphical representation of that relationship (i.e., an increasing line that goes over 1 unit and up 3 units). Note that in situations such as this, the BI-N code was assigned since the corresponding directions of change of the two covarying quantities were linked (L2 covariational reasoning) and connected to the increasing or decreasing behavior of the linear graph (BI-V). However, these occurrences often stopped short of explicitly relating the direction of change to the increasing or decreasing nature of the function itself (e.g., if $x_1 < x_2$, then $f(x_1) < f(x_2)$).

Table 4: Frequency of Slope Components by Approach within Occurrences by Textbook

Textbook (number of slope occurrences)	Slope Components (by Visual, Nonvisual, or Both Approaches)														
	CP			R			BI			S			DP		
	V	N	Both	V	N	both	V	N	both	V	N	both	V	N	both
PTM (n=11)	0	0	2	0	9	0	1	4	0	0	0	1	0	0	0
TM (n=28)	0	14	3	0	19	0	2	6	5	3	0	0	1	0	0
A (n=70)	5	45	8	4	40	5	7	14	10	4	1	1	2	1	4
G (n=21)	0	11	0	2	10	2	3	0	0	3	0	0	10	0	0
AA (n=40)	3	27	0	0	21	4	1	8	4	1	1	1	8	1	0
FST (n=14)	0	9	1	2	3	0	0	2	2	0	0	0	0	0	0
PC (n=17)	0	6	0	0	9	2	1	2	5	0	0	1	1	0	0
Series (n=201)	8	112	14	8	111	13	15	36	26	11	2	4	22	2	4

Figure 1 illustrates the emphasis of each slope component by textbook. In each cluster, the first bar represents the percentage of total slope occurrences across the series attributed to a textbook. The five subsequent bars represent the corresponding percentage of all slope occurrences where a particular slope component was identified in the textbook. For instance, the first cluster shows that the Pre-Transition Mathematics textbook included 5% of all identified slope occurrences across the series, which included roughly 1% of all *Constant Parameter* occurrences, 7% of all *Ratio* occurrences, 6% of all *Behavior Indicator,* 6% of all *Steepness* occurrences, and 0% of the *Determining Property* occurrences. Uniform distribution of slope components across the textbook series would result in approximately equal percentages of each component for a particular textbook. For the most part, this is seen in the relatively equal height of bars within each textbook cluster. However, the *Determining Property* component appears to be heavily emphasized in the Geometry and Advanced Algebra texts (the right most bar in each cluster). The Geometry and Advanced Algebra textbooks included 10% and 20%, respectively, of all slope occurrences but included 36% and 32%, respectively, of the *Determining Property* occurrences. Two-thirds of all *Determining Property* occurrences were identified in these two textbooks even though less than one-third of all slope occurrences occurred in them. Figure 1 also reveals a heavy focus on the *Steepness* component in the Geometry textbook, which might be expected from a geometric (versus algebraic) consideration of lines.

We also considered which slope components were developed together within a single occurrence to determine common component connections. Of the 201 occurrences, 146 included combinations of two more components, while 55 occurrences were assigned a single code. A total of 21 unique coding assignments were made (e.g., *Constant Parameter* only*; Constant Parameter* and *Ratio;* and *Constant Parameter, Ratio, and Behavior Indictor*). Table 5 provides information about each of the coding assignments that were identified in at least 2% of all slope occurrences in the textbooks. Overall, many slope occurrences across the series made connections with the *Constant Parameter*, *Ratio*, and *Behavior Indicator* components. Given the complimentary nature of slope used as a *Behavior Indicator* and *Determining Property* (e.g., recognizing a line perpendicular to an increasing line must decrease), it is also interesting that these two components were linked in only one occurrence and, therefore, were not included in Table 5. *Steepness* was linked with all other slope components at least once throughout the textbook series. However, it had few occurrences across the series, even in the last two textbooks in the series when angles and trigonometry play major roles, and it did not appear in any of the frequent slope component combinations. This is noteworthy since *Steepness*, which can be tied to the tangent of an angle of inclination, is often disconnected from other slope components (Nagle & Moore-Russo, 2013a).

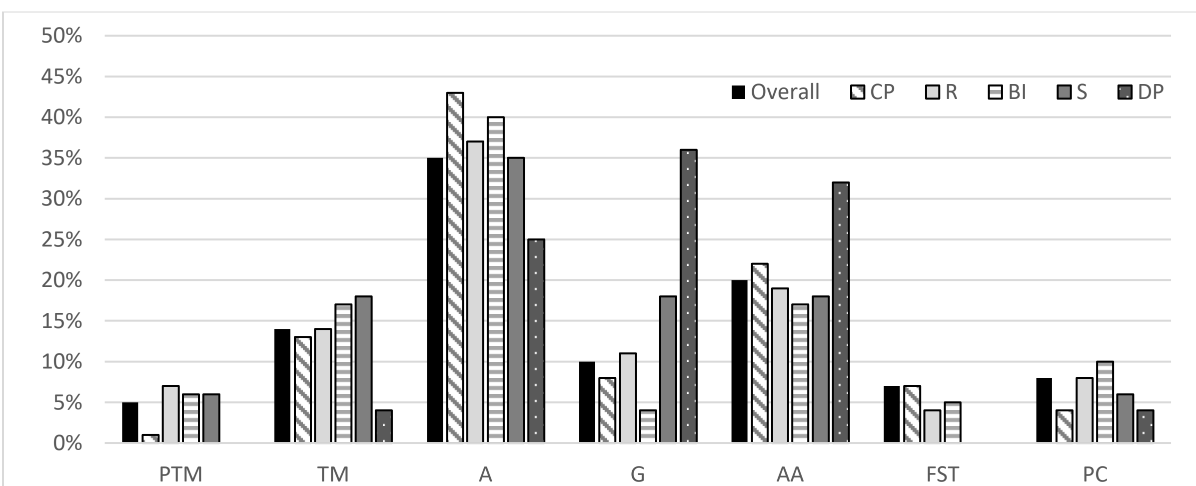

Figure 1. **Relative frequency of occurrences with slope component clusters by textbook.**

Table 5: Prevalent Slope Component Coding Assignments

Individual Component and Component Combinations Codes	% of occurrences (n=201)
CP-R	26.4%
CP-R-BI	12.4%
CP	10.4%
R-BI	10.0%

Covariational Reasoning

Table 6 provides the percentage per individual textbook for each of the four levels of covariational reasoning. Nearly two-thirds of occurrences incorporated some level of covariational reasoning. As might be expected based on the definition of slope in terms of quantifying the ratio $\frac{change\ in\ y}{change\ in\ x}$, the majority of the explanations incorporated L3 covariational reasoning coordinating the amount of change in one variable with the amount of change in the other variable. Table 5 illustrates a shift from L1 reasoning in the earlier books in the sequence to L2 and L3 reasoning in the later books in the sequence. The results reveal a shift to a larger percentage of occurrences that include no covariational reasoning at later stages of the curriculum. Early curriculum explanations relied heavily on describing the covariational relationship between two quantities, even with simple L1 acknowledgment that those changes do in fact correspond. In the series, this led to defining slope as a topic that provides the quantification for this rate of change. Later curriculum explanations then frequently used slope as a tool without recounting its interpretation in terms of covarying quantities. Once slope has been formally defined, it seems as though it is often assumed that the covariation exists, but when covariation is acknowledged in later textbooks, it was at higher levels, as would be appropriate.

Table 6. Relative Frequency of Covariational Levels for Slope Occurrence by Textbook

Textbook	None	L1	L2	L3	L4
PTM (n=11)	9%	82%	9%	0%	0%
TM (n=28)	4%	11%	18%	68%	0%
A (n=70)	33%	1%	13%	51%	1%
G (n=21)	81%	0%	0%	19%	0%
AA (n=40)	45%	5 %	3%	40%	8%
FST (n=14)	50%	0%	29%	21%	0%
PC (n=17)	35%	0%	18%	18%	29%
Series (n=201)	36%	8%	11%	40%	5%

In Table 7, the percentage of slope occurrences assigned a level of covariational reasoning are listed by slope component. The results highlight that *Determining Property* was rarely developed using covariational reasoning. Recall that *Determining Property* and *Behavior Indicator* were rarely combined in occurrences, and that L2 reasoning could provide a foundation on which to build this connection. The lack of *Determining Property* occurrences with L2 reasoning further support this observation. Interestingly, *Constant Parameter* had the next highest percentage of occurrences with no covariational reasoning, because slope is often identified as the leading coefficient in a linear equation without discussion of what that represents and often reported in general terms as what makes a line straight without describing the covariation of rise and run on the line's graph. However, *Constant Parameter* also included a high percentage of L3 covariational reasoning when such as description was present. We do not view this as an indicator that the *Constant Parameter* component was developed without covariational reasoning, but that its applications supported many occurrences that did not explicitly denote the covariational relationship it represents.

Table 7. Relative Frequency of Covariational Levels by Slope Component

Component	None	L1	L2	L3	L4
CP (n=134)	36%	4%	7%	51%	2%
R (n=132)	23%	8%	4%	58%	6%
BI (n=77)	17%	5%	27%	44%	6%
S (n=17)	29%	6%	24%	29%	12%
DP (n=28)	93%	0%	0%	7%	0%

Conclusions and Future Work

This study reports the development of slope in a textbook series' expository content, considering slope components and accompanying covariational reasoning. Results suggest that this textbook series provides consistent opportunities for students to develop the various slope components across the series. As expected, slope receives the most attention in the Algebra and Advanced Algebra textbooks, but the previous and subsequent texts in this series carefully build and extend a foundation including all five of the slope components. Furthermore, covariational reasoning frequently accompanied the development of slope components, particularly in the earliest stages when the notion of slope is first being developed from students' intuitive knowledge of covarying quantities. These approaches align with recommendations from the Common Core Standards (Nagle & Moore-Russo, 2014b).

Slope was, for the most part, richly developed as a notion related to the covariational change between two quantities in a linear relationship. One exception is the lack of *Steepness* component occurrences; this is of concern especially in textbooks where angles and trigonometry are emphasized. Meaningful connections to *Steepness* could be created through covariational descriptions of the severity of change in the output variable relative to change in the input variable in contextual situations. Another exception is the *Determining Property* component, which occurred mostly in the Advanced Algebra and Geometry textbooks. The emphasis was on using the previously developed notion of slope as a tool to describe the parallel or perpendicular relationship of lines (often visually in the Geometry textbook). However, comparisons between slopes were seldom interpreted in relation to how the quantities represented by the linear graphs covaried (e.g., equal slopes suggest the same constant rate of change, so lines don't intersect). Connections to the *Behavior Indicator* component of slope utilizing L2 covariational reasoning might facilitate a more connected view of slope from these lenses.

Although slope was developed in terms of covariational reasoning and connections of various slope components, visual and nonvisual approaches within the slope components were only explicitly connected in a few instances. Nagle and Moore-Russo (2013b) describe the importance of developing a robust, flexible understanding of slope consisting of all five slope components with meaningful connections within approaches and between components. The analysis of this textbook series suggests that while the links between components were developed, the links between visual and nonvisual representations within a single slope component were often underdeveloped. In particular, the *Ratio* and *Constant Parameter* components were built heavily from nonvisual perspectives and seldom included links between visual and nonvisual approaches. Since this analysis only considered the expository material, it is quite possible that some of the additional connections between these components may come from exercises or other features of the textbook. Future analysis should explore additional elements of the textbooks to see whether opportunities for making connections between the visual and nonvisual approaches to these components might be fostered in the exercises.

TRACING BEGINNING TEACHERS' MATHEMATICS CURRICULUM USE IN THEIR FIRST THREE YEARS OF TEACHING

Byungeun Pak

Byungeun.pak@dixie.edu

Corey Drake
Michigan State University
cdrake@msu.edu

This study explores how five beginning elementary teachers used their mathematics curriculum materials in their first three years of teaching. Prior research suggests that teachers' curriculum material use in their earlier careers may not change significantly from year to year (e.g., Valencia, Place, Martin, & Grossman, 2006). Our investigation builds on this prior research with a focus on elementary mathematics curriculum use. We analyzed interview transcripts from five teachers' first three years drawing on a framework developed by Forbes and Davis (2010). Our analysis indicates that these five teachers used their mathematics curriculum in different ways from Year1 through Year 3. They followed their mathematics curriculum with few adaptations in their first year, and then began to modify their curriculum more extensively in their second and third years.

Keywords: Curriculum, Elementary School Education

Purpose

The purpose of this paper is to explore how novice elementary teachers use mathematics curriculum materials in their first three years of teaching. Understanding novice teachers' use of mathematics curriculum materials across the first three years contributes to a body of research related to teacher-curriculum interactions (e.g., Remillard, 2005). Prior research on teacher-curriculum interactions has tended to explore teachers' curriculum use in the short term (e.g., Pak & Drake, 2021; Brown, 2009; Forbes & Davis, 2010; Remillard, 2005). One exception is Valencia, Place, Martin, and Grossman (2006). They investigated beginning teachers' curriculum use related to reading in the first three years because "early teaching experiences lay the foundation for future success in the classroom" (Valencia et al., 2006, p. 99). Building particularly on Forbes and Davis (2010) and Valencia et al. (2006), we focus in this paper on how beginning elementary teachers "mobilize and adapt" (Forbes & Davis, 2010, p. 821) mathematics curriculum materials in the first three years of teaching. In doing so, we aim to contribute to the field's understanding of the beginning teachers' mathematics curriculum use in the early years of teaching. Increasing our understanding of novice teachers' curriculum use, particularly in the current quickly changing and unpredictable curriculum landscape, is important not only in theory, but also in practice as teacher educators and school and district leaders seek new approaches to supporting teachers' curriculum use.

Perspectives

We draw on the two perspectives in this paper, which are related to curriculum use in the contexts of reading and science. In relation to the first perspective, we drew on a finding by a group of researchers who have explored how beginning teachers use curriculum materials in their early careers, including during teacher preparation programs. In a longitudinal study, Valencia and colleagues (2006) conceptualized teaching practices as being shaped by interactions among the curriculum materials, teachers' knowledge, and the contexts. They followed three beginning elementary teachers from a teacher preparation program to their third years of teaching to understand how they used curriculum materials for teaching reading. They found that “over the first three years of full-time teaching, there was relatively little change” concerning “how they used them” (Valencia et al., 2006, p. 111). For example, Dorothy, a beginning teacher in the study, tended to closely follow a reading curriculum in her first three years of teaching reading. Since this study involves novice teachers’ reading curriculum use, this specific finding raises a question as to whether or not beginning elementary teachers closely follow mathematics curriculum in their early years. Further, because the curriculum landscape has changed significantly in recent years, including the availability of a much wider range of resources than in previous years (Aguirre et al., 2019), we were interested in novice teachers’ curriculum use in this new context.

We began to answer this question in another paper (Pak & Drake, 2020) in which we analyzed one beginning teacher’s mathematics curriculum use. Our finding was different from the finding of Valencia and colleagues (2006). In our paper, we found that the beginning teacher followed the mathematics curriculum closely in her first year and began to modify the curriculum in her second and third year of teaching. The finding provided us with a start to understand the patterns of the trajectory related to beginning teachers’ mathematical curriculum use. As such, we investigate in this current paper how five beginning teachers used their mathematics curriculum materials in their first three years of mathematics instruction.

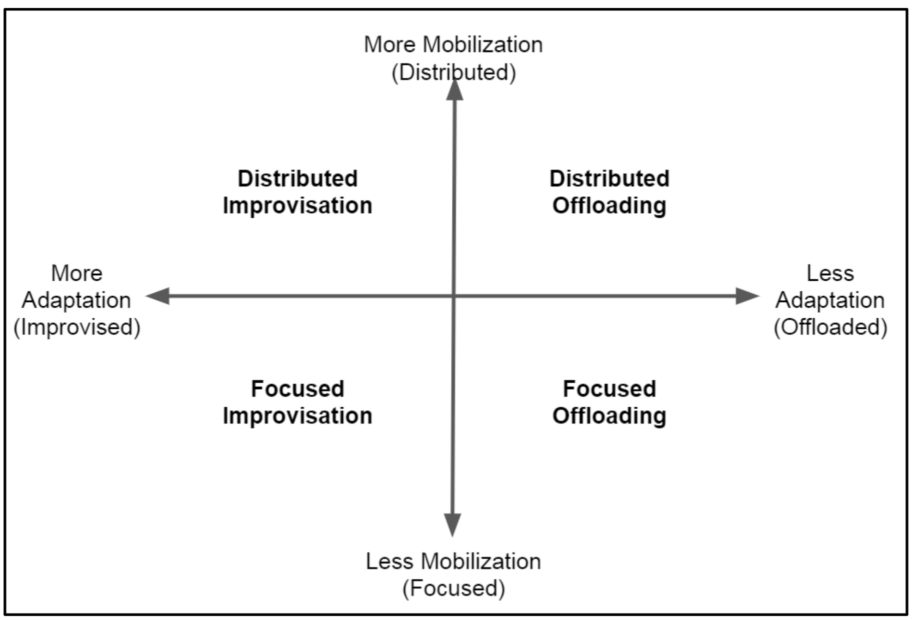

Figure 1. Framework for teacher-curriculum interactions (adapted from Forbes and Davis, 2010, p. 823)

The second perspective is related to a framework from Forbes and Davis (2010). Particularly, our analysis for this current paper draws on the framework and also utilized in our prior work analyzing the curriculum use patterns of beginning teachers in their first year (Pak & Drake, 2021). As we noted in the prior work, the framework is built on the work of Brown (2009) and Remillard (2005) in relation to teacher-curriculum interactions. The framework conceptualizes how prospective teachers mobilized and adapted existing curriculum materials (e.g., lesson plans and students' worksheets) for their science instruction by creating a two-dimensional space (Figure 1). Forbes and Davis (2010) also included a third dimension focused on the "inquiry orientation" of the lesson, but, here, we are focusing only on the dimensions of mobilization and adaptation. According to Forbes and Davis (2010), mobilization refers to the number of different curriculum materials used and adaptation means the degree to which teachers modified curriculum materials.

Building on Forbes and Davis's framework, Figure 1 shows how teachers' use of curriculum materials is conceptualized in this paper. In Quadrant 1, teachers adapt multiple curriculum materials (DI: distributed improvisation). In Quadrant 2, teachers offload teaching responsibility (i.e., make few adaptations) using multiple curriculum materials (DO: distributed offloading). In Quadrant 3, teachers offload teaching responsibility using a single curriculum material (FO: focused offloading). In Quadrant 4, teachers adapt a single curriculum material (FI: focused improvisation). It is important to note that this framework categorizes curriculum use in terms of the quadrants defined by the axes and not in terms of the endpoints of those axes. In other words, we recognize, and also found empirically, that these quadrants represent continua along the dimensions of mobilization and adaptation and that most teachers' curriculum use is not found in the extreme corners of the framework.

We use this framework as our second perspective in this current paper because it guides us to make sense of how beginning teachers mobilized and adapted mathematics curriculum materials in their first three years of teaching. In this paper, we are building on the analysis we did of beginning teachers' curriculum use in their early years (Pak & Drake, 2020) by following five beginning teachers in depth over three years to understand teachers' mathematics curriculum use.

Methods

This study was part of a four-year longitudinal large-scale research project, Developing Ambitious Instruction. The purpose of the larger project was to explore the relationships between teacher preparation and ambitious instruction in elementary mathematics and English Language Arts (ELA). This study recruited 175 participants from five teacher preparation programs in three states. There were two cohorts of participants who completed pre-service teacher preparation in 2016-2017 and 2017-2018, respectively. The project team collected data including online surveys, observations, and interviews. For this paper, we focused on analyzing the interview data from the first cohort (N=69). The project team conducted three, two, and two interviews with each of the teachers in their first, second, and third years if they taught both subjects (ELA and mathematics). Interview questions included questions related to classroom/school/local community contexts, as well as lesson planning and enactment, which led the novices in some cases to talk about ways they used curriculum materials in ELA and mathematics.

Data Sources and Analysis

For this particular study, first, we analyzed interview excerpts from 27 beginning teachers who talked explicitly about how they mobilized and adapted mathematics curriculum materials in their first year of teaching. We identified 84 excerpts from these 27 beginning teachers. The second step was individual coding of each excerpt. In coding, we used codes (DI, DO, FI, and FO) based on the framework (Forbes & Davis, 2010). After individual coding, both authors compared codings to find and resolve disagreement. Building on these codes and excerpts, we then selected five teachers to explore mathematics curriculum use in the first three years of teaching. We chose these five teachers because they demonstrated a clear curriculum use pattern in Year 1 through Year 3, which means we had the full three years of their interview transcripts. We identified 15, 22, and 21 excerpts from these teachers' interview transcripts in the first, second, and third year, respectively.

The last step was looking for common patterns across the three years of all five teachers. The patterns we identified in this step included transitions the teachers made from Year 1, to Year 2, and to Year 3. To visualize the patterns, we created a line chart that showed the numbers of the four codes (FO, DO, FI, and DI) by year (Figure 2). To understand the patterns on the part of individual teachers, we also visualized a coordinate graph for each teacher as described below (Figure 3).

To obtain the final coordinate of each teacher by year, we counted the numbers of I (Improvised), O (Offloaded), D (Distributed), and F (Focused), and found the final coordinate by cancelling different codes on the same axis (Improvised-Offloaded on X axis and Distributed-Focused on Y axis). For example, we coded four excerpts in Year 1 of one beginning teacher as two FOs, one DO, and one FI, respectively. We separated these codes into one I, two Os, two Fs, and one D. By cancelling one I and two Os on X axis, and one D and two Fs on Y axis, we got a coordinate at (1, -1) as the final coordinate.

As shown in Figure 3, some teachers have the same final coordinates, either a given year or in a different year. For example, the final coordinate of three teachers (310.050, 310.115, and 310.076) in Year 1 are placed together at (2, -2), and the final coordinate of one teacher (210.055) in Year 1 and another teacher (310.050) in Year 2 are placed together at (-1, 1). Distance from the origin at the coordinate graph suggests a magnitude of codes of each teacher. If a teacher has similar codes, then the teacher's final coordinate is distant from the origin. For example, since a teacher (310.076) has many similar codes (FI) in Year 3 (Figure 3), the final coordinate (-5, -7) is relatively distant from the origin. By creating this coordinate graph, we attempted to present a way to detail the general patterns (Figure 2) on the part of these individual teachers.

Results

Although the specifics differed for each teacher, we were able to identify some general patterns in relation to how the five beginning teachers used their mathematics curriculum in their first three years (Figure 2).

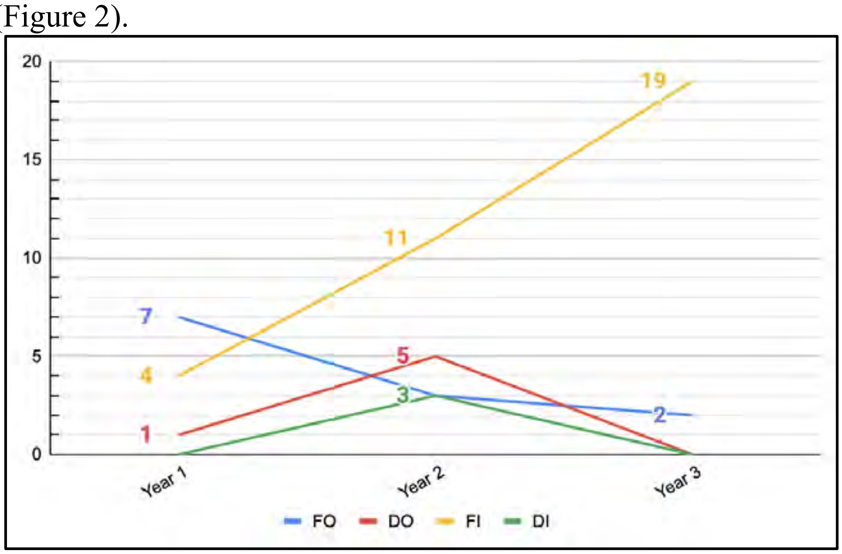

Figure 2. Pattern related to beginning teachers' mathematics curriculum use by year

Year 1 shows more FOs than FIs or DIs, suggesting that these five beginning teachers typically followed their mathematics curriculum materials closely, with few adaptations of the curriculum to meet their students' needs. Year 2 shows a change in mathematics curriculum use on the part of these five teachers. Unlike Year 1, there are higher numbers of FIs in Year 2, indicating that these beginning teachers began to modify their mathematics curriculum in different ways. Year 3 illustrates predominantly FIs, which suggests that these beginning teachers made more consistent adaptations of their mathematics curriculum materials.
To illustrate these patterns, we present an excerpt from Year 3 interview with one beginning teacher who reflected on how she used her mathematics curriculum in her first three years of her teaching. This excerpt describes many of the patterns shown in Figure 2.

> Yes. So my very first year it was, "You're doing this program with fidelity. You are not doing anything else but this program." And so even something as little as like fact fluency, it was like, "No. You are doing this program." Now no one was knocking on our door asking us like, "What do you do for Math?" Or watching our math instruction. But, it was like required for us to do it... Like we have a pacing guide that our instructional coaches came up with, and we were to follow, "OK, this lesson's one day. This lesson's two days. This lesson's one day." You know? And pace it out through there and where we should be by the end of the year and in November and everything. My second year, I moved grade levels, and everything was new to me. So I was taking recommendations from my teammates and how long to spend on certain lessons or like how to do reteaching. But still it was like... People, I think, started to supplement a little more. I know like, for example, I still did the pacing guide with fidelity last year, but I would supplement with like different hands-on games and not use all the materials from *Envision*. Instead I would find different ways to like hit the same standard, but to practice in a different way. And then this year (her third year), it has been kind of like loosey-goosey, like it's like they redid the (inaudible) binder this summer.

As described in the excerpt, this teacher followed her mathematics curriculum material "with fidelity" (FO) in Year One. The fidelity was required and expected by the school and school district through a pacing guide reinforced by her instructional coaches. In another part of the same interview, she mentioned "And supplementing isn't like... I wasn't told not to do it, but it's not like told to do it. Like, really we should be sticking to this curriculum." In Year 2, moving grade levels, she began to modify her curriculum (FI) even though she used the pacing guide with fidelity. Taking advice from her grade teammates, she supplemented *Envision* curriculum materials with "different hands-on games" and she did "not use all the materials from *Envision*." In Year 3, she began to modify Envision (FI) in a "loosey-goosey" way. Another excerpt in the same interview suggests why she became more comfortable at modifying the mathematics curriculum material. She said, "A lot of the reason I'm trying new things this year (third year) is that I'm comfortable at this grade level."

In Figure 3 (below), we present the differences among individual teachers in terms of how they used their mathematics curriculum materials in their first three years. These differences indicate that there are different trajectories among these teachers, each taking their own paths within the general pattern seen in Figure 2. For example, in her first year of teaching, one beginning teacher (210.055) began by using and adapting multiple mathematics curriculum materials using a DI (Distributed Improvisation) approach. In her second year, the teacher tended to follow the multiple curriculum materials more closely. More details about the similarities and differences across the five trajectories will be shared during our presentation.

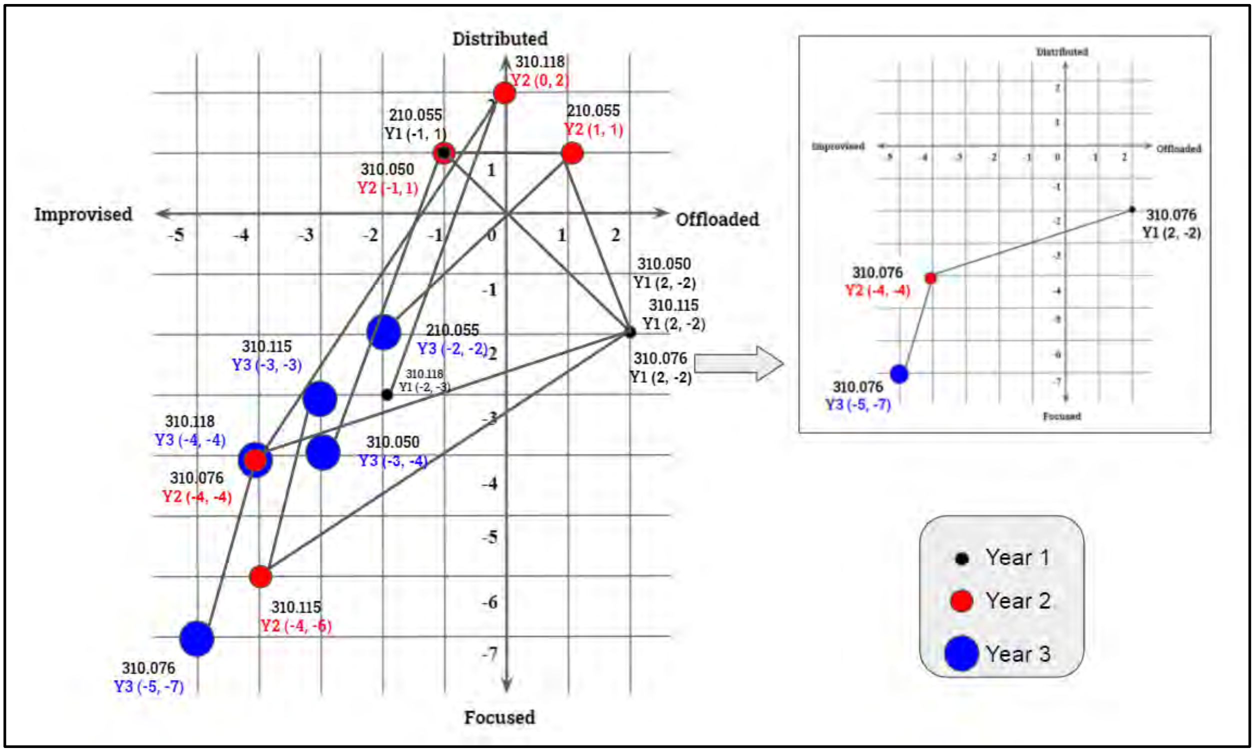

Figure 3. Yearly trajectories of five individual beginning teachers' mathematics curriculum use (each teacher is represented by code number, such as 310.076)

We found that each of the teacher's patterns of curriculum use involved interactions among the teachers' own beliefs, knowledge, and orientations toward mathematics curriculum and the school contexts in which they worked, including school and district policies related to curriculum use and the curriculum use patterns of their colleagues. Nonetheless, as depicted in Figure 3, all five of the teachers' curriculum trajectories arrived by Year 3 in the Focused Improvisation quadrant. Each third-year teacher could provide a clear rationale for their FI approach to curriculum use at that point. For example, one teacher (210.055) said, "And if it's not enduring curriculum, we have the freedom to not spend as much time on it. So that's been good." In other words, in this teacher's case, they were in a school context that required the use of a core curriculum to address the big mathematical ideas of the grade level, but also allowed them the agency to drop or modify less essential curricular components. A different third-year teacher, also in the FI quadrant, described how, through experience at the grade level, she was learning to use and adapt (improvise) her core curriculum materials in a way that was more responsive to her students versus strictly following the curriculum, as she had in her first year (when she was in the FO quadrant):

> So, the benefit of teaching the same grade two years in a row is that I... Like last year I would say I was more like, "OK, what does the book tell me to do?" Where this year, I'm more like, "OK, what do the kids need?" And that has helped a lot to not sound robotic, I guess. And make sure that what the kids are saying are actually what they're saying instead of like, "Oh, the book says that they have to say this, and I think I heard that." Or rephrasing it into like what the book wants them to say. And so the structure of the lesson was very similar to what

> the series structure is, where they start with a collaborative solve and share and then move into some independent practice.

In this excerpt, the teacher describes the elements of the curriculum series she still follows closely (e.g., the lesson structure), but also identifies ways in which both her planning and her classroom interactions are now focused on listening and responding to her students instead of doing what the curriculum "tells" her to do and expecting her students to always say what the book indicates they will say.

Significance

We found that these five beginning teachers changed how they used mathematics curriculum materials over the first three years of teaching. These teachers tended to make a transition from FO (Focused Offloading) or DI (Distributed Improvisation) to FI (Focused Improvisation) in the second and third years. These findings can contribute to the research on teachers' mathematics curriculum use in several ways.

First, this paper offers the field ways to integrate perspectives from research conducted in the context of English Language Arts (Valencia et al., 2006) and science education (Forbes & Davis, 2010) to understand beginning teachers' mathematics curriculum use in their first three years. As mentioned in the introduction section, the literature on teacher-curriculum interactions has explored (novice) teachers' curriculum use in the short term. This current paper allowed us to understand teacher-curriculum interactions in mathematics curriculum in the longer term (their first three years). Our findings differed from those of Valencia and colleagues (2006), which found little change in their first three years. Besides the different nature of mathematics and English Language Arts, one reason for this difference might be that since Valencia and colleagues' study (2006), mathematics teacher educators have been improving ways to help beginning teachers modify and adapt their mathematics curriculum materials, for example, by supporting prospective teachers in using educative curriculum materials in mathematics (e.g., Drake, Land, & Tyminski, 2014). In addition, as mentioned above, the curriculum landscape has changed substantially in the past 15 years. Building on this finding, further research can use the perspectives to understand m in mathematics curriculum use of larger numbers of beginning teachers in their early years.

Second, this paper contributes to the field's conceptual understanding of what a yearly trajectory of individual beginning teachers can look like in their early years. In another paper (Pak & Drake, 2020), we investigated a case of this trajectory with one beginning teacher in her first three years. In this current paper, we extended the number of beginning teachers to five teachers and analyzed excerpts we obtained from these beginning teachers in Year 1 through Year 3. The finding related to the general patterns (Figure 2) provides the field with an initial understanding of beginning teachers' mathematics curriculum use in their first three years. Our finding related to individual teachers' yearly trajectories (Figure 3) also suggests that, within the general patterns, each teacher illustrated a unique story from Year 1 through Year 3. Nonetheless, all five teachers modified and adapted their mathematics curriculum in their third years, suggesting a potential area for the future research in relation to a deeper understanding of individual teachers' mathematics curriculum use.

Lastly, this paper also contributes to developing how to analyze ways beginning teachers use their mathematical curriculum in their first three years. As an analytic tool, we drew on the framework Forbes and Davis (2010). In particular, we analyzed the teachers' movement along the quadrants in the framework (Figure 1). In our prior work (Pak & Drake, 2020; 2021), this framework illustrated well how beginning teachers used their mathematics curriculum. In this current paper, we conceptualized the yearly trajectory in terms of a coordinate graph where we could see each beginning teacher's movement from one quadrant to another (e.g., FO → DI → FO). We think that analyzing and visualizing data in this way shows a way to understand how beginning teachers use curriculum materials in relation to mathematics as well as other content areas (e.g., science and ELA), which would be a contribution to teacher education in general.

In addition to theoretical, conceptual, and methodological implications above, this paper contributes to mathematics teacher education. By providing a detailed understanding of the range of ways in which beginning teachers use curriculum materials in their early years, this paper can support mathematics teacher educators to better prepare prospective teachers to mobilize and adapt their mathematics curriculum. On the whole, we hope that this study can contribute to a deeper understanding of how teachers, including novice teachers, interact with curriculum materials in mathematics (e.g., Remillard, 2005) in their early years of teaching.

Mathematical modeling is a high-leverage topic that involves connecting real-world situations, phenomenon, and/or data with mathematical models. Despite broad consensus of its importance in K-12 mathematics curriculum, instruments measuring mathematical modeling in elementary grades have remained scarce. We addressed this need by designing the Mathematical Modeling Student Assessment (MMSA) for students in grades 3 through 5. In this brief report, we investigate evidence supporting the use of the MMSA for these targeted grades by performing differential item functioning (DIF; Penfield & Camilli, 2006) to investigate potential bias which may impact score interpretations. We describe results and discuss implications for the use of the MMSA, as well as future measurement of elementary mathematical modeling.

Keywords: Assessment, Research Methods, Modeling

Mathematical modeling is a high-leverage topic, involving connecting real-world situations, phenomenon, and/or data with mathematical models (Council of Chief State School Officers & National Governors Association Center for Best Practices, 2010). To date, most of the measurement development and subsequent analyses have focused on upper grade levels. Zöttle and colleagues (2011), for instance, designed and administered an assessment of modeling competency to grade 8 students. To provide a modeling assessment focused on elementary grades, we developed the Mathematical Modeling Student Assessment (MMSA). Previously we have reported on the development (Turner et al., accepted) and presented initial validation results (Turner et al., 2021) based on the five forms of validity evidence (AERA et al., 2014).

Validation, however, is an ongoing process and is only as strong as the evidence supporting the inferences and assumptions foundational to the use of an instrument (Lavery et al., 2019; Zumbo, 2006). As the design of the MMSA is meant to capture mathematical modeling competency for upper elementary students (grades 3, 4, and 5), further validity evidence is needed to support the assumption that the scores are uniformly interpretable (i.e., lack bias). Performing a differential item functioning (DIF) analysis, we focused on the following research questions: (1) Which items, if any, are identified as meaningfully functioning differentially across the grade bands? (2) For items identified as demonstrating meaningful DIF, does the effect reflect relevant or irrelevant differences in mathematical modeling competency?

Perspective

Validity has received increased attention in recent years to ensure high quality measures are being used in mathematics education research (Krupa et al., 2019). A key point in this effort is that validity is not a function of in the instrument itself (Kane, 2013; Lavery et al., 2019; Zumbo, 2006); the underlying assumptions and inferences about the instrument require evidence to support the intended use and interpretation of scores. One approach for providing evidence, DIF analysis, investigates the impact of construct-irrelevant variance due to group membership on the measurement of a targeted construct (Penfield & Camilli, 2006). In short, DIF investigates the impact group association (such as different grade levels) has on score interpretation. DIF has evolved to include statistical methods for identify potential violations which are then examined to understand why particular items may or may not demonstrate DIF (Zumbo, 2007). After identifying stratifying variables (i.e., grouping variables), researchers select appropriate statistical methods for analysis. If DIF is detected, the analysis is rerun, omitting problematic items to ensure the remaining items do not include DIF that was masked by other items (Penfield & Camilli, 2006).

Crucially, these results are not taken at face value. Items deemed to be understandably differential are not removed if the difference in scores reflects the underlying trait (i.e., construct-relevant variance). For instance, grade 3 students might simply have less modeling experience that makes certain items more difficult. On the other hand, if an item reflects a difference outside the construct of interest (i.e., construct-irrelevant variance), the item will need to be changed or removed as it would bias scores and affect interpretations. For example, a complex word problem may benefit grade 5 students because of their higher vocabulary knowledge, not their modeling competency. In this case, the mathematical modeling measurement might be biased, reflecting vocabulary ability. Although preventing such issues was a focus during the MMSA development, further analysis provides stronger validity evidence.

Methods

The data used for the analysis came from the second administration of the MMSA to students in grades 3, 4, and 5. After removing students whose assessments included more than four items with no response which indicated students were unable to complete the assessment for extraneous reasons (e.g., pulled to another classroom or dismissed), our final data included 737 tests collected from two states, including: 320 in grade 3, 250 in grade 4, and 167 in grade 5. Student participants mirrored the demographics of our participating urban schools (with racially, culturally, and linguistically diverse populations) and were roughly consistent across grades.

The MMSA consists of 9 dichotomously-scored (i.e., 0 or 1) multiple-choice (MC) items and 4 polytomous-scored (i.e., 0, 1, 2, etc.) constructed-response (CR) items. The test form was consistent for students in each grade[1]. To calculate a mathematical competency trait score (represented by θ), we used item response theory (IRT) resulting in a best fitting model combination of a two-parameter and generalized partial credit model (for more information about the MMSA see Turner et al., 2021, accepted). The resulting modeling competency estimates can be roughly interpreted as standard deviations (e.g., $\theta = .5$ is roughly .5 standard deviations above average).

For the statistical analysis, we used the *lordif* package (Choi et al., 2011) in *R* version 4.03 (R Core Team, 2020). To identify DIF, this package uses likelihood ratio (LR) tests to first test for uniform DIF by comparing two regression models: one with ability (M1) as a covariate and another with both ability and group membership as covariates (M2). Uniform DIF reflects a consistent difference in scores for all ability levels (e.g., an item is predicted to be more difficult for everyone in grade 3 relative to grade 4). To test for non-uniform DIF, an interaction term of ability and group is included (M3) and compared to M2. Non-uniform DIF indicates differentiation relative to competence. For instance, students estimated to have low competency in grade 3 may have a relative advantage for getting the item right but then high competency students would have a relative disadvantage for the same item. For the LR tests, the null hypothesis states there is no DIF. At a critical level of .05, a statistically significant comparison would identify an item as demonstrating DIF. We then used pseudo-R^2 as a measure of effect size to determine if the statically significant result is meaningful.

Results

Table 1 shows the statistical results for the four MMSA items flagged for DIF. Each of these items had very small effect sizes (Sawilowsky, 2009) meaning that the individual impact on the final scores has little to no practical effect on the final modeling competency estimates. We also found the collective impact had little to no meaningful impact on final competency estimates. The mean difference between the estimates of the original model and a model account for DIF was essentially 0 (sd < .001) with no difference greater than the median standard error of competency estimates (.378). Thus, we concluded that there was no meaningful association between group membership and modeling competency estimates which supports the use of the measure across the target grade levels.

Although we found no practical effect, we proceeded on to analyze the items further to better understand why these statistical results might have occurred to inform future development. CR items 4 and 13 demonstrated uniform DIF. The DIF in item 4 reflected the lower modeling competency required by grade 3 students ($\theta = -.87$) to have a .5 probability to transition from a score of 1 to 2 compared to students in grades 4 ($\theta = -.27$) and 5 ($\theta = -.13$). We reasoned that the DIF likely reflects grade 4 and 5 students embedding more difficult calculation (e.g., trying to directly apply the long division algorithm) into their modeling approach which caused more errors compared to grade 3 students who applied concrete approaches such as visual models.

Table 1. Items Flagged for Statistically Significant DIF

Item	Question Type	χ^2 M1 vs. M2	R^2	χ^2 M2 vs. M3	R^2
3	MC	.004*	.012	.022*	.009
4	CR	.005*	.007	.805	<.001
9	CR	.990	<.001	<.001*	.012
13	CR	<.001*	.013	.254	.001

Note. Only items demonstrating DIF are included in the table. * indicates a significant χ^2 value $p < .05$.

The uniform DIF of item 13 was the result of a higher difficulty in transitioning from a score of 3 to a score of 4. Grade 3 students are estimated to need modeling competency of around 2.95 for a .50 chance of scoring a 4 compared to grade 4 ($\theta = 1.60$) and grade 5 ($\theta = 1.95$) students. Although the score required slightly lower competency estimates for grade 4 than grade 5, grade 3 required a full standard deviation more. We reasoned that this item captures a true difference in modeling sophistication by asking students to complete multiple steps in the modeling process (i.e., identifying relevant quantities, constructing and operating on models, and interpreting results), making this item reasonably more difficult for grade 3 students and roughly equivalent for grade 4 and 5 students.

CR item 9 demonstrated non-uniform DIF indicating that grade 4 students matched to students with equal modeling ability do not always have the same probability answering the item either partially or completely correct. This interaction effect is reflected in the differential item information (*a)*, or slope, estimates for the grade 4 ($a = 3.12$) compared to grade 3 ($a = 2.35$) and grade 5 ($a = 2.44$). Concretely, grade 4 students are predicted to have a lower probability of scoring a 1 and then a higher probability of scoring a 2 compared to grade 3 and 5 students with the same competency estimate. It is difficult to determine what led to the differential probabilities for grade 4 students. The very small effect size makes this item unproblematic overall, but further analysis may be informative for developing future CR items.

Finally, MC item 3 demonstrated uniform and non-unform DIF. While the difficulty for this item was roughly the same for grade 4 (θ = -.98) and grade 5 (θ = -.94) students, the item was more difficult for grade 3 students (θ = -.64). The non-unform DIF resulted from students in low modeling competency grade 5 students having a lower probability to answer the item correctly compared to grade 3 and grade 4 students. However, grade 5 students with average to high modeling competency have higher chances of answering correctly. Both the uniform and non-uniform DIF pattern reflected our expectation for this item. Grade 3 students have a familiarity with the money concepts required in this problem, but decimals as a mathematical concept are not introduced until grade 4 with more opportunities for learning in grade 5. The DIF pattern likely reflects the increasing familiarity students have with the content of this item.

Discussion

Overall, our analysis identified 4 items with DIF: items 4 and 13 for uniform DIF, item 9 for non-uniform DIF, and item 3 for both uniform and non-uniform DIF. The effect sizes for each of these items were negligible with pseudo-R^2 ranging from .007 to .013 suggesting these flags will not affect modeling competency estimates (de Ayala, 2009). The collective effect of these items was also not meaningful. Total score estimates had an average change of 0 with no scores impacted beyond the median standard error of measurement. Taken together, this provides further validity evidence to support the use of the MMSA in grades 3, 4, and 5.

Despite not finding DIF with large effect sizes, further analysis of items 3, 4, and 13 demonstrated the differences likely reflect differences in modeling. We are unsure, however, about item 9. Although it is possible this difference has no explanation, it is also likely that the item captures something tangential, such as understanding of division, which is important to consider in designing future items of this type.

At least two limitations are worth considering in these results. First, a larger sample size would provide more robustness to the results. Given the small effect size estimates, it is possible one or more of the flags were false positives. Second, this analysis assumes homogeneity of students within the grades. Further analysis is needed to investigate any impact or bias that may result from the racial, cultural, and linguistic diversity of the students within each grade.

Conclusion

As underlying populations become more diverse, DIF analyses become an increasingly important component of the ongoing validation process (Gómez-Benito et al., 2018). Understanding how consistent or inconsistent items perform as a function of this diversity provides a more robust collection of evidence for appropriate uses and limitations of instruments. Here, our DIF analysis provided further evidence for a uniformly interpretable modeling competency scores for students in grades 3, 4, and 5. We additionally gained insight into how item designs reflected our assumptions about modeling competencies. By performing similar DIF analysis, a more robust collection of validation evidence can be collected for instruments like the MMSA and provide insights into future directions for instrument development.

Note

[1] Due to a printing error, an item was omitted for 48 grade 3, 83 grade 4, and 64 grade 5 students. IRT is able to handle missing data and we were able to produce estimates for these students (de Ayala, 2009).

In this mixed methods study, we validated a fully online assessment of students' covariational reasoning. We combined qualitative and quantitative methods to analyze 30 responses from undergraduate college algebra students during individual task based interviews. Our findings were statistically significant; students' total number of items correct could be explained by their evidence of covariational reasoning. We conclude with discussion of our work moving forward.

Keywords: Assessment, Technology, Algebra and Algebraic Thinking

Covariational reasoning is a high leverage form of reasoning, which can foster students' understanding of key mathematical concepts, such as rate and function (Carlson, 2002; Thompson & Carlson, 2017). Function is central to the undergraduate college algebra curriculum; hence, promoting students' covariational reasoning dovetails with the goals of the course (Olson & Johnson, 2021). The mixed methods study we report is part of a larger research project designed to promote college algebra students' engagement in covariational reasoning.

We explain how we validated a fully online assessment of students' covariational reasoning. Combining qualitative and quantitative methods, we analyzed 30 responses from undergraduate college algebra students taking part in individual, task-based interviews. Our findings were statistically significant; students' total number of items correct could be explained by evidence of their covariational reasoning. We conclude with discussion of our work moving forward.

Theoretical and Conceptual Background

We ground the construct of covariational reasoning in Thompson's theory of quantitative reasoning (Thompson, 1994), which explains how individuals can conceive of attributes of objects as being possible to measure. For example, consider a toy car moving around a square track. There are a variety of attributes to which students might attend, such as the toy car's total distance traveled around the track or the toy car's distance from a center point. A student engaging in quantitative reasoning could conceive of the attributes as possible to measure. Thompson (1994) calls such a conception a "quantity." For instance, a student may mark off lengths of string to measure one of the distances. To engage in quantitative reasoning, it is sufficient for students to conceive of the possibility of such measurement; they may or may not do the measuring itself.

By variational reasoning, we mean students' conceptions of a single attribute that is not only possible to measure, but also capable of varying (Thompson & Carlson, 2017). For example, a student could conceive of the toy car's distance from a center point as increasing and decreasing, as the car moves around the track. By covariational reasoning, we mean students' conceptions of relationships between attributes that are capable of varying and possible to measure (Carlson et al., 2002; Thompson & Carlson, 2017). For example, a student could conceive of a relationship between the different distances; for instance, the toy car's distance around the track continues to increase while the toy car's distance from the center point increases and decreases.

Students' variational and covariational reasoning intertwine with their conceptions of what Cartesian graphs represent (Johnson et al., 2020). For example, a student engaging in covariational reasoning could interpret a graph as representing a relationship between quantities, such as toy car's total distance traveled and distance from the center. Yet students may conceive of graphs as representing the motion of an object (Kerslake, 1997) or a literal depiction of an object (Leinhardt et al., 1990). For example, students may conceive of a graph of the toy car situation as representing the motion of the toy car around a track or as the literal track itself.

Drawing on Piaget's theory, Moore et al. (2019) distinguished between individuals' figurative and operative thinking when sketching and interpreting Cartesian graphs, as well as graphs with unconventional coordinate systems. Individuals who conceived of graphs as representing literal motion or depictions of objects would engage in figurative thinking. In contrast, individuals who conceived of graphs in terms of quantities and relationships would engage in operative thinking.

Johnson et al. (2020) developed a four-item coding framework in which they made distinctions between students' conceptions of what graphs represent: Covariation (COV), Variation (VAR), Motion (MO), and Iconic (IC). Rather than making fine grained distinctions within covariational and variational reasoning, Johnson et al. (2020) targeted particular levels posited by Thompson and Carlson (2017): gross variation and gross coordination of values. The first marked a student's conception of a quantity as being capable of varying; Johnson and McClintock (2018) called this type of reasoning quantitative variational reasoning. The second marked a student's shift from conceiving of variation in individual quantities (e.g., this one, then that other one) to forming a relationship between quantities (both quantities vary together). Put another way, the COV and VAR codes would evidence operative thinking, while the MO or IC codes would evidence figurative thinking, per the constructs of Moore et al. (2019).

Methods

Assessment Design

To design the covariation assessment, we have integrated different theoretical perspectives and consulted experts in the field (Johnson et al., 2018). The assessment, developed in Qualtrics, is fully online; students can complete it on smartphones, tablets, or computers. There are four items, appearing in random order. Each item incorporates a situation involving changing attributes, with two question groups per item (Table 1). The situations include a turning Ferris wheel (Ferris Wheel item), a person (Nat) walking on a path to and from a tree (Nat + Tree item), a fish bowl filling with water (Fish Bowl item), and a toy car moving around a square track (Toy Car item). We have incorporated innovative elements, including items containing unconventional graphs that do not pass the vertical line test (e.g., Moore et al., 2014).

Table 1: The Covariation Assessment: Item Question Groups

Question Groups	Description
1: Comprehension Check	Play video animation of the situation. State if you understand the situation. If yes, move to question group 2. If no, explain why.
2: Select Graph and Explain	Select a graph (ABCD) that represents a relationship between attributes in the situation. Explain your choice.

Task Based Interviews: Description and Rationale

We hypothesized that students' covariational reasoning could explain their graph selections. Through task based interviews (Goldin, 2000), we were able to gather evidence of students' reasons for their graph selection, and make inferences about their covariational reasoning. If students were selecting correct graphs for reasons not associated with covariational reasoning, for instance, by appealing only to physical features of graphs rather than quantities being represented, we could use that information to revise assessment items.

Data Collection

Participants were undergraduate students enrolled in college algebra at a university located in the metro area of a large U.S. city, serving large percentages of students of color and first generation to college. We selected three groups of 10 participants, interviewed in consecutive spring, summer, and fall semesters. The interviews took place midway during the semester. Student volunteers left for part of class to go to a nearby office for the interview. Our selection method resulted in a not entirely random sample; students who participated in interviews may have been those more invested in the course or more willing to talk about their thinking. Johnson conducted 30 individual interviews, which were video and audio recorded. One graduate research assistant (GRA), either Gardner or Smith, observed each interview. The GRA engaged in two activities: monitoring the video camera and writing field notes. Johnson used a semi-structured protocol for the interviews, to gather evidence of three areas: students' comprehension of assessment questions; students' engagement in covariational reasoning; and students' experiences with the technology. GRAs used the protocol to organize their field notes. Because we designed the covariation assessment to work on smartphones, tablets, and computers, we wanted students to work across a range of devices. Students could bring a device of their choosing. If students did not bring a device, or if students wanted a different device, we had a tablet and a laptop computer available for use. We allowed students to choose a device, because that is what students would do during the actual assessment.

Data Analysis

Qualitative analysis. Johnson led the qualitative analysis, adapting the four-item coding framework from Johnson et al. (2020). Table 2 shows the codes, descriptions, and examples. The COV and VAR codes are bolded, because they represented conceptions of graphs in terms of quantities and relationships. When students reasoning was coded as COV or VAR, they provided evidence of engaging in reasoning consistent with at least the levels of gross variation (VAR) or gross coordination of values (COV), per Thompson and Carlson (2017). When students' reasoning was coded as MO or IC, they provided evidence of a conception of the object's literal motion (Kerslake, 1977) or an object's physical appearance (Leinhardt et al., 1990).

Table 2: Four Item Coding Framework, Adapted from Johnson et al. (2020)

Code	Description	Example
COV	**Relationship between two attributes capable of varying and possible to measure**	**As the toy car's total distance traveled increases, the toy car's distance from the center decreases then increases.**
VAR	**A single attribute capable of varying and possible to measure**	**The Ferris wheel cart's distance from the center gets larger, then smaller.**
MO	Literal motion of an object	Nat walked back and forth, so the graph goes back and forth
IC	The shape of an object	The graph is shaped like a fishbowl.

Johnson watched each student's interview video, drawing on what students said and did as sources of data. For each item, in the order they appeared for each student, Johnson assigned students a single reasoning code. If students demonstrated multiple forms of reasoning, Johnson assigned the most sophisticated one as the overall code, to indicate if students were conceiving of quantities and/or their relationships. For example, if a student said that the graphs showed how the toy car moved around the track (MO), then went on to explain how each of the distances were changing together (COV), Johnson coded the reasoning COV. Prior to our quantitative analysis, Johnson shared the codes and notes with another researcher as a member check.

Quantitative analysis. Analysis of variance (ANOVA) was used to analyze device effects. A simple linear regression model, at 95% confidence, was used to analyze the relationships between students' total number correct and evidence of their covariational reasoning.

Results

Students used a range of devices on the assessment: 13 used a computer, 10 a tablet, and 7 a smartphone. The choice of device did not impact students' reasoning. Students who selected a computer or tablet expressed a preference for a larger screen size or touch screen capability. Students who selected a smartphone preferred to use their own device, which they had with them. None of the students expressed dissatisfaction with the interface on their device.

Across the four items, students selected a correct graph 48% of the time; 55% of student responses provided evidence of covariational reasoning (COV), 23% variational reasoning (VAR), 25% motion reasoning (MO), and 1% iconic reasoning (IC). Across the 30 students, 10% got all four items correct; 23.33% three items correct, 23.33% two items correct, 40% one item correct, and 0.34% zero items correct. The correlation between the total number correct and students' evidence of covariational reasoning was .709, which indicated a significantly high degree of correlation ($p < .01$). The regression analysis also showed that 50.2% of the total variation in the dependent variable, students' total number correct, can be explained by their covariational reasoning, which is also statistically significant ($p < .001$).

Discussion

This fully online assessment, containing built-in video animations, and designed for the undergraduate college algebra population, is the first of its kind. Our results demonstrate its validity, for assessing covariational reasoning, at least at the level of gross coordination of values, per Thompson and Carlson (2017). Furthermore, distinguishing between students engaging in variational or covariational reasoning, rather than motion or iconic reasoning, could be useful for diagnosing students' figurative or operative thinking (Moore et al., 2019) on graphing tasks.

We are encouraged that students' choice of device did not impact their reasoning. Given the prevalence of mobile phones, the feasibility of the assessment for use on this type of device can increase its potential for usability.

Continued validation work with a larger sample size is a vital next step. We are expanding the assessment to include six items and examining the qualitative coding scale via Rasch modeling to quantitatively corroborate its hierarchical nature.

Learning from worked examples is a highly effective pedagogical approach. In this study, we explore a new way of learning from worked examples: comparative judgement. This involves students assessing other students' work in pairs and deciding which of the two they regard as 'better'. We discuss the experience of one student, Rhys, with low prior knowledge as he evaluated a mathematics problem on rational inequalities. Results suggest that Rhys was unable to notice key features of the work he assessed that might have helped resolve his existing knowledge gaps, despite appearing to understand the underlying concepts. We suggest that Rhys was 'metacognitively blind' to the features that might have helped resolve his knowledge gaps and that providing him with problems to practice in between comparisons might have been beneficial.

Introduction

Comparative judgment is a relatively new assessment approach. It involves assessing students' work in pairs from which assessors judge which of the two solutions is 'better'. A reliable rank of students' work from 'best' to 'worst' is then formed after several assessors complete multiple judgements. Most research has focused on the use of comparative judgement as an assessment tool showing that it can be used to form a reliable ranking of students' work that is comparable with traditional marking methods (e.g., Jones et al., 2014, 2019). Recent studies have advocated for its use as a learning tool, typically in the context of peer-review (Bartholomew & Jones, 2021; Strimel et al., 2020). Students review their peers' work comparatively, often giving and receiving feedback that they can then apply to improve their own work. It is argued that the process of comparing makes important features more noticeable for the learner (Holyoak, 2012) thereby making it more likely they will apply such features to their own work. Such an approach seems promising, with many studies reporting that students find comparative judgement to be valuable and worthwhile (e.g., Potter et al., 2017). To support the assumption that comparative judgement might improve student outcomes, we draw upon the literature on learning from worked examples.

Learning from worked examples

Instructional designs where students learn by practicing unfamiliar problems place heavy demands on working memory. When practicing problems learners often must rely on their own ability to find a set of steps that can lead them to the desired goal, because no previous models are likely to be available to them. This is known as a means-end analysis. The learner is required to consider the current problem state, the final goal state, evaluate differences between the two states, and find a set of steps that can be used to move from the current state to the goal state. This process imposes a heavy load on working memory and will generally not lead to learning.

On the other hand, learning from worked examples involves providing students with the following: the problem itself, the steps taken to reach a solution, and the final solution (Renkl, 2014). Students then study and reflect on multiple worked examples before they are expected to try answering similar questions on their own (Große & Renkl, 2007).

Studying worked examples removes the means-end approach. Learners no longer need to search their own prior knowledge for solution methods and instead can focus their attention on current problem states. This reduces working memory and leaves cognitive resources available for self-explanation (Sweller et al., 1998). Only when self-explanation is encouraged, that is, when students explain the reasoning behind a solution, do worked examples appear beneficial (Chi et al., 1989; Renkl, 2014).

One of the key features of comparative judgement is that two solutions must be *compared*. Studies on learning from worked examples strongly suggest that presenting worked examples simultaneously to encourage comparisons between them leads to greater learning outcomes than presenting worked examples one-by-one (Rittle-Johnson & Star, 2007; Star & Rittle-Johnson, 2009). By making all solutions available at the same time, cognitive load is reduced as students no longer need to hold representations from the previous example active in their working memory to compare with the next example (Begolli & Richland, 2016).

One reservation with comparative judgement is the exposure to incorrect examples. Studies have shown that providing students with both correct and incorrect examples is more beneficial to student performance than showing correct examples only (Adams et al., 2014; Booth et al., 2013; Durkin & Rittle-Johnson, 2012). Incorrect solutions can help students recognise incorrect strategy choice by drawing attention to the feature of the problem that makes the strategy inappropriate (Booth et al., 2013; Siegler, 2002), and improve students' error detection skills which is not possible from correct examples alone (Tsovaltzi et al., 2010). Additionally, drawing attention to errors may help students replace incorrect knowledge with correct knowledge (Chi et al., 1981).

Research design

Based on our argument from above, we assumed that comparative judgement would be useful for learning. We were also mindful of the fact that, in our study, because we did not prompt students to self-explain, it may have reduced the likelihood of positive learning outcomes.

Students completed a pre- and post-task where they solved the inequalities $\frac{x+1}{x-7} > 3$ and $\frac{5x-2}{x+5} > 6$. No feedback was provided to students following the pre-task nor were they provided with the correct answer. Following the pre-task, students were shown six pairs, one pair at a time, of other students' solutions of the same problem. Students were asked to choose which of the two solutions in each pair they thought was 'better'. What 'better' meant was left to each student to decide. As each pair of solutions was shown, students were asked to think aloud through their assessments (Ericsson & Simon, 1993). A short semi-structured interview followed once students had completed their six comparisons.

Eight first-year undergraduate students studying an introductory calculus subject in Australia participated in the study. Here we present the case of one student, Rhys, one of four students in the study who reported not finding comparative judgement helpful. We chose to focus on Rhys because he clearly articulated his thinking and provided insight into how comparative judgement could be improved in the future.

Rhys' experience of comparative judgement

Rhys was unable to complete the pre-task. His intended approach was to sketch the graphs of $y_1 = \frac{x+1}{x-7}$ and $y_2 = 3$ on the same axis and visually interpret when $y_1 > y_2$. Rhys did not know how to sketch the graph of y_1 and he did not think to (or know how to) rearrange $\frac{x+1}{x-7}$ as $1 + \frac{8}{x-7}$. Here we discuss Rhys' experience as he evaluated a comparative judgement solution that had used this same graphical approach.

Rhys appeared confused while evaluating this solution and was initially unsure how the student had used their graph to obtain the required interval of solution, $7 < x < 11$.

Rhys: But that doesn't quite… make sense. How did they… what have they done?

He slowly re-read the solution, explaining the solution to himself. This led to an Aha! moment.

Rhys: So, it's… oh. Oh! That's genius. Ok I like this solution then.

Following his moment of realisation, he then provided a full explanation of what the student has done:

Rhys: By drawing the hyperbola, they've managed to figure out that once you draw in a line at $y = 3$, you can make that inequality equal to three and so you know the lower bound. So, you know that's out of the range already [Points at section of graph where $y_1 < y_2$]. So, then you've got 7, to the intersection at 11.

Rhys' explanation suggested that he understood that solving for $y_1 = 3$ rather than $y_1 > 3$ gave the point of intersection between y_1 and y_2, allowing the student to know exactly when $y_1 > y_2$.

Comparing Rhys' pre- and post-tasks, his post-task showed little improvement. During the post-task, Rhys tackled the problem using the same graphical approach he had used during the pre-task but was once again unsure how to sketch the hyperbola. This contradicted what we would have expected from the literature. We anticipated that the combination of an Aha! Moment followed by a detailed explanation of the reasoning behind the solution would have left Rhys primed for learning (Chi et al., 1989). We suspect the lack of improvement was because Rhys overlooked a key part of the worked solution that might have helped him. While he had explained how the student had used the graph to find the solution, he did not make any comments regarding how the student had drawn the graph in the first place.

When asked about any changes he had made between his pre- and post-tasks, Rhys was forthcoming in discussing why comparative judgement may not have been helpful in improving his second solution.

Rhys: I can follow instructions. But they don't stick around long enough in my brain when the instructions are no longer in front of me. So, I literally looked at someone's answers and I still couldn't apply it to another question.

Int: So, you don't think you really changed your method here?

Rhys: No. Cause it's more like my actual mathematical ability rather than memory being tested overall and it didn't change at all between questions. I failed to remember what I should have learnt from the other questions, I think.

Rhys' perception was that he was able to understand and follow the pairwise solutions but was unable to apply what he felt he should have learnt to his own solution. We argue that Rhys overlooked key parts of the solutions that would have facilitated his understanding. This draws on the notion of *abstraction* which Hershkowitz, Schwarz, and Dreyfus (2001) define as "a process in which students vertically reorganize previously constructed mathematics into a new mathematical structure" (p. 195). Abstraction involves three processes: 1) *Constructing* involves integrating abstracted knowledge together to form new knowledge; 2) *Recognising* involves identifying the mathematics that is relevant to the problem; and 3) *Building-with* involves using the mathematical procedures in a new context. We suggest Rhys was able to *recognise* (some but not all) rather than *construct* relevant underlying concepts as he engaged with the graphical solution but was not given the opportunity to immediately use these techniques in a new context. If unable to *build-with*, it is likely that Rhys was unable to reconstruct short-term existing knowledge structures. Subsequently, the process of abstraction did not occur ("I failed to remember what I should have learnt"). For Rhys, comparative judgement provided a space to recognise, but not to build-with, ultimately limiting his ability to construct new insights. Given Rhys was aware of some of his own pre-existing knowledge gaps, we expected Rhys to actively look for queues from the presented solutions to help resolve these gaps. Rather, Rhys failed to notice specific parts of the solution that would have been helpful to him (Chi et al., 1989). In short, Rhys was *metacognitively blind* (Goos, 2002).

Implications for teaching

Comparative judgement may need to be paired with practice problems students can work on immediately following the activity to allow time to build-with. We wonder whether digital-based tutoring systems used when learning from worked examples, such as those described by Adams et al. (2014) and Booth et al. (2013), could be embedded within comparative judgement. Such systems typically encourage self-explanation with the use of drop-down menus. Students complete a sentence about a given worked example by selecting from a number of options from a pull-down menu which are designed to support students' construction of self-explanations. In our context of comparative judgement, drop-down menu prompts could be designed to direct students' attention to aspects of solutions that might be helpful for common misconceptions. Of course, designing scaffolding of this nature may be impractical for a comparative judgement setting. If using students' work for authentic peer-assessment, generating drop-down options specifically tailored for each pairing is unrealistic. Rather, educators might include two or three pre-designed solution pairs with self-explanation prompts as part of the overall comparative judgement process.

Conclusion

Rhys' case-study offers insight into the limitations of comparative judgement for the purposes of knowledge acquisition. Rhys not only generated self-explanations but generated correct explanations. However, because Rhys was unable to immediately practice and apply any skills or concepts he had recognised (build-with), he was unable to apply what he should have noticed from the comparative judgement activity to the post-task.

In this paper, we report findings from a comparative analysis of the introduction and development of triangle congruency from two countries: an eighth-grade mathematics textbook from China and a high school geometry textbook from the U.S. While both textbooks considered triangle congruency as a fertile setting for the development of reasoning and proving, there are both similarities and differences in their approaches to achieve this goal. Building from the transformation conception of congruency, the U.S. textbook provides students with more opportunities to practice writing proofs. Drawing from multiple conceptions of corresponding conceptions of congruency, the Chinese textbook provides students with more varied opportunities to write proofs and make connections to a real-life context.

Keywords: curriculum, geometry and spatial reasoning, triangle congruency

The concept of congruency is an important topic in geometry. Euclid's Elements included three conditions for triangle congruency: side-angle-side (SAS), side-side-side (SSS), and side and two angles (SAA) as propositions 4, 8, and 26. These conditions were then used to prove many subsequent propositions. Ever since, triangle congruency has become a constant feature in upper-level geometry lessons worldwide (Jones & Fujita, 2013). In addition, triangle congruence provides a rich setting for developing students' geometric intuition and encouraging them to form conjectures that create the necessity for the proofs associated with these conjectures (Wang, Wang & An, 2018).

However, students worldwide have found triangle congruence a challenging topic (e.g., Wang et al., 2018). For example, only 35% of the eighth graders participating in the TIMSS 1995 study were able to answer the question in Figure 1a correctly. About 80% of the TIMSS 2003 participating eighth graders from high-achieving Asian countries such as Korea answered the question in Figure 1b correctly, while only 36% of their counterparts from the U.S. did so. The difference in the performance data might be the result of the different approaches mathematics textbooks have adopted to present triangle congruence theorems.

These triangles are congruent. The measures of some of the sides and angles of the triangles are shown. What is the value of x? 	In this figure, triangles ABC and DEF are congruent with $BC = EF$. What is the measure of angle EGC? Figure 1a: A TIMSS 1995 released item (Beaton et al., 1996, p. 32)	**Figure 1b: A TIMSS 2003 released item (IEA, 2005, p. 71)**

Olanoff, D., Johnson, K., & Spitzer, S. (2021). *Proceedings of the forty-third annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Philadelphia, PA.

An in-depth analysis of the introduction and development of triangle congruency theorems in the U.S. and China may provide helpful insights that are critical in promoting student learning of triangle congruence theorems.

Theoretical Perspectives and Prior Studies

González and Herbst (2009) identified four different student conceptions of congruency while using dynamic geometry software. The perceptual conception of congruency determined two figures were congruent by their look, whereas the measure-preserving conception of congruency checked whether the two objects had the same measures to determine the congruency. The transformation conception of congruency concludes that two objects are congruent if there exists a sequence of rigid transformations that can map from one object to the other object. Finally, there is the correspondence conception of congruency, which is supported by traditional teaching practice. González and Herbst asserted that the correspondence conception of congruence is a special manifestation of the transformation conception of congruency.

Jones and Fujita (2013) developed a framework based on these four conceptions of congruency to analyze the introduction and development of triangle congruency in an eighth-grade Japanese textbook. They found that while the Japanese textbook expected students to use various conceptions of congruency to explore ideas of congruent triangles experientially, the student experiences focused almost exclusively on the correspondence conceptions when constructing formal proofs. This approach, shared by many East Asian countries, was different from the approach adopted by the Common Core State Standards for Mathematics, which used the transformation conception as the basis for defining congruency (Usiskin, 2014). However, little is known about how textbooks introduce and develop congruent triangle theorems to their students based on these different approaches. This study will fill the gap by analyzing both the content and problems from the congruent triangle lessons from a Chinese and a U.S. textbook.

Methodology

This is a comparative case study (Stake, 2000) of a set of lessons on congruent triangles from both a U.S. and a Chinese textbook. This study intends to produce a dense narrative and interpretations that answer the central research question, "*How are the criteria of triangle congruence introduced and developed in the U.S. and Chinese textbooks*?"

The content of congruent triangle theorems was listed as a geometry topic for the secondary school, while the same content was found in the eighth-grade standards in the Chinese curriculum guidelines. The *Eureka Math Geometry* (Great Minds, 2015), a Common Core-aligned open resource U.S. textbook, and an eighth-grade mathematics textbook published by People's Education Press (PEP, 2013) were selected for this analysis because of the prominent roles they play in their respective countries. Each textbook devoted four lessons to the five congruent triangle theorems: SSS, SAS, ASA, AAS, and HL. They are lessons 22-25 in Eureka Math and section 12.2 in PEP Math. Focusing on the same content and the same number of lessons in each textbook made the comparison more compatible despite the grade-level difference.

The unit of analysis for this study was a textbook instance, as described by Teuscher et al. (2016), "as the way in which textbook content is delimited or sectioned by authors for the purpose of communicating ideas or providing students opportunities to engage with the mathematics content" (p. 3). The analysis was done in three stages. In the first stage, we identified the textbook instance in each lesson. We then went through each textbook instance focusing on the intended mathematical objectives as well as the conceptions of congruency. Finally, we went through the textbook instances again, searching for additional themes that were not captured by our previous coding. All the identified themes illuminated the introduction and development of congruent triangles in each textbook.

Findings and Discussion

Both textbooks were consistent in their individual lesson structures. Each lesson of Eureka Math opens with some opening exercises, followed by one or two explorations that address the main objectives of the lesson, and ends with a set of exercises that students can practice in class. Each lesson of PEP Math continues to have one or two explorations, work-out examples, and "think about it," although not always in this particular order. It always ends with a set of two exercises. Starting with different criteria for triangle congruence (SAS vs. SSS) naturally led to the different content sequence for each textbook, as can be seen in Table 1. However, the difference went beyond the logical necessity. In the remaining parts of this analysis, we will share three themes we have learned that set these two textbooks apart.

Table 1: Overall Content in Eureka Math and PEP Math

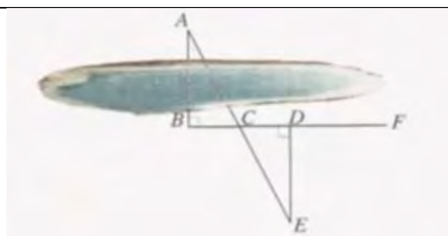
	Number of Lessons	Sequences of Criteria	Number of Exercise
Eureka Math	4	1. SAS	4
		2. Base Angles of Isosceles Triangles	5
		3. ASA & SSS	5
		4. AAS & HL, SSA* and AAA*	2
PEP Math	4	1. SSS	2
		2. SAS, SSA*	2
		3. ASA & AAS, AAA*	2
		4. HL	2

*Criteria that does not lead to congruency

Logical consideration. Both textbooks provide students opportunities to apply the triangle congruent theorems they just learned to prove other theorems. For example, both SAS and SSS were used to prove some properties of isosceles triangles. However, they were applied in a different manner. In PEP Math, SSS was used to prove that the two triangles created by connecting the vertex A and the midpoint of BC are congruent. This is an equivalent conclusion of "two base angles of an isosceles triangle are congruent," the focus of Lesson 23 in Eureka Math, which was proved by applying transformation and SAS. There is one distinct difference in the location of the criteria that did not lead to congruency. PEP Math examined the nature of a set of criteria immediately after a set of similar criteria being proved to be valid in proving congruency, for example, SSA right after SAS and AAS, and AAA right after ASA. Eureka Math, on the other hand, examined SSA and AAA after all five criteria for congruent triangles were established.

Conceptions of congruency. Transformation continued to play a significant role in proving congruency throughout the four lessons in Eureka Math. For example, in Lesson 23, Eureka Math provided two proofs for the "Base angles of an isosceles triangle are congruent" statement; one used transformation and one used SAS criteria to prove that the base angles of an isosceles triangle are congruent. Later in Lesson 24, a rigid transformation, the drawing of an auxiliary line, and the SAS were used to prove SSS. In PEP Math, compass-and-straightedge construction, which was based on the measure-preserving conceptions of congruency, played a similar role as that of transformation for Eureka Math throughout the four lessons. Both Eureka and PEP used previously proved congruent triangle criteria to prove the new ones, which was an approach based on the correspondence conceptions of congruency.

Exercises embedded in real-life context in PEP Math. In Eureka Math, all exercise problems are context-free problems. This characteristic is in sharp contrast to the many exercises embedded in real-life context in PEP Math. The contextual exercises enrich students' understanding of congruent triangles in the following areas: (a) understanding the mathematical rationales behind common measuring tools, (b) solving challenging indirect measurement problems and c) making sense of the distance relationship between angles and distances. Figure 2 below provide examples of two such exercises.

See the diagram below. To measure the distance between two points *A* and *B* from two sides of the pound. You can draw a line segment BF perpendicular to line AB. Identify two points *C* and *D* from BF such that *BC=CD*. Then draw a line segment *DE* perpendicular to BF such that points *A, C* and *E* are on the same line. Then DE and AB have the same length. Why? (PEP Math, p. 38)	See the diagram below. A north-side street connects points *A* and *B*. From point A, walk the same distance to arrive at points *C* and *D*. Will the distance from *C* to *B* equal to the distance from *D* to *B*? Why? (PEP Math, P. 39)
	


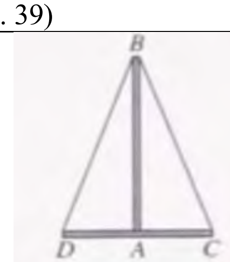


Figure 2: Examples of exercises in real-life context from PEP Math

Conclusions and Implications

In this paper, we investigated how two textbooks help their students to develop their concepts of triangle congruency. The analyses provided the main support for the following main conclusion: both textbooks were very consistent within their own approach but were also very different from each other. The difference went beyond whether they use transformation or correspondence conceptions of congruency. It also reflected on how they sequenced different topics, organized the in-class activities, and designed their end-of-lesson exercises.

Such information makes it possible to develop assessment items that are more sensitive to the country-level factor, such as the mathematics textbook, that might contribute to the difference in student performances. For example, Fan and colleagues (2017) found that the integration of transformation instruction, while created no significant difference in students' ability to solve general proof questions, students in the experimental group performed much better on challenging problems involving constructing auxiliary lines. A similar study with students using PEP and Eureka Math might shed more light on both the role of transformation in constructing geometric proof as well as establishing a better link between the textbook and student learning, as suggested by Fan et al. (2013) as a research area that needs more work.

This study also identified a few other areas that warrant further investigation, for example, the effect of presenting SSA right after SAS vs. after all the true congruent triangle criteria have been established on students' views of the necessity principle of proof. In addition, further investigation should be conducted on the possible effect of using exercises with real-life context on developing students' perseverance in mathematics learning with challenging mathematical topics similar to congruent triangles, which is the theme of the 2021 PME-NA conference.

INVESTIGATION OPPORTUNITIES OF COMMON CORE THEOREMS PRIOR TO PROOF IN HIGH SCHOOL GEOMETRY TEXTBOOKS

Brian Boyd
Wright State University
brian.boyd@wright.edu

Wayne Nirode
Miami University
nirodew@miamioh.edu

Even though prior research has found that textbooks provide limited opportunities for students to engage in proof in high school geometry, there is little research on the opportunities that textbooks provide for students to investigate and make conjectures prior to proof. This study addresses that gap in analyzing investigation opportunities for 17 theorems in the CCSSM across five textbooks. Overall, the five textbooks provide opportunities for investigation about half of the time, although there is a great deal of variation among the number of opportunities offered for each textbook. Theorems about parallel lines and triangles are more likely to have investigations than theorems about parallelograms and converses of theorems.

Keywords: Curriculum, Geometry and Spatial Reasoning, Reasoning and Proof, Standards

Purpose of the Study

The *Common Core State Standards for Mathematics* (*CCSSM*) includes proof as a significant part of school mathematics (NGA & CCSSO, 2010). Within high school geometry, the *CCSSM* states many theorems for students to prove about lines, angles, triangles, and parallelograms, and *CCSSM*'s Standards for Mathematical Practice contain many elements of proof.

The release of the *CCSSM* was a watershed moment in mathematics education in the United States. Because initially 45 states adopted them, there was nearly a de facto national intended curriculum defining "what students should be able to do" (p. 4). But the NGA and CCSSO (2010) were clear that the *CCSSM* "do not dictate curriculum or teaching methods" (p. 5). Therefore, a central question is how the *CCSSM* would be brought to "life" in the classroom. Textbooks, as the written curriculum, often become the implemented curriculum when teaching proof (Bieda, 2010; McCrone et al., 2002). Teachers also follow the teacher's edition closely for planning and pacing on proof (Sears & Chavez, 2014). Thus, research on textbooks is an important part of understanding student opportunities to engage with and ultimately learn proof.

Many studies have examined high school geometry textbooks (e.g., Hummer, 2016; Otten et al., 2013; Otten et al., 2014; Sears & Chavez, 2014). Despite the importance of proof, research consistently has provided evidence that textbooks offer limited opportunities for students to write proofs (Otten et al., 2014; Thompson et al., 2012). Despite studying chapters that were more likely to involve proof in geometry, less than 5% of all exercises coded involved asking students to construct a proof (Otten et al., 2014).

Even when textbooks asked students to write a proof, research revealed a limited exposure to the nature of proof—focusing on particular statements instead of general ones (i.e., proving specific cases instead of proving theorems). Hummer (2016) looked at two geometry textbooks for how proofs aligned with the *CCSSM*. Most proofs in the exercises required writing a proof of specific cases instead of general ones. Otten et al. (2013) found that there were more statements involving general proof statements in the exposition, but in the exercises, textbooks expected students to prove statements about a particular statement instead of a general statement.

Perspectives

Absent from the body of research on proof in textbooks is the opportunities students have for exploration and investigation prior to writing a proof. This type of reasoning that students might do leading up to proof is captured by Stylianides' (2008) framework for reasoning-and-proving. Stylianides (2008) proposed that the mathematical component of this framework could be a useful tool for research on textbook analysis because it views proof from a holistic standpoint rather than isolated from other activities in mathematics. Furthermore, prior research has shown that this treatment of proof has led to abysmal results for students learning proof (Harel & Sowder, 2007; Senk, 1985). Specifically, the mathematical component of the framework delineates four activities associated with proof: (a) identifying patterns, (b) making conjectures, (c) providing non-proof arguments, and (d) constructing proofs. Using the first three activities of the reasoning-and-proving framework as a lens for addressing this gap in the research on proof and textbooks, we report on the results that answers the question: How do high school geometry textbooks engage students with specific theorems listed in the *CCSSM* prior to formal proof? We report the results pertaining to the fourth activity of the framework of how textbooks provide opportunities to construct proofs elsewhere (Nirode & Boyd, in press).

Methods

Although there are a few additional theorems listed for students to prove in the Common Core High School Geometry Standards, we focused on the three standards listed in the *Prove Geometric Theorems Cluster* in the *Congruence Domain* for the basis of this research. These standards focus on lines and angles; triangles, and quadrilaterals G.CO.9, G.CO.10, and G.CO.11 (NGA & CCSSO, 2010, p. 76). These three standards include a total of 17 theorems.

We denote the five textbooks in our study with an asterisk (*) in the references. We refer to them using an acronym based on the publisher's name (e.g., BI, HMH, KH, MHG, and PE). Prior research on geometry textbooks and proof have used earlier editions of these five textbooks (i.e., Hummer, 2016; Otten et al., 2013; Otten et al., 2014; Sears & Chavez, 2014). We also chose textbooks from 2014 or 2015 so publishers had 4–5 years to align to the *CCSSM*.

We conducted both a priori coding and opening coding of the student editions of these five textbooks. We based our a priori codes on the first three parts of Stylianides' (2008) framework. We coded for (a) whether the textbook had students investigate the theorem prior to proof, (b) materials used in the investigation, and (c) whether the conjecture students made was on their own or already partially completely by the textbook (i.e., a fill-in-the-blank conjecture). For the open coding, we coded each student investigation for aspects that were not captured by our a priori codes. To locate opportunities for student investigation, we used the publisher-provided correlation documents.

Results

Of the 85 opportunities to introduce the theorems (17 theorems across 5 textbooks), textbooks stated the theorems without any prior investigation 39 (45.9%) times. Table 1 shows a two-letter code for each of the 46 (54.1%) times where students investigated the theorem prior to proof. The first letter indicates whether the investigation used Dynamic Geometry Software (DGS) or physical materials (e.g., patty paper, compass, protractor, straightedge, or ruler). The second letter uses a "F" if students had to fill in one or more missing words in the provided conjecture and a "L" if the conjecture was left completely to the students. All but one of the 46 investigations were specific about which tools students should use, with 22 using DGS and 23 using physical materials. Thirteen times the conjecture was a fill-in for the students. This usually involved one word left to fill in, for example, “congruent” or “equidistant.” The textbook left the conjecture for the students 33 times, although in 25 of these, the textbook stated the conjecture immediately following the investigation or within the next two pages.

Table 1: Investigation Opportunities across 17 Theorems for Five Textbooks

	Textbook					
Brief theorem description	BI	HMH	KH	MHG	PE	Investigation opportunities
Vertical angles		PL	PF			2
Alternate interior angles	DL		PF	DL	DL	4
Corresponding angles	DL		PF	DL	DL	4
Perpendicular bisector	DL		PF			2
Perpendicular bisector converse			PF			1
Triangle angles	DL	PL	PF	PL	PL	5
Base angles	DL	PL	PF			3
Midsegment	DL	PL	PF		DL	4
Medians	DL		PF	PL	DL	4
Parallelogram sides	DL	DL	PF			3
Parallelogram angles	DL	DL	PF			3
Parallelogram diagonals	DL	DL	PF			3
Parallelogram sides converse	DL					1
Parallelogram angles converse	DL					1
Parallelogram diagonals converse			PL			1
Rectangle diagonals		PL	PF			2
Rectangle diagonals converse	DL	PL	D/PL[a]			3
Total investigation opportunities	13	9	15	4	5	46

Note. D = Dynamic Geometry Software; P = physical materials; L = conjecture left to students; F = student fills in a partially completed conjecture provide by textbook. [a]KH did not specify whether to use DGS or physical materials to investigate.

When focusing on specific theorems, Table 1 shows that only the Triangle Angles theorem was investigated in all textbooks. Students investigated four other theorems in all but one of the textbooks: Alternate Interior Angles, Corresponding Angles, Midsegment, and Medians. Although students investigated each of the 17 theorems in at least one textbook, there were some theorems less likely to have investigations. There was only one investigation for each of the following theorems: Perpendicular Bisector Converse, Parallelogram Sides Converse, Parallelogram Angle Converse, and Parallelogram Diagonals Converse—all converses.

KH and BI both invested heavily into students investigating prior to proof. KH was the textbook most likely to have students investigate a theorem prior to proof. Students investigated 15 (88.2%) of the 17 theorems with 14 using physical materials—typically patty paper. The investigations frequently had four or five numbered steps for students to complete before being instructed to compare their results with others in their group. Then, students were asked to make a conjecture by filling in missing words in an already partially complete conjecture. KH was the only textbook that used partially completed conjectures—occurring in 13 out of the 15 investigations. In BI, students investigated 13 (76.5%) of 17 theorems prior to proof. Students were instructed to work with a partner and use DGS to complete four or five steps before writing a conjecture. Although all the investigations used DGS, BI did not capitalize on the dynamic nature of the software. Ten of the 13 investigations directed students to repeat steps for constructing and measuring a new triangle or quadrilateral as opposed to dragging their constructions to see multiple versions of the same figure. BI left all 13 conjectures for students to make, but BI also stated the theorems for 12 of those within the next two pages.

In HMH, students investigated nine (52.9%) of the 17 theorems: six with physical materials and three with DGS. All nine investigations left the conjectures for the students to make; however, they all subsequently appeared either immediately following the investigation or within the next two pages. Finally, both PE and MHG rarely had student investigate theorems prior to proof—just five (29.4%) and four (23.5%) of the 17 theorems, respectively. Neither textbook provided students investigations for any of the perpendicular bisector or parallelogram theorems (including their converses). PE used one with physical materials and four with DGS. PE left all the conjectures to students, although PE stated four of them within the next two pages. MHG had two investigations with DGS and two with paper. It left all four of the conjectures for students to make, with two of them stated for students within the next two pages.

Discussion

Although textbooks included 46 investigations out of 85 opportunities, and each theorem was investigated in at least one textbook, we had concerns with the meaningfulness of these opportunities. Of the 46, 13 of these were in KH where the conjecture was already partially completed, and students only filled in one or more words. In another 25 of the investigations, the textbook stated the theorem within the next two pages. This means that textbooks only had eight investigations where they truly left something to students to determine a conjecture, with one or two of these investigations in each textbook. Although BI and KH seemed to value students investigating theorems prior to proof, those investigations were overly prescriptive with limited opportunities to identify patterns and make conjectures in significant ways.

A plausible explanation for why textbooks use partially completed conjectures or stated the conjecture as a theorem a few pages after the investigation is that one purpose of textbooks is to be used as a resource outside of class. Not having at least partially completed conjectures or theorems would make it more difficult for the textbook to be used as a resource outside of class. Thus, we posit that there is considerable tension between textbook publishers and authors providing students opportunities for open-ended investigations of theorems prior to proof while also remaining true to textbooks being a resource for use outside of the geometry classroom.

Conclusion

Although there is prior research on proof and high school geometry textbooks, we undertook this study because there is a gap in the research on the opportunities that textbooks provide students to engage in reasoning-and-proving as part of the proof process. We also conducted this research to understand how the intended curriculum of the *CCSSM* becomes the written curriculum in textbooks with respect to investigating theorems prior to proof in high school geometry. Our results show that only a little over 50% of the time do textbooks provide student investigations. Further, there are more opportunities for students to investigate theorems about parallel lines and triangles, then there are about parallelograms and converses. There also is much variation across the five textbooks with respect to frequency of student investigations in each textbook. We suggest further research on whether teacher support materials beyond the student edition provide alternative opportunities for student investigations prior to proof. We also recommend research on if and how teachers implement student investigation prior to proof.

A THEORETICAL ANALYSIS OF TANGRAM PUZZLES

Laura Bofferding
Purdue University
lbofferd@purdue.edu

Alexandra Foster
Purdue University
Foste148@purdue.edu

Although Tangram puzzles are an important tool used in early education to promote students' spatial visualization and composing and decomposing abilities, classification of the puzzles' difficulty is lacking. Current classifications rely on the extent to which particular shapes are distinct within the puzzles. Using a theoretical framework that highlights characteristics of puzzles along two continua (integrating to decomposing and elements to structures), we analyzed 114 Tangram puzzles. This framework can help researchers and educators identify puzzles that target specific spatial visualization strategies.

Keywords: Geometry and Spatial Reasoning, Elementary School Education, Assessment, Curriculum

Working with pattern block and tangram puzzles can support students' developing spatial visualization abilities (National Research Council, 2009; van den Heuvel-Panhuizen & Buys, 2008). Spatial visualization, in particular shape composition and decomposition, underlies students' later work in upper-level geometry (National Governors Association Center for Best Practices & Council of Chief State School Officers, 2010), chemistry, engineering, and other STEM fields (National Research Council, 2006). However, while puzzle-solving is a regular activity of preschool classrooms and advocated as key to supporting students' development on the shape composition and decomposition learning trajectory (Clements & Sarama, 2009), similar activities are not as prominent in early elementary classrooms in the United States (National Research Council, 2009).

The Shape Composition and Decomposition (SCD) learning trajectory suggests that kindergarteners, in general, are moving from the picture maker to shape composer level, where they can solve tangram puzzles with some internal lines to puzzles with no internal lines (Clements & Sarama, 2009). Tangram puzzles belong to a specific class of puzzles made with seven pieces (or tans): two small, right isosceles triangles; two large, right isosceles triangles; one square; one parallelogram; and one medium, right isosceles triangle. As students progress through the levels, they become more intentional about turning and flipping shapes, as well as combining shapes (Clements & Sarama, 2009). Puzzle tasks they suggest using to encourage students to advance from one level to the next include removing more of the internal lines and increasing the size of the puzzles (https://www.learningtrajectories.org/; see also Clements & Sarama, 2009). To move beyond the shape composer level, they suggest having students solve puzzles in multiple ways (Clements & Sarama, 2009). However, there is no standard classification for what makes one tangram puzzle different from another (and therefore potentially more difficult), other than the distinctness of each piece within the puzzle (van den Heuvel-Panhuizen & Buys, 2008). A more detailed classification system could greatly aid researchers and educators in systematically varying what children experience in their puzzle solving to improve their thinking. In this theoretical paper, we present an analysis of tangram puzzles and argue that this classification can support more targeted investigations of students' spatial visualization and development of interventions to support their spatial visualization.

Theoretical Framework

Martin and Schwartz's (2014) creative thinking framework articulates four visual representation strategies involved in creating visuals from data. These strategies involve two dimensions: an elements versus structures dimension and an integrating (or composing) versus decomposing dimension (Martin & Schwartz, 2014). These dimensions form a larger framework that subsumes ideas presented in the SCD learning trajectory and spatial visualization and imagery trajectory (Clements & Sarama, 2009). Choosing puzzles that emphasize certain dimensions could encourage students to use varied spatial thinking strategies. The four quadrants resulting from the intersecting dimensions represent the four strategies.

Flexible abstraction, at the intersection of elements and decomposing, refers to removing details in order to look at data in new ways (Martin & Schwartz, 2014). Interpreted through the lens of classifying tangram puzzles, tangram puzzles range in terms of how much they employ flexible abstraction based on the number of sides they have or the number of sections they have. Puzzles that have more sides, generally result in puzzles in which individual pieces are more defined (Baran et al., 2007), which are considered easier—one exception are puzzles with holes on the inside, which are considered difficult (van den Heuvel-Panhuizen & Buys, 2008). Combinations, at the intersection of elements and integrating, refers to multiple ways to put data together to tell different stories (Martin & Schwartz, 2014). In terms of tangram puzzles, combinations play a key role. Some of the individual tans can be composed to make the larger tans, and pairs of tans can be composed in multiple ways. For example, the two small triangles could form a medium triangle, a parallelogram, or other shapes (see Table 1). Furthermore, combinations of the smaller tans can be combined to combinations of the other pieces (see Table 2). The extent to which tangram puzzles can be solved in multiple ways, or with multiple combinations of tans, could influence their difficulty.

Table 1: Common Combinations Made from the Tans in Tangram Puzzles

Elements	Integration
	

Table 2: Examples of Combinations of Tans That Have a Common Structure

Equivalent Combinations

Reinterpretation, at the intersection of structures and decomposing, involves changing how the data looks in order to think about it in new ways (Martin & Schwartz, 2009). Likewise, tangram puzzles differ in the extent to which students might need to reinterpret how the individual shapes are used. Compared to their standard orientations--where the bottom side of the shapes are horizontal (see Table 3)—some tans may need to be turned (or flipped in the case of the parallelogram), requiring them to be used in nonstandard orientations (Baran et al., 2007). Because students are exposed to limited orientations of shapes (e.g., always seeing a triangle with one point on top, Clements, 2004; Nurnberger-Haag, 2017), the extent to which puzzles have shapes in standard versus nonstandard orientations could influence their difficulty.

Table 3: Standard and Nonstandard Classification of the Tangram Pieces

Shape	Standard Orientation	Nonstandard Orientation
Triangle		Square		
Parallelogram		

Borrowing structure, at the intersection of structures and integrating, involves finding similarities among structures (Martin & Schwartz, 2009). Across tangram puzzles, some puzzles share similar compositions of shapes; therefore, solving puzzles with recognizable, common structures across a series of puzzles may support students in completing the puzzles.

Methods

Materials

We analyzed a series of 114 Tangram puzzles, including all example puzzles from the Mathagon site (https://mathigon.org/tangram), the majority of freely available puzzles from the Tangram channel website (https://www.tangram-channel.com/tangram-puzzles/), and a few from Pinterest when we needed additional puzzles that included particular structures of shapes. We recreated the puzzles using the manipulatives on the Mathagon site, identifying all possible ways to solve each puzzle. For puzzles with shapes that continued to look like recognizable shapes when turned, we also analyzed the turned versions of the puzzles.

Analysis

In terms of flexible abstraction, we analyzed each puzzle's outline for its number of sides and whether the sides were internal (for shapes with holes) or external. For combinations, we identified the number of different ways to solve the puzzle and whether the puzzles had multiple solutions due to symmetry of the shape or multiple solutions due to different combinations of the pieces. For reinterpretation, we identified which pieces required a standard versus nonstandard orientation for each puzzle and its variants. Finally, we identified sets of puzzles that "borrowed" common structures or combinations of triangles and squares.

Results

Flexible Abstraction

Across the puzzles we analyzed, nine of the puzzles had holes on the inside. The other 105 puzzles ranged from having three sides to twenty-five sides. The majority of puzzles, 54 of the 105, had between 10-16 sides; we classify these as medium-sided puzzles. There were 28 small-sided puzzles (3-9 sides), and 22 large-sided puzzles (17-25 sides).

Combinations

Out of the 114 puzzles, 43 (38%) of them had one solution and 71 (62%) of them had multiple solutions. Of these, 12 only had multiple solutions because the puzzle had symmetry. An additional 35 puzzles did not have symmetry but had multiple solutions because the pieces could be combined in multiple ways. Finally, 24 puzzles had additional solutions because they had both symmetry and multiple possible combinations. Overall, for puzzles with multiple solutions, having two solutions was most common (30 puzzles, 26% of puzzles).

Reinterpretation

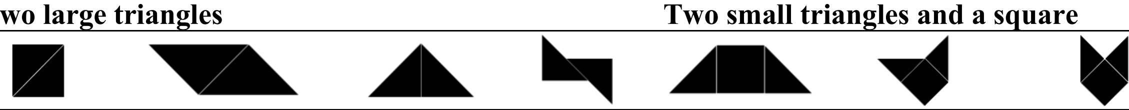
Over half (56%) of the puzzles and their variants involved using three to four of the pieces in standard and three to four pieces in nonstandard orientations. Only 2% had its pieces in only nonstandard or only standard positions. The square and parallelogram were almost equally likely to be in standard versus nonstandard position, and the other three shapes were in the standard position about 40% of the time and nonstandard position about 60% of the time.

Borrowing Structure

Across puzzles, 13% of puzzles shared at least one of three combinations involving two large triangles; these included two triangles forming a larger square, a larger parallelogram, and a larger triangle. The next most likely combination (offset triangles) occurred in 8% of puzzles. Of the combinations with the square and two smaller triangles, the most common was forming a trapezoid (11% of puzzles) and what was often used as a head with two ears where one ear was tilted (10% of puzzles) versus both ears upright (7% of puzzles) (see Table 4).

Table 4: Common Structures "Borrowed" Across Puzzles

Two large triangles				Two small triangles and a square		
Square	Parallelogram	Triangle	Offset	Trapezoid	Tilted ear	Upright ears



Theoretical Discussion

Our in-depth analysis highlights additional aspects of puzzles that may contribute to students' ease or difficulty in solving them, beyond just how distinct the pieces are within them (e.g., van den Heuvel-Panhuizen & Buys, 2008). The number of sides to the puzzles varied greatly, and this information could be helpful when aiming to help students see more or less of the structure. However, very few of the puzzles had pieces only in standard orientations, so even if the puzzles show a lot of the structure (i.e., have a greater number of sides), students may have difficulty solving them if they are not yet intentional in their flipping and turning of shapes (e.g., Clements & Sarama, 2009). Our puzzle classification could help teachers select more appropriate puzzles. For example, teachers could select puzzles not only with more sides but also with more shapes in standard orientation for beginning puzzle solvers. Likewise, puzzles with symmetry or multiple solutions might be easier for students since students are more likely to place a shape somewhere where it would work in the puzzle.

In future work, we plan to test how puzzles' composition (more or fewer shapes in standard orientation or whether there are more solutions), influences their difficulty when students place pieces with and without outlines. Similarly, knowing which puzzles have common structure can be useful for supporting students to borrow structure as a strategy for solving puzzles. If they are given several puzzles that contain similar structure, they may start to look for larger compositions of shapes in new puzzles, rather than only looking for elements. Continued explorations using this framework will help us better understand the roles of flexible abstraction, combinations, reinterpretation, and borrowing structure in students' puzzle solving so that we can create instruction that helps them build upon these spatial thinking strategies as well as add to our theoretical understanding of how these spatial strategies support students' puzzle solving.

Constructing quantities and coordinating covarying quantities is a central component of STEM learning and development. We examined 323 publicly released fourth- and eighth-grade mathematics and science TIMSS 2011 assessment items to explore the extent to which such items could potentially elicit such reasoning. We found items potentially eliciting covariational reasoning across all four assessments, as well as an increase in number and complexity of such questions from fourth to eighth grade regardless of content domain. Further, we highlight the diverse content domains that leveraged graphical representations in such items. We discuss implications of our findings for the teaching and learning of middle-school STEM and for future study of covariational reasoning through international assessments.

Keywords: Middle School Education, Assessment, Integrated STEM / STEAM

Constructing quantities and representing relationships between simultaneously varying quantities (i.e., quantitative and covariational reasoning; Thompson & Carlson, 2017) is a central component of STEM learning and development. For example, numerous researchers have shown that covariational reasoning can be productive for students' and teachers' mathematics development generally (e.g., Carlson et al., 2003; Johnson, 2015; Moore, 2014) and in middle school particularly (Ellis, 2011; Ellis et al., 2015; Lobato et al., 2012; Paoletti, 2019). Further, there is a growing body of evidence that covariational reasoning can be productive for individuals developing key ideas in statistics (e.g., Gil & Gibbs, 2017) and various areas of science, including climate change (Basu & Panorkou, 2019; González, 2021), gravity (Panorkou & Germia, 2020), chemical kinetics (Rodriguez et al., 2019), and physics (Sokolowski, 2020).

Although covariational reasoning is critical across STEM fields, there is evidence that covariational reasoning is more salient in at least some East Asian countries' curricula (e.g., Thompson & Carlson, 2017) and teachers' knowledge (e.g., Thompson et al., 2017). Hence, as part of a larger project, we are interested in exploring if there are differences between countries in student performance on questions that may involve covariational reasoning; such differences could help researchers identify curricula or instructional activities that support such reasoning. In this report, we address a critical first step in this endeavor by describing our process of coding released TIMSS 2011 items as potentially eliciting covariational reasoning. Specifically, we examined 323 released fourth- and eighth-grade mathematics and science TIMSS items to explore the research questions: (RQ1) To what extent could a students' covariational reasoning be productive for addressing TIMSS items across science and mathematics? (RQ2) How does the frequency of such questions vary according to grade and content domain? (RQ3) What representations are used in such items (e.g., tables, graphs, pictures)?

TIMSS Assessment, Covariational Reasoning, and Coding

The TIMSS assessment, a project of the International Association for the Evaluation of Educational Achievement (IEA), aims at measuring trends in mathematics and science achievement in fourth- and eighth-grade students in 63 countries. TIMSS data is often used for international comparisons, which have important implications for educational practice and policy both in the U.S. and internationally (Carnoy et al., 2015; Hiebert et al., 2005). In this study, we examined all of the 323 publicly released TIMSS 2011 mathematics and science items across the fourth- and eighth-grade assessments (available at https://nces.ed.gov/timss/released-questions.asp) to explore if these items could potentially elicit covariational reasoning.

Although there are several descriptions of covariational reasoning in mathematics education literature (see Thompson and Carlson, 2017, for a review), we adopted Carlson et al.'s (2002) definition for this analysis due to its broad nature. Specifically, Carlson et al. (2002) defined covariational reasoning "to be the cognitive activities involved in coordinating two varying quantities while attending to the ways in which they change in relation to each other" (p. 354). Hence, we were interested in examining which items could potentially support students in considering how two quantities vary in relation to each other. Further, as graphs are a common way to represent covarying quantities across STEM fields (e.g., Glazer, 2011; Paoletti et al., 2020), we were particularly interested in the extent to which TIMSS items leveraged graphical representations when potentially eliciting students covariational reasoning.

Coding

To support our analysis, we operationalized the features of an item that we believed could elicit students' strategies entailing covariational reasoning, which we identified as a *potential covariational reasoning item (PCR)*. Specifically, if the researcher was able to 1) identify a way a student might imagine or identify two changing quantities and 2) determine some solution strategy that could reasonably entail covariational reasoning, we coded the item as a PCR item.

For example, consider the fourth-grade mathematics item in Figure 1. Although a student may be able to determine the correct value by using memorized rules, another strategy could entail the student coordinating one-centimeter changes in the map corresponding to four-kilometer changes on land to determine that eight such centimeter changes would result in 32 kilometers traveled, thereby reasoning covariationally to address the item. Given that the researchers were able to identify a way a student might envision two changing quantities and a solution strategy that involves covariational reasoning, we identified this as a PCR item.

The scale on a map indicates that 1 centimeter on the map represents 4 kilometers on the land. The distance between two towns on the map is 8 centimeters. How many kilometers apart are the two towns?

Figure 1: A fourth-grade TIMSS 2011 mathematics item we categorized as PCR (IEA, 2013, p. 12). Copyright © 2013 International Association for the Evaluation of Educational Achievement (IEA).

To develop this coding scheme for a potential covariational reasoning item, the lead author first engaged in semi-open coding (Braun & Clarke, 2006). He initially examined each item against the Carlson et al.'s (2002) definition of covariational reasoning to explore whether an item did, did not, or might elicit such reasoning. He then met with the research team, presenting several examples of each type of item to develop their criteria for a PCR item. The researcher then applied this operationalization to all items across the four TIMSS assessments.

During a second round of semi-open coding, the researcher examined all items coded as PCR to look for commonalities amongst such items. Although many items did not fit within a category (e.g., considering how coarseness of salt influences dissolution speed in fourth-grade science), the researcher did identify two common types of items in the PCR items: 1) items that could potentially require *one-step proportional reasoning* (e.g., Figure 1) and 2) *pattern-finding items* (e.g., tasks like the Tiling a Patio task, Stein & Smith, 2011). The researcher re-examined all items coded as PCR to determine the frequency of such items.

Due to our particular interest in the extent to which TIMSS items leveraged graphical representations, during this process, the researcher also identified the representation(s) that the item included to describe the covarying quantities (e.g., graph, table, equation, written description). If a question used two representations (e.g., a table and a pictorial representation), he counted each representation.

Results

In this section, we highlight particular findings relevant to addressing our research questions. We first describe general trends in the fourth- and eighth-grade items across mathematics and science and compare the prevalence of items across content domains. We then describe the representations used across domains and grades.

Tables 1 and 2 provide an overview of the released mathematics and science items in the fourth- and eighth-grade assessments. We note there were appreciably more questions in the eighth-grade science items (39 out of 90 items, 43%) that could potentially elicit a strategy entailing covariational reasoning (PCR) compared to the fourth-grade science items (23 out of 72 items, 32%). At first blush, there is a comparable percentage of PCR mathematics items across grades: 27 out of 73 items, or 37%, in fourth grade and 31 out of 88 items, or 35%, in eighth grade. However, during the second coding round, we found that of the 27 fourth-grade mathematics items coded as PCR, five were coded as ‘pattern finding’ and nine were coded as ‘proportional reasoning’ items. In contrast, from the 31 eighth-grade mathematics PCR items, only four were coded as ‘pattern finding’ and four as ‘proportional reasoning.’ In total, 23 of 31 (74%) eighth-grade mathematics PCR items did not entail pattern finding or proportional reasoning, compared to 13 of 27 PCR fourth-grade items (48%). Hence, although the percentage of PCR items appears similar, there was greater diversity in the types of PCR items in the eighth-grade mathematics assessment.

Table 1: Number of fourth-grade PCR questions and representations used in them.

Content Domain	*Total*	*PCR*	*Written*	*Pictorial*	*Graph*	*Table*
Number	40	20 (50%)	10	11	0	3
Geometric Shapes and Measures	24	1 (4%)	0	1	0	0
Data Display	9	6 (67%)	0	3	4	3
TOTAL (Mathematics)	73	27 (37%)	10	15	4	6
Life Science	30	7 (23%)	7	2	0	0
Physical Science	28	11 (39%)	9	9	0	1
Earth Science	14	5 (36%)	5	2	0	0
TOTAL (Science)	72	23 (32%)	21	13	0	1

Table 2: Number of eighth-grade PCR questions and representations used in them.

Content Domain	*Total*	*PCR*	*Written*	*Pictorial*	*Graph*	*Table*	*Equation*
Number	20	2 (10%)	1	0	0	0	1
Algebra	30	15 (50%)	1	6	0	5	5
Geometry	20	2 (10%)	2	1	0	0	0
Data and Chance	18	12 (67%)	5	1	5	1	0
TOTAL (Math)	88	31 (35%)	9	8	5	6	6
Biology	32	12 (38%)	2	2	5	3	0
Chemistry	18	6 (33%)	5	1	1	0	0
Physics	24	13 (54%)	12	8	1	0	0
Earth Science	16	8 (50%)	8	2	0	0	0
TOTAL (Science)	90	39 (43%)	27	13	7	3	0

Looking across content domains, we highlight the Data content strand had the highest percentage of PCR questions in both the fourth- and eighth-grade mathematics items, and Geometry had the lowest percentage in both. Further, we highlight that across all eighth-grade science content domains, over 30% of questions were coded as PCR.

Finally, we note that across both fourth-grade mathematics and science PCR items, written and pictorial representations were common, with graphs and tables also being observed but with less frequency. Graphs were not observed in any science fourth-grade PCR items and were rare in the mathematics items, occurring only in the Data Display content domain. Although the eighth-grade science items continued to show a preponderance of written and pictorial representations, the eighth-grade mathematics representations were more evenly distributed (i.e., between 5 and 9 occurrences across all PCR items). Within the eighth-grade mathematics PCR items, we observed tables and equations almost exclusively in the Algebra items and graphs only in the Data and Chance items.

Discussion and Conclusion

We first note, addressing RQ1, that from fourth to eighth grade, the assessment items seem to have an implicit expectation that students will be able to engage in more covariational reasoning in science, and more varied forms of covariational reasoning in mathematics (e.g., more items that move beyond pattern finding or proportional reasoning). Such findings underscore the importance of supporting middle school students in developing their abilities to reason about covarying quantities throughout middle school.

Second, addressing RQ2 and RQ3, when examining the types of representations used, it is perhaps unsurprising that a majority of items across all four assessments relied on written descriptions and pictorial representations. However, in the eighth-grade mathematics assessment, we were intrigued by the limited number of items that used equations (six items) and graphs (five items), and we were surprised that all five items that involved a graph were in the Data and Chance content strand. Further, we note in the eighth-grade science assessment that there were seven items across three content domains that included graphs. This finding, in conjunction with the fact that all four content strands in science and Data and Chance had substantial percentages of items coded PCR, allows us to echo other researchers' calls (e.g., Glazer, 2011) indicating the importance of covariational reasoning and graphical interpretation across STEM fields.

By providing an initial set of items coded as potentially eliciting covariational reasoning, we open avenues for future research exploring middle school students' covariational reasoning in the U.S. and internationally. Such research can add to the body of research examining middle school students' covariational reasoning in mathematics (e.g., Ellis, 2011) and science (e.g., Panorkou & Germia, 2020). We call for continued research in this area, as such experiences could be foundational to students' future STEM courses and careers.

Thompson (2015) proposed that a productive mathematical meaning is one that prepares students for future learning and lends coherence to extant meanings. We propose that a productive mathematical meaning related to expanding algebraic expressions and factoring polynomials revolves around developing an understanding of structural relationships between (binomial) factors and polynomials. We briefly outline a combinatorial approach to support a productive mathematical meaning for expanding and factoring relationships. We then report on our analysis of four Algebra 1 and Algebra 2 textbooks as we investigated their approaches to these topics. Our findings suggest that significant work on curricular development is needed to support productive mathematical meanings in this domain.

Keywords: Curriculum, Algebra & Algebraic Thinking, High School Education, Combinatorics

Introduction

Expanding algebraic expressions and factoring polynomials make up a significant portion of the content in algebra textbooks (Sherman et al., 2016). Moreover, practitioners routinely identify expanding and factoring as an area of struggle for students (Clinch, 2018; Frank, 2019; O'Neil, 2006; Steckroth, 2015). Despite these two considerations, a relatively small amount of research has been conducted on how students engage in this work (Kieran, 2007; Warren et al., 2016) especially for situations involving more advanced, non-linear, algebraic relationships (Stacey & Chick, 2004). The majority of research on expanding and factoring has focused either on how students use computer-assisted software (CAS) to engage in this work (e.g., Jankvist et al., 2019; Kieran & Drijvers, 2006) or how they engage with it in the context of reasoning about functions (e.g., Heyd-Metzuyanim et al., 2018; Mourao, 2002). We posit that one reason for the limited research is researchers' lack of articulation of productive mathematical meanings that could serve to bring coherence to students' mathematical reasoning in this area (Thompson, 2015). Our purposes for this paper are two-fold. First, we use this paper to articulate what we see as components of a productive mathematical meaning for this domain (Tillema & Gatza, 2016; Tillema & Burch, 2020). Second, we analyze four Algebra 1 and four Algebra 2 textbooks to determine how expanding and factoring are typically treated in curricular materials. The following research questions guide this paper:

1. What themes related to expanding algebraic expressions and factoring polynomials emerged from an analysis of Algebra 1 and 2 textbooks?
2. To what extent, is the textbook development of expanding and factoring aligned with developing the productive mathematical meaning as we have described it?

After presenting the textbook analysis, we discuss the ways in which current curricular materials either do or do not support the development of the productive mathematical meaning we outline.

Conceptual Framework

Thompson (2015) described productive mathematical meanings as "propaedeutic (preparing the student for future learning) and [lending] coherence to the meanings students already have" (p. 444). For expanding and factoring, we contend that a productive mathematical meaning is one that allows students and teachers to anticipate structural relationships between (binomial) factors and the corresponding polynomial. Elsewhere, we have outlined various ways to develop such relationships (Tillema & Burch, 2020). Here, we focus on an approach that is rooted in combinatorial and quantitative reasoning—arguing that it has the most promise for supporting productive mathematical meanings. In developing this approach, we have reported on studies that: (a) supported students to develop quantitative and combinatorial reasoning using 2-D and 3-D arrays (Tillema & Gatza, 2016; Tillema, 2018); (b) supported students and teachers to generalize this reasoning to establish algebraic identities like $(x+1)^3 = x^3 + 3x^2 + 3x + 1$ (Tillema & Gatza, 2017); and (c) supported teachers to apply their combinatorial reasoning in purely symbolic problems (Burch & Tillema, 2020; Tillema & Burch, under review). Given space constraints, we focus our conceptual analysis on applying combinatorial reasoning within purely symbolic problems. We use the expansion of $(x+a)(x+b)(x+c)$ to discuss structural relationships between binomial factors and resulting polynomials.

Combinatorially, determining the product of *n* binomial factors can be interpreted as a counting problem where each binomial represents an independent binary event with the resulting polynomial representing the set of outcomes. In the cubic case, $(x+a)(x+b)(x+c)$ involves selecting either the variable, *x*, or the constant term (*a*, *b*, or *c*, respectively) from each binomial. For this reason, each partial product in the final polynomial will have exactly three factors because there are three binomials from which to select. In addition, the total number of partial products in the final polynomial will be 2^3 because each of three binomial factors represents a choice between two possibilities. The partial products can then be organized by the number of times *x* is selected to produce them. Organizing the 2^3 partial products in this way corresponds to the binomial coefficients: for the cubic case, $2^3 = 1 + 3 + 3 + 1$. That is, 1 partial product (of the 8) contains exactly three x's (i.e., $x \cdot x \cdot x$), 3 partial products contain exactly two x's (i.e., $a \cdot x \cdot x$, $x \cdot b \cdot x$, $x \cdot x \cdot c$), 3 partial products contain exactly one *x* (i.e., $a \cdot b \cdot x$, $a \cdot x \cdot c$, $x \cdot b \cdot c$), and 1 partial product contains zero x's (i.e., $a \cdot b \cdot c$). These partial products can be re-written in the final polynomial as $x^3 + (a+b+c)x^2 + (a \cdot b + a \cdot c + b \cdot c)x + (a \cdot b \cdot c)$. Re-writing the polynomial in this way highlights that the coefficients of the resulting polynomial are connected to the roots of the polynomial. For example, the coefficient for the quadratic term in the cubic expansion is the sum of the constant terms of the binomials, which means they are the negative sum of the roots of the polynomial.

Generally, a combinatorial perspective on expansion of an algebraic expression establishes four relationships: (a) relationships between the number of initial factors and the number of factors in each partial product of the final polynomial (in our case three initial factors and three factors in each partial product); (b) relationships among the number of initial factors, the number of terms per initial factor, and the total number of partial products in the final polynomial (in our case 2^3); (c) relationships between the number of partial products of a particular kind (e.g., cubic, quadratic, linear, or constant) and the binomial (or multinomial) coefficients (in our case

$1 + 3 + 3 + 1$); and (d) relationships between the roots of the polynomial and the coefficients of the polynomial (in our case, for example, the coefficient of the quadratic term being the negative sum of the roots of the polynomial). We consider these relationships to be key components of the productive mathematical meaning in the domain of expanding and factoring that we would like to engender in secondary students and teachers. We now analyze how secondary algebra textbooks support the development of expanding and factoring and of connections between these two processes.

Methods

Our sample included one secondary algebra textbook series (Algebra 1 and Algebra 2 texts) from the three predominant publishers in the U.S. secondary mathematics textbook market—Houghton Mifflin Harcourt *Into Algebra* series; McGraw Hill *Algebra 1*, *Algebra 2*; and Pearson Prentice Hall *enVision Algebra* (Banilower et al., 2018; Meaney, 2016). Additionally, we included one reform-oriented series, namely the *Algebra* and *Advanced Algebra* sequence from the University of Chicago School Mathematics Project (UCSMP). We worked from the presumption that textbook authors intended to build ideas across their respective Algebra 1-2 series. Initial analysis focused on the first research question: What themes emerged related to expanding algebraic expressions and factoring polynomials? To answer this question, we coded and discussed the narrative portions of textbook sections involving polynomial multiplication introduced. We draw examples from the textbooks in our sample to illustrate emergent themes regarding how students might understand these concepts given these presentations. We then consider the implications of these themes for developing the productive mathematical meaning as we have described it.

Emergent Themes Related to Expanding and Factoring

Across textbooks, themes emerged related to the development of expanding and factoring and the equivalence of corresponding expressions (i.e., factored and expanded). Here, we present data related to expanding and briefly outline themes related to factoring and algebraic identities. In our presentation, we will present data across all themes.

Themes Related to *Expanding* Algebraic Expressions

We found that all textbooks present the Distributive Property as *the* fundamental mechanism behind expanding algebraic expressions—regardless of the number of factors. Initial development of expanding two binomial factors occurs in Algebra 1 texts as a precursor to working on quadratic functions (Figure 1a). We note that in contrast to initial treatments of the distributive property (e.g., $7 \cdot 13 = 7 \cdot (10 + 3) = 7 \cdot 10 + 7 \cdot 3$), only two of the four books (Pearson *enVision*, UCSMP *Algebra*) gave any numeric examples to motivate the process of two factor binomial expansion (e.g., $13 \cdot 13 = (10 + 3)(10 + 3) = 10 \cdot 10 + 10 \cdot 3 + 3 \cdot 10 + 3 \cdot 3$). Additionally, Algebra 1 textbooks consistently offer at least one alternative strategy for two-factor binomial expansion (e.g., FOIL, table [box method], area model). However, these strategies are presented either as shortcuts for (e.g., FOIL, table) or visual representations (e.g., area model) of the Distributive Property (Figure 1b). Expansion is then revisited in Algebra 2 in the context of determining a polynomial given its roots (Figure 1c). Within presenting these methods, the main focal point is a step-by-step narration (see Figure 1a) of repeatable procedural steps that can be used to guide computational activity.

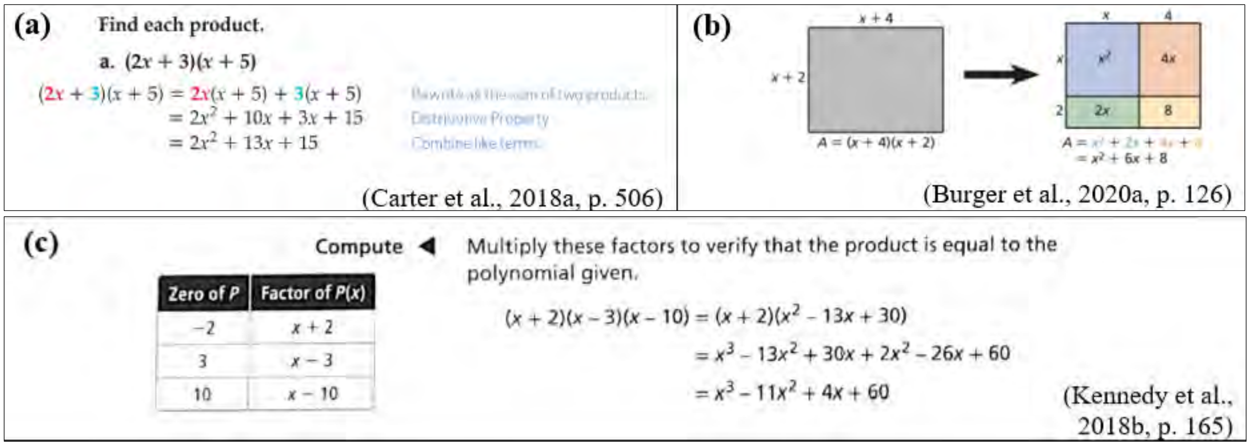

Figure 1: Expanding Algebraic Expressions

Notably absent from all Algebra 1 textbook sections on expanding are prompts to reflect on the makeup of terms in the final polynomial; instead, the focus is on combining like terms and simplifying when possible. For example, in Figure 1b, the coefficient of the linear term is written as $6x$ rather than as $(4 + 2)x$ and the constant term as 8 rather than $(4 \cdot 2)$. We do note, and will discuss in our presentation, that all textbooks present this relationship in the section on factoring monic quadratic polynomials. However, only one of the eight textbooks highlighted such relationships in factoring sections for any other polynomials—HMH *Into Algebra 1* textbook for non-monic quadratics. Taken together, we interpret these choices as missed opportunities in sections on *expanding* to help readers anticipate relationships that would be presented later in sections on factoring, and overall an inconsistent rather than clear focus on these relationships.

Across all four Algebra 2 textbooks, the number of intermediate steps commensurately with the number of factors in the expansion. The UCSMP *Algebra* text set up three-factor expansion by telling students to "multiply any two of its factors. Then, multiply the product of those factors by the third factor" (Brown et al., 2016, p. 755). Using the example in Figure 1c, $(x - 3)$ and $(x - 10)$ are multiplied to produce $x^2 - 13x + 30$, which is then multiplied by $(x + 2)$ to produce $x^3 - 11x^2 + 4x + 60$. We interpret this choice, beginning with two factors and enfolding additional binomials one-by-one, as positioning expansion as a recursive process that naturally terminates when all binomials have been included. The recursive process, coupled with the push to combine like terms between iterations, reinforces equivalence as resulting from a one-directional computation and further obscures relationships between the initial binomial factors and final polynomial.

Discussion & Conclusion

We consider supporting students to develop an anticipation of relationships between factors and expanded polynomials to be a worthy aim of instruction on expanding and factoring. In our textbook analysis, we could not infer intentionality from textbook authors toward developing relationships between initial binomial factors and resulting polynomials. Rather, when expanding binomials, textbooks focused on activating and carrying out sequential procedure with little consideration about what initial factors might mean for the final polynomial expansion. One exception was the UCSMP *Algebra* text that explicitly referenced the Multiplication Principle as useful for anticipating the number of partial products (Brown et al., 2016, p. 681). We acknowledge that textbook authors may rely on teachers to support these connections. However, this presumes that these relationships are inherent to teachers' meanings. Further, we suggest that textbooks miss opportunities to support developing productive mathematical meanings by not explicitly supporting these relationships.

This study explores elementary teachers' use of mathematics curricular resources before and during COVID-19. We administered a survey to a national sample of third through fifth grade teachers. The findings show the prevalence and increased use of teacher-created materials during the pandemic. This has implications for researchers and administrators as they consider how to best support teachers in designing their own curricular materials, especially for diverse learning contexts.

Keywords: Curriculum, Teacher Beliefs, Instructional Activities and Practices, Elementary School Education

Even before COVID-19 upended classrooms, teachers' use of mathematics curriculum was shifting. Many teachers no longer relied on or had access to sets of materials from textbook companies. Instead, pre-pandemic anecdotal evidence suggests an increasing popularity of online, teacher-created curricular materials (e.g., Gewertz, 2014; Monahan, 2015; Ross, 2015). Research has documented teachers' use and modification of published curricular materials (e.g., Choppin, 2011; Remillard, 2005; Sherin & Drake, 2009). These researchers report modifications such as changing physical materials, omitting parts, reorganizing features (such as ungrouping sets of problems), and adding transitional activities to lessons. However, the shift to online resources and teacher-created curriculum is a more dramatic change in teachers' use of curricular materials and one that we know little about.

In this study, we seek to describe the curricular landscape for upper elementary mathematics curricula before and during the pandemic. In particular, we are interested in making sense of what materials teachers are using, including teacher-created materials, and how they are making their curricular decisions.

Online Resources

Recent studies have started to track teachers' use of online resources. Sawyer et al. (2020) found that elementary teachers, regardless of years of experience, were turning to online mathematics resources weekly; 89% reported using Teachers Pay Teachers (TPT) and 74% reported using Pinterest. The limited research literature on teachers' uses of sites such as TPT and Pinterest suggests substantial disagreement about the benefits and limitations of teachers sharing, choosing, and using teacher-created curricular materials from these sites. For example, some research (Shelton & Archambault, 2019; Torphy et al., 2020) highlighted the positive aspects of networks of sharing across teachers without the need to involve administrators and publishers, as well as teachers' capacity to curate the wide range of materials available on these sites and to have immediate access to the materials in order to be maximally responsive to their students' needs. Other research, however, has focused more on the limitations of the activities available on TPT and Pinterest, including the predominantly low levels of cognitive demand of the tasks shared on these sites and the tendency of both sellers and buyers to choose fun, colorful activities (Sawyer et al., 2019). Most existing work concludes with the need for further research to understand how and why teachers are sharing and using teacher-created curricular materials.

Methods

We utilized the services of MDR to assist us with survey design, administration, and analysis. MDR administered the survey in September 2020. In the survey, teachers were asked about their curriculum before the pandemic, during remote teaching in Spring 2020, and their plans for Fall 2020. In the survey, we defined "Mathematics Curriculum Materials" as any materials used by teachers for the purposes of planning, teaching, and/or assessment. We asked teachers questions about the mathematics curricular materials they used in September 2019-February 2020, March 2020-June 2020, and September 2020-December 2020. In addition to the specific curricular options we provided, respondents could also select "I designed my own materials," "Other (please specify)" or "None of the above." Once the curricular materials used were established during each time frame, we asked questions about changes in curriculum reported.

We received survey responses from 524 third, fourth, and fifth grade teachers from across the U.S. Most taught in public schools (90%) located in suburban (54%), urban (28%), and rural districts (17%). The majority of the teachers we surveyed (62%) work in schools with at least half of the students eligible for *free or reduced lunch* (FRL), and many (43%) of the teachers work in schools with at least 75% of the students eligible for FRL. We distinguish between four categories: high FRL level (75%-100% of students qualify), medium-high (50%-74%), medium (15%-49%), and low (0%-14%). Descriptive frequency data for the full sample and for groups based on school FRL levels are reported. In addition, we examined and coded responses to the open-ended questions to further understand the reasons for teachers turning away supplemental and core curricula in the context of COVID-19.

Findings

Teacher Autonomy

We asked teachers how much control they had over curricular decisions during the pandemic. Teachers reported that curricular decisions were primarily made by district leaders (60%), principals (41%), grade-level teams (39%), and school boards (17%), with few teachers reporting that they were completely in control of their curricular decisions (11%).

Teachers from rural, suburban, and urban communities reported a range of control over their curriculum. For example, 16% of rural, 19% of suburban, and 29% of urban teachers reported they had no control over their curriculum. At the other end of the spectrum, 13% of rural, 12% of suburban, and 7% of urban teachers reported they had full control over their curricular decisions. Most teachers reported either "a bit" (35% rural, 40% suburban, 42% of urban) or "a lot" of control (35% rural, 29% suburban, 23% urban).

Shifts Away from Published Core Curriculum

Less than half of teachers (41%) surveyed were using at least one core curriculum prior to the pandemic; this dropped to 37% in Spring 2020 and Fall 2020. The most popular core curricula were Envision Math, Engage NY/Eureka, and Go Math. Many teachers used TPT, Pinterest, and other online teacher-created resources. TPT was the most widely used curricular resource by teachers before and during the pandemic, reportedly used by nearly half of surveyed teachers. Other online curricular supplements such as BrainPOP and IXL were used by approximately one-fourth of the teachers, decreasing slightly in their use during the pandemic.

Interestingly, at the onset of the pandemic, the frequency with which teachers designed their own materials increased. Before the pandemic, 27% of teachers designed their own materials. This increased to 35% in the Spring and 32% in the Fall. We were not surprised by this finding considering that most existing curricular materials were created for in-person contexts.

Digging Deeper into TPT Usage

TPT was the most popular curricular resource across community and economic contexts. As seen in Table 1, in rural and urban settings, the data show a linear relationship between use of TPT and economic status of students they were serving, with more teachers using TPT as the percentage of students receiving FRL increases. Around a quarter of teachers used this resource in suburban settings, regardless of the economic status of students. We have not yet been able to account for the difference in use of TPT across suburban and urban/rural contexts. These patterns do not correlate with core curricula or patterns of teacher autonomy across community contexts.

Table 1: Location and FRL Status of Teachers Using TPT prior to COVID

	Pre-Pandemic				Early Pandemic (Spring 2020)				During Pandemic (Fall 2020)			
FRL	Low	Med	MH	High	Low	Med	MH	High	Low	Med	MH	High
Rural	2%	8%	30%	60%	0%	7%	32%	57%	2%	11%	32%	52%
Urban	7%	15%	8%	66%	6%	14%	9%	67%	6%	15%	10%	64%
Suburb	24%	26%	20%	24%	25%	26%	19%	25%	26%	26%	21%	22%

Interestingly, the use of TPT and Pinterest did not neatly match teachers' reports about their curricular autonomy; in fact, 57% of teachers who reported "a bit" or no curricular control used these resources compared to only 43% of those reporting "a lot" or complete control who reported no control over curricular decisions. It may be that teachers were turning to TPT and Pinterest to supplement their mandated curriculum while those with more control over their curriculum were more satisfied with curriculum from educational publishers.

Teachers' Reasons for Turning Away from Online, Supplemental, and Core Curriculum

We also asked teachers to explain the reasons they stopped using online teacher-created curricula (i.e., TPT, Pinterest), supplemental curricula (i.e., IXL, BrainPop) and core curricula (e.g., Go Math, Envision Math, and Engage NY/Eureka). Teachers' reasons for stopping supplemental curriculum include: there was not enough class time to use supplements, there was not enough time for the teacher to find material, their school used specific curriculum/had enough resources, the resources were not available in electronic or easy to use online format, the teachers did not want to spend the money on resources, their district did not allow use of these resources during remote learning, teachers wanted to limit resources children needed to manage at home, students did not have access to sufficient technology at home/or the resources were not easy for all students to access, the supplemented did not meet the content needs, the resources were not offered by the school anymore, it was not rigorous enough, and they would rather use their own materials or other curricula.

When teachers were asked about the reasons they stopped using core curricula, they explained that they stopped using these resources because they only used physical book version and did not have textbooks at home, the core curriculum was not digital learner friendly, the district got rid of it/switched curriculum, they wanted to limit online platforms to make things easier for kids/parents, there was lack of rigor/declining test scores, and they would rather use their own materials.

Table 2: Reasons for Turning Away from Curriculum

Reasons	Teacher	Supplement	Core
Not enough class time	X	X	
School/district provided curricular resources	X	X	
Materials were in print form/could not be used remotely.	X	X	X
Cost/end of school subscription	X	X	
Needed to limit resources	X	X	X
Not enough time to find material	X		
Materials did not meet the instructional needs		X	X

Discussion

These data point to a novel, potentially pandemic-related trend towards teachers needing to design their own curriculum: teachers were making more of their own materials in contrast to a previously reported general trend toward more online supplemental and teacher-created materials (e.g., Sawyer et al., 2020). Rather than looking online for materials created by other teachers, teachers were inventing their own materials, not to sell, but rather because what they had available was not meeting students' needs during online/remote instruction.

Before the pandemic, our research goals were to learn more about how the curricular landscape had changed as a result of the internet and CCSSM. So many of the changes imposed upon classrooms require that teachers take up the heavy lift of managing the implementation and impact of the change. For CCSSM, teachers became the front-line workers, pulling together new curricula because their classrooms lacked the necessary resources to match the new standards (Pittard, 2017). While principals and others provided important support, the slow pace of infusion of new published curricula meant that teachers were necessarily the ultimate bridge between school shifts and children.

This was just as true during the pandemic. As the pandemic hit and teaching and learning entered entirely new territory, teachers were the ones who were in the best position to keep students learning (and feeling connected to something stable) during the new and changing notion of schooling. The existing curricular resources, including those available online, were not adequately attuned to students' new realities and needs, realities and needs that were best understood by the teachers who were connecting online with students and their families. As a result, teachers found increasing needs to create their own materials.

THE STORY OF DEFINITE INTEGRALS: A CALCULUS TEXTBOOK NARRATIVE ANALYSIS

Amanda Huffman
Purdue University
huffma33@purdue.edu

Keywords: Written Curriculum, Teaching and Classroom Practice, Narrative Framework, Definite Integral

Teachers have to choose appropriate textbooks from a plethora available for every course. While most textbooks incorporate the same content and organize the content in a similar way, it is important for teachers to understand the textbook they have chosen to support their students' learning, as textbooks can have a significant impact on student learning and teacher instruction (e.g., Remillard et al., 2014). Additionally, teachers' understanding of how students negotiate the curriculum can improve student achievement (Larson et al., 2017). This study aims to understand how teachers can best use their resources and read curriculum through a different lens. I was guided by the research question: "How does an analysis of definite integrals through a narrative framework contribute to the understanding of the written calculus curriculum?" I am responding to the call for research on the relationships between stories and knowledge construction (Healy & Sinclair, 2007). Dietiker's (2015) narrative framework was adapted to analyze written calculus curricula introducing the definite integral in working to understand the story of definite integrals and students' knowledge construction of definite integrals when read as stories.

Dietiker's (2015) narrative framework provided a conceptual tool for understanding the story of the written mathematics curriculum. A *mathematical story* as defined by Dietiker (2015) is "the interpretation of the chronological sequence of mathematical changes in a mathematics textbook by a reader" (p. 288). I split the lessons of the definite integral from the five calculus textbooks (Dietiker et al., 2017; Goldstein et al., 2009; Hughes-Hallet et al., 2009; Rogawski et al., 2015; Weir et al., 2008) into "acts," denoted by changes in focus in the lesson. I, then, coded the acts into story arcs, defined as the transitions from asking to answering a question, and I subcoded the story arcs into elements of proposal, explicit question, partial answer, disclosure, and other literary elements to write the story of the lesson. Specifically, the sequencing of each story became a focal point of the study as the sequencing plays into development of the character, the definite integral, and sets the context for future understanding.

Analyzing the mathematical story of the definite integral provided an in-depth comparison of one individual lesson from five different calculus textbooks. Findings suggested key similarities and differences in the five stories. The findings revealed an overarching theme of working towards defining the definite integral. The key question, *What is the definite integral?,* was introduced early and developed throughout the lessons analyzed. However, the path to answering this question varied from lesson to lesson as some focused on the area model and others utilized the Fundamental Theorem of Calculus or introduced properties and formulas to compute definite integrals. Even the lessons focused on using the area model to define the definite integral had different structures. Hughes-Hallet et al.'s (2009) lesson introduced Riemann sums in the lesson, while other lessons revisited Riemann sums and worked toward a more generalized understanding while introducing and working to define the definite integral. These insights provide teachers and researchers a new perspective and a deeper understanding of these textbook lessons and how the variances in a story can alter student learning.

Today's data-driven world demands a data-literate citizenry and a workforce with strong statistical thinking skills. Studies show, however, that schools are neither preparing students adequately nor drawing enough students to data science fields (Henke et al., 2016). The Strengthening Data Literacy across the Curriculum (SDLC) project has developed and is studying two curriculum modules for non-AP high school statistics to promote interest and skills in statistical thinking and data analysis among high school students—particularly those from historically marginalized groups. The modules *Investigating Income Inequality in the U.S.* and *Investigating Immigration to the U.S.* pose social justice questions that students investigate using large-scale socioeconomic data from the U.S. Census Bureau and the Common Online Data Analysis Platform (CODAP). Students enact a four-step data investigation cycle (Bargagliotti et al., 2020) to explore questions like "How much income inequality exists between males and females in the U.S.?" and "How do labor force participation rates for immigrants and the U.S. born compare, before and after controlling for education?" Statistical concepts of focus include measures of center and variability, conditional proportions, and multivariable thinking.

The SDLC modules have been iteratively developed and tested with over 500 students in Boston-area high schools. Design-based, mixed-methods research efforts examine these questions: 1) In what ways do SDLC modules support students' interests in and learning of statistical concepts and practices? 2) To what extent do students who use SDLC modules show improved understandings of important statistical concepts and greater interest in statistics and data analysis? Research data include classroom observations, student work, teacher logs, student and teacher interviews, and pre-/post-assessments. The project team has analyzed qualitative data with *a priori* and open codes to explore participants' views of module activities and student outcomes, and it has examined growth in students' pre- vs. post-module interests and learning with paired *t*-tests. Interest scales were adapted from instruments by Linnenbrink-Garcia et al. (2010) and Sproesser, Engel, and Kuntze (2016), and statistics assessment items were drawn from the LOCUS (Jacobbe et al., 2014) and CAOS (Garfield et al., 2006) assessments.

Findings from the income inequality module show growth in student interest and learning. Students' individual interest in statistics and data analysis was significantly higher after completion of the module, and students' overall understanding of assessed statistical concepts improved significantly between the start and end of the module. These preliminary results suggest that these modules may hold promise for promoting student interest and learning in statistics and data analysis. In a world that urgently needs larger numbers and a greater diversity of students to develop interests and practices in data science, the SDLC project is building

A COMPARATIVE STUDY OF TRIGONOMETRY STANDARDS IN TURKEY, ZAMBIA, AND THE UNITED STATES

Rose Mbewe
Purdue University
rmbewe@purdue.edu

Sezai Kocabas,
Purdue University
skocabas@purdue.edu

Keywords: Standards, Curriculum, Policy, Comparative

There has been a growing interest in how students from different nations learn mathematics (Delice, 2003). Results of international comparative efforts such as Trends in International Mathematics and Science Study and Program for International Student Assessment show differences and similarities in the educational systems across the world (Cai, 2001). We analyzed a secondary mathematics topic, trigonometry, in the U.S., Turkey, and Zambia's mathematics curriculum to assess the similarities and differences in learning expectations for students in three economically, socially, geographically different countries. Engaging with trigonometry enhances students' problem solving, reasoning, and visual representation skills (Fi, 2003; Tuna, 2013). It is perceived as an essential topic to comprehend college-level courses, i.e., "understand periodicity and recognize graphs of periodic functions, especially the trigonometric functions" (Conley, 2003, p. 34).

Only 22% of the students who took the composite test score (ACT) reached the college-readiness level in mathematics, which includes trigonometry standards. A possible reason for the low readiness could be the intended and implemented curriculum (Schmidt et al., 2001). Due to its low achieving, researchers were more likely to compare the United States' mathematical standards with high-achieving countries' educational systems (e.g., Porter et al., 2011; Schmidt et al., 2005). Comparison of developed countries' mathematics curriculum for instance the U.S., with the developing countries' mathematics curriculum such as Turkey and Zambia would add to existing literature. However, there is a dearth of research to inform this kind of work.

We independently analyzed and later together compared cognitive expectations by focusing on verbs of the trigonometry standards based on Webb's (2007) Depth of Knowledge (DOK) framework. This framework has four levels namely Level 1 measuring at recall and reproduction level, Level 2 measuring at skills and concepts level, Level 3 measuring at strategic thinking and reasoning, and finally Level 4 measuring extended thinking, which reflect the complexity of the analysis. We used Hess's (2013) guide to decide the level of verbs in Webb's framework. For example, *working* with special angles refers to Level 2, and *drawing* graphs for functions refers to Level 3. Then, we used a direct analytic approach to compare the three sets of standards side by side (Tran et al., 2016).

Preliminary findings indicated that all three countries' standards have similar trigonometric topics; however, the DOK levels varied across countries. For example, all three countries have standards related to drawing trigonometric functions. Turkey and Zambia have standards with a lower-level verb (to draw) while *CCSSM* used a higher-level verb (to model). *CCSSM* did not have any standards at Level 1 (Recall and Reproduction) while Turkey had [14%] and Zambia [19%]. Likewise, compared with Turkey and Zambia, *CCSSM* [69%] was more likely to emphasize higher-order thinking skills at Level 3 and Level 4. Turkey [43%] as less likely to support higher-order thinking skills than Zambia [51%]. Future studies could extend this study by analyzing additional curriculum resources such as textbooks.

Keywords: Assessment

A way to evaluate an assessment's worth is in its contributions to student learning (Cronbach, 1988). "Classrooms are complex social environments. Economic, language, cultural, and mental health issues are just some of the key variables that need to be considered in relation to students [learning]" (Leighton, 2020, p. 27). Teachers provide a unique influence on their students' learning through their beliefs, content knowledge, and pedagogical content knowledge (Brookhart, 2003). A classroom's social context is an area where teacher-created assessments differ from externally-developed standardized assessments. One goal of standardized testing is to eliminate psychometric noise like social contexts by attempting to account for factors not related to the construct being measured (AERA et al., 2014). On the other hand, teacher-created assessments are contextually relevant as they are developed with certain students in mind (Brookhart, 2003). Teacher-created assessments are more likely to align with a unique social context of a classroom. The purpose of this study is to explore middle grades math teachers assessment practices and impact on student learning.

We address the question: What are middle grades math teachers' perceptions and uses of teacher-created and standardized assessment results when making inferences about student learning? Data were collected for this qualitative study through semi-structured interviews with seven purposefully selected inservice teachers. Interviews were transcribed and themes were identified through open and axial coding (Saldaña, 2015). One finding was that teachers perceived results from teacher-created assessments to be more useful than standardized assessment data when making inferences about student learning. Figure 1 shows participant support of this theme. Teacher-created assessments provided evidence of student thinking like how students solved problems, which standardized assessment results lacked.

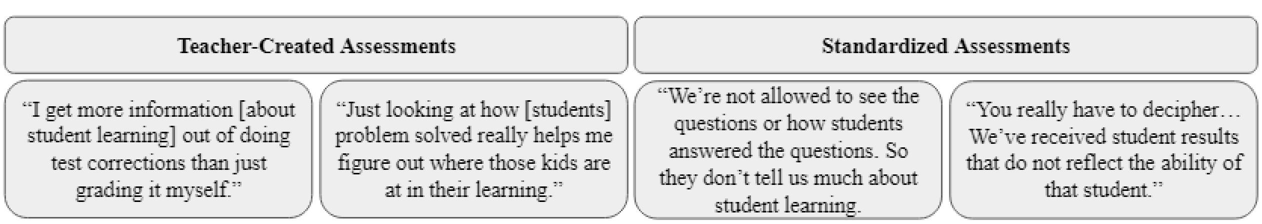

Figure 1. Participating teachers statements about assessment results

THE ROLE OF HUMAN BEINGS IN MATHEMATICS CURRICULUM: CONNECTING UNDERGRADUATE MATHEMATICS WITH TEACHING SECONDARY MATHEMATICS

Rachel Tremaine
Colorado State University
rachel.tremaine@colostate.edu

Elizabeth G. Arnold
Colorado State University
liz.arnold@colostate.edu

Keywords: Curriculum, Mathematical Knowledge for Teaching, Preservice Teacher Education, Undergraduate Education

Mathematics and teaching are human activities: mathematics is taught and learned by people in a social and cultural context. Teachers are called on to engage in interpersonal interactions that require both mathematical expertise and skills for probing student thinking or finding meaning in learners' perspectives (e.g., Ball et al., 2008; NCTM, 2014). As such, mathematics teachers' interactions with learners interweave their content knowledge with their capacity to respond to and guide student thinking, and future teachers need opportunities to engage in these practices throughout their teacher preparation programs (AMTE, 2017). Yet, secondary teachers can have difficulty in recognizing mathematics as part of a social space (Parker et al., 2017). Because prospective secondary teachers are among the population of undergraduates typically enrolled in mathematics major courses, we posit that these content courses can play a large role in providing prospective teachers with opportunities to engage in such practices and to grow in their understanding of mathematics as a human endeavor.

The META Math project has focused on designing and researching the use of tasks (specifically applications to teaching secondary mathematics) in content courses. The tasks highlight connections between undergraduate mathematics and teaching secondary mathematics (see Arnold et al., 2020) and have been designed in a way to emphasize the human element of mathematics so that the prospective teachers who engage with our materials will see that the human context of mathematics is held on par with the mathematics content (see Álvarez et al., 2020). We report on a qualitative case study in which we investigated the following research question: *What is the nature of undergraduate students' experiences with tasks designed to include the human context of mathematics?* Our tasks were implemented in four content courses: abstract algebra, calculus, discrete mathematics, and statistics. We collected all undergraduates' written responses to our tasks and invited a subset of them to participate in interviews.

We found that undergraduates, including those who did not plan to teach secondary mathematics, were thinking about human beings while doing the tasks. Further, the inclusion of these tasks into the curriculum did not detract from their learning of core mathematical content. Although challenging, the undergraduates found value working on these tasks as they made undergraduates "think more critically about the problem." We view our results as confirmation that creating and using tasks that emphasize the human context of doing mathematics is a useful approach to give prospective teachers opportunities in their content courses to engage in practices central to teaching and to see that mathematics and teaching are human endeavors.

RELATIONSHIPS IN MATHEMATICS EDUCATION FOR INDIGENOUS PRE-COLLEGIATE STUDENTS

Tarah M. Donoghue
University of Colorado – Bo1ulder
Tarah.donoghue@colorado.edu

Keywords: Culturally relevant pedagogy; curriculum; First nations & Indigenous cultures

Mathematics curricula are often treated as neutral or infused with contexts that point back to stereotypes about cultural groups. Instead, the conceptual framework for curricular design in this program is derived from core principles of Indigenous perspectives. One of the core principles guiding the design of this project is relationality (Nicol, et al., 2020).

By curriculum, I am referring to not only the content students will be learning with and from, but also the design of the learning environment, including how students interact with each other, their teachers, and their communities both in- and outside of the learning space. This perspective on curriculum calls for mathematics to be utilized as a lens through which to gain perspective and information from the world. This perspective contrasts with that of the traditional, Eurocentric classroom, in which mathematics education is isolated to math classrooms, or the math time of the school day.

Relationships exist at a multitude of levels - human to human, human to more-than-human (e.g., plants, animals, stars, natural phenomena), human to land, etc. (Bang & Medin, 2010; Cajete, 2016; Gutiérrez, 2017; Kimmerer, 2013; McGinty & Bang, 2016; Simpson, 2017; Wilson, 2008). Relationships are also often utilized to describe things mathematically, and mathematical relationships are inherent in the world. In this learning environment, the intelligence of geometry will be embraced, connecting geometry to the students physically, both in body and geographical location, as well as to their cultures (Gutierrez, 2017). The connection of geometrical concepts from standards-based curriculum to stories and significant relationships from students' own cultures provide the college preparatory content required, while also centering Indigenous epistemologies. Students from many tribal nations gather together to participate in the precollegiate program, which means multiple epistemologies are represented in the classroom at any given time.

This qualitative project will collect information from student interviews, reflections, and class work, as well as communications and guidance from Indigenous educators and individuals working with Indigenous students. The connection of geometrical concepts from standards-based curriculum to stories and significant relationships from students' own cultures provide the college preparatory content required, while also centering Indigenous epistemologies.

Keywords: Instructional Activities and Practices, Assessment, and Teacher Educators

Administrators, educators, and stakeholders have faced the dilemma of determining the most effective type of data for informing instruction for quite some time (Pella, 2015). While the type of standardized assessment a teacher gives during instruction is often set at the district or state level, teachers often have autonomy in the formative and summative assessments that serve as the day-to-day tools in assessing a student's progress (Abrams et al., 2016). Choices about in-class assessment and instruction are building blocks towards a student's success on standardized assessments. The purpose of this phenomenological qualitative study is to explore how 4th-8th grade math teachers' preparation and instructional practices are influenced by the types of assessments administered to their students in one school. Research questions are as follows: (a) How do 4th-8th grade math teachers describe the math assessments they use? (b) How do 4th-8th grade math teachers adjust their instructional practices as a result of their students completing formative, summative, and standardized math assessments?

Five rural 4th-8th grade teachers are participants in this case study and took part in a 20-minute semi-structured interview via Zoom that was transcribed verbatim. Two of the researchers conducted open and axial coding to determine emerging themes and consolidated the themes into categories (Saldaña, 2015). The researchers worked to address the four tenets of trustworthiness according to Lincoln and Guba (1985).

Findings showed teachers shared a progression of the ways they described their mathematics assessments. Formative math assessments were described as influencing moment to moment and day-to-day instruction, and the success of students was a clear indication on the difficulty of content and delivery by the teacher. As teachers described summative math assessments, they shared how they viewed these as more of a balance in the success of their students between instruction and student preparedness. Finally, standardized assessments were described as guiding a teacher's planning by addressing standards but not considered in their day to day activities. Two teachers mentioned how it was important for students to have a "blank slate" coming into their classes because each year is different.

Theoretical Framework & Design of Materials

There is strong empirical evidence in support of learning from comparisons in mathematics education research (Rittle-Johnson & Star, 2007; Star, Pollack, et al., 2015; Star et al., 2016). Comparisons have produced gains in students' procedural knowledge, flexibility, and conceptual knowledge of algebra (Lynch & Star, 2014; Star, Newton, et al., 2015; Star, Pollack, et al., 2015). The *Animated Contrasting Cases in Geometry* project seeks to extend this research and transform the learning of geometry for middle school students by designing a supplementary digital animated curriculum.

The curriculum materials for each lesson are organized into Worked Example Pairs (WEPs), which include five unique features: a page for the first student's solution strategy on a given geometry task, a page for the second student's solution to a geometry task (which could be the same or different task as was shown on first student's page), a page with both students' strategies side-by-side, a discussion sheet with four questions for the students to answer, and a thought bubble page summarizing the key mathematical concepts in the problem. The discussion sheet and thought bubble page are designed to make the instructional goal of each WEP more explicit and to scaffold discussions among students as they summarize their work from the WEPs (Star, Pollack, et al., 2015). This paper focuses on the Transformations unit, which is one of four units.

Methods

After fully developing the 8th grade geometry materials, we conducted 56 hour-long think aloud interviews (Piaget, 1976) with individual students ($n = 42$ students). There were 18 think alouds for the Transformations unit conducted with 13 unique students. We transcribed each interview and began *a priori* (Saldaña, 2013) coding based on our key design features. We then added emergent (Saldaña, 2013) Level 1 codes for the students' geometric thinking and curricular form and Level 2 codes as appropriate. In all, there were 556 turns coded.

Findings

We observed 96 (17.27%) turns where students were making comparisons between the WEP characters. Most often they were discussing differences between the characters ($n = 58$), but they also noted similarities ($n = 35$) and used both WEP characters' strategies to verify a mathematical idea ($n = 3$). We observed 119 (21.40%) turns where students were discussing the geometric thinking of the WEP characters. When discussing the thinking displayed by the WEP characters ($n = 44$), students most often provided insight into their personal beliefs about the characters' thinking. Students' geometric thinking accounted for 203 (36.51%) turns of the Level 1 coding. A majority of the codes regarding students' geometric thinking indicated that the student was making sense of the mathematics in the WEP ($n = 105$).

TITLE OF PAPER: USING FIELD-TEST DATA TO INFORM DECISIONS ABOUT USING CONSTRUCTED-RESPONSE AND SELECTED-RESPONSE ITEMS

Robert C. Schoen

Keywords: Assessment, Elementary School Education, Research Methods

Selected-response (i.e., multiple-choice) item formats are commonly used in mathematics assessments in the United States. The selected-response format invokes concerns about convergent thinking, low levels of cognitive demand, and limitations to the inference that can be drawn with respect to student abilities or understanding. Constructed-response item formats also have limitations. They require extensive resources to score, can yield ambiguous responses, and can result in low levels of scoring reliability. Constructed-response items can be especially difficult to score when they are administered to young children whose handwriting and other communication abilities are in nascent stages.

Methods

We present an approach to decision making for item format used in the Elementary Mathematics Student Assessment (Schoen et al., 2016a, 2016b; 2017). The approach involves a multistep process where items are drafted and reviewed by experts. The resulting items are then used in a one-on-one interview setting to enable a think-aloud/cognitive interview protocol. Items are then used in a constructed-response format with a large sample of students in the target population. Final answers are then reviewed. When the four most common answers represent more than about 85% of the responses, we convert the item to a selected-response (i.e., multiple-choice) format, using the responses from the field-test for the response options. When responses to items are more varied, the constructed-response format continues to be used for those items.

Discussion

Selected-response format have several benefits and limitations. We find that examinees from the target population will often respond in predictable ways to items that are used in a constructed-response format, but a large number of examinees will sometimes provide responses that were not expected during item development. Field testing items in a constructed-response format with a sample of examinees from the target population before creating the selected-response options yields response options that align with the answers that would have been provided in a more open-ended format. We assert that this approach to developing selected-response items through empirical response validation improves the testing experience for the examinees and the overall quality of measurement. We recommend that test developers use similar empirical approaches to determining the item format and the response options for selected-response items. We think the process serves to increase efficiency and reliability of the test without sacrificing the quality of the inference that may be drawn from tests using selected-response item formats with respect to student performance or understanding.

We identify storylines about youth from minoritized cultures and/or languages in Norwegian news media to identify positionings made available to migrated and Indigenous mathematics students in this public discourse. Our search from 2003-2020 in a Norwegian media database including newspapers, journals, tabloids, etc, identified 1896 articles, reduced to 96 for relevancy. These storylines were identified: 'The majority language and culture are keys to learning and knowing mathematics', 'Mathematics is language- and culture-neutral', 'Minoritized mathematics students are motivated by gratitude', 'Extraordinary measures are needed to teach students from minoritized groups mathematics', 'Students from minoritized groups must put in extraordinary effort to learn mathematics', 'Students from minoritized groups' mathematics achievements are linked to culture and gender', and 'Students from minoritized groups underachieve'

Keywords: Communication, First nations and Indigenous cultures, Social Justice

Our investigation of news media launches the beginning of a longitudinal, participatory research project with school leaders, teachers, youth, community members, and families to understand the storylines at play and enact the ones that would position youth in asset-based ways. Mathematics education scholars have shown for decades the inequities in students' opportunities to learn mathematics, and we are driven by this fact and focusing on the Scandinavian context because this issue has become more pressing with recent migrations (Källberg, 2018; Ryan, 2019, Udir, 2018). We also know that the positionings presented in news media may affect individual students' and groups of students' identities (Mendick, 2005; Wagner, 2019), the relations with and expectations of mathematics education and thereby opportunities for mathematics learning and life choices. These are the reasons for us to investigate storylines about youth from minoritized cultures and/or languages in news media with the goal to identify positionings made available in this public discourse. Although we focus here on storylines in Norway, the methods and findings are relevant elsewhere. That is, news media concurrently reflects and influences public opinion on mathematics and mathematics education, and about migrated and Indigenous youth everywhere.

We here use the word *minoritized* for the groups and youth we are interested in. We note here that we are aware that any wording contains possibilities for misunderstanding, possibly stigmatizing or are unfamiliar for the people themselves. The alternatives—*nondominant, minority, othered, non-Norwegian, multicultural*, etc.—all rest on attributions that are not always consensual and they imply problematic power relationships.

Storylines

According to positioning theory, people interpret their experiences through storylines – through "lived stories for which told stories already exist" (Harré, 2012, p. 198) such as for instance a coach/athlete storyline. Berman(1999) pointed out that the multiple storylines at play "are organized through conversations around various poles, such as events, characters, and moral dilemmas. Cultural stereotypes like nurse/patient, conductor/orchestra, mother/son may be called on as a resource" (p. 39).

Storylines make positions available, which could be either accepted or resisted—e.g., a parent helping a child with homework could position himself as a teacher in a teacher/student storyline. The child could resist and try to interact within a different storyline. Hence storylines are negotiable; they are reciprocal and contingent (Wagner & Herbel-Eisenmann, 2009).

Storylines about Mathematics and Mathematics Education in Public Media

Recent scholarship has begun to identify storylines present in news media on mathematics and mathematics education. One such storyline is *mathematics equips society* identified by Herbel-Eisenmann et al. (2016). This storyline connects mathematics with the pursuit of economic growth and national prosperity and positions students and their mathematical achievements as national commodities valued by means of global ranking systems such as PISA and TIMMS (Lange & Meaney, 2018). Yasukawa (2019) described how these rankings translate into national pride or shame. In contrast to the storyline that positions countries as competitors, the storyline *mathematics equips the individual* positions individuals as combatants in pursuit of social and economic advancement (Wagner, 2019) or as citizens equipped for collective action (Jablonka, 2003; Rodney, Rouleau & Sinclair, 2016).

Storylines in Norway

Although the media storylines discussed in the previous section apply to many contexts, different countries also have storylines that might be more particular to that context. In Scandinavian societies, it takes a 'mathematics for all' approach (Nortvedt, 2018) as for example the Norwegian national curriculum where qualities such as social justice, equity, and equal opportunities are emphasized. As stated in the introduction, however, such ideals in education and mathematics education, may not have been realized for minoritized groups in Scandinavia.

In Norwegian contexts, several groups with a different origin than Norwegian are mentioned, often with a reference to a connection to a (former) nation state. These groups are mainly seen mentioned from the 1970s and onwards when migrant workers from Pakistan, Turkey, and Morocco started to arrive in Norway. More recently immigration also comprises people from other European countries and from conflict areas in, for example, Asia and Africa (Reisel, Hermansen & Kindt, 2019). In addition to these, there are six peoples/nations of Norway (without their own nation state) that appear in the contexts we are interested in; the Kven and Sami peoples belonging to the northern part of Norway, the Forrest Finns in the South, and the non-territorial Romani, Rom and Jews. These minorities have suffered from various injustices and assimilation policies over the centuries—e.g., for the Romani people the most important measure for assimilation was that children were taken away from their families and placed in Norwegian families, later supplemented with forced sterilisation of Romani women (Kommunal- og moderniseringsdepartementet, 2015).

For our research, such context is part of the data because it provides sources of potential storylines. What people say about a country and its inhabitants are storylines. For minoritized groups in Norway there are (historically shifting) storylines, some of which several of the groups have in common. Some might be seen as positive: e.g., they are good for the labour force; are necessary for the growth of Norway; they produce high quality trade and handicrafts. Others are not positive: e.g., the culture and languages of the peoples are unwanted; the groups do not share with others; the groups do not comply to norms of the society.

Methodology

This research is part of the MIM-project, that in collaboration with partners in the U.S. and Canada investigates educational possibilities and desires, here in Norwegian contexts, particularly focused on mathematics education in times of societal changes and movements. Although we focus on the Norwegian context, we recognize that these kinds of societal changes and movements impact many countries throughout the world. With these changes and movements of people, language diversity may be the most obvious challenge in mathematics classrooms, but they connect to cultural differences and conventional characteristics of the discipline. Indigenous communities have experienced linguistic and other challenges for decades as a result of colonization. Such tensions are now appearing in "ordinary" Norwegian classrooms because tensions in education are intensified by language and cultural differences in times of large migration (Cenoz & Gorter, 2010). These tensions are reflected in public news media. They are local but reflect global trends. News media reflects these trends and thus reifies them as public storylines, which impacts students' potential positionings.

We drew on text-based mass media sources that acknowledge Redaktørplakaten, an ethical codex for publishers in Norway: including daily newspapers, weekly or monthly journals, tabloids, etc. We focused on articles published from January 2003 to September 2020 to include the time in which a new national syllabus was launched in 2004 and the discussion leading to the launch. A librarian supported our search of the Norwegian database Atekst (http://retriever.no) to identify articles that included words from each of three groups that represent the categories shown below with their groups of words (these are English translations of the actual words):

A) Indigenous and migrational contexts: Indigenous, monitories, migration, immigration, Sami, Kven, Forest Finns, Romani, Jews, multilingual, multicultural, diversity

B) Education: education, school, upper elementary, high school, teaching, pedagogy, didactics, class, classroom, teacher, student, assessment, grades

C) Mathematics: mathematics, math, mathematics didactics, science (2 different words), economy, statistics, coding, geometry

We use positioning theory and ask: What storylines about minoritized youth and their relationship with mathematics education are portrayed in the news media articles?

To answer our question, we read the identified 1896 articles and narrowed them to 501 after removing articles deemed irrelevant to our research focus. In this reading, positioning theory focused our attention towards how a) mathematics and b) minoritized students were portrayed and positioned and how those positionings were enacted as interconnected in and across the articles. While reading the newspaper articles we noted 25 concepts which roughly expressed the positionings we were paying attention to and hence could provide preliminary grounds for storyline identification. Based the presence of 25 concepts in the 501 newspaper article titles we selected 96 articles for further analysis. We operationalised some of the concepts into words that could be applied as search words in the freeware AntConc's concordance tool to identify excerpts in which the words appeared. This generated 319 excerpts which we read several times and preliminarily coded in an iterative process based on the positionings we found in relation to the search words. To identify storylines of minoritized students required us to look at how students from the dominant group were positioned too, due to the reciprocity of positioning. The process was conducted both jointly among us and individually which allowed us to compare and refine our coding. Finally, we grouped the excerpts according to the coding and re-read the excerpts to articulate the broader storylines about minoritized youth (See Table 1).

Table 1: Storylines identified in Norwegian media and their coding.

Final coding of excerpts	Storyline
Excerpts that explicitly or implicitly position students from minoritized groups by explaining their (lack of) opportunities in mathematics education in relation to the majority society.	*The majority language and culture are keys to learning and knowing mathematics*
Excerpts that position mathematics in relation to students from minoritized groups.	*Mathematics is language- and culture-neutral*
Excerpts that explicitly or implicitly evaluate students from minoritized groups' mathematics achievements.	*Minoritized mathematics students are motivated by gratitude*
Excerpts that explicitly or implicitly position students from a minoritized system/curriculum/teaching.	*Extraordinary measures are needed to teach students from minoritized groups mathematics*
Excerpts that position minoritized students as the ones who need to give extra effort.	*Students from minoritized groups must put in extraordinary effort to learn mathematics*
Excerpts that explicitly or implicitly explain students' (lack of) opportunities in mathematics education in relation to aspects of them being students from minoritized groups.	*Students from minoritized groups mathematics achievements are linked to culture and gender*
Excerpts that point out students from minoritized groups' (lack of) achievements in mathematics education without giving reasons.	*Students from minoritized groups underachieve*

Results

The storylines that we identified are entangled and sometimes overlapping. Other well-known storylines in mathematics education that do not solely relate to students from minoritized groups such as *mathematics is a gatekeeper to success* were also present in the data material, either as connected to or separated from the seven storylines we identified. Some of the excerpts of texts seemed contradictory or resistant to the storylines that we identified, but they were still positioned in relation to the storylines of the article. We provide examples of each of these storylines in the next sections. All the quotes are our translations to English.

The majority language and culture are keys to learning and knowing mathematics

The majority language and culture are keys to learning and knowing mathematics is the most commonly occurring storyline in our data. We find it referenced by students, educators, policy makers and everyday citizens. The student, NN[1], is quoted: "Norwegian is the key. If you know Norwegian, you can learn math and science as well, says NN, who will take up health subjects this autumn" (*Aftenposten*, 5 August, 2014). An educator is quoted: "They spend a year here learning different subjects such as Norwegian, English, science, social studies and mathematics. We focus mostly on Norwegian because they are immigrants" (*Arendals Tidende,* 6 December, 2016). And policy-maker "HH in the Education Association believes much of the explanation lies in the language. Those who do not master Norwegian well enough also have difficulty keeping up with the math lessons, she believes" (*Aftenposten,* 19 September, 2007). When text in the media is not attributed to individuals in the education system, we see it as a representation of common citizen views—for example, "With poor knowledge of Norwegian, this also leads to weaker results in other core subjects in upper secondary school. Today, parents themselves must buy a Norwegian mathematics book in order to be able to assist their children which shows that we are 'astray' in Sami school policy" (*Finnmark Dagblad*, 19 November, 2008)

There is, however, some recognition of complexity in this storyline. The fact that this complexity needs to be explained also reminds us that the simplistic storyline is dominant. For example, a teacher is referenced here: "[EL] has experienced that foreign language students have had great difficulty understanding professional language, even though they cope/do well with the [majority] language in daily life" (*Kommunal Rapport*, 26 October, 2005). Both complex and simplistic versions of the storyline suggest a competition that is set in a storyline of limited resources. For example, the questioning of the value of the Sami language: "There has been too much focus on Sami textbooks in all subjects which has harmed the quality of language subjects and mathematics for the students" (*Finnmark Dagblad,* 6 November, 2008). This storyline positions minoritized groups' languages and cultures as irrelevant or unwanted. Despite the evidence that minoritized groups' languages and cultures are resources for mathematics learning (Huru, et al., 2018; Planas & Setati-Phakeng, 2014), this is still a prevailing storyline.

Mathematics is language- and culture-neutral

Mathematics is language- and culture-neutral is a storyline that is well-known in mathematics education (e.g., Wagner & Herbel-Eisenmann, 2009) but has not been analyzed in news media. The storyline appears contradictory to other storylines we identified, including *the majority language and culture are keys to learning and knowing mathematics* and *students from minoritized groups' mathematics achievements are linked to culture and gender*. The storyline appears explicitly, as in "mathematics and physics are the subjects where the cultural barriers are least/smallest. They are universal subjects" (*Aftenposten,* 3 May, 2010). The storyline also often appears tacitly, for example, visible by pointing to the fact that other subjects are language and culturally rich: "You do not need to learn much more than 'open up' in a new language, smiles dental student [AAY] (35) who originally comes from a Kurdish area in Turkey" (*Osloby*, 10 April, 2014). Another example of this storyline being represented comes in the newsworthiness of culturally-based mathematics programs, which would not be newsworthy if the public recognized the cultural aspects of mathematics: "They pointed out that Sami culture must be the starting point for teaching and not just a supplement. … They first arranged a culture-based mathematics day at several grade levels, which was so successful that they also arranged a culture-based oral exam in mathematics" (*Finnmark Dagblad,* 5 March, 2014).

Minoritized mathematics students are motivated by gratitude

The storyline *minoritized mathematics students are motivated by gratitude* is a tacit storyline that appears in positionings of obligation, gratitude and benevolence. This storyline is closely entangled with a storyline about the 'grateful immigrant' which imposes certain societal behaviours, expectations and obligations such as willingness to work hard, gratitude to the host nation and unwillingness to be a burden to the state resources (Schwöbel-Patel & Ozkaramanli, 2017). It suggests that the model student from a minoritized group must excel in education, contribute to labour, and display vulnerability and weakness to honour the benevolence and superiority of the host county's culture (Thiruselvam, 2019).

Gratitude and benevolence materialize, for example, on the 17th of May, the Norwegian National Day, when it is common for immigrant students to express their gratitude in speeches at their schools. This newspaper article reports on how an immigrant girl exclaims gratitude for her life and the opportunity to go to school in Norway as part of such celebrations. Her exclamation makes available a benevolent position for the society to inhabit, as the reciprocity of positioning requires an analogous positioning for majority culture: "'Dear all,' she begins, 'I am so grateful! Thankful that I get to go to school here in Norway'" (*Haugesunds Avis*, 9 December, 2019).

This debt of gratitude implies an expectation of loyalty: "Norway has given us a safe place to be. Then we must show Norway respect back. I cannot sit still and wait. Only I can help my children to become good people, to get good jobs that will help Norway" (*VestNytt,* 28 June, 2019). To succeed and pay their debt students from minoritized groups must work harder and be more ambitious than students from the dominant group—an effort that is expected of them as part of the storyline about the grateful immigrant (Schwöbel-Patel & Ozkaramanli, 2017): "Immigrant youth have higher ambitions than the rest of the students. But they struggle at school" (*Aftenposten,* 19 September, 2007). Herbel-Eisenman et al. (2016) identified a storyline present in the public realm which imply that the main goal of mathematics education is to produce a STEM workforce. This is how mathematics equip society (Wagner, 2019) and how students from minoritized groups' mathematical knowledge can materialize the "Norwegian dream" as exclaimed by a former Norwegian prime minister.

Extraordinary measures are needed to teach students from minoritized groups mathematics

The storyline *extraordinary measures are needed to teach students from minoritized groups mathematics* is entangled with the storyline *the majority language and culture are keys to learning and knowing mathematics* because they each position students as lacking the majority language and culture. Therefore, this storyline connects to work about in(ex)clusiveness and positioning of students from minoritized groups as the deficit other. This positioning has been comprehensively discussed in mathematics education research (e.g., Gutiérrez, 2008; Källberg, 2018). Here, the reporter notes that teaching in multilingual classrooms requires extraordinary measures: "The math teacher speaks clearly. He paced off and showed with his whole being how they can calculate the area and volume of the classroom. The large differences in knowledge in the class require a little extra from the teachers" (*Bergens Tidende,* 26 November, 2018). To a professional teacher these two teaching strategies may appear mundane, but the reporter communicates them to the public as newsworthy and thus extraordinary. The positioning of the "large differences in knowledge" is not about valuing knowledge as a resource but indicates that it is extra work for a teacher because dominant knowledge is what matters most.

This storyline also intersects with the *gratitude* storyline as the benevolence of the society materializes in extraordinary measures on policy levels: e.g., introduction classes, summer schools, special language programs, and national syllabuses for Sami students. These special measures position additional languages (additional to the two Norwegian standard written varieties *Nynorsk* and *Bokmål*) as problems rather than resources, which is a phenomenon of interest in multiple contexts of mathematics education (e.g., Planas & Setati-Phakeng, 2014).

Students from minoritized groups must put in extraordinary effort to learn mathematics

In contrast to the storyline above, *students from minoritized groups must put in extraordinary effort to learn mathematics* says that students from minoritized groups work extra hard and put in more effort to learn and perform well in mathematics. One student is quoted "I go for the best possible grades. In the other subjects, I can read most things, but in mathematics I have to understand all the concepts" (*Aftenposten,* 19 September, 2007).

Some migrant students go to community-governed extracurricular Saturday schools to do better at the compulsory school: "Principal DD says the Saturday school did not come about because the children learn too little at the regular Norwegian school. But they need someone who pushes them further, and here they learn a culture to work, he says. *(Bergens Tidende,* 27 December, 2015). Some migrants volunteer to help fellow migrant students to pass compulsory school courses in mathematics: "MM (16), who is very good at math, helps the less experienced SS. The talk goes. In both Somali and Norwegian." *(Bergens Tidende,* 26 November, 2018). Additionally, the schools offer extra courses: "Many of the students at TT spent the last holiday week closing knowledge gaps in mathematics in the transition between lower secondary school and upper secondary school. (*Arendals Tidende,* 14 August, 2018).

Lastly, a migrated student offers advice: "If you have to choose; should the kids master math, or should they master Nynorsk [the non-dominant Norwegian standard variation]? Make a priority, because there is a real need to spend more time on mathematics, Bokmål [the dominant Norwegian standard variation] and so on. Subjects we actually need later in life." *(Altaposten*, 23 May, 2018). This storyline intersects with the gratitude storyline: students themselves recognize the extra work that is expected (Schwöbel-Patel & Ozkaramanli, 2017).

Minoritized students' mathematics achievements are linked to culture and gender

The storyline *minoritized students' mathematics achievements are linked to culture and gender* is often present in communication acts in the media which refer to statistical surveys. Roughly this storyline suggests that some immigrant boys fail at school and consequently in the society at large. Immigrant girls, on the other hand, are usually positioned as more successful than students from the dominant group. "Less than half of those who start upper secondary school complete on time, i.e., three years. This gloomy statistic is extra gloomy for boys with immigrant backgrounds. Only one in three with such a background gets through in three years" (*Nordlys,* 29 May, 2008). "About half of the girls with non-western backgrounds in [school name] take higher education. It is far above average and shows what a resource the students from minoritized groups are to the Norwegian society" (*Romerikes Blad*, 27 June, 2012.).

This storyline is connected to other storylines involving cultural superiority and inferiority stereotypes: "[NN, MM and PP] won the math competition. 16 of 38 finalists had a background as students from minoritized groups, as did six of nine winners. […] Researchers believe this is due to the fact that math has a higher status in Asian countries" (*Aftenposten,* 3 May, 2010). "Many are positively surprised that a boy from Eritrea can do so well. The fact that people are surprised motivates me a lot to continue to work hard" (*Innherred,* 18 August, 2018). This storyline intersects with racial narratives about academic ability (Shah, 2017).

Students from minoritized groups underachieve

The storyline *students from minoritized groups underachieve* intersects with the storyline *students from minoritized groups' mathematics achievements are linked to culture and gender* but differs because it makes no distinctions among genders and cultures and offers no causes for the underachievement. For example, "In Norway, Sweden, Belgium and France, more than 40 percent of first-generation students lack elementary math skills. This also applies to a third of the students with a background as students from minoritized groups who were born in Norway" (*Aftenposten,* 19 September, 2007).

Mathematics is a subject that stands out in students from minoritized groups' underachievement: "The most visible is the difference in subjects such as main/chosen

Norwegian standard variety and mathematics, where immigrants got more than half a grade lower than other students. Norwegian-born students with immigrant parents have somewhat higher grades than immigrants, but on average somewhat lower than other students" (*Østlendingen*, 18 November, 2011. This storyline is closely entangled with and perhaps even an inevitable consequence of the storyline *the majority language and culture are keys to learning and knowing mathematics* since the majority language is a necessity for being positioned by the dominant group as knowledgeable in mathematics. Further, it relates to well-known storylines about achievement gaps among different groups (e.g., Gutiérrez, 2008)

Discussion

Our motivation to investigate the storylines about youth from minoritized groups in the Norwegian text-based mass media sources was initiated by an urgency to understand some of the storylines and positionings that might be available in this context. This investigation is the beginning of a longitudinal project in which we are collaborating with teachers, administrators, community members, youth and families to understand what storylines they would like to have made available to them in the teaching and learning of mathematics. Drawing on a participatory design, these storylines can then be used to imagine new positionings and practices in mathematics classrooms and in schools. We started with an analysis of media to sensitize ourselves to some of the existing storylines and, thus, to recognize storylines already potentially available and shaping positionings. Our hope that our sensitization to existing societal storylines will help us, our collaborators, and hopefully others to (re)imagine and to enact storylines that position minoritized youth in asset-based ways.

Our investigation shows that minoritized youth are positioned in relation to an array of storylines that sometimes overlap, intersect or contradict each other. What strikes us about our findings is how the storylines (once again) show that the burden is put upon minoritized youth with no recognition of history, systems or structures that contribute to inequities. According to some of the storylines they are expected to work hard at learning the language and practices of school academic mathematics and also at learning the majority language. While working hard through this double learning burden, minoritized youth also carry the burden of being thankful and expressing gratitude towards the benevolence of the majority society for undertaking extraordinary measures on their behalf. Taking the storyline *students from minoritized groups underachieve* into account here suggests that minoritized students carry the burden of the majority society's disappointment—despite the extraordinary measures, minoritized youth do not seem to meet the expected learning outcomes. Positioning theory reminds us that positionings and storylines are negotiable. This means that minoritized students' available positionings can be renegotiated, for instance by actions that remove burdens and deficit-based storylines.

We are also struck by how contradictory language appears in the storylines. Language and culture appear to be keys to learning and knowing mathematics. Concurrently mathematics appears to be language- and culture-free. We are intrigued to further investigate how this contradiction makes its way into mathematics classrooms as one tension that becomes intensified in times of national and international migration (Cenoz & Gorter, 2010). Dealing with this tension influences how minoritized students might be positioned in asset-based ways and consequently involves actions that can remove burden.

Note

[1] Two cap letters are used to pseudonym people in the data.

NARRATIVES OF RAZA IN MATHEMATICS EDUCATION RESEARCH LITERATURE

Stacy R. Jones

nico.gomez@utexas.edu

We present a finding from a literature analysis of Raza populations published in top-tiered peer reviewed mathematics education journals. We look at how narratives are perpetuated and resisted at the intersections of Raza, mathematics education, and research. The findings reveal the field of mathematics education research is perpetuating deficit narratives of Raza through 1) simplistic descriptions of Raza which perpetuate a racial hierarchy; 2) white institutional spaces group, order, and Americanize Raza populations; and 3) counter-stories of La Raza; however, we will only concentrate on the first finding for this manuscript. The examined literature continues to center Anglos' narratives and values while maintaining a social hierarchy and the assimilation and Americanization of La Raza. Finally, we provide implications for disseminating our research to go beyond simplistic demographics of social constructs.

Keywords: Equity, Inclusion, Diversity; Research Methods; Social Justice; Systemic Change

There is a long history of racism in the making of a capitalist society by Anglos in the United States (Haney López, 2006; Molina, 2014; Peller, 2012; Yancey, 2004). Westward expansion and building the economy is a romanticized story passed from one generation to the next when in reality "the massive extermination of indigenous people provided our land base; the enslavement of African labor made our economic growth possible; and the seizure of half of Mexico by war…extended this nation's boundaries" (Martínez, 2017, p. 43). Furthermore, dominant narratives describe Raza as lazy, dirty, ignorant, untrustworthy, and unambitious (see Gonzalez, 1990; Muñoz, 2007; San Miguel, 2001) allowing Anglos to justify the brutal violence and lynching of La Raza (Martinez, 2020). We use the term Raza and La Raza as a political move to disrupt Anglos' oppressive strategies of naming, defining, and centering Eurocentricity in order to maintain dominance (see Anzaldúa, 1987; Martínez, 2017; Gutiérrez, 2001). La Raza is a term derived from the community, loosely translating to "The People" or "The Race". This term has been used previously in political uprisings, such as El Movimiento, in phrases such as "Viva La Raza" to energize and empower La Raza to work towards social justice (see Gutiérrez, 2001).

An Anglified history has omitted the lived experiences, knowledges, stories, and contributions of Asian, Black, and Raza communities. Anglos have always been positioned as the heroes, saving others; this is the consequence of telling history from only the perspectives of Anglos (i.e., Texas Rangers, see Swanson, 2020). Dominant narratives strategically erase the contributions, voices, and lived experiences of Raza populations. Raza have been responsible for the development of land and building the U.S. economy, active in politics and government affairs, enlisted in the U.S. military and gave their lives in wars, and persistent in acquiring better and more just educational experiences for themselves and future generations (Muñoz, 2007; San Miguel, 2001). Further, Raza continue to be active in the previously mentioned ways in spite of being treated as second class citizens, where they are oppressed, segregated, manipulated, de-humanized, and lynched by Anglos (Martinez, 2020).

The previously mentioned deficit narratives, histories, and ways of acting are embedded within our ways of knowing and doing in the present (racism as permanent and endemic in our society; Delgado & Stefancic, 2017). In order to make changes to the system, we must reveal, interrogate, and dismantle deficit storylines of La Raza. Oftentimes, we justify actions and dialogue because 'that's the way it's always been done' or by calling actions and dialogues 'norms'. There is also an apprenticeship mentality in academia where doctoral students and early career faculty are expected to follow the ways of their predecessors. Just as society has found ways to perpetuate racism without (always) being explicitly racist, academia perpetuates racism without (always) being explicitly racist as well. These implicit ways of perpetuating racism also permeate mathematics education research. In this paper, we share one of our findings from a critical literature analysis on the narratives being written in mathematics education research on Raza populations. We use a critical lens to uncover how racism is perpetuated in mathematics education scholarship.

Theoretical Framework

In this section, we describe Critical race theory and Latinx critical theory as a framework guiding our critical analysis of the literature in mathematics education research on Raza populations.

Critical Race Theory and Latinx Critical Theory

Thus far, we have provided a history of racism in regard to Raza as well as an understanding of racism as permanent and endemic in our society. The belief that racism is permanent and endemic within our society is the first tenet of critical race theory (Bell, 2018) and consistent with other critical race scholars (e.g., Delgado & Stefancic, 2017; Solórzano & Yosso, 2002). Bell, along with other legal scholars, activists, and lawyers, developed critical race theory in legal scholarship to "combat the subtler forms of racism that were gaining ground" when the Black Power and Chicano Movements of the 1960's began to subside (Delgado & Stefancic, 2017, p. 4). Latinx critical theory extends critical race theory to highlight the racialized experiences of Raza communities. Raza have unique experiences being racialized based on language, citizenship, immigrant status, phenotypes, and surname. Therefore, Latinx critical theory's specificity to the Raza community will provide a more targeted lens for this literature analysis.

Other tenets of critical race theory and Latinx critical theory vary, however, the tenets guiding our work are the social construction of race, challenging the dominant ideology, and centering experiential knowledge of Raza (Delgado & Stefancic, 2017; Solórzano & Yosso, 2002). The social construction of race "holds that race and races are products of social thought and relations…Not objective, inherent, or fixed, they correspond to no biological or genetic reality; rather, races are categories that society invents, manipulates, or retires when convenient" (Delgado & Stefancic, 2017, p. 7). Anglos have constructed narratives in order to place races in a hierarchy, always with Anglos at the top of the hierarchy as a superior race. Furthermore, critical race scholars challenge dominant ideologies (i.e., colorblindness, neutrality, meritocracy, equal opportunities) and "argue that these claims act as a camouflage for the self-interest, power, and privilege of dominant groups in U.S. society" (Solórzano & Yosso, 2002, p. 26). We highlight this tenet through our critical literature analysis by revealing how dominant ideologies have been camouflaged in mathematics education research and perpetuate racial hierarchies.

The final tenet of critical race theory and Latinx critical theory used to frame the critical analysis is centering experiential knowledge. Delgado and Stefancic (2017) assert that:

> The voice-of-color thesis holds that because of their different histories and experiences with oppression, [B]lack, [Indigenous], Asian, and [Raza] writers and thinkers may be able to communicate to their white counterparts matters that the whites are unlikely to know (p. 11).

Therefore, we take a critical look at the narratives being perpetuated about Raza communities. In centering our own voices, as Raza, we are able to reveal the racism being perpetuated in mathematics education research.

Using critical race theory and Latinx critical theory, we conducted a critical literature analysis on the narratives of Raza in mathematics education research. The purpose of this literature analysis is to understand the narratives of Raza students in mathematics education research literature. An interrogation of the narratives being told will provide insight into how racism is embedded within our practices, how dominant ideologies are perpetuating racism, and how the field of mathematics education research can be more equitable.

The research questions guiding the overall literature analysis are: 1) How are Raza populations discussed in mathematics education research literature? 2) How might mathematics education research perpetuate deficit narratives and/or racial hierarchies of La Raza? 3) How are mathematics education researchers challenging dominant narratives of La Raza? For this paper, we focus on the second research question.

Methods

Data collection involved conducting a comprehensive search of relevant literature and identifying specific criteria for selecting and appraising appropriate primary research, which served as the data set for the critical literature analysis.

Phase 1: Journal and Article Identification Process

To locate relevant articles, we began with Williams and Leatham (2017) list of top-tiered journals in mathematics education research. The purpose for choosing top-tier journals in mathematics education research is the impact these journals have on the field, therefore, the narratives constructed in these journals are more likely to be representative of acceptable narratives within mathematics education research. Williams and Leatham (2017) compiled a list of journals based on opinion- and citation-based criteria. We used journals which appeared on both lists (opinion and citation) and could access. The journals, in alphabetical order, include: *Educational Studies in Mathematics*, *For the Learning of Mathematics*, *International Journal of Mathematical Education in Science and Technology*, *Journal of Mathematical Behavior*, *Journal of Mathematics Teacher Education*, *Journal of Research in Mathematics Education*, *Journal of Urban Mathematics Education*, *Mathematics Education Research Journal*, *Mathematics Teaching and Learning*, *School Science and Mathematics*, and *ZDM*.

Once the journals were identified, a list of keywords were compiled which captured how Raza are described as a population. The following keywords were used to search in each of the 11 journals using their home database search engines (e.g., JSTOR, Wiley): Chicana, Chicano, Chicanx, Chican@, Hispanic, Latina, Latino, Latinx, Latin@, Latino/a, and Latina/o. Using the keyword search and journal selection criteria, 447 articles were identified.

We did not use terms around language which are often used to describe Raza populations, such as Emergent Bilingual, Limited English Proficiency, English Language Learner, English as a Second Language because these terms are not specific to Raza populations. We argue in order to make claims about Raza populations in the circumstances of language, then these identity markers would need to be supplemented by the use of the above keywords used in our search.

Furthermore, we analyzed articles which only took place in the United States. We chose this criterion in order to be consistent with the ways Raza are oppressed and dehumanized within the same context as well as there to be a familiarity of this oppression and dehumanization with our audience. Finally, the ages of Raza in the data range from pre-K to adults: children ages 3 or 4 to parents, teachers, and preservice teachers.

Phase 2: Identifying Relevant Articles

During the second phase, we searched each article for the keyword term(s) to determine the capacity in which they were being used within the publication. The articles which only used keyword(s) in the references were not considered for analysis. Further, articles were discarded that were book reviews, research commentaries, or conference proceedings. Additionally, we excluded articles published prior to 2000 in order to provide a more contemporary analysis of the literature. At this point, there were 256 articles.

Next, we determined our inclusion criteria for data synthesis to include empirical studies where the Raza population was at least 50% of the population being studied or there were specific claims being made about Raza populations within their study. For example, in Jackson et al. (2015) students self-identified as 10% and 2.4% Raza in each of the middle schools, however, the authors make specific claims to Raza populations. They state, "As we examine the data by race, the largest average gain from pre to post of the experimental group was by the African American students…whereas the lowest average gain were [Raza] (2.44%), and whites had a gain of 5.44%" (p. 339). While the Raza population is below 50%, the authors make claims specific to La Raza, which help to understand the narratives of Raza in mathematics education research (research question 2). This criterion was set because making an argument about the narratives specific to Raza from these findings would be challenging. Even with a Raza population of 40%, unless the author(s) make specific claims about the Raza population somewhere else in the article (i.e., results, discussion), we were not convinced a strong enough argument could be made about their findings in regard to Raza. Therefore, the articles that only mentioned the keyword(s) as a percentage of their population, and the percentage is below 50% do not help in answering our research questions. After applying each of the criteria to determine relevant articles, we had 52 articles to analyze.

Synthesizing Articles

We analyzed all of the articles using a grounded theory approach to allow themes to emerge from the data. In order to more fully understand how narratives of Raza are discussed in mathematics education research literature it was important to allow the themes to emerge as opposed to applying an initial coding scheme to the data. We felt this would provide the opportunity to uncover instances that a coding scheme may be blinded to. For each article, we identified the background literature, research questions, description of the population, results, and implications. We also kept track of any comparisons of populations based on race/ethnicity, how Raza populations were being positioned, and if being Raza was necessary to the research questions, framing, results, or implications. Analyzing the data from the description of the population being studied provided the foundation for our first finding, which we will concentrate on in this paper. Further, keeping track of comparisons helped to understand how racial hierarchies play a role in the construction of narratives of Raza populations. We also needed to understand the different ways Raza populations were being positioned within the article, this allowed us to categorize articles which perpetuated a deficit narrative of Raza populations in comparison to articles which provided a counter to dominant narratives.

In the second iteration of analyzing the data, each aspect of an article, background literature, methods (including the description of the population as a separate category), results, and implications, were each coded as either providing a dominant narrative, countering dominant narratives, or neither. This allowed the authors to analyze each section of an article independently to understand how aspects of an article may perpetuate or counter dominant narratives, as well as see the article as a whole to understand how narratives of Raza are being perpetuated or countered. In doing so, we were able to categorize articles and sections of articles as perpetuating or countering a dominant narrative. For example, we categorized Roy and Rousseau (2005) as countering a dominant narrative because they describe a teacher with high expectations and his success in working with Raza populations. In the description of the population studied, however, they also perpetuate a racial hierarchy of ability stating,

> Matthew was a mathematics teacher in an urban high school in the Midwestern United States. The school served a large [Raza] population (approximately 60%) with smaller populations of [African American], Asian, and white students. The student population of the high school was predominantly of low socioeconomic status, with 65% of the student body eligible for free or reduced lunch…Matthew was assigned to teach some of the lowest-level mathematics classes offered at the school (p. 16).

Our analysis allowed us to see Roy and Rousseau (2005) as a counter to dominant narratives because of the entire paper; however, when looking specifically at the description of the population being studied, they perpetuate a deficit narrative of Raza. Therefore, in order to more fully understand how mathematics education research literature is perpetuating or countering dominant narratives, we needed to look at each section of the article as well as the article as a whole with a critical lens. In doing so, we were able to tease out any nuances in how the field works to perpetuate dominant narratives as well as how some scholars are disrupting these norms in order to provide a more complete understanding of Raza populations in mathematics education research.

Upon dissecting each article, we were able to form themes on the narratives of Raza populations. The initial themes include 1) Raza described as low income, low mathematics ability, and disabled; 2) white institutional spaces group, order, and Americanize Raza populations; and 3) counter-stories of Raza populations. We will concentrate on the findings for the first theme.

Descriptions of Raza Populations Perpetuate a Dominant Narrative

In this section, we present findings related to the second research question: How might mathematics education research perpetuate deficit narratives and/or racial hierarchies of La Raza? We provide representative examples of the articles within this theme as opposed to an exhaustive review of each article due to the conceptual nature of this critical literature analysis (see Harper, 2019). Our analysis produced three major findings; however, we are only concentrating on the first finding for this paper.

When considering the context of the study within an article, the field of mathematics education research perpetuates the use of nominal social constructs, such as race/ethnicity, class, gender, and ability to be included in order to provide the reader with an understanding of where the study is taking place. After critically analyzing the literature, we found it necessary to think more deeply about how norms have been constructed for the purposes of creating and maintaining a social and racial hierarchy. Of the 52 papers analyzed, two-thirds of them used deficit narratives of social constructs to provide context to the study. We, the authors, have also been guilty of perpetuating deficit narratives of Raza populations in the context of our work (see Gomez et al., 2020). It is important, however, to critically analyze how we frame participants within the storylines we write because social constructs are attached to white superiority ideology and used and created to other certain communities (see Haney López, 2006). In our critical analysis, we found the format of perpetuating deficit narratives of Raza varies from one piece of data to the next, however, when interrogating dominant narratives about Raza populations, deficit framings were consistent in perpetuating dominant narratives: Raza populations are low income, do not succeed academically, and are disabled.

We begin with an example from equity focused scholars to highlight how perpetuating norms are not divided along an equity lens, but stem from white ideology of what it means and looks like to do research. Therefore, such norms go unnoticed even with well-intentioned equity scholars. This speaks to the pervasiveness of white supremacy and how we have all been socialized in the academy, a white institutional space, to perform certain acts even when our research works to dismantle systemic racism. Battey and colleagues (2016) state, "[I]t was one of the lowest performing districts in California...100% of the students served were students of color (73% Latin@, 27% African American), 58% were classified as English language learners, and 93% received free or reduced-cost lunch" (p. 6). The authors relate low academic performance to social constructs of race/ethnicity, language, and income status; perpetuating a narrative of what it means to be Raza. However, it is not necessary for the authors to make this connection because we have been socialized to believe large populations of Raza students relate to low income, language inefficiency, and low academic performance (Gándara & Contreras, 2010). The above quote is not an anomaly in academia, but a confirmation of the storylines we perpetuate of the Raza community. Furthermore, Battey and colleagues perpetuate a norm of telling a partial story of their participants through the nominal demographics of race/ethnicity, language, and socioeconomic status as determined by students receiving free and or reduced-cost lunch.

As previously stated, the format of perpetuating deficit narratives varies and can be less discernible through the use of charts and tables. In the following representative example, Hunt (2015) used a table to provide context to the study, naming students' ethnicities, gender, age, and ability. While these social constructs seem harmless, social constructs carry meaning and provide a racial and social hierarchy of ability. Hunt described the three third graders she worked with in the context of the study:

> This exploratory case study sought to uncover how one third-grade child with LD (i.e., "Bill"), one third-grade child deemed as low achieving (i.e., "Carl"), and one third-grade child deemed typically achieving (i.e., "Albert") ...The researcher classified children by their performance on three standard mathematics tests as typically achieving (25th percentile or above on all tests), low achieving (15–25th percentile on all tests), or LD (below 15th percentile on all tests). (Hunt, 2015, p. 96)

Hunt (2015) provides a hierarchy of ability in her positioning of children based on their mathematical performance. This positioning further maintains a racial hierarchy of ability with the following table where the students' ethnicities become part of the story:

Table 1
Student characteristics.

Name[a]	Age	Gender	Ethnicity	LD status and IEP goals	Performance, Woodcock Johnson III (Percentile)	Key Math-R, mental calculation (Percentile)	Key Math-R, numeration (Percentile)
Albert (TA)	9	Male	Caucasian	None	37th	35th	45th
Carl (LA)	9	Male	Hispanic	None	16th	15th	20th
Bill (MLD)	9	Male	Hispanic	LD, math-based	9th	4th	6th

[a] Names have been changed to protect student identities.

Figure 1. Table from Hunt (2015).

In this example, students' ethnicities are not relevant to the rest of the study. Hunt does not mention any more about how their ethnicities play a role in the context of her study, being Caucasian or Hispanic as she described, is not influential in any other parts of the article. Therefore, it is important to take a critical look at the reasons we are including nominal characteristics when providing context to our research.

Furthermore, some authors perpetuated dominant narratives of a racial hierarchy without the use of numbers to describe the population. For example, Selling (2016), described the participants in her study as follows:

> Jorge, Luke, and Carlos had all finished 7th grade in their various schools, but they differed noticeably in their prior academic achievement in math. Luke had previously found success in school math, achieving an A in the final quarter before the summer. In contrast, Jorge arrived at summer school an F, and Carlos had arrived with a D. Jorge and Carlos are both [Raza]. Luke is White (p. 193).

Selling's discourse did not use numbers or percentages to present a racial and social hierarchy based on letter grades. Selling makes it a point to identify the ethnicity of each participant after discussing their academic abilities, positioning the Anglo student as successful and the Raza students as unsuccessful. While Selling does argue Jorge and Carlos find success and contribute to the mathematical discussions in positive ways in the findings of the article, the storyline in the description of the population being studied perpetuates a racial hierarchy of ability with Anglo students at the top and Raza students at the bottom.

Finally, we would like to consider the following example where Gutstein (2016) provides a detailed history of the school where his study took place. Gutstein states:

> Lawndale has suffered disinvestment and neglect for years but has a strong history of activism and efforts toward community betterment. White flight occurred in the 1960s and 1970s, and Lawndale became overwhelmingly populated by people of color, many working in nearby factories. Deindustrialization seriously injured Lawndale: Chicago lost 330,000 manufacturing jobs from 1967–1990 (Betancur & Gills, 2000). Concurrently, the city cut services, property tax revenue fell, and the area suffered. Nevertheless, individuals, community and civic organizations, and churches throughout the neighborhood have worked hard to improve conditions, secure more city support, and develop cultural programs and social services (p. 462–463).

Gutstein, however, goes on to perpetuate the norms of mathematics education researchers by including nominal social constructs to provide context to his study, stating, "Each of the four schools on campus has roughly 375 students, originally 70% Latin@, mainly from Little Village, and 30% Black, from North Lawndale…Sojo has overwhelmingly low-income (approximately

98%) students of color (100%). Students' ACT scores averaged 16.0" (p. 463). The history included in this study provides the reader with an understanding of how racism and capitalism concurrently impacted the community and schools. The history situated Gutstein's work within historical, racial, and social contexts as opposed to being neutral or blind to how these factors impact the community, schools, and students. Gutstein also provides us the opportunity to consider and compare how the nominal social constructs tell a colorblind and race neutral story of the same context, sans historical and social influence on the community.

As the field continues to provide research from only one perspective, that of Raza who are low income, low performing, English language learners, we argue, using nominal social constructs, such as race/ethnicity, class, gender, and ability is problematic when these demographics are not considered in historical contexts. The U.S. has a long history of defining citizenship, ability, and success from an Anglo, male, middle- and upper-class perspective (Martinez, 2020; Muñoz, 2007; Yancey, 2004). Furthermore, the demographics we use to provide context to studies are socially constructed in order to justify privileges or withhold privileges from certain groups (i.e., racism, sexism, classism). Therefore, we have been socialized into bringing in assumptions about each of these nominal social constructs; using demographics to provide context to our work perpetuates dominant narratives about equal opportunity, who can do mathematics, and what it means to be Raza. By including historical and racial contexts within our work, we not only acknowledge how history and racism influence our communities, but we also rehumanize our work and the communities with whom we work.

Discussion

Feagin & Cobas (2014) assert that "[m]ost [Raza] regularly face social environments where whites have the power to racially characterize who they are, including their racial identities" (p. 24). In this article, we use critical race theory and Latinx critical theory as a lens to critically analyze the narratives specific to Raza in mathematics education research. We find it necessary to take a critical look into the literature and stories mathematics education research values and perpetuates of Raza populations based on its choices in publications. Our findings reveal, question, and disrupt the ways we position Raza, and more broadly our participants in general, through our publications. We argue for a more critical look at the field of mathematics education research and the norms that have been set for conducting, disseminating, and reflecting on research endeavors.

Our findings highlight the deficit narratives being perpetuated of Raza populations through the descriptions of La Raza in mathematics education research. The purpose in providing details about race, ethnicity, gender, class, and ability are justified in order to give context to the study. These demographics are included to tell the reader important information, but we cannot determine what information these percentages and descriptions are providing to our audience. We argue the need to be more critical of how we are positioning the populations with whom we are working; they are the ones providing information to us, not the other way around. We need to be respectful of the narratives we are providing for others to read and make sense of. Instead of providing surface level characteristics, which are stereotypes, perpetuating deficit narratives, and complying with and continuing the narratives of a racial hierarchy of ability and belongingness, we need to dig a little deeper with the context of our research. Providing information on the history of the place, the organizational logic, laws and policies in place which impact the humans with whom we work, and other factors which place our human participants in their current situations provides pertinent information for the reader to understand the research and findings.

Furthermore, it also prevents the reader from having to make assumptions about meritocracy or a long history of discrimination, policies, and social hierarchies about who belongs and who is capable.

During the COVID-19 pandemic, many urban schools relied on community centers with existing computer labs and high-speed internet that could provide in-person support for a small number of children engaging in online learning. Using a digital storytelling approach, this research report analyzes the mathematics identities of 14 informal adult educators. Situating the stories shared though Critical Race Theory counternarratives, this study enables participants to ground their narratives within their own spaces of power–to tell and forge their own digital mathematics story. Because informal adult educators are not family members nor school-based educators, they often are invisible variables in conceptualizing a child's mathematics learning. This research seeks to elicit their mathematics stories and understand how to enactment digital mathematics storytelling through listening to how the community positions and visions math.

Keywords: Equity, Inclusion, and Diversity; Design Experiments; Informal Education; Technology

Perspectives

The Shift in Education during COVID-19

During the COVID-19 pandemic, many urban emergent school districts[1] in the United States of America, already dealing with racial and socioeconomic segregation, had to switch to a completely remote model of learning, meaning that children were expected to engage in all their school interactions online (TODOS, 2020). This forced adoption of virtual and online learning exasperated already stark divides in technology access, requiring children to have access to high-speed internet, a stable tablet or computer, and a regular work space just to attend school. This was an almost impossible ask of families and communities who have historically been marginalized in multiple ways, resulting in many of the largest urban and urban emergent school districts in the U.S.A. reporting that as many as 70% of their students were not attending online schools (Christakis et al., 2020).

One community-based approach that rose to address the needs of families struggling to support their children's education is the Learning Extension Center (LEC), community centers with existing computer labs and high-speed internet that could provide in-person support for a small number of children engaging in online learning. These LECs are partnerships between the school district and "community, faith based, and other public sites that provide physical space within the facility to allow workstations for students. The purpose of the LECs is to provide educational and social-emotional support to Columbus City School students in a safe environment and welcoming environment during our prolonged period of virtual learning" (*Columbus City Schools 2020-21 Reopening Archive / Learning Extension Centers*, 2020).

These types of partnership sprang up in urban emergent communities across the country (Greenberg et al., 2020), filling in the gaps in technology access by providing a meeting space for a child to use a sanitized computer, an adult educator who provided nominal technology and instructional support, snacks and meals, and a feeling of community for children. While these LECs were not able to, nor designed to, replicate the affordances of a school classroom, they did provide a necessary space for children in urban emergent communities to continue their school-based learning during the COVID-19 pandemic. The LECs, thereby, became a place where masked children could attend in order to connect with other children, complete online school lessons, and work with an informal adult educator. For many, the LECs played a crucial role in supporting urban emergent families and communities.

Informal Adult Educators

The LECs are staffed by informal adult educators, usually community members dedicated to supporting children, but who are not formally trained or certified teachers. These informal adult educators bring many backgrounds with them. Some might be college students studying to eventually become teachers, local sports coaches who regularly work with community youth, or community members whose other employment was disrupted by the COVID-19 pandemic. Because these informal adult educators are not formally prepared teachers, they often bring more mainstream perspectives to mathematics learning. For instance, informal adult educators may express anxieties and fears about mathematics based on prior experiences. Additionally, informal adult educators may also have limited experiences with inquiry-oriented mathematics pedagogy and therefore position mathematics learning as heavily procedural and focusing on memorization because of their own experiences. Finally, while informal adult educators might be comfortable with using technology in their own lives, they often may have limited experiences with instructional technology (e.g., Google Classroom, Flipgrid).

Informal adult educators are rarely studied within the mathematics education research, partially because their limited role often exists entirely outside of the classroom. However, due to COVID-19 pandemic, informal adult educators now found themselves as the only *adults* outside of a child's household that were regularly physically working with children. Informal adult educators were no longer positioned as supplementary workers or after-school helpers. Due to community-based restructuring of our nation's schools during the COVID-19 pandemic, new roles and possibilities involving the nature of informal adult educators and their impact on children's mathematical learning became apparent. And therefore, as the informal adult educators' roles in urban emergent communities grew, the question we as mathematics education researchers ask is: How do informal adult educators narrate and conceptualize their own relationship to math–their own mathematics identities?

Community and Family Mathematics vs. School Mathematics

These informal adult educators, suddenly tasked with supporting students as they engaged in learning traditional school mathematics, hoped to find ways to explore their own mathematical knowledge in juxtaposition the mathematics they were seeing in online and hybrid learning models they were supporting their children with. One approach to address this issue to connect out-of-school mathematics with in-school mathematics is through recognizing the mathematics knowledge shared in community spaces (Aguirre et al., 2013). For instance, when someone shares about the daily mathematics checks they do to make sure that each of their animals is fed, juggling the feeding schedules of lizards who eat every other day, fish that eat multiple times a day, and birds that eat every day, the mathematics of finding common factors emerges. Mathematics that exists within the community is often dismissed as not "real" mathematics because family and community mathematics often operates socially, involving storytelling and group problem solving, while school mathematics is often positioned as internal knowledge measured individually (D'Ambrosio, 1985; González et al., 2001; Powell & Frankenstein, 1997).

Mathematics Identity

Mathematics identity, often only explored as a students' mathematical identity or as a mathematics teachers' identity, has been shown to be positional, performative, and socially constructed (Esmonde & Langer-Osuna, 2013; Holland et al., 1998; Martin, 2000; Wenger, 1998). For teachers, mathematics identity involves the negotiating of one's provisional self with regard to various sociopolitical positions taken when teaching mathematics (e.g., sexuality, ethnicity, and economic status) (de Freitas, 2008a, 2008b). Additionally, mathematics teacher identity can involve the position a mathematics teacher takes to either confront or reify the oppressive practices within traditional mathematics teaching and learning (Gutiérrez, 2013; Herbel-Eisenmann et al., 2013). Mathematics teacher identity, therefore can "consists of knowledge and lived experiences, interweaving to inform teaching views, dispositions, and practices to help children learn mathematics." (Aguirre et al., 2013, p. 27).

Intersectionality, a lens with roots in Critical Race Theory, Feminist Theory, and Poststructuralism, focuses on examining the intersection of various social spaces of oppression (Crenshaw, 1991). Research examining issues of equity and identity can sometimes position social identities as static variables (Darragh, 2016), leading to generalizations that erase voices and position all members of a category as similar. An intersectionality approach allows participants to present the nuances within their various social identities, showing ways in which they are individually unique and human (Leyva, 2017). Each of these social identities carries with it some artifact of oppression and opportunity. An intersectionality approach, therefore, examines the stories where these multiple social identities overlap. The stories revolve around lived experiences, not second-hand evaluations or judgments (Solorzano & Bernal, 2001), valuing the varying narratives that the adults tell about their backgrounds, pedagogies, beliefs, and positions (Walshaw, 2013).

Work that conceptualizes identities from a *Critical Race Theory* perspective, and *LatCrit* specifically, draws attention to the multiple layers of subordination based upon race, class, gender, language, immigration status, accent, and phenotype experienced by Latinx communities (Delgado Bernal, 2002; Johnson & Martinez, 1998; Lopez, 1997; Solorzano & Bernal, 2001). This LatCrit perspective draws a cultural connection between participants' stories and the cultural construct of *testimonios*–first-person narratives one tells about one's self to others (Gutiérrez, 2013). These narratives often reveal accounts of systemic oppression hidden from more structural modes of inquiry (Yosso et al., 2009). Mathematics identity therefore, from a LatCrit perspective, can be understood as these specific narratives that directly expose or confront oppression (Solórzano & Yosso, 2002; Zavala, 2014).

An intersectionality and LatCrit approach moves away from characterizing identity as a categorical adjective or noun; instead identity becomes a verb, something in-flux, being made and remade, as a sociopolitical act. Identity through storytelling is agentive–an emancipatory act in which adults construct counter narratives that confront and claim power within the oppressive worlds they live in (Aguirre et al., 2013; Gutiérrez, 2013). Since identity involves the telling of one's stories (Sfard & Prusak, 2005), the counter narratives themselves become a theoretical, methodological, and pedagogical means of understanding a mathematics identity (Solorzano & Bernal, 2001).

Storytelling

The most active way to explore mathematical identities involves storytelling. When members of urban emergent communities tell narratives about their out-of-school mathematical experiences, they position themselves and their communities as mathematical (Aguirre et al., 2013; Love, 2014). Given the popularity of video and image-sharing platforms like TikTok, YouTube, and Instagram for sharing personal stories (Auxier et al., 2020; Rideout, 2017), there is a strong case for utilizing these emerging digital literacies to connect out-of-school mathematics to in-school mathematics (Ozpinar et al., 2017) for exploring mathematics identity. In this study, we explore Digital Mathematics Storytelling (DMST), a mechanism for using videos, photographs, and audio to craft and share mathematically-rich narratives from communities, to potentially connect out-of-school mathematics with in-school mathematics in informal education settings and explore identity.

Activity Theory

Cultural-historical activity theory (CHAT) positions learning as occurring when individuals participate in culturally organized activities that are constituted by six essential entities: human subjects (individuals or groups), objects (artifacts and motivations), instruments, rules, community, and division of labor (Engestr m, 1987). This activity system can be depicted as an "activity triangle" (see Figure 1) that is useful in examining and interpreting artifact-based interactions in social learning contexts.

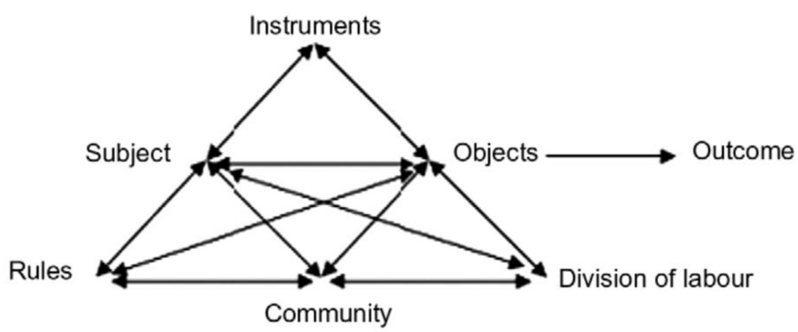

Figure 1. The structure of a human activity system in CHAT. (Engestr m, 1987, P.78)

CHAT attempts to explain the distributed and situated nature of knowing in human activities mediated by artifacts and culture (Engestr m, 1987). When achieving objects in an activity, subjects not merely produce outcomes but also produce or reproduce themselves (Wenger, 1998). It is this dialectic relation between subject and object that prompts the transformations of learners' identities and their learning community.

Digital mathematics storytelling can be situated as a CHAT-oriented learning activity that involves informal adult educators (subjects) using digital technologies (instruments) to create mathematically-rich personal narratives (objects) in the online storytelling circles (community). Through participating in a digital mathematics storytelling experience, adult educators' craft and hear each other's narratives around mathematics, impacting their evolving mathematics identities.

Objectives

This research study focuses on 3 objectives: (1) To develop a protocol for Digital Mathematics Storytelling through Participant Design Research in partnership with adult educators who work in urban emergent community centers, (2) To listen to the stories that informal adult educators tell when given the opportunity to create Digital Mathematics Stories to understand their narrative-based mathematics identity, and (3) To explore the impact of Digital Mathematics Storytelling on their mathematics knowledge, digital literacies, and feelings of connection with the communities they serve. Simply put, this research report analyzes the role of adult informal adult educators within two community learning extension centers during the COVID-19 pandemic. Through the lens of mathematics identity through storytelling from a Critical Race Theory Counternarrative perspective, we explore a framework of mathematics identity specifically involving informal adult educators who work within marginalized urban emergent communities.

Research Modes of Inquiry

Researching Identity

Studying something as personal and complex as identity, particularly when working with communities that are often oppressed and marginalized, requires research strategies and tactics that avoid deficit colonizing perspectives (Patel, 2016). This requires eliciting narratives, and recognizing that these narratives are the participants' identities (Sfard & Prusak, 2005), thereby avoiding unnecessary evaluation and judgment from the researcher. This narrative-biographical approach to studying identity also enables participants to ground their narratives within their own spaces of power–simply, participants tell their own story (Kelchtermans, 1993).

Community-based Participatory Design Research

The community-based participatory design research methodology builds upon design-based research by positioning all participants as integral to the designing of research goals (Bang & Vossoughi, 2016). The first objective of this research project involved developing a model digital mathematics storytelling protocol for the informal adult educators to adapt and use with the children at their LEC. From there, feedback from participants shaped the refinement and modification of the protocol for use with other students in the local community. Within the workshop itself, informal adult educators had the opportunity to question and reshape the research team's plans, while also engaging in an iterative process of telling, refining, sharing and imagining to refine their own digital math stories.

Participants.

This project involved 14 adult educators across two community LECs who work directly with over 100 K-8 children in an urban emergent community. Of the 14 adult educators, all 14 identified as a Black or a Latinx person of color, and had lived in or had substantial roots to the communities they worked in.

The Data Collection Phases

The data collection took place over four phases, with at least one week passing between each phase. In the first session, the participants engaged in a workshop to explore their own feelings towards mathematics and to brainstorm the ways mathematics exists in their lives. Between the first and second session, participants created a draft video in which they shared the ways math might exists in their live. In the second session, the participants engaged in a facilitated reflective protocol called the Storycircle, in which each participant shared their initial story, received feedback from their peers, and thought out loud about how to refine their mathematics story

(Lambert, 2013). Between the second and the third session, the participants worked on crafting their Digital Mathematics Stories, a 3-5-minute video in which they shared a story about mathematics and how it related to them. These videos focused not on a mathematics problem, but on the ways that mathematics occurs in a story that only the participant could tell. In the third session, the participants presented their finished Digital Mathematics Stories and also give feedback and commentary to their peers' stories. After this "screening" session, each informal adult educator engaged in a 1-on-1 interview with one of the authors to discuss how this process connected to their mathematics identity, how it affected the way they helped their children with mathematics in the LEC, and how they might alter the protocol to for their own community.

Measurement/Instrumentation

We focus on three measures in this report.

Digital Math Stories. The informal adult educators created, workshopped, and refined their own short videos stories. Both the draft and the final stories were analyzed.

Weekly Comments. The adult educators also added significant online comments, feedback, and questions to shared, online documents during and after every weekly session and also in the chat feature within the online conferencing platform. These comments and questions involved questions to the research team, feedback to the other informal adult educators, and advice or even further stories and anecdotes about implementing Digital Math Storytelling in their LEC.

Interviews. After the informal adult educators finished their workshops, they each engaged in a 1-on-1 interview to discuss the effect of this experience, how they thought about implementing digital storytelling in their own work at the LEC, and how this experience affected their feelings of connectedness to the community.

Analysis

In order to analyze this data, the research team used constant comparison analysis (Corbin & Strauss, 2008) and narrative inquiry (Clandinin & Connelly, 2000) to compare data from the informal adult educators' digital stories and their written comments during workshops in order to understand the changing aspects of the educators' mathematics identities (Aguirre, et al., 2013; Langer Osuna & Nasir, 2016) and their ability to employ digital tools to meet their needs as storytellers, educators, and mathematical actors. In the analysis, we focused specifically on connecting the ways that the informal adult educators (1) expressed their sense of agency and comfort with mathematics; (2) imagined the process of engaging children in telling their math stories; and (3) gave one another feedback on the stories they shared. The written contributions were analyzed alongside the digital video stories that adult educators created.

Results

Informal Adult Educators' Mathematics Identity

Generally, each informal adult educator expressed trepidation about mathematics in their initial story, revealing fears and anxieties about mathematics based on their own experiences in school. These stories focused on feeling "dumb" or "stupid" in their mathematics class, racial and gender stereotyped reinforced by educators and other adults in the community, and a focus on school mathematics as being about following directions and preparing for tests. Overall, we found that the first sessions of working with the informal adult educators required listening to stories of frustration coupled with empathy for the violent and oppressive mathematics experiences that most of the informal mathematics educators had experienced.

However, in the short time between the initial and the final mathematics stories, many of the informal adult educators had quickly shifted in the way they positioned themselves towards mathematics. Based on the sharing of the stories, the feedback and the commentary of shared negative experience in mathematics, and the shepherding of the research team that mathematics is not about judgement or evaluation but about problem-solving and creativity, the informal adult educators generally showed major shifts in their stories.

For instance, one educator, who was also a college student, shared about how this experience gave her the confidence to sign up for a mathematics course, even though she had been avoiding taking mathematics courses throughout her matriculation. Another educator shared a story about how she felt engaged in the validating the mathematics she did each morning to calculate whether or not she had time to stop for a cup of coffee. And another student shared a story about connecting to the indigenous mathematics knowledge he was curious about in ways to mix specific herbs and plants together to create healthy teas and potions. Overall, the stories showcased the ways that the adult informal educators had found aspects of mathematics in their own lives, but more importantly were not able to recognize that they themselves were mathematically powerful.

The Types of Digital Math Stories

In analyzing the stories, we found that in terms of mathematics content, the stories could be categorized as either *a quantity-based mathematics story* (e.g., how much money do I have in my budget?) or a story involving a *basic arithmetic scenario* (e.g., how do I figure out how much food I need to feed my pets?). In terms of the context, we found that the stories fit within four specific types that each illuminated aspects of the storyteller's life: (1) Work or time management (e.g., how much time do I need to commute to work?), (2) Money or budget management (e.g., will I have enough money to pay for a *Disney+* subscription if I move to a different apartment?), (3) Hobbies or sports (e.g., how can I mathematize my improving basketball playing ability?), and (4) Caregiving (e.g., How do I create a system for taking care of my plants?).

Insight into Supporting Children's Emerging Mathematics Identities

The stories and the commentary surrounding the stories showed how the informal adult educators felt about their math self-efficacy (e.g., negative personal experiences with timed test), how they were starting to grow in their beliefs about mathematics learning (e.g., recognizing the need to listening to children's mathematical thinking), and their approach to enacting mathematics storytelling either through engaging children in a math problem or eliciting mathematical routines or stories directly from children. Additionally, the informal adult educators delved into discussions around the ways they would talk about and position mathematics, particularly paying attention to the mathematics terminology they used in their stories (e.g., tallying vs. counting; being clear about units). These emerging insights show that, while these informal adult educators had little formal mathematics teacher preparation, just going through this exercise engaged them in conversations that dominate most inquiry-oriented university-based mathematics methods courses.

Digital Literacies

Finally, the informal adult educators showed a wide-range of comfort in their "digital literacies" enacted as they created and crafted their videos. They often commented to each other about the "crispy"-ness of each other's videos, focusing on the attention-grabbing transitions and inviting visual techniques used in the videos. Yet, many of the comments also expressed frustration with the availability and usability of the video editing tools they had access to, focusing on what it even means to be "digitally literate." For instance, while we as a research group assumed from the initial conversations that the informal adult educators were well-versed in creating videos for Instagram or TikTok, the commentary around the digital stories showed that many of the informal digital educators used this experience as an opportunity to create their first ever Instagram or TikTok video. We are still unpacking how this might challenging the definitions and forms of what it means to be "digitally literate", that it is less about technical skill or familiarity, but more about opportunities to tell "your" story.

Discussion

While we are still analyzing the stories, the commentary, and the interviews for deeper insights, we will share that this experience of working with informal adult educators has helped us conceptualize the importance of engaging and listening to community members that impact our children's mathematical learning. The informal adult educators live in a unique space; they are not family members nor are they school-based educators. They often are ignored in the conceptualization of the many variables affecting a child's mathematics learning. Yet, community centers and the informal adult educators who work within them are integral members of the community, and their stories and enactments of mathematics has a significant impact onto how our children thereby position and see mathematics in their own world.

Note

[1] The term urban emergent signifies communities in large cities, but not as large as metropolitan areas such as New York or Los Angeles. These urban emergent communities, however, encounter the same scarcity of resources and historical issues of segregation (Milner, 2012).

To develop an equity-centered orientation in teacher education programs, it is essential teacher educators recognize what prospective teachers attend to in classroom events and how they relate these events to mathematics instruction. In this study, we examine what prospective teachers attend to in a classroom vignette focused on cultural, racial, and economic biases. Using the Equity Noticing Framework, we identify what prospective teachers attend to, how they critically examine hidden biases, and what actions they would take to be change agents. The results indicate the importance of providing opportunities for prospective teachers to become aware of systems of oppression and ways to foster change in the mathematics classroom.

Keywords: Equity, Inclusion, and Diversity; Preservice Teacher Education; Teacher Noticing

Teaching mathematics from an equity stance requires teachers to understand that students from diverse backgrounds come into mathematics classrooms with different worldviews. Equitable mathematics instruction requires each and every learner has the opportunity to participate in high-quality instruction as a valued member of the mathematics community. However, within the United States K-12 educational system, students from non-dominant backgrounds are often denied equitable opportunities to learn (Wager, 2014) especially when their teachers are different from their own culture and background (Futrell et al., 2003; Turner et al., 2012). Black and Latinx students are more likely to face deficit perspectives from teachers in the mathematics classroom (Berry, 2018). Although mathematics education researchers have examined ways to teach mathematics to diverse populations of students (e.g., Vomvoridi-Ivanovic & Chval, 2014), documented disparities exist for minoritized students (Berry, 2018; Lambert, 2018). Without explicitly recognizing the barriers minoritized populations face from systemic oppression, the vision for equitable mathematics instruction is nullified (Shah & Coles, 2020). Knowledge of these disparities emphasizes the need to better prepare prospective teachers (PTs) to effectively teach each and every learner by developing PTs' orientations toward equity in teacher education programs. Furthermore, "teachers' perceptions of cultural and linguistic competency as they relate to helping children achieve academic and social potential play a very critical role in the type of educational services provided to culturally and linguistically diverse children" (McSwain, 2001, p. 54). Mathematics teacher educators must recognize what PTs attend to in classroom events and how they relate these events to mathematics instruction because teaching expertise requires the ability to notice and interpret classroom events (Mason, 2008). The purpose of this study is to examine what PTs attend to in a classroom vignette focused on cultural, racial, and economic biases.

Equity Noticing Framework

Teacher noticing is an integrated process comprised of three distinct, yet interrelated, levels: (a) attention, (b) interpretation, and (c) instructional decisions (van Es & Sherin, 2002). The process begins when a specific event captures the teacher's attention and heightens their awareness of specific phenomena (Shah & Coles, 2020). Once a teacher focuses their attention on specific components of a classroom episode, they immediately interpret the event and make pedagogical decisions in response to the classroom phenomena (Jacobs et al., 2010; Shah & Coles, 2020; Wager, 2014).

Traditionally, researchers focused teacher noticing on students' thinking; yet the field has expanded the locus of attention to include equity and equitable practices (Hand, 2012; Louie, 2018; Thomas et al., 2020; Turner et al., 2012; Wager, 2014). Because individual preferences and biases impact teachers' locus of attention when examining classroom events (Patterson et al., 2019; Star & Strickland, 2008) and their pedagogical decisions based on the interpretations of the events, teachers' noticing can be productive or unproductive. Consequently, mathematics teacher educators must provide opportunities for PTs to recognize and respond to perceptions that lead to deficit views that negatively impact students' access to high-quality mathematics, academic achievement (I et al., 2020), and identities as mathematics learners. Our Equity Noticing Framework (see Figure 1) is designed to identify what teachers' notice and position them as agents of change who critically examine how bias permeates educational systems, structures, methods, and pedagogies and then strengthens their resolve to act against oppression.

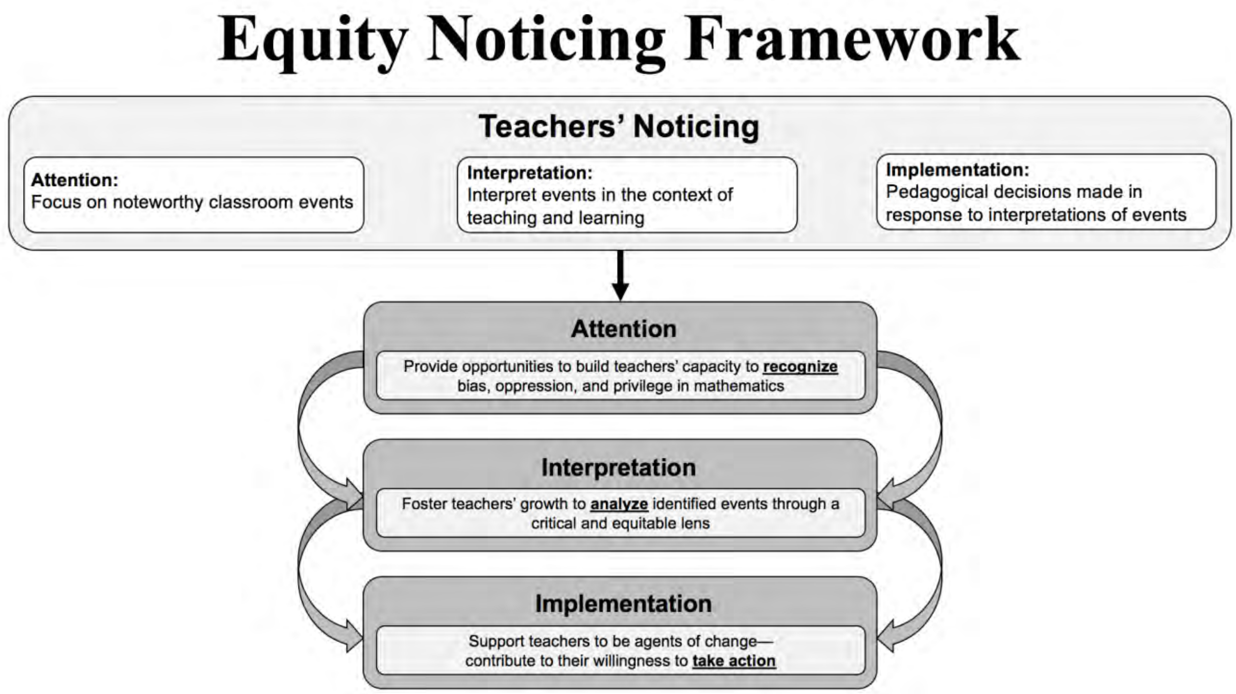

Figure 1: Equity Noticing Framework

The Equity Noticing Framework begins by utilizing the three levels of noticing to engage PTs in explicit analyses regarding salient features in mathematics classrooms and identifying how pedagogical decisions result from teachers' interpretations of the noteworthy events. From the teachers' noticing, the framework identifies the next steps in the role and responsibilities of mathematics teacher educators as they provide insight into how observations and subsequent instructional decisions reveal biases that future teachers must confront.

At the attention level, mathematics teacher educators provide opportunities where PTs attend to what was noticed in vignettes or classroom videos and subsequently build their capacity to recognize oppression and privilege. Interpretation in our framework fosters PTs' growth by engaging them in explicit discussions that situate their analysis of the noticed events through a critical lens such as colorblindness, microaggressions, or privilege. In the third level, implementation expands beyond pedagogical decisions and also involves tasks that contribute to PTs willingness to take action against systemic bias and become supportive agents of change.

Methods

Prospective early childhood and elementary teachers (n=209) from four different universities in the United States participated in the study. Data consisted of PTs' individual responses to prompts from a classroom vignette (see Figure 1) on an authentic topic focused on an elementary teacher who did not take time to develop relationships with her racially diverse students. Since elementary teachers are primarily white women and K-12 classrooms are becoming more diverse, the first author created a vignette, to mirror a white woman teaching diverse students, to engage PTs in analyzing systems of oppression and privilege. We intentionally asked our PTs to respond to a written vignette instead of watching a video clip to ascertain what they noticed. This way, PTs had time to process the scenario and consider how they would respond. Furthermore, by providing a written vignette, we narrowed the focus of what PTs could attend to by excluding extraneous classroom details (Wilkerson et al., 2018). In van Es and Sherin's (2006) study on mathematics teachers' noticing in a video club, they found teachers tended to focus on details that were not specific to the lens they were asked to view the video. The open-ended nature of the prompts allowed PTs to choose what they attended to in the vignette, how they interpreted those events, and how they positioned students of color in the mathematics classroom.

Case: Ms. Roberts

Ms. Roberts, a Caucasian elementary teacher grew up in a rural farming community, where her interactions with students of color had been limited to migrant farm workers who rotated in and out with the growing seasons. Before she entered the teaching profession, Ms. Roberts had limited experiences with people from other cultures. In her school, eighty-five percent of the students are students of color and their socio-economic status is at or below the poverty level. She believes that "people are people, no matter what color they are." Early in the school year she had to confront her true beliefs. During mathematics instruction, one of her students started crying. She went over to comfort the student, but she felt herself hesitate for a moment. This haunted her for weeks and weeks.

1. What are your thoughts on the above scenario?
2. How do we "get over" our perceived doubts and fears so we can positively work with students who are "different"?
3. How do you view your role as an elementary mathematics teacher who has to deal with "hidden" biases?

Figure 1: Ms. Roberts Vignette

Data were analyzed using the Equity Noticing Framework for a priori coding. We then used pattern coding to appropriately group and label similarly coded data as a way to attribute meaning (Saldaña, 2016) and identified common them1es (Delamont, 1992). Finally, we discussed the appropriateness of the themes. All discrepancies were resolved.

Results

After providing an opportunity for our PTs to respond to the Ms. Roberts vignette, we discovered some PTs were aware of their own biases. For example, one PT expressed, "Even though we don't want to and don't like it, we all hold some kind of judgment in our head and that at times it can come out and make us uncomfortable." Some PTs identified with Ms. Roberts as noted by one PT,

> I also grew up in a rural farming community, so com[ing] into the city, while not huge, was somewhat of a culture shock to me. I ran into people on campus of all sorts of culture, and I realized that I often automatically stereotype them without meaning to.

Although the PTs were able to identify with Ms. Roberts, there were some who denied having any biases. For instance, one PT stated, "I honestly have not had a problem with it. I have grown up around many brown people, so I do not think this affects me as much. It is our job to model the proper behavior." Moreover, PTs expressed it was their responsibility to treat all students equally. A PT commented, "All students are students. They are there to learn and you are there to facilitate that learning. Colors, sexuality, religion doesn't mean anything." In these instances, it appears the PTs equate being around other people of color eliminate any bias they may have, and students' identities do not play a role in their learning. However, some PTs recognized the importance to identify their own privilege, and it would be challenging to "change (positive or negative) [because it] is hard for most people." But, they articulated change was necessary.

> I feel it's extremely vital that we push the views, thoughts, and actions facing American society today, out of our minds. There is so much hate and discrimination about hate and discrimination that as teachers, we have to be the ones to stand tall and not be affected or swayed by the negativity in the nation.

In order to take action, the PTs expressed the importance of educating themselves and investing time in their students' community. A PT noted, "I think for me the biggest help has been becoming educated on topics surrounding these issues. Having open discussions has been very beneficial as well. As a teacher…we can use that to make positive social change." Another PT commented,

> As an elementary teacher who has to deal with hidden biases, I hope to spend time learning about the community I will be teaching in, getting to know a little more about the traditions and expectations held, as well as the cultures present in my own classroom.

One PT succinctly summarized the findings stating, "A hidden bias cannot be hidden anymore if you face it [recognize], learn about it [analyze], and respond in a positive way [take action]."

Conclusion

Teacher preparation programs must provide opportunities for PTs to move beyond teaching mathematics from a Eurocentric viewpoint. The results from this study continue to reinforce the importance of devoting time to helping PTs become more cognizant of their own beliefs about equity and equitable mathematical practices and providing opportunities to analyze these beliefs through research-proven attitudes and practices (Jackson & Delaney, 2017). The implications of this work expand both research and practice. Enhanced teacher preparation means emphasizing strategies that meet the needs of each and every learner, but also requires PTs have the opportunity to develop their orientations toward equity with respect to students' social identities in mathematics content and methods courses. Discussions generated from vignettes, like Ms. Roberts, not only enrich PTs' pedagogical noticing, but these conversations also challenge existing stereotypes, hidden biases, and unproductive beliefs about students from diverse backgrounds (Jackson & Delaney, 2017). Thus, PTs' pedagogical noticing evolves to also emphasize equity noticing: (a) developing an awareness of equity, (b) defining and interpreting what equity means in classroom instruction, and (c) implementing equitable practices within the mathematics classroom. Moreover, researchers must investigate how teacher educators structure experiences that encourage PTs to begin facing existing—and often hidden—biases in order to broaden PTs' ways of seeing (Jackson & Delaney, 2017; Jackson, et al., 2018) and foster positive, equitable change in the mathematics classroom.

CLIMATE JUSTICE ALGEBRA: WHAT ARE THE TENSIONS BETWEEN THE MATHEMATICS AND CULTURALLY RELEVANT PEDAGOGY?

Chelsea Muhs
Portland State University
Ched@pdx.edu

In this article I examine a new course offering at an urban high school, Climate Justice Algebra, to determine if the course is Culturally Relevant Pedagogy (CRP). I examine the tensions between academic success (grade level mathematics learning) and climate justice learning found during two tasks administered to the class. I consider the antagonism between covering grade level mathematics standards and engaging students in Culturally Relevant tasks when melding the two practices together.

Keywords: High school Education, Culturally Relevant Pedagogy, Social Justice, Curriculum

In this article, I examined two Advanced Algebra tasks designed for a high school Climate Justice Mathematics class. By utilizing components of Culturally Relevant Pedagogy (CRP; Ladson-Billings, 1995), I analyzed the tensions between focusing on *academic success* and focusing on *cultural competence* and *critical consciousness.* In the Climate Justice Algebra class, I found that an antagonism exists between meeting required mathematical standards and engaging students in culturally relevant tasks for the social/social justice portion of class. The two topics—mathematics & climate justice—compete for time, engagement, and buy-in from students. To explore these tensions that arise while designing social justice tasks, I examined the design and implementation of two tasks with respect to the three elements of CRP. My research question is: *What tensions arise between academic success, critical competences, and critical consciousness when enacting Advanced Algebra tasks with a climate justice focus?*

Background

This study took place in an urban, comprehensive high school in the Pacific Northwest. At this school, the mathematics department follows a traditional course offering along with optional International Baccalaureate (IB) advanced courses.

Theoretical Framework

Ladson-Billings (1995) defines Culturally Relevant Pedagogy using three elements: *student achievement*, *critical(cultural) competence*, and *critical(cultural) consciousness*. First, student achievement can be described as computing, posing, and solving problems while participating in peer review of proposed and enacted activities. Then, in order to attend to cultural competence, students are supported in maintaining their cultural identity while succeeding academically. Lastly, Ladson-Billings introduced cultural consciousness (critique), in which teachers are expected to support students to "recognize, understand, and critique current social inequities" (Ladson-Billings, 1995, p. 476-7).

Effective classrooms can be thought of as ones in which students are learning content under CRP including all three components simultaneously (Ladson-Billings, 1995). As shown in Figure 1, CRP is achieved when the components of CRP are balanced.

Figure 1: Balanced CRP

The Climate Justice Class

To offer students a more holistic approach to mathematics, I created Climate Justice Algebra, which is an algebra course that satisfies the graduation requirement (three years of math are required in this state).

Climate Justice Algebra covers the advanced algebra mathematics standards. The scope is broad, and the sequence does not provide much time to delve deeper into all the standards. The climate justice topics include different energy types (coal, wind, solar, etc.) and their community impacts. Discussing climate justice is an essential part of Climate Justice Algebra. There is a shared understanding that we will talk about social inequities as a necessity for learning math in this course. This eliminates the question from students, *"Why are we talking about this in math class?"* and addresses the notion that mathematics is never politically neutral (Gutiérrez, 2013).

One goal of Climate Justice Algebra is for students to be actively engaged in solving problems. This goal aligns the concept that math should be inquiry based, interactive, and incorporate student interests (Thomas & Berry, 2019). By approaching the algebra class through a climate justice lens, students can approach problems in a more culturally conscious and relevant way. However, the disconnect between standards and applications causes tension between CRP and mathematics pedagogy (Enyedy & Mukhopadhyay 2007, Rubel 2017).

Climate Justice Algebra is bound by the scope and sequence of mathematical content created by the school district, including a suggested time frame and correlating priority standards. Therefore, as a teacher, I still have to "play the game" (Gutiérrez, 2013) while attempting to find equity through playing and then changing the game (Rubel, 2017, p. 78). Harper (2019) states in a metasynthesis that teaching math for social justice did not necessarily incorporate grade level mathematics content (Harper, 2019), which was evident in my course.

Methods

Students enrolled in the Climate Justice Algebra class were recommended by previous teachers or were seniors who previously failed a math course and needed the course to graduate. Section 1 had 23 students and Section 2 had 17. Student demographics are presented in Table 1. The student demographics in Climate Justice Algebra did not reflect the school population, which punctuates the importance of CRP.

Table 1: Student Racial Demographics, Climate Justice Algebra vs. School Wide

	White	Latinx	Black/African American	Multiple	Asian	Pacific Islander
Class	57.5%	17.5%	10%	7.5%	5%	2.5%
School-wide	69%	8%	2%	10%	10%	<1%

The Tasks

The first task was designed as a hands-on lab to support our climate justice learning target relating to coal energy. Creating and implementing a task that is hands-on is one identifier for students of the innate difference between Climate Justice Algebra and Advanced Algebra. The second task is a follow up of Task 1 and is an exploration of a GIS map. Task 2 depicts a more "normal" lesson in our Climate Justice Algebra class. The task swings between climate learning targets (coal) and grade level mathematics learning targets (parent graphs).

Task Evaluation

Tasks were evaluated by coding segments of two video recordings of 2020/21 class periods with respect to the three components of CRP. For relevance, I only considered the mathematics and climate justice segments. I also considered how the mathematics and climate justice were paired and if there was any overlap of mathematics standards.

Task One: Cookie Mining

The Cookie Mine (2017) was planned as a lab activity and was our first hands-on task of the course. I chose to analyze this task because I felt that the elements within the triangle of CRP (Figure 1) were not equally attended to during the class lesson. Task 1 was coded "no" for segmented due to the fact that the lesson was continuous for the entire class period. Further, there was also no distinct transition to "math" or cuing for notes as seen in Task 2. Observations on Task 1 include:

- **Academic success** was not met in terms of mathematical standards. The lab covered addition, subtraction, and multiplication with integers. Students created an area model and a sketch of their "topography" from their cookie mine. See Figure 2.
- **Cultural competence** was met. Within the Ladson-Billings framework (1995), students were able to be authentic during this task and able to code switch between academic language (reclamation form) and non-academic ("Do you just put your cookie in the middle?").
- **Critical consciousness** was met during this task as students started to calculate their profit/loss. Students who expanded their mines were then made aware of the cost that a mining company incurs.

Task Two: GIS Map Exploration with Notes

In task two, students explored various topography ideas, a GIS map looking at coal mining in Kentucky, and a lecture on exact equations. Task 2 was segmented by topic, math and climate justice. Observations include:

- **Academic success** was met in terms of the standards covered in the unit. Students worked on writing exact equations in vertex form from a given graph. See Figure 2.
- **Cultural competence** was lacking as students did not demonstrate high engagement, as measured by student voice & text input, students did not demonstrate code-switching
- **Critical consciousness** was not met during this task. While students did consider a GIS map of Kentucky and the proximity of mines to towns, there was no further exploration of this topic. Students were not critiquing cultural norms or institutions that might be responsible for the proximity of the mines near the towns, for example. See Figure 2 for this representation.

Results: CRP Components Unbalanced

In my findings**,** there were two different ways the tasks were unbalanced:

- Low *academic success* (see Figure 2 left) with the other two components showing up (*critical competence* and *critical consciousness*)
- High *academic success* thus affecting the other two components to be marked as "low" (Figure 2 right)
-

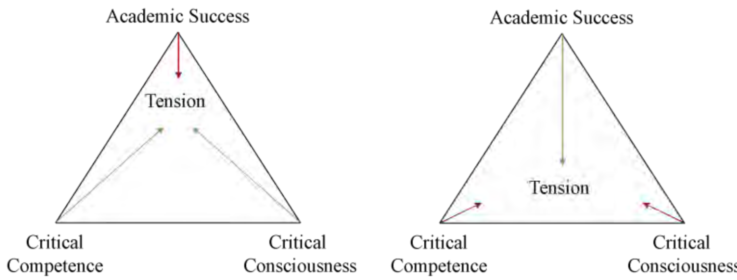

Figure 2: Unbalanced CRP; Low Academic Success vs. Low Critical Competence & Critical Consciousness

If we consider that the three components of CRP balance an activity, a class, or a task, then when one component is lacking, the balance is altered, and strain is created. For Task 1, tension was created by low *academic success* and the balance was altered as shown in Figure 2 left. The math in the activity did not necessarily pertain to the math standards that were relevant to the course, despite the activity pertaining to the climate justice lens. With increased *critical competence* and *critical consciousness,* I found a higher level of student engagement and the lesson ran more cohesively (not segmented).

In Task 2, we see the balance is altered again as shown in Figure 2 right. Tension appears with a lower amount of *critical **c**ompetence* and *critical **c**onsciousness*, despite having high *academic success*. The math standards of the activity met those in the Advanced Algebra ¾ standards. However, with high *academic success*, students were less engaged, used less student voice, and did not readily critique cultural norms or attend to potential social justice inequities.

When examining my two tasks, I first consider time as a tension followed by rigor. In considering tasks, lesson planning, and assessment, CRP is ultimately my goal. After I examined Task 1 and Task 2, I noticed that they were not balanced among the CRP components.

Conclusion

In teaching the Climate Justice Algebra course, I acknowledge that tensions are present. Regarding my goal in considering what the tensions are when one tries to meld advanced algebra with climate justice, I've found *academic success* in balance with *critical competence* and *critical consciousness* to be the main tension. Strain also manifests in time management, which refers to the first tension: how much time is spent on mathematics compared to other elements of Climate Justice Algebra? While I have no immediate solution for these tensions, I believe the first step is to be aware of them as they happen, and to reflect on how the blend of mathematics and social justice components might become more fluid.

Acknowledgments

I would like to acknowledge my students who have been ready and waiting patiently for this course. Endless gratitude to our previous college and career coordinator, Emily Hancock, for

calling wind farms endlessly while I waited with bated breath during my prep period.

CHALLENGING AN AFFECTIVE BINARY IN MATHEMATICS EDUCATION

Abhinav Ghosh
Harvard University
abhinavghosh@g.harvard.edu

A long-standing focus on quantitatively measuring affective responses in mathematics education research has created a binary perspective of seeing affect as either positive or negative. In this paper, I examine this through a preliminary analysis of research on affective responses in the latter half of the 20th century in the United States. Subsequently, I problematize this affective binary, not just for its limited theorization of affect, but also for the exclusionary mechanisms it enables in the form of comparison, surveillance, and intervention.

Keywords: Affect, Emotion, Beliefs, and Attitudes. Equity, Inclusion, and Diversity

Getting students to feel *positively* about mathematics has been a long-standing goal within mathematics education, not just in the United States, but globally. Boaler (2009) mentions:

> There are two versions of math in the lives of many Americans: the strange and boring subject that they encountered in classrooms, and an interesting set of ideas that is the math of the world and is curiously different and surprisingly engaging. Our task is to introduce this second version to today's students, get them excited about math, and prepare them for the future. (p. 12)

The desire of transforming students' affective responses (for e.g. – beliefs, attitudes, emotions, confidence, etc.) towards mathematics has produced numerous books, articles, and research studies that address and attempt to 'fix' students who feel or think negatively about mathematics. These attempts often share a common goal of getting students to develop certain pre-determined affective responses that are considered desirable. Studies on the affective domain in mathematics education have historically provided ways of classification of students through the creation of a *positive-negative* binary (Zan and Di Martino, 2007). Such classifications have established a normative learner of mathematics with specific beliefs, emotions and feelings about mathematics – towards which all students are expected to converge. In this paper, based on preliminary analyses of studies on affective responses in the United States in the second half of the 20th century, I briefly show that quantitative studies of affective responses using measurement scales reinforced a binary view of affect. I, then, problematize this dichotomy, not just for its limited theorization of affective responses, but also for the mechanisms of comparison and surveillance that it enables. Engagement with the affective in mathematics education is often reduced to the identification, classification, and 'correction' of students who do not have desirable affective responses – an approach that requires scrutiny and rethinking towards a more holistic perspective.

Conceptual and Methodological Notes

McLeod (1992) refers to the affective domain in mathematics education as comprising "a wide range of beliefs, feelings, and moods that are generally regarded as going beyond the domain of cognition" (p. 576). I derive my arguments in this paper from the idea that there exists an implicit classification of affective responses as either *positive* or *negative.* This binary is closely related to the *positive-negative* dichotomy of 'attitudes – an idea that became a naturalized assumption in most lines of mathematics education research (Zan and Di Martino, 2007). According to Zan and Di Martino (2003), even though the notion of attitudes towards mathematics is significantly complex, this dichotomy prevailed due to the fact that "most studies have concentrated on the creation of measurement instruments, rather than on the development of a theoretical base" (p.2). An ambiguous understanding of attitude and other affective responses such as beliefs and emotions has led to their conflation. For example, a *positive* belief about mathematics (such as seeing it as useful) might be significantly different and exclusive to a *positive* emotion (such as joy while solving a problem) – but the two are often assumed to be related under a bigger umbrella of *positive* affective responses. Furthermore, the tendency of "classic studies" to only "investigate the correlation between positive attitude and success" (Zan and Di Martino, 2007, p.158) has resulted in positing certain ways of thinking and feeling – unrelated and yet tied together by statistical correlations – as *positive*, and all else as *negative*.

What this binary view of affective responses then provides are ways of classifying not just children's emotions, feelings, and mental processes, but children themselves. This is tied to the idea of governing children – where governing is the "the visualizing and inscribing of distinctions that classify and order a child's conduct, action, and participation" (Popkewitz, 2004, p. 4). The standardization of what counts as affectively *positive* enables comparative logics based on imaginary empirical scales (Popkewitz, 2004) – resulting in new categories of children in the mathematics classroom such as the *mathematically anxious*, the *underconfident*, the *disinterested*, etc. Such classifications earmark these children for intervention by "informed rescuers'' (p.13), and encourage a new objective of changing the affective responses of these children towards characteristics deemed desirable by the *positive-negative* dichotomy.

As a part of a larger historical study of how perceptions of affective responses towards mathematics have changed over time in the United States, I looked closely at mathematics-related educational and psychological research in the second half of the 20th century. This period was marked by an increased volume of studies on the affective in education – the ideas and methodologies of which continue to persist even today in educational research. Besides searching for individual journal articles and book chapters, I also used reviews of research (published in journals, handbooks, NCTM Yearbooks, etc.) on the topic from this period, such as Feierabend (1960), Aiken (1970), Kulm (1980), and McLeod (1992), to understand the landscape of affect-related research from the 1950s to the turn of the century. Viewing previous research done on affective responses in mathematics as empirical 'artifacts', I use this paper to report my initial findings and arguments based on my preliminary analyses of them.

Initial Findings and Analysis

Conversations about mathematics-related affect in the first half of the 20th century viewed affective responses as 'non-cognitive' and often clubbed them under the general idea of *love* or *liking* for the subject (Reeve, 1925; Butler, 1930; Cook, 1931). However, in the post-World War II period, relationships between the affective and the cognitive began getting highlighted due to the increased uptake of psychological tools and methods in mathematics education research (McLeod, 1992; Pais and Valero, 2012). The methodological approaches of most of these studies were aimed at quantifying affective responses, particularly attitudes, for the purposes of statistical correlations. In this era marked by process-product research to identify mediating factors towards student achievement, the studies of attitudes towards mathematics were initially triggered by an interest in making sense of differences in problem solving ability on the basis of sex (Feierabend, 1960). Attitudes and motivation towards mathematics, thus, started getting used as justifications for differences in performance when 'ability' was held constant. Most of the research on attitudes during this period was "characterized by its emphasis on definition of terms, its preoccupation with measurement issues, and its reliance on questionnaires and quantitative methods" (McLeod, 1992, p. 577). Given the efforts to establish correlations between attitudes and achievement, student attitudes were 'measured' in most studies using Thurstone and Likert type scales (Feierabend, 1960) – a fairly common practice even today.

Commonly used attitude scales – such as Dutton's (1954) – were developed by recording student responses and creating statements from those corresponding to equally spaced scores on a number line – for example, 1 indicating a strong dislike and 10 showing a strong liking for mathematics. The use of such scales to study affective responses enabled two things. First, the assignment for scores for each item on the scales facilitated a quantified *positive-negative* evaluation for them. Associating certain attitudes with higher numbers and others with lower numbers on this scale acted towards strengthening a binary understanding of attitudes (Zan & Di Martino, 2003; 2007). Second, most attitudes towards the higher end of such scales were already correlated with high test scores – often due to the very process of designing these scales. This rendered those attitudes as desirable, making others on the lower end of the scale as *negative* or undesirable. Research conducted in the 1970s-1990s would go on to adopt these naturalized assumptions about an affective binary, extending the perspective of seeing certain affective responses as desirable based on their correlation with test scores (Kulm, 1980; Aiken, 1970). This approach was applied to research on other affective responses too such as beliefs, emotions, and self-efficacy (McLeod, 1992; Hackett and Betz, 1989; Reyes, 1984; Fennema, 1989). Despite significant differences in how various affective responses were theorized, the extension of a similar quantitative thinking across them caused the various meanings of *positive* for each to overlap and collapse into a singular *positive* affective response. This broad categorization of affect often urged individuals to place others or themselves on either the *positive* or the *negative* side – reifying a polarized notion of affective responses towards mathematics.

This binary notion of affective responses posited specific ways of feeling and thinking about mathematics as desirable – a view which percolated well into the 21st century. This 'standardization' of affective responses towards mathematics can be seen as a direct consequence of the quantitative reasoning in earlier studies. For example, the National Research Council (NRC) (2001) describes a 'productive disposition' as a "habitual inclination to see mathematics as sensible, useful, and worthwhile, coupled with a belief in diligence and one's own efficacy" (p. 116). Comparing this description to an earlier attitude scale used by Dutton (1962), some of the attitude statements with the highest assigned scores – the '*positive* attitudes' – align with the elements of a productive disposition, such as – 'Arithmetic is very interesting', 'Working with numbers is fun', 'I like arithmetic because it is practical', 'I think about arithmetic problems outside school and like to work them out', and 'I never get tired of working with numbers', among others. By holding up productive dispositions as necessary for mathematical proficiency, NRC's description reinforces the *positive* end of attitude scales as desirable in a student of mathematics. Students are then expected to necessarily possess this 'productive disposition' – and are pushed towards developing the same if they already do not.

Discussion

Quantitative measurement and reasoning used by researchers in studies of affective responses in the past strengthened binaries of *positive* and *negative* affective responses. While an individual analyzed in such studies might have had different *positive* and *negative* scores on scales used to measure different kinds of affective responses, these studies often took a sum of all these scores to generate a single *positive* or *negative* evaluation (Zan and Di Martino, 2007). A *positive* affective response then became an umbrella term that implicitly assumed certain ways of thinking and feeling about mathematics as desirable – without theorizing about the different kinds of affect or considering the multiplicity of affective states. Moreover, the quantification of affective responses facilitated an ordered classification of students – often in the attempts to correlate affect with achievement. Establishing the normative with respect to affective responses, thus, became a way to standardize 'mathematical minds'. Such a standardization often creates an imaginary empirical scale (Popkewitz, 2004) that enables discourses of difference such as *negative* attitudes and beliefs, 'low' confidence and motivation, and *mathematically anxious* by measuring affective responses against it. These discourses produce new empirically-identifiable categories of students in the mathematics classroom who are unlike the normative learner – resulting in closer examinations and further surveillance of children's affective responses.

The focus on desirable affective responses sets in motion a subjectification that is carried out in school mathematics, with the purpose of "providing an effective governmentalization of the learners into a reduced form of identity as a mathematics learner that has to converge towards the social norms of a mathematical culture" (Pais & Valero, 2012, p. 17). I problematize the governmentalization done by the *positive-negative* affective dichotomy for three primary reasons. First, seeing a student as having *positive* or *negative* affective responses towards mathematics assumes 'mathematics' as a singular entity. A student who specifically 'dislikes' fractions might be assumed to dislike other topics in school mathematics too. At the same time, this dichotomy also clubs together different affective responses under each category, despite possible areas of exclusivity. For example, a student with a *positive* self-efficacy in relation to solving mathematical problems might be inaccurately assumed to also have *positive* beliefs about the usefulness of mathematics. Both such assumptions are inhibitory of a holistic theorization of distinct affective responses in mathematics education.

Second, the binarization of affective responses due to quantitative measurements enables a 'logic of comparison' – practices of division that construct different kinds of students in need of different strategies of intervention (Kirchgasler, 2019). Making students' affective states converge towards certain ways of thinking and feeling about mathematics is highly reductive of the myriad complex ways in which students learn and experience mathematics. Any effort to make 'all' students feel a certain way about mathematics demands a prerequisite of identifying students who do not already do so – a mechanism of exclusion that is central to such efforts. This mechanism is not only harmful due to its exclusionary logics of marking students for intervention, but also for its limited perception of the complex multiplicity of affective responses and ways of learning. Third, the subjectification that gets set in motion with an aim to identify and correct children without desired affective responses enables surveillance practices in education. While these practices have existed earlier in the form of observing a student's demeanor, body language or discourse to categorize them 'affectively', recent times have seen the use of digital technologies such as student sensor bracelets to determine stress, fear or engagement (Williamson, 2016) in classrooms. Such practices of laying bare a student's embodied processes for examination and analysis are deeply dehumanizing – and bring to the fore deeper ethical questions about research on student affect.

The consideration that has been given to students' affective responses in mathematics education is certainly important – because it offers meaningful ways to understand the complex ways in which students learn, feel about, and experience mathematics. However, a narrow and binary theorization of affect based on quantitative reasoning is not only reductive of this complexity, but also damaging due its exclusionary tendencies. Conversations about students' affective responses towards mathematics, thus, need to take these limitations into consideration, and scrutinize their own aims and orientations.

"DEAR MATH, I'M NOT A FAN OF YOU": SHIFTING MIDDLE SCHOOL GIRLS' PERCEPTIONS OF MATHEMATICS

In this study, we collected data from 48 middle school girls who attended a five-day residential summer mathematics program. At the program beginning and end, the girls wrote a brief "Dear Math" letter to share their thoughts and feelings about mathematics, and they were asked to draw a picture of themselves doing math and to explain it. Participant data were analyzed into themes, and pre- and post-program data were compared to look for evidence of change. The data show favorable movement, particularly in viewing mathematics as being more collaborative and less procedural.

Keywords: Affect, Emotion, Beliefs, and Attitudes; Gender; Informal Education; Middle School Education

Women are underrepresented in mathematics and other STEM disciplines. Interventions often target the middle grades as a way to "reach" girls to support their continuation in the school-to-career pipeline. To gauge the influence of a summer program for girls, we administered an instrument at the beginning and end and here reflect on the results of our preliminary analysis.

Purpose of the Study

The purpose of this study is to investigate the difference in middle-school girls' apparent perceptions of mathematics as a discipline and of doing mathematics through writing a letter directly to "Math" and creating a self-portrait of engaging with mathematics. The letters and portraits were collected at the beginning and end of a five-day residential summer camp for young women entering the seventh or the eighth grade. The program aims to engage participants in mathematics using contemporary teaching strategies that lean heavily on problem solving and social construction of mathematics understanding. The central research questions for this study were:

- What influence does participation in a five-day math program have on middle school girls' perception of mathematics?
- What influence does participation in a five-day math program have on middle school girls' perceptions of themselves as doers and thinkers of mathematics?

Conceptual and Theoretical Framework

Women continue to be underrepresented in mathematics-based fields (e.g., Makarova et al., 2019). Various performance-related and social, psychological, and emotional factors can influence women's pursuit of and perseverance in mathematics. Unfavorable gender stereotypes in STEM (science, technology, engineering, and mathematics) are a major culprit (Cheryan et al., 2015; Makarova et al., 2019; Zhao et al., 2018). Girls and women thus tend to hold lower self-concepts, expectations for themselves, and career intentions in relation to STEM compared with boys/men (Robnett, 2016; Robnett & Thoman, 2017; Song et al., 2017).

One promising approach to supporting girls/women in STEM is out-of-school-time (OST) learning. OST programs have been shown to increase participants' STEM knowledge and performance, engagement, and career aspirations (Allen et al., 2019; Author2 et al., 2021; Demetry & Sontegrath, 2020). Importantly, these programs have also been found to improve girls' STEM identities (Allen et al., 2019; Hughes et al., 2013) and their dispositions toward STEM (Author2 et al., 2021).

Although societal change is necessary to address gender-STEM stereotypes, classroom teaching can also influence students' relationship with STEM in general and along gendered lines. OST programs tend to use contemporary methods that are more conducive to favorable outcomes. Whereas traditional mathematics teaching tends to be teacher-oriented with passive students who are expected to acquire prescribed knowledge and procedures, often through memorization, contemporary methods emphasize active student involvement that employs critical and creative problem-solving and sense-making approaches that make use of written and oral communication, interaction with others, hands-on approaches, productive struggle, and real-world applications (Li & Schoenfeld, 2019; Noreen & Rana, 2019; Yuanita et al., 2018).

To frame our work, we align with the social constructivist view that cultural background and social interactions affect cognitive development and influence how one thinks and what one thinks about (Vygotsky, 1978). Vygotsky (1978) argued that "every function in the child's cultural development appears twice, first on the social level and later on the individual level" (p. 57). This phenomenon includes learning events that happen at home, in classrooms, in the community, in OST experiences, and in any other formal or informal settings where learning might occur. Boaler and Greeno (2000) found that different math learning environments (social level) where one focused on group problem solving and the other on lecture developed different mathematical identities (individual level). Young women encounter an array of events while learning mathematics. A learning event can be considered "leading" or critical, not because of its dominance in the present, but due to its role in shaping a person's thinking processes and a person's development in relation to such activities (Leont'ev, 1981, as cited in Black et al., 2010). We specifically chose to personify math by having study participants write a letter directly to "Math" and draw a picture of themselves doing mathematics to potentially elicit both social and individual perceptions of mathematics as a discipline, as well as themselves as doers and thinkers of mathematics.

Methods

Participants and Context

The Northern Nevada Girls Math and Technology Program was founded in 1998 to increase girls' knowledge, skills, and confidence in mathematics and technology in order to enhance mathematical and technological competence in girls' personal, academic, and occupational lives. A five-day residential summer camp is the signature event for the program and serves as the context for this study. Content chosen for the camp includes topics considered particularly important for students in general or for girls in particular (e.g., areas in which they tend to demonstrate weak performance and/or dispositions). All students do geometry/measurement, problem solving, and spatial skills and are exposed to female role models in mathematics and computer science. The rising eighth graders also learn algebra, whereas the rising seventh graders have lessons on data analysis/probability. Instructors use the following approaches: collaborative group work, student communication, technology use, and hands-on learning.

Participants in this study were 48 Nevada girls ages 12-13 who attended the camp in the summer of 2019. Only data from girls who attended the full camp and completed both the pre- and post-assessment were included. Of the study sample, 26 were rising seventh-grade students (i.e., would attend the seventh grade the following fall) and 22 were rising eighth graders. Because participants in the summer program were drawn randomly from those who applied, the girls had varied ability levels, background experiences, community types, and other background characteristics.

Data Collection Procedures

Participants completed the same prompt at the beginning and the end of the five-day residential camp. They were asked to write a letter directly to "Math" and create a self-portrait of themselves doing mathematics accompanied by a description of what appears in the drawing. Autobiographies as pre/post "allow a broader opportunity for descriptions of experiences" and the researchers are able to record "a transition in attitudes based on further experiences" (Ellsworth & Buss, 2010, p. 357). A self-portrait might also provide an opportunity for metacognition and self-assessment by removing the barrier of language and instead relying on a visual and emotional perception of impactful mathematics learning experiences (Mukhopadhyay, 1996). By collecting self-perceptions through multiple, mediums it might also be possible to identify contradictions in reported self-perceptions (Hall et al., 2018).

Data Analysis

Student responses were anonymized by a program intern and given to the researchers with and a code that corresponded to demographic information. Participant responses were compiled, and all data for each participant was analyzed concurrently. Data were first analyzed by the research team using line-by-line open coding. Through this process the researchers generated a list of codes. The research team then used the codes to analyze participant responses. They then jointly read, re-read, coded, and re-coded the data to refine prior codes (Emerson et al., 2011). The codes were revised, eliminated, or added based on discussion by the research team. During team discussion, the lead researcher kept notes on the meanings of each code and discussion points highlighted by the team. The research team used frequency counts of codes to identify major or "grand" themes across the analyzed data. At the time of this proposal, 25% of the data had been analyzed.

Results

Codes constructed by analyzing the data were categorized as more favorable (e.g., math as utilitarian, positive dispositions, communicative approaches) or less favorable (e.g., math as procedural, negative dispositions, teacher-oriented) in terms of participants' views of mathematics as a discipline or of themselves as mathematical doers and thinkers and with support by the mathematics education literature. In looking across the codes from pre-test to post-test in relation to the subset of data analyzed thus far, the most favorable change noted was from participants viewing mathematics as a solitary endeavor to that which involves student interaction in the form of group/peer work. (See Figure 1.) Somewhat less salient, but still notable, was a view of mathematics and mathematics teaching/learning as less traditional (e.g., computational and teacher-oriented) to more a contemporary characterization (e.g., use of multiple paths for solving problems and active student involvement). Overall, responses moved from less favorable to more favorable–or at least neutral–perspectives.

Figure 1: Pre (left) and Post (right) Self-Portraits of Learning Mathematics

Discussion

Our preliminary analysis of participants' letters to mathematics and self-portraits of doing mathematics shows that a five-day OST STEM program for middle school girls can favorably influence participants' perceptions of 1) mathematics as a discipline, and 2) themselves as thinkers and doers of mathematics. For example, in many of the self-portraits on the pre-assessment, students drew themselves alone and completing computations as a critical learning experience. A clear shift took place in the girls' perceptions of learning mathematics in the post portraits, with participants drawing themselves working with other students and communicating about mathematics. This change is, of course, dependent on the type of learning experience provided in the intervention, which was designed to align with dominant current thinking in the field about teaching and learning mathematics.

Cognizant of educational debts (Ladson-Billings 2006) for Latinas in math, as well as for students with Learning Disabilities (LD), we seek to develop understanding of the experiences of Latinas with LD in math classrooms. To do so, we need theoretical and methodological tools to analyze the emotional, embodied experience of learning mathematics within figured worlds of mathematics classrooms. Scholarship on identity in math currently lacks a systematic theoretical and methodological grounding that would allow for critical analysis of both intersectionality, relationships and emotion. Using analysis of a how a Latina with LD was described by her teachers, this paper describes a collaborative, interdisciplinary theoretical and methodological project to develop these theoretical tools.

Keywords: Equity and Diversity; Critical Special Education; Disability Studies in Education

Educational equity demands an increased focus on mathematical learning for students from historically multiply marginalized non-dominant backgrounds. For too long, mathematics education has not done enough to develop understandings of the mathematical experiences of students of color, students with disabilities, and girls, among other overlooked identity and power categories. Additional attention is needed to develop understanding of students' intersectional identities particularly for students of color with disabilities, as very little research exists for this group of students (Lambert & Tan 2020). Bringing the theory of *complex embodiment* from Disability Studies into mathematics education (Lambert 2019; Siebers 2008), we map embodied differences, as well as social construction and feeling-meaning making (Lemke 2013) around those differences creating a new theory of Complex Embodiment in Mathematics. Embodiment matters for how math class is experienced, and how individual and collective feeling-meaning-making happens in mathematics. To better understand intersectionality, we map circulating master narratives and how students are positioned in terms of race, disability, gender and emotionality. To illustrate our arguments, we present data from an ethnographic and interview study of Latinx students with learning disabilities (Lambert 2015).

RQ1: How can we theoretically and methodologically expand complex embodiment to mathematics, including emotion, intersectionality, relationships and the embodied experiences of learners with LD of color in mathematics classrooms?

RQ2: What cultural practices and discourses circulate in the figured world of the mathematics classrooms that position Latinas with LD?

Conceptual Framework

To understand the processes through which individual students come to identify, or not, with mathematics, we use a *practice theory of identity* (Holland et al., 1998). We understand mathematics classrooms as *figured worlds*, activity systems where participants create meaning around through shared participation in cultural practices and discourse. Learning mathematics occurs within racialized spaces (Nasir & Royston, 2013). As individuals participate in figured worlds, they internalize some circulating discourses and reject others, rearranging self-understandings around mathematics (Bakhtin 1981). Contradiction between multiple discourses creates space for change. Circulating discourses can include master narratives (Bamberg & Andrews, 2004) about ability and disability in mathematics (Lambert 2015), as well as stereotypes about race, disability and gender (Lambert 2018; Lambert, Hernández-Saca & Mireles Rios, 2020). Research on Latinx identity processes must account for how students understand master narratives of achievement (Zavala & Hand, 2018). Undergraduate Latinas negotiated a complex set of discourses to be successful in math, some of which were specific to Latina experience such as pressure to be a mother (Leyva 2016). Additionally, research has shown that for Latina elementary school girls showed that more communication where their mom was associated with higher grades in math and liking math more (Mireles Rios & Romo, 2010).

Understanding how important relationships with teachers and peers are for learning mathematics (Black et al., 2009), we seek to understand how relationships with peers in the mathematics classroom and relationships, particularly with mothers, matter for mathematical identity of Latinas with and without LD. We know that while peer support has been found to be important for students of both genders, it may be especially beneficial for adolescent girls' engagement with STEM subjects, given their greater interest in and emphasis on relationships with peers (Fredricks et al., 2018). A study conducted by Riegle-Crumb et al. (2006) found that high school girls who reported having female friends that excel in math and science courses were more likely to subsequently take advanced courses in those subjects themselves. Perceived peer support has also been linked to an increase in adolescent girls' cognitive and social engagement with science and math, and several studies have found that greater perceived support from peers is associated with more positive emotionality towards science and math, as well as greater self-efficacy in these subjects (Fredricks et al., 2018). Peers also play a role in adolescent girls' development of future identities. Thus, a number of studies have demonstrated a link between adolescent girls' relationship with math and science and peer relationships/support. This may be even more important for Latina girls whose teachers may hold lower expectations for their academic achievement (Mireles Rios & Romo, 2014).

Methodology

Using a longitudinal ethnographic case study design, this paper comes from a larger study which analyzes the identification processes of Latino/a focal students and teachers as they participate in a seventh-grade mathematics classroom (Lambert 2015; 2017; 2019). The research was designed to provide multiple data sources, both of the classroom and individuals. At the classroom level, data were collected through participant-observation, video recordings, and classroom artifacts. Interviews were the primary source of data at the individual level. Trustworthiness was established through triangulation of these multiple data sources, concurrent data analysis and member checks.

Participants

The student, Rita, identified herself as a girl, as "Dominican", and as "always good at math." From formal school records, Rita was also a long-term English Language Learner and received special education services for a Specific Learning Disability. She attended a school in which 98% of students were identified as Hispanic, and 85% were classified as low-income. Her school had features that supported the growth of students: stable leadership, teacher autonomy, and a vibrant arts program. The school used a co-teaching model for students in special education, in which a general educator and a special educator shared teaching responsibilities for a class that included both students with and without disabilities. The sixth-grade special education teacher, Ms. Emerson, was white and in her third year of teaching. Her co-teacher, Mr. Pierce, was also white and in his third year of classroom teaching.

Data Collection and Analysis

Multiple sources of data were necessary to understand the relationships between the construction of ability and disability through cultural practices and individual student identity processes including field notes from participant-observation, classroom artifacts (worksheets and photographs of student journals), and video recordings. Teacher level data included field notes, formal and informal interviews, some during class time and others held separately. Student level data included all the aforementioned, with the addition of student interviews. All data was collected by the first author, who also did the initial data analysis. Our collective analysis sessions focused on reanalyzing data through our new theoretical lens.

Findings

We focus in this paper on the relational aspects of our work. Her 6th grade special education teacher, Ms. Emerson, described Rita's entry into sixth grade dramatically:

Ms. Emerson

> [Rita] came in as like, hmmm, for a lack of another way of putting it, the uber special ed kid, cried on her way to school, really was always upset, very, seemingly struggled a lot,
>
> she also seemed like she used to a lot more be between Spanish and English, and I don't know whether it was like . . . fear of speaking in English.

Rita was named as the "uber special ed kid," and the immediate evidence was emotional: "cried on her way to school." This description was painful for the first author to hear, and was very different from observations of Rita, who was a focused and engaged student by the time the first author entered her classroom. The sixth-grade teachers painted a portrait of Rita that I could not understand: "crying," "struggled a lot," "not a lot of basic skills." Rita is positioned here not only as "the uber special ed kid" but also as an emergent bilingual. This highly negative, emotionalized portrayal of a student, however, cannot be understood in isolation, because both teachers used this picture to immediately emphasize Rita's transformation into the confident student observed in class in the second half of the year. Her transformation was understood as relational and embodied, based on her relationship with a girl named Shaundra. As Mr. Pierce narrated it,

Mr. Pierce

> [Rita] took on the persona almost of Shaundra, people just grouped them together [puts hands out, hands come together], *oh there is Shaundra and Rita they are both smart*, and Rita kind of grew into being,[hands together come up] a pretty good student, when at the beginning of the year she seemed not so good.

Rita brought this new set of behaviors, a new role as a serious, smart student into seventh grade, and was easily recognizable as a serious student. Additional analysis of Rita includes her own emerging narrative of herself in relationship to math, which particularly connect to her relationship with her mother, a part of the data that is critically important because it portrays Rita's agentic self-authoring and resistance to being framed as an educational problem.

Discussion

We return to the themes that we believe will deepen scholarship in math identity development: emotional, relational, and intersectional, focusing on the relational. Rita's transformation is relational, through her friendship with Shaundra. This was not the only instance in the data from this study in which students learned mathematics in close relations with friends. Another pair of girls always worked together, one girl counting on her fingers under the table and then whispering her answers to her friend. Friendships and relationships seem critical in the process through which students learn to identify with math, or not. As we noted, interviews with Rita in her 7th grade year focus on her relationship with both math and her mother, which is closely intertwined. We see female relationships at the forefront of Rita's construction of mathematical identity. Her relationships with her friends mediate her learning of mathematics and her relationship with mathematics. Her relationship with her teachers, particularly her Latina seventh grade teacher, mediates her learning of mathematics and her relationship with mathematics. Her relationship with her mother mediates her learning of mathematics and her relationship with mathematics.

We present this work as our emergent theorizing of how complex embodiment in mathematics could deepen current analysis of identification processes in math. Absent from this data is student authoring, which we also include in our data. How does Rita self-author in the face of her positioning? How does she craft a math identify for herself? Again, this analysis of her self-authoring will analyze emotion, relationships, and intersectionality.

MATHEMATICAL ACTIVITY AS A SITE FOR TEACHERS TO DEVELOP A CRITICAL MATHEMATICAL CONSCIOUSNESS

Sandra Zuniga-Ruiz
University of California, Berkeley
zuni5344@berkeley.edu

Mallika Scott
Cal State Fullerton
mhscott@fullerton.edu

Preparing teachers to create more just mathematics classrooms entails supporting disciplinary aspects of teaching while also helping teachers attend to power and privilege. While these aspects of the work of teaching are often considered separately, we are interested in working at their intersection. In this paper, we argue that teachers need opportunities to make sense of ideologies at the interactional level, in mathematical activity. We propose the conception of critical mathematical consciousness, as a framework to support teachers to investigate the ways individual math learning is nested within specific math contexts, ideologies about mathematics, and the larger sociopolitical context. We propose principles to support the development of critical mathematical consciousness, which we illustrate through our respective projects which center mathematical activity as a site to disrupt existing mathematical ideologies.

Keywords: Equity and Justice, Pre-Service Teacher Education

Disciplinary aspects of teaching are often addressed in teacher preparation programs in content and methods courses that are separated from critical and justice-oriented aspects of education. Both aspects matter for preparing teachers; teaching mathematics well depends on thinking deeply about how to support students to make sense of content (Hill & Ball, 2009, Lampert et al, 2013) and understanding the ways injustice is built into systems (Freire, 1996) and shaped and reshaped in mathematics classrooms (Gutierrez, 2013; Gutstein 2006; Martin, 2013). Drawing on the observation of Philip and Gupta (2020) that "it is in interactions that the cultural and historical traces of power are rendered visible, remade, and/or challenged", our work starts from the assumption that preparing teachers to create more just mathematics classrooms entails learning to analyze the ways reproduction of social hierarchies occurs at the interactional level.

To support teacher learning toward this aim, we reconceptualize the role of doing mathematics in teacher preparation as a site to investigate the intersection of mathematical learning and ideology. We view mathematical participation as socially constructed and connected to human activity (Esmonde & Langer-Osuna, 2013; Gresalfi et al., 2009; Nasir & Hand, 2008) and we consider that activity to be shaped by ideologies and the ways they are embedded in discourse, practice, and institutions (Hall, 1981; Philip & Gupta, 2020). As people engage in new forms of activity, disruptions to those ideologies can be created and new ways of being become possible. Doing mathematics with preservice teachers can thus become a productive space to make visible the ways that opportunities for learning are afforded and constrained in moment-to-moment interaction and connected to larger systems of oppression. The approach we outline in this paper aims to bridge disciplinary and justice-oriented aspects of teaching to foster what we call *critical mathematical consciousness*.

Background

To help us conceptualize the intersection of justice and disciplinary learning in the work of teaching, we draw on scholarship that treats learning and ideology as intrinsically linked (Philip, 2011; Philip et al., 2018; Philip & Gupta, 2020). We define ideology as "socially shared systems of representation" that guide how human beings experience and make sense of the world (Philip et al., 2018, p. 4). As people interact with their world, they develop different ideological chains of meaning such as what it means to be mathematically proficient. These systems of representation are intertwined with learning in that "the interactional forging and working out of ideological convergence can either afford or constrain learning as an activity of heterogeneous meaning making" (Philip et al., 2018, p. 6). This conception of ideology as dynamic, constructed in interaction, and shaping learning underlies our approach to supporting teacher learning toward justice-oriented mathematics teaching.

The notion of ideology has been explored in mathematics education in various ways. The sociopolitical turn (Gutiérrez, 2013a) has led to the emergence and understanding of mathematics and mathematics education as a racial project (Martin, 2013). This work helps situate constructions of mathematics and mathematical competence in a cultural and historical context that is designed to uphold racialized hierarchies of mathematical ability (Gutiérrez, 2013b). Building on these ideas, research on racial narratives and storylines has helped to illuminate how ideologies of mathematics and of race intertwine and shape meaning-making in the mathematics classroom (Nasir et al., 2012; Nasir & Shah, 2011; Shah, 2017). Bringing this into the work of teaching, recent work on teacher noticing in mathematics education has begun to elaborate the social and cultural construction of what teachers attend to and interpret in the mathematics classroom and the implications for reproducing or disrupting dominant hierarchies of power and privilege (Louie, 2018; Shah & Coles, 2020; Wager, 2014).

In addition to these approaches to thinking about mathematics and ideology, there is a growing body of scholarship that examines how positioning and power shape identity and participation in mathematical interaction among students in the classroom (Esmonde & Langer-Osuna, 2013; Langer-Osuna, 2011, 2015). While this work does not directly address ideology, these lines of inquiry have helped to elaborate the social construction of engagement in mathematical activity, and the ways this construction is shaped by understandings of social categories and hierarchies such as those related to race and gender. This body of work has informed our thinking about social interactions in mathematics classrooms as functioning to challenge, perpetuate, or create inequities in participation.

The insights we have described above related to learning and ideology and their specific intertwining within the mathematics classroom have led us to reexamine the role of doing mathematics in teacher preparation as a site to begin to develop critical mathematical consciousness. We define critical mathematical consciousness as reasoning and making connections across the different nested layers shown in Figure 1.

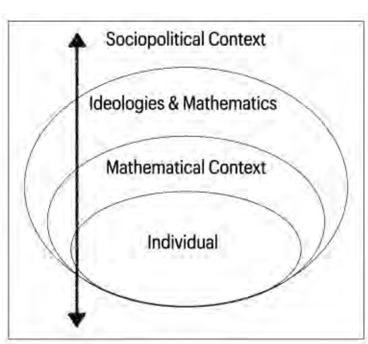

Figure 1: Critical mathematics Consciousness

We define critical mathematical consciousness as reasoning and making connections across the different nested layers shown in Figure 1. This image depicts the ways individual learners are nested within a specific mathematical context that affords and constrains mathematical participation. This context is shaped by narratives and ideologies related to mathematics and mathematical competence, and these in turn are part of a larger sociopolitical context that makes available particular ideological chains of meaning. We consider the work of creating more just mathematics classrooms to entail thinking across these different layers to make sense of the ways mathematical learning is continually shaped and reshaped in interaction. As working toward justice is an ongoing project, in our conception, critical mathematical consciousness is always in progress rather than an outcome or destination.

Fostering a Critical Mathematical Consciousness with Pre-Service Teachers

To support pre-service teachers to make connections across these nested layers, we have developed a set of principles that guide our work: 1) Begin with personal mathematical histories, 2) Situate teachers as mathematical learners, 3) Attend to mathematics as a human activity that involves emotion and relationships, 4) Use personal experiences as math learners to explore and interrogate ideologies toward creating more just mathematics learning environments.

We start with personal mathematical histories as a way to help novice teachers reflect on their own experiences, and begin to consider mathematics classrooms as racialized, gendered, and classed environments that can be experienced quite differently by individuals (Marshall & Chao, 2017). We view testimonios as a productive tool for this principle since it comes with the premise that an injustice exists and demands for a call to collective action (Delgado Bernal et. Al, 2012). For elementary teachers who have had a wide range of experiences during their own math journeys, sharing and discussing personal math histories can also be a place to heal from any anxiety or trauma they may have experienced and to learn from each other's different journeys. Personal mathematical journeys thus serve as a resource for pre-service teachers to begin to connect with young people in the human experience of doing mathematics.

In tandem with reflecting on past experiences, we also seek to expand possibilities for pre-service teachers by providing opportunities to engage with mathematics as learners. Our purposes for doing mathematics differ somewhat from the purposes that have been written about more extensively in the literature of developing content knowledge or mathematical knowledge for teaching (Ball, 2017; Hill & Ball, 2009) and/or learning specific teaching practices (Lampert et al., 2010; Lampert & Graziani, 2009). While we recognize and value these purposes, we also consider mathematical activity to be a generative site for investigating how teaching choices and learning environments function to reproduce or to disrupt existing social hierarchies from a more personal, learner-centered perspective. With this shift in purpose, we hope to support new ways of relating to mathematics, and more expansive ways of thinking about how to design classroom math communities that build from the diverse resources each learner brings to mathematics.

In supporting teachers' as mathematical learners, we treat mathematics as an embodied activity that involves human relationships and emotion. We seek to design mathematical experiences that support learners to bring their full selves as they engage with mathematics (Gutierrez, 2012; Takeuchi & Dadkhahfard, 2019). This requires choosing tasks that are meaningful and invite diverse ways of knowing, fostering productive norms of interaction, and structuring participation so that learners have opportunities to authentically engage with each other's ideas (Bartell et al., 2017). We also encourage reflection as an ongoing component of mathematical activity to help pre-service teachers connect their embodied experience as learners to aspects of mathematical learning environments as well as to ideologies about mathematics and to the larger sociopolitical context.

By centering and attending to mathematical activity in this way, teachers' personal histories and ongoing experiences can then become resources for them to interrogate the ways mathematics classrooms function to reproduce or disrupt injustice at the level of interaction. By offering ongoing opportunities to connect the nested layers of individual, math context, math ideologies, and sociopolitical and sociohistorical contexts, we aim to support pre-service teachers to construct new ideological chains of meaning that challenge injustice as enacted in day-to-day teaching.

Methods and Research Approach

In bringing these principles into our work with pre-service teachers, we draw on social design-based approaches that are founded in Cultural-Historical Activity Theory. Social design-based research focuses on designing at the level of the activity system and thus attends to the ways different intertwined aspects of design, such as the tools and artifacts provided, the roles participants occupy, and the norms that guide interaction, work together to mediate learning toward a shared goal (Engeström, 2011; Gutiérrez & Jurow, 2016; Gutiérrez & Vossoughi, 2010). Across our different research contexts, doing mathematics is a central part of the design of the activity system, so that teachers have ongoing opportunities to think about how mathematical learning is afforded and constrained within nested layers. To design for this shared goal, we attend to the mathematical tasks used, the roles participants are able to take on, the artifacts and tools made available for engaging with mathematics and with ideology, and the implicit and explicit norms that guide interaction. The projects we are working on include the (re)design of math methods courses and the co-design of learning communities with preservice teachers that take place outside of institutional contexts.

Moving Forward

Across our two very different contexts, we treat mathematical activity as a site for beginning to develop a critical mathematical consciousness. Mallika works within the constraints of teacher preparation as it currently exists by infusing an attention to identity and ideology throughout mathematics methods coursework. Sandra works with women of color outside of a formal institution with an explicit attention to rearticulate new meanings with and of mathematics. In both contexts, opportunities for participants to engage in mathematics and then reflect on the experience are treated as central to a rearticulation of ideologies. We acknowledge that the work is complicated and messy and thus the relational aspect of how we engage with one another is important and foundational to productive discussions. In our projects, creating spaces of trust and vulnerability supported engagement with the real tensions and contradictions of trying to engage in critical work in institutions. Such an approach avoids the "rhetoric of 'us' and 'them'" that can sometimes dominate in critical educational spaces (Philip & Zavala, 2016, p.660). We offer a framework and principles to foster critical mathematical consciousness as a way of supporting preservice teachers to grapple with the complexities and nuances of working to create more just mathematics classrooms.

In this paper, we describe the theory guiding the development of microlearning modules connecting noticing and equity in mathematics. Gutiérrez's (2009) four dimensions of equity framework is used to inform the modules. The professional noticing of children's mathematical thinking (Jacobs, Lamb, & Philipp, 2010) is also woven into the module development. We analyze data from preservice elementary teachers' ideas about equity and responses to a video to inform our project and discuss the importance of making equity explicit in mathematics methods courses. Results indicate that preservice elementary teachers' ideas of equity primarily fall into the dominant axes of access and achievement, but also show evidence of the critical axes of identity and power in responses to the classroom video.

Keywords: Equity, Inclusion, and Diversity; Teacher Noticing; Preservice Teacher Education; Instructional Activities and Practices

Culture permeates every aspect of life by definition; thus, it has some impact on how students think about mathematics (Civil, 2018), and should be recognized when considering equitable contexts for the teaching and learning of mathematics. Students from non-dominant cultures should be encouraged to draw upon their experiences to think critically in mathematics. Projects like Funds of Knowledge (Civil, 2007; Moll, Amanti, Neff, & Gonzalez, 1992) propose teaching structures that include and use individuals' unique cultural experiences and knowledge. While culture may be a positive and powerful classroom dynamic, teachers' assumptions about mathematical ability based on any student attributes are an inequity that comes from student culture (Gutiérrez, 2002). Students' understanding of dominant mathematics, or what counts as mathematics, can also hinder equity (Civil, 2014; Gee, 2002) through the reinforcement of their positioning within a cultural outgroup (Gutiérrez, 2008). This research responds to the call for equity to be used as a lens to enhance the collective mathematics education research enterprise by challenging "the false dichotomy between equity and mathematics education research" via the fundamental conjoining of equity concerns with responsive mathematics teaching practice (Aguirre et al, 2017, p. 130). In this paper, we describe the theory that guides the development of microlearning modules integrating noticing and equity in mathematics. We include baseline results from preservice elementary teachers' (PSET) ideas about equity that inform our project and discuss the critical importance of making equity explicit in mathematics methods courses.

Theoretical Frameworks

There is emerging interest in connecting and studying aspects of equity in conjunction with professional noticing (Jong, 2017). For example, both Kalinec-Craig (2017) and Hand (2012) have examined student positioning and power in the context of professional noticing. Such connections are consistent with portrayals of professional noticing as contested and political space (Lefstein & Snell, 2011; Louie, 2018). Regarding the pedagogical activity that might productively influence such spaces, van Es et al. (2017) posited several practices and associated foci for professional noticing that they describe as *noticing for equity*.

Gutiérrez (2009) describes four dimensions of equity as a way to frame the complex ways in which equity plays a role in mathematics education. The dimensions include access (resources children have available), achievement (student outcomes), identity (connecting to students' backgrounds), and power (voices in the classroom and challenging structural inequities). She notes that access and achievement are part of the dominant axis, yielding to the status quo, whereas identity and power comprise the critical axis, confronting or challenging the status quo. Gutiérrez (2002) makes it clear that the two axes are essential, and may even act symbiotically.

Teacher noticing literature frequently emphasizes a cognitive perspective, concerned with the cognition needed to recognize and act on mathematical thinking. Jacobs, Lamb, and Philipp's (2010) work expressly addressed professional noticing of children's mathematical thinking defined as three interrelated components, attending, interpreting, and deciding. Recent studies consider the three components in the context of the broader construct of teacher competence and address a situational aspect of noticing under the perception, interpretation, and deciding, or PID, model (Blömeke, Gustafsson, and Shavelson, 2015). Jong et al.'s (2021) empirical study demonstrated support for this proposed relationship between dispositional resources and noticing (i.e. PID). Santagata and Yeh (2016) further proposed that the continuum is not linear, but that practice, too, influences PID; this idea is evident in Louie, Adiredja and Jessup's (2021) work. These situational, or ecological, approaches to noticing are relevant when Gutiérrez' dimensions of equity (2002). Teacher noticing along both axes has the potential to broaden equity through the dynamic interplay of cognition, attitudes, beliefs and practice with noticing. The microlearning modules incorporate situational noticing to increase PSETs' knowledge and shift their beliefs regarding equity and support the development of equitable noticing practices.

Methodology

Project Design

For this project, we focus on microlearning experiences as an avenue for the construction of equitable professional noticing practices which will enhance learning compared to more traditional modalities across a range of subjects (Mohammed, Wakil, & Nawroly, 2018). The titles of the modules indicate the mathematical and some of the equity-based concepts they contain: Intro to Professional Noticing and Equity, Fractions and Productive Struggle, Number Talks and Smartness, Patterns and Student Work, Functions and Inclusive Story Problems, Ratio and Language, Fractions and Representations, and Social Justice Applications. Instructors implementing these modules start with the introduction but can select which other modules are included based on preference and instructional goals. Each module after the introduction contains a review of the components of professional noticing and the dimensions of equity highlighted in that module, a segment which focuses on the language of teachers and how chosen words can be harmful to students in marginalized populations, and a wrap-up of the theories explored with an opportunity for discussion of the highlighted components and dimensions.

Data Collection and Analysis

PSETs in three sections of mathematics methods courses completed a survey at the beginning and end of the semester in fall 2020. Using random selection, 200 responses from pre- and post-surveys of 50 PSETs inform the initial stage of analysis. The first item inquired about PSETs' own ideas of equity (Q1, Table 1). Then, the PSETs viewed a brief (74-second) clip of a diverse group of second grade students engaging in a number talk. After the video, they were asked one question each concerning the professional noticing components about the video followed by a prompt relating the video to equity (Q5, Table 1). Preservice teacher responses to the two equity items were analyzed through the lens of Gutiérrez's (2009) four dimensions of equity; a codebook was created to determine which phrases would code a PSET response with a specific equity dimension. (e.g., "differentiation, opportunity to learn, teaching in a fair way", were coded as *access*, and "gender, race, connecting to students' lives, or representation" were coded as *identity*). Four members of the research team individually coded each response for the four dimensions to include any/all that applied, and inconsistencies were negotiated by pairs of coders to achieve complete agreement (Campbell et al., 2013).

Results and Discussion

Table 1: Frequency of Responses by Equity Dimensions

	Q1. What does equity in teaching mean to you?			Q5. Describe how equity relates to this classroom scenario.		
Equity Dimensions	Pre	Post	Total	Pre	Post	Total
Access	45	50	95	32	28	60
Achievement	17	23	40	5	7	12
Identity	13	6	19	15	19	34
Power	1	2	3	33	35	68

The Dominant Axis: Access and Achievement

The most common views in all responses were about giving all students the same opportunities or some notion of fairness. While both ideas are basic and could be categorized into the access dimension of equity, there is a distinction between ideas of equality and equity. While we coded access responses with notions of equality or mentions of being "fair" to all students, we also looked for other key indicators, such as differentiation, use of multiple strategies, mentions of manipulatives, and responses that mentioned the use of resources. In a broad sense, the PSETs think equity in teaching does mean some level of fairness; however, those responses of fairness come with varying sophistication. For example, in a pre-response to question 1, a PSET stated "…I will be fair when it comes to all my students. I will try my best to meet the needs of all my students when teaching," which indicates a baseline approach to the notion of fairness. A post-response that addresses and interprets multiple dimensions of equity from a different PSET was,

> "Equity in teaching means that all students are presented with what they need to be successful in the classroom. Despite a child's backgrounds or specific needs, they are able to reach their goals by whatever means possible in the classroom. This means that the teacher provides the necessary components for each student to be successful. This could mean that instruction is differentiated to fit individual students' needs. Each student with an IEP is accounted for and is given the appropriate help. Students with language and cultural differences are given what they need specifically to succeed."

When identifying responses as "achievement", we used codes such as a mention of student success, expectations, standards, quality of education or learning, and references to "correctness" of the mathematics. Substantial increases in the pre to post responses in the achievement dimension were not evident in either question. Perhaps the most interesting outcome was that only twelve of the 100 responses from question 5 contained a reference to achievement, eleven of which mention "correctness" of mathematics. This is likely linked to the specificity of the video and many of the codes from achievement were links to broader scale observations that are not necessarily evident in a short video clip. Those broader scale responses would be evident in question 1 that prompts for their overall understanding of equity. Most of those indicated the teacher let students share responses, regardless of whether it was correct or incorrect.

The Critical Axis: Identity and Power

Limited responses to the first question touched on the dimension of identity by stating that regardless of students' backgrounds, they should have access. One part of a response that was coded as identity stated, "Every student has different life experiences and backgrounds and we have to be aware of these things." It was somewhat surprising that identity responses decreased for the item. While many more included the word "differentiate" in post-responses, this was not enough for the identity code. However, many more responses to question 5 were coded as identity, which increased slightly from pre to post. The limited responses informed the project team of the need to focus more teacher education instruction on students' identity through more interactions that involve connections to students' culture, language, and experiences.

It was somewhat surprising that preservice teachers' responses to question 1 did not include more characteristics of power at the end of the mathematics methods course. In the few instances, there was mention of listening to students and allowing them to share their ideas. Thus, it was not a connection to broader power structures for question 1. However, there was a dramatic increase in the responses coded as the power dimension for question 5. This was likely due to the video including three students who were selected to share their three unique answers to the open-number sentence and an explanation of their thinking. Thus, student voice, sharing strategies, and eliciting multiple strategies were all aspects of the power dimension. The brief video limits connections to the power dimension; however, our goal is for PSETs who participate in the social justice module to empower students to use mathematics to change the world.

Conclusion

Preliminary results indicate a need to engage preservice elementary teachers in more critical dimensions of equity (Gutiérrez, 2009). Students' backgrounds and identities can serve as an asset to teaching, and power can be incorporated as a way for their students to have a voice in their mathematics learning and use mathematics as a tool to analyze the world around them.

Our results show varying operationalizations of complex ideas such as fairness and opportunity. For some, these are signified by the equalizing of instructional practices across students, others see them as the product of differentiation, and for others, these ideas are taken as self-evident and left unclearly defined. Our next analytical steps will be to consider varying levels of each dimension and examine anti-deficit language in responses as we establish a more complex process in understanding PSETs ideas and patterns (Jacobs, 2017). We are encouraged by PSETs' capacity to perceive different dimensions of equity. Across both presented items, we observed each of the dimensions within our response set. Interestingly, although PSETs tended not to personally connect to the equity dimension of power (Q1), when presented with an instructional vignette, PSETs perceived aspects of the power dimension therein. This suggests a relatively broad formation of equity ideas within our sample of PSETs that might connect an instructional moment to broader sociopolitical contexts (Louie et al., 2021).

CONCEPTUALIZAR MÓDULOS DE MATEMÁTICAS QUE INTEGRAN LA MIRADA PROFESIONAL Y LA EQUIDAD

GENDER DIFFERENCES IN STUDENTS' SENSE OF BELONGING IN MATHEMATICS: THE ROLE OF THE INSTITUTION

Ciera Street
Colorado State University
ciera.street@colostate.edu

A student's sense of belonging can strongly influence their decision to stay in STEM. This influence is especially strong for women, who often report a lower sense of belonging in math (Good et al., 2012; Rainey et al., 2018). In this study, we utilize sociopolitical theory to analyze select statements about students' perceived frequency of classroom activities related to sense of belonging from the Progress Through Calculus census survey. Results show that this perception differs between genders, with the majority showing women constituting a higher proportion of low frequency responses and a lower proportion of high responses. We also see this relationship vary across surveyed universities, with further exploration of two particular institutions. We discuss how these results fit within previous literature in this area as well as expand on the sociopolitical perspective around institutional norms about inclusion and exclusion.

Keywords: Equity, Inclusion, and Diversity, Gender, Calculus, Undergraduate Education

In many STEM fields, women remain underrepresented and are significantly more likely than men to switch out before obtaining the degree (Ellis, Fosdick, & Rasmussen, 2016). Women receive less than half of mathematics and statistics bachelor's degrees and this proportion continues to decline (National Science Foundation and National Center for Science and Engineering Statistics, 2017). One factor shown to influence students' decision to stay in STEM is their sense of belonging, referring to "students' sense of being accepted, valued, included, and encouraged by others (teachers and peers) in the academic classroom setting and of feeling oneself to be an important part of the life and activity of the class" (Goodenow, 1993, p.80). This association is particularly important in mathematics and in relation to gender, whereby women in mathematics often report a lower sense of belonging which can mediate leaving STEM (Good, Rattan, & Dweck, 2012; Rainey, Dancy, Mickelson, Stearns, & Moller, 2018). Rainey et al. suggest four areas as especially important for students' sense of belonging: interpersonal relationships, competence, personal interest, and science identity. The combination of these factors all affect a students' sense of belonging in mathematics and could be particularly influential in retaining women in mathematics. Thus we ask in this study (1) What is the relationship between gender and the perceived frequency of certain classroom activities related to a student's sense of belonging? And (2) In what ways does this relationship change, if any, when considering the institution as the bounds of the mathematics culture system?

Theoretical Perspective

The aforementioned characteristics of a sense of belonging interact within the system of the mathematics environment, as informed by sociopolitical theory (Adiredja & Andrews-Larson, 2017). Sociopolitical theory emphasizes the connections between knowledge, power, and identity within the mathematics culture system, encircled by the math classroom, the department, and/or the institution. Knowledge, power, and identity within the system emerge and are often constrained by the norms of the environment, constructed from the words, actions, and relationships therein. The sociopolitical viewpoint questions the currently "accepted" norms within the culture of mathematics, which often inequitably affect students' perceptions of their sense of belonging in the field. Sociopolitical theory rejects student assimilation into the current dominate culture and instead promotes fostering students' sense of belonging within a system that considers, supports, and affords space to various backgrounds and identities.

Methods

The data for this project originate from the Progress Through Calculus census survey from Fall 2017. This survey was administered to introductory mathematics students from 12 different institutions in the US approximately ¾ths into the semester. This survey aimed to explore different aspects of these institutions' mathematics courses, programs, and departments. Included in this survey were statements about students' perceived frequency of classroom experiences on a scale from (1) Does not occur to (5) Very descriptive. This analysis focuses on 8 of these statements as informed by Rainey et al.'s (2018) four categories related to students' sense of belonging in mathematics and Good et al.'s (2012) Math Sense of Belonging Scale. The selected 8 statements are: (1) The class activities connect course content to my life and future work; (2) A wide range of students respond to the instructor's questions in class; (3) The instructor knows my name; (4) Class is structured to encourage peer-to-peer support among students; (5) There is a sense of community among the students in my class; (6) I share my ideas (or my group's ideas) during whole class discussions; (7) A wide range of students participate in class; and (8) My instructor uses strategies to encourage participation from a wide range of students.

The survey asked students to describe their gender identity from selecting all that applied from the following options: Man, Woman, Transgender, and Not listed (please specify), or Prefer not to disclose. To define gender, we grouped respondents into the categories Man and Woman to include any student who selected *at least* Man or Woman, respectively. Students who selected both Man and Woman were placed into both categories. We recognize the limitation that "the process of converting life experience into data always necessarily entails a reduction of that experience – along with the historical and conceptual burdens of the term" (D'Ignazio & Klein, 2020, p. 10). We hope that our gender definition mitigates this reductionism and emphasizes the shared experience of women in an inequitable environment such as in the field of mathematics.

With this gender categorization, our data set consists of 18,061 responses with 10,069 Men and 7,992 Women. We first use descriptive statistics and univariate analysis to examine the overall relationship between gender and students' perceived frequency of the 8 statements related to sense of belonging. We consolidated the answer choices into two bins: Low to represent frequencies of Does not occur and Minimally Descriptive and High to represent frequencies of Mostly Descriptive and Very Descriptive. This removes the middle answer choice to better compare non-neutral responses. After reviewing the overall trends, multivariable analysis assesses these trends across the 12 universities. For each statement, we compare the patterns seen across the universities to the Overall Trend as determined by the univariate analysis. Multivariable analysis then informs our exploration of two institutions as particularly interesting cases with additional qualitative data to supplement and understand their unique results.

Results

Looking at the overall relationship between gender and the perceived frequency of the 8 selected classroom activities shows differences within this perception. Two main patterns emerge. The first is that women constitute higher proportions of Low responses and lower proportions of High responses. This pattern arose to varying degrees, with the largest gender gap occurring in statement (1) (Low gap = 8.6%, High gap = 6.7%) while the smallest gap appears in statement (5) (Low gap=3.3%, High gap=1%). The second pattern shows women constituting the larger proportion of Low responses and being marginally higher but practically equal in High responses. This happens in both statements (3) and (4). Figure 1 shows an example of each of these patterns (the percentages do not equal 100 due to removing the middle response). The results of each statement within this analysis is called the Overall Trend.

Figure 1: Examples of the Two Patterns for Overall Trends

The multivariable analysis of these data adds in the additional component of institution. For each institution, we use bar charts and contingency tables to compare the same relationship between gender and perceived frequency in each of the 8 selected statements. We found that for each statement, variation emerges between the institutions. Each statement has at least two institutions that do not match the Overall Trend. Out of the 12 institutions, two did not fit the Overall Trend in statements (1), (6), (7), and (8), four did not fit in statements (2) and (5), five did not fit in statement (3), and 8 did not fit in statement (4). Figure 2 below showcases different trends across three institutions for statement (7).

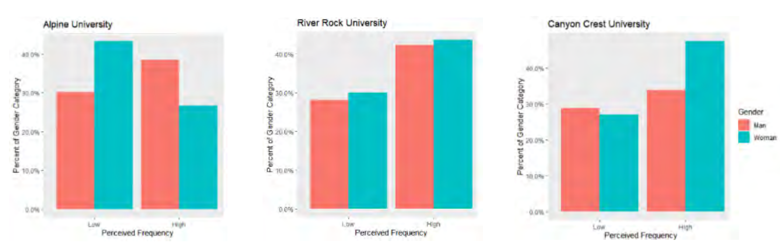

Figure 2: Gender versus Participation across Three Institutions

The Overall Trend for this statement has women constituting a higher proportion of Low responses and a lower proportion of High responses, which matches Alpine University. River Rock University has women producing just slightly higher proportions in both Low and High responses. Canyon Crest University portrayed opposite to the Overall Trend such that women constitute a lower proportion of Low responses and a higher proportion of High responses.

Comparisons of trends within each institution led to noticing two in particular that consistently produced noticeable characteristics across the 8 statements. For all 8 statements, Alpine University follows the trend by which women constitute a higher proportion of Low responses and a lower proportion of High responses (even when the Overall Trend did not represent that pattern) and each statement portrayed the relatively largest gender gap. In four of the statements, Canyon Crest University follows the trend that women constitute a lower proportion of Low responses and a higher proportion of High responses which is not seen in any Overall Trend. Additionally, they represent one of the relatively smallest gender gaps for statements in which they do follow the Overall Trend. To explore these two unique cases further, we brought in pre-collected qualitative data (Fall 2017) providing a thick description of each institution. Table 1 displays six areas of relevant comparison between the two institutions.

Table 1: Areas of Comparison of Canyon Crest University and Alpine University

Area of comparison	Canyon Crest University	Alpine University
Gender percentages overall	47% men and 53% women	54% men and 46% women
Gender counts of survey respondents by course	PC: 94 men and 105 women C1: 58 men and 81 women C2: 50 men and 75 women	PC: 912 men and 886 women C1: 804 men and 619 women C2: 622 men and 183 women
Class sizes in calculus sequence courses (P2C2)	30-40 students across P2C2 courses	50-90 students in PC and C1 20-40 students in C2
Students enrolled in P2C2	454 students	3996 students
Teaching methods	A variety of pedagogy across courses, including lecture, active learning, and IBL	Mainly lecture or lecture with minimal active learning components
Diversity supports	First Year Academic Success program but relatively few initiatives to support HU students in STEM	Emerging Scholars Program focused on HU students but mainly catered to first generation more generally

Discussion

The overall trends we see within the 8 selected statements related to a sense of belonging in math support previous literature in this area. Both Rattan et al. (2018) and Good et al. (2012) found that perceptions of the math classroom differed based on gender, and men often report higher feelings of belonging. The latter result parallels the first Overall Trend where women constitute higher proportions of Low responses and lower proportions of High responses. This perception can have critical outcomes for women pursuing additional math courses. The second Overall Trend may relate to areas in which women are more attuned, thus showing up more prevalently in both Low and High responses. The two statements with this trend particularly connect to student-instructor and student-student interactions, both of which strongly influence women's further enrollment in math (Gayles & Ampaw, 2014, Kogan & Laursen, 2014).

We see important variability in student perceptions across institutions. This supports the sociopolitical perspective in which each institution carries their own mathematics culture that influences the accepted norms around who belongs in that space. Even with the variability, though, many of the institutional trends overall still portray women making up the higher proportion of Low responses. This may imply that many of these institutions still conform to traditional norms of mathematics culture that continue to exclude women students – Alpine University especially fits within this idea. Canyon Crest University breaks from these expectations and portrays a contrary case. The notion of representation may play a role here, with sense of belonging relating positively with the number of same gender peers within the major (Rainey et al., 2018). Not only does Canyon Crest University overall have a higher percentage of women, but in all three P2C2 courses in the survey, women make up the majority. We see that men dominate all of these spheres for Alpine University. The teaching methods may also promote Canyon Crest University's results, as active learning and methods such as IBL can especially support women students in mathematics, while Alpine University utilizes mainly lecture (Cooper et al., 2015; Laursen et al., 2014). Further exploration of these cases will involve looking into how class size may impact instructor-student relationships and the gender demographics of instructors as potential role models.

This paper examines how mathematics teacher-researchers (TRs) talked about students while involved in equity analytic work in a partnership with university-researchers. We draw on interview transcripts from a professional development setting to understand how ideologies of race, gender, and competence became instantiated as the TRs characterized their students as "shy," "quiet", or "confident". We explore how these characterizations may have been shaped by privileged mathematics teaching narratives and the research environment itself.

Keywords: Equity, Inclusion, and Diversity; Gender; Professional Development

Implicit biases and ideologies shape the everyday work of teaching (Battey & Leyva, 2018; Gilliam et al., 2016; Louie, 2018; Philip, 2011). We investigated these biases and ideologies as revealed during teacher-researchers' (TRs) reflections with analytic summaries of student participation. Although implicit race and gender biases have been investigated in laboratory settings (Amodio & Devine, 2006; Gilliam et al., 2016), few studies have examined the impact of teachers' implicit biases in classrooms. Our analysis echoed the innate complexity of equity work (Gutiérrez, 2009) and the ways ideologies about race, gender, and competence can become instantiated in authentic professional development settings. To do so, we attended to social narratives that were indexed in the words and syntax of TRs in reflective conversations with university-researchers (Urs) discussing equity analytics collected in TR's classrooms. We conclude that (a) TRs instantiated ideologies about race, gender, and competence in complex, uneven ways when discussing their students as shy, quiet, or confident (or their opposites), (b) the instantiation of these ideologies cannot be disentangled from (1) mathematics education narratives that assert discourse as necessary for learning and (2) the research environment itself. We explore the nuances of how racial, gender, and competence narratives, as parts of ideologies that shape mathematics teaching, are not statically innate emanating from the minds of teachers.

Racial, Gender, and Competence Narratives in Mathematics Teaching

Racial and gender narratives are dynamic, relational, and context-dependent connections of traits and characteristics to racial (Nasir et al., 2012; Shah 2017) and gender (Langer-Osuna, 2011; Mendick, 2005) identity markers. These narratives are expressed through discourse that hierarchically restricts available positions of individuals and groups (Wagner et al., 2019). Hall (1986) defines ideology as "the mental framework—the languages, the concepts, categories, imagery of thought, and the system of representation—which different classes and social groups deploy in order to make sense of, define, figure out, and render intelligible the way society works" (p. 29). Social narratives are instantiations of racial and gender ideologies. Mathematics education has addressed racial narratives (see e.g., Lei, 2003; Shah, 2017) and racialized gender narratives (see e.g., Gholson, 2016; Gholson & Martin, 2019; Morris, 2007).

Importantly, these narratives do not play out in isolation and impact how students enact and perceive race and gender (Gholson & Martin, 2014) as well as how teachers perceive students' performance (Lei, 2003). The interplay of racial and gender narratives and context have a complex impact on teaching. Morris (2007) noted that the treatment of Black middle school girls was uniquely "influenced by dominant ideas of race, class, and gender more broadly" (p. 510). Elsewhere, educators explained away the non-participation of Asian-American students in athletics with the racial narrative that Asians are not good at sports yet Asian-American students noted racial tensions and employment constraints as the primary factors of their non-participation in school athletics. Crucially, the evocation of these narratives can powerfully restrict students' participation in classrooms and their development of positive identities as students.

We analyze reflection interviews between TRs and Urs to identify words and word combinations that index social narratives, thereby identifying ways TRs may be taking up racial and gender ideologies as they made sense of and talked about data from their own classrooms. This professional development used Complex Instruction (Cohen & Lotan, 2014), which supported discussions of competence, status, and positioning in terms of participation equity.

Data and Methods

This study involves a nine-year partnership focused on facilitating classroom discourse (Herbel-Eisenmann et al., 2017). Across the district, approximately 40% of the students were from non-dominant communities (primarily African American students) and about 35% of the students qualified for free and reduced lunch. About 15% of students were emergent bilinguals. The TRs were aware that studies had documented boys receiving a disproportionately greater number of high-level questions than girls (Sadker et al., 2009) and similar patterns where Black students are relegated to lower-level aspects of mathematical tasks (McAfee, 2014). In 2017-2018, five of the TRs decided to focus on implicit bias in their classroom discourse. In particular, they all focused on identifying students as girls/boys and as Black, White, Latinx, Middle Eastern, and Asian. The TRs were all White, had 10-30 years of experience, and taught a range of secondary mathematics.

We used the EQUIP (Equity Quantified In Participation) app, a classroom observation tool that helps teachers identify patterns of implicit bias (see Reinholz & Shah, 2018) and provides quantitative information on the distribution of participation and participation opportunities to particular groups and individual students. Lessons were video recorded monthly and coded based on which student participated during a given participation sequence and aspects of the participation such as teacher solicitation method. At three times across the school year, the TRs examined their analytics and then were interviewed by one of the Urs.

To surface prevalent descriptors of students, we used Antconc, a concordance software that was designed to work on large data sets. Based on the literature, one co-author used the software to search for and examine particular descriptive words (e.g., confiden*, quiet, loud). Another co-author looked at a frequency list of words generated by Antconc and grouped words based on the kind of descriptor they were (e.g., mental verbs like "reflective"). We compared our lists and focused on a subset of recurring words (e.g., shy, quiet, dominat*, engage, confiden*). In our findings, we focus on these words and answer: How do mathematics teachers index social narratives about race and gender while talking about their students in the context of engaging in equity work? Further, how does teachers' use of language get mediated by norms shaped by situational factors of the classroom and the research setting itself?

Findings and Discussion

We discuss two situational factors that mediated the ways ideologies of race, gender, and competence were instantiated as the TRs talked about their students during debrief interviews related to the equity analytics partnership work. We situate our discussion in the context of other initial findings, to be discussed at length in a subsequent paper, where we counted the number of times the TRs used the terms shy, quiet, and confident/confidence ("confident") to refer to their students across the entire corpus of interview transcripts. The frequencies, disaggregated by the race and gender of the referenced student, revealed that TRs were not consistently drawing on stereotypical racial and gendered narratives about students. For instance, in contrast to the literature, Black girl students were most frequently described as shy and not confident compared to all other demographic groups and were also often described as quiet. These results motivated us to examine situational factors to explain the differences.

Situational Factors: Quiet with Shy and Quiet with Not Confident

We explored how TRs used combinations of "quiet," "shy," and "confident" to describe their students. For instance, Ms. Snow combined quiet and shy to describe Sapphire, a Black girl student. While looking at a bar graph that plotted the number of contributions each student made during four classroom observations, Ms. Snow described Sapphire as "very bright but quiet" and noted Sapphire was "very excited about meeting with [the UR]. She comes up to me one on one and will talk with me. Maybe it's just that she's just nervous or shy." In the same debrief, Ms. Snow noted that the two questions she directed to Sapphire were what-questions which received what-answers. Ms. Snow said, "[I] need to work on that part 'cuz she's a very strong student. She just is very shy, I think, and quiet in class. I need to work on positioning her to be seen as more of a competent student." In these two conversational turns, Ms. Snow's use of "but" and "just" seem to indicate that a "bright" or "strong student" is expected not to be "quiet." This indexes a social narrative of bright students as participatory. The context here is important as the research partnership included discussions about Complex Instruction. Ms. Snow's expressed need to position Sapphire as competent references competence as a status marker in a community of learners and not a static characteristic of a person; this use of status markers and positioning was shared theoretical ground for the Urs and TRs.

This awareness is also evoked when, later, one of the Urs and Ms. Snow looked at the bar graph for question type by race. Although Sapphire was not explicitly discussed at that point, Ms. Snow's desire to position Black students as competent echoed her desire to position Sapphire as competent. The multiple layers of linking quiet and shy revealed the messiness of implicit bias: something is happening because Ms. Snow thought the equity ratios of question type would be better, yet her language did not consistently evoke racial or gender narratives that would suggest a one-to-one implicit bias.

We also identified instances of collocation of "quiet" and "confident": for all but one of these, quiet was paired with low confidence. In one instance, Ms. Hill, described a White girl, Mary, as quiet and added, "I think she's confident though". The use of the contrasting connective *though* positions confidence as a trait contradictory to the behavior of quiet. This languaging of quiet as contradictory to confidence was a part of the other six conversational turns that contained both confident and quiet. One contrasted quiet in a White boy with confidence through the phrase "doesn't have a lot of confidence". The remaining five positioned students who were quiet as having less confidence. Thus, less participation seemed to also index less confidence.

Situational Factors: Gestures and Bars

Here, we look at how the data analytics became an important situational factor in how the TRs talked about their students. Figure 1 shows a scene from a debrief interview with Mr. Smith during which he talked about a bar graph showing various "equity ratios", defined as the amount of actual student participation divided by expected participation based on demographic characteristics, disaggregated by race.

UR:	Let's look at race. I think out of this—I want us to focus on Black students and Latinx students.
Mr. Smith:	I think the Latinx numbers are up cuz they were down at the beginning of the year.
UR:	That's right. I think you have two Latinx students in your class, Maria and Opal, right? I agree. I've noticed that too. If you look at—
Mr. Smith:	Maria's feeling really good right now. She is really taking the bull by the horns, and she's got a ton of confidence.

Figure 1: Debrief Interview with Mr. Smith

The concept of "equity ratio" acquired social meaning when Mr. Smith talked about the equity ratio for Latinx students. Figure 1 began when the UR prompted Mr. Smith to discuss his Black and Latinx students. Pointing to the data visualization, Mr. Smith swept his finger across the screen from right to left while stating, "I think the Latinx numbers are up cuz they were down at the beginning of the year". The phrases "the numbers are up" and "they were down" are reminiscent of increased efforts to use data for instructional decision making and are associated with desirable and undesirable, respectively. Further, Mr. Smith's statement "because they were down at the beginning of the year" and his comment about Maria "taking the bull by the horns" suggest that he equated more participation with something positive.

Mr. Smith might have used similar language without the data visualization, but we find his physical gestures noteworthy. Moving his finger parallel to the horizontal line on the graph, which represents an equity ratio of one, Mr. Smith divides the graph into two pieces. Parts of the graph above the horizontal line are desirable while parts of the graph below it are undesirable. The bar for Latinx students surpassed this horizontal line, and Mr. Smith conjectured that Maria, who "got a ton of confidence", was likely responsible for this increase.

Looking Forward

In this paper, we highlighted how racial, gender, and competence narratives, as part of larger ideologies that shape mathematics teaching, became operationalized in an equity-focused professional development setting. To do so, we explored how two situational factors potentially shaped teacher discourse during such professional development. Our findings suggest that further research is needed to better understand teachers' conceptualization and interpretation of student behaviors and performed racialized and gendered identities within the context of the teachers' pedagogical choices. Such work would provide an understanding of the inconsistent use of words that traditionally index racial and gender narratives.

BLACK STUDENTS' MATHEMATICS IDENTITIES IN RURAL APPALACHIA

Sean P. Freeland
West Virginia University
sfreelan@mix.wvu.edu

The ways in which Black students identify with and experience mathematics is contextual, so it is necessary to explore the peculiarities and complexities of the experiences of Black learners of mathematics in various spaces and geographies while also attending to the intricacies of individual and schoolwide interactions. One context that needs this attention is rural Appalachia. The region is defined by a normative Whiteness and by economic issues, resulting in issues of race being made invisible. This study explores the mathematics identities and experiences of Black students in rural Appalachia. One in-progress counterstory of a Black student in the region is presented here. This highlights the necessity to explore mathematics identity and socialization in the context of rural Appalachia.

Keywords: Equity, Inclusion, and Diversity; Social Justice

Background

There has been a recent sociopolitical turn (Gutierrez, 2013) in mathematics education research that focuses on issues of identity and power in the field. This movement has led mathematics education researchers to bring issues of race to the forefront in their work. Martin (2009) calls for work with an emphasis on the racialized way in which students learn mathematics. It is necessary to examine the ways that Black students and other students of color view their mathematics abilities and develop identities as mathematics learners. While a colorblind lens is popular among some educators, it is essential to recognize that race affects the way that students experience the world and mathematics education (Chapman, 2013). The ways in which Black students are socialized into mathematics is also highly contextual, making it necessary to explore the peculiarities and complexities of the experiences of Black learners of mathematics in various spaces and geographies while also attending to the intricacies of individual and schoolwide interactions (Martin, 2009).

In this work, I apply the focus on racialized mathematics identity and socialization to rural Appalachia. Because of its perceived "rural, normatively white population" (Anglin, 2002, p. 566), little scholarly work has attended to Black lives in central Appalachia and racial issues are often disregarded in the region (Blee & Billings, 2001). Because of the normativity of Whiteness and the monolithic representation of Appalachians as impoverished, class and economic issues are in the forefront of the narrative about Appalachia. This emphasis on "white problems" has created a situation in which racial issues in Appalachia are ignored (Cabell, 1985, p. 3). In fact, some White people see economic concerns as being overshadowed by fights for LGBTQ+ and racial justice (Catte, 2018). The entanglement of race, the economy, and education in rural Appalachia leads me to the following questions: (1) How do Black students construct racialized mathematics identities in rural Appalachia? (2) What experiences lead to this construction?

Theoretical Framework

In order to address these questions, I draw on Martin's (2000) framework for research on mathematics identities and socialization. This tiered framework acknowledges that mathematics learning is affected by the sociopolitical and historical context, the communities and schools in which students live and learn, and students' individual agency and efficacy. This examination of micro-, meso-, and macro-levels (Martin, 2013) of mathematics learning while Black is especially important in rural Appalachia.

Mathematics Identity and Socialization

While there are multiple conceptions of mathematics identities (i.e. Cobb et al., 2013), I draw on Martin's (2000) definition that mathematics identity is students' beliefs about multiple aspects of mathematics learning: their ability to perform, the importance of mathematics, roadblocks and opportunities to learn, and motives and methods for learning. This definition attends to the ability for students to define "what it means to be African-American in the context of mathematics learning" (Martin, 2000, p. 20). Mathematics socialization is closely intertwined with mathematics identity. Martin (2000) defines socialization as the "processes and experiences by which individual and collective mathematics identities are shaped in sociohistorical, community, school, and intrapersonal contexts" (p. 19).

There is an abundant body of extant research examining the construction of the racial and mathematics identities of successful Black males (Berry, 2008; Berry et al., 2011; Noble, 2011; Jett, 2011, 2019). These studies cite a dearth of research on mathematics achievement in Black males and an essentialization of them as lacking persistence and a drive to succeed. A smaller, but growing, field of research uses feminist theory as a frame for studying Black girls and their mathematics identities (Johnson, 2009; Gholson & Martin, 2014; Leonard et al., 2020). The Black feminist viewpoint allows researchers to examine the unique perspective of Black girls in the White male dominated field of mathematics. Some studies on mathematics identities allow for Black males and females to "share theoretical spaces" (Gholson, 2016, p. 297). Many of the studies focused on mathematics socialization also address identity issues (Walker, 2016; Jackson, 2009; Stinson, 2006, 2008, 2011, 2013).

Critical Race Theory (in Mathematics Education)

This study is framed by Critical Race Theory (CRT). Some of the principles that drive CRT have allowed researchers to center educational issues on race and to highlight the way that racial inequities manifest and function in American schools. There is an emerging body of research in mathematics education that uses CRT as a framework for work with Black students (Davis & Jett, 2019). This study draws on the work of various CRT scholars and theorists (Bell, 1980; Harris, 1993; Ladson-Billings & Tate, 1995; Delgado & Stefancic, 2012) and builds on their work to situate it within a context in which race is rarely examined, especially in mathematics education. I draw on tenets of CRT including that racism is endemic in American society and schools, that they are based on property and economics, and that experiential knowledge of Black students is a rich source of knowledge. Other guiding principles are a resistance to neutrality on issues of race and a focus on counterstories from individuals.

Methods

This report is part of a larger, in-progress study being conducted with Black students in West Virginia. I use a critical race methodology incorporating aspects of narrative inquiry. CRT can provide a "methodological instrument for collecting and understanding the perspectives of marginalized groups" (Morris & Parker, 2019, p. 25). Narrative inquiry is the study of human lived experiences in the form of stories (Clandinin, 2013). These stories are embedded in interactions and societal structures, and they relate to power, status, and identity (Atkinson &

Delamont, 2006). This study uses counterstories because "in CRT, narrative is counter-storytelling" (Berry & Cook, 2019, p. 88).

I recruited participants through my work in an after-school science and mathematics program. Through this work, I have a mentorship relationship with the students and have known each of them for multiple years. I first asked the students to write mathematics autobiographies that allowed them to reflect on their experiences learning mathematics throughout their lives. I used these to guide my semi-structured interviews with them relating to mathematics identities and socialization. Autobiographies and interview transcripts were coded according to macro- and meso-level aspects of the context and for examples of mathematics identity and socialization. Critical events (Webster & Mertova, 2007) were also noted, and they guided narrative development. From these codes, I constructed narratives for each student that serve as critical race counterstories (Berry & Cook, 2019). Here I present one in-progress counterstory from the larger study to illustrate the necessity to explore mathematics identity and socialization in the rural Appalachian context. Multiple phases of member checking have happened and will continue to occur, and all quotations in the narrative are LaMarcus' words.

Findings: LaMarcus' Counterstory

Located in the heart of coal country in southern West Virginia is Martin County. LaMarcus has lived in the town of East Branch, "a simple town" with a Family Dollar and a gas station, his entire life. It is a place with little opportunity for recreation or other activities, where you "are more likely to get … a four wheeler or a dirt bike … than a real bike." It is a rural area, and LaMarcus' first descriptor for the town was "poverty." His immediate surrounding community is made up of other Black people, and his school has "a pretty good mix of Black and White" students. This is significant considering the population of West Virginia is less than five percent Black/African American. While already known for its economic issues, Martin County became infamous with the election of Donald Trump and the rise of so-called Trump Country.

> It might not be nothin' like uh compared to what you see on CNN, but yeah. You have your rebel flags all the time especially when Trump came into office and said certain things … I had so many debates with some of the people I know…they be like "He (Trump) saved coal!" and they'll say stuff like that.

LaMarcus attends Hilltop High School which is in a combined building with the middle school of the same name. He refers to Hilltop as a normal high school in West Virginia. However, he believes it is seen as a "black cloud" by surrounding schools because of the relatively large proportion of Black students at the school. This has led to racist comments that end in scuffles in athletic competitions. LaMarcus says that he hears the occasional "N word" at school but that it is not too often. There are occasional fights between Black and White students around racial stereotyping, racism, and racist comments, but "it's not like every month."

LaMarcus' mathematics identity has been consistently defined by his self-professed struggles with the subject which has led to a dislike. He says, "Learning math in elementary and middle school was difficult for me. For most of it I didn't like any of it." It seems that many of his negative feelings towards mathematics come from an embarrassment that has come from being asked to publicly solve procedural problems with speed. He states that, "You had to worry about other people making fun of you for not knowing something." He also cites a mathematics relay race causing anxiety that contributed to his early negative feelings towards the subject.

In middle school, because of lagging grades, LaMarcus was moved to a remedial mathematics class. While not what he wanted, he did believe that his teachers and family had his best interests in mind. However, he worked hard and had positive mathematics experiences to work back to "on-level" courses by his sophomore year of high school. His progress seemingly came undone because of a racist incident at school during that year.

> I had this guy … he said the "N word" and it went from like joking, like I said I don't pay it no mind, but ya know he was joking and ya know and he was playing around and he just end up pushing me a little too hard at one moment and it was just like, I … I snapped. And I pushed him right on back. And that turned into a little fight.

This led to a ten-day suspension from school for LaMarcus. After the suspension, he fell behind in his mathematics class and was placed back in a remedial class in the middle of the year. LaMarcus feels that his time in remedial classes has led to a lack of access to mathematics content that he perceives as important for college, including content that is found on the ACT. About the content on the ACT he says, "I can do certain things. My biggest issue is most of the math … is I've just never seen it before." He believes he has strong skills in real world mathematics and dealing with money, which he perceives as very important. This stems from his time working the cash register at a local store: "But when I had that job working the cash register counting like money and stuff, yeah, it helped me."

While LaMarcus views mathematics as extremely important, mostly from others telling him that it is, he still has developed a frustration from his time in school. It began from a young age when he felt like he did not get the assistance he needed. When asked what could have helped him, he replied, "Maybe got the extra attention that I needed as a kid" in his mathematics classes. LaMarcus is graduating from high school this spring and plans to attend college. Even with his negative mathematics experiences, he is still planning to pursue a STEM career. This pursuit has been aided by his own perseverance, the support of his mother and family, and his participation in an after-school program. LaMarcus would have liked to be a cancer therapist, but he has decided on a career in exercise science because he believes it will require less mathematics. His lack of confidence in mathematics still shows, "Hopefully I can get the proper tutoring if I need it."

Discussion and Implications

LaMarcus' story exemplifies many of the problems facing Black students in rural Appalachia when learning mathematics. First, LaMarcus must deal with implicit and explicit racism on a regular basis. While he often "doesn't pay it no mind," sometimes it leads to a defensive response which in turn affects his academics and mathematics learning. His experiences have also led to a mathematics identity that involves valuing and believing in the importance of mathematics but also feeling like it is a constant struggle. These include a procedural, public, and competitive way of learning and a denial of access to certain concepts or topics. While he has found a way to thrive and to choose a path he is happy with, mathematics is keeping him, at least currently, from what he would really love to do.

LaMarcus' narrative shows the importance of a closer look at the intersection of context and mathematics education, particularly in rural Appalachia. His experiences in Martin County illustrate the endemic racism that is present in the region. While the racism that LaMarcus faces is not unique to Appalachia, its intersection with economics and education is novel and will be examined further in this study. We should also aim for an expanded view of what mathematics teaching and learning can be and what success in mathematics is defined as. Other data in this study will explore the experiences in which LaMarcus and other students have achieved success in mathematics, what assets they bring to mathematics classes that are devalued, and what an ideal mathematics education would look like for them. This study will also look at the nuance of racialized mathematics identities in different locales and schools and in different individuals across the region.

PERSPECTIVES ON REHUMANIZING UNDERGRADUATE MATHEMATICS: ELEVATING THE VOICES OF LATINA AND MIXED-RACE WOMEN

Kelly MacArthur (she/her)

Tracy Dobie (she/her)
University of Utah
tracy.dobie@utah.edu

Building on the recent sociopolitical turn in mathematics education research (Adiredja & Andrews-Larson, 2017; Aguirre, et al., 2017; Gutiérrez, 2013), this research takes up calls to rehumanize mathematics classes (Gutiérrez, 2018) with a particular focus on Latin (Leyva, et al., 2021) and mixed-race women. This case study explores the experiences and ideas of four STEM majors who took a Calculus 2 class with the first author in order to determine what they find rehumanizing in their STEM learning experiences. Using Gutiérrez's eight rehumanizing dimensions (2018), we find that the central themes emerging from these students' comments aligned with the dimensions emphasizing one's participation and positioning, ownership, and living practice. We explore the specific themes arising in these dimensions and discuss potential teacher moves that could help to create more humane mathematics classes.*

Keywords: Calculus; Undergraduate Education; Gender; Equity, Inclusion and Diversity

Introduction

Many compelling arguments have been made for a sociopolitical turn in mathematics education research (Adiredja & Andrews-Larson, 2017; Aguirre, et al., 2017; Gutiérrez, 2013). Gutiérrez (2018) more specifically calls for mathematics courses to be rehumanized with a primary focus on Black, Indigenous and Latin* (Leyva, et al., 2021) students, who the system has failed, and to find ways to identify and draw on their strengths in our research and teaching. Furthermore, focusing on women who belong to these groups is particularly important given the white patriarchal norms that dominate mathematics education in the United States (e.g., Leyva, 2021). These norms, including an emphasis on competition and individualism, create a system that poses particular challenges for Black, Indigenous, and Latin* women in STEM (e.g., Charleston, et al., 2014; Ong, et al., 2011).

This research seeks to center students as experts in their own experiences and explore what concrete steps are being done or can be done in undergraduate mathematics classrooms to move toward rehumanization, specifically for Latina and mixed-race female STEM major students. (Note: We focus on Latina and mixed-race women students because we did not have any Black female students in the Calculus 2 course from which participants were drawn for this study.) In attempting to fill a gap in the research literature in this regard, we aim to answer the following research question: What classroom practices and structures are perceived as rehumanizing by Latina and mixed-race women calculus students? We then use these findings to suggest implications for undergraduate mathematics teaching, also calling for more research including a wider range of voices.

Rehumanizing Mathematics Framework

There have been many calls for mathematics teaching practices that are inclusive and equitable (e.g., Abell et al., 2017; Bressoud et al., 2015; National Council of Teachers of Mathematics, 2014). However, as Gutiérrez (2018) points out, equity is often perceived as a destination, when in reality it should be seen as a continual process. Thus, she introduces the term *rehumanizing* to highlight this focus on action.

Gutiérrez (2018) outlines eight dimensions of mathematics classes that might count as rehumanizing. These include (1) participation/positioning, (2) cultures/histories, (3) windows/mirrors, (4) living practice, (5) creation, (6) broadening mathematics, (7) body/emotions, and (8) ownership. Of particular interest for this paper are domains 1, 4, and 8. The *participation/positioning* category includes shifting the authority and power dynamics in the classroom between teacher and students, with a focus on student relationships and student interaction. The *living practice* dimension includes rule breaking, divergent thinking, and doing math for one's own purposes; whereas *ownership* includes posing new mathematical questions and grappling with math problems outside of school time. To date, there is not a large body of research indicating what students view as rehumanizing, particularly at the undergraduate level. One question this brings up then is what kinds of learning experiences Latin*, Black, and Indigenous students perceive as rehumanizing, which is where we situate this work.

Researcher Positionality

To align this work with explicit calls for mathematics education researchers to consider how our identities impact our research, we'd like to offer some clarity about our positionality as researchers (Aguirre et al., 2017). Both researchers identify as white, cisgender women. One researcher is a tenure-track professor in an education department (focusing on mathematics education), while the other researcher is a teaching professor in a mathematics department (and was the instructor of the focal course being studied in this research). As women, we have both experienced alienation in various male-dominated mathematics spaces. At the same time, we recognize the privilege we have received due to our race. This has led us both to center and learn from the voices of Black, Latin*, and Indigenous women, whose everyday experiences and identities are often not recognized or elevated in the mathematics classroom.

Research Approach & Data Collection

This study was conducted with a small subset of students who took the first author's Calculus 2 course in fall of 2018 at a large R1, predominantly white institution in the western United States. Over a few-year period, and as part of an effort to rehumanize her calculus courses, the instructor implemented many changes in her Calculus 2 courses, including flipping the course structure, incorporating active learning strategies, sending out a weekly email highlighting mathematicians from institutionally marginalized groups, incorporating a class mission statement, and implementing group exams (see Dobie & MacArthur, 2021 for more details on the group exam structure). During the Fall 2018 semester, survey data was collected from all Calculus 2 students who were willing to participate (approximately 84% of the 223 students who finished the course) to better understand their experiences in the course, and with group exams, in particular. Analyses of two survey questions revealed negative or lukewarm sentiments towards the idea of group exams as rehumanizing mechanisms among six Latina and mixed-race women students–standing in stark contrast to the majority of students who expressed positive feelings (MacArthur, 2021). These women were thus identified as candidates for a case study, as a purposive sample (Devers & Frankel, 2000; Patton, 1990), to better understand both their experiences with group exams and their ideas about rehumanizing mathematics, more broadly. Of the six students who were invited to be interviewed, four agreed to participate via Zoom. Denise and Sofia both identified as Latina; Selena identified as white, Asian, and Pacific

Islander; and Lilly identified as white, Hispanic, and Native Hawaiian/Pacific Islander (note that all names are pseudonyms). The case study approach was chosen specifically to meet the goal of reporting a rich description of the experiences of these students (Creswell & Poth, 2018).

Following up from the survey data, a primary theme explored in the interviews was what makes mathematics, and STEM learning experiences more broadly, rehumanizing versus dehumanizing. Specific interview questions in this area explored what it would look like for a STEM learning experience to feel humane; prior STEM learning experiences at the university that the students would describe as humanizing or dehumanizing; views on whether group exams are humane or inhumane, and why; and suggestions for instructors to rehumanize STEM learning experiences and assessments.

Data Analysis of Interview Data

We utilized a thematic analysis process (Braun & Clarke, 2006) to analyze the data from the interviews for all four students. After first transcribing the interviews and reading through the transcripts at least once each, we extracted all excerpts where students identified rehumanizing, or humane, aspects of learning environments. Then we conducted open coding of those excerpts, and organized them into themes, agreeing upon each theme. We then worked together to determine where each of these themes fit within the eight rehumanizing dimensions, leaving open the possibility that some comments or themes might not fit squarely in one of the eight dimensions. All four interviews were coded by both researchers, and any discrepancies were resolved. To increase trustworthiness and credibility, we use direct quotes when sharing our findings in order to convey the students' thoughts and feelings as authentically as possible.

Findings

Themes emerging from these analyses fell primarily into three of the rehumanizing dimensions: participation/positioning, ownership, and living practice. As such, we focus the remainder of our findings within these domains.

In the participation/positioning dimension, three out of the four interviewees focused on how important interaction, dialogue, and relationships are for creating a humane environment in the mathematics classroom. In this dimension, there were two sub-themes that emerged from analysis of these excerpts: (a) accessibility and opportunities for interactions with the instructor and (b) interaction and dialogue with peers.

The first sub-theme focused on the importance of the student-instructor relationship. When asked about how to create humane STEM classes, Sofia stated that "having a good relationship with your professor" and the "support of professors" made classes feel rehumanized. In particular, Sofia highlighted how that support made her math classes "more approachable and less overwhelming." Similarly, Denise noted that her Calculus 2 instructor "became human to me" because of the instructor's attempts to make students "feel comfortable" in the class and because of how she structured the class. Regarding this last point, one aspect of the structure that Denise noted is how the class "permits for social engagement in different ways," a central part of the next theme.

Second, the interviewees frequently commented on how interaction and dialogue with other students in the class felt humane to them. Denise suggested that to humanize the classroom, we need "that aspect of dialogue with other individuals," referring to other students. One aspect of group exams that Sofia found rehumanizing was that students "could all contribute and [they] could collaborate with things they didn't agree on." Selena also emphasized how interaction and collaboration with classmates during group exams made the exams more humane. She spoke of the value of "shared responsibility...as a team," highlighting how it is humane to succeed and fail together, rather than alone. This notion of the value of working together with others was captured by Denise with the term "two-way learning," which she used to center "interaction" and the need to "supplement" one's "knowledge with someone else's and have dialogue."

At the intersection of living practice and ownership, three out of four women commented on the importance of mathematics being relevant for and useful in their lives. Lilly said that math classes are rehumanized when they address her question of "what are we going to use it for?" Denise voiced a similar sentiment, adding that she wanted "real-life applications" as part of her homework assignments, as well, to make math classes rehumanized. Finally, Selena explained that an example provided by an instructor in one of her math classes felt "really useful" to her and like a "real thing that we can do," which "felt rehumanizing."

Discussion

In this study, we learned that the students interviewed perceived discourse and relationships, both between teacher and student and among peers, and real world relevance as playing a dominant role in rehumanizing their undergraduate mathematics classes. Their comments suggest implications for both how we understand the rehumanizing dimensions and how we as educators structure our courses and implement rehumanizing efforts for our students. Regarding the former, the relatively brief descriptions of the rehumanizing dimensions (Gutiérrez, 2018) and little research thus far using the dimensions as an analytical tool leave room for expanding our understanding of aspects that might fall within each dimension. Based on these students' comments, we propose expanding the participation and positioning dimension to consider not only shifted authority to students and a focus on student interaction but also supportive teacher-student relationships that are characterized by opportunities for meaningful interaction with one's instructor. Additionally, findings highlight that some themes cut across categories, and we should not lose sight of these potential rehumanizing mechanisms that do not fit neatly within one category or another, such as real-world relevance.

In terms of implications for educators, working to shift the power dynamics in mathematics classrooms through relationships, interaction, and dialogue can help to rehumanize the math learning environment for undergraduate students. Such moves might be especially powerful for Latina and mixed-race women, as shifting power dynamics helps to move us away from white patriarchal norms that focus on independence and competition (Leyva, 2021). It is also important to note that while we discuss the relationship with the instructor as a rehumanizing mechanism, this relationship should center students and position the instructor as an approachable, accessible support, rather than the authority in the classroom. Finally, instructors should work to make connections between STEM content and students' everyday lives.

Moving forward, research should focus on collecting data from a wider range of women at different institutions, particularly including Black women's voices since they were missing from this study but are critical for this work. Future interview questions should also investigate undergraduate students' perceptions of some of the rehumanizing dimensions not explored in this study. While we did not seek generalizability in this research, we hope that these findings serve as a productive starting point in elevating the voices of Latina and mixed-race women and learning from their experiences.

Acknowledgments

We'd like to thank Selena, Denise, Sofia and Lilly for participating in the interviews and graciously sharing their experiences with us.

(UN)PRODUCTIVE STRUGGLE IN MATHEMATICAL SPACES: WOMEN'S PERCEPTIONS OF COMPETENCE AND BELONGING

Seyda Uysal
Florida State University
su17b@my.fsu.edu

Kathleen M. Clark
Florida State University
kclark@fsu.edu

We present data from a pilot study that took place between Spring 2019 and Spring 2020. The goal of our analysis was to gain a deeper understanding of women and racial/ethnic minority students' experiences during the secondary school-tertiary transition in mathematics. In this brief report, we draw upon a three-dimensional model of attitude (Di Martino & Zan, 2010) to examine students' perceived competence in mathematics and its relation to emotions. We focus on a nascent mathematician's productive struggle in mathematics to discuss associations between perceived competence in mathematics and sense of belonging. We also highlight gendered stereotypes and raise awareness about women's struggles with these during their secondary-tertiary transition.

Keywords: Affect, Emotions, Beliefs, and Attitudes, Equity, Inclusion, and Diversity, Gender, Undergraduate education

Recent studies have documented that women and racial/ethnic minorities persist as underrepresented populations in STEM-related fields (Anderson & Kim, 2006; Nix & Perez-Felkner, 2019). Sax et al. (2015) found that females reported lower mathematical self-concept than their male counterparts despite women's slightly better representation in mathematics discipline compared to other STEM domains. Yet, increases in representation often do not ensure that women and racially/ethnically minoritized students equally participated in public spaces such as classroom discourse. In an examination of classroom discussion, Ernest et al. (2019) found that males tended to dominate public talk even if females similarly contributed to discussions in small groups. While men are typically recognized as full participants of the mathematics community given their stronger beliefs in abilities for success, women must contend with gendered stereotypes to acknowledge their potential in mathematics (Solomon, 2007). Considering the established norms in traditionally male-dominated mathematics communities, women are inclined to question their mathematical competence which has detrimental influences on their mathematician identity construction (Solomon et al., 2011).

Belonging and developing positive feelings are essential social aspects and affective components of meaningful participation, along with communicating mathematically in the process of involvement in a new community (Lave & Wenger, 1992). Women's sense of belonging is prone to decrease when they are exposed to gender stereotyping and environments that view ability as innate and fixed (Good et al., 2012). Sense of belonging to an academic community becomes an important element in understanding and explaining women's representation and perseverance in mathematics (Good et al., 2012). Women's perception of themselves as learners of mathematics is often conflicted with traditionally masculinized mathematical communities, which impacts their belonging and thus limits their participation.

Considering these issues, we address women's perceived competence in mathematics and its potential connection to their sense of belonging within mathematical communities. Next, we highlight certain historical gendered stereotypes and norms that play a role in women's identity construction in becoming a mathematician. Also, we explore how these factors relate to women's participation in mathematical spaces, which can be taken as a component of one's belonging.

Theoretical Perspectives

In our investigation of students' experiences in the transition from school to university mathematics (Uysal & Clark, 2020), we draw upon a three-dimensional model of attitude towards mathematics (Di Martino & Zan, 2011). The model conceptualizes the relationship among and between students' vision of mathematics (i.e., beliefs on the nature of mathematics), perceived competence in mathematics, and emotional dispositions towards mathematics in transition from secondary school to university mathematics Di Martino & Gregorio, 2019). They claimed that first-time experiences in university settings lead students to evaluate their mathematical competence and question the nature of mathematics, accompanied by emotions.

In the study, we investigated affective dimensions of students' experience during their transition from school to university mathematics. However, we also noticed that the social construct of belonging to an academic community is emerged, particularly with respect to the development of women and racial/ethnic minorities' mathematics learner identities (Master & Meltzoff, 2020). Accordingly, we focus on the influence of affective dimensions (i.e., perceived competence and emotions) and sense of belonging on how students perceive of and how they view their participation within the undergraduate mathematics program, especially when considering women's engagement with mathematics as one aspect of their learner identity.

Method

Participants and Settings

The research described in this brief report is part of a pilot study in which we focused on students majoring in mathematics, all of whom were from racially/ethnically minoritized populations (e.g., women, students of color). Twelve students participated in the Women and Underrepresented Minorities in Mathematics (WURMM) pilot study, which took place from Spring 2019 to Spring 2020. Here, we focus on the second seminar, which comprised one component of the WURMM study in Spring 2020. Our overall aim of this seminar was to make sense of students' transition experiences by addressing affective factors (e.g., perceived competence) in mathematics and mathematical identity. Four undergraduate mathematics students participated in the seminar. Three students were pure mathematics majors (Amelia, Dana, and Sunny), and one student (Manuel) was double majoring in secondary mathematics teaching and pure mathematics. We captured students' perceptions of the attributes of mathematicians as a result of addressing notions of mathematics identity and perceived competence in mathematics during the seminar activities. The data sources include videorecording of the four seminar sessions (each session was two hours in duration), post-survey responses, and students' written artifacts from the fourth session's activity. Prior to the seminar, we also conducted interviews with three of the four participants, including Dana.

Session 4 Activity: Exploring Attributes of Mathematicians

We implemented an activity designed to motivate discussion about a mathematician's identity and to capture the prominent attributes of a mathematician from the students' perspectives. The goal of the activity was to prompt students to elaborate on what it means to be a competent mathematician and make sense of students' ideas about their own perceived competence in mathematics. The activity entailed sharing a Google document divided into four quadrants with a guiding question for each:

- Who is a mathematician?
- What does a mathematician do?
- What does a mathematician say?
- What do you consider a mathematician is not?

Each participant populated the document with phrases that captured their response to each question. Additionally, we asked the same questions in the post-survey to provide students with the opportunity to articulate their personal views without the in-the-moment influence of other participants' responses.

Preliminary Findings

In this brief report, we present aspects of Dana's case regarding her perceived mathematical competence, as well as how she described the attributes of a competent mathematician. We found especially remarkable that Dana selected phrases that deviated from those of her peers. In response to "Who is a mathematician?", Dana included attributes of critical and creative thinking. Likewise, in her contribution to "What does a mathematician do?", Dana focused on recognizing relationships and engaging in an action that involves perseverance (e.g., "partake in trial and error"). During discussion on the different attributes, Dana was able to relate her experiences to multiple aspects of interest, such as gender and perceived competence in mathematics, in a way that also manifest affect and sense of belonging in mathematics discipline.

When we asked participants about the salient characteristics of a competent mathematician related to a mathematician's identity, actions, and discourse (i.e., what a mathematician does and says), Dana responded with: "The way in which they communicate automatically provokes thinking critically and stimulates conversation" (Dana, Post-survey 2020). When we probed about how mathematicians can change their confidence, Dana's post-survey response was similar to her previous comment during the seminar: "by 'doing' more mathematics, and by surrounding themselves in a supportive environment that promotes intellectual conversation about mathematics without rejecting the ideas of others" (Dana, Post-survey 2020). Her responses to these two prompts illustrated her perceptions of a competent mathematician that are aligned with participation and engagement in an intellectual mathematical community.

Participants were also asked about their perceived competence in mathematical spaces (e.g., classrooms, study groups). Dana articulated a perception of herself as a mathematics learner conflicted with what she values in a competent and confident mathematician. In the beginning, Dana described a significant aspect of her mathematical confidence related to being able to determine relationships between different abstract concepts as she progressed in her course work:

> I feel as if in a way... it has made me feel more confident, but also less confident for different reasons. Like for example, I feel more confident because of these higher-level math courses. I'm learning about math as this abstract concept and the more I'm just learning about these different concepts and I'm able to connect different relationships that are allowing me to just form different connections and different relationships. And so, in that way, I begin to feel more confident. (Dana, Seminar 2020)

However, Dana also expressed views that seemed to perturb her perception of her mathematical competence and which made her question her mathematical confidence:

> But also [I'm] just less confident. The more I'm surrounded by people that are just really, really brilliant and … I don't know how to explain it. I feel as if, even though I am in the same classes as them and I do have a right to be there, I always just, never built up enough confidence to, like, for example, just ask a question or just be involved and I feel not to turn this into a whole gender thing, but I feel as if … Because … mathematics still is more of a male based subject, it's hard for me to really voice my opinions and voice what I feel. When I am in a group of all guys during a study group or like when I'm just doing partners, you know, I just tend to get less confident. (Dana, Seminar 2020)

Dana's description of her identity as an emerging mathematician evoked emotional responses pertinent to her perceived competence in mathematics and sense of belonging to the mathematics community in which she was participating. Throughout Dana's seminar participation, she presented several examples of tensions in her negotiations of her mathematical identity, particularly in instances of participation as a woman in mathematical spaces. Her previous experiences, such as being one of few young women in her high school mathematics courses, even led her to question her sense of belonging in mathematics as a discipline. Despite these, Dana eloquently described her struggles of rejecting societal norms against women in mathematics as a potential conflict with her participation in the mathematics classroom, despite her outstanding academic success and enthusiasm in mathematics.

Discussion

We sought to demonstrate Dana's ongoing yet productive struggle toward breaking the "glass ceiling" equivalent in the discipline of mathematics, and in the near future, to persist in mathematics as a woman. Dana's significant interest, curiosity, and skills in mathematics are important assets for her to be academically successful in her major. Yet, some of the deficit beliefs on women's perceived competence in mathematics pervasive in a patriarchal society's actions seem to constitute psychological tensions for Dana. Evidence of the lived experience of Dana, a young woman, and a thus-far successful emerging mathematician, demonstrated an example of hidden mathematical competence that takes place when gendered underrepresentation is prevalent (Ernest et al., 2019).

Women, including those in mathematics, are challenged mentally and psychologically which results in an identity negotiation pertinent to what they can or cannot achieve. Challenges related to the masculinity of mathematics might lead women to unproductively question their sense of belonging which has the damaging potential to limit their active participation. Even though Dana believed in her mathematical abilities (i.e., perceived competence), gendered stereotyping (Leyva et al., 2021) appears to have created obstacles preventing her from participating in mathematical discourse—which can be intricately related to sense of belonging.

The secondary-tertiary transition involves many complexities. Consideration of intersectionality in learners' identities such as gender, race, and/or ethnicity can broaden our understanding (Leyva, 2017). The types of obstacles that confront students are also contingent upon a community's culture and systems of power. Individuals' actions are significantly influenced by how they are historically treated and positioned in society according to these values. Our research provides insights into women's experiences with mathematics and illustrates negative impacts of gendered biases on their perceived competence in mathematics. Our pilot study provides a potential new lens from which to examine the complexities of the secondary-tertiary transition and to extend the work of Di Martino and Zan (2011) regarding their three-dimensional model of attitude. Moreover, we highlighted the associations between perceived competence and sense of belonging that inhibit women from participating in mathematics. Our analysis indicates that patriarchal values potentially curtail possibilities for women to demonstrate their mathematical competence and thus perpetuate their marginalization. Therefore, women subtly acquire their secondary role in communities of practice in mathematics, which can have the effect of disregarding their skills and mastery in mathematics.

Recent growth in attention to data has led to calls to incorporate data science education (DSE) into the school mathematics curriculum. Many calls for reform, however, do not explicitly attend to the central role that data, writ large and through associated social structures, play in historical and ongoing systems of inequality and oppression. This paper offers a theorization of the interplay between data and power relevant for education and concludes with suggestions for reimagining K-12 DSE.

Keywords: Equity, Inclusion, and Diversity; Social Justice; Data Analysis and Statistics

A popular movement is underway to include data science education (DSE) as the centerpiece of high school mathematics (e.g., Boaler & Levitt, 2019). This is in parallel with related calls for efforts to improve mathematical, statistical, and quantitative literacies (e.g., Craig, 2018). While claiming that these literacies provide greater access to participation in workforce arrangements, these calls typically do not explicitly attend to power or the central role that either mathematics or data play in shaping and reinforcing systems of oppression. A pattern of simultaneously advocating for inclusion yet failing to attend to power could be seen as being complicit with those systems (Gutiérrez, 2013; Martin, 2019). We problematize approaches to DSE or statistics education that do not attend to, or downplay, power, like Weiland (2017). As an alternative, we explore an intersectional feminist approach to data science put forward by D'Ignazio and Klein (2020).

Playing Versus Changing the Game

Data science, like mathematics, tends to be positioned as neutral and objective (Benjamin, 2019). Yet both play a gatekeeping role that reinforces current hierarchies, particularly around race and gender (Gutiérrez, 2013; Martin, 2019). Gutiérrez's (2007) model of equity along dominant/critical axes is instructive. Its dominant axis includes access and achievement and relates to resources and participation to impact "how well students can play the game called mathematics" (Gutiérrez, 2011, p. 20). The critical axis includes identity and power, which acknowledges students as historicized, racialized, gendered, and classed selves and seeks to "build critical citizens so that they may change the game" (p. 21). DSE is often positioned as essential to playing the game, but less attention has been paid to the need for a DSE oriented around changing the game (i.e., challenging and dismantling the systems, structures, and institutions that produce those inequities). In this paper, we consider the tension between the dominant (play the game) versus the critical (change the game) with respect to K-12 DSE, through a comparative reading of the *PreK-12 Guidelines for Assessment and Instruction in Statistics Education II* (GAISE II, Bargagliotti et al., 2020) and *Data Feminism* (D'Ignazio & Klein, 2020).

Methodological Approach

We chose GAISE II as a text of analysis because it represents an official position of the National Council of Teachers of Mathematics and is endorsed by the American Statistical Association. GAISE II is an update of an earlier GAISE report (Franklin et al., 2005), which championed data and statistical literacy across PreK-12; the update reflects the growth in data science (as an interdisciplinary field, arguably distinct from statistics) in recent years. We chose *Data Feminism* as a text due to its potential to speak to issues of data and power within DSE. We engaged in a discourse analysis of these texts, drawing inspiration from Gee's (2011) building tasks of language. These building tasks are premised on how language builds or destroys "things in the world" (p. 88). We drew on one area of reality built through language according to Gee: the connections building tool, which focuses on how words and grammar build or destroy connections or relevance between things. We created tables of excerpts in which authors used the word "power" to attend to its explicit use and considered, for example, the grammatical role it played, other nouns (e.g., data, counting) being put in relation to power, the types of metaphors, what was indexed in the use of power, etc. We developed a theorization of data and power organized along thematic categories and informed by Gutiérrez' (2011) distinction between playing and changing the game.

Findings

In this section, we present thematic categories that theorize the relationship between data and power in ways that are useful for statistics and DSE practitioners and researchers and illustrate these themes through a comparative reading of GAISE II and *Data Feminism*.

Securing Access to Participate in Systems of Power

The first thematic category refers to who is permitted to participate in the data pipeline and how cultures of data science view and treat people, institutions, and communities. This theme reflects the perspective that access to skills for navigating and innovating with data is a promising path toward economic upward mobility. We found that GAISE II epitomizes the "play the game" perspective, arguing for the ubiquity of data, which, as "models of reality," "shape us," and are a "means of communication, community building, and discovery" (p. 12). "Power" appears three times in GAISE II, to characterize data tools and reasoning as conferring power to individuals to make decisions, to find meaning, and to compute statistics. This power is portrayed as neutral, focusing on the data processes while ignoring the imbalance of power in the contexts in which these processes exist. For example, one extended example in GAISE II pertains to potential statistical studies of music preferences. Despite this subject's racialized nature, there is only a surface-level nod to multiculturalism through the inclusion of genres commonly associated with African American people. Such a move could further alienate marginalized students and would not allow for developing data literacy about race or, as Philip et al. (2016) note, racial literacy about data. An intersectional feminist alternative, instead, acknowledges oppression as a beginning assumption and replaces cautions about bias with goals of data justice and co-liberation.

Reifying Systems of Power

The second category refers to how historical and contemporary data practices shape and reinforce existing systems of power and privilege. Here we expand on Gutiérrez's (2011) play the game/change the game distinction and add that data and data science are used to establish the metaphorical game's parameters. That is, governments, corporations, other institutions, and individuals use data and data science to sway the game and make it systemically unfair. Yet power as a concept scarcely appears in GAISE II. Rather, we note a thematically related emphasis on the importance of interrogating data as a regular part of the data reasoning process. Forms of interrogating appear 18 times across the text. The emphasis of this interrogation of data is on finding potential biases emerging from the processes rather than from existing structural inequality and oppression. That is, human actors–those who use, benefit, or profit from data or those who generate data but are systematically excluded from its benefits or profits–are not mentioned. Nor does GAISE II mention how distinctions among people who benefit or do not benefit from data typically correspond to gender, race, and their intersections.

GAISE II emphasizes the importance of "knowing how and when to bring a healthy skepticism to information gleaned from data" (p. 3). That is, in this text, the science of playing the game is acknowledging and guarding oneself against the fact that the game itself could be unfair by design. It is framed as individual-level self-protection, in the form of skepticism. The GAISE II report stresses the importance of questions that interrogate data but only briefly cautions that "without this interrogation, biases and misuses might emerge" (p. 12). To instantiate this claim, the report points readers to a data-based investigation of criminal justice systems (Angwin et al., 2016), citing that it "reveals inequities" in those systems (p. 12). Even this small mention of bias, especially in relation to a highly racialized and politicized criminal justice system, could be groundbreaking for a mainstream DSE position statement. Nevertheless, we note the use of the tentative and passive tense "might emerge" frames bias as a stochastic process rather than a likely outcome of systemic oppression. This description of Angwin et al.'s report suggests a location of bias in faulty algorithms, rather than as part and parcel of the oppression that is perpetuated by broader, entrenched systems of domination. There is no discussion of using data or data science to change the game, only cautionary references to bias. Myths that people can use data science (like mathematics) to objectively and reliably approximate past, present, and future reality, free from bias or ethical obligation, allow data science to be used as a tool to consolidate and maintain systems of power (Benjamin, 2019). Being a "healthy skeptic" (p. 67), as recommended in GAISE II, can expose unfairness in a dataset but falls short of seeking accountability or justice.

Transforming Systems of Power

The third category centers the capacity for people, institutions, or communities to leverage data practices to redress and challenge existing power relations. This category refers to the use of data to challenge and change systems of power or the transformation of data practices themselves. Whereas the process described in GAISE II emphasizes reflexive, but supplemental, questioning and acknowledgement of cautionary bias, the intersectional feminist approach described in *Data Feminism* takes as a premise historical and ongoing oppression and inequality. Concepts like ethics, bias, and fairness, D'Ignazio and Klein (2020) argue, are inadequate on their own to challenge existing hierarchies.

D'Ignazio and Klein (2020) rely on Crenshaw's (1991) concept of intersectionality and Collins' (2008) matrix of domination and use the term "power" to "describe the current configuration of structural privilege and structural oppression" (p. 24). The concept of power is explicitly woven throughout the text, appearing 192 times in 121 excerpts, in various forms. D'Ignazio and Klein structure *Data Feminism* around seven core principles/chapters, one of which is to challenge power. "Power" appears 50 times in 27 excerpts in this chapter alone.

After showing how data can be used to examine power, D'Ignazio and Klein name a series of actions to challenge power. A starting point is to use data science to expose inequalities. D'Ignazio and Klein refer to the same Angwin et al. (2016) report cited as an example in GAISE II. D'Ignazio and Klein not only describe how the report exposes inequalities in the criminal justice system but also trace how the report spurred legislation in New York City about algorithmic accountability, meaning legal responsibility for an algorithm's impact. D'Ignazio and Klein describe how Angwin et al. used data science methods to prove systemic racial bias in the algorithms that defend processes in the criminal justice system as raceless and neutral. D'Ignazio and Klein caution, however, that equal outcomes ought not to be the guiding goal. Rather, a goal of co-liberation leads to alternative kinds of investigations and projects and demands different metrics and other kinds of relationships with communities. For example, seeking counterdata with and from communities can generate missing stories and needed conclusions. Underlying the recommended actions is how DSE could be oriented with particular goals of demographic shifts in the field of data professionals to include, for example, women, BIPOC, and nonbinary people.

This third category aligns with critical conceptions of equity akin to Gutiérrez's (2011) notion of *changing the game*, which include using mathematics to critique society, examining alternative notions of knowledge, and rethinking mathematics as a field. In the context of data science and DSE, the third category involves a similar range of transformative work that include traditional uses of data to effect change and innovative uses that challenge data science as a field.

Discussion

How might an intersectional feminist view of data and power guide a reimagining of K-12 DSE so as to extend beyond dominant orientations to equity? We raise this question for reflection, discussion, and empirical investigation. An intersectional data feminist perspective suggests that DSE activities need to explicitly attend to power. DSE designs that center power would ask students to not only engage in discussions or demonstrations of discriminatory bias but also reconsider and envision alternative data metrics or measures for data collection and analysis. Second, an intersectional data feminist approach suggests that DSE should be committed to goals of co-liberation. In addition to encouraging students to use data science practices to expose unfairness in their communities and society at large, co-liberation aims to direct students toward dismantling unjust systems of power by harnessing the power of data and reworking data practices. The goal of co-liberation results in a fundamentally different path for DSE and different metrics for what individual and collective success in DSE looks like. We emphasize that co-liberation is not a goal to be pursued "out there" but rather, requires that students be able to find themselves and their communities in data. This suggests a need for educators to make space for this crucial step as an intentional and early part of any instructional design. Such an approach might support better statistical understandings and foster deeper understandings of the relationship between data and power relative to questions or problems that matter to students, which is a necessary precursor to transformative, co-liberatory change.

ENTANGLING AND DISENTANGLING INQUIRY AND EQUITY: VOICES OF MATHEMATICS EDUCATION AND MATHEMATICS PROFESSORS

Amanda Jansen & Center for Inquiry and Equity in Mathematics
University of Delaware & Education Development Center
jansen@udel.edu

Keywords: Equity, inclusion, and Diversity; Instructional Activities and Practices; Social Justice; Teacher Educators

Inquiry – asking and investigating answers to meaningful questions (Brown & Walter, 2005) – is promoted for multiple purposes across mathematics education, including developing meaningful understandings of mathematics (Goldin, 1990), fostering productive dispositions among learners such as self-efficacy in mathematics (Cerezo, 2004), or promoting powerful identities (Melville, Bartley, & Fazio, 2013). Teaching approaches aligned with inquiry include guided reinvention (Freudenthal, 1973; Gravemeijer, Cobb, Bowers, & Whitenack, 2000), discovery learning experiences (Goldin, 1990), or problem-based learning (Roh, 2003). Tang and colleagues (2017) asserted that common themes across inquiry-based mathematics courses, such as student ownership of developing mathematics knowledge or collaborating with peers, can align with four dimensions of equity (access, achievement, identity, and power) (Gutiérrez, 2002). However, the enactment of inquiry-oriented teaching alone does not ensure equitable outcomes or equitable experiences for students (Johnson et al., 2020; Lubienski, 2002).

In this poster, we extend Tang and colleagues' (2017) reflections on alignment between inquiry and equity in pursuit of the following research question: *How and in what ways can inquiry and equity be viewed as intersecting?* Data for this study consists of interviews with 24 professors who identify as mathematics education professors and/or mathematics professors. These professors participated in a week-long summer institute, during which they pursued an inquiry project and reflected equity in the experience of inquiry. During the institute, there appeared to be a shared perspective that inquiry and equity could not be separated. We examined this perspective through two interviews with each participant, the second interview being a member check, and by using a co-writing methodology (Manning, 2018).

Results illustrated three possible categories of intersections between inquiry and equity: (a) equity possibilities and dilemmas are always present during inquiry; (b) equitable inquiry is a vision for how collaborative inquiry can operate; and (c) inquiry can be a vehicle that moves us toward greater equity. For example, equity is always present in inquiry because ways of knowing mathematics are culturally and historically situated (de Freitas & Sinclair, 2020), and inquiry becomes more inequitable if ways of knowing mathematics aligned with the dominant culture are privileged. Power and status dynamics are always at play during collaborative inquiry (Cohen, 1994); equitable inquiry includes recognizing and valuing strengths of fellow inquirers. Inquiry questions that address socio-political issues can provide insights in moving toward a more equitable world (Felton-Koestler, 2020), but inquiry is not enough to achieve equity. Understanding these multiple perspectives can allow colleagues to communicate about their efforts to increase opportunities to engage students in inquiry and to promote equity by anticipating various viewpoints as we dialogue with one another, because different perspectives on equity and inquiry may be held to achieve different goals (Gutstein et al., 2005).

RACE IN MATHEMATICS EDUCATION: WHAT TOPICS APPEAR AND HOW THEY CHANGE OVER TIME?

Sheunghyun Yeo

Keywords: Equity, Inclusion, and Diversity, Social Justice, Research Methods

A growing body of studies has documented racial issues in the field of mathematics education (Wagner et al., 2020). Even though many scholars conducted literature reviews in this field (e.g., Gholson & Wikes, 2017; Larnell et al., 2016; Martin, 2009; Nasir & Hand, 2006), those studies only focused on a particular field. Thus, we have little information regarding what topics appear and how they change over time. In this study, we examined all articles relevant to race and mathematics all time from a database using topic modeling methods (Blei et al, 2003). We focused on the following questions: 1) What are the research topics of race-math related studies that appear in the field of educational research? How do the research topics change over time? 2) How do topics classify into equity framework? How do research trends of race in mathematics education change over time?

We used the ERIC database to collect relevant research studies. After the screening, a total of 1,600 abstracts were used for topic modeling analysis. Based on two indices (complexity and harmonic mean), we agreed 20 was the most reasonable number of topics for this data set. Then, examining top 10 keywords and relevant articles, we labeled the 20 topics. In addition, we classified each topic into the four dimensions based on Gutiérrez's (2012) equity framework which consists of four dimensions: access, achievement, identity, and power. Last, we examined how each topic and dimension evolve over time.

Of the 20 topics, early 2000s seems a critical turning point for racial issues related to mathematics. Especially between 2010 and 2020, some studies related to 'achievement gap', 'academic success in college', 'culturally responsive teaching', 'Achievement of immigrant students', and 'achievement related to SES' topics showed a high increase compared to other topics. We classified 20 topics into four dimensions of equity framework and calculated the weight of each dimension. The achievement dimension took the highest weight followed by access, identity, and power. Only about 25% of the articles were related to identity or power. The studies related to identity and power were rarely conducted before 2005, whereas the studies related to achievement and access were continuously conducted from the 1980s. We found that a majority of the studies found in the search were mainly related to achievement and access. While we found a gradual increase in the studies related to power and identity, these studies took a relatively small portion compared to the other two dimensions, especially achievement. To answer the patterns that we have identified in this present study, an additional study is required to better understand the research trends within each of the four dimensions. The findings of the current study will inform researchers how race (e.g., racial, cultural aspects) and mathematics have been used in and beyond the field of mathematics education.

PRODUCTIVE STRUGGLE EVEN IN MATHEMATICS INTERVENTION? YES!

Lisa Amick
University of Kentucky
Lisa.Amick@uky.edu

Lara Jasien
CPM Educational Program
LaraJasien@cpm.org

Keywords: Affect, Emotion, Beliefs, and Attitudes; Middle School Education; Special Education; Problem-Based Learning

Topic Overview

Inspirations & Ideas (*I&I*; Lindemer et al., 2015) is a problem-based intervention course intended to be a companion course for students enrolled in 8th grade mathematics. *I&I* is unique because it provides opportunities for students who have struggled in mathematics to engage in conceptual understanding, collaboration, critical thinking, productive struggle, and mathematical visualization. The course goals of *I&I* include *(1) creating a community of mathematicians, (2) bolstering students' problem-solving skills, and (3) getting students to fall in love with mathematics.*

Conceptual Perspective

Algebra readiness is a marker of success in the mathematics community, and high school readiness is of equal importance. This research is guided by the perspective that students learn more with contextualized instruction as opposed to a traditional skill-based instructional setting (Boaler, 2002) and that those effective teaching practices can also be successful in intervention settings.

Research Design & Questions

In order to examine the effectiveness of curricular features in reaction to the course goals, this poster draws on data from three distinct studies of *I&I* conducted in the academic years between 2018 and 2020. Each study involved 6-9 teacher participants and their *I&I* students. All three studies included electronic pre- and post- teacher surveys, two studies also included student surveys, and one study included teacher interviews and classroom observations using Swivl technology. Two studies during *I&I*'s pilot year focused on curriculum strengths and growth areas as well as students' interactions and experiences throughout the course. The one study the following year centered on teachers' enactment of the curriculum and how those supported or hindered students' mathematical sense making, learning, and dispositions.

Data Collection Techniques & Analysis

The data from the three studies were aggregated into smaller themes following the recommendations of Creswell (2013). Matched pair responses from pre and post surveys were used to note changes over time, and teacher interviews were utilized to better understand the uniqueness of each class in the study. Classroom observations were transcribed and coded for emerging themes and were used for validation of the emerging themes in the surveys and interviews.

Findings & Implications

Researchers were specifically looking to see if/how the three course goals were being met and how teachers and students experienced and reacted to the curriculum. Data suggest that following one year with the program, students' habits of mind, such as motivation, confidence, and problem solving skills were fostered, as evidenced by pre- and post- survey growth and teacher interview reports. Students' academic achievement also improved, as evidenced by various progress monitoring tools. Teachers reported, "*I&I* took seventh grade followers and turned them into eighth grade leaders." And classroom observations showed evidence of a positive learning communities. These findings were validated with classroom observations that showcased positive classroom cultures. The implications of these findings are vast. This curriculum could be the key to providing equitable instruction for at risk students who need it the most, and could be a tool used to get students both academically and dispositionally ready to be successful in high school mathematics.

DECENTERING WHITENESS IN A SOCIAL JUSTICE MATHEMATICS COURSE

Michael Lolkus
Purdue University
mlolkus@purdue.edu

Keywords: Curriculum, Professional Development, Social Justice, Teacher Educators

While research has moved to investigate whiteness in mathematics education (e.g., Battey, 2013; Harper et al., 2020; Martin, 2009; Stinson, 2011), efforts to decenter whiteness in mathematical spaces, such as equity-oriented pedagogies, can still perpetuate whiteness (Berry et al., 2014; Harper, 2019). Given the need for ongoing efforts to decenter whiteness and produce culturally relevant pedagogies, I detail an action research study (Kemmis et al., 2014) on how a critical investigation of whiteness (Frankenberg, 1993) in a social justice mathematics course I designed (i.e., *Knowing the World Through Mathematics* [*KWM*]*;* Lolkus & Newton, 2020) informs (a) my work as a mathematics teacher educator (MTE), and (b) revisions of *KWM*.

Framing and Methods

Frankenberg (1993) conceptualized whiteness as "the unwillingness to name the contours of racism, the avoidance of identifying with racial experience or group, the minimization of racist legacy, and other similar evasions" (p. 23). While mathematics is often conceptualized as a colorblind discipline (e.g., Stinson, 2011), mathematical spaces often ignore or devalue the values, cultures, and experiences of people of color, and Black and Indigenous communities (Gutiérrez, 2017a, 2017b). To support the examination of racist structures in mathematics education, Battey & Leyva (2016) outlined three dimensions of Whiteness: *institutional, labor,* and *identity.* In this study, I specifically explored the *institutional* dimension, which includes, for instance, how mathematics is often taught as neutral or cultureless, whose voices and histories were privileged, and what forms of mathematical representation were given space in *KWM*. Drawing from action research (Kemmis et al., 2014) and the qualities of critical research in mathematics education (i.e., *current situation, imagined situation, arranged situation*; Skovsmose & Borba, 2004), I engaged in a critical reflection of how I perpetuated whiteness in *KWM*. This action research study foregrounds my efforts, as a white, cisgender, male MTE, to disrupt and challenge the oppressive nature of mathematical spaces that reinforce whiteness.

I used thematic analysis (Braun & Clarke, 2012) to explore all evidence sources. My analysis was guided by a critical perspective (Skovsmose & Borba, 2004), and Battey and Leyva's (2016) *institutional* dimension of whiteness in mathematics education. Following Nowell et al.'s (2017) recommendations for trustworthiness in thematic analysis, I relied on critical friends for triangulation of findings (Flick, 2018), and maintained documentation of the coding and debriefing processes throughout each phase of thematic analysis in reflexive journals.

Summary of Findings and Implications

This action research study informs efforts to decenter whiteness in mathematics education through a critical reflection of implicit connections to whiteness in a social justice mathematics course. I provide preliminary examples of my own complicity in perpetuating whiteness, and how I am taking action to revise the curriculum by centering ethnomathematics (D'Ambrosio & Rosa, 2017) and voices of activists and policy makers central to our mathematical investigations.

DEVELOPING PRESERVICE MATHEMATICS TEACHERS' POLITICAL CONOCIMIENTO THROUGH DATA SCIENCE

Kevin Pelaez
San Diego State University
kpelaez10@gmail.com

Keywords: Mathematical Knowledge for Teaching, Social Justice, Preservice Teacher Education, Data Analysis and Statistics

This poster brings together a discussion about data science education, teaching for social justice (Berry et al., 2020; Gutstein, 2006; Lesser, 2007), and preservice mathematics teachers' (PMTs) political conocimiento (Gutiérrez, 2012, 2017). It is crucial that teacher preparation programs provide experiences for pre-service math teachers (PMTs) to engage with statistics as a pathway to data sc2ience (Gould et al., 2017), including developing statistical literacies. Given the impact of data-informed decisions and centrality of contexts in statistics (Cobb & Moore, 1997), statistics provides an avenue to develop critical literacies (Weiland, 2017). To realize the full potential of statistics and data science, PMTs should be provided opportunities to develop understandings of how statistics classrooms can serve as spaces to learn about data science as well as how data can be used to identify, critique, and challenge social injustices.

Teaching Statistics for Social Justice (TSSJ) is a related body of research (Berry et al., 2020; Gutstein 2006; Lesser, 2007). TSSJ invites teachers to design justice-oriented instruction that interweaves content goals that focus on statistical literacies with social justice goals that focus on critical literacies. Combined, the content and social justice goals may help develop teachers' political knowledge. Particularly, Gutiérrez's (2012, 2017) political conocimiento for teaching mathematics framework builds on traditional teacher knowledge models that include content and pedagogical content knowledge (Ball, 2008; Hill et al., 2008; Shulman, 1986). Political conocimiento adds that teachers also need political knowledge about navigating the sociopolitical landscapes of teaching, such as using data can be used to advance social justice. This research is guided by the following research question: What design features support the development of PMTs political conocimiento for teaching mathematics?

This research discusses the findings of a teaching experiment (TE; Prediger et al., 2015) that uses a social justice approach to teach data science for PMTs. The TE takes place at a four-year public Hispanic Institution in the US-Mexico borderlands of Southern California. The TE includes 12 one-hour lessons on study design and regression. All lessons discuss issues of race and racism in educational contexts. The TE includes 16 participants, 14 of which are PMTs.

This work is in progress, but preliminary findings may be used to guide considerations for designing data science, social justice, and teacher preparation learning environments. For example, to avoid gap-gazing (Gutiérrez, 2008), pedagogies of despair (Giroux, 2001), or reifying deficit narratives, PMTs should consider how data and analyses reflect individual or systemic structures (e.g., how the "achievement gap" may inherently place blame on individuals and does not account for systemic racism). Further, there may be challenges with scaffolding when presenting a social justice problem context. For instance, providing too much information without allowing students to create their own knowledge and judgements may disempower students (Brantlinger, 2013), leading to in the banking method (Freire, 2018) that positions students as passive learning and). Thus, it is important for instructors to allow for multiple entry points for PMTs to develop their own critical consciousness (e.g., learning from community members, being aware of their own positionality, reading related news articles and literature).

DISABILITY IN MATHEMATICS EDUCATION RESEARCH: A CALL TO ACTION

Kathryn R. Westby
Michigan State University
westbyka@msu.edu

Keywords: Students with Disabilities; Social Justice; Research Methods; Doctoral Education

Mathematics education research perpetuates structural and epistemological obstacles to the inclusion of disabled people, as disabled bodyminds are not considered knowledge creators and are excluded from our rank and file through the structures of our doctorate degrees. I use the term disabled to mean a complexly embodied sociopolitical location that is dynamically relational (Kafer, 2013; Siebers, 2011), and I use identity-first language as a reclamation of power that socioculturally situates disability as an identity marker (Andrews et al., 2019). I use the term bodymind as a disruption of the assumption of separation of body and mind and as a call to the embodied impact of oppression (Schalk, 2018). I here call our field to action: expand disability epistemologies in our research and disrupt ableist structures in our doctorate programs.

Through Critical Disability Studies, DisCrit, and Disability Studies in Education, mathematics education researchers have begun to expand epistemologies. Our ontology of disability has been challenged (e.g. Lewis, 2014), and our epistemologies within the experiences of students (e.g., Lambert, 2019), pre-service teachers (e.g., Tan & Padilla, 2019), in-service teachers (e.g., Tan & Thorius, 2019), and instructional pedagogies (e.g., Lambert, 2015). Epistemological assumptions of whose knowledge is privileged have been challenged by Lewis and Lynn (2018). As we continue these epistemological and ontological pushes, I call on us to learn *from* Disability Justice Communities, which remind us that interdependence is pivotal to justice (Sins Invalid, 2019). Through interdependence, we can challenge assumptions that prioritize researchers' knowledge and collaborate with disabled communities.

Additionally, access to the power of "researcher" is kept behind the gate of a doctorate degree, therefore the available researcher standpoints are limited to those who have been able to complete such programs within institutions that continue to instantiate ableist academic structures (Dolmage, 2017). I call on us to push against this gatekeeping. We must interrogate how pedagogies and languages in our courses marginalize disabled students. If we seek inclusive pedagogies and instructional design, then we can move away from compliance as sufficient. Also, we must examine and interrogate program trajectories and requirements to understand their role in exclusion.

The mathematics education research community must privilege the knowledge of disabled people by expanding our epistemologies and our doctorate programs. Three ways we can widen our epistemology are: (a) collaborate with disabled communities; (b) increase liberatory and emancipatory research; (c) learn from disability justice communities. Three ways we can address the gatekeeper aspects of doctorate programs are: (a) interrogate the ways disabled students are positioned in courses, (b) resist the idea of accommodation as a singular *post-hoc* fix, and use inclusive course design and instructional pedagogies, and (c) identify and "try out" ways to increase, without capping, the flexibility of program trajectory. Who conducts our research and how they do so does not exist separate from the inequities of our world. The pandemic has reminded many that disabled bodyminds are lower priority for both disease management and educational systems: we can use this reminder to motivate us to increase equity for disabled people in mathematics education.

INTEGRATION OF MATHEMATICS HISTORY INTO MODEL-ELICITING ACTIVITIES FOR MAKING SENSE OF NEGATIVE INTEGERS

Serife Sevinc
Middle East Technical University
sserife@metu.edu.tr

Busra Ay
Middle East Technical University
bsra.ay4@gmail.com

This study aims to explore seventh-grade students' understanding of negative integers as they engaged in mathematics history integrated model-eliciting activities in small groups. For this educational case study, we designed model-eliciting activities based on six design principles of the models-and-modeling perspective that incorporated history of negative integers. Both written data and video records of students were analyzed to elicit the facets of their models of negative integers. We found that students' thought that either daily life contexts or people's need drove the invention of negative integers. The findings also indicated students' reasoning on the evolvement of mathematics ideas by contribution of different culture, revealing the role of math history integration into the modeling process. In this sense, our study presents a unique approach in modeling literature.

Keywords: History of mathematics; models-and-modeling perspective; model-eliciting activities; negative integers

Negative integers have always been an interesting topic in mathematics education research, and related studies indicated that although students could perform the operations with integers, they struggled in making sense of negative integers (Lyte, 1994; Steiner, 2009). One of the major reasons for this struggle was the difficulty of connecting negative integers with real-life situations (Gallardo, 2002). Therefore, we approached to this phenomenon, making sense of negative integers, from the Models-and-Modeling Perspective that was centered around meaningful situations in developing a mathematical model (Doerr & Lesh, 2003). We, on the one hand, aimed to elicit students' understanding of negative integers through model-eliciting activities; and, on the other hand, incorporated mathematics history into model-eliciting activities. Hence, our study presents a unique approach in modeling literature by addressing the following research question: *What understandings do 7th grade students develop negative integers as they engage in mathematics history integrated model-eliciting activities in small groups?*

In the sections below, we briefly presented our theoretical framework involving history of mathematics and models-and-modeling perspective and presented our findings regarding 7th grade students' understandings of negative integers.

Theoretical Framework

History of Mathematics

The integration of history of mathematics into mathematics education has been on the agenda of many mathematics education researchers (Fenaroli, Furinghetti, & Somaglia, 2014). While some investigated the ways of including historical origins of mathematical concepts in teaching (Tzanakis & Arcavi, 2000), some explored the role of math history in teacher education (Clark, 2012; Fenaroli, Furinghetti & Somaglia 2014).

The use of history of mathematics in mathematics education was analyzed by Jankvist (2009) in terms of reasons (the whys) and integration ways (the hows) of history of mathematics in mathematics teaching and learning. The two main reasons of integration of the history of mathematics are (i) to assist mathematics instruction (i.e., use of history as a tool) and (ii) to learn the history of subject (i.e., use of history as a goal) (Jankvist, 2009). The first reason focuses on improving students' understanding in terms of cognitive and affective aspects of mathematics learning with the help of history of mathematics. The second addresses that history of mathematics encourages students to considering about the evolution of mathematics and role of humanity on the development of mathematics (Jankvist, 2009).

National Council of Teachers of Mathematics (NCTM) pointed out that mathematics is affected by different cultures and inherited to humanity, and students should be allowed to notice and perceive worldwide human effect on the field of mathematics (NCTM, 2000). With this in mind, Jankvist (2009) stated three basic approaches to include history of mathematics in mathematics education: (i) the modules refer to the integration of history of mathematics into a range of mathematics lessons related to topic, (ii) the history-based approach in which mathematics lessons are fully arranged taking the history and evolution of mathematics into account, (iii) the illumination refers to include some historical facts and information in mathematics lessons.

Several researchers mentioned about the benefits of integrating math history in mathematics education (e.g., Fried, 2001; Liu, 2003; Tzanakis & Arcavi, 2000). These benefits can be listed as follows:

- It encourages students to value mathematics as cultural and human product.
- It makes mathematics more interesting, understandable, and attainable for students by helping to perceive mathematical concepts, problems and their solutions.
- It facilitates learning activities by enhancing mathematical thinking ability.
- It affects students' affective dispositions towards mathematics.
- It guides teachers for the learning and teaching activities while asserting that the difficulties mathematicians encountered in the past helps teachers to identify and prevent the problems of students of today.

Regarding the last point, Jankvist (2009) claimed that historical development of a subject provides a parallel path to learn this subject within context revealing relationships between ideas, definitions, and applications: "To really learn and master mathematics, one's mind must go through the same stages that mathematics has gone through during its evolution" (p.239). Similarly, Savizi (2007, p.46) stated: "For students, issues of past real world are more tangible and understandable than today's problems or solving problems from real life by using human approaches may work better than application of complicated methods or offering high amount of information." That also improves students' self-confidence and encourages them to believe in their own abilities as human beings (Savizi, 2007). Moreover, recent studies on this field have indicated that students experiencing mathematical concepts within a meaningful historical context developed more positive attitudes towards concepts (Lim & Chapman, 2010).

When the mathematical concepts are presented as disconnected from real-life, students demonstrate difficulties in understanding the mathematical concepts, and in this vein the integration of history of mathematics enables students to understand the need for the concept (Gulikers & Blom, 2001). Since one of the distinctive features of the modeling perspective was the reality or meaningfulness of the context (Lesh, Hoover, Hole, Kelly, & Post, 2000), we considered the models-and-modeling perspective as a complementary strand of our theoretical frame.

Models-and-Modeling Perspective

The activities with meaningful contexts make students more willing to learn about the subject while they understand the importance of mathematics and real-life relevance of the concept (Lim & Chapman, 2010; NCTM, 2000). The models-and-modeling perspective proposed a problem-solving approach that involves problem-solvers' making sense of the real-life context mathematically, mathematizing the context, and developing a mathematical model that was expressed, tested, and revised iteratively until it provides a sufficient solution for the real-life problem (Lesh & Zawojewski, 2007). The term "mathematical model" refers to the conceptual systems that are built, defined, emphasized mathematically significant products, processes and mathematical reasoning (Doerr & Lesh, 2003). In modeling classrooms, teachers focus on students' understanding and processes of constructing, expressing, reasoning abilities while solving mathematically word problems rather than solely arithmetic computations (Lehrer & Schauble, 2000). However, eliciting students' models was not an easy task, and therefore Lesh and his colleagues proposed a genre of modeling activities called Model-Eliciting Activities (MEAs) (Lesh et al., 2000).

The MEAs involves real life situations in which students make meaningful mathematical explanations (Doerr & Lesh, 2003). To foster students' development of mathematically significant models, Lesh and colleagues (2000) identified six design principles of MEAs: (1) model-construction principle, (2) model-documentation principle, (3) reality (meaningfulness) principle, (4) self-assessment principle, (5) model shareability and reusability principle, and (6) effective prototype principle. Therefore, via MEAs, students produce mathematically significant, shareable and reusable model related to real-life situations. Moreover, these thought-revealing activities allow students assess their thinking and encourage working in groups to produce better models.

With these in mind, we, in this study, integrated history of negative integers into the MEA approach and conjectured that integration of math history would not only take students' interest but also provide them a deeper understanding of negative integers.

Students' Understanding of Integers

There have been many studies investigating how to advance students' understanding of integers by neutralization and number line models (Lyte, 1994). Whilst the neutralization model includes physical objects such as two-colored counters to represent negative and positive integers and operations with integers, the line model focuses on operation with integers considering the position and distance of integers by the direction of movement on the number line (Lyte, 1994).

The concept of negative integers and making sense of the use of negative integers in real-life was difficult for students because it was not as easy to grasp negative integers contextually as natural numbers (Whitacre et al., 2017). There have been several studies arguing that students had difficulty in understanding negative integers as they tried to accommodate their prior knowledge about natural numbers (Gallardo, 2002; Whitacre et al., 2017). This transition between natural numbers and integers led to difficulties in terms of number sense and making sense of the negative integers. In addition, the sense of negative integers and the idea of a number less than zero seemed nonsense for most of the everyday contexts from the viewpoints of students (Whitacre et al., 2017).

Although students meet negative integers in their everyday life, after they encounter and focus on operational procedures in school, they do not make connection between outside-the-school learnings and school instruction (Steiner, 2009). The related studies showed that the real-life contexts, word problems and models including incomes and expenses, assets and debts, elevators, weather temperatures support students' understanding and reasoning about integers (Pettis & Glancy, 2015; Stephan & Akyuz, 2012). However, students might still struggle in comprehending situations involving opposites such as incomes and expenses, weather temperatures and elevators (Pettis & Glancy, 2015). Thus, it is important to encourage students to think within the context to improve their understanding of integers, for which we designed mathematics history integrated MEAs in this study.

Mode of Inquiry

To explore students' understanding of negative integers, we designed mathematics history integrated MEAs and carried out a qualitative educational case study with eight groups of 7th grade students (29 students in total). We explained characteristics of the case participants and the nature of data collection and analysis below.

Participants

The participants of this study were 7th grade students (15 male and 14 female) of a public middle school class in Istanbul, one of the metropolitan cities in Turkey. The students engaged in mathematics history integrated MEAs in small groups and randomly assigned to groups by the second author who was also the mathematics teacher of the classroom. Ten groups were formed in the classroom but only eight of them whose parents provided the consent for their participation in the study were included in the data set. A general view of the mathematics teacher for the participating students was that most of the students' prior knowledge and mathematics backgrounds were similar to each other because they attended the same classes during the primary and middle schools, and their mathematics achievement was average.

Data Collection Procedure

Students' group work was video recorded during the implementation of mathematics history integrated MEAs. There were eight groups containing 3-4 students per group; 29 students in total. The data set involves their written work in activity sheets and video records of their work during the implementation of the activities.

The mathematics history integrated MEAs were implemented with the aim of guiding students to achieve related objectives of middle school mathematics teaching program. The activities covered three dimensions of students' understanding on integers: (i) why negative integers were needed in mathematics, (ii) how to identify positive and negative integers, and (iii) how to use negative integers in real life contexts. In this proposal, we delimited our focus only on one MEA called "The Problem of Diophantus" that addressed the first dimension. The MEAs were designed considering the six design principles and implemented in a one lesson hour. Before the implementation of activities, any prior teaching about integers was not provided to the students. During the implementation of the activities, students were expected to reflect their understanding and making sense of negative integers. The essential principles followed during the implementation sessions were: (i) students should study as small groups and interact with each other, (ii) after they finished their studies, students should be encouraged to share their works and opinions with the guidance of teacher during whole class discussion, (iii) teacher should guide students when they needed without providing any right answer for the questions of the activities, and (iv) students should be allowed to reveal and reflect their own experiences by making connection with everyday life contexts.

The Problem of Diophantus. In this MEA, we aimed to take students' attention to the origins of negative integers. First part of the activity emphasized how people use the negative integers in daily life and why people needed negative integers in the history. The researcher intended to help students to consider and question necessity and need for negative integers not only for mathematical operations but also in everyday problems. The second part of the activity contains information about Diophantus, a mathematician, and is followed by a problem (i.e., 4×?+20=4) which is called as "absurd" by the Diophantus because of its' negative solution (Hettle, 2015). Students were expected to write a letter explaining their rationale for why mathematicians needed negative integers, their solution to the Diophantus's problem, and their reasoning for why Diophantus might have called the solution as absurd. Although not readable, the screenshot of the MEA (in original language) was given below to help readers make sense of the material that students received as a math history integrated MEA.

Tatilde okuduğum bir matematik dergisinde yazanları size anlatacağım. M.Ö. 2. yüzyıl ve 4. yüzyıl arasında Diophantus adında İskenderiyeli Yunan bir matematikçi yaşamış ve bizim g6. Sınıfta öğrendiğimiz cebirsel ifadeler konusunda çalışmış ve 130 problemden oluşan Arithmetica adlı bir kitap yazmış. Diophantus "cebirin yaratıcısı" olarak biliniyormuş. Aslında cebir çok daha önceki zamanlarda bile kullanılıyormuş. Merak edip araştırdım Rhind Papirüsü de M.Ö. 1650 yılında Mısırlı Ahmes tarafından yazılmış ve çarpma, bölme, cebirsel ifadeler gibi konuları içeriyormuş. Birçok ileri matematik konusunun gelişimine katkıda bulunan eski uygarlıkların ve matematikçilerin negatif tam sayıları anlamaları aslında çokta kolay olmamış ve çeşitli zorluklar yaşamışlar. Tıpkı bizim gibi!

Arkadaşlar dergide Diophantus'un bir problemin çözümünde karşısına çıkan

$$4 \times ? + 20 = 4$$

ifadesinin çözümü için "absürt (saçma)" ifadesini kullandığını okudum.

1. Acaba Diophantus neden bu problemin çözümü için saçma demiş olabilir?
2. Arkadaşlar soru işareti yerine gelecek olan tamsayıyı bulmama yardım eder misiniz?
3. Diophantus'un kendinden önceki cebir çalışmalarını bir araya toplayarak geliştirmesi bize matematik bilimi hakkında ne fikir verebilir?

Cevaplarınızı ve açıklamalarınızı bana mektup olarak gönderirseniz okul dergisindeki yazımda paylaşacağım. Mektuplarınızı dört gözle bekliyorum.

Sevgili Ali,

Figure 1: The Problem of Diophantus MEA-Part 2

Data Analysis Procedure

Students' performances on MEAs were recorded in written form on activity sheets and as video and audio records. These written data were coded through two cycles: (1) initial coding and (2) descriptive coding (Saldana, 2009). In the first cycle, the written data of each group first examined holistically, and then open codes were identified to make sense of students' conceptions. In the second cycle, these open codes were revised to create categories that were more descriptive of students' conceptions. Afterwards, the resulted codes were checked with the video and audio data. Specifically, audio and video records were not coded separately but used to make sure about students' conceptions written in the activity sheets.

The codes were then checked by another researcher, the first author, for the interrater reliability (Lincoln & Guba, 1985). Multiple sources of data helped to triangulate the findings. In addition, the second author, implementer of the MEAs, kept a research journal during both data collection and data analysis. Writing each step of the study transparently contributed to the credibility of the interpretations (Lincoln & Guba, 1985).

Findings

In this section, we present the findings including seventh-grade students' models of the negative integers that they developed during their small group engagement in math-history integrated MEAs. Lesh and Harel (2003, p. 150) defined the models as "conceptual systems that generally tend to be expressed using a variety of interacting representational media, which may involve written symbols, spoken language, computer-based graphics, paper-based diagrams or graphs, or experience-based metaphors." Hence, the students' models presented in this section were in the form of verbal descriptions and mathematical symbols and more importantly indicated their conceptual structure of negative integers.

Making Sense of Appropriate Contexts for Negative Integers

Seventh grade students' understanding of negative integers were associated with four contextual situations: (i) representation of weather temperature, (ii) representation of the debt and loss, (iii) representation of elevation, and (iv) an indication of floor numbers in elevators. Although the last two situations were related, students differentiated them. Group #1 and #5 identified a reference point and indicated that the interval below the reference point would be considered as negative. For Group #1 the sea level was a reference point (zero), and below sea level is represented with the negative integers. Similarly, Group #5 accepted the ground floor as a reference point (zero), and they represented the flats under the ground floor with negative integers. On the other hand, the fourth context, indication of floor numbers in elevators, referred to a static position. For instance, Group #2 and #4 stated that the buttons in the elevator included negative integers as symbolic representations of the levels of the floors.

Furthermore, students reasoned about the origins of negative integers and why people needed them. In this regard, Group #2, #4, and #5 stated contextual reasons and Group #1, #6, and #8 indicated that people such as mathematicians, scientists, folks needed and invented negative integers to illustrate the values less than zero. Groups considering contexts such as very cold weather, and debt and loss situations stated that people needed negative integers for their daily life requirements such as trading. For instance, one of the students from Group 5 stated that "one day, when the weather was too cold and snowy, people used negative integers to express the very cold weather." Students mentioning the scientists or mathematicians, on the other hand, stated that people needed to represent numbers less than zero: "A scientist might have invented negative integers to help his calculations with a scientific experiment" (A student from Group #1).

Making Sense of the "Absurd" Problem of Diophantus

In the second part of the MEA, groups were expected to write a letter to help a peer student's school magazine involving their thinking about the problem of Diophantus and possible reasons of why this problem might have called "absurd" by Diophantus. All groups of seventh-grade students thought that it was due to the lack of knowledge of negative integers by then. Regarding this, they had two slightly different aspects:

- A problem is called absurd when one does not have the knowledge of negative integers.
- A problem is called absurd when one cannot find a solution for a mathematics problem.

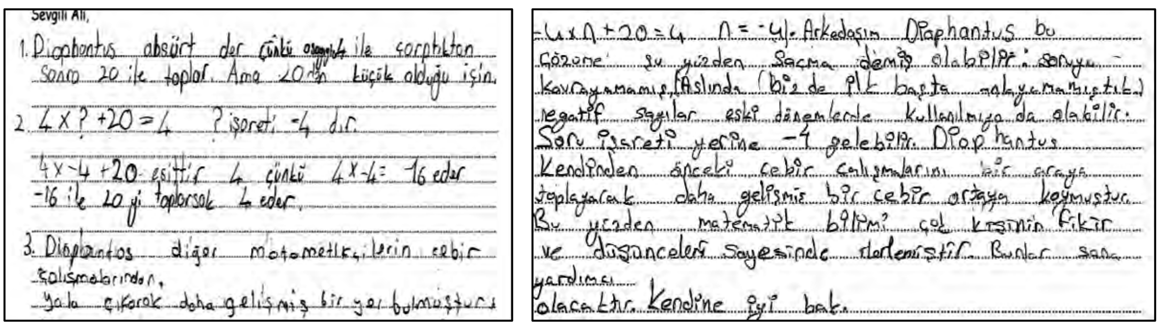
When students engaged in finding the value of the unknown shown with a question mark on the given problem (i.e., 4x?+20=4), the students used trial and error method in two different ways:

- Some groups stated that the unknown cannot be a positive integer, so they accepted the unknown as a negative integer. They tried negative integers respectively to find the value of unknown.
- Some groups tried zero and positive integers at first, but they didn't find a correct solution. Therefore, they tried negative integers to find the correct value for the unknown.

Moreover, groups discussed their interpretations about how mathematics evolved, considering the given information that Diophantus gathered the algebra studies before his era and developed his studies based on the prior work of other mathematicians. Students' discussion revealed three aspects:

- Mathematics is a continuously evolving field.
- A single math idea was developed by contribution of many peoples thinking and studies.
- Various mathematicians and cultures contributed to the field with their work evolved one after another.

These aspects along with the two ways of using trial and error method that were associated with how students made sense with the absurdity of the answer indicated the facets of students' models of negative integers. These facets were illustrated in the letters of the two groups given in Figure 2a and 2b below.



Sevgili Ali,
1. Diophantus absürt der çünkü 4 ile çarptıktan sonra 20 ile toplar. Ama 20'den küçük olduğu için.
2. 4 x ? +20 = 4 ? işareti -4 dir.
4 x -4 +20 eşittir 4 çünkü 4 x -4 = -16 eder
-16 ile 20 yi toplarsak 4 eder.
3. Diophantos diğer matematikçilerin cebir çalışmalarından,
yola çıkarak daha gelişmiş bir yol bulmuştur.

-4 x n +20 = 4 n = -4 Arkadaşım Diophantus bu
çözüme şu yüzden saçma demiş olabilir: soruyu
kavrayamamış. (Aslında (biz de ilk başta anlayamamıştık.)
negatif sayılar eski dönemlerde kullanılmıyor da olabilir.
Soru işareti yerine -4 gelebilir. Diophantus
kendinden önceki cebir çalışmalarını bir araya
toplayarak daha gelişmiş bir cebir ortaya koymuştur.
Bu yüzden matematik bilimi çok kişinin fikir
ve düşünceleri sayesinde ilerlemiştir. Bunlar sana
yardımcı
olacaktır. Kendine iyi bak.

Figure 2a and b: The letter of Group #2 (on the left) and Group #7 (on the right)

As the letter of Group #2 stated, the problem was called absurd since the unknown number multiplied by 4 and added to 20 and somehow the result would be less than 20. Similarly Group #7 expressed that negative integers were not known in the past, and so the question did not make sense; that's why the given problem was called absurd. Students in Group #7 also stated that mathematics developed with the help of many people's opinions and Diophantus collected and improved the algebra studies based on the prior work, which was also observed in other groups' letters. Hence, with help of the math history integrated MEA, students could develop a rationale about the historical development of mathematics and improved their understanding of why people needed negative integers in daily life.

Conclusion and Discussion

We observed that seventh-grade students who encountered the integers formally for the first time with math history integrated MEAs found the topic interesting. The MEAs not only took their attention but also motivated them to understand why people needed integers in the history and what kind of mathematics equation would lead to a negative integer answer. Developing models of negative integers in small groups could reveal students' understanding. More specifically, although they used symbolic representation of a negative integer in their explanations, they also supported their statements with the contextual illustrations. Real-life contexts identified by the participating seventh-grade students included incomes and expenses, assets and debts, elevators, and weather temperatures, which were also observed in the related literature about integers (e.g., Stephan & Akyuz, 2012; Pettis & Glancy, 2015).

One of the major contributions of this study was integrating mathematics history into the modeling perspective, which has not been present in the related literature yet. This integration increased the motivational and attitudinal effect of MEAs as Savizi (2007, p.46) stated: "For students, issues of past real world are more tangible and understandable than today's problems or solving problems from real life by using human approaches may work better than application of complicated methods or offering high amount of information." To illustrate, in the Problem of Diophantus MEA, students studied on a problem called "absurd" by the Diophantus because of its' negative solution and noticed that Diophantus also did not make sense with the problems, likewise the students who sometimes do not make sense with math problems.

In this study, math history integrated MEAs activities brought real-life related mathematics problems from the past and the present together. After the implementation of the MEAs, most of the students expressed their wishes to continue mathematics lessons by working on similar modeling activities, which confirmed other researchers' claim that including history of mathematics could help students overcome their math anxiety (Liu, 2003; Tzanakis & Arcavi, 2000). Similar arguments regarding the affective benefits of modeling experiences were also exist in the models-and-modeling literature (English, Lesh & Zawojewski, 2003). In this sense, mathematics history integrated MEAs were beneficial tools to create a meaningful and real-life related learning environment in which modeling is significant not only for computing, but also for constructing, describing, mathematical reasoning and understanding (Doerr & Lesh, 2003). Comprehending the situations involving opposite directions such as incomes and expenses and cold and hot weather was not easy for students (Pettis & Glancy, 2015), but possible with encouraging students to think within the context (Whitacre et al., 2017). Furthermore, focusing on only operations with integers in school hindered students' understanding of situations involving negative integers in real-life problems (Gallardo, 2002). Our study showed that with the help of mathematics history integrated MEAs, students made sense of negative integers in historical situations.

This study involved three mathematics history integrated MEAs and in this proposal we focused only on one of them. Although the implementation of the activities was arranged considering the middle school mathematics teaching program and limited with the annual plan of mathematics lessons, more meaningful data about the students' understanding of negative integers might reveal if more time was spent and more activities were implemented. Another suggestion could be expanding the use of math history integration into different mathematics topics. In other words, we recommend a future research considering different mathematics topics in different grade levels for the integration of the mathematics history into the modeling perspective. Although the present study investigated the role of mathematics history integration into MEAs on students' understanding, these activities can also be used to improve mathematics teachers' education for their teaching repertoire. Thus, this study also suggests a professional development aiming to train teachers how mathematics history and modeling perspective can be used to enhance students' mathematical understanding.

WHEN IS A GUESS MORE THAN JUST A GUESS? MIDDLE-GRADES STUDENTS' GUESS AND CHECK STRATEGIES

Karen Zwanch
Oklahoma State University
karen.zwanch@okstate.edu

The appropriateness of guess and check as a problem-solving strategy has been debated. This qualitative study examines the use of guess and check by middle-grades students to solve linear systems of equations. Students' reasoning is examined within the number sequences framework, which is based in part on students' units coordination. Only students at the fourth and fifth stages (out of five) correctly solved systems of equations algebraically; this is attributed to their operations on two- and three-level unit structures, and to a disembedding operation. Students at the third stage applied strategic guess and check methods, which is attributed to assimilating with composite units (i.e., units of units), but these students could not correctly use an algebraic method. For students at the second stage, guess and check was non-strategic, which is attributed to their construction of composite units in activity. Implications for instruction are discussed.

Keywords: Algebra and Algebraic Thinking; Middle School Education; Number Concepts and Operations

Literature Review

Guess and check is a common strategy for students to apply in problem solving situations (Johanning, 2004). *Systematic guess and check* is form of reasoning in which a student "works with the situational context and applies relational reasoning to solve the problem" (Johanning, 2010, p. 123). Thus, students operate within the problem-solving context while simultaneously reasoning about the quantitative relationships to arrive at increasingly better approximations of the solution. More general definitions of guess and check range from trial-and-error (Gallagher et al., 2000), which may or may not be systematic, to "random guess and try" (Capraro et al., 2012, p. 112).

Guess and check is particularly relevant to solving algebra problems. While Knuth and colleagues (2006) define guess and check strategies as pre-algebraic, Kieran (1996) describes global meta-level activity as an algebraic activity that aligns closely with systematic guess and check. Therefore, it is unclear to what extent guess and check, and particularly systematic guess and check, is a productive algebraic strategy.

Johanning (2010) asked middle-grades students to solve linear systems of equations word problems and found that systematic guess and check was the most common method applied. She argued that guess and check is algebraic in nature and supports students in developing more sophisticated algebraic methods. By this rationale, systematic guess and check is a worthwhile skill with the potential to improve students' reasoning about systems of equations. In contrast, Malloy and Jones (1998) found that eighth-grade students who applied guess and check to linear systems of equations problems often failed to find a solution and did not initiate the use of alternative methods when guess and check failed. As these studies demonstrate, the conclusions surrounding the productive nature of guess and check are inconsistent. Furthermore, the research does not offer a theoretical rationale for students' widespread dependence on guess and check. This study asks, in what ways do the number sequences account for students' guess and check solutions to linear systems of equations? And, are students' strategies for solving systems of equations more closely tied to their number sequence or course enrollment?

Theoretical Framework

Olive and Çaglayan (2008) framed middle-grades students' algebraic solutions to linear systems of equations within their units coordination. The number sequences are based on units coordination (Steffe, 2010; Ulrich, 2015; 2016a), but also take into account mental operations such as iterating and disembedding (Steffe, 2010). This allows the number sequences to distinguish among three groups of students with varying stages of fluency operating with composite units (Ulrich, 2016b). Students who have constructed the tacitly nested number sequence (TNS) construct composite units in activity (Steffe, 2010); students who have constructed an advanced tacitly nested number sequence (aTNS) assimilate with composite units (Ulrich, 2016b); and students who have constructed an explicitly nested number sequence (ENS) assimilate with composite units, iterate units of one, and disembed (Steffe, 2010). Zwanch (2019, in review) demonstrated that the distinction among these three stages can be used to model their representations of multiplicative algebraic relationships. As such, the number sequences will be used to analyze students' use of guess and check to solve linear systems of equations.

Tacitly Nested Number Sequence (TNS)

TNS students assimilate with one level of units and construct a second level, or *composite unit*, in mental activity (Steffe, 2010; Ulrich, 2015). The operations of a TNS support double counting because TNS students can monitor the number of times that they count on. Consider the problem asking, what is seven more than 24? To a TNS student, the number word "seven" stands for a counting sequence from one through seven, but in mental activity can be chunked into one composite unit containing a counting sequence of seven units. Thus, TNS students can transpose the counting sequence to monitor their counting beginning at 24 and increasing to 31.

TNS students' algebraic reasoning. TNS students do not disembed, but Hackenberg (2013) found that disembedding is critical to algebraic reasoning. *Disembedding* is a mental operation that allows students to think about removing one unit from another without destroying either unit, and to reflect on the relationship between the two units (Steffe, 2010). For instance, to abstract the relationship between quantities such as 10 and 8 or 6 and 4 as x and $x - 2$, requires the student to disembed the smaller quantity from the larger and reflect on the relationship (Hackenberg, 2013). This reflection supports the algebraic representation of the two related quantities. As TNS students do not disembed, Hackenberg's (2013) findings suggest that TNS students will be limited in their symbolic representations of related unknowns.

Advanced Tacitly Nested Number Sequence (aTNS)

aTNS students assimilate with composite units and construct or coordinate a third level of units in activity, but do not disembed (Ulrich, 2016b). To *assimilate* with composite units implies that aTNS students can immediately perceive of a number word, like "seven," as one unit containing seven units of one. This allows aTNS students to reason strategically by operating on embedded composite units (Ulrich, 2016b). For example, an aTNS student may find the difference between 39 and 62 is 23 by reasoning that 40 plus 22 is 62, and 39 is one less than 40, so the difference is one more than 22. aTNS students are only tacitly aware of the nesting of the subsequences, 39 and 23, within 62. This makes explaining their thought process challenging (Ulrich, 2016b).

aTNS students' algebraic reasoning. Zwanch (2019, in review) found that aTNS students can write algebraic equations to represent additive and multiplicative relationships, but they do so inconsistently. Their algebraic reasoning is supported by assimilatory composite units, which

Hackenberg et al. (2017) find support operations on unknowns. However, aTNS students' algebraic representations are inconsistent due to not disembedding (Zwanch, in review). This research demonstrates that aTNS students can write symbolic equations representing one-step additive and multiplicative relationships because they can operate on composite units in activity, thereby forming a third level of units. Following mental activity, however, the third level of units decays. As aTNS students cannot disembed one quantity from the other to reflect on the relationship following this mental decay, they have no material for reflection (Zwanch, 2019, in review).

Explicitly Nested Number Sequence (ENS)

ENS students also assimilate with composite units, but in addition can disembed and iterate units of one (Steffe, 2010; Ulrich, 2016a). Iterable units of one and disembedding support multiplicative reasoning (Steffe, 2010) because ENS students can, for instance, think about removing a unit of one from a composite unit of seven and repeating the unit seven times to fill the whole – seven is seven times the size of one.

ENS students' algebraic reasoning. Olive and Çaglayan (2008) utilized the coin problem (Figure 1) to examine how units coordination was related to students' algebraic solutions to a linear system of equations problem. One participant, Ben, who assimilated with composite units, wrote the equations $(.05N) + (.1D) + (.25Q) = \$5.40$, $D = N + 3$, and $Q = N - 2$. Although Ben explained that N, D, and Q represented the numbers of nickels, dimes, and quarters, respectively, he struggled to substitute $n + 3$ and $n - 2$ in place of D and Q. When he was pressed to do so, he conflated the numbers of dimes and nickels with their values. This was a limitation of his units coordination because he could not operate on the initial equation, which represents a three-level unit structure (i.e., the value of a single coin, within the number of a type of coin, within the total value, $5.40; Olive & Çaglayan, 2008).

Generalized Number Sequence (GNS)

A GNS is the most sophisticated number sequence, and GNS students assimilate with three levels of units and can construct four or even five in activity (Steffe, 2010; Ulrich, 2016a). One mental operation of a GNS is iterable composite units. This implies that GNS students can "collapse" a composite unit to form a "singleton unit" (Steffe, 2010, p. 42), and conceive of composite units as identical, which allows them to be iterated to solve problems (Steffe, 2010).

GNS students' algebraic reasoning. In response to the coin problem (Figure 1), Maria, who assimilated with three levels of units wrote the equation $.05N + .1(N + 3) + .25(N - 2) = 5.40$ with "ease" (Olive & Çaglayan, 2008, p. 280). Assimilating with three levels of units allowed Maria to operate on the initial equation, a three-level unit structure, by substituting expressions for D and Q without the same difficulty as Ben.

Research Questions

The literature demonstrates that students' algebraic reasoning can be modeled by their number sequences. Additionally, differences in students' fluency with composite units and the construction of a disembedding operation are critical to their algebraic reasoning. Therefore, this study asks, in what ways do the number sequences account for students' guess and check solutions to linear systems of equations? Furthermore, the literature is unclear as to the appropriateness of guess and check strategies. This study will also ask, are middle-grades students' solution methods for linear systems of equations more closely related to their number sequence or course enrollment?

Methods

This study included 18 students in grades six through nine at a rural middle and high school in the southeastern United States. Students are listed in Table 1 by math class and number sequence. The first letter of each pseudonym matches the first letter of their number sequence attribution. According to the state standards and the teachers of these students, Math 6, Math 7, and Pre-Algebra did not include any instruction on solving systems of equations. Algebra 1, Algebra 1 Parts, and Algebra 2 did include instruction on algebraic methods for solving systems of equations. Students with an asterisk are students who had received instruction on algebraic methods for solving systems of equations in their math class. Students' number sequence was determined by a survey (Ulrich & Wilkins, 2017) and confirmed by screening questions during semi-structured clinical interviews. Clinical interviews were conducted with each student on two occasions, for approximately 45 minutes each, and in addition to confirming their number sequence attribution also included algebra tasks. The tasks reported here are the coin problem and the modified coin problem (Figure 1). Students were given time to solve each problem with any method they chose but were prompted to try an algebraic method if they did not do so independently.

Table 1: Participants by Math Course and Number Sequence

	Math 6	Math 7	Pre-Alg	Alg1	Alg1 Parts	Alg2
TNS	Tabitha				Travis*	
aTNS	Aaron	Alyssa		Amanda*	Alex*	
	Abby	Andy				
	Ann	Ava				
ENS	Elle		Emily	Erin*	Elizabeth*	Emma*
	Evan					
GNS			Greg	Gavin*		

*Denotes students who received instruction on algebraic methods for solving systems

<u>The Coin Problem (Problem 1; from Olive & Çaglayan, 2008)</u>: Ms. Speedy keeps coins for paying the toll crossing on her commute to and from work. She presently has 3 more dimes than nickels and 2 fewer quarters than nickels. The total value of the coins is $5.40. Assuming that she does not have any pennies, find the number of each type of coin she has.
<u>The Modified Coin Problem (Problem 2)</u>: I have 17 coins – some quarters, some dimes, and some nickels. I have 6 more dimes than nickels and 1 fewer quarter than nickels. Find the number of each type of coin that I have.

Figure 1: The Coin Problem and Modified Coin Problem

Results and Analysis

This study asked whether students' methods for solving systems of equations were more closely tied to their math class or number sequence. Table 2 shows that the two TNS students correctly solved problem 2 using guess and check, although one had taken algebra and the other had not. All six aTNS students who attempted problem 1 used guess and check, and seven of eight aTNS students used guess and check on problem 2. This was also regardless of whether they had taken an algebra course. Thus, students who had constructed only a TNS or an aTNS tended to use guess and check, regardless of whether they had received instruction on algebraic methods to solve systems of equations. GNS students always used algebraic methods on problems 1 and 2, regardless of whether they had received algebra instruction. ENS students' methods varied. On the coin problem (1), all ENS students attempted an algebraic method, although only one ENS student was successful. The other five ENS students did not arrive at an answer algebraically and did not guess and check when the interviewer suggested it, presumably due to the quantitative complexity of problem 1. In contrast, on the modified coin problem (2), which involves less quantitative complexity, all three ENS students who had not received algebra instruction used guess and check, and all three ENS students who had received algebra instruction solved problem 2 using an algebraic method. Middle-grades students' solution methods to linear systems of equations were more closely tied to their number sequence than their course enrollment, with the exception of ENS students. ENS students' solutions were more closely tied to their course enrollment and the quantitative complexity of the problem. This pattern is indicated in Table 2 by the cluster of grayed cells among all TNS and aTNS students, and those ENS students who had not received algebra instruction, as well as the second cluster of grayed cells among all GNS students and the ENS students who had received algebra instruction.

Table 2: Results of the Coin and Modified Coin Problems by Number Sequence, Solution Method, and Math Course

	Coin Problem (Problem 1)				Modified Coin Problem (Problem 2)			
Method	Guess and Check		Algebraic Method		Guess and Check		Algebraic Method	
Course	<Alg	Alg	<Alg	Alg	<Alg	Alg	<Alg	Alg
TNS					1/1	1/1		
aTNS	¼	½			5/5	2/2	0/1	
ENS			0/3	1/3	3/3			3/3
GNS			1/1	1/1			1/1	1/1

Each numerator represents the number of students who correctly solved the problem with that method in that number sequence stage, compared to the number who attempted it (denominator). Grayed cells indicate 50% or more of solutions were correct. Neither TNS student attempted problem 1 due to their perceived frustration level. Two aTNS students did not complete problem 1 due to time. <Alg indicates a math class that did not offer algebra instruction. Alg indicates a math class that did offer algebra instruction (see Table 1).

This study also asked to what extent students' number sequences could be used to model their guess and check solutions to linear systems of equations. For brevity, this analysis is limited to the modified coin problem, and GNS students' solutions are not presented, as they did not guess and check. One response from each number sequence was selected to be representative.

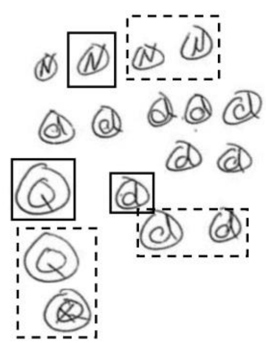
TNS Students' Solutions

Travis guessed on the modified coin problem by saying, "I'm trying to get a number … [of] dimes that have six more than nickels so that I can see how many quarters…" This shows that he was thinking about each type of coin sequentially. His first guess was 13 dimes, 7 nickels, and 6 quarters. He was satisfied that this was the answer until the interviewer asked if there were 17 coins total. This is evidence that Travis did not keep track of the dual goals of utilizing all 17 coins and maintaining the relationships between the numbers of coins. Once he finished the problem, he summarized his solution: "I would pick a number [for dimes] and … see what would be 6 less than that, and one less than that. Then I would add them all up and see if they would equal 17." His summary shows the sequential nature of Travis's guess and check process.

Building on Olive and Çaglayan's (2008) analysis, Travis's sequential determination of the numbers of dimes, nickels, and quarters is due to a limitation of the units coordination defined by his TNS. Travis could assimilate the task with one level of units (e.g., a number of dimes) and construct a second level in activity (e.g., a number of nickels in relation to a number of dimes). This facilitated his double counting and supported the sequential determination of the numbers of each type of coin. Following mental activity, the relationship between the numbers of coins decayed and Travis could only reflect on his answer. Travis's need to construct composite units in activity also limited his reflection on the relationship between his guess and the total. His first guess of 13 dimes, 7 nickels, and 6 quarters was, from the interviewer's perspective, implausibly large. To Travis, the guess was not concerning because he could not conceptualize the number of each type of coin embedded within the total number, so he worked through the problem by sequentially calculating the numbers of coins, and retrospectively checking the relationship to the total.

aTNS Students' Solutions

Abby solved the modified coin problem by drawing 17 circles to represent the coins. This shows that she anticipated the need to exhaust all 17 coins. Then she filled one circle with an N to represent one nickel, seven circles with ds to represent seven dimes, and no circles with Qs. Because she did not fill all of the circles, she knew her answer was not correct (Figure 3). Next, she made incremental adjustments to the coins by adding one nickel, dime, and quarter to her drawing, and then two nickels, dimes, and quarters. These incremental adjustments are evidence that Abby understood adding the same number of each type of coin would maintain the necessary relationships. Finally, she concluded that the solution was 4 nickels, 3 quarters, and 10 dimes.



Unboxed coins show Abby's initial guess.
Solid rectangles show Abby's first incremental adjustment.
Dashed rectangles show her second incremental adjustment.

Figure 3: Abby's Representation of the Modified Coin Problem

Abby's guess and check included two key components – dual awareness of the goals of finding 17 coins total and of the relationships between the numbers of coins. This was supported by an assimilatory composite unit. Prior to activity, Abby could conceive of the situation holistically as a composite unit of 17 coins, containing 3 tacitly embedded composite units representing the numbers of dimes, nickels, and quarters. As aTNS students cannot disembed, Abby relied on figurative materials to support her reasoning. However, her operations on embedded composite units supported her understanding that she could make incremental adjustments to each guess; this is a form of strategic reasoning. In total, seven aTNS students solved the modified coin problem using guess and check, six made incremental adjustments to their guesses, and they all used figurative material to support their reasoning.

ENS Students' Solutions

Emily guessed the correct solution on the first try. She drew 4 nickels, then directly above the nickels she drew 10 dimes, and below the nickels drew 3 quarters (Figure 4). While drawing, she said, "Well, if there's 4 nickels then that would be 6 more dimes is 10, and 1 less quarter is 3. So that works." When asked how she generated that guess, she responded, "I just thought if it's 4 nickels, then 6 more is 10 dimes so that's 14 right there, and so the 3 [quarters] just worked out." Emily's explanation does not indicate how she arrived at four nickels as an initial guess, but there is no indication that she guessed other combinations of coins prior. Similarly, Evan guessed the correct solution on the first try "by accident."

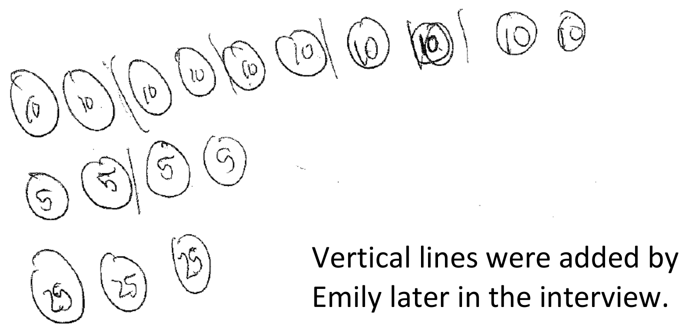


Figure 4: Emily's Representation of the Modified Coin Problem

ENS students' guesses were supported by an assimilatory composite unit, similar to aTNS students, which allowed them to conceive of the situation as a composite unit of 17 coins containing three embedded composite units representing the numbers of dimes, nickels, and quarters. However, the ease with which Emily and Evan guessed the solution indicates, however, that their reasoning was more sophisticated than that of the aTNS students. Based on the limited evidence provided by these two ENS students, it is difficult to attribute this sophistication to any particular mental operation. Elle's solution will be presented next because her work provides more clear evidence that a disembedding operation supported the accuracy of their guesses.

Elle used an unwinding strategy to solve the modified coin problem. This is another pre-algebraic strategy in which students solve a problem "by working backward through the constraints provided in the problem… by inverting operations and performing arithmetic operations rather than using algebraic manipulation" (Knuth et al., 2006, pp. 301–302). Elle applied an unwinding strategy when she said,

> I'm subtracting the amount of dimes from that that we already have [writes 17 minus 6 equals 11]. And I'm just trying to figure out, like, how many nickels and dimes. … So that [subtracting six] sort of equalizes the number of dimes and nickels, doesn't it, but we have one fewer quarter than nickels. … Well, we already have one less quarter than nickels, so that's one more [writes 11 plus 1 equals 12]. [Adding one] sort of balances it, quarters with the nickels.

Elle divided 12 by 3 to find that the solution was 4 nickels, 10 dimes, and 3 quarters.

Elle's unwinding strategy is evidence that she applied both an assimilatory composite unit and a disembedding operation. As with the ENS students who guessed and checked, Elle assimilated the situation as a composite unit of 17 containing 3 embedded composite units. Disembedding allowed Elle to simultaneously conceive of the relationship between the numbers of dimes and nickels to the total, which supported her reasoning that equating the number of dimes and nickels would reduce the total to 11. She then applied the same disembedding operation to consider the relationship between the numbers of nickels and quarters to 11. Thus, Elle leveraged her reflection on the relationships between the numbers of each type of coin to simply the problem context. Although neither Emily nor Evan seemed overtly aware of this process, it is possible that similar reasoning supported their "accidental" guesses.

Discussion

Studying algebraic solutions to linear systems of equations is typical of middle- and high-school Algebra 1 curricula (e.g., CCSSI, 2010), but guess and check remains prevalent (Johanning, 2004). This study offers a lens to interpret these difficulties and implications for students' preparedness to receive instruction on solving linear systems of equations. TNS students did not solve systems of equations algebraically, regardless of their course enrollment. However, they did correctly solve a linear system of equations with limited quantitative complexity using guess and check. This was supported by their construction of composite units in activity. Although it is unlikely that these students are prepared to accept instruction on algebraic methods to solve systems of equations, they may benefit from instruction that promotes systematic guess and check. Knuth et al. (2006) maintain that guess and check is pre-algebraic. While this may be so, supporting TNS students' use of systematic guess and check may be more productive than attempting to teach them to apply algebraic methods without understanding.

aTNS students also did not use algebraic methods, regardless of their course enrollment, which implies that they are also unlikely prepared to accept instruction on algebraic methods for solving systems of equations and apply those methods in novel problem-solving situations. However, aTNS students had access to more sophisticated solutions than TNS students, including systematic guess and check. Thus, aTNS students may benefit from instruction that includes active reflection on the relationships between the unknown quantities in systems of equations to support that readiness for instruction. Additional longitudinal research is necessary to assess an instructional trajectory that may engender aTNS students' construction of disembedding. However, Zwanch and Wilkins (2021) found that students who have constructed an aTNS by sixth or seventh grade are more likely to construct an ENS and a disembedding operation by the time they enter eighth grade, when compared to students in sixth and seventh grades who have not yet constructed an aTNS. This implies that the early middle grades are a critical time in students' construction of number, particularly in supporting the construction of an ENS. In combination with the present study, these findings suggest that supporting aTNS students' construction of disembedding to support their preparedness to learn algebraic methods of solving systems of equations is likely more productive in the early middle-grades.

ENS students capitalized on the algebraic methods taught in their algebra classes, if they had taken one. This indicates that their assimilatory composite unit and disembedding operation prepare ENS students to accept instruction on algebraic methods for solving linear systems of equations. However, their success with these methods was limited to situations such as the modified coin problem, which had limited quantitative complexity. Longitudinal research should consider how to support ENS students' solutions to systems of equations with greater quantitative complexity, such as the coin problem, in novel problem-solving situations. Overall, these results demonstrate that providing instruction on linear systems of equations in a middle- or high-school Algebra 1 course is most likely to be productive if instruction is differentiated to support solution strategies that students are prepared to accept.

ELEMENTARY PATTERNING PROBLEMS: VISUAL AND NUMERICAL STRUCTURING

Leah M. Frazee
Central Connecticut State University
frazee@ccsu.edu

Adam R. Scharfenberger
The Ohio State University
scharfenberger.6@osu.edu

Research on elementary students' reasoning on patterning problems with pictorial representations has illustrated that students can visualize structure in patterns in different ways. In this paper, we offer a characterization of students' spatial structures and numerical structures and explain how the link between these two structures can support students' generalization of a pattern or prediction of a future value.

Keywords: Elementary School Education, Algebra and Algebraic Thinking

Reasoning about and with functions is a foundational topic in K-12 mathematics. Functional thinking in algebra can be defined as "representational thinking that focuses on the relationship between two (or more) varying quantities, specifically the kinds of thinking that lead from specific relationships (individual incidences) to generalizations of that relationship across instances" (Smith, 2008, p. 143). Functional thinking builds from patterning in elementary grades to generalized algebraic equations in secondary mathematics. In grades 3-5, elementary students are expected to "describe, extend, and make generalizations about geometric and numeric patterns; represent and analyze patterns and functions, using words, tables, and graphs" and use equations to express mathematical relationships, inherently linking patterns, relations, and functions (NCTM, 2000, p. 158). To prepare students for functional thinking in later grades, Blanton and Kaput (2004) propose that elementary students should move beyond simple patterns in one variable to focus on problems in which two or more quantities vary simultaneously. Indeed, such complex patterning problems are often included in research studies with elementary students (e.g., Stephens et al., 2017; Wilkie & Clark, 2016) and on standardized assessments for elementary students, such as the National Assessment of Educational Progress (NAEP) mathematics assessment and Trends in International Mathematics and Science Study (TIMSS).

The mental activities used by students to generalize a pattern from a table, graph, or pictorial representation are of particular interest in studying students' functional thinking (Smith, 2008). Recent research on student thinking about patterning problems considers both functional thinking and spatial visualization. By analyzing student work on patterning problems from both an analytic and visualization perspective, researchers can understand the ways students reason with and about different function representations, including figures, tables, and generalized rules. While other studies have reported on students' spatial visualization when solving patterning problems with pictorial representations (Hershkowitz et al., 2001; Wilkie & Clark, 2016), in this paper, we identify both the spatial and numerical structures students use when solving a patterning problem and describe how linking a spatial structure with a numerical pattern structure can support a student's generalization of a pattern or prediction of a future value. "Spatial structuring is the mental act of constructing a spatial organization or form for an object or set of objects. Numerical structuring is the mental act of constructing an organization or form for a set of computations" (Battista et al., 2018, p. 211). *Spatial numerically-linked structuring* is a coordinated process in which numerical operations are performed based on a linked spatial structuring (Battista et al., 2018).

Literature Review and Framework

Three modes by which researchers analyze student reasoning about functions and patterning problems with two varying quantities are recursive, covariation, and correspondence approaches (Blanton & Kaput, 2011; Stephens et al., 2017). The *recursive* approach describes the change within a sequence of values (Blanton & Kaput, 2011). It indicates how to obtain the next value in a sequence given the current sequence value. In a two-column table with two varying quantities, a student using a recursive approach would identify the change in one column independent of the other column and use this change to move from one value to the next within a column. The *covariation* approach describes how the change in two quantities is related (e.g., as x increases by one, y increases by 2) (Confrey & Smith, 1991). The *correspondence* approach describes a rule or mapping that relates any given x-value to a unique y-value (e.g., y = 2x + 3, indicating y-values are 3 more than twice the x-values) (Confrey & Smith, 1991).

While there are multiple learning progressions in the literature describing the ways elementary students may develop these different types of functional thinking (Blanton et al., 2015; Stephens et al., 2017; Wilkie & Clark, 2016), the progressions all provide evidence that students typically begin with recursive or covariational approaches and move toward more sophisticated correspondence approaches. In studies with students in elementary grades, researchers often present patterning problems by providing a series of figures or manipulatives that show a growing pattern in two variables (Stephens et al., 2017; Wilkie & Clark, 2016). This offers an opportunity for students to recognize the relationship between two variables. At times, tables are used to organize or display patterns and data (Schliemann et al., 2001). Standard questions include "far-prediction" problems or tables with a break in the sequence of values which have been used to encourage students to shift their approach from a recursive strategy to either a covariational or a correspondence approach or from a specific relationship between two items to a generalization for the whole set (Blanton et al., 2015; Blanton & Kaput, 2004; Schliemann et al., 2001; Stephens et al., 2017). In general, these studies have shown that young children are capable of functional thinking.

When functional relationships are represented pictorially, spatial thinking becomes an important part of students' reasoning with functions. Students identify and visualize changes from figure to figure in a pictorial representation in many different ways (Hershkowitz et al., 2001). Visualization is the process involved in constructing and transforming visual mental images (Presmeg, 1997) and impacts the resulting spatial mental image that encodes properties such as location, size, and orientation (Sima et al., 2013). Battista (1999) defines spatial structuring as the mental process by which a person constructs an organization for a set of objects. The process of spatial structuring includes identifying the spatial components of the figure and organizing the components into composites with certain relationships between them. This is of particular interest for patterning problems with pictorial representations because the way a student sees the figure components, figure composites, and interrelationships between figures becomes a part of the student's reasoning process. Visualization and the resulting spatial structures have the potential to enhance a student's understanding of algebraic and function concepts (Boaler et al., 2016) and can sometimes influence the way in which a student generalizes a visual pattern or predicts future values. Wilkie and Clark (2016) found that students sometimes transition between multiple visualizations of a pattern while solving a single patterning problem and report that these visualizations likely lead to specific types of generalizations of the numerical pattern.

Method

To explore students' thinking with pattern and relationship problems, clinical interviews (Ginsburg, 1981) were conducted with a convenience sample of three 4th grade students at a public elementary school in the United States. The students were all in the same mathematics class. According to the teacher, the three students represented the typical range of mathematical abilities in her classroom. The problem chosen for this study was the Pattern of Circles Item (**Figure 1**) of the 4th Grade 2011 TIMSS Questionnaire for which 75% of U.S. students (International 68%) correctly answered Part B, while only 47% of U.S. students (International 39%) correctly answered Part C (IEA, 2013). The problem provides opportunities for students to reason with both pictorial and table representations while predicting a future value. Students were asked to solve the problem while the researcher (second author) observed and asked the students to clarify their thinking. The video and audio recorded interviews were transcribed and reviewed by both authors, examining for evidence of the spatial structure students used when working with the pictorial representation, how they interacted with the table, and how they predicted the number of circles in future figures in the pattern. (Note: Figures in bold refer to the inserted figures in the paper. Figures not in bold refer to the Figures in the Pattern of Circles item of the 4th Grade 2011 TIMSS Questionnaire).

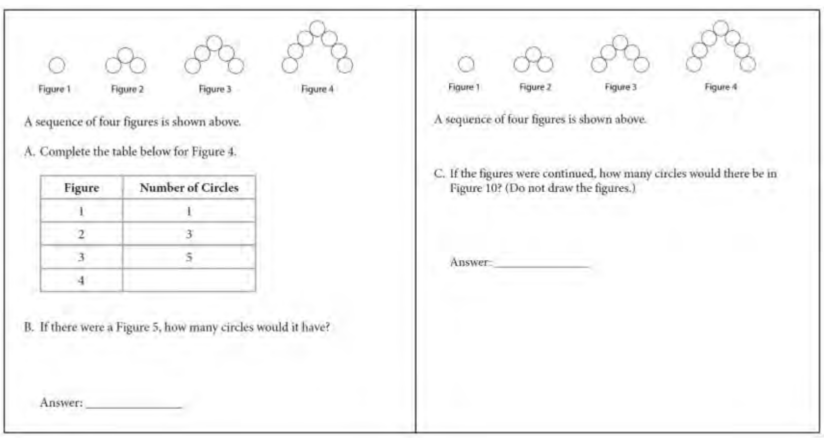

Figure 1 Figure 2 Figure 3 Figure 4

A sequence of four figures is shown above.

A. Complete the table below for Figure 4.

Figure	Number of Circles
1	1
2	3
3	5
4	

B. If there were a Figure 5, how many circles would it have?

Answer: ____________

Figure 1 Figure 2 Figure 3 Figure 4

A sequence of four figures is shown above.

C. If the figures were continued, how many circles would there be in Figure 10? (Do not draw the figures.)

Answer: ____________

Figure 1: Pattern of Circles Problem TIMSS 2011 Assessment (IEA, 2013)

Findings

Student 1: Dennis

Two students in the study, Dennis and Miles, used the same spatial structure (Battista, 1999) when describing the pictorial representation provided in the Pattern of Circles Problem (**Figure 1**). In Part A, Dennis stated, "I know the sequence, it's just adding on two [points to the circles at the bottom of each 'leg' as highlighted in **Figure 2**]." Dennis identified the way he saw the two additional circles in successive figures as the bottom two circles on each 'leg.'

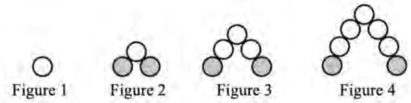

Figure 2. Dennis' Spatial Structure for the Pictorial Representation

While Dennis recognized the pattern in the pictorial representation of the problem, he stated "I don't really get this table." When the researcher explicitly asked Dennis what the numbers in the table might mean, he correctly related the first column to the figure number. The researcher further prompted him by asking what the second column in the table refers to and Dennis replied, "Oh, okay, … The numbers of circles that are in each triangle shaped thing." He then filled in the missing value in the table with the numeral "7".

To solve Part B, Dennis drew Figure 5 consistent with how he spatially structured the two additional circles in successive figures and counted to correctly conclude that there were nine circles in Figure 5. The order in which circles were drawn for Figure 5 is shown in **Figure 3**.

Figure 3: Dennis's Drawing of Pattern of Circles Figure 5

For Part C, Dennis attempted to count the number of circles in Figure 10 by tapping his pencil from left to right under each 'leg' of Figure 4 while counting aloud from circle seven: "8, 9; 10, 11; 12, 13; 14, 15; 16, 17 [see **Figure 4**]. So, I think it's 17." However, this is the correct number of circles for Figure 9, rather than Figure 10.

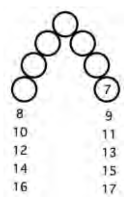

Figure 4: Dennis's Visualization and Counting of Additional Circles

When prompted to further explain his thinking, Dennis recounted the number of circles in Figure 10 using the same spatially structured counting method but was more explicit about the way he kept track of the figure numbers and the number of circles. Starting from circle seven in Figure 4 he stated, "So 8, 9, that would be one [figure more]; 10, 11, that would be two [figures more]; 13, 14 that would be three [figures more]; 15, 16 that would be four [figures more]; 17, 18, that would be five [figures more]." Two errors occurred when Dennis counted the second time. The first error was that he counted five figures from Figure 4, rather than six just as he did the first time he counted. The second error was skipping the number 12 when counting the circles. Coordinating the number of figures and the number of circles at the same time was challenging.

When asked how he knew when to stop adding circles, Dennis stated, "You only need to do five times two. Just need to do two five times. That's how you get your answer." While further explaining his thinking, Dennis corrected his counting error: "Because it says 10. Wait, six times [not five]. If you work with [Figure] four. Yeah, it's six times." Dennis again recounted the number of circles, using the same spatially structured counts illustrated in **Figure 4** and reached the correct number of circles, 19. He then generalized the counting process. "So yeah, you do two six times. Two times six, plus seven…Because there's only Figure 4, not Figure 5. If there was a Figure 5, then you only need to do five times, but there's no Figure 5."

Dennis correctly concluded he would need to add six sets of two circles to build Figure 10 from Figure 4, and extended his thinking in a way that would have facilitated starting with a different figure number. Dennis developed his generalization by imagining the changes from Figure 4 to Figure 10 using the spatial structure he described when looking at the figures (**Figure 2**), while explicitly stating the relationship between the addition of two circles and the successive figure in the sequence.

Student 2: Miles

In contrast to Dennis for Part A, our second student, Miles immediately wrote "7" in the table for the number of circles in Figure 4, making an unprompted connection between the pictorial and table representations.

> Miles: So, I saw one here [points to the one circle in Figure 1 and to the "1" in the output column], three here [points to the three circles in Figure 2 and to the "3" in the output column], five here [points to the five circles in Figure 3 and to the "5" in the output column]. So, I counted these [the circles in Figure 4], and I got an answer of seven, so I put that in the box.

When asked how he determined the number seven, Miles described the same spatial structure as Dennis (**Figure 2**).

> Miles: So, I saw figure one, and then I saw figure two, and right away I saw that it added two more circles [points to the bottom two circles on each 'leg' of Figure 2]. So then in figure three, I saw it add two more circles [points to the bottom two circles on each 'leg' in Figure 3]. And again, in figure four, I saw it add two more circles [points to the bottom two circles on each 'leg' in Figure 4]. So, I thought there was an addition of two from one going up to seven.

For Part B, Miles added two plus seven to correctly conclude that Figure 5 would have nine circles without producing a drawing. In explaining his reasoning, Miles stated, "I knew that there was a pattern of adding two [gestures from left to right over the figures]. So, I just add two to seven, if there was a figure five, and I got nine."

For Part C, Miles generalized from Figure 5 and stated that the answer would be 19 circles, because, "I knew that after each figure, two [circles] would be added. So, if there were five figures [from Figure 5 to Figure 10] and two were being added each time, I knew that it would be 10. So, I add 10 plus nine to get my answer of 19." Miles made this generalization without drawing or explicitly visualizing additional figures like Dennis did; rather Miles used the difference in figure numbers from five to ten to generalize the pattern.

Student 3: Margot

The third student, Margot, recognized the addition of two circles for each successive figure, but she saw the additional two circles in a different spatial structure than Dennis and Miles. After reading Parts A and B of the question, Margot initially analyzed the figures, saying, "Um, first you do like—so two [moves pencil across Figure 2 as shown in **Figure 5]**, two [taps Figure 3 as shown in **Figure 5**]. Um, two [moves pencil across Figure 4 as shown in **Figure 5**]. It would be like, 1, 2, 3, 4, 5, 6, 7 [counts Figure 4 as shown in **Figure 5**]." Rather than seeing the additional two circles in each figure added to the bottom 'legs' of the previous figure as Dennis and Miles did, Margot saw the two circles on one 'leg' of the figure. From her comments in later dialogue, we infer that she saw the number of remaining circles in the figure as equal to the number of circles in the previous figure, indicating that she may have recognized the recursive nature of the pattern.

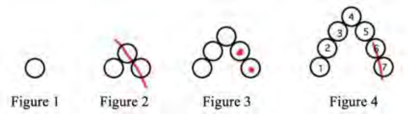

Figure 5: Margot's Spatial Structure for the Pictorial Representation

Initially when answering Part A, Margot incorrectly wrote "6" in the table as the Number of Circles in Figure 4. When the researcher asked her to explain her thinking, Margot responded, "Um—I just think—oh, now I know [erases the "6" and puts "7"]. Seven, because like, … I think it just matches. I don't know." Though Margot's second answer of seven was correct, she had difficulty explaining her reasoning within the table representation. The researcher then asked if she knew what the table was referring to, and Margot was prompted to relate the table to the figures. She verified her answer of seven in the table by recounting the number of circles in Figure 4, "Yeah, 1, 2, 3, 4, 5, 6, 7," (as illustrated in **Figure 5**). While Margot's reasoning with the numerical values in the table was imprecise, she ultimately relied on the pictorial representation to definitively and correctly state the number of circles in Figure 4.

When asked to solve Part B, Margot, like Miles, correctly predicted the number of circles in Figure 5 by simply adding two to the number of circles in Figure 4 without producing a drawing. However, she still indicated the additional two circles in each figure as shown below.

> Margot: Pretty sure I know it's nine…It's nine…Because there's—so one [points to the one circle in Figure 1], three [points to the three circles in Figure 2], because these are—and there's two more [gestures to the right 'leg' of Figure 2 as indicated in **Figure 6**] than each of them. Two [gestures to right 'leg' of Figure 3 as indicated in **Figure 6**], Two [gestures to right 'leg' bottom two circles in Figure 4 as indicated in **Figure 6**] more than each of these other ones, so I'm pretty sure it's nine. Because seven plus nine is, wait, seven plus two is nine.

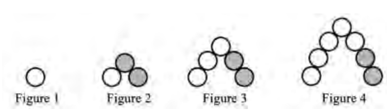

Figure 6: Margot's Gesturing of the Two Additional Circles in Each Figure

For Part C, Margot attempted to draw the figures up through Figure 10, but did not continue the pattern of circles following the spatial structure of adding two illustrated in **Figure 6**. Instead, she drew long, straight chains of circles to represent each figure but did not consistently draw the straight chains with an accurate number of circles (**Figure 7**). At times she added two circles to the next figure and at times she added three, ultimately leading to a series of figures that produced an incorrect answer.

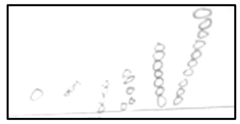

Figure 7: Margot's Figure Growth Drawings for Part C

Discussion

Two of the three participants in our study, Dennis and Margot, faced challenges when determining the number of circles in Figure 10 in Part C. By characterizing the spatial structures used by the students as spatial numerically-linked structures (Battista et al., 2018) or non-spatial numerically-linked structures, we provide insight for when a spatial structure may support students' reasoning about patterning problems.

The spatial structure utilized by Dennis and Miles (**Figure 2**) can be classified as a spatial numerically-linked structure (Battista et al., 2018) which has the potential to support student reasoning about far-prediction problems. By seeing the two additional circles at the bottom of the figure, Dennis and Miles were using a spatial structure that is aligned with a recursive numerical process. Numerically, a recursive pattern adds a value to a previous value; spatially, this can be thought of as adding objects to a previous congruent figure. Dennis' and Miles' spatial structuring organized the components of the figures, the circles, into composites: one part is the previous figure and one part is the two additional circles for each successive figure (**Figure 8**). This organization includes the geometric properties of symmetry within the figures and congruence between figure components. Even though neither Dennis nor Miles stated these geometric properties, these visually salient qualities may support imagining or visualizing future shapes.

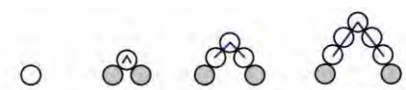

Figure 8: A Spatial Numerically-linked Structuring for the Pictorial Representation

A spatial numerically-linked structuring can provide a way to coordinate the two varying quantities in a patterning problem. The way in which Dennis saw the additional two circles added to each figure provided a way for him to coordinate the figure number and number of circles resulting in a numerical structure that provided an organization for his set of computations (**Figure 9**). Each time he imagined a new pair of circles being added, he moved to a new row and tapped his pencil adding the additional circles in an organized way. Even when he made two counting errors, he was able to recognize and correct those errors and generalize his process because his spatial structure and numerical structure were linked.

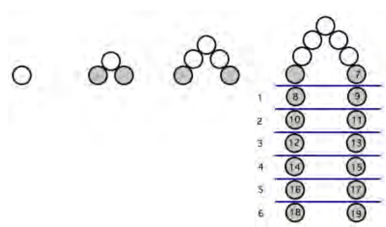

Figure 9: Dennis' Spatial Numerically-linked Counting

In comparison, Margot, did not reach the correct solution for Part C. One explanation for why Margot's visual structure did not support predicting the number of circles in Figure 10 is that the spatial structure was not linked to a numerical structure for adding on two circles in an organized way. Like Miles and Dennis, Margot also recognized that two circles were added in each successive figure. However, the way in which she saw the two additional circles within the figure (**Figure 6**) did not show the addition of the circles to a congruent previous figure or maintain the symmetry of the figures. Because the spatial structure was not linked to the recursive numerical pattern she verbalized, it was very difficult for Margot to imagine or draw the next figure even though she could explain the provided figures using her spatial structure. By observing her gestures and descriptions of the pattern, we hypothesize that she verified the pattern by recognizing that the collection of three white circles in Figure 3 were the three circles from Figure 2 in a different spatial arrangement (**Figure 10**). She used similar gesturing to verify that the collection of five white circles in Figure 4 is just a different spatial arrangement of the five total circles in Figure 3. But without a symmetric, congruent spatial structuring, creating a new figure, such as Figure 5, using the recursive relationship of adding two circles is very challenging, making a resulting numerical structure for computations to determine the number of circles in Figure 10 very difficult to coordinate with the pictorial representation.

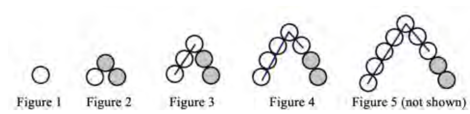

Figure 10: Margot's Spatial Structure

Indeed, for Part C, Margot did not attempt to draw using the same spatial structure. Instead, she drew long chains of circles to represent each figure (**Figure 7**). However, Margot's second spatial structuring was also not a spatial numerically-linked structure because it was not connected to the numerical recursive pattern of adding two. We hypothesize that Margot's re-arrangement of the figures into long strings of circles could be spatially linked to the numerical structure if the straight lines were maintained and the circles were congruent (**Figure 11**). This would offer the same spatial-numerical link as Miles' and Dennis' structure because the additional two circles would be added to a previously congruent figure. While symmetry within the figures is not as visually salient, the equal "heights" of the strings could have helped coordinate the additional two circles added to congruent strings. However, because Margot's drawings did not incorporate these features, it became very difficult for her to keep track of the total number of circles in each figure and to consistently add two circles to each string ultimately causing her to reach an incorrect solution.

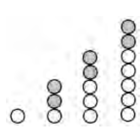

Figure 11: A Spatial Numerically-linked Structure Example

While spatial numerically-linked structures can help students reason about pattern problems with pictorial representations, it is certainly not required if other representations are utilized. A student could have been successful on the Pattern of Circles problem without such a structure by using the table representation to add two to the previous output value, extending the table to determine the number of circles in Figure 10. However, none of the students in the study explicitly reasoned with the table. Miles was the only student who did not draw additional figures while predicting future values. While it is possible that he used information from the table to support the development of his generalization, he also used the same spatial numerically-linked structuring as Dennis while reasoning about the problem.

Conclusion

Research has shown that students can think about pictorial representations with different visual structures, and we have offered evidence that these visual structures can support student thinking about patterning problems when the spatial structure and the numerical structure are adequately linked. By identifying features of spatial structures and numerical structures that are helpful for students when solving patterning problems, we can better understand how students' visualizations can facilitate the development of numerical generalizations and predictions.

In this study, we investigated how sixth and seventh grade students used CODAP to make sense of roller coaster data while engaged in Exploratory Data Analysis (EDA). Using instrumentation theory, we examined students' instrumentation approaches, as well as the types of instrumental orchestration utilized by teachers as they interacted with student pairs during EDA.

Keywords: Data Analysis and Statistics, Technology, Instructional Activities and Practices

Introduction

Statistics has gained prominence in school curricula in the US (Franklin et al., 2007; National Council of Teachers of Mathematics, 2000; National Governors Association Center for Best Practice & Council of Chief State School Officers, 2010), which includes a focus on reasoning about data. One way to encourage students to reason about data is providing opportunities to engage in Exploratory Data Analysis (EDA). EDA first developed by Tukey (1977), involves exploring data to summarize main characteristics. EDA is the "art of making sense of data by organizing, describing, representing, and analyzing data, with a heavy reliance on informal analysis methods, visual displays" (Ben-Zvi & Ben-Arush, 2014, p. 197). While approaches often use visual methods, such as graphs and other representations, statistical measures are sometimes calculated to make sense of data. Ben-Zvi (2004) points out that exploring data involves examining features such as shape, center, and spread; it involves considering graphs and looking for other characteristics of data like clusters, gaps, and outliers. Cobb and McClain (2004) recommend that EDA should be the focus of early experiences with instruction because of the emphasis on finding trends and patterns.

EDA often involves the use of technology, and there is evidence that innovative technology tools aide students in developing statistical thinking (e.g., Biehler et al., 2013). We are interested in understanding students' engagement with the Common Online Data Analysis Platform (CODAP), (https://codap.concord.org/), which has many powerful dynamic visualization and calculating capabilities that make it an ideal tool for engaging in EDA. Specifically, we investigated the following research questions:

- *RQ1: How do students use CODAP to make sense of data while engaged in EDA?*
- *RQ2: What types of orchestration emerge as teachers interact with students as they engage in EDA using CODAP?*

Theoretical Perspectives

Our study draws on two theoretical perspectives from instrumental theory: instrumental genesis and instrumental orchestration. To understand students' learning processes as they made sense of data during EDA using CODAP, we used Ben-Zvi and Ben-Arush's (2014) types of instrumentation. Instrumental orchestration was used to understand teachers' interactions with students as they explored 157 US roller coasters using CODAP (Drijvers et al., 2010).

Instrumental Genesis

Five components comprise instrumental genesis (IG) (Ben-Zvi & Ben-Arush, 2014). The *subject* is a learner who accomplishes a task using an instrument. An *object* is a specific task. An *artifact* (a component of a tool) is a physical or virtual device that is used by the subject, which has no meaning for the learner in isolation. A *utilization scheme* is a cognitive scheme that the subject uses to accomplish a task using one or more artifacts. When the subject has successfully used the utilization scheme to accomplish a task, the artifact becomes an *instrument* for the learner to use. The authors indicate that IG occurs when a subject uses utilization schemes to transform an artifact into an instrument that can be used as a meaningful tool to achieve a particular goal.

There are two components of IG, *instrumentalization*, the ways in which the subject's prior knowledge acts on the tool, and *instrumentation*, the way the instrument influences the subject's learning process. In this work, we are interested in instrumentation. Ben-Zvi and Ben-Arush (2014) identify three processes of instrumentation that learners use to investigate data: unsystematic, systematic, and expanding. An *unsystematic* approach to investigating data involves actions that are not intentional or systematic, where learners make sense of a few basic artifacts and associated actions. *Systematic* instrumentation involves intentional and somewhat organized exploration, occurring after the learner has become familiar with artifacts, and may be more focused on the tool rather than the task. The third process involves *expanding* emerging instrumentalization (i.e., ways in which students' prior knowledge acts on the tool) of an artifact and associated actions that transform into a more usable and powerful instrument that can be used in a meaningful way in new contexts and situations.

Instrumental Orchestration

Instrumental orchestration is the teacher's intentional and systematic organization and use of various artifacts in a learning environment to guide the learners' instrumental genesis in relation to a mathematical task (Drijvers et al., 2010; Trouche, 2004), or in our case a statistical task. The three elements within instrumental orchestration include the following: a) *didactical configuration*, referring to the design of the teaching setting and artifacts, b) *exploitation mode*, referring to the ways the teacher makes decisions to exploit the didactical configuration to achieve the learning goals, and c) *didactical performance*, referring to the in the moment decisions made by the teacher on how to act on the didactical configuration and enact the exploitation mode. While Drijvers et al. and Mojica et al. (2019) identified orchestration types of teachers' purposeful use of technological tools during whole class instruction, we are interested in teachers' orchestration as they interact with pairs of students.

Participants and Context

Participants in this study were 19 sixth grade and 25 seventh grade students between the ages of 11 and 12-years old from a small urban school in the southeastern US. The school is racially diverse, and 48.6% of the students receive free/reduced lunch. Less than half of the students are proficient in mathematics (40.2%), as compared to 63.2% in their district.

We report on the same 72-minute mathematics lesson, implemented in both a sixth and seventh grade classroom, where students engaged in EDA using CODAP to make sense of roller coaster data. This lesson took place during the second week of the school year, prior to any formal instruction on statistics. This was students' first experience with CODAP. Both classes were taught by an experienced researcher, from a large research university in the southeastern US, with expertise in the teaching and learning of statistics, as well as using technology tools. The regular mathematics classroom teachers were also present during the lesson and interacted with students while they engaged in EDA. Since this paper focuses on how the teachers interacted with students only as they worked in pairs (not as a whole class) during EDA, we refer to all as teachers.

Each lesson consisted of four parts: 1) teacher launching the investigation (whole class); 2) teacher introducing CODAP as a tool using a small data set (whole class); 3) student pairs investigating larger data set using CODAP (pairs); and, 4) teacher facilitating discussion as student pairs present interesting noticings (whole class), the results of their EDA. The teacher launched the lesson by asking students to consider aspects of roller coasters that might make the ride thrilling or scary and then showed a video of a wooden roller coaster from the data set, from the point of view (POV) of a rider, to introduce the context of the data. Students discussed attributes of coasters they thought might be thrilling or scary, and then the teacher introduced students to CODAP by facilitating the exploration of a small data set of 31 US roller coasters using a CODAP document. Our analysis focuses on part 3 of the lesson where students worked in pairs to explore a larger data set of 157 US roller coasters, with 15 numerical and categorical attributes (e.g., name, location, design, top speed, maximum height, etc.). Students were encouraged to ask their own questions and find interesting things they could share about the coasters using features in CODAP, such as graphs. While student pairs engaged in EDA, all teachers monitored student work and interacted with students.

Methods

Data collected for this study is part of a larger project. Classes were video recorded using three cameras from multiple perspectives. While student pairs used CODAP to investigate the roller coaster data, all cameras recorded the teachers' interactions with student pairs or focused on student pairs as they worked. Six student pairs' laptop screens were recorded as screencasts throughout the entire class. The regular mathematics classroom teachers selected pairs to represent divergent student thinking. We used a deductive approach to selecting video for analysis (Derry et al., 2010). To examine how students used CODAP to make sense of data, we selected video recordings from the screencasts of students' laptops while they were engaged in EDA with the 157 roller coaster data set using CODAP, as well as video recordings from cameras that showed students' and teachers' interactions. All selected video was initially viewed to identify episodes, our unit of analysis. Episodes were defined as an action or group of closely related actions that resulted in a process of instrumentation. After multiple researchers had viewed the video, episodes were established after arbitration and agreement was reached.

Once episodes were identified, we created content logs to provide a time-indexed description of the events on the video (Derry et al., 2010). Each episode was coded by two different researchers. Episodes of student pairs' screencasts were coded to identify the processes of instrumentation that learners used to investigate data (Ben-Zvi & Ben-Arush, 2014): unsystematic, systematic, and expanding. To identify the types of instrumental orchestration that emerged, we first identified all questions and interactions between the teachers and students as they worked in pairs. We used open coding until themes emerged to identify orchestration types. When disagreements between coders occurred, the authors arbitrated until consensus was reached, and in some instances a third researcher made the final decision.

Results

Students' Use of CODAP to Make Sense of Data

To investigate how students used CODAP to make sense of data, we identified the instrumentation processes that six student pairs used to reason about 157 US roller coasters. The number of episodes, where an action or group of closely related actions resulted in a process of instrumentation, varied across pairs. Table 1 shows the instrumentation process identified for each pair as they engaged in EDA. Unsurprisingly, all pairs initially engaged in unsystematic instrumentation. While pairs 1, 2, 5, and 6 moved between unsystematic and systematic instrumentation, only pairs 3 and 4 engaged in unsystematic, systematic, and expanded instrumentation. Pair 2 is the only pair that worked unsystematically for most of their EDA.

Table 1: Instrumentation Processes of Student Pairs

Pair	Ep 1	Ep 2	Ep 3	Ep 4	Ep 5	Ep 6	Ep 7	Ep 8	Ep 9
1	Unsys	Unsys	Sys	Sys	Sys				
2	Unsys	Sys	Unsys	Unsys					
3	Unsys	Unsys	Sys	Exp					
4	Unsys	Unsys	Unsys	Sys	Sys	Exp	Unsys	Unsys	Unsys
5	Unsys	Sys	Unsys	Sys	Sys	Sys	Sys		
6	Unsys	Sys	Sys	Sys	Sys	Unsys	Sys	Unsys	

Example of pair that used unsystematic and systematic instrumentation. Pair 6 is an example of a pair that engaged only in unsystematic and systematic instrumentation. They began their exploration by clicking on different features of CODAP, including the map feature, slider, and opening graphs. It is important to note that opening a new graph window results in cases being displayed as a configuration of randomly scattered data points. Additionally, the map and slider features of this CODAP document were not linked to the data. This unsystematic approach enabled them to identify CODAP features that were available to them that could be potentially used to make sense of data. The pair quickly took a systematic approach by adding different attributes to a graph. Figure 1a shows the graph that was created after one student asks if the *maximum drop* is affected by the *number of inversions*. After answering a few questions about the data, the pair is then curious about how many attributes they can include on the graph, which leads them to unsystematic instrumentation as they create a new graph, see Figure 1b. Using a trial and error approach, they add three attributes, *state, year opened,* and *top speed* to the graph to conclude that at most three attributes can be added.

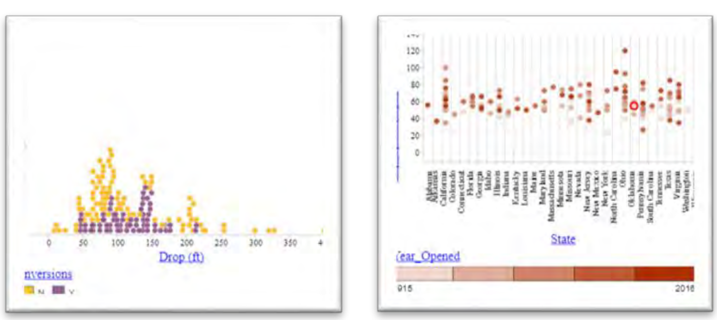

Figure 1a and b: Examples of Systematic (1a) and Unsystematic Instrumentation (1b)

Example of pair that used unsystematic, systematic and expanded instrumentation. Pair 3 not only used features in CODAP in an intentional way to make sense of data, they engaged in expanded instrumentation. For example, they created a scatter plot comparing the *maximum drop* to the *top speed*, and then overlaid *type* on the graph to investigate if the material a roller coaster is made of affects the relationship between *top speed* and the *maximum drop* (see Figure 2). This made the use of the graph more powerful for them by allowing them to pose and answer a new question while using more features of CODAP. One of the students concluded that a lot of wooden coasters are slower and have a "shorter" drop, and the fastest ones are steel.

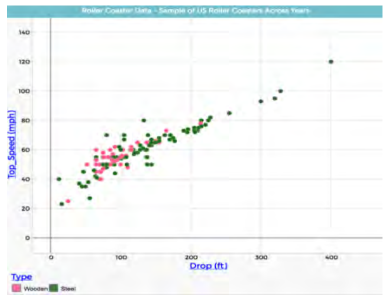

Figure 2: Student Created Scatterplot

Types of Teachers' Orchestration that Emerged

We identified 42 instances of orchestration by the teachers that were categorized into eleven different types. Table 2 illustrates the types, provides a definition and example, as well as indicates the percent of time each type occurred. Several of these orchestration types seem applicable to contexts beyond statistics and data analysis and using technologies other than CODAP, such as inserting terminology (2.38%) and providing technical assistance (4.76%). However, most of the orchestration types related specifically to teaching statistics, such as noticing trends or relationships in data and suggesting data moves. Suggesting a data move (28.57%) and assessing students' progress in their EDA (21.43%) accounted for a majority of the orchestration types. Four of the orchestration types occurred only one time (2.38%): insert terminology, clarify, focus on a case, and link multiple representations. Noticing trends and/or relationships (11.90%), making a claim or inference (9.52%), and explaining statistical reasoning or supporting a claim (7.14%) made up 28.56% of the orchestration, which are all significant in designing learning environments to support students in developing productive statistical thinking. It is beyond the scope of this paper to provide examples of every orchestration type. Therefore, we will focus on suggesting a data move and inserting terminology.

Table 2: Orchestration Types for Interactions with Student Pairs

Type	Percent	Definition	Example
Assess Progress	21.43	Assess where students are in their exploration or statistical investigation cycle (pose, collect, analyze, interpret).	What are you exploring? What are you looking at in your graph?
Relate to Context	7.15	Discuss own experiences or students' experiences related to the context.	I've never been to Carowinds, but I go to Busch Gardens a lot.
Insert Terminology	2.38	Introduce statistical terminology.	Officially that is called a scatterplot. You'll learn a little bit more about those later. It is where you are looking at two variables at the same time.

Provide Technical Assistance	4.76	Provide technical assistance – help student perform specific data move or use features of CODAP.	Click on that and remove it.
Clarify	2.38	Clarify directions or information	In case you don’t know, you’re supposed to be answering question number 8.
Focus on Case	2.38	Focus students’ attention on specific case.	Who is that?
Suggest Data Move	28.57	Suggest a data move.	I’m gonna throw a twist into your graph, and see if you guys can make sense of this. Ok? I want you to grab wood vs. steel. I think it is type. Grab type. Put it in the middle of your graph.
Link Multiple Dynamic Representations	2.38	Draws students’ attention to the dynamic nature of multi-linked representations in CODAP.	Did you notice that when you click on the case here in the other graph it shows up and in the table it will show up, too.
Notice Trends and/or Relationships	11.90	Encourage students to notice trends or patterns, which may include relationships between multiple attributes.	Ok, and do you think that it matters whether you are inverted or not and how fast you go?
Make Claim or Inference	9.52	Encourage students to make a claim or inference.	What states tend to have coasters that go really fast?
Explain Statistical Reasoning/Support Claim	7.14	Provide opportunity for students to explain their reasoning and/or support a claim/inference with evidence	What does the graph tell you?

Suggest a Data Move

Almost 30% of the orchestration types were identified as a suggest a data move. Within this type, we noticed two distinct themes, which resulted in different learning opportunities for students. An example of each kind will be illustrated below. The first shows the way a teacher interacted with Pair 3, a seventh-grade pair, whose scatterplot was previously shown in Figure 2.

Teacher 1: So, I’m gonna throw a twist into your graph, and see if you guys can make sense of this. Ok.
Student 1: Yeah.
Teacher 1: So, I want you to grab wood versus steel. I think it’s type. Here we go. Grab type. Put it in the middle of your graph.
Student 1: Yeah.
Teacher 1: Yep. What did it do?
Student 1: That’s pretty cool. It’s telling us right now which parts are wooden and which coasters are steel.
Teacher 1: There we go. Take a look at that, and see in a little bit if you could tell the class anything that you might notice that’s interesting.
Student 2: How about …
Student 1: A lot of wooden ones are slower and have a shorter drop, and the fastest ones are steel.

Pair 3 had already constructed a scatterplot while exploring the relationship between *drop* and *top speed*, and the teacher suggested that they drag and drop the attribute *type* in the center of the graph, coloring wooden coasters pink and steel coasters green. After the teacher suggested adding the categorical attribute to the graph, she followed up with a question that encouraged students to notice a relationship. Almost immediately, Student 1 was able to reason about the relationship between three attributes. When this teacher suggested a data move, she almost always followed it by a question encouraging students to notice a trend in the data or a relationship when exploring multi-variate data.

The following shows the way another teacher interacted with a different seventh-grade pair.

Teacher 2: Here, drag this a little bit so you can see. Where's your graph?
Student 3: Our graph is down here.
Teacher 2: [Takes control of the mouse.] Oh, ok, so what you can actually do is drag a category here and one right here so you can compare two things. So, compare, like, the max height to the max speed, see if they correlate.
Student 3: You have to create another graph though.
Teacher 2: No, you don't. Let me show you. Now you can see there's a trend, that has the height increases the speed increases.

In this instance, the teacher also suggested a data move. In contrast to the previous example, the teacher did not merely make a suggestion but took control of the mouse and created a scatterplot to show the relationship between *maximum height* and *top speed*. Rather than encouraging the students to notice a relationship between these two attributes, the teacher describes a positive relationship. We argue that this type of orchestration limited students' opportunity to reason statistically. It is plausible to infer that the students thought the teacher was suggesting that *maximum height* and *top speed* be graphed as dotplots on two separate graphs, since Student 3 indicated she thought they needed to create another graph. Perhaps these students may not have been ready to reason about the relationship in the way that the teacher suggested and ultimately constructed for them.

Insert Terminology

After the seventh-grade Pair 3, described earlier, had created a scatterplot (Figure 2), comparing *drop* and *top speed*, the teacher asked students what kind of graph they created. One student responded that it is a "spaceship", and the other student responded that it is an "aurora". The teacher then explained, "Officially that is called a scatterplot. You'll learn a little bit more about those later. It is where you are looking at two variables at the same time. So, what does that graph tell you?" As indicated in the section above, the students were able to reason about the relationship. While this only occurred one time, it provides an example of an appropriate way to introduce statistical terminology. Students were able to reason without knowing the name of the graph and learned new vocabulary. We conjecture that the second example in the previous section shows a way that using new terminology may have limited students' thinking. While we do not have evidence as to whether or not the students knew what correlate meant, we argue that using this terminology likely did not provide an opportunity to support students' reasoning.

Discussion

Our analysis of student pairs conducting an EDA using CODAP has provided evidence of how students make use of artifacts in CODAP to create instruments to answer meaningful questions of their own interest. We found that students who were able to transform the artifacts in CODAP to meaningful tools (i.e., going from unsystematic to systematic to expanding instrumentation) were able to pose and answer more robust questions that surfaced during EDA. All of the student pairs, except one, were able to move from using an unsystematic to a systematic approach to making sense of data. Two of the six pairs were even able to use an expanded approach that transformed features in CODAP into a more usable and powerful instrument that were used in a meaningful way in new situations. While this did not occur many times and for all student pairs, we hypothesize that this was likely due to the fact that this was students' first exposure to CODAP, as well as many students' first experience engaged in EDA. Nonetheless, this provides evidence that even students' initial experiences with using CODAP during EDA can support them in developing statistical reasoning as they make sense of data. An important implication for designing learning environments is that given an appropriate tool and well-designed task that uses real data, students can learn to use a tool while engaging in EDA. While teachers often acknowledge the affordances of using technology to support student learning, they sometimes argue they have insufficient time to do so. We suggest that these findings indicate that teachers do not need to teach students to use a tool first and then provide opportunities to engage in statistical thinking later.

Additionally, we found that students' interactions with teachers often impacted how they moved between *different* types of instrumentation. In some cases, students move from unsystematic to systematic approaches was preceded by an orchestration by the teacher. In fact, in all cases of students using expanded instrumentation, the approach was always preceded by an interaction with the teacher. We were not surprised that most orchestration types categorized as suggest a data move since this was students' first experience with CODAP. Nor were we surprised that merely suggesting a move and then the teacher making explicit their own conclusions about relationships between attributes limited students' opportunities to reason statistically. However, this work provides direct evidence of what we know anecdotally. Our findings indicate that at least one way a teacher can support students moving from unsystematic to systematic or systematic to expanding instrumentation is to explicitly encourage them to notice a trend or relationship. Further, this work shows that different orchestration types provided different learning opportunities for students to develop statistical thinking. Future work should examine this relationship between students' instrumentation and teachers' orchestration more closely.

In conclusion, we believe that providing opportunities for students to engage with well-designed tasks that use real, motivating data are fundamental aspects of designing learning environments that support students' statistical thinking. We also argue that providing opportunities for students to reason about data using dynamic statistical tools, like CODAP, is a fundamental component of learning environments that develop students statistical reasoning. Interactions with such technologies and teachers' orchestration impact learning opportunities for students.

INTERPRETING WORKED EXAMPLES OF INTEGER SUBTRACTION

Laura Bofferding
Purdue University
Lbofferd@purdue.edu

Mahtob Aqazade
Purdue University
maqazade@purdue.edu

Drawing on research around the utility of worked examples, we examine how 29 first- and 27 third-grade students made sense of integer subtraction worked examples and used those examples to solve similar problems. Students first chose which of three worked examples correctly represented an integer subtraction problem and used the example to solve a similar problem. Later, we presented only the correct worked example and had them solve another similar problem. Our results highlight how their initial ideas around which worked example was correct supported or constrained their later interpretation and use of the correct worked example. Students were attuned to the number of jumps shown in the examples; however, they sometimes misinterpreted the jumps' direction. Students' visual answers were correct more than their written answers, suggesting further attention to visuals could support students' reasoning.

Keywords: Number Concepts and Operations, Cognition, Elementary School Education

Students with strong schemas for a particular concept may be more resistant to changing these schemas, even with instruction; for example, upper elementary students who more frequently used a limited addition schema (i.e., A + B = C) had difficulty solving equivalence problems (i.e., A + B = ___ + D) even after being shown correct solutions to the problems (McNeil & Alibali, 2002). To help students revise their existing schemas, many studies described the use of worked examples as a support that can effectively promote middle-school students' increased conceptual understanding (Booth et al., 2013), especially for students with lower prior knowledge (Atkinson et al., 2000; Schwartz et al., 2016). Worked examples can engage students in productive struggle, drawing students' attention to relevant features in their current schemas or important underlying features when extending their schemas and highlight alternative ways of thinking about problems (Booth et al., 2015; Lange et al., 2014). Yet, students with lower prior knowledge might not know which features are relevant to pay attention to (Booth & Davenport, 2013; Crooks & Alibali, 2013). With integer operations, there are many features for students to pay attention to, and their use of them can vary greatly depending on their number schemas (e.g., Aqazade & Bofferding, 2019; Bofferding, 2019). In this study, we further explore how elementary students, who attend to different problem features based on their schemas, interpret integer worked examples and investigate how their prior knowledge schemas correspond to their application of worked examples.

Theoretical Framework

From a blended theory of conceptual change perspective (Scheiner, 2020), students' understanding of negative integers and operations changes through an interaction between their number schemas (e.g., a mental integer number line, Bofferding, 2014; see also Case, 1996, McNeil & Alibali, 2002) and pieces or features that comprise the schemas (e.g., order, value, symbols, operations, Bofferding, 2019; see also Booth & Davenport, 2013; Case, 1996; Crooks & Alibali, 2013). Students might solve 3 – 5 in many different ways, depending on their integer schemas and interpretation of the problem features. Some students might interpret the problem as 5 – 3 (Bishop et al., 2014; Bofferding, 2010) due to a positive integer schema that you cannot

Olanoff, D., Johnson, K., & Spitzer, S. (2021). *Proceedings of the forty-third annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Philadelphia, PA.

subtract a larger number from a smaller number (Karp et al., 2014) together with a flexible interpretation of the order of the features in the problem (i.e., a student could read the problem as three taken away from five). Students who understand that order matters in subtraction but have a strong whole number schema might pay attention to the features, start with three, and argue that the answer is zero or that you cannot take away more than three (Bishop et al., 2011, 2014; Bofferding & Wessman-Enzinger, 2017). Finally, students who have an integer schema might count back from three and answer negative two (Aqazade et al., 2016; Bishop et al., 2011).

Including negative numbers within the problems themselves may cause additional struggles for students. For example, when solving integer subtraction problems, such as -2 – 4, students need to distinguish the minus sign feature appended to the two (i.e., negative sign or unary meaning of the minus sign, Vlassis, 2004, 2008) from the minus sign feature between the two and four (i.e., subtraction sign or binary meaning of the minus sign, Vlassis, 2004, 2008). In fact, students who attend to subtraction signs and reason based on a whole number schema might ignore the negative sign or interpret it as an indication to subtract two (Bofferding, 2019). Other students might think the negative sign needs to be part of the answer and append it to the answer after solving 4 – 2, getting -2 (e.g., Bofferding, 2010; Bofferding, 2019). Students who know the order of negative integers, might still struggle with interpreting their value; therefore, they may vary in whether they subtract by getting numbers smaller in absolute value, counting toward zero and answering "2," or by getting numbers smaller in linear value and answering "-6" (Ball, 2013; Bofferding, 2019).

When analyzing worked examples, students with particular schemas might look for particular features that align with their schemas in order to make judgments about why worked examples are correct or not or to apply ideas from a worked example to a similar problem that they need to solve themselves. In this study, we add to previous literature by focusing in particular on the ways that elementary students interpret and use integer subtraction worked examples, highlighting what features (e.g., number of jumps, direction) students use and their reasoning when making use of the worked examples. Our research questions include:
How do first and third graders make use of integer subtraction worked examples?

1. How do they interpret and determine a correct worked example?
2. Which features are important to them when they try and solve a similar worked example?

Methods

Participants, Setting, and Data Sources

Twenty-nine first-grade and 27 third-grade students from a public elementary school in the midwestern United States with 9% English-Language-Learners and 46% economically disadvantaged participated in this study. As a part of a larger study, students completed two worked example tasks involving integer subtraction about one month apart. The first worked example task included three potential solution strategies for 3 – 5 associated with a number path model: one correct (B) and two incorrect: 3 – 5 = 0 (C) and 3 – 5 = 2 (A) (see Figure 1).

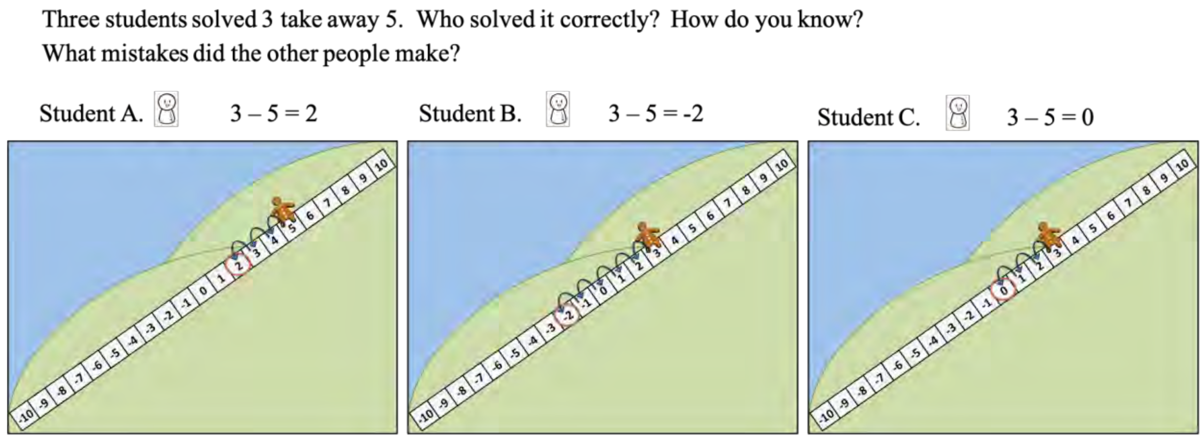

Figure 1: First Worked Example Task

Students were asked to choose the worked example that is correct, explain their reasoning, and describe the mistakes in the other two examples. Next, without receiving feedback on their response, we encouraged them to use that example to solve 1 – 4 and use an empty number path model to draw their solution (see Figure 2A). The second worked example task (see Figure 2B) showed students the correct solution for 3 – 5 = -2 illustrated on a number path. Next, students were asked to solve -2 – 4 and draw on an empty number path using this worked example.

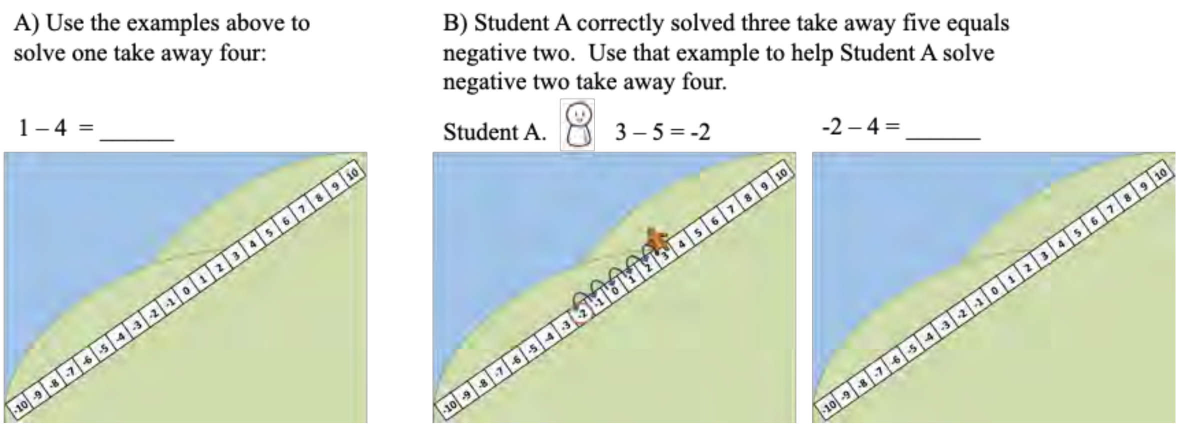

Figure 2: A: First Worked Example Task (cont.) and B: Second Worked Example Task

Data Analysis

On the first worked example task, we determined the number of students who chose A, B, or C as the correct worked example for 3 – 5. Next, we determined if they solved 1 – 4 by using a similar strategy to A from the worked example (i.e., reversed the order of the numbers and answered 3), B from the worked example (i.e., counted through zero and correctly answered -3), C from the worked example (i.e., stopped at zero and answered 0) or *other* (i.e., an answer not aligned with one of the three strategies presented in the first worked example or if their picture did not match their written answer). Then, we noted whether their strategies for both problems matched (e.g., did they answer zero for 1 – 4 if they had selected C for 3 – 5). Finally, we analyzed the explanation of their choice and identified elements or features they focused on, including number of jumps, starting number, ending number, or direction.

On the second worked example task, we calculated the number of students answering correctly and if their written answers matched with the number they landed on on the number path or the number they circled. To better understand their strategies, we analyzed their drawings based on the direction of jumps, starting number, number of jumps, ending number, and circled number. Lastly, we looked for any patterns between the first and second worked example tasks in students' solution strategies.

Findings

First Worked Example Task

The majority of students at both grade levels chose 3 – 5 = 2 (A) or 3 – 5 = -2 (B) as the correct worked example for solving 3 – 5 (see Table 1). When applying this example, overall, 17% of first graders and 44% of third graders correctly solved 1 – 4 as represented in their written answer; however, 38% of first and 48% of third graders showed the answer correctly through their drawing on the empty number path. Among these students, only 14% of first and 37% of third graders solved 1 – 4 correctly both on the written response and on the number path.

Table 1: Students' Choice of Correct Worked Example for 3 – 5 and Solutions to 1 – 4

		First Worked Example Task			
	First Graders (*n*=28) [a]	**1 – 4 → 3**	**1 – 4 = -3**	**1 – 4 → 0**	**1 – 4 → other**
(A)	**3 – 5 = 2** (*n*=9, 31%)	2 (22%)	4 (44%)	0 (0%)	3 (33%)
(B)	**3 – 5 = -2** (*n*=14, 48%)	0 (0%)	6 (43%)	0 (0%)	8 (57%)
I	**3 – 5 = 0** (*n*=5, 17%)	1 (20%)	1 (20%)	1 (20%)	2 (40%)
	Third Graders (*n*=27)	**1 – 4 → 3**	**1 – 4 = -3**	**1 – 4 → 0**	**1 – 4 → other**
(A)	**3 – 5 = 2** (*n*=7, 26%)	2 (29%)	1 (14%)	1 (14%)	3 (43%)
(B)	**3 – 5 = -2** (*n*=16, 59%)	1 (6%)	11 (69%)	0 (0%)	4 (25%)
I	**3 – 5 = 0** (*n*=4, 15%)	1 (25%)	1 (25%)	2 (50%)	0 (0%)
	Overall (*n*=55) [a]	**1 – 4 → 3**	**1 – 4 = -3**	**1 – 4 → 0**	**1 – 4 → other**
(A)	**3 – 5 = 2** (*n*=16, 29%)	4 (25%)	5 (31%)	1 (6%)	6 (38%)
(B)	**3 – 5 = -2** (*n*=30, 54%)	1 (3%)	17 (57%)	0 (0%)	12 (40%)
I	**3 – 5 = 0** (*n*=9, 16%)	2 (22%)	2 (22%)	3 (33%)	2 (22%)

Note. The table shows the number and percent of students who picked a particular worked example (i.e., A, B, or C) who also solved 1 – 4 in a particular way. For example, in the first row with the nine first graders who thought the worked example A (3 – 5 = 2) was correct, two of those students (or 22% of those selecting A), also solved 1 – 4 with an answer of 3. [a] One first grader did not choose a worked example for 3 – 5, so this student was not included in the data presented here.

Choosing A: 3 – 5 = 2 and Applying This Worked Example to Solve 1 – 4

Students' explanations for why they chose A as the correct worked example were often focused on the number of jumps or reinterpreting the subtrahend as being three (seeing the problem as 5 – 3), which was coupled with referencing the starting and ending number (or answer) in the problem. For example, Horse2$_{(3rd)}$ focused on the expected answer and the subtrahend as being three and said, "Took away three and they had two." Bat6$_{(1st)}$ chose to focus on the subtrahend as three and the starting number as five, "He's on five, and he only has to move three spaces." Likewise, when students then explained why B and C were not the correct worked examples for solving 3 – 5, they also pointed out the starting number, ending number, or the number of jumps. For example, Rabbit5$_{(3rd)}$ said, "He put a minus two" for B and she "did five minus three–one, two, three, so it's two." Robin3$_{(1st)}$ chose A because "he jumped three" and B was not correct because "he was supposed to jump three."

Out of 16 students who chose 3 – 5 = 2 (A), only four students' (two first and two third graders) responses to 1 – 4 were aligned with this choice. They made use of 3 – 5 = 2 the same way and applied it to their strategy for 1 – 4 to answer 3. Interestingly, five students (four first-grade and one third-grade) solved 1 – 4 correctly, which corresponds to 3 – 5 = -2 (B). One third grader's answer to 1 – 4 represented the incorrect 3 – 5 = 0 worked example as they answered 0. Even though Sheep6$_{(3rd)}$ wrote "3" and said, "One take away four," when drawing on the number path, her movements showed that she interpreted 1 – 4 as -1 + 4, perhaps because she misinterpreted the direction of the arrows on the examples: "Because they're subtracting one minus four, and I thought you started at the minus one and you go up to the three like those two [options B and C]." Finally, five students' solution strategies for 1 – 4 were not aligned with their choice of 3 – 5 = 2 and indicated either making an exact copy of 3 – 5 = 2, doing 1 + 4, putting the number of jumps as the answer (i.e., 4), or jumping the wrong number on the number path. We classified these types of responses as *other*.

Choosing B: 3 – 5 = -2 and Applying This Worked Example to Solve 1 – 4

Similar to students who incorrectly chose A as the correct worked example for 3 – 5, students with the correct choice of B also referred to the number of jumps, starting number, and ending number when explaining why A and C were incorrect worked examples and B was correct. For instance, Robin4$_{(1st)}$ counted the number of jumps to justify her choice, "One, two, three, four, five" and for C, said, "It didn't get far enough." Duck3$_{(1st)}$ explained why A was not the correct worked example, "They started on the five and landed on two." He, for B, counted from -2 to 3 and confirmed it was 5 and said, "I think it would be in the minuses." Finally, for C, he referred to the answer, "It's not on the zero, it's not on the minus."

Out of 30 students with the choice of 3 – 5 = -2 (B), 17 students' (six first and 11 third graders) responses to 1 – 4 were aligned with this choice. They correctly made use of the 3 – 5 = -2 worked example, wrote -3 for 1– 4, and correctly showed their solution on the number path. Nine students (six first and three third graders) made use of the 3 – 5 = -2 worked example to some extent when solving 1 – 4. Some of them started at an incorrect number (e.g., 0 or 3) but counted backward the correct number of jumps to get into the negative numbers. Some other students answered 1 – 4 correctly when using the empty number path but said the answer was three and wrote three on their paper. Only one third grader—Goat2$_{(5th)}$—despite choosing B for the correct worked example of 3 – 5, answered 3 for 1 – 4 seeing it as 4 – 1. Two first graders' responses to 1 – 4 did not align with their choice of B because they started at an incorrect number and jumped an incorrect amount. Finally, one third grader skipped this problem.

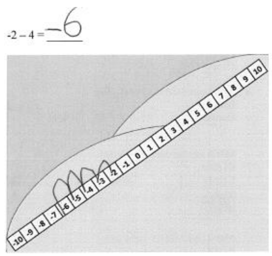
Choosing C: 3 – 5 = 0 and Applying This Worked Example to Solve 1 – 4

Interestingly, rather than primarily referring to the number of jumps, students who chose C for the correct worked example of 3 – 5 often focused on the starting or ending number. As an example, Goose9$_{(1st)}$ rejected A and B because their answer was not zero. Duck1$_{(1st)}$ used his fingers to take away five from three and, similar to Goose9$_{(3rd)}$, thought A and B were incorrect worked examples because “It only gets two” or “Three minus five is not two, it’s zero.”

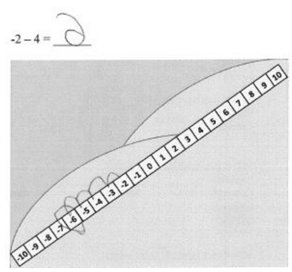
Out of nine students choosing 3 – 5 = 0, only two third graders and one first grader applied the same strategy when solving 1 – 4 and answered zero. One first and one third grader answered -3, corresponding to the correct 3 – 5 = -2 worked example. One first and one third grader solved 1 – 4 as 4 – 1 reflecting the incorrect 3 – 5 = 2 worked example. One first grader—Bat5—used her fingers to count and answered 0. However, when drawing on the number path, she correctly showed -3 as the answer for 1 – 4. Lastly, one first grader did not provide any answer for 1 – 4.

Second Worked Example Task

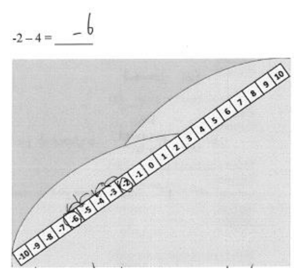
On the second worked example task, 33% of first and 54% of third graders correctly solved -2 – 4 on the written response (43% overall), but even more students solved it correctly using the empty number path (52% of first and 65% of third graders; 58% overall). In fact, 43% of students (33% first and 54% third graders) correctly answered on both the written response and the number path because if they wrote the correct answer, they also illustrated it correctly. Among these students, seven (four first and three third graders) had chosen 3 – 5 = 2 (A), 13 (four first and 11 third graders) had chosen 3 – 5 = -2 (B), and three (one first and two third graders) had chosen 3 – 5 = 0 (C) in the initial worked example task. These students’ drawings on the empty number path indicated that many correctly identified the important features of the 3 – 5 = -2 worked example including the starting number and number of jumps to use when solving -2 – 4 on an empty number path (see Figure 3 for examples). However, many did not show the ending number (or answer) by circling it or circled both the starting and ending numbers. Some of them did not show the directional movements on their jumps. Thus, from only drawings, it was not clear where the starting and ending numbers were and which direction they jumped. In fact, Rabbit3$_{(3rd)}$ only put a mark on -6 and explained, “I went to four [-4] and one, two [referring to the jumps],” and she ended at -6.



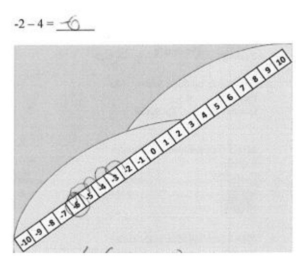
Duck2$_{(1st)}$ showed non-directional jumps and did not circle the answer.



Goose3$_{(1st)}$ showed non-directional jumps and circled the answer.



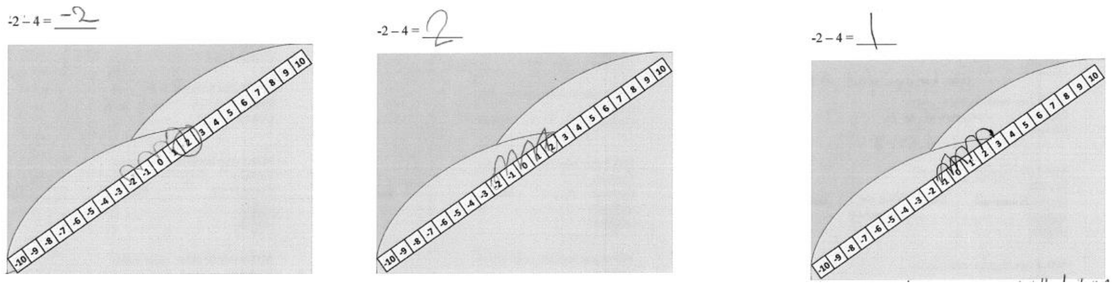
Horse4$_{(3rd)}$ showed directional jumps and circled the start and answer.



Horse8$_{(3rd)}$ showed directional jumps and circled the answer.

Figure 3: Examples of Students Solving -2 – 4 Using an Empty Number Path

Of those students who chose 3 – 5 = 2 (A) on the first worked example task and did not answer -2 – 4 correctly, a few answered two–solving it as 4 – 2—or negative two—solving the problem as 2 – 4 (see Horse9$_{(3rd)}$ in Figure 4). Their drawings on the empty number path demonstrated that they often started at an incorrect number (e.g., copying the exact 3 – 5 worked example and starting at 3) or jumped in an upward direction (see Figure 4 for more examples).



Horse9$_{(3rd)}$ started at 2 and jumped downward.

Goose4$_{(1st)}$ jumped in an upward direction.

Bat6$_{(1st)}$ started at 3 as in the example but jumped 6 (using the 2 and 4) by going down and up.

Figure 4: Examples of Students Solving -2 – 4 Incorrectly

One first grader—Robin3—correctly made use of the worked example when using the empty number path, saying, "Start up at negative two, and three, and four, and six [ending at -6]" but wrote down six as his answer. Among students who chose 3 – 5 = -2 (B) on the first worked example task, seven (four first and three third graders) also correctly made use of the second worked example task when using the empty number path but did not answer correctly on the written response. For example, Robin2$_{(1st)}$ said, "Take away four," drew four jumps between -2 and -6 on the number path, but said, "It's six" and wrote "6."

Other common answers of -2 – 4 among the students with the choice of B included -2, 2, and 0. Students' strategies for -2 – 4 as shown in their drawings on the empty number path often resulted in an incorrect answer because they started at 2 and jumped downward 4 to get to -2 or started at -2 and jumped 4 upward to get to 2. An interesting example was Goose6$_{(1st)}$ who started at -2 and made jumps to 4. She then counted the jumps (or distance) between -2 and 4; however, she did not take account of the direction and answered 6.

Some of the students who chose 3 – 5 = 0 I on the first worked example task and were incorrect on -2 – 4 responded 0 or 2. For example, Bat5$_{(1st)}$ said, "Of course I'll have to start at 2" but actually started at -2 on the number path and justified starting at -2 because, "It showed me (pointing to the -2 in the problem)." Then, she made four jumps upward, "One, two, three, four" and said, "It equals two." After she wrote 2, the interview asked her why she went up, and she referred back to the worked example, misinterpreting it by explaining, "Because this one, it says 3 – 5 equals negative two, and I saw that you had to go up instead of down." Goose9$_{(1st)}$ answered 0 on the written response because she used her fingers; she held up two fingers and then put them down when trying to take away four. To model this, on the empty number path, she correctly started at -2 but then jumped upward twice and stopped at 0.

Discussion and Implications

When given the option to choose which worked example correctly illustrated 3 – 5, students' inclination to choose 3 – 5 = 2 (A) indicates that about a third of the students had a strong prior schema for subtraction as subtracting a smaller number from a larger one (i.e., 5 – 3) (e.g., Bishop et al., 2014; Bofferding, 2011; Murray, 1985). Their whole number subtraction schema was strong enough that even when presented with the correct example (worked example B; 3 – 5 = -2), they did not determine it as a match. However, when then asked to solve 1 – 4, a few of these students—especially first graders—were able to answer correctly by starting at the correct initial number. These results suggest that introducing negative numbers as a result of subtraction (i.e., 3 – 5 = -2) could support students in developing a directional interpretation of subtraction and weaken (or eliminate) the schema that you can only subtract a smaller number from a larger one.

Students often focused on the number of jumps but, especially on the first worked example task, aligned their interpretation of jumps to how they viewed the problem (e.g., if they interpreted the problem as 5 – 3, they talked about it as having three jumps); sometimes they misinterpreted the direction of the jumps in the worked example, which was more prevalent with the second worked example task (-2 – 4). Students might have counted from -2 to -1, 0 and so on instead of -2 to -3, -4, and so on to align with interpretations of subtraction as getting smaller in absolute value (because it wouldn't make sense for them to go in a direction where the numbers were increasing in absolute value). Thus, students might need more experience interpreting and using number path and number line visuals, which could support their developing understanding of integer order and values and help those students who primarily relied on using their fingers and thought the answer to the first worked example task was zero.

In our previous work, we found that many students would solve integer subtraction problems by ignoring the negative signs, subtracting the number with smaller absolute value from the number with larger absolute value, and then append a negative sign to their answer (e.g., Aqazade et al., 2018); in this case, students would solve -2 – 4 as 4 – 2 = 2 and then make the answer -2. However, we did not see any students use this strategy, suggesting both their focus on the jumps and use of the worked example visuals helped them avoid this misinterpretation.

Overall, encouraging students to make sense of and use the integer worked examples provides opportunities for productive struggle and potential to resolve those challenges over time. Particularly, such encouragement in using the visual as presented in the worked example did help the students because they had higher performance on the visuals than when writing numerical answers. Part of the difference between the two formats is that students who were not familiar with negative numbers did not include the negative sign in their written answers, even if they landed at a negative number. Therefore, the tasks also revealed what elements or features students interpreted as important and provided insight into their number schemas. Further, our work adds to our understanding of the usefulness of worked examples (e.g., Booth et al., 2013; Booth & Davenport, 2013); by the second subtraction worked example task, the first graders' performance was closer to the third graders, so the worked examples seemed to help the novices begin to make sense of the problems.

POSITIVE OUTCOMES OF A STUDENT'S STRUGGLE WITH NEGATIVES

Zarina Gearty
University of Massachusetts- Dartmouth
zmadan@umassd.edu

Operations with negative numbers are taught to students several years after solely dealing with positive numbers. However, only one unit of one year is devoted to learning and becoming proficient in operating with both negative and positive numbers. This particular study reports on a student who has been taught the concept of negative numbers but not formally introduced to strategies or rules for operations. During clinical interviews, the student was given open number sentences and asked to explain how she would solve for missing values. Her explanations reveal that working with adding and subtracting negative numbers was a form of productive struggle that had potential to build connections and illuminate mental inconsistencies. These type experiences could be beneficial for both students and teachers.

Keywords: Instructional Activities and Practices; Middle School Education; Number Concepts and Operations

Introduction

Working as an 8th grade math teacher, I noticed that my students' experiences with the algebra content was greatly shaped and influenced by their ability to accurately operate with integers, which is a concept addressed in a 7th grade standard (National Governors Association Center for Best Practices & Council of Chief State School Officers, 2010). Many of my students did not feel confident and often misapplied integer rules; they would tell me that they are just "not good with negatives". Research into student learning of integers has consistently found that operations with negative numbers is a difficult concept for students (e.g., Bishop et al., 2014; Bofferding et al., 2018; Chiu, 2001; Prather & Alibali, 2008). So why is it that students spend most of their elementary years developing a robust understanding of operations with positive numbers, but then only a couple of months on operations with negative numbers? Negative numbers are introduced in the 6th grade curriculum (National Governors Association Center for Best Practices & Council of Chief State School Officers, 2010), but as one 6th grade teacher told me, "I make sure to not assign problems with negative number operations, because they don't learn those until 7th grade". As a response, I thought why not? Could students reason through such problems before formal instruction but after being introduced to negative numbers? How would they reason and struggle through it? And most importantly, what benefits could arise from these struggles?

Research conducted by Laura Bofferding and colleagues (Bofferding et al., 2018) pointed to the idea that students as young as first grade can invent their own notations for negative numbers and use it to work through adding and subtracting positive and negative numbers. Bishop et al. (2014) investigated how fourth graders, who had not been formally introduced to negative number in the classroom setting, used their knowledge of whole number arithmetic to solve problems with negative numbers. However, I found few studies that explored how students who *had* been formally introduced to the concept of negative numbers in the classroom, but not yet to integer operations could reason about arithmetic with this newly learned concept**.** This gap in research led me to work with 6th grade students to conduct an exploratory qualitative study to investigate the type of thinking that the students would demonstrate when asked to work with integers. The research question for my study was:

How do these 6th grade students, who perform at grade level, reason about the addition and subtraction of negative number before receiving formal instruction?

Conceptual Framework

Theoretical Framework

I situate my study under the theory of constructivism. Under this theory, learning is an active process of constructing a system of concepts, the smallest unit of which are referred to as schemas (Skemp, 1987; von Glasersfeld, 1995). This construction of knowledge occurs at the individual level; the learner organizes new information into already existing schemas, assimilating to build new knowledge, or reconstruct previous schemas in order to fit new information (Skemp, 1987). This reconstruction can happen as a result of cognitive dissonance, which is when one encounters a piece of information that does not fit into previous schema (von Glasersfeld, 1995). I view this cognitive dissonance as an example of productive struggle, where students engage in "some perplexity, confusion or doubt" (Dewey, 1933, p. 12).

In this study, my assumption is that each student has their own unique set of schemas and constructs for the concepts of numbers. I will use the phrase formal instruction to refer to formal instruction of integer addition and subtraction.

Student Reasoning

Reasoning is a fundamental aspect of mathematics and the main construct in my study. I define reasoning as the process of mental actions involving the use personal mental schemas to solve a problem (Piaget, 1970). I look to research that studied students without experience of formal, classroom instruction on integer arithmetic, particularly exploring their thinking and reasoning on tasks via interviews. Lamb et al. (2018) conducted an investigation of student reasoning with integers and integer subtraction and addition across multiple grades (2, 4, 7, and 11) using clinical interviews and a constructivist theoretical lens. They previously developed and refined a framework which categorized solutions and views of numbers as order-based, analogy-based, formal, computational, or emergent. After analyzing interviews of 160 students, researchers saw that the type of reasoning used varied across those students without formal instruction in grades 2 and 4 and students right after instruction in grade 7. Specifically, in students without formal instruction, the researchers saw that students applied knowledge of addition and subtraction of positive numbers to solve problems with all negatives. For example, so solve -9 + -1, student would state that since 9 + 1 is 10, -9 + -1 would be -10.

Another way that reasoning has been studied is through metaphors of addition and subtraction. Kilhamn (2018) studied three metaphors used in arithmetic reasoning: measurement, motion along a path, and object collection. She observed how these metaphors appeared in formal instruction of the concept of subtraction. The measurement metaphor was defined as students viewing numbers as lengths of segments. Motion along a path was viewed as interpreting numbers are locations and operations as movement along the locations. She categorized the idea of comparing sets of numbers and phrases such as smaller number taken from larger number as examples of object collection metaphor. These metaphors apply to arithmetic with positive numbers and therefore could be constructed by individuals based on their previous experiences.

Methodology

Setting and Participants

There were two participants in the study. However, in this brief research report, I will focus only on Julia (pseudonym) because she demonstrated reasoning that was not using algorithms or rules. Julia attended a public middle school for grades in Northeastern USA. I chose grade six because it is the grade where students are introduced to negative numbers but not yet shown strategies for operating with them.

Data Collection

Two clinical interviews (Ginsburg, 1997) were conducted with each participant. Since the main goal of this study was to explore students' reasoning, clinical interviews were appropriate because this methodology is used to "gain insight into many aspects of the children's thought" (Ginsburg, 1997, p. x). The interviews were conducted virtually through Zoom due to schools and public places being shut down during the Covid-19 pandemic.

In the first interview, I asked general open-ended questions (Ginsburg, 1997) about integers, such as "how would you describe negative numbers?" and then open number sentence (Bishop et al., 2018) questions such as $-8 + 12 = \square$. In the second interview, the number sentence questions had the missing number in different places, such as $-5 - \square = -14$. A total of 13 number sentence questions were asked in the two interviews. Using the virtual whiteboard feature on Zoom, I asked the participants to visually demonstrate their thinking. I used their written work as a secondary data source.

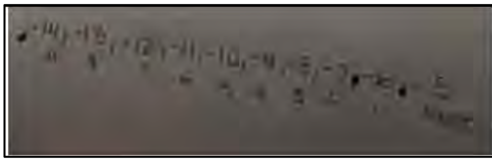
Data Analysis

After I transcribed the interviews, I conducted an initial round of open coding (Corbin & Strauss, 1990), coding for the indicators of definitions and descriptions of negative number, as well as my interpretation of the participant's explanation. My analytical framework was inferred by the Ways of Reasoning framework developed by Bishop and colleagues (Bishop et al., 2014) and Kilhamn (2018) and then evolved as I worked through the data. I looked for codes that were indicators of the concept of negative/positive numbers, such as statements about negatives to the right of zero or viewing numbers as lists. Statements about reasoning such as breaking into parts or jumping to zero were indicators of the types of reasoning. Lastly, strategies such as counting by 1s or moving on a number line were indicators of arithmetic metaphors. I grouped another set of themes based on my interpretation of how the participant thought of the addition/subtraction: increase/decrease sequentially or combining groups. During this process, I re-watched the recordings to ensure consistency between my notes, the transcript, and my memory. To ensure validity, I triangulated the data from transcripts with the data of participant's written work. Additionally, I presented two pieces of data to other research colleagues for feedback on my interpretations.

Results

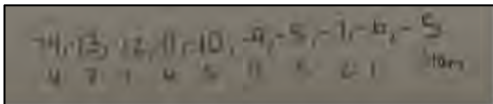
In this section, I report on my findings regarding the way that Julia approached the open number sentences. I chose to showcase Julia because she did not use any computational rules or procedures to solve the tasks but rather seemed to be using strategies from positive number operations.

Julia's main way of reasoning to determine the missing values in the number sentences included writing out numbers as a list and counting on. The lists were similar to a number line, but distinct in that the order was not always consistent; reading left to right, the order of the list was decreasing for two problems and increasing for the rest. However, when asked about how she visualized positive and negative numbers, Julia drew a number line. When using lists of numbers, Julia started with the first value given and then sequentially by 1s counted up to the other value in the number sentence in solving -5 – □ = -14 (see Fig 1). She then counted how many numbers it took to get to the final value and gave that as the answer, similar to the measurement metaphor (Kilhamn, 2018). The noteworthy finding was that Julia did not change her approach when the task was slightly changed to -5 + □ = -14 (see Fig 2).



R: So walk me through how you got 9.
J: Okay so I did a number line. I started at negative 5 on the right and I went all the way back to negative 14. I started at negative 5 and counted it to negative 14 and I got 9.

Figure 1: Julia's explanation and visual for the task -5 – □ = -14



R: Show me how you worked out this problem.
J: So this is my number line. I started at negative 5, kinda like the same as the previous number. I went up to negative 14 and got 9.

Figure 2: Julia's explanation and visual for the task -5 + □ = -14

My interpretation is that it seems Julia is not attending to the operation of addition versus subtraction, but instead focusing on the values, with the missing number representing the amount of numbers between the given values. Julia did not seem conflicted about her answers until I pointed out the fact that she answered 9 for both tasks, to which she changed her answer for -5 – □ = -14 to -9 because " maybe instead of adding 9, subtract negative 9 to get -14".

Discussion

The experience of the two tasks reported in the results can be viewed as Julia engaging in productive struggle as defined by Hiebert & Grouws (2007) – when students "expend effort to make sense of mathematics, to figure something out that is not immediately apparent" (p. 387). During this struggle, Julia's reasoning is illuminated so it could be interpreted for any hindrances or obstacles. After these tasks, Julia has the potential to make connections between the connection of adding negatives and subtracting positives. Despite not being formally introduced to strategies for operations with integers, Julia was able to apply her reasoning to solve problems with negative numbers. This finding is consistent with Bofferding et al. (2018) and Bishop et al. (2014) who saw that young learners can conceptualize negative numbers.

The main implication from the presented results is that giving a student the opportunity to reason about integer arithmetic prior to teaching him/her the commonly used strategies can provide access to student thinking that may both inform the teacher and motivate the student. The experience may illuminate any mental inconsistencies the student has; activities can be planned that use student thinking as a starting place, such as looking at similarities and difference between operations. Such experiences would allow for student engagement in ways that applying integer rules cannot support. For example, true/false number sentences can be used to develop and challenge students' conception of equality with both positive and negative numbers (see Carpenter et al, 2003 for more).

AN EXPLORATION INTO CHILDREN'S THINKING ABOUT LEARNER-GENERATED INTEGER DRAWINGS

Sailer Galusha-McRobbie
George Fox University
sgalushamcrobbie18@georgefox.edu

Nicole M. Wessman-Enzinger
George Fox University
nenzinger@georgefox.edu

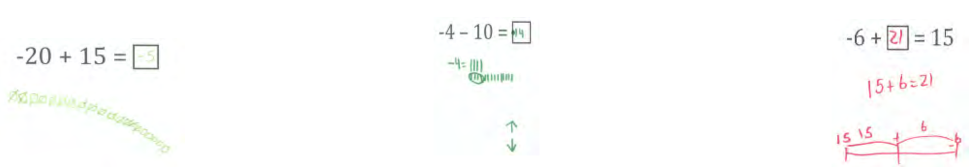
Learner-generated integer drawings are representations for integer addition and subtraction created by children. We present a study where six grade 5 participants examined and unpacked other children's learner-generated integer drawings for integer addition and subtraction. Themes that emerge included: (a) Participants' initial reasoning often did not align to the drawings; (b) and, without prompting the participants critiqued the drawings. Because participants' reasoning differed from the drawings presented and they critiqued the drawings, this offers potential for learner-generated drawings as a pedagogical tool.

Keywords: Cognition; Elementary school education; Mathematical representations; Number concepts and operations

Children's thinking about integers is beautiful. It is beautiful in the sense that children extend and enhance their whole number reasoning with negative integers (Bofferding, 2014; Bishop et al., 2014); they invent their mathematics with negative integers as young mathematicians. Children create unique drawings (i.e., learner-generated drawings; van Meter & Garner, 2005) when they solve integer addition and subtraction problems for the first time (Wessman-Enzinger, 2019a, 2019b). Integer learner-generated drawings (van Meter & Garner, 2005; Wessman-Enzinger, 2019b) are constructions that children create for solving integer addition and subtraction problems. The integer learner-generated drawings are a type of representation for integers that is created by the children, rather than teachers or researchers. An important pedagogical consideration is how children make sense of other children's learner-generated integer drawings. The following research question guided this work: *How do children make sense of other children's drawings for integer addition and subtraction?*

Theoretical Framing: Learner-generated Integer Drawings

Learner-generated integer drawings can exhibit children's thought processes as they work through solving unfamiliar problem types (Wessman-Enzinger, 2019a). Children create a variety of different types of drawings for integer addition and subtraction: single set of objects (e.g., Figure 1a), double set of objects (e.g. Figure 1b), number sequences, empty number lines (horizontal or vertical; see, e.g., Figure 1c), number lines (horizontal or vertical), number sentences (horizontal or vertical; see, e.g., Figure 1c), emphasis on plus, minus, and negative signs (see, e.g., Figure 4 below where a minus signed is changed to a plus sign).



(a) (b) (c)

Figure 1: (a) Single set of objects, (b) double set of objects, and (c) empty number line.

Learner-generated drawings for integers vary from typical integer instructional models (Wessman-Enzinger, 2019a, 2019b). Consider the empty number line in Figure 1I. The negative numbers are on the right-hand side and positive numbers on the left-hand side of the number line; this differs from traditional number line instructional models where negative numbers are on the left-hand side of the number line (e.g., Nurnberger-Haag, 2007, 2018; Saxe et al., 2013; Stephan & Akuyz, 2012).

As teachers and researchers, if we wish to support students' constructions and representations in classroom discourse, it is first necessary to consider the ways in which children invent, use, and make sense of their own ***and others' drawings***. This study, therefore, aimed at extending the prior work that has been done with learner-generated integer drawings (e.g., Wessman-Enzinger, 2019a, 2019b) by studying how children make sense of other children's drawings. It is critical to understand how children make sense, not only of models of integers, but other children's learner-generated integer drawings. Insight into how children make sense of these drawings will offer insight not only into research on children's thinking about integers, but also understanding of the potential these drawings have as instructional models or representations for integers.

Methods

Six grade 5 participants (Lucy, Maggie, Evan, Hudson, Megan, Estrella) volunteered to participate in three, structured task-based interviews (Goldin, 2000) in May and June 2020. We met virtually on Google Meet for the interviews for 45 to 60 minutes and some children could not participate in all three interviews. All children participated in the first interview (n = 6). One child did two of the three interviews (Evan); three children did all of the interviews (Hudson, Megan, Estrella)—resulting in a total of thirteen interviews.

For the interviews, we created tasks by using actual learner-generated integer drawings and we tried to vary the types of drawings we used (e.g., single set of objects, double set of objects, empty number line). Figure 2 shows a sample task from interview 1: *Students solved problems with negative numbers for the first time and you will see their solutions and drawings. Help us make sense of the student's thinking. Share if you agree or disagree with anything* (see, e.g., Figure 2).

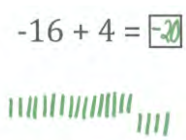


Figure 2: Sample task from interview 1 that uses a double set of objects.

Figure 3 shows a task from the second interview with the following directions: *Students worked on problems. Sometimes they were unsure. The students shared different solutions they thought might work. Sometimes they determined correct solutions; sometimes they did not. Sometimes none of their solutions were correct.* We asked the children to explain the drawing and if the student changed their mind correctly or incorrectly.

Figure 3: Sample task from interview 2 with an empty number line drawing highlighting a student changing their mind from 3 to -1.

The third interview consisted of showing the participants two drawings, where one was correct and one was incorrect. We provided the following directions: *We are going to show you students' solutions, drawings, and work again. The students solved open number sentences (e.g., 7 - __ = 9; ___ + 3 = -10). They found the number that goes in the box. We will play: This or That? One of the solutions is correct and one is incorrect. Help us!* We asked the children to select "this or that" as the correct or incorrect solution and describe the drawings.

For data analysis, we transcribed all of the interviews, took notes, and engaged in open coding (Corbin & Strauss, 2015; Teppo, 2015). As part of open code discussion, we drew on our previous discussions, the transcripts, and notes. As we identified themes, we created intermediate codes, where we started writing out the themes and revisiting the transcripts. We then coded all of our units of analysis (i.e., transcripts of student responses) and negotiated differences (coded 103 units of data related to making sense drawings). In this research brief, we will discuss two of the themes we found: reasoning and critique of drawings.

Results: Reasoning

There were three types of reasoning that our participants used when they were presented with the tasks: (1) using the drawing explicitly, (2) using reasoning related to the drawing, or (3) using unrelated reasoning.

When using the drawing explicitly, participants directly referenced what they saw in the drawing to aid their reasoning (8% of units of coded). When using reasoning related to the drawing, students did not explicitly state that they were referring to a specific part of the drawing, but the language they used aligned with part of the drawing in some way (39% of units coded). When using unrelated reasoning, students expressed their thinking, used examples, or shared analogies that did not align to anything seen in the drawing (53% of units coded).

When shown the open number sentence -6 + • = 15 with a number line drawing, our participant Hudson said "as you can see in the drawing" and reference the movement on the number line with an explicit reference. When shown the open number sentence, -4 – 10 = • and drawings with tallies in Figure 1b (above), our participant Evan began talking about the idea of numbers being leftover. Although he never explicitly referenced the drawing, his reasoning aligned with the drawing because the drawing also had the idea of leftovers, as referenced by the circled tally marks in the drawing that were leftover. For the category of using reasoning not related to the drawings, our participant Megan was shown the task below (see Figure 4) and started using an analogy of owing her mom money. Although a helpful analogy, her reasoning was not related to the drawing because there is nothing in the drawing that indicates debt or money.

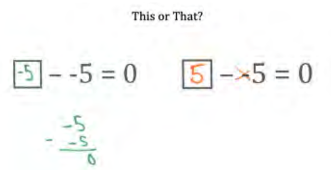

Figure 4: Vertical number sentence (left) and symbolic markings (right).

Results: Critique on other Students' Drawings

Another theme of examining others' drawings is that our participants critiqued the drawings they were shown. Critiquing other students' drawings occurred in 20% of the units of data. When our participants did not comment on the drawings and interacted with them without making additional commentary on the design of the drawing itself, we did not consider this a critique (80% of the units of data).

Evan, when examining the drawing in Figure 1c (see above) for -6 + • = 1 5, critiqued this number line drawing, with negative integers non-traditionally placed on the right-hand side, Evan stated, "I think it [reference to -6] should be switched with the 15," he suggested moving -6 to the left side of the number line and moving the 15 to the right-hand side of the number line, a more traditional approach to ordering numbers on a number line. He stated, "I think it just maybe makes it a little more confusing." When he referenced the negatives on the right-hand side of the number line as confusing, he offered a critique of the drawing.

Lucy, when examining the drawing in Figure 5 for -11 – -2 = •, bot h critiqued and affirmed the drawing presented to her. Lucy explicitly critiques the number sentence and offers a different interpretation; she also affirmed the vertical number line and offers how it provided her a new way of thinking. Lucy noticed that -11 – -2 in the problem presented does align with -11 + -2, which the student wrote:

> I would do different with that problem is so I would take away the negatives so that it would be less confusing and I would change it back so I would show, so that means like I would show that is also another way to solve negative 11 minus negative 2 instead of showing that negative 11 plus negative 2 gets you negative 13. …

Because we considered number sentences that were learner-generated to be drawings as well, we considered this to be a critique of the drawing. In a similar way, Lucy also noticed that the number line created by the student is something different than what she would create (e.g., "I actually wouldn't think of it like that…); but, she affirmed that it can be solved that way and provided her a different way of thinking about integers.

> So it looks like there is a number line going up and down which I actually wouldn't think of it like that I would think of it across but I like the way they thought of that, um it does make a little bit more sense than going crosswise.

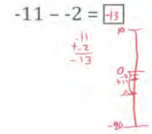

Figure 5: Problem presented to Lucy in the first interview.

Concluding Remarks

The themes described here highlight ways that children engage with drawings they did not produce. A noteworthy take-away is that children may not prefer using the drawings directly; however, their reasoning may be related to the drawings. Using learner-generated drawings may offer new insights or ways of thinking to a child that they had not previously been considered.

Critiquing others' reasoning is an important part of doing mathematics (National Governors Association Center for Best Practices & Council of Chief State School Officers, 2010). In this study, children critiqued the learner-generated drawings without being prompted to do so. When students critique drawings, it invites the possibility for teachers to leverage that critique in a follow-up task wherein, students are asked to make their own drawings.

EL MODELO DE LA RECTA NUMÉRICA COMO ESPACIO DE REPRESENTACIÓN HOMOGÉNEO

THE NUMBER LINE MODEL AS A HOMOGENEOUS REPRESENTATION SPACE

Sharon Samantha Membreño Estrada
Cinvestav-IPN
ander.membreno@cinvestav.mx

Claudia Margarita Acuña Soto
Cinvestav-IPN
claudiamargarita_as@hotmail.com

En el presente trabajo se investiga el tránsito de los signos desde índices hasta símbolos en tareas de desigualdades numéricas e inecuaciones lineales, usando el modelo de la recta numérica. En un estudio de caso con una estudiante que tiene buen manejo de la numerabilidad, encontramos que existen complejidades en el uso de los signos y otra de tipo lógico en la interpretación de indicaciones simultáneas cuando el modelo es una representación homogénea.

Palabras clave: Conceptos numéricos y operaciones, cognición, educación secundaria, representaciones numéricas.

Antecedentes

El modelo de la recta numérica ha sido usado como recurso didáctico del que se han destacado distintas propiedades que van desde la medida hasta la operación. Este modelo se usa con o sin marcas, como una guía, Diezmann et al. (2006, 2010), o se abunda en el orden sin considerar la distancia, Teppo et al. (2013).

Aquí consideramos a la recta numérica como un espacio de representación homogéneo, Nemirovsky (2003) donde la posición de los signos es su única propiedad, para abordar tareas de desigualdades numéricas e inecuaciones lineales. En particular, analizamos el papel de las marcas y números enteros respecto al orden, posición relativa y ubicación espacial con carácter numérico. En este entorno los segmentos unitarios son la base del modelo tanto numérico como espacial.

Marco referencial

Desde el punto de vista de Radford, en la teoría de la objetivación el saber no puede ser algo de lo que podamos apropiarnos o lo que podamos poseer, sino que "es un proceso de elaboración activa de significados" (Radford 2006[a], p. 116).

La objetivación está ligada al uso de instrumentos, signos o artefactos que no son ayudas para el aprendizaje, sino medios cuya presencia y uso imprimen un sello distintivo sobre lo re-construido a través de una mediación semiótica, desarrollada en una praxis reflexiva (Radford, 2004, p. 13)

Para establecer las funciones de los distintos tipos de signos usados en las tareas planteadas vamos a considerar que los segmentos pueden ser tanto índices como símbolos matemáticos, Pierce (2005) dependiendo del uso que le dé el estudiante.

Finalmente, en este trabajo la recta numérica será un artefacto regulado por las propiedades de orden, posición relativa y ubicación espacial donde los números, las marcas e incluso los segmentos unitarios son parte de la estructura semiótica del modelo.

Metodología

El objetivo de este estudio es indagar el uso semiótico del modelo de la recta numérica para la interpretación de las desigualdades numéricas e inecuaciones lineales del tipo $x < b$ o $x > b$ con x y b enteros, a través de un enfoque cualitativo que produce datos descriptivos, apoyándose en un estudio de caso llevado a cabo en condiciones de cuarentena durante el año 2020, cuyos instrumentos fueron un cuestionario a través de GeoGebra y una entrevista – intervención vía Zoom que propició una práctica reflexiva en el caso presentado.

La participante es una estudiante de octavo grado con 14 años del Instituto Genaro Muñoz Hernández de Siguatepeque, Honduras, quien a lo largo de este estudio mostró tener un buen manejo de la estructura semiótica del modelo de la recta numérica, tanto de números enteros como de decimales con base en la numerabilidad previamente adquirida.

El cuestionario fue aplicado en dos partes, en la primera se plantearon desigualdades numéricas y en la segunda las inecuaciones, la entrevista se realizó en línea sobre las respuestas incorrectas o incompletas en la entrevista intervención, las cuales se centraron en 1. La localización de la zona solución de dos desigualdades numéricas y 2. La detección de la zona solución de dos inecuaciones simultáneas.

Resultados

En las respuestas sobre la localización de la zona solución, las marcas usadas originalmente por la estudiante eran inexactas, como en el siguiente ejemplo, donde se solicita que marque la zona de los números mayores que 5 y la zona de los números mayores que 7.

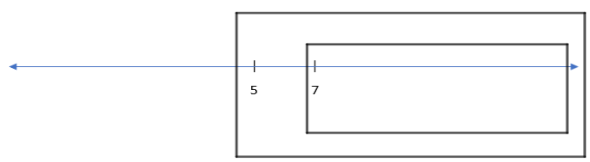

Imagen 1: Respuesta de la estudiante a la tarea

La respuesta que se dio por separado dio motivo al siguiente diálogo:

28. I. … ¿Algún entero cumplen las dos condiciones?
29. E: Mmm… (Silencio)
30. I: ¿Algún entero cumple que es mayor que 5 y es mayor que 7?
31. E: Sí
32. I: ¿Cuáles?
33. E: Todos los que siguen después del 5 y después del 7
34. I: Pero ¿6 cumple esa condición?, ¿Cumple las dos condiciones al mismo tiempo?
35. E: Ahhh … no.
36. I: Ah ok, entonces solo cumple una

Aquí confrontamos el carácter de índice de la solución usada por la estudiante y la no consideración de la zona con dos condiciones numéricas simultáneas, que pudo resolver correctamente por separado, debido a una interpretación lógica inadecuada. El diálogo continúa como sigue:

40. I: Para que me cumpla las dos condiciones ¿Qué número tiene que ser?
41. E: Tiene que ser un número que sea mayor que 7

La estudiante puede darse cuenta de sus errores, sin embargo, considerar las dos indicaciones al mismo tiempo representó un reto para su interpretación.

Esta problemática, aparecerá nuevamente en las inecuaciones, como vemos enseguida:

129.I: Ok aquí vuelvo a ver la misma zona, ¿Qué le pedían en esta tarea? En esta tarea se le pedía que representara en la siguiente recta numérica la solución. Esto es, marca la zona de los números si son enteros o no y cumplen las dos condiciones x > 5, pero también x > 7. ¿Cuál sería esa zona? ¿Es una zona o son dos zonas?
130. E: ¿Es UNA zona que cumple las dos condiciones?
131. I: Correcto
132. E: Ahhh … entonces sería la zona después del 7, a partir del número 7 hacia después
133. I: Ah perfecto. ¿La puede dibujar?
134. E: ahí está (La dibujó inmediatamente)

Ella no se había percatado de que la solución es una única zona, aunque ya se había discutido una situación parecida en el caso numérico (*ver línea 132*), discusión que transcurre en adelante desde 1. Un momento de duda ante la anticipación, 2. La verificación y 3. La posterior *objetivación,* todo ello producto de una práctica reflexiva desde el punto de vista de Radford (2006b).

En la siguiente imagen podemos ver que en esta ocasión si responde a las restricciones numéricas adecuadamente.

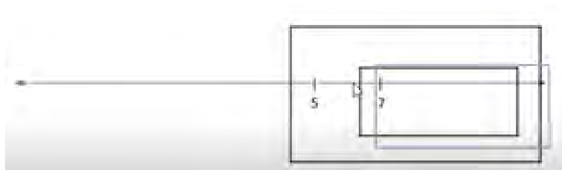

Imagen 2: Respuesta de la estudiante a la tarea en la entrevista

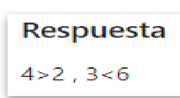
Por último, la tarea presentada a la estudiante estaba relacionada con el cumplimiento de dos condiciones simultáneas con inecuaciones, que incluía una combinación del signo de desigualdad y números positivos, donde pedía lo siguiente:

Da un valor entero para x que cumpla con las siguientes condiciones: x > 2, pero también x < 6



Respuesta
4>2 , 3<6

Imagen 3: Respuesta original de la estudiante a la tarea 19 de la actividad 2

Se llevó a cabo el siguiente diálogo para discutir la respuesta original dada a la tarea en el cuestionario.

155.I: Ahora ésta otra, un valor entero para x que cumpla con las siguientes condiciones x > 2, pero también x < 6
156.E: El número 1, ehh … no. ¿Un solo número para los dos verdad?
157.I: Correcto
158.E: El número 3

Hay un nuevo momento de duda en su interpretación (*línea 156)* aumentado con la complejidad de los dos tipos de signos de desigualdad usados, pese a haber resuelto con éxito el caso numérico con dos condiciones simultáneas. El siguiente diálogo se refiere a esta tarea:

167.I: Entonces cuando le preguntan acá, ¿Cuántos enteros cumplen las dos condiciones al mismo tiempo? ¿Cuál fue su respuesta?
168. E: Todos
169. I: Entonces ahora ¿Cuál es su respuesta?
170. E: Eh sería, mmm … todos los números que son menores que 6
171. I: Menores que 6 ¿Segura? Recuerde que la condición es que sea mayor que 2, pero también menor que 6 ¿Cuántos enteros hay que sean mayor que 2 y menor que 6?
172. E: Que sean mayor que dos y menor que seis. Ah no… Eh (silencio largo)
173.I: Dejémoslo ahí, ahora vamos a pasar a su representación. Ahí está representando los números mayores que 2 y los números menores que 6 ¿Sí? ¿Cuál sería la zona?

Luego de un largo momento de reflexión, el uso del artefacto medió su respuesta y finalmente logro una interpretación adecuada para los dos eventos .

179.I: Ok, ahora que me cumpla las dos condiciones al mismo tiempo
180.E: Mayores que dos y menores que 6, ¿Verdad? …
181.I: Marque la zona, ¿Cuántas zonas serian, una, dos o cuantas?
182.E: (repetía en voz baja varias veces: mayores que dos y menores que seis) Sólo sería la zona que está entre el número 2 y el número 6.
183.I: ¡Correcto, ahora márquela!
184.E: ¡Yuju!
185.I: Marque la zona
186.E: (Guarda silencio y la marca correctamente) …

La reflexión interna observada que tuvo el apoyo del artefacto (*línea 182*), permitió marcar la zona correcta

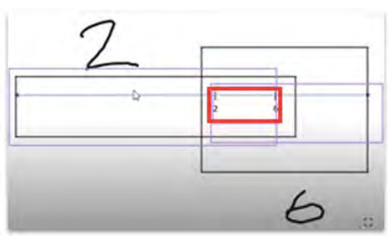


Imagen 4: Respuesta de la estudiante en la entrevista a la tarea 22

Luego del diálogo interno de la estudiante, que da cuenta de la práctica reflexiva mediada por el artefacto e interpreta la solución correctamente sobre el modelo de la recta numérica usado como un espacio de representación homogéneo.

Conclusiones

Este trabajo permitió observar el papel de los diferentes signos presentes al usar el modelo de la recta numérica para trabajar con tareas de desigualdades numéricas e inecuaciones lineales de la forma $x < b$ o $x > b$ con x y b enteros. Encontramos que los signos del modela presentan distinto tipo de complejidades, una de ellas se surge cuando la estudiante hizo uso de los segmentos como índices para establecer una dirección, lo que fue resuelto por el carácter de representación homogénea del modelo. El otro conflicto se representó cuando se deben atender dos indicaciones simultáneas y el uso de diverso de signos para marcar la zona solución, lo que fue resuelto mediante una práctica reflexiva que dio paso a una objetivación al verificar y estimar sus supuestos sobre la representación homogénea y los intervalos unitarios.

THE NUMBER LINE MODEL AS A HOMOGENEOUS REPRESENTATION SPACE

Sharon Samantha Membreño Estrada
Cinvestav-IPN
ander.membreno@cinvestav.mx

Claudia Margarita Acuña Soto
Cinvestav-IPN
claudiamargarita_as@hotmail.com

In this paper we investigate the change of signs from indexes to symbols in numerical inequalities and linear inequalities tasks, supporting by the model of the number line. In a case of study one student who has a good manage of numeracy, we found that there are complexities to use of signs and their logical organization when she has to interpret two simultaneous indications to the solution zone under the look of that this model is a homogeneous representation, complexities that was solved by a praxis reflective.

Keywords: Numerical concept and operations, cognition, secondary education, numerical representations

Background

The number line model has been used as a didactic resource of which different properties ranging from measurement to operation have been highlighted. This model is used with or without marks, as a guide, Diezmann et al. (2006, 2010), or no marks in order without considering distance, Teppo et al. (2013).

Here we consider the number line as a representation space homogeneous, Nemirovsky (2003) where the position of the signs is their only property, to address tasks of numerical and linear inequalities. We analyzed the role of integers and theirs marks with respect to order, relative position and spatial location with numerical character. In this setting unit segments are the basis support both numerical and spatial modeling.

Referential framework

From Radford's point of view, the objectification theory of knowledge cannot be something we can appropriate or possess, but "is a process of active meaning making" (Radford 2006a, p. 116).

Objectification is linked to the use of instruments, signs or artifacts that are not learning aids, but means whose presence and use imprint a distinctive stamp on the re-constructed through a semiotic mediation, developed in a praxis reflexive (Radford, 2004, p. 13).

In order to establish the functions of the different types of signs that are using in the proposed tasks we will consider that segments can be used both as indexes as mathematical symbols, Pierce (2005) depending on the use given to them by the student.

Finally, in this work the number line will be an artifact regulated by the properties of order, relative position and spatial location where numbers, marks and even unit segments are part of the semiotic structure of the model.

Methodology

The goal of this study is to investigate the semiotic use of the model of the number line for the interpretation of numerical and linear inequalities of the form: $x < b$ or $x > b$ with x and b integers when the model is a representation space homogeneous. We development a qualitative approach with data that supported by a case study carried out in quarantine conditions during the year 2020, whose instruments were a GeoGebra supported questionnaire and an interview – intervention by Zoom to promote a praxis reflective, Radford (2004) in the case presented.

The participant was a 14-year-old student of eighth grade from the Genaro Muñoz Hernández Institute of Siguatepeque, Honduras, who showed a good treatment of numerability and the semiotic structure of the number line model, both of whole numbers and decimals in a previously learning.

The questionnaire was proposed in two connecting sections, first part was about numerical inequalities and second she solves linear inequalities, the interview was conducted online where we based on her incorrect or incomplete answers to develop the intervention-interview, which focused on: 1. The location of the solution zone of two numerical inequalities and 2. The detection of the solution zone of two simultaneous linear inequalities.

Results

Originally, the marks to frame the solution zone were inaccurate, in the following dialogue between Researcher (I) and Student I, we were asking her to mark again the zone of numbers greater than 5 and the same time the zone of numbers greater than 7.

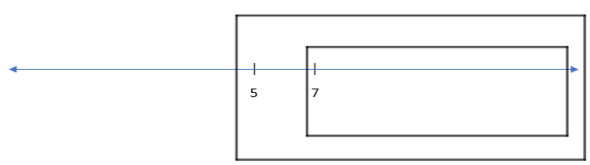

Figure 1: Student's response to the question

The solution was given by parts and then the following dialogue occurs (to see Figure 1):

28. I. ... Do any integers meet both conditions?
29. E: Mmm ... (Silence)
30. I: Do any integers meet that it is greater than 5 and at the same time is greater than 7?
31. E: Yes
32. I: Which ones?
33. E: All the ones that follow after 5 and after 7.
34. I: But does 6 meet that condition, does it meet both conditions at the same time?
35. E: Ahhh ... no.
36. I: Ah ok, then it only fulfills one

Here we confront her about the index character of the solution used by the student and the non-consideration of the zone with two simultaneous numerical conditions, due to an inadequate logical interpretation, which she was able to solve correctly by parts. The dialogue continues as follows:

40. I: In order to meet both conditions, what number does it have to be?
41. E: It has to be a number that is greater than 7.

The student can realize her mistakes, however, considering the two indications at the same time represented a challenge for her interpretation.

This problem will appear again in the linear inequations, as we see below:

129. I: Ok, here I see the same zone again, what we were asked in this task? In this task I asked you to mark the solution on this number line. That is, mark the numbers zone if they are integers or not and meet two conditions: x > 5, and also x > 7. What would that zone be? Is it one zone or two?
130. E: Is it ONE zone that meets both conditions?
131. I: Correct
132. E: Ahhh ... so it would be the zone after the 7, from number 7 onwards.
133. I: Ah perfect, can you draw it?
134. E: there it is (she drew it immediately)

She had not realized that the solution zone is a single area, although a similar situation had already been discussed in the numerical case (see line 132), the discussion goes from 1. She had a moment of doubt before the solution 2. Verification and 3. Subsequent objectification, like a product of a praxis reflective from the point of view of Radford (2006b).

In the following image we can see that on this occasion she answers to the numerical frame adequately.

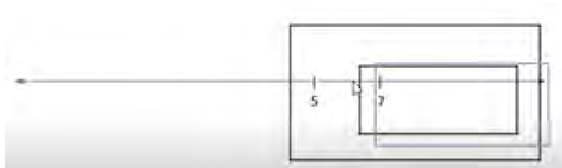

Figure 2: Student's response to the task in the interview.

Finally, the task presented to the student answer was successful to two simultaneous conditions with linear inequalities, which included a combination of the different inequality sign and positive numbers, where we asked the following:

"Give an integer x that satisfies the following conditions: $x > 2$, and $x < 6$"

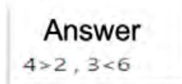

Figure 3: Student's original response to Task 19 of Activity 2

Then the following dialog was held to discuss the original answer given to the task in the questionnaire.

155. I: Now this one, an integer value for x that satisfies the following conditions $x > 2$, but also $x < 6$.
156. E: The number 1, ehh ... no. One number for both, right?
157. I: Right
158. E: The number 3

There is a doubt again in her interpretation (line 156) it increased with the complexity of the two types of signs of inequality used, despite have been successfully solved the numerical case with two simultaneous conditions. The following dialog refers to this task:

167. I: So, when asked here, how many integers meet the two conditions at the same time? What was your answer?
168. E: All of them
169. I: So now what is your answer?
170. E: Uh it would be, um... all numbers that are less than 6.
171. I: Less than 6, are you sure? Remember the condition is greater than 2, but also less than 6 How many integers are there that are greater than 2 and less than 6?
172. E: Greater than 2 and less than 6. Ah no... Eh (long silence)
173. I: Let's leave it there, now let's move on to its representation. There you are representing the numbers greater than 2 and the numbers less than 6, Yes? What would be the area?

After a long moment of reflection, the use of the artifact mediated her response and finally achieved an adequate interpretation for the two events:

179. I: Ok, now that it fulfills both conditions at the same time.
180. E: Greater than two and less than 6, right? ...
181. I: Mark the zone, how many zones would it be, one, two or how many?
182. E: (repeated in a low voice several times: greater than two and less than six). It would only be the zone between number 2 and number 6.
183. I: Correct, now mark it!
184. E: Yay!
185. I: Then you mark the zone
186. E: (Keeps silent and marks it correctly) ...

The internal reflection observed was supporting by the artifact (line 182), allowed to mark the right zone

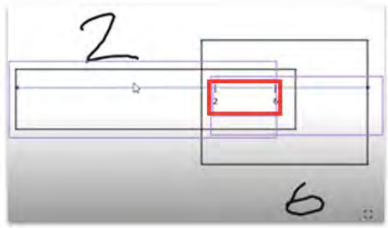

Figure 4: Student's response in the interview to the assignment 22

After the student's internal dialogue (line 182), which accounts for the praxis reflective mediated by the artifact and she interprets the solution correctly on the model of the number line used as a representation space homogeneous.

Conclusions

This work allowed us to observe the role of the different signs present when using the number line model to work with numerical and linear inequalities tasks of the form $x < b$ or $x > b$ with x and b integers. We found that the used of signs of the model present different kinds of complexities, one of them arising when the student made use of the segments as indices to establish a direction, which was solved by the homogeneous representation character of the model. The other conflict was rise when two simultaneous indications must be attended and also the use of different signs to mark the solution zone, which was solved by a praxis reflective that gave way to an objectification by verifying and estimating of her assumptions about the homogeneous representation and the unit intervals.

We investigated how 28 first graders and 27 third graders, who analyzed worked examples as part of a programming intervention, debugged (identified and fixed bugs) and reasoned about double-counting errors in mathematics and programming tasks. Students completed the tasks on a pretest, a midtest (only programming tasks), and a posttest. Results showed that identifying double-counting errors positively correlated with fixing those errors in both programming and mathematics tasks and that students made more gains if they had analyzed worked examples during their programming, game-playing sessions prior to the test. The results suggest the importance of two-dimensional coordination in programming and mathematics debugging.

Keywords: Computational Thinking, Computing and Coding, Number Concepts and Operations, Elementary School Education

Computational Thinking (CT) includes cognitive skills, e.g., abstraction, problem-solving, or debugging (e.g., Wing, 2006, 2011), which align to key computer science standards (NGSS Lead States, 2013) and mathematical practices (National Governors Association Center for Best Practices & Council of Chief State School Officers, 2010). Prior research in elementary education has shown a correlation between programing and mathematics scores (Grover et al., 2016; Lewis & Shah, 2012) and indicated that learning programming helped students extend mathematics content knowledge and develop problem-solving skills (Ahmed et al., 2011; Fessakis et al., 2013; Friend et al., 2018). At the same time, elementary students encountered difficulties in counting while debugging a program (Bofferding et al., 2020; Kocabas et al., 2019). We further explore the relation between debugging in programming and mathematics for early elementary students by focusing on this fundamental skill: counting.

Debugging and Counting “Bugs”

Debugging is difficult for students who have little programming experience (Fitzgerald et al., 2008; Murphy et al., 2008). Studies have reported that fixing errors in a program is harder than identifying them (Fitzgerald et al., 2008; Katz & Anderson, 1987; Lewis, 2012) and that fixing an error becomes easier if the error has already been identified, when students pay attention to relevant features (e.g., Lewis, 2012). On the other hand, having no or little programming experience might lead students to introduce new errors while trying to identify the existing error in a program (Gugerty & Olson, 1986; Nanja & Cook, 1987). Therefore, they are more likely to do extra, unneeded, modifications in a program (Ahmadzadeh et al., 2005; Nanja & Cook 1987).

Double counting, counting the same object or space twice, is a common difficulty for young students in programming (e.g., Kocabas et al., 2019) and mathematics (e.g., Fuson, 2012). Fuson

(2012) found that three- to five-year-olds made more double-counting errors when objects were disorganized than when they were displayed ordinally. Kocabas et al. (2019) reported that first and third graders double counted the spaces on a programming path where it switched directions. Similarly, Battista and colleagues (Battista, 1999, 2010; Battista et al., 1998) reported that second graders without row and column structures may double count where rows and columns overlap. When counting down, as for solving 14 – 6, children say 13 while putting up one finger to indicate that one less than 14 is 13 and gradually say "12, 11, 10, 9, 8" while sequentially raising five more fingers (Maclellan, 1995; Wright et al., 2006); however, some students may count the 14 as one taken away. Encouraging students to debug could help draw their attention to such counting errors. We combine a focus on debugging and counting in this study through the following research questions: (1) How do first and third graders make sense of double counting errors in programming versus mathematics debugging tasks? (a) To what extent does success in debugging double-counting errors correlate between programming and mathematics tasks? (b) How does students' success in debugging change after counting to make programs in a coding game? Does analyzing worked examples earlier versus later affect the changes? (c) What are possible explanations for students' debugging reasoning (different or similar) in programming and mathematics?

Methods and Analysis

For this study, we analyze data from 28 first graders and 27 third graders from a public elementary school in the Midwest. The students completed a pretest, three 20-minute sessions playing *Osmo™ Coding Awbie* in pairs, a midtest, participated in a 30-minute presentation on programming applications, three additional 20-minute sessions of game play, and a posttest. Before the sessions, students were randomly assigned to either the immediate-worked-examples (immediate) group or the delayed-worked-examples (delayed) group. During the first three sessions, students in the immediate group analyzed a set of programming worked examples (<10 minutes) and then played the game without interruption (>10 minutes), while students in the delayed group just played the game. After the midtest, during the second three sessions, the immediate and delayed groups switched their activities.

In this paper, we focused on one programming debugging item (see Figure 1, left panel: bug 1) included on the pretest, midtest, and posttest and one mathematics debugging item (see Figure 1, right panel) included on the pretest and posttest. In both cases, students watched a video of the counting bug occurring and were asked to find and fix the bug. We interviewed the students individually. We ran correlational analyses to determine if there was an association between students' identifying and fixing (debugging) programming and mathematics counting errors.

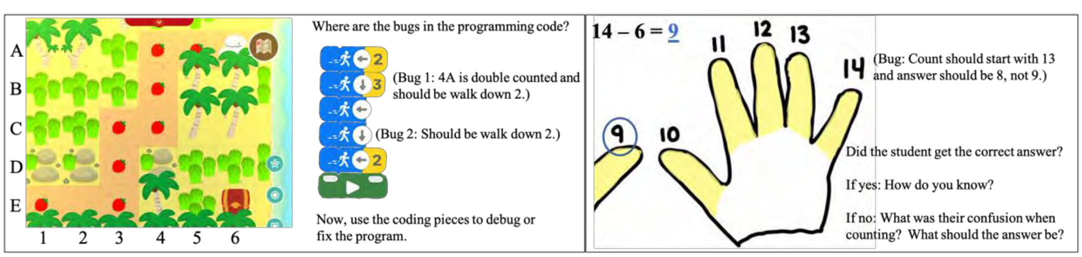

Figure 1: Program Debugging (left panel) and Mathematics Debugging (right panel) Items

Further, we used McNemar tests and Mann-Whitney U tests to determine whether there were significant differences between immediate and delayed groups from the pretest to posttest. For qualitative analysis, we then grouped students based on whether they (1) did not identify or fix, (2) identified but did not fix, (3) did not identify but did fix, or (4) identified and fixed the errors. To provide a clear picture of students' debugging performance, we identified qualitative descriptions of students' reasoning based on their interpretation of the given visuals and their use of additional strategies (e.g., creating their own code rather than modifying given code or counting on their own fingers to determine the answer). Within each group, across the mathematics and programming items, we looked for commonalities in their reasoning.

Findings

Students' identifying and fixing the mathematics bug were significantly correlated within the pretest (immediate group: r=.750, p<.001; delayed group: r=.727, p<.001) and within the posttest (immediate group: r=.806, p<.001; delayed group: r=.802, p<.001). Similarly, identifying and fixing the programming bug were significantly correlated within the pretest (immediate group: r=.650, p=.001; delayed group: r=.606, p=.002), midtest (immediate group: r=.793, p<.001; delayed group: r=.512, p=.009), and posttest (immediate group: r=.651, p=.001; delayed group: r=.592, p=.004). The only other significant correlation for the delayed group was fixing the pretest math counting bug with fixing the midtest programming bug (r=.421, p=.029). On the other hand, the immediate group had a significant correlation with identifying the pretest programming bug with identifying the posttest math bug (r=.430, p=.022) and identifying the math and programming bugs on the posttest (r=.426, p=.027).

Overall, based on a McNemar test of change, students in the immediate and delayed groups made significant gains in fixing the programming bug from pretest to posttest (χ^2= 5.06, p=.021 and χ^2= 8.64, p=.002 respectively), but did not make significant gains in fixing the mathematics bug (χ^2= 1.13, p=.289 and χ^2=.13, p=.727, respectively) (see Table 1). Further, based on Mann-Whitney U tests, the gains in fixing bugs between the two groups from pretest to posttest did not differ significantly on the programming debugging item, U=320.00, z=-.60, p=.550, or on the mathematics debugging item, U=416.00, z=1.46, p=.146. However, based on a McNemar test of change, students in the immediate group made significant gains in fixing the programming bug from pretest to midtest, χ^2 = 6.13, p=.008, unlike the delayed group, χ^2= 2.50, p=.109. Neither group made significant gains from midtest to posttest.

Table 1: Percent of Students Who Identified and Fixed the Math and Programming Bugs

	Mathematics				**Programming**					
	Identify		**Fix**		**Identify**			**Fix**		
Group	**Pre**	**Post**	**Pre**	**Post**	**Pre**	**Mid**	**Post**	**Pre**	**Mid**	**Post**
Immediate [a]	32%	54%	29%	43%	29%	42% [b]	54%	29%	54% [b]	64%
Delayed [c]	30%	28%	26% [d]	20% [d]	19%	22%	56% [d]	15%	37%	60% [d]

[a] n=28. [b] n=26 because two students missed the midtest. [c] n=27. [d] n=25 because two students moved before the posttest.

Programming and Mathematics Debugging Reasoning

For the program debugging item, students were more likely to fix the bug once they identified it. Interestingly, students who did not identify the bug sometimes inadvertently fixed the bug when rewriting the code. Yet, when rewriting the code, some of these students created new double-counting or directional bugs. For instance, two first graders succeeded in correcting “walk down 3” to “walk down 2” but changed the first correct code “walk left 2” to “walk left *3*” or “walk *right* 2” (see Figure 1). A few students identified the bug but did not know how to fix it. Students who did not identify or fix the bug often double counted the space A4; they had difficulty structuring their counting, i.e., separating the horizontal code (walk left) from the vertical code (walk down), and identifying that space A4 was counted in the first line of code.

For the mathematics debugging item, although approximately 25% more of the immediate group identified and fixed the bug on the posttest compared to pretest, students in the delayed group did not show similar improvement. Similar to programming, once students identified the bug, most of them fixed it. Students who did not identify the math bug but still fixed it either knew the answer should be eight or correctly took six fingers away to get eight; however, they did not have a problem with the picture showing the count starting at 14. Students who neither identified nor fixed the error agreed that “six fingers are taken away.” However, they did not realize that the first count incorrectly started with 14 instead of 13. On the other hand, about 10% of students did identify the bug but failed to fix it. These students indicated that the answer of nine was not correct (often by counting on their own fingers to check), but when they counted the fingers on the picture, they ended up agreeing with the counting strategy and did not fix it. The group of students who succeeded in identifying and fixing the bug often reasoned that “fourteen doesn’t count” and avoided double counting.

Discussions and Implications

Our study confirmed previous findings that once identifying bugs, students could fix them in programming (e.g., Fitzgerald et al., 2008) and mathematics contexts. For the delayed group, there was a correlation between fixing the pretest mathematics bug and the midtest programming bug, building on similar correlational findings by Lewis and Shah (2012). On the other hand, these items were not correlated for the immediate group, possibly because thinking critically about the worked examples from the beginning helped students even if they had not fixed the mathematics bug on the pretest. Moreover, identifying the bugs in the mathematics and programming items on the posttest were correlated for this group, once again suggesting some relation between mathematics and programming. Future studies could balance programming and mathematics debugging experiences to further investigate how they relate.

Overall, we found that students struggled with coordinating horizontal movements with vertical movements (lines 1 and 2 of the programming code in Figure 1) and with aligning pictorial representations with their own finger counting. In both situations, students showed a lack of global structuring of the information (Battista et al., 1998; Battista & Clements, 1996). In the programming item, the grid organization may not have alleviated students’ inclination to double count because they were asked to track the position and its result in their heads and may not have considered overlapping spaces. Likewise, for the mathematics item, they saw a static representation of the finger counting (with highlighting to show action), so they may have had difficulty tracking what the count corresponded to in relation to the picture. The fact that even some third graders, who had initially indicated the answer should be eight, ended up agreeing with the answer of nine because the picture looked right, highlights the need to help students analyze and reason about visuals (as was done with the programming worked examples).

In this paper we examine sixth grade students' constructions and reorganizations of variational, covariational, and multivariational reasoning as they engaged in dynamic digital tasks exploring the science phenomenon of weather. We present case studies of two students from a larger whole-class design experiment to illustrate students' forms of reasoning and the type of design that supported those constructions and reorganizations. We argue that students constructed multivariational relationships by bridging, transforming, and reforming their reasoning and that the nature of the multivariational relationship being constructed affected this process.

Keywords: Algebra and Algebraic Thinking, Design Experiments, Integrated STEM/STEAM

Background

According to the National Research Council (NRC) and Mathematics Learning Study Committee (2001), students "must learn to think mathematically, and they must think mathematically to learn" (p. 1). As the NRC argues, mathematics has facilitated the advancement of science, technology, engineering, business, and government. Mathematics interacts with these disciplines in the form of expressing the variation of multiple quantities. For example, in science, weather forecasters study the variation in air temperatures and dew points to predict the chances of a rainy day. These phenomena usually involve complex relationships between multiple quantities that vary. Although people need to understand this complex variation in many facets of life, school often neglects the study of change in multiple quantities and focuses only on changes in one (variation) or two quantities (covariation). Only one source was found to examine multivariational reasoning, with a focus on undergraduate education (Jones, 2018).

In this paper, we discuss how our project that engaged students in a study of earth and environmental phenomena supported them in reasoning multivariationally. In previous iterations, we found that by engaging with our tasks, simulations, and questioning, students were not only coordinating the change in two quantities but they also reasoned about changes in multiple quantities (e.g., Basu et al., 2020; Panorkou & Germia, 2020a; 2020b; in press). These findings informed our subsequent iterations that aimed to engineer more opportunities to prompt students to study the variation in multiple quantities and reason multivariationally. This paper describes three of those opportunities and discusses how students' thinking progressed from variational, to covariational, and then to multivariational reasoning. Specifically, we explored: 1) How does students' reasoning progress from variation to covariation and then multivariation while engaging with our design? And 2) How does our design support this progression of reasoning?

We use a quantitative reasoning (Thompson, 1994) lens to examine and characterize students' thinking. A quantity is a measurable conceptual attribute that exists in the conception of a situation. Reasoning quantitatively involves constructing the quantities involved in a situation, recognizing which quantities change, and constructing relationships between the changes in pairs of quantities. Thompson and Carlson (2017) define variational reasoning in terms of envisioning "that the quantity's value varies within a setting" (p. 425) while covariational reasoning involves envisioning two quantities' values varying simultaneously.

Our goal was to examine the progression of students' reasoning from variation to covariation and then to multivariation. Because knowledge is dynamically constructed through constructive activity, we aimed to understand how students' meanings about varying quantities could be shaped and reorganized as students interact with our task design, simulations, and questioning. By *meaning*, we refer to "the space of implications that the current understanding mobilizes – actions or schemes that the current understanding implies, that the current understanding brings to mind with little effort" (Thompson et al., 2014, p. 12). By *reorganization* (Piaget, 2001) of students' meanings, we refer to humble inferences we make about their reflections and projections of particular meanings about the quantities and their relationships to a higher conceptual level where these initial meanings become part of a more coherent whole.

Methods

We followed a whole-class design experiment (DE) methodology (Cobb et al., 2003). Our Des were conjecture-driven, in that the research team constructed some initial conjectures about supporting students' quantitative reasoning and these conjectures evolved as the experiment unfolded. In this paper, we present the design of one task focusing on weather, which involves asking students to explore a dynamic simulation and the variation of its quantities.

We designed the Hot Air Balloon simulation to show the relationship between the size of the flame in a hot air balloon, the temperature of the air inside the balloon, the density of that air, and the balloon's altitude. We chose to model a hot air balloon to encourage students to reason about the properties of air masses, such as temperature and density, which can affect how air masses interact to form weather patterns. The student can change the temperature of the air inside the balloon using the "turn flame up" and "turn flame down" buttons. Increasing the size of the flame also increases the temperature of the air inside the balloon, which decreases the density of that air, which increases the balloon's altitude (Figure 1).

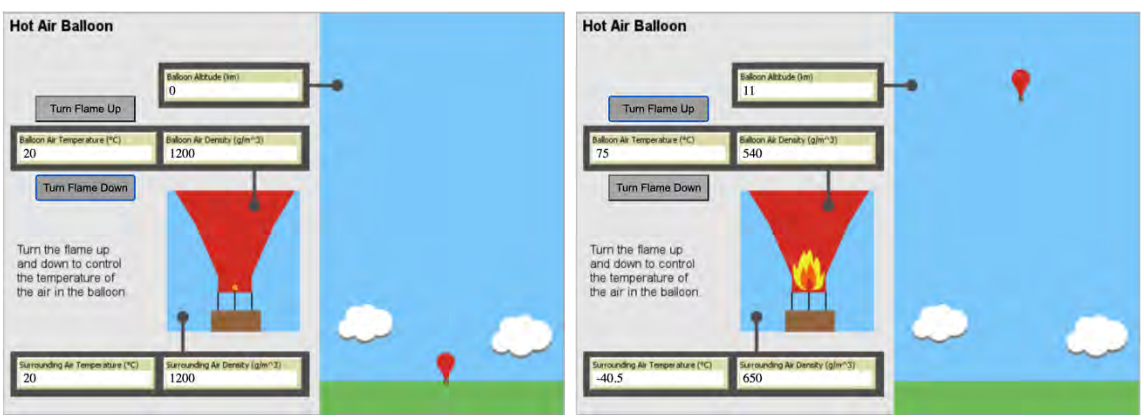

Figure 1: The Hot Air Balloon simulation

We collected data from a sixth-grade classroom from the Northeast of the US. The Des consisted of 15- to 50-minute sessions in which we interviewed the students during their virtual classes in Google Meet. In this paper, we focus on the retrospective analysis (Cobb et al., 2003) of one pair of students, Anne and Violet, to discuss their constructions and reorganizations of variational, covariational, and multivariational reasoning.

Findings

We organize our findings according to how Anne and Violet's constructions and reorganizations took place: by *bridging*, *transforming*, or *reforming*. We also present the type of questioning that might have supported these constructions and reorganizations.

Bridging

Anne and Violet first identified varying quantities as they explore the simulation and its controls. For example, when asked to describe what she noticed in the Hot Air Balloon simulation, Violet clicked to change the flame height and described how altitude, density, and temperature all changed. This showed that Violet constructed variational reasoning about these quantities during her initial explorations of the simulation. Our questioning then turned the students' attention to relationships between these quantities. For example, Anne described relationships between the flame and the balloon's altitude ("when I was turning the flame up, it [the balloon] would like go up") and the flame and the air density ("whenever you turn it [the flame] down, it goes, the density becomes higher"). These excerpts show that she was making connections between pairs of simultaneously changing quantities, thus reorganizing her initial variational reasoning into covariational relationships.

To encourage students to merge the relationships they had reasoned about, we then asked students about the relationships between more than two variables. For example, Anne reasoned, "for the temperature, when you turn it [the flame] down, it gets cooler. And then for the density, it decreases." In this statement, she expressed her reorganization of the covariational relationship she had previously identified into a multivariational envisioning of all three quantities changing at the same time, thereby *bridging* her multiple covariational relationships into a single multivariational relationship.

Transforming

In one case, we observed Violet expanding a single covariational relationship rather than bridging such relationships together in pairs, instead *transforming* one by including new quantities. Violet originally constructed a covariational relationship between her control of the flame and the resulting changes in the balloon's altitude. Then, when we asked her to describe the changes in the density of the air inside the balloon, she clicked to turn the flame up three times and observed, "What happens is that when I go higher [turn up the flame to lift the balloon], the density inside the balloon gets lower." Then, immediately following this, she clicked to turn the flame up three more times and added, "But the temperature goes higher." We interpret her statements to show that she had added two new quantities to her reasoning, thus *transforming* her single covariational relationship between the flame height and altitude by reorganizing it to construct a multivariational relationship in which changes in the flame height resulted in changes in both the density and the temperature, as well.

Reforming

We also observed students *reforming* their multivariational relationships into relationships with different structures after considering more covariational relationships they found during their explorations. The Hot Air Balloon simulation offers a nested multivariational relationship in which changes in one quantity (flame height) affect the next (air temperature), which affects the next (air density), and then the next (balloon altitude) in a nested sequence. Initially, both Violet and Anne constructed multivariational relationships in which changes in the flame height caused simultaneous changes in the simulation's other variables. However, in subsequent DE sessions, both Violet and Anne further considered other covariational relationships in the simulation and then used these to reorganize their multivariational reasoning.

For example, Anne reasoned that "whenever you turn it [the flame] down, it goes, the density becomes higher." Similarly, Violet argued that "the hotter the air inside the balloon is … the more its density decreases." Then, when we asked Violet to explain her reasoning in this statement, she added, "when you turn up the flame, it gets hotter, the density decreases, and it makes the balloon fly up higher." Violet's wording in this excerpt seems to indicate that she had reorganized her reasoning about the multivariational relationship to construct it as a chain of related dependencies, rather than describing a change in one variable causing simultaneous changes in three other variables as she had before. She had *reformed* her multivariational relationship to include her reasoning about the new covariational relationships.

Similarly, Anne first reasoned that "for the temperature, when you turn it [the flame] down, it gets cooler. And then for the density, it decreases," constructing a multivariational relationship in which a change in one variable caused changes in two others. Later, after she had constructed the covariational relationship between temperature and altitude, we again prompted Anne to reason about all of the quantities. She responded, "When I turn up the temperature, the density starts getting low and then altitude, it shows how like the balloon is going up." We consider this excerpt to show that Anne had reorganized her construction of the multivariational relationship into one in which changes in each of the quantities caused a change in the next in sequence, engaging in *reforming* similar to Violet.

Conclusions

Our analysis shows that the simulations provided opportunities for students to see, control, and reason about multiple changing quantities. As we questioned them about the relationships among higher numbers of these quantities, we observed that the students progressed along a trajectory of first constructing variational reasoning and then reorganizing this into covariation and then into multivariation. Specifically, questions about noticing and describing change such as "What is changing in this simulation?" encouraged students to identify variables and reason variationally about individual quantities. Questions about noticing and describing relationships such as "What is the relationship between depth and temperature?" or "What is the relationship between temperature, dew point, and cloud altitude?" then encouraged students to reorganize their thinking first into covariational and later multivariational relationships.

In this paper we have discussed how students engaged in bridging, transforming, and reforming of their reasoning in different multivariational situations. Specifically, students engaged in a *bridging* form of reorganization in which they first constructed two covariational relationships and then merged these into a single multivariational relationship. However, we also saw Violet engage in *transforming* her existing construction of a single covariational relationship into multivariation by reorganizing it to include the addition of new variables. Moreover, both Violet and Anne engaged in *reforming* their initial multivariational reasoning after considering more of the covariational pairs that make up the larger nested relationship in the simulation. This may indicate that the nature of nested relationships has some effect on students' progressions of multivariational reasoning. This shows that students go through different mental actions, and thus different constructions and reorganizations, based on the type of relationship they have to construct. We thus believe that more research is needed on characterizing students' constructions and reorganizations in different types of multivariational situations.

STUDENTS' EARLY CONSTRUCTING AND INTERPRETING THEIR DATA DISPLAYS OF CATEGORICAL DATA

Leslie Nabors Oláh
Educational Testing Service
lnaborsolah@ets.org

Eun Mi Kim
University of Kansas
kimeun23@msu.edu

Constructing and interpreting data displays are crucial for statistical learning as well as college and career readiness. The findings presented in this paper are part of a larger study of the development of statistical concepts and skills. Thirty students organized data, constructed their own graphs, and interpreted values and patterns in their graphs. Preliminary findings indicate that organizing data by groups may relate to understanding that data can be aggregated in the data display. In addition, choosing which type of data display to construct appears to impact interpretation of data shape or patterns, even in this simple case. Implications for educators and researchers are discussed.

Keywords: Data Analysis & Statistics, Elementary School Education, Mathematical Representations

Study Objectives and Background

The U.S. Common Core State Standards for Mathematics (CCSSM, Common Core State Standards Initiative [CCSSI], 2010) indicate that instruction in data display should begin at Kindergarten and continue through the upper grades, and the American Statistical Association's *Guidelines for Assessment and Instruction in Statistics Education (GAISE) Report* (Franklin et al., 2007) addresses the use of "graphical displays" of data (data displays or statistical graphs) in data analysis and interpretation of results of the statistical problem-solving process, promoting the statistical competencies students need for college and career readiness. Thus, students need to learn how to construct and interpret data displays. The findings presented here are part of a larger study of the development of statistical concepts and skills investigating the relationship between constructing and interpreting data displays. Our research question is: how do students construct and interpret statistical graphs for categorical data?

Framework

The CCSSM expects students in grades 3 to 5 to "represent and interpret data" (CCSSI, 2010), yet attending to both data and its context can be challenging for students. They may disregard data and attempt to make statistical inferences based on personal beliefs or, conversely, focus on numerical quantities without considering the data context (Groth, 2021). Unfortunately, instruction in data display at the elementary level tends to "facilitate a view of graphs as illustrations, rather than reasoning tools …" (Fielding-Wells, 2018, p. 1125). In this study, we investigated how students analyze and display raw data in an extended task and with a given purpose in mind. We previously published a hypothesized learning progression (LP) to represent qualitative shifts in constructing and interpreting data displays from 2nd grade to post-secondary education (Kim et al., 2020). This LP is used in the current study as an analysis framework to analyze student knowledge and understandings about constructing and analyzing data display.

Methods

This study reports on student work with *Summer Math Camp*, an extended task designed to elicit evidence of students' knowledge and understandings of constructing and interpreting statistical graphs for categorical data. We recruited students in grades 4 to 6 because the CCSSM expects students to construct and interpret bar graphs as early as 2nd grade (CCSSI, 2010); thus, we could expect that participants would have worked with this type of graph. Students were presented with a set of completed paper surveys from 45 fictional summer math camp participants indicating which of four activities were their favorite among Forecasting the Weather, Reading Math Stories, Building a LEGO® City, or Programming Robots. Students were asked to organize the categorical data, create a graph to show the results of the survey, and identify quantities, group differences, and patterns in the data. Students independently created a graph and provided written responses to questions. We then conducted semi-structured cognitive interviews with each student to better understand their thinking as they engaged with the task. Responses were audio-recorded, and the workspace was video-recorded (i.e., no student's faces were captured in the video).

A diverse sample of 30 of 31 students completed the task and interview (one student chose to stop participating). The sample included eleven 4th-grade, eleven 5th-grade, and eight 6th-grade students. Slightly more girls than boys participated, with 18 students identifying as female. One student identified as Native American or Alaska Native, two as Hispanic or Latino, six as Asian American, five as Black or African American, and 16 as White. Most students attended traditional public elementary or middle schools, with one student attending an independent school and two attending parochial schools. Reported school math achievement varied from grades of C or "meets expectations" through A+.

We used Nvivo 12 to code transcripts of the video and student work by using the LP descriptors in Kim and colleagues (2020). This allowed us to describe students' knowledge and understandings of constructing and interpreting data displays. We then produced a matrix of all descriptors, pre-graphing activities, and types of graphs by participant examined the display for patterns.

Results

Pre-Graphing Activities

We had not initially planned to attend to students' pre-graphing activities but were struck by the variation in student approaches to organizing the given set of data (i.e., surveys indicating a favorite math camp activity). Seventeen students began by sorting the surveys into four piles by preferred activity. Five other students hesitated or tried different ways of sorting the data before realizing that making four piles could support their construction of a display of categorical data. Four students used the graph itself as an organizer by going through the surveys one-by-one and increasing the height of one of the bars or the number of Xs for each new survey in the pile. Four remaining students used a tally chart as an organizer before constructing their graph. The type of organizing was not related to students' choice of appropriate graphs for the given data set, but only students who sorted surveys into piles or who used tally charts later produced graphs with cases aggregated into fives. It is possible that some pre-graphing organizing is more likely to lead to an aggregate view of data.

Choosing Appropriate Graphs for Categorical Data

We observed great variation in the types of graphs produced, including a few students who answered questions about the data without creating any graph at all. Sixteen students chose graphs appropriate for displaying categorical data (i.e., pictographs, pie graphs, and bar graphs), while others created inaccurate bar graphs (e.g., no spaces between the bars), histograms, tables, tally charts, idiosyncratic diagrams, or iconic drawings. Most students constructed their bar graphs by individual cases and used a one-unit scale on the y-axis, yet some students realized that the number of surveys each chosen camp activity was divisible by 5, and thus used a five-unit scale on the y-axis. In spite of their success in creating appropriate graphs for categorical data, however, most of these students could not explain why they chose that type of graph or explained constructing a bar graph because they were familiar with the graph type, such as Student 1, who responded: "Well, it was just the first thing, like I usually do this [points to the bar graph] in school."

Constructing and Interpreting Bar Graphs

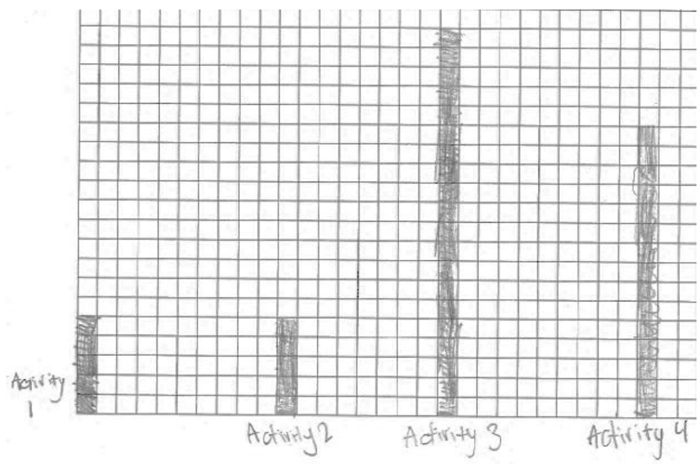

Figure 1: Bar Graph from Student 22

Almost all students who accurately constructed bar graphs were able to interpret the meaning of individual data values (e.g., how many students chose Activity 4 [Programming Robots] as their favorite activity) and describe differences in values between groups (e.g., how many more or fewer students chose Activities 1 and 3 [Forecasting the Weather and Building a LEGO® City] than Activities 2 and 4 [Reading Math Stories and Programming Robots]?). However, students who produced no graphs (e.g., iconic drawings) could also answer those three questions, probably because the data set was small enough to allow them to recall the relevant values.

Only students who accurately or inaccurately constructed bar graphs were able to write about or comment on the shape of or patterns in the data. In all cases, students used everyday language to describe these patterns, such as Student 13, who wrote "low, low, higher, medium" to describe the order of bars representing values of 5, 5, 20, and 15, respectively. Although students could preview all the questions we were going to ask them on their worksheet, most students constructed graphs with the bars in the order of activity number (see Figure 1) and did not seem to consider that because the data were categorical, the bars could be presented in any order to more effectively see the shape of or patterns in the data. Student 22, for example, described that she constructed the graph "So I started the activity one and then it's from lower because activity one and two they have five, and activity three and four have fifteen and twenty. So, I wrote them from lower to higher," but did not follow this logic to the end by presenting her bars in order of

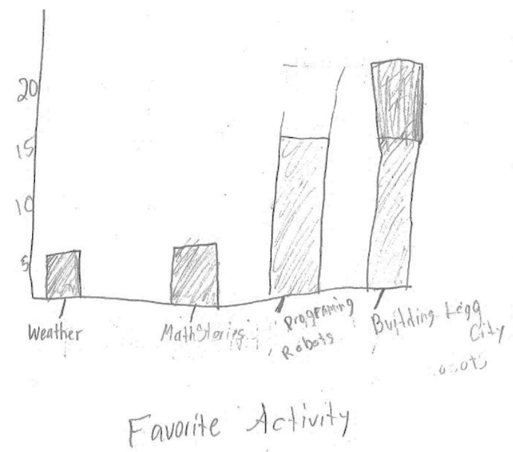

Figure 2: Bar Graph from Student 21

increasing value. Student 21 (see Figure 2) was the only student who recognized that she could change the order of the bars so that they formed a more consistent pattern; she switched the order of the bars for Programming Robots and Building a LEGO® City and explained that she intended to create a consistent order: "One pattern of my graph is ordering them by the amount of students who chose … who chose their favorite thing that they did."

Conclusion and Discussion

The findings of this study are limited in generalizability because the sample of students is not representative of U.S. students in grades 4 to 6. In addition, the findings apply to students' work with categorical data only, while the larger study will include these students' engagement with numerical data in the final results. In spite of the limitations, these preliminary findings suggest that it is important to investigate connections between pre-graphing, constructing, and interpreting data display as students begin to work with formal graphs (see Lehrer & Schauble, 2000). In the case of categorical data, organizing data by groups may relate to understanding that data can be aggregated in the data display, although the direction of this relationship cannot be determined from this study. Choosing which type of data display to construct appears to impact interpretation of data shape or patterns, even in this simple case. Few students, however, could explain their reasons for choosing to construct a specific data display, even when they constructed an appropriate and accurate one. Educators should consider the opportunities that students have to work with raw data and to choose the most appropriate data display for the intended purpose. Research can continue to investigate pre-graphing activities and the relationships between these activities and the construction and interpretation of data displays.

EXHIBITING INTEGERS' CONFLICT AND RESOLUTION USING A MATHEMATICS STORYBOOK: THE CASE OF FOUR FIFTH GRADERS

Mahtob Aqazade
Purdue University
maqazade@purdue.edu

Students often struggle to make sense of integer concepts because they contradict their whole number understanding. In this paper, I unfold how four fifth graders interpret a story conflict and its resolution within different interactive versions of a mathematics storybook, which was designed to highlight the contradictory ideas between the absolute and linear values of integers in the context of temperature. Over three sessions of reading and retelling, students paid more attention to the differences between positive and negative numbers' order and value and more often referred to the mathematical conflict and its resolution. This study informs the effectiveness of introducing the concept of integers by presenting conflict and illuminates ways that students can be supported through the resolution process.

Keywords: Number Concepts and Operations, Cognition, Elementary School Education

Negative numbers are difficult to learn because of their abstract nature, the difficulty of relating them to quantitative interpretations, and their contradictions with whole number knowledge (Bofferding, 2014; Whitacre et al., 2011). Therefore, identifying ways to help students make sense of the conflict between numbers' absolute values ($|-5| > |-3|$) and linear values ($-5 < -3$) is essential. One way to expose students to a conflict and propose a resolution of it is through stories. However, a story's effectiveness in helping students make sense of a conflict and assimilate the story's resolution may depend on students' prior knowledge of the topic (in this case, integer order and value) as well as the supports provided to make sense of the story's content. In this paper, I investigated the role of three types of supports within a temperature-related mathematics storybook—*Temperature Turmoil*—on students' understanding of the conflict between negative and positive numbers' order and value and its resolution.

Theoretical Grounding and Literature Background

Based on Piaget's theory of cognitive development, children's learning process begins with noticing a conflict, internalizing it, and engaging in assimilation, accommodation, or equilibration (Piaget, 1952). Although exposing students to a conflicting situation may initiate the learning process by triggering students' cognitive conflict, doing so is not sufficient without also providing opportunities for resolving the conflicts (e.g., Limón, 2001). Research not only needs to detail students' cognitive conflicts but also should explore and facilitate their resolution process. Mathematics storybooks can convey conflicting, new mathematical ideas that build on children's prior knowledge and further provide opportunities to make meaning of such conflicts through the story's narrative and illustrations within a real-world context (Ginsburg et al., 2018; Moyer, 2000). When reading a mathematics storybook, children can construct their knowledge through reciprocal interaction between their social environment and their internal interpretation of the story. Some of these interactions can emerge during children's explorations (e.g., questions that they ask an adult or peers), some might be embedded in the story for the children to act upon (e.g., stories that have questions in them), and some can reflect a teacher's (or adult's) conversations with children. One way to promote children's interactions with a storybook without an adult or peer present is to embed interactive features within the storybook.

In this study, the narrative and illustrations in the mathematics storybook—*Temperature Turmoil*—introduce a mathematical conflict between positive and negative numbers' order and values and later demonstrate the mathematical resolution of the conflict. For instance, a comparison between two lands' temperatures—one with positive temperatures and one with negative temperatures—along with directed magnitude language unfolds in a conversation between two characters. Curt Cozy: "Your 20 [-20] is more cold than back in my land [land of positive temperatures only]." Ilana Icy: "Your 20 [+20] is more hot than back in my land [land of negative temperatures only]." The resolution of this conflict begins when one character says, "Each 20 is far from zero but in an opposite spot." Besides the story resolution, interactive features provided additional support to facilitate the resolution process. I examined:

(1) What are the effects of embedded interactive features within a mathematics storybook on students' ways of resolving the positive and negative numbers' order and value conflict?
(2) How did students interpret the story conflict and its resolution during retellings?

Methods

Participants, Study Design, and Data Analysis

Six fifth graders participated from a public elementary school in the Midwest, United States (45% were economically disadvantaged and 11% were English-Language-Learners).

Pretest and posttest. I interviewed students individually, examining their integer knowledge including order and value test items. Each test took approximately 40-minute.

Sessions 1-3: Reading and retelling. After the pretest, for three sessions, students listened to a version of *Temperature Turmoil* written by Laura Bofferding: *control*, *interactive question*, *interactive visual*, or *interactive mixed*. The interactive versions differed in terms of additional resolution support in the form of hotspots. In the **Control**, students listened to the electronic version of the book without any interactive support. In the **Interactive Question**, activating a hotspot resulted in a mathematical question + feedback after responding, which was designed to reinforce the directed magnitude language in conjunction with numbers. In the **Interactive Visual**, activating a visual hotspot resulted in an animation, a slider, or a combination thereof that centered on a thermometer representation, which emphasized the numbers' continuity. In the **Interactive Mixed**, hotspots contained both interactive visuals and questions. After each session, students retold the story and drew a thermometer to show the story resolution.

I present a multiple-case study (Yin, 2018) of four fifth graders—Harry $_{\text{(control)}}$, Lola$_{\text{(question)}}$, Claire$_{\text{(visual)}}$, and Chase$_{\text{(mixed)}}$. Based on Bofferding's (2014) integer mental model levels and scores on order and value test items, I classified the extent to which students exhibited conflicts between positive and negative numbers' order and value and identified a resolution: no-resolution (i.e., initial level and scoring at most 40% correct); partial-resolution (i.e., transition I level and scoring at most 60% correct, magnitude level and scoring at most 85% correct, or transition II level and scoring at least 85% correct); or complete-resolution (i.e., formal level and scoring 100% correct). I categorized students' descriptions of story conflict and its resolution during retellings (see Table 1). Further, I classified students' drawn thermometers as *no-resolution* (i.e., *one* thermometer of positive numbers); *beginning-resolution* (i.e., *two* thermometers: one of positive and one of negative numbers); *middle-resolution* (i.e., *one* thermometer with 0 and -0); or *complete-resolution* (i.e., *one* thermometer of positive and negative numbers).

Table 1: Classification of Students' Story Conflict and Resolution

		Categories		
Story conflict	**Ignore-conflict**	**Contextual-conflict**	**Partial-mathematical-conflict**	**Complete-mathematical-conflict**
Example	"I don't know"	"There are two lands: hot and cold lands and they don't like it"	"The people of two lands used different numbers"	"One land's temperature was above 0 and one land's temperature was below 0"
Story resolution	**No-resolution**	**Contextual-resolution**	**Partial-mathematical-resolution**	**Complete-mathematical-resolution**
Example	"They will get used to being cold and hot"	"They will switch lands"	"They will use a new thermometer"	"They will use positive and negative numbers to see the difference"

Findings

On the pretest, all four fifth graders were classified as partial-resolution with Harry$_{\text{(control)}}$, Lola$_{\text{(question)}}$, Claire$_{\text{(visual)}}$, and Chase$_{\text{(mixed)}}$ scoring 89%, 76%, 55%, and 99% respectively. Harry and Chase exhibited the transition II level and Lola, and Claire showed the magnitude level. Only Harry improved to the complete-resolution category by the posttest, and Lola scored higher (91%) and exhibited transition II level. The other two were classified the same as their pretest.

Sessions 1-3: Readings and Retellings

Session 1. Harry's$_{\text{(control)}}$ and Chase's$_{\text{(mixed)}}$ first retellings contained evidence of complete-mathematical-conflict and complete-mathematical-resolution. Further, except for Lola$_{\text{(question)}}$ drawing a thermometer representing no-resolution, all students' drawn thermometers represented the middle- or complete-resolution. Harry$_{\text{(control)}}$ described two lands' temperatures:

> So, their temperatures are different because this one is *going up from zero* and this one is *going down from zero*. This one, I think it's *negatives* and this one, is *positives*. So, they think that's the same temperature cause thirty-three positive and thirty-three negative.

On the other hand, Lola's$_{\text{(question)}}$ and Claire's$_{\text{(visual)}}$ first retellings referred to a contextual-conflict and contextual-resolution. For instance, Claire focused on the "hotness" and "coldness" of two lands, "Each other temperatures are different from what they have it. Cause there is hotter people and colder people." She described the resolution of the story as "going back home."

Session 2. Lola$_{\text{(question)}}$ was the only one to not refer to at least partial-mathematical-conflict in the second retelling. Lola explained the two lands' conflict as "it was getting too cold in Cozyland and it was getting too hot in Icyland" and resolution of "figuring out the problem like drawing out and seeing the difference," which implicitly reflected her way of thinking about two lands' opposite thermometers. Therefore, Lola referred to contextual-conflict and partial-mathematical-resolution of the story. Although Claire$_{\text{(visual)}}$ more explicitly described the differences of two lands' thermometers, "They drew the thermometer and saw that theirs was *opposite* from each other," she did not articulate a way to distinguish them and exhibited partial-mathematical-conflict and partial-mathematical-resolution. Chase$_{\text{(mixed)}}$ said, "They didn't know what to do and they couldn't figure out what's wrong cause they both had the *same temperature, but it wasn't*" and their conflict was resolved by using "*negatives* and *positives*." Therefore, Chase was classified as complete-mathematical-conflict and complete-mathematical-resolution. With the same classification as Chase, Harry$_{\text{(control)}}$ described the notation that distinguishes positive and negative numbers, "They *made a line* next to the negatives because there's a line [for numbers] below zero and it was colder. So, then you could tell it was different going down below [zero]." Only Chase and Harry represented complete-resolution in their drawn thermometers (Lola: Beginning-resolution and Claire: No-resolution).

Session 3. All students' drawn thermometers were categorized the same as session 2. All students referred to a partial- or complete-mathematical-conflict and partial- or complete-mathematical-resolution in the third retelling. For instance, Lola's$_{\text{(question)}}$ interpretation of the story conflict and its resolution showed the most growth:

> Why it was getting *more cold* in one land and *more hot* in the other and they got confused because they didn't know that hot is like that way [thermometer going up] and cold is like going [thermometer going down] …They drew a little chart out on the ground, and they saw their thermometers in their world. That's how they figured out that *there's difference*.

Even though compared to the previous session Lola provided a more detailed description of the mathematical conflict and its resolution, the absence of referring to positive and negative numbers put her in partial-mathematical-conflict and partial-mathematical-resolution category. Despite Claire's$_{\text{(visual)}}$ reference to the opposite thermometers, she did not articulate further how the oppositeness of two categories of numbers can be distinguished and was classified as partial-mathematical-conflict and partial-mathematical resolution. Harry$_{\text{(control)}}$ and Chase$_{\text{(question)}}$ both exhibited complete-mathematical-conflict and complete-mathematical-resolution. Harry said:

> So, they decided to make a different thermometer. Since that one [Icyland thermometer] is *going down* and that one [Cozyland thermometer] is *going up*, they decided to make a big thermometer that showing *positives* and *negatives*. So, for the Icyland, they're in the negatives and they're cold, so *they're not really the same thirty*; they're different and so in the Cozyland it's hot [and] up here in the positives.

Discussion and Implications

On the pretest, all students were categorized as partial-resolution but Harry$_{\text{(control)}}$ and Chase$_{\text{(mixed)}}$ started higher compared to Lola$_{\text{(question)}}$ and Claire$_{\text{(visual)}}$. On the posttest, only Harry exhibited the complete-resolution category, but Lola made the most growth. Even though it is difficult to make a strong argument about the role of interactive features in the development of the mathematical resolution, Lola seemed to benefit the most based on her scores and integer mental model level from pretest to posttest. Overall, the reading and retelling sessions gradually drew students' attention to the differences between absolute values versus linear values (Bofferding, 2019) and resulted in more references to the mathematical conflict and its resolution during their retellings. The results show that students needed a second reading to absorb the complexity of the story elements and attend more to the story's mathematical conflict and its resolution rather than contextual conflict and its resolution. The use of directed magnitude language and reference to the thermometers increased throughout the sessions, which suggests the promises of using the *Temperature Turmoil* book in highlighting the mathematical language and visual representation and in establishing opportunities for productive struggle. Perhaps, the mixed interactive version has a higher potential to draw students' attention to both the visual and language. The implication of this research provides insight into viable forms of literacy and mathematics integration.

USE OF ZIG-ZAG TO REPRESENT MATHEMATICAL THINKING ABOUT ANGLE

Ekta Shokeen

Angle is a prominent feature of shapes which make it important to provide students with opportunities to carefully explore the idea of angle beginning in the elementary grades. But developing the understanding of angle concept is complex (Tanguay & Venant, 2016; Alyami, 2020). The purpose of this study was to understand students' use of angle within the Tinker Lab, a non-formal making space. We examined the situated use of the informal term zig-zag to develop and communicate mathematical ideas about angle from an embodied perspective (Kirsh, 2013). With the research question – *How is the term 'zig-zag' used to convey ideas of angle in the context of a making activity?* The video data was collected from three groups, one group each in Grades 3-5, participating in a 25-minute activity. The activity consisted of two phases: (1) making a path by placing the tape on the floor from one side of the room to the other; and (2) programming Dash (a toy robot) on the path laid by the other group.

In answer to our research question, results showed that students regularly used 'zig-zag' to communicate in two different types of scenarios: (a) **about a single angle** – communicating about a specific angle between two adjacent sections of tapes. To form an angle, students negotiated about two parameters – the length of the tape (i.e., length of rays) and direction of connection between two sections of tape (i.e., the angle between the rays) (Refer Figure 1); and (b) **about a broader pattern which consists of multiple angles –** communication about the path without referring to a particular section of tape as a base arc for the angle or about a particular angle composed of rays (Refer Figure 2);. We found that students struggle to communicate about angles, but the use of a casual term 'zig-zag' allowed them to facilitate their group communication. Zig-zag' was found to be a more powerful – if less precise – way to communicate that does not require students to have the same perception of magnitude or even be talking about the same arc (Williams-Pierce et. Al., 2021).

Figure 1: A representation of 'zig-zag'

Figure 2: A broader zig-zag pattern

The findings of this study implies that students' perceptions, intuitions, and physical gestures compose their understanding and use of angles, these non-formal representations can be leveraged to better develop their understanding of the concept of angle. This study signifies students rely on the use of informal mathematical language and physical gestures to form and communicate mathematical reasoning around angle within the situated use of zigzag.

The COVID-19 pandemic has ravaged onward over the last year and has greatly impacted student learning. An average student is predicted to fall behind approximately seven months academically; however, this learning gap predicts Latinx and Black students will fall behind by 9 and 10 months, respectively (Seiden, 2020). Moreover, the shift to online instruction impacted students' ability to learn as they encountered new stressors, anxiety, illness, and the pandemic's psychological effects (Middleton, 2020). Despite the unprecedented circumstances that students were precipitously thrust into, state testing and assessments continue. Assessments during the pandemic are likely to produce invalid results due to "test pollution," which refers to the systemic "increase or decrease in test scores unrelated to the content domain" (Middleton, 2020, p. 2). Considering the global pandemic, test pollution is prominent and worth exploring as it is uncertain whether state testing can identify the impact COVID is having on student learning.

NWEA produces the Measures of Academic Progress (MAP) assessment test. NWEA argues that MAP testing can also provide school districts with the ability to "identify trends for students, create flexible learning groups, and target professional development for teachers" (Belgard, 2017, p.1). This case study research aims to identify if current learning conditions have impacted MAP scores in a rural school setting due to the pandemic. The three research questions are: (a) Is there a statistically significant difference in 4th grade MAP math scores between students in the September 2019 cohort and September 2020 cohort? (b) Is there a statistically significant difference between 4th-grade math MAP scores based on gender within this rural school district between September 2019-September 2020? (c) Is there a statistically significant difference between this school districts' 4th grade math scores and national 4th grade math MAP scores for September 2019 -September 2020?

Data analyses suggest no statistically significant difference between the two cohorts, nor is there a statistically significant difference in 4th grade MAP math scores between male and female students. Data findings suggest no statistical significance between our case study cohorts' mean math scores and the comparison groups: the case study district, and the national norm data. While COVID has a wide-reaching impact on school activities, our findings indicate that the COVID-19 pandemic may not necessarily affect student learning outcomes as measured using MAP scores. Future studies that utilize qualitative methods, such as teacher and student interviews, should be conducted to problematize these findings.

A LOCAL INSTRUCTION THEORY FOR EMERGENT GRAPHICAL SHAPE THINKING

Teo Paoletti

Keywords: Learning Trajectories and Progressions, Design Experiments, Algebra and Algebraic Thinking, Middle School Education

Emergent graphical shape thinking (or *emergent reasoning*) entails conceiving of a graph as a trace that represents a covariational relationship between two quantities' magnitudes (Moore, 2021; Moore & Thompson, 2015). Despite the importance of such thinking to graph construction and interpretation in mathematics and other subject areas (e.g., Glazer, 2011; Paoletti et al., 2020; Potgieter et al., 2008), researchers have indicated emergent graphical shape thinking is non-trivial, even for U.S. teachers (Thompson et al., 2017). Though such studies reveal challenges in expressing this way of thinking, some middle and high school students have demonstrated elements of emergent reasoning during teaching experiments designed to achieve other goals (i.e., Ellis et al., 2015; Johnson, 2015). These studies suggest that such reasoning is within reach for these populations.

Our study sought to develop a learning progression to address the following research question: "How can we support eighth grade students to develop emergent graphical shape thinking as part of their stable meanings for constructing and interpreting graphs?" Our report responds with a *local instruction theory* (hereafter, LIT), which is a generalized, reasoned, and adaptable learning path that can inform instruction toward a specific mathematical goal (Gravemeijer, 2004). We conducted a series of six small group teaching experiments in a diverse middle school in the northeastern United States, culminating in a full-class teaching experiment with eight eighth-grade students who had just completed a high school level Geometry course. For each teaching experiment, we obtained parental consent and student assent, openly video- and audio-recorded the students as they worked, and collected and digitized written work samples. We analyzed the data using ongoing and retrospective analyses, consistent with the teaching experiment methodology (Steffe & Thompson, 2000). During each iteration, we designed and revised the task sequence as well as our underlying LIT.

In this poster, we present our theoretically- and empirically-grounded LIT to support students in developing stable meanings for graphs that entail emergent graphical shape thinking. Specifically, our LIT posits repeated engagement with and a fundamental relationship between 1) quantitative and covariational reasoning (e.g., Thompson & Carlson, 2017), 2) reasoning within a coordinate system (e.g., Lee, 2016; Paoletti et al., 2020), and 3) emergent reasoning. We illustrate the interrelationship of these ways of thinking through examples from two focal students as they engaged in a task sequence designed in alignment with our LIT. We present implications that span both research and practice, with particular emphasis on designing instructional supports for supporting middle and high school students' graphical fluency.

Early middle school students have a strong tendency to adhere to the left-to-right principle when solving math problems, which may lead them to overlook the role of brackets within math expressions (Blando et al., 1989; Gunnarsson et al., 2016). However, perceptual features, such as the spacing between symbols, can direct students' attention to salient features of math expressions that support efficient problem-solving (Goldstone et al., 2017; Harrison et al., 2020). Similarly, superfluous brackets—brackets that do not change the meaning of notation, but can guide learners' attention to the correct procedure—can help students achieve higher success rates in solving problems (Hoch & Dreyfus, 2004; Marchini & Papadopoulos, 2011). Here, we examine how the presence of superfluous brackets and the position of higher-order operands (i.e., multiplication and division) within an expression affect student performance in an online assignment, as measured by assignment mastery speed and average response time.

We are conducting a 3 (Operand position: left, center, or right) X 2 (Superfluous brackets vs. no brackets) design study in an online tutoring system, ASSISTments (Heffernan & Heffernan, 2014). Approximately 280 sixth and seventh-grade students will complete an assessment of their baseline math knowledge, then be randomly assigned to one of six conditions: 1) brackets-left (e.g., (5*4)+2+3), 2) no brackets-left (e.g., 5*4+2+3), 3) brackets-center (e.g. 2+(5*4)+3), 4) no brackets-center (e.g., 2+5*4+3), 5) brackets-right (e.g., 2+3+(5*4), and 6) no brackets-right (e.g., 2+3+5*4). Students will complete problems in an ASSISTments' Skill Builder where the goal is to "master" the content by answering three questions correctly in a row (Kelly et al., 2015). We will conduct two ANCOVAs to examine how operand position and superfluous brackets affect student performance as measured by average response time (i.e. total time on Skill Builder divided total problems a student attempted) and mastery speed (i.e. the total count of problems a student attempted before reaching mastery).

Data collection is on-going; results will be included in our final submission and presented at the conference. This study will advance research on the roles of perceptual cues in math notation by shedding light on how the presence and position of superfluous brackets affects student performance. We aim to provide recommendations for the presentation of expressions in online learning platforms to support learning.

WHY DO STUDENTS PICK THE WRONG ANSWER ON FRACTION MULTIPLE CHOICE WORD PROBLEMS?

Erik Jacobson
Indiana University
erdajaco@indiana.edu

Pavneet Kaur Bharaj
Indiana University
pkbharaj@iu.edu

Jinqing Liu
Indiana University
jinqliu@iu.edu

Solving word problems with understanding is challenging as it demands the comprehension of the quantitative meaning of two (or more) numbers, how these quantities are related to the result by a mathematical operation, and an anticipation of the meaning of the number attained after the procedural manipulation (Duzenli-Gokalp & Sharma 2010; Wyberg et al., 2012). Multiple choice questions force students to pick an answer, and researchers, teachers, and other stakeholders often assume that this choice meaningfully indicates what students understand. In this study, we examined the connections between how students interpret and solve a strategically designed multiple choice word problem, with an aim to explore why students picked the wrong answer. The goal of our larger effort is to understand how teachers and researchers make inferences about student knowledge based on students' multiple-choice answers, and to what extent such inferences are accurate.

Our work is guided by the ideas related to *operation sense*, defined as the ability to make sense of the quantitative meaning related to basic arithmetic operations (Baroody et al., 2006; Verschaffel et al., 2000). Operation sense involves understanding the underlying structure and properties that the operation possesses (Briars and Larkin, 1984), and the various forms and contexts in which the operation could exist (Carpenter, 1985). Verschaffel et al. (2000) discussed two ways students' operation sense is revealed in their problem solutions: how a word problem *situation* is transformed into a simplified model in the *translation process* and how *mathematical symbols and operations* are used to produce a result. We designed multiple choice problems to assess how students interpreted the problem (*situation)*, chose a specific arithmetic operation (*translation*), and performed computation (*mathematical operation*). As a paradigmatic example, we present results related to one problem that addresses a Grade 5 standard for fraction subtraction (CCSS.MATH.CONTENT.5.NF.A.1). We analyzed both the answer choices as well as qualitative data drawn from students' written work to examine the operation sense that supported their choices. The data is drawn from a sample of Grade 5 students ($N = 1465$) from a Mid-Western state and part of a larger study. The students' answer choices and written work was examined using thematic coding (Braun & Clarke, 2006). Within each response option, we coded for distinguishing features and themes in students' operation sense.

Around 35% of the students struggled in the translation process because they used addition or multiplication. Although most students (64%) translated the problem as a subtraction problem, only 47% chose correct answer. Notably, there were substantial differences among the students who selected the same multiple-choice option in terms of their mathematical operation. For example, some operated with the mixed fraction as a sum of a whole and a fraction whereas others converted to an improper fraction.

These results illustrate how inferences about students' operation sense from multiple choice word problems depend largely on the set of provided answer choices. This demonstrate that even with a carefully designed set of options such inferences may be more warranted for translation than they are for mathematical operation. This finding has implications for teaching and research by clarifying the affordances and limitations of multiple-choice assessments.

YOUNG CHILDREN'S USE OF GESTURING DURING DURATIONAL REASONING

Amy Smith
Stetson University
asmith92@stetson.edu

Keywords: Measurement, Cognition, Early Childhood Education, Elementary School Education

Children attend to many different attributes when reflecting on the duration of past experiences, such as their perceived efforts or the accumulating activities of their experience (Smith, 2021). Their verbalizations of these attributes provide evidence of how they might quantify the duration of their experiences. For example, a 6-year-old explaining that vacuuming took a long time because it was hard work. Here, it seems that the child correlated her efforts (hard work) with the duration of her experience (long) and expressed this through her words.

I found that when describing the duration of their lived experiences, some 4- and 5-year-olds used iconic gestures (gestures that parallel the action or object being described; McNeill, 1992) in conjunction with their words. Such spontaneous gestures can provide an "observable…interpretable…index" of children's understandings (Goldin-Meadow, Wein & Chang, 1992). I conjecture, therefore, that these gestures might serve as further evidence of young children's conceptions of duration as a measurable quality of their world (Smith, 2021).

During one conversation, 4-year-old Cody (pseudonym) described the duration of flying on an airplane to a different state. As he described his experience, Cody first verbalized that it took a long time. When I asked how he knew it took a long time, Cody spread his arms as wide as he could (Figure 1). I inferred that Cody was reflecting on the far distance of his travel, which he embodied through his iconic gesture (McNeill,1992) of a wide arms-length. Here, it seemed that Cody was relating duration with a length-based measure (Earnest, 2019). I inquired about the length that he displayed by posing, "That long?" Cody then changed his gesture to a fast movement of an "airplane" (Figure 2) as he verbalized that "because the airplane is fast and then it took a very fast time." Here, again, Cody seemed to use his gesturing to support his conception that the speed of the airplane impacted the duration of his experience, a common conception among children (Piaget, 1969).

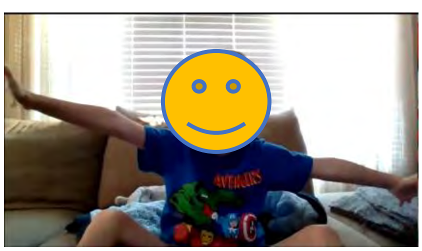

Figure 1: Cody Gesturing the Far Distance of his Travel

Figure 2: Cody Gesturing the Fast Movement of the Airplane

McNeill (1992) asserted that "Gestures and speech grow up together" (p. 295). When considering duration—an invisible, intangible quantity (Earnest, 2019; Long & Kamii, 2001)—how young children might utilize gestures in their descriptions of duration may enable researchers and teachers to better recognize what conceptions they have.

INVESTIGATING CONNECTIONS BETWEEN COVARIATION AND UNITS COORDINATION IN MIDDLE SCHOOL STUDENTS

Sarah Kerrigan
Virginia Tech
stk123@vt.edu

This poster presents some preliminary results from study investigating connections between the middle school students' Units Coordination (UC) and Covariational Reasoning (CR). UC has been shown to be important in elementary and middle school mathematics (Hackenberg and Lee, 2012; Olive, 2001; Steffe, 1992) whereas CR has been shown to be important in high school and undergraduate mathematics (Carlson et al., 2002; Johnson, 2015). However, little is known about connections between a student's UC and CR. This study used a Piagetian perspective to frame students' mathematics in terms of their mental actions in line with theoretical groundings of UC and CR to answer: How do middle school students' units coordinating structures contribute to their ability to conceptualize how two quantities covary?

To answer this question, semi-structed clinical interviews were done over Zoom with 6 middle school students. Students were selected based on UC stage (Norton et al., 2015). This poster reports results some preliminary results from three of the six students: a 6th grader at Stage 2, a 7th grader at Stage 3, and an 8th grader at advanced Stage 2. The sample task reported on here consists of an animation of a triangle with green side decreasing discretely exponentially with the orange side growing continuously linearly. Students were asked a series of questions designed to elicit their covariational reasoning about how the green side and orange side changed in relation to one another. Student work on the task is shown in Figure 1.

(a) (b) I

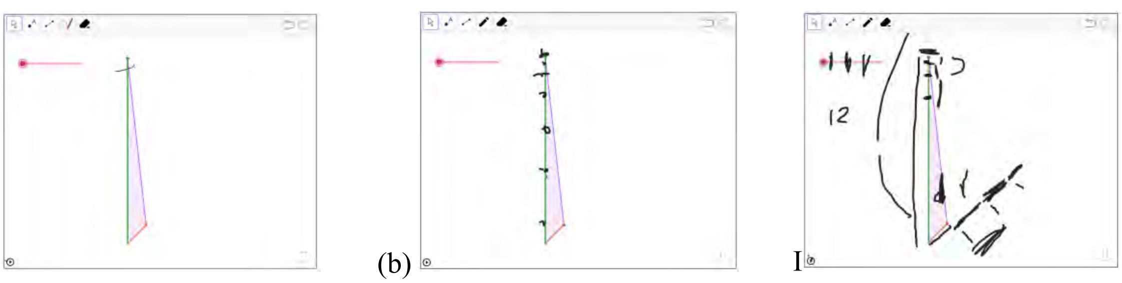

Figure 1: (a) 6th grade Stage 2; (b) 8th grade advanced Stage 2; (c) 7th grade Stage 3

Video data and student written work were analyzed using Thompson and Carlson's (2017) Levels of Covariational Reasoning framework. Based on some preliminary analysis, students at different UC stages reason differently in covariation tasks. For example, in Figure 1, we see that the Stage 3 student was able to attend to both quantities whereas both Stage 2 students only focused on one quantity. Both Stage 2 students were not able to form a relationship between the orange and green line beyond gross coordination of the direction of change; however, the advanced Stage 2 student was able to describe how the green line was changing for equal amounts of time passes. This indicates an ability to reason at a higher level than just gross coordination when one of the variables is time. The Stage 3 student was able to coordinate amounts of change in both quantities and seemed to create a multiplicative object of the two quantities changing together. In line with Hackenberg and Lee's (2015) and Boyce and colleague's (2020) findings, I've observed that students with high-level units coordinating structures (higher UC stage) are able to engage in more sophisticated mathematical reasoning.

A TOOL FOR COMPARING FRACTIONS OR A TOOL FOR DISPLAYING CONCLUSIONS? STUDENTS' FRACTION NUMBER LINE USE

Jinqing Liu
Indiana University
Jinqliu@iu.edu

Erik Jacobson
Indiana University
erdajaco@indiana.edu

The number line is a powerful visual model of quantity and is widely prevalent in mathematics curriculum. Empirical studies found that students' ability to use a fraction number line for comparing fractions predicted their later mathematical achievements, such as their algebra performance (Booth & Newton, 2012; Torbeyns et al., 2015). Given algebra is also a gateway to post-secondary mathematics and STEM; it is no exaggeration to say that mastery of the number line should be a critical goal of elementary mathematics education.

Researchers (e.g., Teppo & van den Heuvel-Panhuizen, 2014) have synthesized a wide range of pedagogical uses for the number line across several curricular topics in the elementary and secondary curriculum. Still, we know little about how students use the number line as a tool to solve mathematical problems. In this study, we examined fourth graders' use of fraction number lines to answers the following two research questions: RQ1. To what extent do fourth graders use number lines to solve fractional tasks? RQ2. How are fraction number lines used?

We surveyed 214 fourth graders from ten elementary classrooms in a Midwest state as part of a larger research project. These ten classes were in seven different elementary schools across five different counties. The survey included four open-ended tasks with one task addressing each of the following topics: fraction comparison, fraction equivalence, fraction additions, multiplication of fractions by a whole number. To answer RQ1, we counted all the student responses that include a number line for justification in each task and calculated the percentages. To answer RQ2, we examined the fourth graders' written work who used number lines on the fraction comparison task. We only examined the case of the fraction comparison task because only one student used a number line on any of the other tasks. We grouped the responses shared similar features to identify the themes of students' number line use.

We found 13 students used number lines for fraction comparison (6%, N=214), one did so on the fraction equivalence task (0.5%), one on the fraction addition task (0.5%), and none on the fraction multiplication task. These results revealed that very few students chose number lines to explain fraction concepts. By scrutinizing the 13 responses, we identified three fraction number line use themes: to determine the size of a fraction (one student), (2) to support benchmark reasoning (two students), and (3) to represent comparison conclusions (ten students).

Our findings revealed that only a limited number of students chose number lines to explain fraction concepts. What's more, most students used the number line to display number order among this limited number of students. Very few used the number line for displaying equivalence or additive or multiplicative relationships (Teppo & van den Heuvel-Panhuizen, 2014). We also noticed a connection between students' conceptual understanding of fractions and their conceptualization of number lines. In particular, six of the ten students used number lines to represent comparison conclusions with whole number biased misconceptions (Ni & Zhou, 2005; Lai & Wong, 2017; Vamvakoussi & Vosniadou, 2010). Students' low tendency to use the number line model is an alarm that emphasizes the need for more regular and meaningful instructional experiences with the fraction number line. Moreover, the result suggests that professional development and teacher education may be needed to expand teachers' knowledge for teaching number lines more effectively throughout the curriculum.

ISOMORPHISM AND HOMOMORPHISM AS TYPES OF SAMENESS

Rachel Rupnow
Northern Illinois University
rrupnow@niu.edu

Peter Sassman
Northern Illinois University
psassman1@niu.edu

Isomorphism and homomorphism are topics central to abstract algebra, but research on mathematicians' views of these topics, especially with respect to sameness, remains limited. This study examines 197 mathematicians' views of how sameness could be helpful or harmful when studying isomorphism and homomorphism. Instructors saw benefits to connecting isomorphism and sameness but expressed reservations about homomorphism. Pedagogical considerations and the dual function-structure nature of isomorphism and homomorphism are also explored.

Keywords: Advanced Mathematical Thinking, Undergraduate Education

Students' understanding of isomorphism in abstract algebra has been studied for over twenty-five years (Dubinsky et al., 1994), but research explicitly on students' understanding of homomorphism has begun more recently (e.g., Melhuish, et al., 2020; Rupnow, 2021). In an effort to position students' understanding, we wanted to learn more about how mathematicians position these topics in relation to notions of sameness. Thus, in this paper we address the following research questions: (1) What connections do algebraists see between sameness and isomorphism? (2) What connections do algebraists see between sameness and homomorphism?

Literature Review and Conceptual Framework

Prior work on students' understanding of isomorphism has shown associations between isomorphism and sameness. Leron et al. (1995) described a course in which students were taught to focus on sameness with isomorphic groups. Subsequent literature has confirmed references to sameness in the context of isomorphism by other groups of students and professors (e.g., Rupnow, 2021; Weber & Alcock, 2004). However, large-scale research has not verified whether this emphasis on "sameness" is normative across mathematicians.

Furthermore, small-scale research on mathematicians has revealed other types of language commonly used to describe isomorphism and homomorphism. Weber and Alcock (2004) highlighted algebraists' references to relabelings. Hausberger (2017) observed use of "structure-preservation" to refer to the homomorphism property. Rupnow (2021) observed renamings, relabelings, and structure-preservation as well as references to operation-preservation, disembeddings, and use of equivalence classes to describe isomorphism and homomorphism. However, the prevalence of these types of language among algebraists has remained unknown.

Our theoretical lens is conceptual metaphors (e.g., Lakoff & Nú ez, 1997), in which a source domain is used to structure understanding of a target domain. For example, "An isomorphism is an operation-preserving map" is a conceptual metaphor that describes the target domain (isomorphism) in terms of a source domain (operation-preserving map) to provide a way of thinking about isomorphism. In this case, the metaphor encourages focus on the homomorphism property, which guarantees a similar type of behavior in both structures (e.g., groups). In this paper, we build on Rupnow's (2021) previous isomorphism and homomorphism metaphors.

Methods

Data were collected from a survey sent to every 4-year college/university math department in the United States. This survey addressed how algebraists think about sameness in general and in specific mathematical contexts. Participants were 197 mathematicians from 173 institutions who had taught at least one abstract algebra or category theory course in the last five years.

The four survey questions relevant to this paper, numbered below, queried participants' beliefs about sameness related to isomorphism and homomorphism, and were the first reference to isomorphism or homomorphism in the survey text itself. These questions followed questions on the nature of sameness in math and about how similar particular objects were.

1. How might sameness be helpful when thinking about isomorphism/isomorphic structures? (Q1)
2. How might sameness be harmful when thinking about isomorphism/isomorphic structures? (Q2)
3. How might sameness be helpful when thinking about homomorphism? (Q3)
4. How might sameness be harmful when thinking about homomorphism? (Q4)

Responses to the isomorphism questions were grouped together for coding as were responses to the two homomorphism questions. Each paired response could receive multiple codes. To ensure coding validity, we used investigator triangulation with two members analyzing the data. Each member would independently code the data using the agreed codes; we then discussed any coding discrepancies and came to consensus on the final codes. These discussions included any modifications for future coding, such as refined code definitions or new codes for consideration.

The data were analyzed in accordance with thematic analysis (Braun & Clarke, 2006). First, we used versus coding (Saldaña, 2016) to identify different beliefs about sameness based on the help vs. harm contrast. However, after coding, we determined that these codes did not effectively capture all nuances in the data. We then revised codes, using descriptive coding (Saldaña, 2016) to supplement our initial coding. These second-round codes permitted clearer connections to our conceptual framework by incorporating codes based on Rupnow's (2021) prior work.

Results

We present mathematicians' responses about the helpfulness and harmfulness of sameness to considering isomorphism and homomorphism. Code frequencies and percentages are presented in Table 1. Participants largely viewed sameness as conceptually relevant to isomorphism. However, pedagogical issues and the context-dependent nature of isomorphism were noted as potential difficulties if using "sameness" as a substitute for isomorphism. In contrast, participants viewed sameness as needing to be qualified or viewed sameness as irrelevant to homomorphism.

Helpful or Harmful

Based on the question format, where we asked participants about how sameness might be helpful or harmful for thinking about isomorphism and homomorphism, our default expectation was for respondents to address both helpful and harmful aspects of sameness. This was the case for isomorphism, where 72% of respondents were coded as helpful/harmful. For example:

> [Helpful:] Isomorphism is a kind of sameness, so certainly you have to have some sense of sameness to understand the idea behind isomorphism. [Harmful:] Maybe thinking that sameness = identical in every aspect? At some point you always have to move away from

intuition coming from English (and "sameness" is certainly not a mathematical concept) and rely only on mathematical definitions to make progress.

In this participant's view, isomorphisms are a type of sameness, but issues arise if one relies on a concept without a formal mathematical definition. Another participant had a different interpretation, focusing on the specific aspects that are and are not the same:

> [Helpful:] We all like to group things that are the same together, and it is useful to think that two very different looking objects (e.g., rings) that have the same algebraic properties should be put in the same group. We want to emphasize that algebraic objects should be studied based on their algebraic properties, not on the choice of names for their objects. [Harmful:] If a student starts to think isomorphic objects are the same as sets and mixes up elements of the objects, that could be harmful. If we use the wrong sort of sameness and think that the identity of a group must always be 0, for example, we could easily become very confused.

Table 1: Frequencies of Codes.

Category	Code	Isomorphism n(%)	Homomorphism n(%)
Help/Harm	Not harmful	18(9%)	5(3%)
	Helpful/harmful	142(72%)	72(37%)
	Not helpful	15(8%)	35(18%)
	Similar	0(0%)	38(19%)
	Not relevant	1(1%)	12(6%)
Pedagogical Considerations	Motivating instruction	15(8%)	7(4%)
	Leveraging intuition	33(17%)	8(4%)
	Misconceptions	25(13%)	20(10%)
	Imprecise language	29(15%)	14(7%)
Types of Sameness	Context-dependent	77(39%)	16(8%)
	Levels of sameness	11(6%)	6(3%)
	Generic identical	30(15%)	2(1%)
	Generic equal	20(10%)	6(3%)
	Isomorphism vs. homomorphism	1(1%)	76(39%)
Informal Sameness	Relabeling	10(5%)	0(0%)
	Matching	13(7%)	4(2%)
	Same behavior	48(24%)	36(18%)
	Same properties	7(4%)	7(4%)
	Structure preservation	9(5%)	12(6%)
	Operation preservation	5(3%)	20(10%)
	Disembedding	0(0%)	18(9%)
	Equivalence classes	0(0%)	3(2%)
Functions vs. Structures	Isomorphism vs. isomorphic	15(8%)	0(0%)
	Homomorphism vs. homomorphic	0(0%)	38(19%)
	Fundamental Isomorphism Theorem	0(0%)	12(6%)

This participant described isomorphisms as a way to classify objects into categories and viewed sameness as helpful for that grouping but emphasized that identification between objects was not required and could cause confusion for students (e.g., names of elements can differ).

In contrast, only 37% of respondents clearly highlighted both helpful and harmful aspects of homomorphism. For example:

> [Helpful:] It can be helpful, say to emphasize that it preserves some information, but not all. For instance, I like to say that homomorphisms from something complicated to something easier to work with or better understood are often the right approach (e.g., representations). Though one may lose info, by working with something easier you may still learn something new about the original. [Harmful:] Similar to the above, it should be emphasized that a lot of info can be lost, or that homomorphism is far from saying they are exactly the same, but is maybe a tool for extracting some information about sameness.

Note that the participant highlighted preservation of some aspects but a loss of some information, indicating utility but the need for care when discussing sameness with homomorphism.

Some participants only saw benefits to using sameness. For isomorphism, 9% of participants only expressed a helpful view of sameness: “Well, it’s the essential notion of isomorphism. In no way [harmful], but it is important that we understand sameness to mean sameness of underlying structure, not sameness of superficial characteristics, like labels.” Here we see the participant considered sameness to be the conceptual point of isomorphism, and thus did not consider sameness harmful. 3% of participants expressed an exclusively helpful view of sameness for homomorphism. For example: “[Helpful:] Same as isomorphism, except now we are only identifying a part of each of the two structures that behave the same algebraically. [Harmful:] Again, with carefully presented examples I don’t think there is harm per se.” Notice, even though the participant claimed sameness was helpful and not harmful for homomorphism, this sameness only referred to parts of structures instead of whole structures.

Although most isomorphism responses received a not harmful or helpful/harmful code, 19% did not. One participant was coded as not relevant: “When Isomorphism is being considered, isomorphism defines the sameness, and what makes the isomorphic objects “different” is to some extent obvious, but not really of interest. So considering sameness is neither a help nor a hindrance.” They saw the reverse connection of isomorphism giving some insight into sameness but did not consider this notion to be important for understanding isomorphism. Others saw sameness as relevant, but it was unclear whether they viewed sameness as helpful, harmful, or both: “[Helpful:] I like distinguish equality (for subsets of a given ambient object) and isomorphism. [Harmful:] The idea [of] flexible notions of equality or sameness is pretty subtle and counterintuitive.” While this participant typed distinct responses in the two boxes for the “helpful” and “harmful” responses, their response did not directly address how sameness might be helpful or harmful for understanding isomorphism, so it was not given any of those codes. Finally, 8% of respondents only expressed a harmful view: “Helpful? I don’t think it is. There’s nothing added to the concept of isomorphism by saying the word “same”. Well, homomorphisms also preserve something. Bijections also preserve something. So, talking about “same” is going to blur some distinctions.” This participant only saw a lack of clarity arising from sameness.

Participants expressed more skepticism to using sameness to discuss homomorphism, with 61% of responses *not* receiving a helpful-related code. 18% of participants considered sameness not helpful to describing homomorphism: “I think tying “sameness” to any homomorphism that is not an isomorphism is misleading at best. Not a fan.” Others were unwilling to use sameness but allowed similarity: “A homomorphism provides a notion of similarity.” 6% of participants considered sameness irrelevant to homomorphism: “Homomorphism is restricted version of the “sameness” defined by isomorphism. Usually when trying to show homomorphism exists, it is trying to show that a certain defined property holds and I do not see how sameness either helps or hinders.” Other participants acknowledged the relevance of sameness to homomorphism, but whether they viewed it positively or negatively was unclear. For example: "[Helpful:] Can there be a connection between these two structures even though they are different? We are locating a connection that is not as deep as isomorphism. [Harmful:] Homomorphic structures may not be isomorphic." Here, the participant described some connections between structures and compared the relationship to isomorphism, but it was unclear what they meant by this connection.

Pedagogical Considerations

In addition to the notions of helpfulness and harmfulness explicitly prompted by the questions, a number of respondents focused on pedagogical implications of using sameness. Some specifically highlighted how sameness could be useful for motivating isomorphism or for connecting to students' intuition: "Different levels of "sameness" and different informal definitions of "sameness" can be used to motivate the formal definition of isomorphism." The participant here explained how formalizing sameness could provoke a need for isomorphism. Leveraging intuition was also described: "It might be helpful for students to think of sameness in a familiar context (e.g., geometry or linear algebra) in order to appreciate the notion of isomorphism in algebra." Here, the participant described how students' intuition and prior experiences with sameness in math could be used to help them understand isomorphism.

However, some respondents highlighted pedagogical concerns like student misconceptions or imprecision. Misconceptions often addressed difficulties with names of elements or objects: "Students often think that if two sets have different looking objects (integers vs matrices, for example), then they can't be "the same." This makes it more difficult for them to understand the more meaningful examples in class." Here the participant observed students could struggle with identifying superficially different objects. Another common concern was that using sameness may lead to imprecision in exercises and proofs: "Two objects can be isomorphic as groups under their additions, but not as rings, when both addition and multiplication are involved. The idea of sameness must be carefully used especially with students since they tend to forget the context." Here, the respondent worried that using sameness haphazardly could lead students to confuse different types of isomorphism and to not attend to context.

Although some participants described ways sameness could be helpful for teaching homomorphism (motivating instruction and leveraging intuition) this happened less than with isomorphism. Some motivated a specific aspect of homomorphisms: "Help understanding the importance of study of kernels." Others described how sameness can aid intuition: "If [a homomorphism] is injective, you could talk about how the structure of the domain is the "same" as the structure of the range, and again this informal notion could make the concepts accessible for students." Again, this participant did not make a blanket statement about sameness in homomorphism but qualified it as useful for considering injective (one-to-one) homomorphisms.

Pedagogical concerns about using sameness for homomorphism were similar to isomorphism concerns. Respondents often described misconceptions about the strength of sameness in homomorphism. For example: "Again, the wrong sort of sameness, as in equality of elements of sets, could be problematic if the student, for example, thinks all identities are actually the element 0." Participants also described issues with being imprecise, including difficulties that could arise when students wrote proofs: "If students get too comfortable expressing things "are the same" without being formal, their proofs can very quickly become incorrect." Although this participant had previously noted utility in thinking about sameness with homomorphism as it connected to the isomorphism theorems, they acknowledged dangers in using loose definitions.

Types of Sameness

Other responses focused on the nature of sameness and specific types of sameness. Some detailed problems if using sameness for specific concepts by highlighting the context-dependent nature of sameness. For example: “The context and criteria for sameness need to be clear for isomorphism to be something that can be empirically verified as true.” This highlights the necessity of describing the context in which sameness is used but gives few details. Others were more specific, describing different levels of sameness: “There are different “strengths” of sameness: equals, equivalent, related to, almost/weakly equivalent, etc. There is not a one size fits all to sameness.” This provides a variety of types of sameness that might be placed on a continuum for strength comparison.

Similarly, the participants were specific about other concepts that could be confused with isomorphism, such as being equal or identical. Consider a confusion with equality example: “Isomorphic is not the same thing as “equals” as it does not imply a canonical identification. The word “same” can trip people up in that way.” Here, confusion between different mathematical understandings of sameness, isomorphism and equality, are specifically highlighted. Similar issues arose with identical: “In common, nonmathematical parlance, same means identical, so when students hear the word “same” they may think identical.” Note this participant’s identification with sameness and identical, a strong type of sameness.

Many respondents compared isomorphism and homomorphism (39%), with a focus on the strength difference. For example: “Same has too strong a connotation in most students minds and they may interpret this to mean isomorphism rather than homomorphism.” Implicitly, the participant seems to suggest that sameness implies a strong relationship, so students will identify the stronger concept (isomorphism) with sameness.

Informal Sameness

Participants used descriptive language of varied specificity to highlight sameness in isomorphism and homomorphism. Some participants highlighted shared defined properties or generally referred to same behavior. For instance, this participant was coded as same properties: “…Also, the facts that properties like cyclic and Abelian are preserved by isomorphisms.” Notice, the respondent referred to defined properties that are shared by isomorphic structures. Other participants wrote generally of shared behavior for isomorphism or homomorphism: “The idea of an isomorphism is that two different sets of objects can behave the same in certain scenarios.” And “With a homomorphism, the objects of the image will behave in “the same” way as the domain (or quotient based on the domain).” While highlighting the sameness of objects linked by a morphism, such responses did not provide details on the shared sameness.

Participants also used renaming/relabeling and matching language to describe isomorphism and, to a lesser extent, homomorphism. This participant described isomorphism in terms of a renaming of elements: “I like to emphasize to students that algebraists care about the algebraic structure and equations, and we don’t care nearly so much about what we choose to name the elements in these structures.” Note they highlighted the arbitrary nature of element names in keeping with Rupnow’s (2021) distinction between renaming/relabeling and matching. Another participant described isomorphism in terms of matching: “For finite groups where Cayley tables are not too time-consuming either to make or to understand, one beneficial way is to see that they can be arranged to have the same overall pattern.” Notice this respondent referred to rearranging Cayley tables to demonstrate a matching between appropriate elements in isomorphic objects.

Structure-preservation and operation-preservation were used to describe both isomorphism and homomorphism, but slightly more often for homomorphism. For example: “It gives a colloquial way of saying 'the algebra doesn't change' for particular structures. Things like order, dimension, and so on are preserved." Some explicitly connected structure-preservation to homomorphisms: "I teach homomorphisms as functions which preserve group structure. Homomorphic images are 'large scale structure' while subgroups are 'small scale structure' (at least in examples like symmetric groups and matrix groups)." We believe this participant means that homomorphisms reveal aspects of the domain group's structure by examining a simpler image. Most operation-preservation seemed focused on the homomorphism property: "A homomorphism preserves the operations of the algebraic structures. For example, it will take the identity element of one algebraic structure to the identity element of another algebraic structure." This explanation of operation-preservation foregrounds an identity connection, which highlights a specific type of shared structure.

Disembedding examples highlighted shared properties of the domain and codomain. This example highlighted how relevant shared structure could give insight into a group:

> Sometimes it is useful to think of a group as "sitting inside of" another group, even if in a literal sense the subgroup you are thinking of is not a subset of the bigger group. For example, one might think of some copies of the dihedral group D_4 sitting inside of the symmetry group of the cube…

Notice, although D_4 describes the symmetries of a square and a similar pattern of symmetries exist in the symmetry group of the cube, the underlying elements are not interchangeable, and we would not consider D_4 a subset of the symmetry group of the cube. Nevertheless, recognizing their shared structure could yield insight into the symmetry group of the cube.

Forming equivalence classes was used to discuss sameness of elements in homomorphisms:

> We often build new structures from old by a quotient structure which makes use of an equivalence relation. A homomorphism is one source of such an equivalence relation (but not the only example). I certainly believe that this is an immensely useful way to build structures. And the 'sameness' concept is at its root (in the quotient structure, elements are identified as 'the same' if they lie in the same equivalence class).

Observe that equivalence class language groups elements of a similar nature together into the same equivalence class, which highlights a similarity among these elements within the structure.

Functions vs. Structures

8% of respondents contrasted mapping (isomorphism) and structural (isomorphic) aspects of the concept of isomorphism. For example: "Two groups (for example) can be isomorphic, but the isomorphism may not be obvious….the groups $(C, +)$, and $(R, +)$, are isomorphic because they are isomorphic as Q-vector spaces, but it is fundamentally impossible to write down an explicit isomorphism!" Here the respondent emphasized that objects being isomorphic did not imply that an isomorphism specifying which elements act the same would be easy to find or define, despite such an identification being a likely criterion for considering objects the same.

More commonly (19%), responses detailed the difference between mapping (homomorphism) and structural (homomorphic) interpretations of homomorphism. For example:

> Students who are used to thinking about isomorphic = "the same" will want to think the same thing about homomorphism and will start taking about "G and H being homomorphic" without realizing that the concept is meaningless, and that when studying homomorphisms, we are typically more interested in the properties of the function itself rather than in what it tells us about the structures independently from the function.

Unlike isomorphism, where function and structural aspects are both commonly discussed, the participant here emphasizes that the mapping is the important part of homomorphism.

Some participants provided a way to interpret homomorphism structurally by involving isomorphism. Specifically, 6% of participants referenced the Fundamental Isomorphism Theorem to provide a way to connect sameness, isomorphism, and homomorphism. For example, one participant observed: "I guess the First Isomorphism Theorem should come to mind here. If you quotient out by the kernel, then you get the "same" group as the image, right?" Here we see how the concepts of homomorphism, isomorphism, and quotient groups are linked via theorem: the quotient and image are isomorphic, and the homomorphism defines the kernel.

Discussion and Conclusions

In this large-scale study, we confirmed some findings of prior small-scale studies. Specifically, relabeling/renaming, matching, structure-preservation, operation-preservation, and generic sameness metaphors like same behavior (Hausberger, 2017; Leron et al., 1995; Rupnow, 2021; Weber & Alcock, 2004) were all used by some mathematicians to describe isomorphism. Similarly, structure-preservation, operation-preservation, disembedding, and equivalence class metaphors (Hausberger, 2017; Rupnow, 2021) were used by respondents when describing homomorphism. However, none of these particular metaphors were used by more than a quarter of participants. Furthermore, though it appeared, only three mathematicians described homomorphism in terms of equivalence classes, although it was commonly used by one of Rupnow's (2021) algebra instructors. These differences may indicate that Rupnow's (2021) instructors used uncommon language for homomorphism or could suggest that examining language in instruction as well as out-of-class contexts is important to examine the breadth of language used for isomorphism and homomorphism. Future research should examine the prevalence of these metaphors in instruction for larger groups of mathematicians.

This study also shows a difference between mathematicians' perceptions of the relevance of sameness to isomorphism and homomorphism. This was demonstrated through limited resistance to the concept of sameness for isomorphism (81% of respondents coded with a partly helpful code), and resistance to "sameness" largely related to imprecision, not irrelevance. In contrast, a majority of respondents resisted or did not clearly relate sameness to homomorphism (39% of respondents coded with a helpful-based code), and the "sameness" in homomorphism related only to parts of structures, not whole objects. Differences were also emphasized through participants' portrayals of the function and structure aspects of these concepts (isomorphism vs. isomorphic and homomorphism vs. homomorphic) that highlighted whole object and partial object differences between isomorphism and homomorphism. While these results are not very surprising, they confirm that sameness is relevant to isomorphism and can be a conceptual base for making connections to other subjects as long as the reduction in precision is acknowledged.

Finally, the context-dependence of sameness was a clear theme in participants' responses. Distinguishing isomorphism from other, potentially "stronger" forms of sameness, like equality and being identical, as well as "weaker" forms like homomorphism relates to the importance of precision: what exactly or how much needs to be the same in a particular situation. Similarly, participants' concerns about misconceptions largely related to confusion about whether elements or groups need to look the same or what happens when intuition about sameness leads astray. However, content-dependence can also be viewed as a purpose for examining mathematical sameness. Considering how sameness appeared through equality in prior classes and relating that to isomorphism could create new connections for students and help them appreciate the subtleties of mathematical definitions, which we know are often problematic for students (Edwards & Ward, 2008). Future research should examine how many of these sameness connections are already made by students as well as examine how to help students make such connections, both to help future teachers appreciate how different notions of sameness have appeared in K-12 settings and to help math majors reexamine their prior learning.

Many educators and researchers advocate for student engagement in disciplinary activity. This is especially the case in advanced undergraduate courses taken by mathematics majors. In our respective design-based research projects, we found a need to better operationalize the activity of mathematicians in order to both plan for and document student engagement in disciplinary activity. In this report, we share our literature-based efforts to identify the tools and objects used by pure mathematicians in their work. We share the overarching framework we developed, Authentic Mathematical Proof Activities (AMPA), and illustrate the ways we have used this framework to analyze teacher-student activity using an activity theory lens. We conclude with reflections on how tensions between authenticity-to-the-discipline and authenticity-to-the-students shape the teacher-student activity system.

Keywords: Undergraduate Education, Advanced Mathematical Thinking, Design Experiments

What does it mean to document participatory learning in a proof-based classroom? Analysis of classroom activity at this level often focuses on cognitive analogs (such as documenting taken-as-if-shared practices) and analyzing argumentation through lenses such as Toulmin's argumentation scheme (e.g., Rasmussen & Stephan, 2008). While such analyses can provide important insights into student activity, we have found them insufficient for analyzing student activity in relation to our *authentic mathematical activity* design principles. That is, such analyses enable documentation of students' progressing related to content and arriving at mathematical argumentation goals but may oversimplify the nuances involved in the disciplinary mathematical activity we hope to engender.

In mathematics education, the term authentic mathematical activity or practice is often used in conjunction with two simultaneous, but sometimes competing goals: (1) Staying authentic to the disciplinary activity of mathematics and mathematicians; (2) Staying authentic to student communication, activity, and thinking. Lampert (1992) noted that authenticity needs to go back and forth between "being authentic (that is, meaningful and important) to the immediate participants and being authentic in its reflection of a wider mathematical culture" (p. 310). Herbst (2002) has referred to the tension between students having the opportunity to engage in authentic activity and need for proofs to progress in normative ways as a *double bind* when teaching proof. Dawkins et al. (2019) has elaborated on this in the undergraduate proof setting in which such a bind was felt between "supporting success for all students and authentic mathematical activity" (p. 331). As design-based researchers, we have observed a similar tension in our work, resulting in a need to better operationalize authentic activity at this level in order to plan for and then analyze such activity. In this report, we share our efforts using Activity Theory (Engeström, 2000) to better articulate the authentic activities from the discipline and how such activities may or may not be authentically observed in student activity.

Theoretical and Analytic Framing

Activity occurs within larger systems informed by cultural history and norms. Both research mathematicians and students operate within *activity systems* (Engeström, 2000) which account for individuals' goal-driven actions and the way a community works together when they share a common object. These systems consist of: the acting subject, objects (where the action is focused; the motive will be embedded within the object), tools (the means by which the subject acts in relation to the object), the community, the norms and rules of the community, and the division of labor between members of this community as they work towards a goal. We focus heavily on *tools* as the culturally-situated ways that a subject can transform an object toward a desired outcome. Further, we focus on *objective* as a means to capture the compound notion of both a focal object and the embedded motive consistent with Kaptelinin et al. (1995) and Engeström's (2000) treatment of objects.

Researchers in science education have pointed to the key role of tools and usage of tools towards disciplinary objectives in both engendering and analyzing students' disciplinary activity (Nolen et al., 2020). Classroom activity systems may differ substantially from mathematician activity systems in terms of the community, norms, and division of labor; however, tools and objectives can theoretically exist across systems. Instructors, members of both communities, often play a boundary crossing (Akkerman & Bakker, 2011) role connecting between the disparate settings. While work in other contexts has focused primarily on material tools, we argue that conceptual and procedural tools play a more substantial role in the activity of pure mathematicians due to the abstract nature of the discipline. This leads to the natural question:

- What tools towards what objectives do mathematicians use in their discipline that have the potential to be used by undergraduate students in proof-based contexts?

Authenticity to the Discipline: Tools and Objectives

In order to answer this question, we conducted a thorough literature review of both mathematics education research journals and journals that publish mathematician research activity. We created categories of tools and objectives found in student activity from research projects that shared our basic assumptions around desiring student engagement in authentic disciplinary activity (such as inquiry-oriented and anthropological theory of didactic studies). In alignment with concerns voiced in a recent issue of *ZDM* (Hanna & Larvor, 2020; Weber et al., 2020), we verified that such tools and objectives have been documented in empirical studies of mathematicians. We worked reflexively from the two literature bases to arrive at a three-dimensional framework focused on tools and objectives decomposed into motives and objects. Motives include *understanding*, *testing*, and *constructing* (cf. Selden & Selden, 2017) which exist in relation to mathematical objects: *proofs*, *concepts* (including definitions), and (propositional) *statements* (cf. Dawkins, 2015). For example, the mathematical activity of conjecturing would link to the objective: constructing a statement. In terms of tools, we identified nine categories described in Table 1.

Table 1: Mediating Tools in Mathematician Activity

Tool	Description
Analyzing/ Refining	A process of analyzing and/or refining a proof, statement, or definition via attention to the strength and consequence of assumptions.
Formalizing/ Symbolizing	A process of translating informal ideas into symbolic or formal rhetoric form.
Warranting	A process of inferring why a particular claim is true based on the provided premises.
Analogizing/ Transferring	A process of importing a proof, statement, or concept across domains and adapting to the new setting.
Examples	A specific, concrete instantiation of a mathematical statement, concept, or proof representing a class of objects.
Diagrams	A visual representation of a mathematical object (statement, concept, or proof) that captures structural features.
Logic	The rules of logic which allow for precisely quantified statements and deductive arguments.
Structures/ Frameworks	A top-level structure for a proof (or modular section of a proof) which is determined by statements to be proven.
Existent PSC Objects	Proofs, statements, and concepts (definitions) that are accepted as valid in the community.

Detailed case studies of mathematician's work (e.g, Fang & Chapman, 2020, Fernández-León, et al., 2020; Martín-Molina, et al., 2018) reflect several other themes in the ways in which mathematicians use tools towards objectives. Notably, their activity involves coordination of tool use (both in tandem and succession and the use of tools within and outside of the formal-rhetoric system) and transition of objects to tools for continued mathematical activity. Consider an example from Fernández-León et al.'s (2020) study of a mathematician's conjecturing and proving activity. The mathematician (and their colleagues) began with an *existent statement*: "all complete CAT(0) spaces satisfy the (Q4) condition" (p. 7). They then *analyzed/refined* the statement through the process of exploring *examples* to arrive at a new, stronger statement *formalized* as: "every CAT(0) spaces satisfy the (Q4) condition" (p. 12). This statement is *tested* with additional *examples* aided by a *diagram* which rejection of the statement, and a new *refined* statement was *constructed*: "any CAT(0) space with constant curvature satisfies the (Q4) condition" (p. 12). The mathematicians then *tested* this statement with a new *example* producing a proof of the Q4 condition being met (using *logic/framework*) and *analogizing* the proof process in this context. This proof then served as a generic example for *constructing the proof* of the statement (and thus a final *testing* of the statement). Such illustrations help to bolster the claim that authentic mathematical activity is nonlinear, or "zig-zagging" as argued by proponents of authentic activity (e.g., Lampert, 1992) in which a multitude of tools are used to meet objectives and prior objects become tools for continued mathematization.

Authenticity to the Student: Division of Labor, Norms, and Community

A set of mathematician tools and objectives provide a means to document some engagement in disciplinary activity; however, they need to be paired with exploration of other components of the activity system to reflect authenticity to students as well. A traditional undergraduate course tends to contain a division of labor in which students are responsible for taking notes and answering largely closed-form questions, while the instructor presents definitions, theorems, and formal proofs accompanied by verbal informal explanations (Artemeva & Fox, 2011; Paoletti et al., 2018; Weber, 2004). Thurston (1994) and others have questioned the authenticity of the focus on formal products rather than the informal, nonlinear processes involved in the creation of such products. Further, advocates for students to engage in more authentic activity have suggested images of instruction with differing norms and division of labor focusing on student activity driving the mathematical agenda (e.g., Laursen & Rasmussen, 2019).

From an observable standpoint, the division of labor can evidence whether activity is more or less authentic to students. For example, Herbst (2001) illustrated the division of labor in a geometry class in which the community was working collaboratively to produce a proof, but ultimately the teacher introduced the key idea. Thus, this activity may become less authentic to students in order to meet goals of staying authentic to disciplinary aims. Division of labor can provide insight into *agency* and *authority* (e.g., David & Tomaz, 2012; González & DeJarnette, 2012). We operationalize agency as the freedom to make decisions and create tools in the activity system such as who prompts the use of a tool or who creates a tool. Whereas authority reflects how mathematical tools and objects are determined to be valid. The more division of labor reflects students taking on these roles, the more authentic the activity is to them.

Setting and Analysis Process

The driving force behind this theoretical exploration was a need to better analyze the activity of undergraduate students participating in our design-based research studies. Our framework affords analyses of how a tool is introduced by who, and the degree to which student and teacher contributions shape the overall activity (working towards a particular objective). In order to illustrate the potential of our framework to document student activity and provide a means to make claims about authenticity, we share an episode from one of our projects. This episode stems from a larger project aimed at adapting instructional practices from the K-12 literature base (e.g., Stein et al., 2008) to an undergraduate proof-based setting (introduction to abstract algebra) in order to promote student engagement in more authentic proving activity. The project consists of cyclic task development and instructional supports through a series of task-based design experiments starting with small groups of students and then tested in a classroom setting. For the scope of this paper, we share an episode from the second cycle in which we engaged four undergraduate students in a series of task-based interviews. This episode stems from a task (Melhuish, et al., 2020) in which students compare proof approaches and use these proofs as a springboard to refine and test versions of the theorem establishing that the Abelian property is structural (that is, if two groups are isomorphic, and one is commutative, the other is as well).

Our analysis process was as follows: First, we focused on the degree to which the activity was authentic to the discipline. To do so, we coded all tools and associated objectives from the AMPA framework. We then considered how this tool use approximated the complexity of mathematicians (e.g., Are multiple tools being used in conjunction and in succession towards an objective? Do prior objects become tools for new objectives?). To analyze the degree to which the activity was authentic to the student, we analyzed the division of labor in goal-directed actions (e.g., Who introduces the tools? Who uses the tools? Who connects the tools to the objectives?). As a result of analyzing the two facets of authenticity, we further identified shifts in authenticity and provided robust descriptions of these changes to better understand the activity system. The analysis proceeded in several passes – first focusing on the tools and objectives, then focusing on the division of labor and shifts in authenticity. In each stage, at least two researchers analyzed the data with one researcher serving as a first reader and second researcher serving to challenge interpretations. Disagreements were resolved through discussion.

An Illustration of Analyzing Student-Teacher Activity

The following episode describes the student-teacher activity as they used disciplinary tools toward the objective: *construct* a *statement*. This episode occurred after students spent time *understanding* a theorem *statement* (including subdividing the theorem into a set of assumptions and conclusion) and then *understanding* two student *proof* approaches and comparing across them. During this activity the students identified several differences between the proofs including the use of *warrants*. One proof did not appear to use the fact that an isomorphism is 1-1 and onto to warrant any claims whereas the other approach did. The episode began with the teacher researcher prompting students to use the *analyzing/refining* tool in conjunction with the *existing* theorem and proofs to decide, "So, the big question is, did we actually need all of the assumptions in this statement?"

The teacher-researcher positioned the statement and proof as existent objects in which students used their understanding developed in the prior episodes to move forward. The students responded:

> StudentC: Yeah, we definitely, if the final proof is H is abelian, for sure G is abelian.
> StudentA: Because that's the property that we use, and we also used isomorph- [cross talk]
> StudentD: You would need everything for isomorphic, because you need to know that it is isomorphic.
> StudentC: I mean, couldn't we prove it with homomorphism?
> [continued cross talk]
> StudentC: Our proof worked [proof that did not use onto or 1-1]
> StudentD: All you need to know is that G and H are homomorphic.

The teacher-researcher asked the students to explicitly construct a revised statement based on the homomorphism-only suggestion. One of the students suggested replacing "isomorphic" with "homomorphic." The teacher-researcher slightly altered the statement and wrote the conjectured theorem on the board: *Suppose there exists a homomorphism from G to H. Then if G is Abelian, H is Abelian.*

At the beginning of this episode, we can see the students *warranting* by referencing the necessity of abelian in the proof and disagreeing over the necessity of 1-1 and onto warrants. After some cross talk, the students arrived at the antecedents needed to *construct* a new *statement*. The division of labor at this point included the teacher-researcher prompting a tool to use (*analyze/refine*) and the students using this tool in conjunction with their understanding of the statement and proof from their prior activity. Further, the students engaged in debate, reflecting authority in determining what is mathematically true. At the end of the episode, the teacher-researcher rephrased the student suggestion to align with convention reflecting the teacher-researcher using the *formalizing* tool. This was a place in which authenticity to the discipline and authenticity to student objects converged, with the teacher-researcher preserving some aspects of the student object while also acting to bring it closer to the mathematical community standards.

After the new statement was written, the teacher-researcher again prompted for a specific tool use, *testing* the *statement* with *examples,* or producing a counter*example*. This was a consistent role the teacher-researcher assumed. The students began trying to generate *examples* while explaining their strategies such as, "I'm trying to think of groups under specific operations that wouldn't map correctly to other groups. So, maybe a different operation, but I don't know exactly how a homomorphism looks in that sense," and "... so, since we lost one-to-one and onto, maybe think of some element in H that doesn't have a pre-image." We can see in these contributions that the students were linking the objective (*testing the statement*) with the tool (*examples*) drawing upon *existent* concepts such as the meaning of onto and relationship with the pre-image. The students began suggesting different groups, but also voiced their uncertainty about whether they were creating counterexamples. At this point, the division of labor shifted as the teacher-researcher began scaffolding the tool generation by asking questions about what would need to be true about G, *phi*, and H with students suggesting, "abelian," "homomorphism," and "non-abelian," respectively. While the students confidently answered abelian and homomorphism, their "non-abelian" response conveyed hesitancy, to which the teacher-researcher took on authority to endorse the correctness of non-abelian.

The teacher-researcher next asked for example groups to meet the abelian and non-abelian requirements. The students suggested a number of examples which the teacher-researcher would challenge with questions by asking if the examples met the requirements to be abelian or a group. For example, a student suggested the *example*, "Integers under subtraction, they don't have the abelian property." When the teacher-researcher asked if this was a group, the students disagreed. To resolve this disagreement, the teacher-researcher prompted for the use of an *existent definition*, "So, what properties are you checking right now to decide if it's a group or not?" The students could list the properties of a group, and the teacher-researcher began asking about them one-by-one. The students suggested "0" as the identity to which the teacher-researcher prompted for the definition of identity. Several students made suggestions including, "any other element yields that element," to which another student responded, "So, a minus zero would still be a." The teacher-researcher then asked, "What about zero minus a?" A student shared, "negative a" with two students voicing that was not a group structure. We can see that students used their *definition* for group and the various group properties. We can also see that the division of labor reflected the teacher using the *definition* of group to ask a series of questions to check the properties. As such, the students' agency was more limited. This was another instance in which the teacher-researcher provided scaffolding questions to implicitly challenge a student *tool* that was not conventionally accurate. In terms of authenticity to the students, this episode reflects a shared distribution of labor in which the teacher-researcher never explicitly stated the structure was not a group, but asked questions that implicitly alerted students that more needed to be explored. Through asking these questions, the teacher-researcher changed the *objective* from *testing* the revised *statement* to *testing* the implied *statement: The integers with subtraction is a group.* The students did appear to link the tool and the objective agreeing ultimately that the failure of the identity property (using the *definition*) meant that statement was untrue.

At this point, the teacher-researcher resolicited for a non-abelian group with students making some suggestions and the teacher-researcher taking up the suggestion of the dihedral group *example*. Unlike the first instance, the students engaged in using the *existent definition* to *test* the implicit *statement* that the dihedral group was non-abelian, and came to an agreement using the *example* elements r and s ("$rs \neq sr$"). The spontaneous use of the definition and example reflected a different distribution of labor with students taking on more agency. The students then suggested an abelian group ($\{-1,1\}$), but voiced confusion about creating the homomorphism map. At this point, the teacher-researcher interjected to introduce the *diagram* tool and drew a function diagram with the co-domain and domain group. The teacher-researcher further asked the leading question, "If we have a homomorphism, where do we know this identity has to go?"

with a student stating to the "identity." Another student asked, "[can] we just pick another one for the negative one to go to?" The teacher-researcher challenged, "do we need to pick a different one?" with a student returning to the assumptions in the statement to say, "it's not 1-1 or onto." Ultimately, the teacher-researcher introduced the map of sending all elements to the identity. While the counterexample was co-constructed by the teacher-researcher and students, there were a number of places in which the authenticity to the students was limited due to the teacher-researcher introducing the tool or providing guiding questions that resulted in students having less degrees of freedom.

The teacher-researcher then asked if this was in fact a counterexample and prompted for the students to explain. A student shared, "Because we have an abelian group that maps to non-abelian group, therefore H does not always have to be abelian." This student's contribution evidenced that they were seeing the *example* as a tool to meet the objective of *testing* the statement, which also provides some indication that limited authenticity to the students' contributions may still be authentic to their activity. This was further evidenced in the next episode when the teacher-researcher had students return to proofs and examples to determine whether 1-1 and/or onto was needed in the statement. The labor shifted from the teacher-researcher providing a specific tool for students to use to allowing students the agency to use whatever they wanted to *test the statement.* For the sake of space, we do not share a detailed analysis of this next portion, but we do note that students used the prior tool for further reasoning. They repurposed the counter*example* and *diagram* (Student C: If you just say one-to-one …) as a means for continued *analysis* and *testing* the onto assumption of the statement, noting that altering the map to make it 1-1 did not fix the issue (Student D: So, yeah it would still be wrong; Student A: Yeah, it contradicts.). The remainder of this task session involved the students and teacher-researcher using both the proofs and examples to arrive at a final statement.

Discussion

We selected the above episode because it provided nuance to authenticity and illustrated a time in our design experiment in which the teacher-researcher shifted the division of labor. We would conjecture that some researchers may read the exchange and feel it was inauthentic because the teacher-researcher engaged in much of the labor, including focusing student objectives and suggesting the type of tools for students to use. Further, at some points, the students themselves did not generate the tool without the teacher-researcher scaffolding. However, it is likely that other researchers would see this episode as illustrative of authentic activity because students engaged with tools of the discipline towards disciplinary objectives and students' contributions were an expected part of the labor throughout. These differing, yet viable, interpretations lend credence to the notion that authenticity is not a binary construct.

Some of this nuance may be attributed to differing types of authenticities and the tensions involved between maintaining authenticity to the discipline and authenticity to the students (Lampert, 1992; Ball, 1993, Dawkins et al., 2019). Weiss et al. (2012) further identified two distinct types of authenticity to the discipline which they deem authentic to practice and authentic to discipline. We conceptualize this divide as a practice and content distinction. For example, this distinction can be seen in Chazan and Ball's (1999) discussion of convention for "testing ideas, for establishing the validity of a proposition, for challenging an assertion" (p. 7) and "definitions, language, concepts, and assumptions" (p. 7), respectively. From our framing, practice is reflected in types of tools and motives, and content is reflected in types of objects. Although unproblematized in the literature, we would argue that student authenticity can similarly be subdivided into content and practice. Practice can be thought of as authentic to students if students have agency to create tools and use them to meet objectives related to knowledge generation. From a content perspective, we can also consider the authenticity in terms of how student-generated tools and objects are positioned in the activity. That is, are student contributions legitimized, and are objects (proofs, statements, and definitions) that students generate used for further mathematical activity?

Because of these differing aspects of authenticity, a student-teacher activity system is likely to be rife with tensions stemming from differences in traditional classroom activity systems and mathematician activity systems. For example, the division of labor in the teacher-student activity system likely necessitates teachers providing tasks and thus setting some of the objectives in the classroom setting. Further, the student-teacher activity system has competing goals related to apprenticing students in mathematician activity while also developing proficiency with conventual mathematical content. Engeström (2001) points to the role of "historically accumulating structural tensions within and between activity systems" (p. 137) as propagating system change – a notion we see reflected in our own work in which the teacher serves a unique role as a member of both the mathematician and undergraduate community, and thus serves as a boundary crosser for the respective activity systems. Teacher scaffolding serves both the role of "help[ing] learners use cultural tools" (Belland, 2016, p. 32) and managing the tensions involved in authentic activity (Williams & Baxter, 1996). We point to these tensions, and the role of the teacher, to emphasize that authenticity is not a binary construct, rather, activity can be authentic in different ways and to different degrees when analyzing an activity system.

The particular episode we selected illustrates a situation in which students were prompted to use certain tools for a certain objective, but had agency in the specifics involved while generating those tools, leading to the construction of a statement that would not be valid in the mathematician community. In terms of content, the student objects stayed centered (although formalized by the teacher-researcher). However, there was variation in how much agency students had in creating the examples to test the statement. In particular, the students seemed at an impasse around generating a counterexample, and so the division of labor shifted to the teacher-researcher. Although, there was a dip in authenticity for the students in trade for authenticity to discipline and practice, we would argue that this ebb in authenticity opened a space for students to engage more authentically in the next portion of the task as students both had increased agency in what tools to use and repurposed the co-constructed counterexample.

We developed the AMPA framework to provide a concrete way to analyze and evidence student engagement in authentic activity. The framework contains operationalizations of mathematician tools and objectives that had the potential for use in the undergraduate setting. As an analytic tool, we complemented the tool and objective analysis with considerations of complexity and division of labor. Student activity more closely approximates disciplinary activity when tools are used in more complex ways and prior objects become tools to meet new disciplinary objectives. This activity is likely to be authentic to student practice if students play a substantial role in the division of labor, have agency to generate tools towards an objective, and authority to evaluate the validity of objects. While our initial attention was to focus on elements of practice, we note that the tension in terms of student-generated and disciplinary content also played a larger role in the activity system. Future research could develop additional analytic tools to further parse the ways that the four types of authenticity (authentic to disciplinary content and practice / authentic to student practice and content) shape school activity systems in both research and classroom settings.

ANALYTIC EQUATION SENSE: A CONCEPTUAL MODEL TO INVESTIGATE STUDENTS' ALGEBRAIC MANIPULATION

Yufeng Ying

Kevin Moore
University of Georgia
kvcmoore@uga.edu

In this paper, I propose a new construct named analytic equation sense *to conceptually model a desired way of reasoning that involves students' algebraic manipulations and use of equivalent expressions. Building from the analysis of two existing models in the field, I argue for the need for a new model and use empirical evidence to explain the new model.*

Keywords: Algebra and Algebraic Thinking, Cognition

Students' success in learning algebra has concerned educators for decades, and researchers have stressed algebra's importance to students' learning and growth extensively and repeatedly (Kaput, 2000; Usiskin, 1995; Wu, 2001). A central difficulty to students' algebra learning, as Behr et al. (1980) captured, is a sense of "extreme rigidity about written sentences," which includes "an insistence that statements be written in a particular form" and "a tendency to perform actions (e.g., add) rather than to reflect, make judgments, and infer meaning" (p. 16). Such a sense of rigidity in doing algebra appears in scenarios such as students interpreting an equal sign as "calculate the left side" (e.g., Knuth et al., 2006), students meeting difficulties in using the substitution method in solving equations (e.g., Jones, 2008), and students hesitating to transform an expression into its equivalent expressions when beneficial (e.g., Ying, 2020).

The field has conducted many studies regarding a sense of rigidity that appears in students' conception of the equal sign and students' use of the substitution method (e.g., Alibali et al., 2007; Baroody, 1983; Knuth et al., 2008; McNeil., 2006, Jones et al., 2012). Comparatively, less research has focused on the sense of rigidity in students' symbol manipulation and use of equivalent expressions for problem-solving (such as given $x+y=2$, $xy=2$, students should be able to evaluate x^2+y^2 without solving for x and y but realize $x^2+y^2= (x+y)^2-2xy$). On the one hand, such an area that is challenging to research as 1) the idea of using equivalent expressions or symbol manipulation is so general that converting $2+x=5$ to $x=5-2$ can also be argued as using equivalent expression; 2) a flexible use of symbol manipulation and equivalent expressions may be influenced by a complicated set of mathematical knowledge and is hard to list out clearly (Hoch, 2006); 3) it is doubtful whether some algebraic manipulations are just symbol playing which carry little educational value (Booth, 2018). However, on the other hand, studies have reported an important connection between students' flexibility in using algebraic manipulation and their success in mathematics (e.g., Novotona & Hoch, 2008; Vincent et al., 2017; Kieran, 2006) and how some delicate algebraic manipulations echo the essential aesthetic nature of mathematics and are accompanied by deep mathematical thinking (e.g., Arcavi, 1994; Dreyfus & Eisenberg, 1986).

The aforementioned difficulties and affordances of reasoning flexibly with algebraic equations collectively suggest the need to construct a conceptual framework in studying students' algebraic manipulation and the use of equivalent expressions. Accordingly, the paper reports a result from an ongoing research effort in constructing such a conceptual framework. Specifically, the paper begins by discussing the affordances and limitations of two existing constructs. Building from this analysis, the paper proposes a new construct named *analytic* *equation sense* with empirical evidence illustrating a) how the construct was conceptualized from analyzing students' algebraic manipulations and b) three factors that the construct captured as the core elements in supporting students' algebraic manipulation and use of equivalent expressions.

Existing Constructs in Studying Algebraic Manipulations and Use of Equivalent Expressions

One of the early studies that drew attention to algebraic manipulation and equivalent expressions was Arcavi's (1994) work on symbol sense. Arcavi established the construct of symbol sense as an analog to number sense in the context of algebra. The definition of symbol sense included all sense-making activities relevant to symbols, which includes students' algebraic manipulations and use of equivalent expressions but extends much further.

Specifically, the idea of symbol sense addresses algebraic manipulations that are complemented with what Arcavi calls *reading through symbols*. As Arcavi (2005) indicated, the detachment of meaning in symbol manipulation helps with efficiency, but reading through symbols adds a layer of meaning and connectedness to performed manipulations. One example Arcavi (1994) provided was the problem of finding the numerical property of the result n^3-n when n is an integer. Arcavi suggested the problem could be solved by converting the expression n^3-n to the expression n(n-1)(n+1) and realizing that the latter term was the product of three consecutive integers, which further implied that n^3-n can be divided by 6. Arcavi argued in such a solution, one had to both apply manipulations (convert n^3-n to n(n-1)(n+1)) and read through symbols (conceive n(n-1)(n+1) as representing three consecutive integers) to fully solve the problem. Consequently, Arcavi argued that algebra manipulations and reading through algebra symbols are complementary to each other.

In the case of using equivalent expressions, Arcavi suggested that equivalent expressions can be conceptualized with non-equivalent meanings. Using the same example above, Arcavi believed the expression n(n-1)(n+1) helps students to interpret the term as the sum of three consecutive integers, which is an observation that the original expression n^3-n may not afford directly. Similarly, many expressions, when transformed into different equivalent expressions, can generate a richer set of implications and meanings. Therefore, Arcavi suggested an important aspect of symbol sense is to treat the result of manipulations not only as results but also as "potential sources of new meaning" (p.28).

Collectively, Arcavi's idea of symbol sense stresses the importance of incorporating a search for meaning while performing algebraic manipulation and using equivalent expressions. In other words, educators should attend more to symbol manipulations that are accompanied with meanings.

Nevertheless, since symbol sense also contains many other aspects, researchers have adopted the term in a broad range of areas. For instance, symbol sense was also used in studying students' conception of the minus sign (Lamb et al., 2012), students' understanding of the quantitative relationship between different expressions (Pope & Sharma, 2001), students' calculus performance (Thompson et al., 2010), and students' function graphing skills (Kop et al., 2020). As a result, the versatile use of the construct symbol sense has the risk to obscure researchers' real interest when working with such a construct. As Pierice & Stacy (2004) categorized, the applicability of symbol sense contains almost everything involving symbols. Furthermore, as Bokhove & Drijvers (2010) stated, "observing symbol sense is not a straightforward affair," as students "exhibit both symbol sense behaviors and behavior lacking", and it was hard to decide whether students "are relying on standard algebraic procedures or are actually showing insight into the equation of expression" (p.48). In summary, it is questionable whether the idea of symbol sense is at an appropriate grain size for studying algebraic manipulations and the use of equivalent expressions, and the definition of symbol sense might be too general to provide sufficient details to pinpoint students' cognitive difficulties in algebraic manipulations.

Another widely adopted framework in the field was Hoch's (2003) idea of structure sense. Building on Arcavi's symbol sense, Hoch narrowed her scope of interest to manipulations that leveraged algebraic structures. Hoch & Dreyfus (2005) defined algebraic structures as combinations of external appearances (the way an expression is written) and internal orders of an expression (the potential implications of an expression). As an oversimplification, one might interpret Hoch's definition of algebraic structures as almost all possible information that one can derive from algebraic expressions, and the conception of structure sense is then a collective set of skills in leveraging the derived information to make manipulations and use equivalent expressions. In short, Hoch's idea of structure sense is a trimmed version of symbol sense that focuses on students' flexible algebraic manipulations.

Many researchers have used Hoch's idea of structure sense and studied relevant students' algebraic manipulations. Hoch and Dreyfus (2005) primarily investigated students' structure sense by asking students to solve problems that contain some "cancelable" parts on both sides of the equation, such as solving for x knowing $(x^3 + 2x) - x = 5 + (x^3 + 2x)$. During the study, Hoch found only 6.3% of the students recognized the cancellation without a bracket, 13.6% with one bracket, and 17.7% with two brackets. Hoch and Dreyfus (2006) found that structure sense increases students' accuracy in solving algebra problems, but even high performers lack structure sense. Jupri and Sispivati (2017) reported that experts (mathematics lecturers in college) would solve some challenging problems in a consistent way with Hoch's picture of structure sense. An interesting observation by the authors was that sometimes experts started the problem by following procedural solutions without exploiting algebraic structures, and then these experts came back to leverage structures when they met difficulties. Researchers have also used the idea of structure sense in a broader setting, including college algebra and basic arithmetic (e.g., Novotna et al., 2006; Novotna & Hoch, 2008; Meyer, 2017; Bishop, 2018), and the lack of structure sense among teachers and students was a common theme across many findings (e.g., Musgrave et al., 2015; Vincent et al., 2017).

The idea of structure sense has a much smaller grain size than the idea of symbol sense, and researchers have applied the term with more coherence in studying students' algebraic manipulations. However, the construct still suffers from salient constraints: namely, if one carefully reviews the mathematical tasks that researchers have used in studying structure sense, one may find a lack of clarity in the mathematical understanding that the idea structure sense tries to capture. Consider the following three questions as examples:

Q1: $\frac{1}{4} - \frac{x}{x-1} - x = 5 + (\frac{1}{4} - \frac{x}{x-1})$; Q2: (x-3)4-(x+3)4 ; Q3: 10012-9992;

All three questions are taken from Hoch and Dreyfus's (2005, 2006) research. Hoch and Dreyfus believed that students' abilities in solving these questions elegantly measured their structure sense. In the appearance, all four questions do measure students' abilities in performing certain algebraic manipulations, but it is doubtful whether the intellectual capacities required in each task are well-connected or consistent. For instance, Q1 requires students to be sensitive toward a potential cancellation on both sides of an equation, Q2 expects students to view a compound expression (x-3) as a single entity, and Q3 asks students to apply the property of (a^2-

b^2)=(a+b)(a-b) into a numerical expression. Cognitively, each task seems to demand a different set of mathematical knowledge. In relating those tasks to the broader field of mathematics education, one may find Q1, Q2, and Q3 all indeed align with different existing research topics. For instance, Q1 overlaps with Carpenter's (2005) idea of relational thinking, which models students' coordination between both sides of an equation (e.g., realizing cancellation). Q2 touches on the broader topic of transitioning between arithmetic and algebra, and many researchers have studied students' difficulties in forming an algebraic way of thinking and mastering algebraic rules (e.g., Carraher et al. 2006; Filloy & Rojano, 1989; Herscoviss & Linchevski, 1994; Kirshner, 2004). Q3 brings the theme of creativity in mathematics problem solving and number sense. As a result, the cognitive commonalities between these tasks and between the thinking required in these tasks are unclear. Consequently, without explicating students' thinking behind all those tasks, to group those tasks under the same quilting of structure sense might be counter-productive in helping teachers to locate students' real struggles with the learning of algebra.

The lack of cognitive explanation on the thinking behind the construct structure sense is most salient for the question that asks the student to prove $(x+y)^4=(x-y)^4+8xy(x^2+y^2)$ (Hoch & Dreyfus, 2006). In Hoch and Dreyfus's writing, this question should be solved with certain manipulation tricks. However, why students should not just expand the polynomial on both sides? As Jupri and Sispivati (2017) illustrated, experts also attempt problems by procedural solutions, and it is psychologically natural for students to take an approach that is less cognitively demanding. Therefore, we remain cautious in believing all manipulation problems share equal values. Moreover, to help differentiate between random symbol playing and desired manipulations, I believe a cognitive explanation to the thinking behind algebraic manipulations is needed.

In summary, both the constructs of symbol sense and structure sense have helped researchers studying students' symbol manipulations. However, both constructs lack specificity and cognitive explanatory power in a) identifying beneficial and preventive factors that are relevant to students' algebraic manipulation; b) explicating a way of reasoning that teachers and students can adopt in engaging algebra manipulations. Some studies also touch on such an area, such as Harel & Soto's (2017) work on structural reasoning, Hausberger's (2015) work on structuralist thinking, and Schoenfeld's (2014) work on problem-solving. Similarly, their works situate in different grain sizes and lack specialized cognitive analysis of the thinking behind desired algebraic manipulations. Still, all aforementioned works are indispensable, and they are the giants' shoulders the paper stands on.

Method and Methodology

The ongoing research project aims to design a conceptual framework in studying students' flexible and meaningful algebraic manipulation and use of equivalent expressions in problem-solving. The term conceptual framework follows Thompson's (2008) writing on conceptual analysis. Epistemologically, we share many premises with general constructivism (e.g., Glaserfeld, 1995) and believe that students construct their own mathematics. Accordingly, the building of a conceptual framework creates a hypothetical thinking model through observing and analyzing students' thinking so that such a framework becomes a viable way of assessing students' mathematical knowledge and provides a viable way of thinking that students and teachers can adopt in relevant tasks (Thompson, 2008, 2013).

Up to the date when the manuscript was written, we conducted four semi-structured clinical interviews (Barriball & While, 1994) separately with four pre-service high school teachers, and the length of each interview varied between two to three hours. We have only recruited pre-service teachers so far as 1) pre-service teachers' knowledge is an important factor that influences the general teaching quality (e.g., U.S Department of Education, 2000); 2) pre-service teachers share similar mathematical understandings with high school students on K-12 math content (Carlson, Oehrtman, & Engelke, 2010). All participants have completed several college-level math courses (e.g., multi-variable calculus) but not high-level analysis courses (e.g., complex analysis). In each session, we asked the participant to go through 6-8 sequenced algebra problem, and a talk-aloud approach was adopted. Such approach asks interviewers to encourage the participant to share their thinking at every step verbally, while staying cautious in not intervening participants' own thought process (Carlson & Bloom, 2005). Most of the problems were challenging algebraic questions with multiple solutions, and we do not expect nor push participants to solve all of them. Instead, we encourage each participant to try as much as possible, and view both their successful attempt and unsuccessful attempts as valuable data in indicating their thought process. We transcribed all recordings and used open coding (Khandkar, 2019) to find emergent themes that assisted the modeling of students' thought process.

Analytic Equation Sense along with empirical supports

Based on the empirical findings, the paper proposes a conceptual model named analytic equation sense (AES). We define AES as a positive cyclic reasoning process with three important aspects:

1. Equation aspect: Students should conceptualize an equation as generative to further equivalences.
2. Analytic aspect: Students should analytically navigate between different equivalences in a given problem beyond solely relying on visual clues.
3. Sense aspect: Students should reflect on the encountered problem to gain more knowledge about the potential affordances and limitations of different manipulations and equivalent forms. The reflection, in return, strengths students' awareness that an equation have multiple equivalent forms and helps students to develop stronger skills in navigating between various equivalent forms.

Equation Aspect

We chose the term equation as we found that students' conceptualization of an equation plays an important role in performing algebraic manipulation and using equivalent expressions. In specific, we build off Ying's (2020) research on differentiating between two different conceptions of the equation: Students with a type A conception conceive an equation as representing one equivalent relationship, and that students will be able to substitute quantities that are shown in the relationship. For instance, when given the equation $x^2-x+1=0$, students with type A conception can substitute the term x^2 with the term x-1 when needed. Students with type B conception will further conceive an equation as also representing a family of equivalent relationships, and that students will be able to transform the equation to generate substitutions for new quantities. For instance, when given the same equation $x^2-x+1=0$, students with type B conception can also generate a substitution for unappeared terms, such as $\frac{1}{x}$. The student may realize $x^2-x+1=0$ implies $x-1+\frac{1}{x}=0$ and then aware that $\frac{1}{x}$ can be substituted with the term 1-x when needed. We argue students' flexible algebraic manipulations require students to develop the type B conception.

We use students' work on the following task as an illustration: "Given $a^2-3a+1=0$, find the value of $3a^3-8a^2+a-1+\frac{3}{a^2+1}$". A challenge in solving this problem is tackling the term $3a^3$ and $\frac{3}{a^2+1}$ (using the fact $a^2-3a+1=0$, the term $\frac{3}{a^2+1}$ equals $\frac{1}{a}$). One way to substitute both terms is to transform the given equation $a^2-3a+1=0$ into $a^3-3a^2+a=0$ (multiply a on both sides) and $a-3+\frac{1}{a}=0$ (divide a on both sides) and use those two new equations for substitution. All participants displayed a sense of struggle with this problem, especially with tackling the term $3a^3$ and $\frac{3}{a^2+1}$. We believe many of the observed struggles related to their lack of type B conception, which is the conception that an equation represents a family of equivalent relationships, consider: In dealing with the term a^3, students did not attempt substitute a^3 directly (which can be accomplished through converting $a^2-3a+1=0$ to $a^3-3a^2+a=0$). Rather, students rewrote a^3 as $a(a^2)$ and substitute a^2. Such manipulation displays a sense of preference to operate only with the term that was shown in the given equation $a^2-3a+1=0$. Similarly, in dealing with the term $\frac{3}{a^2+1}$, all participants deduced that $a^2-3a+1=0$ implies $a^2+1=3a$ and rewrote $\frac{3}{a^2+1}$ $as\,\frac{3}{3a}$. However, when tackling the term $\frac{3}{3a}$ or $\frac{1}{a}$, all participants were puzzled and confused. When we asked participants whether they could infer anything about 1/a from the given equation $a^2-3a+1=0$, they suggested no. Since all participants performed substitution, we believe students have developed the type A conception of an equation. However, their inabilities to deal with the term 1/x and their preference to only operate with the term that was shown in the original equation indicated their potential lack of the type B conception.

After showing the solutions to the students and asking for their feedback, all of the participants expressed a sense of shock regarding the possibility of transforming the given equation to generate new equations. Their feedback reaffirmed our hypothesis that students may not conceptualize an equation as representing a family of equivalent relationships. In specific, one participant said, "I automatically think of modifying what's already there as opposed to changing the equation itself before we begin to solve, before we begin to work and solve actual problem." He also elaborated, "you are given these two equations, so the major response was to, ok, what can we do with these two, by themselves, to get the answer. Rather than what can we change about these two, you know like multiplying by a on both sides and dividing a on both sides before we begin actually go about solving." Similarly, another student stated, "I was thinking a lot of it like taking things like this (circling the original equation $a^2-3a+1=0$) as it was instead of moving terms around." In another problem, one participant also shared a similar sense of reluctance in transforming the given equation and stated that "these numbers are kind of sets, and usually I guess, these are usually presented in the way that is easiest to solve." Based on those responses, we infer that many students do not conceptualize an equation as a potential source to generate new equations, and such thinking thwarts students' flexibility in performing algebraic manipulations and their use of equivalent expressions.

In short, we use the term equation to highlight the need for students to understand that an equation can be transformed and leveraged in various equivalent forms, and educators should be aware of some unproductive beliefs, such as that equations "are usually presented in the way that is easiest to solve."

Analytic

We chose the term analytic as we found that an analytic way of reasoning plays an important role in doing algebraic manipulation and use of equivalent expressions. In specific, we followed Stylianou's (2006) research on differentiating between three different types of proof schemes, which are external (random guess), empirical (based on old memory or visual similarity), and analytic (with mathematical rationale). We believe a student displays an analytic way of reasoning in algebra manipulations if the student can provide a mathematical rationale or justification for the manipulation he or she wants to perform and performed. In contrast, we believe that a student does not display an analytic way of reasoning if he or she performs an operation solely based on random guesses or visual similarities. We argue that an analytic way of reasoning helps students with flexible algebraic manipulations. Consider the following two scenarios:

The first scenario is the case where the student adopted an analytic way of reasoning. The problem is "given a=2003, b=2007, c=1997, Evaluate $a^2+b^2+c^2$-ab-bc-ac". One way to solve the problem is realizing that the targeted expression equals $\frac{(a-b)^2+(a-c)^2+(b-c)^2}{2}$.

The student started the problem by writing down the expression $(a-b)^2$. Interestingly, he did not remember the exact formula but quickly calculated (a-b)(a-b) on paper to derive the expansion. He then wrote out the expansions for $(b-c)^2$ and $(c-a)^2$. And he said that he was going to try to use these three perfect squares expressions to get the answer. Finally, he realized that $(a-b)^2+(a-c)^2+(b-c)^2$ is $2(a^2+b^2+c^2$-ab-bc-ac) and solved the problem. When the interviewer asked about his thought process in deciding such an approach, he replied, "the way the question is framed, with the squares, and also the subtraction of ab, bc, and ac. That makes me think of this formula how a different of squares will get you… get you there…Also I am seeing, after I saw this that, it will be easier to get a square if I can subtract out some of the larger number from each other". Later, he also explained that he wrote out all three expressions because he believed all three perfects squares were needed to substitute the terms "ab," "bc" and "ac that were shown in the expression.

Such a process displayed a desirable analytic way of reasoning. The student started the problem by trying to establish associations between the expression that he needed to evaluate ($a^2+b^2+c^2$-ab-bc-ac) and the expression that he was acquainted with ($(a-b)^2$). After making such an association, he reaffirmed those associations' usefulness by realizing their potential in simplifying calculation (notice the difference between a,b, and c are relatively small). He further noticed that since the three middle terms were "ab," "bc," and "ac", if he wanted to rewrite the entire expression based on those perfect squares, he would also need $(b-c)^2$ and $(a-c)^2$. In such a thought process, his final success in finding the solution was accompanied by mathematical rationales, and those rationales guided and reaffirmed his choices of manipulation.

The second scenario is where the student adopted a non-analytic way of reasoning. When solving one problem, the student needed to evaluate $x^2-1+\frac{1}{x^2}$ from given equation $\frac{1}{x}+x=1$. One possible approach was to take squares on both sides of the equation $\frac{1}{x}+x=1$. Facing the problem, the student stated, "this expression (referring to $x^2-1+\frac{1}{x^2}$) was kind of similar to the one we were given (referring to $\frac{1}{x}+x=1$) , but I need to substitute something to replace the

x^2". After some thought, the student decided to substitute x^2 by x-1 (which derived from timing x on both sides of the equation $\frac{1}{x}+x=1$) and transformed $x^2-1+\frac{1}{x^2}$ to $(x-1)-1+\frac{1}{x-1}$, and then she was puzzled and stuck. We asked why she performed such a substitution, and she explained, "you wanna have similar terms on each of these, so just thinking about how a manipulation will help you give you something similar to whatever the expression is you are trying to find the value of."

From her response and writing, we infer the mathematical operation that she performed was largely motivated by pursuing visual similarities, and she might regard $\frac{1}{x}+x=1$ and $(x-1)-1+\frac{1}{x-1}$ as similar since those two expressions visually appear so. Nevertheless, visual similarities between equations do not always translate into the similarities between equations' mathematical meanings. In this case, the student's pursuing of visual similarities thwarted her chance to find the solution, since converting between $\frac{1}{x}+x=1$ and $(x-1)-1+\frac{1}{x-1}$ takes much more effort than converting between $\frac{1}{x}+x=1$ and $x^2-1+\frac{1}{x^2}$. Indeed, during our study, many students displayed non-analytic ways of reasoning and chose to perform some manipulations for reasons such as "this is what I did in the previous problem" or "I want to make this look like that". Frequently, those non-analytic ways of thinking lead students in an unproductive direction. More importantly, without analytic ways of reasoning, students frequently meet difficulties in evaluating whether a particular approach is worth continuing.

Based on the contrast between these two scenarios, we argue that students who are guided solely by visual features of expressions without analytically considering their mathematical meanings will have a more challenging time performing appropriate algebraic manipulations and use appropriate equivalent expressions. In summary, we chose the term analytic to highlight the necessity of helping students to generate a mathematical rationale regarding every manipulation that students made in solving algebra problems.

Sense

We inherit the word sense from Arcavi and Hoch's writings as we believe students' algebraic manipulation and use of equivalent expression is essentially a sense-making process in solving algebra-related problems. Since we do not believe one may develop his or her sense-making ability all in a sudden. We believe students' skills in algebraic manipulation and use of equivalent expression, as one's skill in sense-making, requires continuous effort in practicing and reflecting.

In the example provided above where the student decided to substitute x^2 by x-1 for the expression $x^2-1+\frac{1}{x^2}$, it is worth noticing that such substitution was derived from actively transforming the given condition $\frac{1}{x}+x=1$ to $x+x^2=x$. But that student, in the earlier problem which is "Given a^2-3a+1=0 and evaluate $3a^3-8a^2+a-1+\frac{3}{a^2+1}$", did not attempt to change the given equation. Similarly, after solving one problem which required taking the reciprocal, that same student actively started to try to take reciprocals in the next problem. Unfortunately, we cannot prove that she gained these insights by reflecting on the earlier problem. However, her performance does raise the possibility that one's intuitions and skills for algebraic manipulations can be gained through practice and reflecting on encountered problems. Those practices and reflections, in return, can strength students' awareness that an equation have multiple equivalent forms and helps students to develop stronger skills in navigating between various equivalent forms. Therefore, we use the term sense to indicate our belief that the development of algebraic manipulation skills is a constant learning process that requires continuous effort in practicing and reflecting.

Conclusion

In a nutshell, the conceptualization of AES represents a sincere effort to capture the potential sense-making process in which students can engage in algebraic manipulation and use of equivalent expressions. AES can be used both as a way of reasoning that students can adopt in solving algebra problems or as a research framework in understanding relevant students' difficulties. In a broader context, AES speaks directly to the general theme of rigidity that educators try to tackle, and the construct encourages students to engage in algebra problems flexibly, analytically, and creatively.

THE PRODUCTIVITY OF TRANSFORMATIONAL REASONING: STUDENTS' WAYS OF UNDERSTANDING CONGRUENCE BASED ON LEARNING EXPERIENCES

This study explores how students reason about congruence based on their high school learning experiences. We developed an online survey to characterize how students understand congruence and gather their recollections about high school geometry coursework. Three ways students understood congruence emerged from data analysis: pictorial, measurement-based, and transformational. Our results indicate that (1) transformational reasoning was the most productive among students' meanings but was exhibited by less than one-fifth of participants and (2) that diverse contexts encourage critical and productive thinking about congruence. In this paper, we discuss the implications of our findings to research and teaching of congruence.

Keywords: Transformational reasoning, Geometry, Congruence, Secondary education

Introduction

There are two main approaches to introducing congruence in school geometry. One approach focuses on polygons and defines the congruence between two polygons based on the equivalent measures of their corresponding parts (Bass et al., 2001; Boyd et al., 2004). The other approach focuses on congruence as a mapping from one figure to another using rigid motions (translations, rotations, and reflections) (Wu, 2013). This transformational approach might provide a way to promote coherence in students' understanding of congruence of all figures including non-polygons (Wu, 2013). Math educators thus proposed to structure school geometry curricula with definitions of congruence and similarity based on rigid transformations and dilations (e.g., Common Core State Standards for Mathematics, CCSSM) (National Governors Association Center for Best Practices, 2010). Though many studies document the importance and strengths of CCSSM (Harel, 2014; Gaddy et al., 2014; Wu, 2013), few document classroom teachers' instruction of congruence via transformational geometry and the meanings students make from this approach after its implementation (Hollebrands, 2003; Yanik, 2014). This paper focuses on the following research questions: *What meanings do students have for congruence based on their secondary school experiences, and are these meanings productive across various contexts?*

Theoretical Perspective

We adopted Piaget's genetic epistemology as the lens for analyzing data in this study. This perspective assumes that individuals idiosyncratically organize their experiences within mental schemes (Glasersfeld, 1995; Piaget, 1971; Piaget & Inhelder, 1969). The contents of those schemes provide a space of implications for an individual's reasoning (what is also called the student's *meaning (in the moment)*) (Thompson, Carlson, Byerley, & Hatfield, 2014). Patterns in how an individual reasons describe that person's *way of thinking* relative to those meanings (Harel, 2008; Thompson et al., 2014). For example, when a student is presented with two triangles and asked if they are congruent, the student's answer might include an explanation of the figures both being triangles and both having corresponding angles of equal measure (saying nothing about other features). This gives *some* insight into the student's scheme of triangle congruency. Looking at how that student answers other questions that we (as researchers) interpret to be about triangle congruency can provide additional support for hypotheses about the student's way of thinking. Thus, we focused on looking at trends in how students reason about a variety of tasks that we interpret to be about congruence in an effort to gain insights into students' schemes related to this idea.

Methodology

We distributed an online survey to thirty-three undergraduate students at a large public university in the United States. These students were enrolled in a college-level mathematics course but had not yet begun any college-level geometry course. The survey was divided into four parts. The first three consisted of tasks that measured participants' comprehension of congruence and required participants to explain their reasoning or solution process. In Part 1, students were asked to identify congruences in real-world images and create a definition of congruence to use throughout the survey to complete the tasks. In Part 2, they were asked to determine whether two geometric shapes were congruent. In Part 3, they were asked to construct congruent shapes digitally (given support on how to use the tools). At the end of these two parts, participants were given the opportunity to revise their definition of congruence if they felt it was warranted. The fourth part of the survey asked participants to reflect on their experiences in high school geometry courses.

Our goal in data analysis was to examine students' observable behavior (the answers they gave and the work they provided) to gain insights into their ways of thinking. We did not pre-determine categories for data analysis; rather, we searched for trends in students' solution processes, vocabulary, definitions, and explanations to create normative categories by which to classify their thinking. In this exploration, it became evident that students' schemes commonly involved one or more of three expectations about congruent figures: (1) a general "sameness" in two shapes' form or characteristics; (2) the equal measure of the shapes' corresponding parts (such as sides and angles); and (3) the existence of one or more transformations that maps one shape to the other. We refer to these three meanings for congruency relationships as pictorial (P), measurement-based (M), and transformational (T), respectively.

Results

In Part 1, the majority of responses (84.7%) reflected P, M, or P&M categories of meaning. Students typically found congruences between objects that resembled geometric shapes, such as rectangular windows. Commonly-noted congruences between non-geometric shapes occurred in objects that were close in proximity or formed patterns, such as adjacent slices of toast and equally-spaced candies on the roof of a gingerbread house. Students also considered whether non-mathematical, qualitative characteristics of objects were requirements of congruence. Some of these characteristics included color, perspective, and whether objects were machine- or hand-made (and therefore likely to contain accurate or inaccurate measurements, respectively).

In Part 2, responses were coded both by the meaning(s) they reflected and whether students were successful. Being "successful" entailed correctly identifying whether two geometric shapes were congruent, even if the reasoning was incorrect or incomplete. Table 1 shows the success rate for students' responses reflecting each category of meaning (bottom row) along with the success rate of the general population on each question (right column).

Students were most successful on Question 2, an image of two congruent circles. Some noted that one could imagine congruent radii or diameters (M) or map one circle to the other by one rigid motion (T). Others offered less specific reasoning, such as the circles being the same shape (P) or the same size (M), or even incorrect reasoning, such as "all circles have 360 degrees" (M).

Table 1: Success Rates per Question and per Category of Meaning

Meaning / Question	P	M	T	P & M	M & T	P & T	P, M, & T	Population Success Rate**
1 (equilateral and isosceles triangle; not congruent)	5/5	14/14	4/4	7/8	-	-	1/1	31/32 = 96.9%
2 (two circles; congruent)	2/2	7/7	7/7	8/8	-	-	3/3	27/27 = 100%
3 (two curved polygons; congruent)	¾	4/4	8/9	10/10	1/1	-	1/1	27/29 = 93.1%
4 (two similar triangles; not congruent)	¼	15/18	1/1	2/3	1/1	1/1	0/2	21/30 = 70%
5 (two squares; congruent)	¾	5/6	6/7	14/14	-	-	1/1	29/32 = 90.6%
6 (two line segments; congruent)	5/6*	11/12*	3/3	8/9*	-	0/1*	-	27/31 = 87.1%
Success Rate Per Interpreted Category of Meaning	19/25 = 76%	56/61 = 91.8%	29/31 = 93.5%	49/52 = 94.2%	2/2 = 100%	½ = 50%	7/8 = 87.5%	

*non-represented students indicated they were unsure (and therefore were not successful)
**some students responded with no or inconclusive reasoning, and were thus not included

Students were least successful on Question 4, an image of two similar triangles. Students who described a dilation and transformation(s) (T) or reasoned that the corresponding sides of the triangles did not appear equal in length (M) were successful. Unsuccessful students determined the triangles were congruent because their angles were congruent (M) or because the size was not relevant (only being the same "shape" was) (P).

The most commonly employed categories of meaning were P, M, T, and P&M. The most successful categories of meaning were M, T, P & M, and M & T, with success rates between 91% and 100%. Students were much more likely to reason based on a transformational meaning in questions that dealt with curved shapes and squares than the remaining questions concerning line segments or triangles. We note that Question 6—which presented an image of two congruent line segments—led some students to doubt whether congruent shapes had to be polygons.

In Part 3, responses were again coded both by the meaning(s) they reflected and whether students were successful. The criteria for success in Part 3 was reproducing precisely the original shape and providing an explanation of the solution process. Our analysis for Part 3 is based on the responses of two-thirds of participants who completed the activities (the remaining students did not submit completed responses, so their responses could not be analyzed). Table 2 relates each approach taken in the construction of congruent shapes to a category of meaning.

Table 2: The Understanding that Underlies Each Student Approach to Construction of Congruent Shapes

Meaning	Approach Taken to Construct a Congruent Figure
Pictorial (P)	Create a Shape of Same Type of Polygon
Measurement-based (M)	Create a Shape with Equivalent Corresponding Measurements (and therefore the same type of polygon)
Pictorial & Measurement-based (P & M)	Create a Shape of Same Type of Polygon and Approximately or Exactly Equal Size
Transformational (T)	Create a Transformation that Maps the Original Shape to a New Shape

Part 3 consisted of two tasks: constructing a congruent triangle and constructing a congruent circle. Participants had a 40.9% success rate on the first task and a 57.1% success rate on the second task. In both tasks, roughly half of the students chose a measurement-based approach, attempting to replicate the exact lengths of the triangle's sides on Task 1 and the exact length of a radius or diameter on Task 2. These students were more successful in Task 2 but averaged a 47.8% success rate on both tasks. Students who chose a pictorial approach (and did not consider size as a factor by any means) had a 0% success rate. Students who employed both a pictorial and measurement-based approach, who accounted for roughly one-quarter of the responses, had a 12.5% success rate. In contrast, students who employed a transformational approach accounted for roughly one-quarter of responses and had a 90% success rate. These students created a point, line, or vector about which to rotate, reflect, or translate the original shape, respectively.

Part 4: Classroom Experience

Part 4 of the survey gathered information on students' impressions of their geometry course (which was not coded by meanings reflected in responses or accuracy). Of the thirty participants who took high school geometry, 73.3% felt they understood the content at least at an average level and 90 % indicated the course was coherent or somewhat coherent. Almost all of the students recalled determining whether two shapes were congruent, and roughly two-thirds recalled learning about congruence between polygons and triangle congruence criteria, using rigid transformations to create patterns or copy shapes, and constructing congruent shapes using construction tools. On the other hand, only about one-third of the students recalled proving two shapes congruent with or without a two-column (or "t-table") proof. There was no significant correlation between the meanings we coded in Parts 1-3 and responses to these questions.

Discussion

Due both to the format of the study (which did not allow for clarifying questions) and many instances of inconsistent reasoning among individual participants, the most powerful data resulted from our analysis in trends rather than individuals' schemes. Our conclusions are therefore based on the frequency and accuracy for responses of each category of meaning.
The study's results indicate that reasoning based on all four of the most common categories of meaning (P, M, T, and P&M) are conducive to successfully identifying congruent shapes, while only a transformational meaning—which was exhibited by less than one-fifth of participants in their definitions—is consistently conducive to successfully constructing congruent shapes. However, our results confirm a common observation among educators and researchers: that

students rely more on empirical data rather than definitions and theorems to solve problems (Mizayaki et al., 2017; Herbst & Brach, 2006).

With inconsistent reasoning across tasks came another important insight: the power of varying contexts, specifically those with non-geometric or non-triangle shapes and real-world images. In particular, contexts in our survey with curved shapes and non-triangle polygons led more participants to consider the relationship between two shapes as a whole rather than their corresponding parts. This variation reveals that different types of tasks assimilate to different schemes for students. Exposure to diverse tasks (diverse meaning likely to assimilate to different schemes about congruence) may encourage students to reflect on and modify their schemes to reorganize them to be more robust, flexible, and interconnected. Even further, real-world contexts inspired questions from participants that would likely not come to mind in a purely geometric context.

This study examined how undergraduate mathematics students engaged in self-regulatory activities while performing routine and non-routine proofs. We used Zimmerman's model of self-regulated learning (SRL) theory, which emphasized the sequential, cyclic nature of self-regulation feedback loops in learning and task performances to better understand the difficulties students faced with proof-construction. Two students participated in think-aloud interviews, solving both a routine and non-routine number theory proof. Using qualitative data analysis, we found that students engaged in fewer cycles of self-regulation during the routine proofs, while self-regulation in non-routine proofs involved a broader range of strategies and more negative self-reactions. Our findings can inform instructors about practices that better support proof-construction – particularly approaches that are more metacognitive and reflective.

Keywords: Metacognition, Reasoning and Proof, Undergraduate Education

Introduction

Proof-construction and comprehension are important skills for undergraduate mathematics students to develop as they transition to upper-division courses. However, they face substantial difficulties in developing these skills, including focusing their attention to format, rather than content (Stylianou et al., 2015; Harel & Sowder, 1998), and these difficulties contribute to students not continuing in upper-level mathematics (Selden & Selden, 2008). The cognitive demands of proof-construction and its associated processes, including proof-writing and proof-validation, are starkly different than the demands of prior courses, such as calculus or linear algebra, that require more procedural fluency (Mujib, 2015). As a result, introductory proof courses are significant mathematical junctions, because they signify a drastic shift in the problem-solving experience of students. This poses a problem for undergraduate STEM retention, particularly in mathematics, because proof-based courses serve as a gate-keeping course to the major (van den Hurk et al., 2018).

While research on proof-construction has grown in the last few decades, there is still limited work on exploring how mathematics students engage with proofs through a metacognitive lens (Papaleontiou-Louca, 2003). Finding its roots in social cognitive theory (Bandura, 1986), self-regulated learning (SRL) theory is one cyclic model that attempts to explain students' contextual metacognitive processes (Zimmerman, 1989; 2000). This study provides a better understanding of mathematics students' cycles of self-regulation to potentially equip instructors of proof-based courses with tools and strategies. We engaged students in routine and non-routine proofs (Kablan & Ugur, 2020) in order to examine their cycles of self-regulation in tasks with varying cognitive demands to contribute to the existing body of task-specific, metacognitive research in mathematics education. Our research question was: How did undergraduate mathematics students engage in self-regulatory activities while performing routine and non-routine proofs?

Framing

We used Zimmerman's (2000) cyclical phase model of SRL, which emphasized the sequential, cyclic nature of self-regulation feedback loops in learning and task performances (Cleary & Chen, 2009). These feedback loops, or cycles of self-regulation (Zimmerman, 2000; 2013), attend to students' cognitive processes and accompanying motivational beliefs and are situated in three self-regulatory phases: (1) *forethought*, (2) *performance*, and (3) *self-reflection* (Zimmerman, 2013). The *forethought* phase encompasses students' task-analysis and self-motivation beliefs about themselves and the task at hand. This includes identifying a strategy to pursue and is related to students' self-efficacy beliefs. In proof-construction, this could involve analyzing a proof, deciding how to approach the proof, and having feelings related to completing the proof (e.g., confident). In the *performance* phase, students execute cognitive processes associated with their chosen strategy and engage in self-observation and monitoring of their progress. In proof construction, this could involve self-instruction or self-guidance through tasks, while monitoring progress by comparing their work to prior proofs they had done. Finally, the *self-reflection* phase includes self-evaluations and judgements of performance, including associated reactions and affect. This could involve making a judgment of a strategy that was ineffective and perhaps feeling frustrated that their efforts were not successful. Each subsequent cycle of self-regulation is the result of evaluating one's performance, identifying one's errors, and deciding to re-engage in task-analysis, thus signaling the forethought phase of a new cycle of self-regulation. We posit that the key distinctions between routine and non-routine proofs (Kablan & Ugur, 2020) are also reflected in students' cycles of self-regulation.

Methods

Eleven undergraduate students in a Minority-Serving Institution in California participated in a larger research project about transfer students' experiences in mathematics courses. Purposeful sampling (Creswell, 2013) was used to select two of these students for this study because of their course enrollment; one self-identified as male, and the other self-identified as female. In Fall 2020, the participants enrolled in a transitory course that introduced students to rigor and proof in mathematics designed to prepare them for upper-division coursework. Number theory and set theory were used as a backdrop to introduce students to proof-writing strategies and conventions.

We conducted think-aloud, task-based interviews (Leighton, 2009) in the quarter after students enrolled in the transitory course. Students verbally reported their thoughts as they worked on a routine and non-routine number theory proof. Number theory was used as the content area for the proofs because students encountered it in the transitory course. The routine proof used in this study was (1) *Prove that if* n^2 *is odd, then* n *is odd*; and the non-routine proof was (2) *Is it possible to create a square, with whole number side lengths, that has an area equivalent to the sum of the areas of two other squares, each with an odd area and whole number side lengths?*

We qualitatively analyzed students' think-aloud by watching videos of the interviews, creating content logs, reviewing students' written work, and writing memos about the observable cycles of self-regulation in which students engaged. Within each cycle, a priori coding (Miles et al., 2020) was used to distinguish each SRL phase. We determined that changes in strategy or method of approaching the proofs indicated a new cycle; however, students self-regulated and engaged in other metacognitive processes beyond the scope of what they verbalized out loud.

Findings

Broadly, our findings center around the number of cycles of self-regulation (hereafter just referred to as cycles) in which students engaged and the differences between phases of the cycle in routine and non-routine proofs. We found that students engaged in fewer cycles of self-regulation during the routine proof in comparison to the non-routine proof. Jason (a pseudonym, used for all proper nouns), for example, engaged in three cycles during the routine proof, and seven cycles during the non-routine proof. Ava, engaged in two cycles during the routine proof, and five cycles during the non-routine proof. We linked this difference in number of cycles to students' experiences in early introduction to proof-writing, where they are often taught specific strategies (e.g., direct proof, contrapositive, contradiction, etc.) and conventions to logically connect a premise and a conclusion. Such rote approaches to proof-writing likely constrain the number of strategies students use, as was reflected in Jason's and Ava's engagement in fewer cycles in the routine proofs. We present findings specific to students' phases of self-regulation, particularly highlighting differences in *forethought*, *performances*, and *self-reactions*.

Phases of Self-Regulation in Routine Proofs

Students evoked prior understanding of formal proof-writing and exhibited implicit self-motivation beliefs during the *forethought* phases in the routine proof. Jason mentioned, "So you have to follow the premises first," exhibiting an understanding of premises and conclusions. Ava accessed her prior knowledge, noting, "I remember from the class the definitions," as she made sense of the odd numbers in the proof and wrote: "$n^2 = 2k + 1$." Both students' task-analysis heavily relied on prior knowledge of proof-writing strategies, definitions, and conventions, and this was likely attributed to their work with routine proofs in the transitory course. In terms of their self-beliefs, students were less vocal about self-motivation or perceptions about themselves and the task.

Both students easily performed procedures associated with their chosen strategies in their *performance* phases. We observed students self-instructing or students guiding themselves through the mechanics as they executed their task strategies. For example, Jason decided to begin with n to reach a conclusion about n^2. He wrote, "$n = 2k + 1$.", then he engaged in the mechanics of squaring n while describing the process of squaring the binomial $2k + 1$. The other primary component of the *performance* phase is self-observation, and we noticed students relied heavily on the phrasing of the proof, particularly using the premise and conclusion to determine if the logic of their work aligned with what they were being asked to prove. Interestingly, Ava also used her perception of formal proofs to monitor her progress. She continually asked, "Is this rigorous enough?," referencing prior expectations of proof-construction.

Results of students' monitoring of their progress were illuminated in their various *self-reflection* phases, particularly culminating in students' self-judgements and reactions to the effectiveness of their performances. For example, Jason's approach began with squaring n, and writing "$n^2 = (2k + 1)^2$." He then said, "Give me one second. [Paused to erase work.] I was thinking about it the opposite way." He monitored his work via the phrasing of the proof, particularly realizing his approach began with the original intended conclusion. His *self-reflection* phase involved judging his original efforts as ineffective. This then prompted a new cycle as Jason analyzed the task and pursued an alternative strategy. In terms of affect and emotion, both students were less verbal about this facet of the cycle during the routine proof.

Phases of Self-Regulation in Non-Routine Proofs

Students' *forethought* phases in the non-routine proof involved a wider range of strategies, a lack of clarity in goal setting or planning, and more instances of self-motivation, albeit with more negative motivations and lower self-efficacy. Both Jason and Ava began their non-routine proof task-analyses with geometric interpretations, but later pursued a different approach. Neither student attempted to approach the problem via formal proof until the very end, which we posited resulted in a lack of formal proof-writing as a problem-solving strategy. In the *forethought* phases, the students also verbalized more negative perceptions of themselves and the task than with the routine proof. For example, Jason shared, "Yeah, I don't know how well I'm gonna do with this one," exhibiting negative perceptions of his abilities and lower self-efficacy.

We found that students were less systematic about performing the procedures associated with their chosen strategy in the *performance* phases, likely influenced by a lack of confidence and clarity in their goals during the *forethought* phase. Contrary to the routine proofs, Ava and Jason sought out help from the interviewer and attempted to regulate with the non-routine problem. Both students elicited assistance in clarifying the question and made attempts to change the non-routine proof as a result of their perceptions of the level of difficulty. For example, Jason decided that since the non-routine proof did not have explicit constraints on the two squares being the same size, he would represent the two respective sides as "$a = 2k + 1$" and "$b = 2k + 1$" to "make it easier." Ava decided to disregard the whole number side-lengths portion of the proof to attend to the difficulties she faced. The students also monitored and tracked the effectiveness of their strategy based on the phrasing of the problem, similar to their monitoring in the routine proof. Re-reading the problem in each *performance* phase was a distinct behavior both students exhibited as a way of tracking their progress.

Students expressed more negative self-judgements and reactions in their *self-reflection* phases. As students evaluated their efforts, they repeatedly noted their ineffectiveness and shared that these efforts were not leading them to correctly answer the question. However, it was unclear whether or not their self-judgements were the result of comparing their work to the phrasing of the problem or if they had just exhausted a particular strategy. Lastly, with these self-judgements came more instances of negative self-reactions. In one particular *self-reflection* phase, Ava shared, "Oh no, I don't think I thought this through very well." Interestingly, while both students mentioned feeling unclear about what to do next, their *self-reflection* phases still elicited a subsequent cycle of self-regulation. Students still persisted in continuing to work on the non-routine proof until the end of the allotted time.

Discussion and Conclusion

We found key differences in students' cycles of self-regulation in routine and non-routine proofs. In routine proofs, students engaged in fewer cycles of self-regulation, used a limited number of strategies, and exhibited more procedural performance. On the other hand, students' self-regulation in non-routine proofs involved a broader range of strategies and interpretations, fewer systematic performances, and more negative self-reactions. Understanding students' self-regulation in proofs illuminates some of the challenges they face at this crucial junction. This research can inform metacognitive practices that better support students' proof-construction such as more reflective approaches to analyzing difficult tasks and exercising agency over their affect and motivations. Furthermore, situating SRL theory in this context allowed us to further distinguish routine and non-routine proofs through a metacognitive lens, and provided insight on how to support students to persevere through cognitively demanding proofs.

The students' fractions knowledge is considered a determining factor for success in their school years. Thus, the interest arises to evaluate the understanding high school students have about this concept. To achieve this goal, three skills are evaluated in this work: graphic representation, arithmetic and word problem solving; as well as the effect of the first two on the third. A test was applied on two different students' groups (198: first grade, 112: second grade) from public schools in Mexico City. After a quantitative analysis, the results show that students from the second-grade group had greater ability in word problem solving and representation, but not in the case of arithmetic, with which the first-grade students were more successful; in that group, a high association between representation and arithmetic with word problem solving is shown.

Keywords: Graphical fraction's representation, Fractions' arithmetic, Word problems solving

Problem Approach and Research Objectives

The specific study of fractions begins in primary school and gradually gives way to rational numbers, so those who begin high school education should have developed specific knowledge and skills to be competent when using fractions. However, previous research showed this is a difficult content to teach and to learn (Siegler & Pyke, 2013), because of that the idea about 15 years old students still have difficulties when solving fractions tasks persists.

Problem solving has been proposed for teaching and learning since the 1980 (Lambros, 2002). However, the school tradition uses exercise and practice-style problems to consolidate or to apply the knowledge students acquired (Sanz & Gómez, 2018), and not to reflect on the resolution process. The graphic representation of fractions is linked to the teaching-learning model in which the students participate, and the models used can be an obstacle to developing the understanding of fractions (Lamon, 1999). On arithmetic with fractions, Braithwaite, Pyke, and Siegler (2017) hypothesized that poor learning of fraction arithmetic procedures reflects poor conceptual understanding of them. Based on the above, the next objectives were proposed: 1) to evaluate the abilities of students between 15 and 17 years old (first and second grade) to solve tasks that involve solving word problems with fractions, their graphical representation, and their arithmetic. 2) to analyze the possible differences between first and second-grade high school students' skills.

Theoretical Framework

Nicolaou and Pitta-Pantazi (2015) determined that the fractions understanding in students between 11 and 12 years old is based on seven skills: a) fraction recognition; b) definitions and mathematical explanations; c) argumentations and justifications; d) relative magnitude; e) representation; f) Connections of fractions with decimals, percentages and division; and g) reflection during the solution of fractions problems. In this work, of these skills, the fractions representation and the problem solving were considered to evaluate the developed skills of students between 15 and 17 years old. In addition, the fractions arithmetic was incorporated. To describe the specificities with which the test was designed, the framework on the uses and aspects of fractions made by Valenzuela et al. (2017) was taken as a reference, which is derived from the ideas of Freudenthal (1983). In this framework, the uses of fraction as descriptor and comparator in everyday language are distinguished, and at a more abstract level the uses of fracture, comparer, measurer, operator, and number. Figure 1 details the particularities for the design of the instrument in this work.

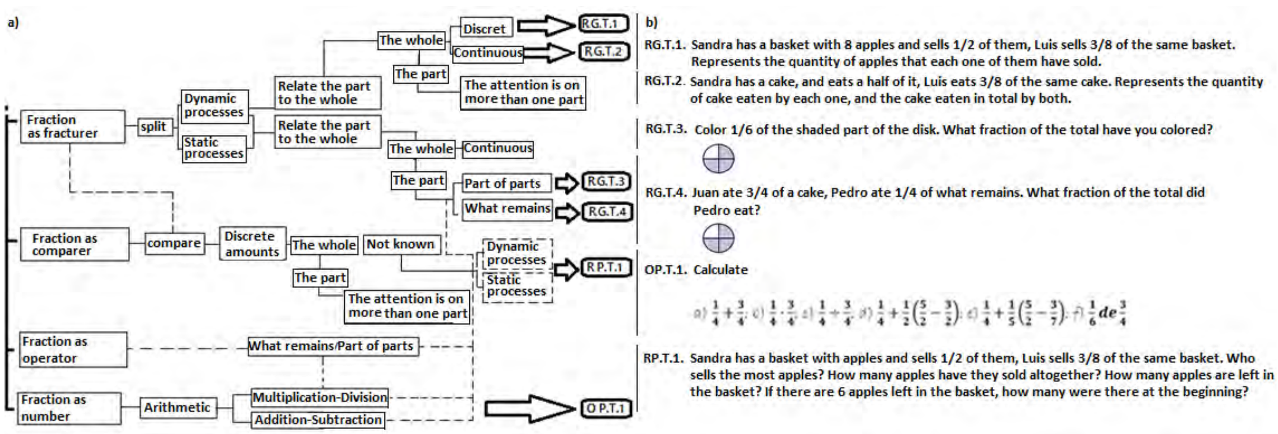

Figure 1: a) fractions uses that describe the design of the tasks and b) the instrument.

In Figure 1 (a) the dotted lines indicate the relationships between the particularities among each of the uses of the fraction involved in the design of the test. The codes enclosed in an oval, indicate the evaluated skills.

Methodology

Sample. The study was carried out on a sample of 310 students from five public schools in Mexico City. Two groups were distinguished: 198 students from the first grade (15 and 16 years old), and 112 students from the second grade (16 and 17 years old). All the data in the study sample are comparable since possible differences in the results of the test due to the geographical inequalities of the centers and the economics of the families, as well as those related to gender were rule out (test of difference of proportions each variable with p-values> 0.05).

Instrument. The test, see Figure 1 (b), is made up of six tasks supported by the Nicoloau and Pitta-Pantazi (2015) and Hart (1981) research. The four tasks that start with the RG code evaluate the graphic representation, in two of them it is requested to represent parts of a whole, but they differ due to their context -discrete (RG.T.1.) or continuous (RG.T.2.)-. The other two determine the skills related to the representation of parts of part, evaluating whether it is on the part (RG.T.3.) or on the complement to the unit -or what remains- (RG.T.4.). The fractions´ arithmetic is presented in OP.T.1. Finally, a word problem (RP.T.1) is presented in which the comparison of fractions, addition, subtraction, and arithmetic (assumed value determined) or algebraic resolution (generic value through unknown) is required.

Method. The test was applied without allowing the use of digital tools and lasted 60 minutes. To analyze the responses, the following were considered: 1) the descriptive analysis, which allows observing the trends of the two populations studied from the percentages obtained; and 2) an inferential analysis that determined the association between graphical representation and arithmetic with problem solving. In this case, Cramer's V coefficient was used as it allows knowing the degree of association between nominal variables.

Results

First, the general results on the three skills under study are presented, and then the results related to the association between the skills of graphical representation and fractions arithmetic with word problem solving are presented.

Graphic Representation tasks. In both grades, difficulties are highlighted in relation to the ability to represent situations related to "Part of parts" and "What remains". The deficit of success does not come from the representation, comes from the lack of interpretation since, of the percentage that was not successful, 78.3% (first grade) and 77.7% (second grade) drew the "part of parts" indicated in the sentence, and 58.3% (first) and 63.4% (second) drew the statement of "What remains". The percentage who was unsuccessful with representation in the discrete context (48.3% of the first grade and 52.7% of the second grade) used the area model instead of a discrete model in their representation. The area model was also used in the representation in the continuous context (88.3% of the first and 92.9% of second grade).

Arithmetic with fractions tasks. The results indicate that only 3.9% in the first grade and 1.8% in the second grade do all the operations correctly. The differences between school grades are notorious in all operations, being the first grade the most successful, and in the case of subtraction the difference is statistically significant.

Word Problem Solving task. Success in solving the word problem is 22.8% in the first grade and 24.1% in the second grade with no significant differences between both grades. In the resolution processes, was observed significant differences in the process to comparing the fractions, with higher success in first grade students. In addition, a greater success in arithmetic resolution than in algebraic processes was observed.

Association between graphical representation and arithmetic with word problem solving. It is highlighted that for first grade students it is obtained that the ability in graphical representation and arithmetic with fractions is highly associated with success in solving word problems. In contrast, in second grade, only the arithmetic ability in addition and subtraction of fractions is associated with word problem solving.

Table 4. Association of skills with Cramer's V fractions (p-value)

		1st Grade (15-16 years old)	2nd Grade (16-17 years old)
Graphical Representation vs success word problem solving	Discreet success	0.707(<0.0001) *	0.074(0.436)
	Continuous success	0.717(<0.0001) *	0.006(0.925)
	"Part of parts" success	0.710(<0.0001) *	0.087(0.358)
	Success what remains	0.733(<0.0001) *	0.181(0.055)
Arithmetic vs word success problem solving	Success Sum	0.712(<0.0001) *	0.208(0.028) *
	Success Subtraction	0.709(<0.0001) *	0.229(0.016) *
	Success Multiplication	0.715(<0.0001) *	0.099(0.297)
	Success Division	0.727(<0.0001) *	0.106(0.261)

	Success Part of Parts	0.717(<0.0001)*	0.068(0.773)
	Global arithmetic success	0.710(<0.0001)*	0.097(0.590)

Conclusions

The results show difficulties and the need to improve the understanding of high school students (15 and 17 years old) associated with the skills to solve word problems, represent graphically, and operate fractions with some particularities.

In relation to graphic representation, the need to incorporate in the instruction tasks that allow students to interpret and represent situations, in different contexts, related to "Part of parts" and "What remains" is highlighted. In addition, there is evidence of a preference to use the area model to make graphical representations, despite the task being in a discrete context.

On arithmetic with fractions, in correspondence with other investigations, there is evidence that the ability to solve addition and subtraction decreases as the age of the learners increases. In this regard, an instruction is suggested that associates the procedure with contexts and not only introduces algorithms to be memorized.

In word problem solving there is a tendency for the arithmetic process over the algebraic one. Thus, it is hypothesized that fractions are being widely taught in arithmetic contexts, but perhaps not in algebraic ones. Finally, to first grade students, graphing and arithmetic with fractions are highly associated with success in word problem solving, while for second graders it is arithmetic that becomes decisive for successful word problem solving.

THE IMPACT OF COMPUTER SIMULATIONS ON LEARNERS' IDEAS ABOUT SAMPLING

Karoline Smucker
The Ohio State University
smucker.37@buckeyemail.osu.edu

This report presents preliminary results from the initial survey and task within an ongoing design study investigating preservice elementary teachers' approaches to sampling. Nineteen preservice teachers enrolled in an elementary mathematics methods course completed an initial survey involving tasks related to sampling and inference, followed by a series of designed activities using computer simulations as a tool for inquiry of these concepts. Of interest were the preservice teachers' initial ideas, and how exposure to the simulations may have impacted their approaches. Initial analysis of the surveys suggests that participants' ideas about sampling showed similarities to research involving K-12 students. Their work during the first task suggests that computer simulations may help learners make more reasonable predictions within sampling contexts, along with providing a way to quantify the likelihood of those predictions.

Keywords: Data Analysis and Statistics, Probability, Instructional Activities and Practices, Technology

Topics related to sampling and sample size in the context of making conclusions or inferences are important for K-12 students and contribute to the development of statistical literacy (i.e., Pfannkuch et al., 2015; Shaughnessy & Ciancetta, 2002; Watson, 2006). Research indicates that students have strongly held misconceptions about sampling, sampling distributions, and sample size prior to any instruction which may be difficult to overcome even with instruction (Fischbein & Schnarch, 1997). Students may believe that "anything is possible" when sampling (Watson, 2006), have inaccurate models of sample space and variation (English & Watson, 2016; Noll & Shaughnessy, 2012), and struggle to differentiate between the distribution of a single sample and its sampling distribution (Saldanha & Thompson, 2014). Research also suggests that teachers' approaches to stochastic tasks may be similar to those of K-12 students (Leavy, 2010; Lovett & Lee, 2017).

Recent research in both K-12 and at the undergraduate level has also emphasized simulation within statistics and probability instruction (Garfield et al., 2015; Pfannkuch et al., 2015; Watson & Chance, 2012). These tools give students the opportunity to manipulate variables like sample size, observing the effects of these manipulations dynamically and making connections between various graphical representations (Pfannkuch & Budgett, 2016; van Dijke-Droogers et al., 2020). However, research suggests that students may not engage productively with these kinds of simulations without guidance (i.e. Lane & Peres, 2006; de Jong & Van Hoolingen, 1998). Students may change variables at random or change several variables at once, making it difficult to formulate and test hypotheses. In addition, more open investigations may not prompt students to confront their current ideas and common misconceptions. Instead, a more systematic/guided approach to inquiry with simulations is proposed.

In this research, preservice elementary teachers' approaches were investigated through implementation of a task which involved sampling from a bag of marbles. The following questions guided the inquiry: How do preservice teachers approach tasks related to sampling and inference, and what shifts occur in preservice teachers' thinking related to these concepts in the presence of designed computer simulations?

Theoretical/conceptual framework

This research is concerned with understanding how humans' approaches to probabilistic and stochastic tasks may be impacted as the result of engagement with a computer simulation which allows for dynamic sampling and the adjustment of variables like sample size. This aligns closely with the premises of sociocultural theory of learning developed by Vygotsky (1987) which emphasizes the important role that tools and interactions play in mediating learning; these tools include both physical and virtual manipulatives, along with language (Kazak et al., 2015a). Simulations in particular have the ability to allow students to confront the extent to which their initial probabilistic intuitions are accurate through implementing trials of a particular scenario (Kazak et al., 2015b). There has been extensive research on the ways that intuitions about chance concepts can lead to faulty conclusions, especially when contexts involve sample space and sample size (i.e. Fischbein, 2002; Fischbein & Schnarch, 1997; Kapon et al., 2015). These misconceptions can be deeply held. Lane and Peres (2006) suggest the importance of making hypotheses and predictions as a route to confronting initial conceptions in probability and statistics. As such, simulations can be a platform for testing predictions efficiently. They can provide an avenue to help students confront these ideas through the use of both physical manipulatives and technology, which can also provide dynamic visual representations to emphasize important probabilistic and stochastic concepts.

Methods

This study investigates participants' initial approaches to sampling and inference and how these approaches may be impacted by exposure to computer simulations using principles of design research (Cobb et al., 2003). These studies are interventionist, and often theorize sequences of tasks in order to examine the learning of a group or individual. Researchers engage in an iterative process of theorizing about the impact of an intervention, followed by refining/adjusting their hypotheses after implementation. Analysis is ongoing throughout a design study; researchers use what occurs to inform their next steps and refine/test their ideas, while also engaging in more in-depth retrospective analysis after the study is complete.

Nineteen preservice elementary teachers enrolled in a mathematics methods course during Spring 2021 at a large university in a Midwestern state completed an initial survey which involved tasks related to sampling, inference, and stochastic modeling. This survey was followed by three investigations involving computer simulations using the Common Online Data Analysis Platform (CODAP, www.codap.concord.org) related to these concepts. In addition, the participants completed focused reflections (either written or video via Flipgrid) after each task. Students submitted their work on both the survey and tasks virtually, including written documents and screen shots at various stages, along with their reflections.

This paper focuses on preliminary analysis of one item from the initial survey, along with the first designed task, both of which considered what would happen when 10 marbles are drawn without replacement from a bag containing 50 red, 30 blue, and 20 yellow marbles. Of interest were their responses for (1) Expected number of blues, (2) How likely they would consider a draw of 3 blue marbles (less than 50%, greater than 50%, or around 50%), and (3) What number of blue marbles they would find to be "surprising" in their draw. Theoretically, using the hypergeometric distribution, there is a 95% probability of drawing between 1 and 5 blue marbles, with a most likely outcome of obtaining exactly 3 blue (28%).

Analysis involved coding participants' responses before and after engaging with the simulation to the three questions highlighted above, looking for patterns in terms of both their initial responses/justifications and changes in response/justification after working with the simulation. In particular, researchers wondered to what extent patterns suggested by prior research with K-12 students in sampling contexts (i.e. Saldanha & Thompson, 2014; Noll & Shaughnessy, 2012; Watson, 2006) would be evident before and after the computer simulation. Moments when participants changed a prediction based on simulation results or connected their ideas to a theoretical model were also noted as potentially significant (Lane & Peres, 2006; English & Watson, 2016).

Preliminary Results

Survey results

On the survey, while a majority (74%) of respondents noted that they expected 3 blue marbles to be drawn out of 10, their ranges for what they would be "surprised" by varied and were at times at odds with their initial predictions. For example, one student predicted 3 blue marbles while also stating that she would be "surprised" by a draw of 3 blues later on. Over half (63%) provided ranges skewed above or below their expected outcome, often leading to fairly narrow intervals. This tendency to skew predictions either above or below the expected value and propose extremely wide or narrow intervals has been noted by researchers when working with K-12 students (Noll & Shaughnessy, 2012). In this case, the predictions tended to skew below the expected value (3); several students mentioned the large number of reds in the bag (50/100) as the reason why they would be surprised to get even 4 blues.

Ten students suggested that they believed the probability of obtaining 3 blues would be less than 50%, but their reasons for this belief varied. A common reasoning was that the probability would be close to 30% because 30/100 of the marbles in the bag were blue; other research has noted that students may struggle to differentiate between the distribution of an individual sample and the sampling distribution of all possible samples (Saldanha & Thompson, 2014). Only one student reasoned that obtaining 3 blues would have less than 50% likelihood because of how many other possibilities could occur (any number of blue other than 3). Four students suggested that the probability of obtaining 3 blues was actually greater than 50%; these students seemed to expect the theoretical breakdown of 3 blues, 5 reds, and 2 yellows would almost always occur, another characteristic of students' conceptions of sampling that was noted by Shaughnessy and Ciancetta (2002). The remaining students believed that the likelihood was around 50%, giving a variety of reasons. For example, one student suggested that she believed it was 50/50 because it was impossible to know whether you get the exact probability of anything, echoing the "anything is possible" notion of probability which has been found in research with K-12 students (Watson, 2006). Several responses mentioned not being sure why they made the choice they did or stated that they based their response on a feeling, emphasizing the role that intuition plays in student approaches to tasks involving chance (Fischbein, 2002).

Designed Task

A task with similar questions to the survey was implemented alongside a computer simulation designed using CODAP. The investigation allowed students to simulate draws of 10 marbles from a virtual bag of 100 marbles and observe how many of each color were selected, displaying their results with a dot plot representing how many of a certain color were obtained.

Students were prompted to run increasing numbers of trials (8, then 50, then 150) and observe how many blues were drawn.

Several student responses suggest that the computer simulation may have impacted their thinking about the likelihood of getting various combinations of marbles from a sample of 10, leading to more reasonable predictions for what may occur when compared to the theoretical probabilities. In general, their prediction intervals became wider and more symmetric. While on the initial survey it was common for respondents to provide intervals either ranging above or below their prediction of 3 blues, during the activity all responses were either symmetric (i.e. 1-5) or nearly symmetric (i.e. 1-4), and were often justified by what occurred during the simulation. One student who on the survey stated she would be surprised by any number of blues above 2 predicted a range of 0-6 blues within the activity. Another student used the simulation results to provide the empirical probabilities of each number of blues to justify why she would not be surprised to get anywhere from 1-5 blues. This student had considered 0-3 blues as reasonable on the initial survey, focusing on the large number of reds and yellows in the bag to justify her response. The simulation appeared to not only lead to more reasonable predictions, but also provided another way for the student to justify her conclusions.

The tendency to conflate the proportion of blues in the bag with the probability of drawing that number of blues was less evident in the activity responses (only one response indicated this reasoning), with most students justifying their thinking about the likelihood of drawing 3 blues using their simulation results. For example, one student obtained 3 blues in 17/50 trials (34%), and used this evidence (along with the large number of trials with 2 and 4 blues) to convince herself that her original prediction of more than 50% likelihood was probably incorrect. However, it is unclear whether the activity prompted students to truly confront the difference between the proportion of blues in the bag and the probability of drawing 3 blues. In addition, while researchers had hypothesized that some participants might consider how they could model/determine the likelihood of drawing 3 blues without a simulation after seeing the simulation results (for example using sample space), responses did not show evidence of this.

Discussion/Limitations/Next Steps

This paper provides initial analysis of one survey item and task within a larger study of preservice teachers' ideas related to sampling and inference, and how their approaches to these concepts may change in the presence of designed activities involving computer simulations. While these conclusions are certainly limited by the preliminary nature of this work, analysis suggests that preservice teachers showcase many of the same initial ideas of sampling in chance contexts as K-12 students. Most participants recognized the relationship between the proportion of blue marbles in the bag and what they would expect from a sample, but participants also predicted ranges which were skewed below the expected value and seemed to equate the distribution of a single sample with the sampling distribution. Within the designed task, the participants confronted some of these ideas after simulating the marble bag. Their prediction ranges became more reasonable, and the simulation also provided an opportunity for quantifying likelihood using the empirical results in a way that was not evident prior to exposure to the simulation. While the simulation did provide a way for participants to quantify the chance of drawing 3 blues, it did not appear to lead to insights on how they might determine the likelihood without the simulation. It was also unclear whether the simulation allowed participants to truly distinguish between the proportion of blues in the bag and the chance of drawing that proportion of blues. More research is needed to investigate these ideas further, and also to consider how exposure to designed computer simulations might impact approaches to sampling in other/future contexts. Analysis of the two additional simulation tasks in the larger study, along with future iterations of implementation of the Marble Bag Task, may provide insight on these questions.

We investigate the algebraic discourse of secondary mathematics teachers with respect to the topic of equation solving by analyzing five teachers' responses to open-ended items on a questionnaire that asks respondents to analyze hypothetical student work related to equation solving and explain related concepts. We use tools from commognitive analysis to describe features of teachers' explanations, and we use these survey responses as examples to illustrate a distinction in discourses about equation solving that has implications for students' learning of common procedures for finding solution sets of equations and systems.

Keywords: Algebra and Algebraic Thinking, Classroom Discourse, Reasoning and Proof

The Common Core State Standards suggest that students should come to view equation solving as a form of inquiry whose goal is to identify all solutions of an equation, and learn that steps in an equation-solving process represent successive deductions about a hypothesized solution (6.EE.5, A-REI.1, NGA & CCSSO, 2010). However, discourse about equation solving in algebra courses does not always capture this sense of discovery and deduction (Patterson & Farmer, 2018). In this report we investigate inservice teacher thinking about solving equations with respect to its treatment of mathematical objects, symbols, and routines and explore implications for classroom discourse and opportunities for students' algebraic reasoning.

Theoretical Framework

In describing discourse about equation solving, we mark a distinction between an *extractive discourse* and an *inferential discourse* for solving equations. In the extractive discourse, one describes an equation-solving routine as a sequence of actions on mathematical symbols. In the inferential discourse, one describes an equation-solving routine as using properties of numbers and relations to generate a sequence of endorsed narratives (or inferences) about a hypothesized solution to an equation or system. The routine as a whole produces a conditional: "If the original equation [or system] is true, then the value of the variable must be …" One defining distinction between extractive and inferential discourses is that extractive discourse contains more lexical markers of human agency in the equation-solving process, such as "I moved the $2x$ to the other side" or "you need to set both factors equal to zero." This is consistent with extractive discourse as primarily focused on actions on mediators ("moved", "set", "plugging") and is an example of *personalization* in mathematical discourse (Ben-Yehuda, Lavy, Linchevski, & Sfard, 2005).

Our focus on the concepts of extractive and inferential discourse is rooted in the work of Sfard (2016) who described *ritualized* and *explorative* participation in mathematical discourse. Ritualized discourse is defined as a "discourse-for-others" (Sfard, 2006) in which learners talk about mathematics according to the goals and motivations of others, without clearly identifying mathematical objects (such as numbers, functions, or solutions) as objects of the discourse. By contrast, in explorative discourse, participants strive to know more about mathematical objects and are not constrained to reasoning moves and routines set by others. Literature from the commognitive perspective indicates that explorative participation in mathematical discourse entails meaning for the objects of the discourse that may not be accessible to learners engaged in ritualized participation (e.g., Ben-Yehuda et al., 2005). We hypothesize that developing an inferential discourse for equation solving entails developing three mathematical meanings (Thompson, 2013): (1) to solve an equation is to find value(s) of the variable(s) that make the equation true; (2) we can assume that the variable(s) have value(s) that make the equation true, and each step in the process asserts that an equality is true provided that the previous equality is true; and (3) the converses of the conditional statements generated in this process may or may not be true, depending on whether the functions applied to both sides are invertible.

As part of a larger study (NSF Award #1908825), we use these ways of thinking about teacher mathematical discourse to investigate the question: *What language do middle and high school mathematics teachers use to describe and explain routines commonly used in algebra?*

Method

A 13-item survey on algebra concepts was administered to five teachers. This report focuses on responses to two items on procedures for solving equations (Table 1). The participants are teachers in an urban school district in the southern United States. Diann, Felicia, and Teodora are high school teachers, while Vanessa and Tanya are middle school teachers. All teachers were teaching at least one Algebra 1 class at the time they completed the survey. We analyzed each teacher's responses, noting how their uses of words and mediators, endorsements of narratives, and descriptions of routines aligned with extractive or inferential discourses for equation solving.

Table 1: Two Items in the Solving Equations Strand

Description / Questions Asked (Separate cells indicate separate pages)
Meaning of Solve: "What does it mean to *solve an equation*?"
[A correct solution of the equation $13 + 3x = 48 - 4x$ is provided.] "Thinking about this problem-solving process as a whole – without analyzing each individual step – why does this process produce a number ($x = 5$) that is a solution to the original equation given?"
Special Systems of Linear Equations [A correct solution of the inconsistent system of equations $\{15x + 3y = 33;\ 5x + y = 14\}$ using the substitution $y = 14 - 5x$ is provided. The hypothetical student obtains the equation "42 = 33" and writes, "This is never true, so the system has no solutions."] In the work above, is the equation $15x + 3(14 - 5x) = 33$ a true statement? Why or why not? The student then simplifies the equation $15x + 3(14 - 5x) = 33$ to obtain the equation $42 = 33$. Is this new equation a true statement? Why or why not? Does the reasoning shown here support the conclusion that the system has no solutions? If so, explain why. If not, explain what is wrong with the reasoning shown.
[A solution of the dependent system of equations $\{4x - 12y = 28;\ x - 3y = 7\}$ using the substitution $x = 3y + 7$ is provided. The hypothetical student obtains the equation "28 = 28" and writes, "This is true for all numbers x and y, so <u>all</u> ordered pairs (x, y) are solutions."] Does the reasoning shown here support the conclusion that all ordered pairs (x, y) are solutions to the system? If so, explain why. If not, explain what is wrong with the reasoning shown.

Results and Analysis

In our analysis we describe teachers' responses to the three items in Table 1, whose names we abbreviate *Meaning* and *Systems*. Our goal is not to characterize any one participant's discourse for equation solving as particularly extractive or inferential; we found that each teacher's responses contained elements of both, often within the same response.

Discourse About the Meaning of "Solve" and the Equation-Solving Process

Each teacher's response to the first page of *Meaning* suggested that solving an equation involves finding a value (or all values) of the variable that make the equation true. Responses differed with respect to the importance of finding all solutions of an equation: Felicia said, "Solving an equation is usually finding the value(s) of a variable that makes that equation true," while Teodora said, "Solving an equation means finding a value of x, that when substituted, will make the left side of the equation equal to the right." We do not consider this distinction as having any bearing on the extractive-inferential distinction. However, we also note that while Felicia describes solutions as "the value(s) of a variable that makes that equation true," suggesting independence from the actions of the solver, Teodora's description is suggestive of the process of substituting a value for the variable to verify that it is a solution. We therefore characterize Felicia's response to this question as closer to the inferential end of the spectrum because it describes the idea of solution in a manner independent of human action.

On the second page, Tanya's and Teodora's responses only verified that 5 is a solution of the original equation. By contrast, Diann and Felicia addressed the equation-solving process directly. Diann said, "By performing the inverse operations on both sides of the equation, you are reversing the operations on the $x = 5$ that ended with that result." This response focuses on performing appropriate actions on the "sides of the equation" based on the structure of each side; the word "reversing" may refer to the order in which these actions should be taken. This focus on actions on signifiers points toward extractive discourse. Felicia responded, "There is an assumption that both sides are equal and basically the whole process is manipulating things while keeping that equality until the x is isolated." This response also contains markers of extractive discourse ("manipulating things," identifying the step when the mediator x is "isolated" as a termination condition for the routine), but also stipulates the assumption that the two sides are equal and states that equality should be preserved at each step, which points toward inferential discourse. Both discourses have benefits to offer: the inferential discourse focuses on the equality of values of the expressions at each step, while the extractive discourse highlights strategic knowledge that would help a person reduce the equation to a simpler form.

Shedding Light on Special Cases: Discourse About Linear Systems

The item *Systems* asks respondents to address implications that occur in the process of solving a "special" system of two linear equations in two variables. The first question on the first page asks whether the equation $15x + 3(14 – 5x) = 33$, resulting from a correct substitution, is a true statement. The next question then asks whether the equation $42 = 33$, a correct simplification of the prior equation, is a true statement. From an inferential perspective, the equation $15x + 3(14 – 5x) = 33$ is true under the assumption that (x, y) is a solution, and the fact that this statement implies the false statement $42 = 33$, yielding a contradiction, shows that our original assumption (that there is a solution) must be false. We analyzed how teachers dealt with the apparent contradiction in saying that the equation $15x + 3(14 – 5x) = 33$ is true but $42 = 33$ is false.

Teodora considered the first question from a global perspective: "No, it is not a true statement. When solving, we are looking for a value that will make it true. The student finds that solution does not exist and therefore the statement will never be true." This points toward inferential discourse: because the truth of the equation $15x + 3(14 – 5x) = 33$ (along with the truth of the equation $y = 14 – 5x$, not mentioned in the response) would imply the existence of a solution, and we know that no solution exists, it is not possible for the equation to be true. On the other hand, Tanya, Diann, and Felicia all responded that this equation was true. Tanya said, "Yes, this used substitution. Substitution is one method for solving a system of equations." This response endorses the narrative $15x + 3(14 - 5x) = 33$ based on the use of a standard routine without reference to properties of numbers and relations, and thus we view it as an example of extractive discourse. Diann's and Felicia's responses were both suggestive of taking the truth of the original equation $5x + y = 14$ or the equivalent $y = 14 - 5x$ as a premise; Diann said, "From the above line if $y = 14 - 5x$ then y is equal to $14 - 5x$ so they can be replaced to represent the same value. It did not change the value of the equation since they were equal before the substitution." While this response contains some references to actions on symbols ("replaced"), it also grounds its argument in narratives about the equality of numbers based on the assumption that an original equation is true, which we expect to find in inferential discourse.

Asked about the truth of $42 = 33$, Diann responded, "The simplification was correct. After distributing the 3, the terms with x will cancel out to zero. The new equation $42 = 33$ is not a true statement because those two numbers are not equal or the same." Felicia said, "The new equation is not a true statement, $42 \neq 33$." We wondered how each teacher viewed the conclusion that the system has no solutions. Diann said simply, "The reasoning is correct, this system has not [*sic*] solution. There is no coordinate pair (x, y) that will make the equations true." Felicia said, "The reasoning is that there is no value of x that will give us a true statement, therefore no solution to the system." While we cannot be certain what Felicia meant by "true statement," the fact that she identified the statement $42 = 33$ as untrue suggests that she understands that no value of x will avoid this contradiction and concludes that no value of x (and y) can solve the system.

Discussion

We view extractive and inferential discourses as complementary ways of communicating about processes for solving equations. While the extractive discourse provides access to language and narratives that help solve equations mechanically and fluently, the inferential discourse offers a conceptual microscope under which learners can examine unexpected wrinkles in solution processes. Developing an inferential discourse for equation solving may unlock opportunities for productive struggle in students' learning of algebra, because this discourse allows learners to examine novel features of equation-solving processes based on foundational principles rather than uncritically memorizing routines for classes of problems. Investigating teachers' discourse about equation solving is an important first step in this work because their discourse can afford or constrain students' opportunities for conceptual thinking.

Our analysis is based on teachers' untimed responses to survey questions. Because teachers understood that they were explaining concepts for researchers and not for their own students, we cannot claim these survey responses as a model for explanations that teachers might give in the algebra classroom, where timing, assessment of students' needs, and curricular context might influence decisions about discourse. However, the variety of responses to the two items in this report is evidence of the diversity of explanations available to teachers when they encounter an opportunity for conceptual development. While teachers may not have access to all of these explanations depending on their knowledge and prior experience, we anticipate that through collaboration and professional development teachers may gain access to a greater range of discursive tools for helping students build conceptual understanding of algebraic procedures.

Isomorphism and homomorphism are important concepts in introductory abstract algebra courses (Melhuish, 2015). Notice that the term "isomorphism" can be taken two ways; it can refer to the property of being isomorphic (i.e., bearing a particular equivalence relation), or it can refer to the function—a particular kind of homomorphism—that witnesses this property. We use the term "isomorphism property" to refer to the former, and "isomorphism function" to refer to the latter. Observe that the concept of homomorphism does not have the property-function duality that isomorphism has—there is no meaningful sense in which two groups (rings, fields) are "homomorphic". While Melhuish (2015) describes the ways that textbooks informally describe the concept of isomorphism, she does not differentiate between the isomorphism property and the isomorphism function. Accordingly, we address the following question: how do textbooks informally describe the isomorphism function, the isomorphic property, and the homomorphism function?

We analyzed the same textbooks as Melhuish (2015) did, namely, those identified as the four most commonly-used introductory abstract algebra texts: Fraleigh (2003), Gallian (2009), Gilbert and Gilbert (2009), and Hungerford (2012). We examined each text's "isomorphism" and "homomorphism" sections to search for examples of informal descriptions of isomorphism. Additionally, we used optimal character recognition (OCR) to examine each place in which the texts included the strings "iso" and "homo". We also examined instances of what Melhuish (2015) calls an *Example Motivating a Definition (EMD).*

Every portion of text quoted by Melhuish (2015) to describe textbooks' usage of informal ideas of "isomorphism" is limited to the isomorphism property. In each text, the informal description appeals to the general notion of sameness. There are two senses in which textbooks have informal counterparts to the isomorphism function. The first uses informal language to describe attributes of the isomorphism function such as "preserve the operation". Since this language describes the homomorphism property, we identify it as an informal description of homomorphism functions. Such informal language occurs in the Gallian and Gilbert & Gilbert texts, whereas Fraleigh uses "structure relating map" to describe the homomorphism function. The second sense uses informal language to describe a function itself (rather than using the word "function"). We call this the *correspondence sense* of the isomorphism function. It occurs prominently in the Fraleigh and Hungerford texts in the context of EMDs involving tables, in the same block of text as the quotes highlighted by Melhuish (2015). The correspondence sense involves an alignment of elements ("relabeling") between structures in order to prove that they are isomorphic. Interestingly, both the Fraleigh and the Hungerford texts use this notion of correspondence as a way to demonstrate the informal counterpart of the isomorphism property (one must see the relabeling in order to see that the structures are isomorphic). Our future work will further examine how textbooks position the relationship between the isomorphism function and the isomorphism property.

STRUCTURAL CONVENTIONS FOR EQUATIONS IN MIDDLE SCHOOL MATHEMATICS TEXTBOOKS

Chelsea Dickson
Brigham Young University
anderb.toler@gmail.com

Daniel K. Siebert

dsiebert@mathed.byu.edu

Keywords: Algebra and Algebraic Thinking, Middle School Education

An important topic in the teaching and learning of algebra is *expressions and equations* (NGA & CCSSO, 2010). While the literature has addressed student's difficulties in reasoning about the equal sign and making sense of equations (Kieran, 1981; Knuth et al., 2005; Matz, 1982; Prediger, 2010), less attention has been given to the way that equations are organized in solutions to show and justify the symbolic manipulations that lead to the answer. We refer to the norms associated with organizing related equations in a solution as structural conventions for equations. As students progress through middle school mathematics topics, equations play an increasingly central role in nearly all topics. However, little empirical research has been done to document the types of structural convections students must learn as they work with equations in middle school mathematics.

In this study, we examined the structural conventions for equations in two series of 7th and 8th grade mathematics textbooks: *Connected Math 3* Grades 7-8 (CMP3, Lappan et al., 2014) and *Eureka Math* Grades 7-8 (*Eureka Math*, 2015). According to a recent RAND report (Opfer et al., 2016), both of these textbooks are widely used and highly aligned with the Common Core State Standards for Mathematics (NGA & CCSSO, 2010). Equations were coded for equation type and structural conventions. Interrater reliability was 88% for CMP3 and 93% for Eureka Math. Over 90% of the data was coded by both authors, with the remaining 10% coded by the first author.

The two main types of structural conventions for equations in these textbooks were *lists of equations* (LOEs) and *strings of equalities* (SOEs). We defined LOEs as equations listed sequentially (either vertically or horizontally) without any text between them. LOEs were common in all of the sections we sampled from each textbook. We found that the equations in an LOE were often linked explicitly or implicitly by equation operations (Eos) that were performed on previous equations and reported in subsequent ones. We identified six different types of Eos, with reductions and deductions (Matz, 1982) being the most common. To successfully make sense of LOEs, students need to compare each equation with the equation that preceded it to identify the EO that links them. However, we found that some LOEs were written in a way that it was not possible to tell which Eos had been used to link equations. Other LOEs listed equations that were not related by Eos, and thus could be confusing to students.

We defined SOEs as lists of expressions linked by equal signs. SOEs were also common across the sections we sampled from the four textbooks. SOEs ranged from 3 to 8 expressions linked with equal signs. We noted that SOEs presented particular challenges for students, because they often involved different equation types and meanings for the equal sign in the same string of equalities.

Interestingly, neither curricula contained explicit discussions about structural conventions for norms, nor suggested instructional strategies for helping students learn structural conventions. Given the variety of equations types and equal sign meanings in LOEs and SOEs, an implication of our study is that students would benefit greatly from instruction that identifies structural conventions and explicitly models appropriate ways of reasoning about LOEs and SOEs.

USING MULTIPLE STRATEGIES TO SOLVE ALGEBRA AND ARITHMETIC PROBLEMS

Soobin Jeon

Knowing multiple strategies and being able to apply them adaptively to various situations, which is also known as flexibility, links to higher academic achievement and can increase transfer across many problem-solving domains (Hiebert & Carpenter, 1992). This study explores high school students' use of standard and better-than-standard strategies when solving problems, with a particular focus on whether strategy differences exist between students' work on arithmetic and algebra problems.

A question of interest is whether students' strategy usage is influenced by the use of a particular task that has been commonly incorporated into prior research on mathematical flexibility (Star & Rittle-Johnson, 2008; Star & Seifert, 2006; Xu et al., 2017). In the present study, 450 high school students in the United States engage in the task of solving five arithmetic and algebra problems and then re-solving the same problems, after being instructed to use a different strategy. Our research questions are: (1) To what extent do students rely upon standard and better-than-standard strategies? (2) Are students' strategy repertoires influenced by whether the attempted problems are arithmetic or algebra problems? (3) Are strategy repertoires influenced by whether the problems are being solved for the first time or being resolved?

Results show that students relied much more upon the standard strategy on the first attempt and more upon the better-than-standard strategy on the second attempt. This raises the possibility that asking students to re-solve pushed them to consider strategies other than the standard and generate better strategies. We also see that students' strategy repertoires were influenced by whether the problems were arithmetic or algebraic, and by whether the problems were being solved for the first time or being resolved. In particular, there seemed to be higher preference to use the standard strategy on algebra problems than on arithmetic.

Table 1: Percentage of strategies used on attempted problems

	First Attempt			Second Attempt		
Strategies	All	Arithmetic	Algebra	All	Arithmetic	Algebra
Better	19%	28%	5%	32%	32%	32%
Standard	62%	44%	88%	23%	19%	29%

MAKING SENSE OF NON-INTEGER EXPONENTS USING A NUMBER LINE MODEL

One area of difficulty for students when reasoning about exponential expressions is correctly manipulating and making sense of exponents (Berezovski, 2004; Cangelosi, et al., 2013; Gol Tabaghi, 2007). Common curricular approaches develop the idea of an exponent as the number of times a number is multiplied by itself (Ellis et al., 2015). However, a central limitation of this “number of factors” meaning for exponents is an inability to make sense of non-integer exponents. While progress has been made in addressing this concern through the expansion of approaches to developing meaning for exponents (Thompson, 2008; Ellis et al., 2015; Kuper and Carlson, 2020), questions remain about how to engender scaling-continuous covariational reasoning (Ellis et al., 2020) to supports students in calculating non-integer exponents. While in scaling-continuous covariation students think about change as it happens over an interval of a fixed size, they can also continuously resize the intervals, a process called zooming. We argue that exponentially scaled number lines can support students in applying scaling-continuous covariational reasoning about non-integer exponents.

An exponentially scaled number line is a number line where same-sized segments of the line represent an increase by the same multiplicative factor. For example, if students were asked to model the growth of bacteria whose amount triples each hour, students might create equally spaced tick marks on a number line labeled 1, 3, 9, etc., on one side of the number line to represent the number of bacteria and 0, 1, 2, etc., on the other side to represent the elapsed time. With support, students could eventually come to realize any same-sized segments of the line represent an increase by the same multiplicative factor of the bacteria. They could also come to realize that on one side of the number line there are exponents, while on the other there are the corresponding powers of three. Students could then make sense of expressions such as $3^{1/2}$ by leveraging the idea that this represents the number of bacteria after half of an hour and will be represented on the number line by a segment that is half as long as the whole hour segment. They could then reason that over the two half-hour segments the number of bacteria grew by the same factor, which means they need the number that when multiplied by itself gives 3, namely $\sqrt{3}$.

We see this model as productive because we believe that it fosters scaling-continuous reasoning. An exponential number line is consistent with representing growth that is continuous and is also consistent with resizing chunks continuously. As students use the number line to explore values between their chunks they will need to reason simultaneously with the change in time and the change in the number of bacteria. Analogous to the linear reasoning behind positioning day 0.5 at the midpoint between of hour 0 and hour 1, the multiplicative reasoning of the number line directs students to find a multiplicative value for a half hour period growth such that two half hour growths results in a one hour growth. This process can then be repeated and the same reasoning applied for successively smaller segments of a growth. We believe this allows for both zooming in on the number line and a continuous image of the exponential function, vis-à-vis the number line, to emerge.

THE MULTIPLICATIVE REASONING OF A HIGH SCHOOL SENIOR

Shaver, N. F.
University of Cincinnati
shavernf@mail.uc.edu

Dejarnette, A. F.
University of Cincinnati
dejarnaa@ucmail.uc.edu

Keywords: cognition, high school education

Multiplicative reasoning (MR) is essential for understanding elementary and secondary math concepts. MR can be measured by how a student conceptualizes and utilizes groups of numbers in multiplicative situations defined by how many groups of numbers they can coordinate simultaneously known as their level of unit coordination (Hackenberg, 2010; Steffe, 1992; Ulrich & Wilkins, 2017). Studies have found that students who have not fully developed MR as measured by their unit coordination struggle to understand improper fractions (Hackenberg, 2007) and linear equations (Zwanch, 2019). MR has been measured for students in the 1st through 4th grades (Askew et al., 2019; Kosko & Singh, 2018a; Mulligan & Mitchelmore, 1997; Smith & Smith, 2006; Steffe, 2002) and 5th through 6th grades (Brickwedde, 2011; Hackenberg, 2007; Kosko, 2019; Norton et al., 2015; Ulrich & Wilkins, 2017; Zwanch, 2019), however, the MR of high school students is currently understudied.

Our question for this research project is: What is the MR of a high school senior struggling with high school math? To answer this question, we focus on a high school senior (Sunil, pseudonym) who was selected based on their poor performance on a pre-assessment. We followed up with a written based MR assessment (Ulrich & Wilkins, 2017) that measured his unit coordination and then follow up with a diagnostic interview which gave evidence of not having fully developed MR.

On the written based MR assessment, Sunil struggled to accurately estimate the size of partitions. This suggests that he was not able to mentally iterate the smaller piece accurately across the whole to determine the correct size. In the follow up interview when asked how he determined his answer, Sunil mentioned he counted the small spaces he drew on the smaller bar to determine the partition size. After asking him why, he mentioned he didn't know. Upon guided questioning, he determined that the smaller piece "fits into" the larger piece 4 times. On another interview task, Sunil was asked if he earned \$360 a week, how many weeks would he have to work to earn \$7,000. After considerable work, he determined 20 weeks by skip counting with \$360 to 20 weeks. When further asked for a more accurate answer using division, he was not able to use division to determine a different approach.

Although this sample of his reasoning is not complete, this research further illuminates Sunil's reasoning on other situations and includes a high school junior's reasoning. The overarching goal of this research is to highlight determining struggling students' MR as a pathway to build their reasoning through targeted instruction.

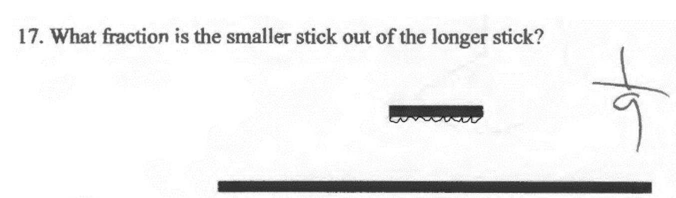

Figure 1: Written based evidence for not fully developing MR

One of the most important factors in teaching and learning mathematical concepts is connecting mathematics to our real-world experiences. As mathematics educators, we either start with a concept and then connect it to a phenomenon in the real world, or we model a real-world problem, then mathematize it to clarify the concepts and to deepen our students' understanding. Regardless of the instructional path, it is crucial to make these connections in consistent and coherent ways. Yet, in some instances, when it comes to academic mathematics vocabulary, we use terms and definitions in different ways in everyday language and in academic contexts. As a result, students who come from diverse linguistic and cultural backgrounds often find mathematics in their home language or culture disconnected from academic mathematics. One of the primary focuses of high school geometry includes geometric transformations (NCTM, 2018), and students spend a good amount of time exploring the concept of orientation. However, within the mathematics education research literature, the term orientation has two different definitions, and these definitions are not consistently used within mathematics education research and curriculum material.

1. Orientation as a shape's position with respect to the axis and the Cartesian System's origin, or any other points as the origin (Battista, 2007; Sinclair, Cirillo & De Villiers, 2017).
2. Orientation as the relative position of a shape's vertices to each other (Sinclair, et al., 2012).

While the first definition is the closest to the everyday use of the word and is most often discussed in mathematics education research, the second is the one that is often what we focus on in school mathematics, particularly as it connects to attributes of different transformations.

These inconsistent uses and definitions often cause confusion for students as their everyday experiences are not always coherent with academic experiences. In order to support each and every student, and particularly multilingual students, it becomes necessary to discuss strategies to leverage the role of language to support students in learning math while also engaging them in learning the language through math. Examples of strategies include the use of multiple representations and the use of dynamic software applications that can help students transfer mental images of concepts to visual interactive representations that can lead to more robust understandings and connections between language and mathematical concepts (Dick & Hollebrands, 2011). In general, to achieve equitable learning experiences for each and every student, as mathematics educators we need to leverage our students' linguistic and diverse cultural backgrounds as we support them in rich mathematical experiences.

REPRESENTATIONS AS TOOLS OR TASKS IN FUNCTIONS OF TWO VARIABLES

M. Kathleen Heid
Pennsylvania State University
mkh2@psu.edu

Matthew Black
Pennsylvania State University
mvb16@psu.edu

Keywords: Mathematical Representations, Advanced Mathematical Thinking

Access to mathematical objects occurs through their representations (Duval, 2017). Understanding students' understanding of mathematical objects is assisted by analysis of their interactions with representations of those objects. The concept of functions of two variables has grown in prominence and importance in today's technological world. Nevertheless, this concept is underdeveloped in school mathematics and is understudied in students who are prospective secondary mathematics teachers (PSMTs). This study examines PSMTs' understanding of functions of two variables by investigating how they deal with related one-variable functions.

Perspective

As Duval (2017) has pointed out, two inscriptions represent the same objects when there exists a one-to-one mapping of pieces of meaning between the features of the representations. Researchers have studied students' understanding of representations of functions of one variable (Even, 1998) but few studies (Martínez-Planell & Trigueros Gaisman, 2009, 2012; Weber & Thompson, 2014) have investigated of student understanding of two variables. The purpose of this research was to examine PSMTs' mapping of pieces of meaning (or features of the representation) within a representation and across representational registers.

Methods

PSMTs took part in task-based interviews in which they were given a symbolic rule for a function of two variables and asked to describe the corresponding graphical representation. The researchers analyzed video recordings of these interviews, using thematic analysis to identify patterns among the participants' work with representations. The researchers constructed descriptions of participants' actions and verbalizations, developed consensus on participants' use of representations, and, identifying patterns, characterized participants' use of representations.

Results

Our analysis of the data has led to features of our participants' work with representations.

Participants used representations as tasks lacking meaning or meaningfully as tools.

An instance of P6's work provides an example of using representations as tools. In her analysis of the graph of $g(x,y) = xy^3$, she compared the width of $g(x,y)$ for varying values of x, noting that as the value of x increased, the shape of $g(x,y)$ evolved from a downward sloping cubic function to a horizontal line to an upward sloping cubic function. This revealed her mental construction of the 3D graph. Another participant, P7, used representations as tasks, consistently following the procedures exactly as she had learned them and producing template conclusions.

Participants reacted differently after noticing conflicts among representations.

For example, when P1 isolated one feature of the graph of $g(x,y)$ (that inputs of 0 yield outputs of 0) that was not consistent with her reasoning about the graph slices being cubic. She resolved the dilemma by concluding that there must be a break in the graph. When P6 encountered the same aberration, she reasoned correctly that the cubic functions evolved into a flat line, which was followed by cubics of the opposite orientation.

STUDENTS' CONCEPTION OF CONFIDENCE INTERVALS: STATISTICAL LITERACY REFLECTED ON THE COVID-19 VACCINE MEDIA REPORTS

Joo young Park
Florida Institute of Technology
jpark@fit.edu

Due to the COVID-19 pandemic, the need for statistical thinking, ability to understand, interpret, and evaluate data from numerous media reports in decision-making has been increased. Such ability was defined as statistical literacy in the literature (e.g., Gal, 2002): "(a) ability to interpret and critically evaluate statistical information, data-related arguments, or stochastic phenomena, which they may encounter in diverse contexts, and when relevant (b) their ability to discuss or communicate their reactions to such statistical information" (pp. 2-3). Inarguably, statistical literacy entails conceptual understanding in statistics, which allows students to transfer knowledge to novel problems (e.g., Bude, Imbos, van de Wiel, & Berger, 2011), understand data (e.g., Garfield & Chance, 2000; Jones et al., 2011), interpret results (e.g., Gal & Garfield, 1997; Jones et al., 2011), and think critically (e.g., Garfield & Chance, 2000) (Crooks, Bartel, & Alibali, 2019). Learners' adaptation of their knowledge structures appeared to be often inaccurate in some contexts (Smith, diSessa, & Roschelle, 1994; Crooks, Bartel, & Alibali, 2019).

The purpose of this pilot study was to examine students' conception of Confidence Interval (CI) and identify student difficulties associated with Cis presented in media reports on the COVID-19 vaccines. Studies suggested that CI is one of the difficult concepts for students (e.g., Coulson, Healey, Fidler, & Cumming, 2010; Cumming, 2006, Henriques, 2016). The study's participants were fourteen graduate students in the STEM education program at a private research university in Southeastern State. The assessment consists of six questions, including open-ended items based on news media reports on the efficacy rates of COVID-19 vaccines presented with Cis, which the author created. The questions are based on the key concepts of CI: (a) understanding the definition of the term "confidence interval," (b) understanding the distinction between sample and population means and how they are related, (c) understanding the notion of confidence level (i.e., 90% vs. 95% CI), (d) understanding how various factors (e.g., sample size, sample variability) affect CI width, I understanding what can be inferred about future replications based on Cis, and (f) understanding how to interpret Cis accurately (Crooks, Bartel, & Alibali, 2019). Students were asked to complete the assessment and answer probing questions through individual interviews. Students' interpretations of Cis were coded by two independent raters using the conceptions and difficulties identified by the previous studies (Castro Sotos, Vanhoof, Van den Noortgate, & Onghena, 2007; Cumming & Maillardet, 2006; Fidler, 2006; Grant & Nathan, 2008; Greenland et al., 2016; Henriques, 2016). Findings highlight students' difficulties in interpreting confidence intervals displayed in graphic representations. The poster will present the assessment items and prevalent student conceptions probed by the items in the context of media reports on the COVID-19 Vaccines.

Rate of change is a core idea that cuts across secondary school and tertiary mathematics education. Prospective secondary school mathematics teachers re-encounter rate of change in a variety of undergraduate mathematics and science courses. Hohensee (2011) introduced the construct of *backward transfer* to capture how prior knowledge changes as new knowledge is built upon it. Rasmussen and Keene (2019) identified rate of change in differential equations as a concept ripe for backward transfer. However, simply re-encountering an idea in more advanced courses may not necessarily lead to any substantive enrichment in one's understanding of the idea. We conjecture that intentional instructional efforts are needed to realize the transformative potential of re-encountering an idea for enriching conceptual understanding of that idea. In this poster we take up this conjecture by analyzing the work of eight prospective secondary school teachers in an inquiry-oriented course in differential equations. Data includes students' end of semester portfolios and video-recorded oral presentations of those portfolios. The portfolio included seven self-selected entries that showcased their mathematical work and a rationale statement explaining the personal significance of each entry. The portfolio also asked for an eighth entry focused explicitly on all of the ways in which they now think about rate of change, with examples of their mathematical work from the semester. We used thematic analysis (Braun & Clarke, 2006) to collaboratively interpret and code the rate of change entries and presentations. Results revealed that students significantly enriched their understandings of *dy/dt* as a rate of change, as compared to the meanings they reported on a pre-semester survey. These new understandings of dy/dt include: a dynamic slope, a tool to know solutions, an operator that acts on other functions, and a function in and of itself. The poster presentation will provide illustrative examples of each of these expanded ways of understanding rate of change. We also discuss implications for the teaching of differential equations and other mathematics courses in order to deepen future secondary school teachers' understandings of core mathematical ideas.

Proportional reasoning problems can be solved using algebraic reasoning. Therefore, making connections between proportional reasoning and algebraic thinking is important for solving problems. This study examined K-8 teachers' problem-solving strategies as they worked out a real world multi-step problem that involved proportional reasoning and algebraic thinking. The findings revealed that many teachers found this problem challenging. Particularly, some teachers had difficulty figuring out how to translate the variables into an algebraic equation. Some teachers who used variables as labels tended to engage in additive reasoning. They had difficulty representing the proportional problem context algebraically and solving the problem for the unknown quantity. Implications for further research are discussed.

Keywords: Teacher Knowledge, Proportional Reasoning, Algebraic Thinking

Proportional reasoning and algebraic thinking are often taught independently of each other. Therefore, when encountering a real-world problem that involves proportional reasoning and algebraic thinking, students who only developed procedural knowledge find such problems difficult to solve. This is because teachers tend to focus on aspects of problems that require only procedural knowledge, with a singular solution, strategy, and representation (Glassmeyer & Edwards, 2015). Teachers need to develop a deep understanding of the interrelationship between the conceptual and procedural knowledge to support their students to engage in problem solving and reasoning (Ma, 1999; Rittle-Johnson, Siegler & Alibali, 2001). Researchers suggest that many teachers struggle with understanding proportional reasoning (Riley, 2010; Cohen, Templin & Labato, 2010; Weiland, Orrill, Brown & Nagar, 2019). Particularly, this is the case with distinguishing proportional and non-proportional situations. Furthermore, teachers tend to focus on additive reasoning as opposed to proportional reasoning. There is very little research on teacher knowledge on proportional reasoning (Weiland, Orrill, Brown & Nagar, 2019).

This study investigated teacher's ability to translate a proportional relationship into an algebraic equation. More specially, pre and post test data on how teachers solved a multi-step problem involving proportional reasoning and algebraic thinking after participating in content based professional development was analyzed.

This study focused on answering the following research questions:

1) Did the professional development improve in-service teachers' overall conceptual understanding involving proportional reasoning and algebraic thinking?
2) Did the professional development improve in-service teachers' conceptual understanding in algebraic thinking?

3) Did the professional development improve in-service teachers' conceptual understanding in proportional reasoning?

Proportional Reasoning

A proportional situation is one that has "structural relationships among four quantities, (say *a*, *b*, *c*, *d*) where there is a covariance of quantities and an invariance of ratios, where a ratio is a comparison of two quantities" (Weiland et al, 2019. P. 233). The components involved in reasoning with proportions are unitizing, rational numbers, ratio sense, partitioning, quantities and change, and relative thinking (Lamon, 1999). Uniting is a cognitive process that assigns a unit of measurement to a specific quantity (Lamon, 1996). The ability to form and operate within complex unit structures allows for higher ordered and flexible thinking. An example of uniting would be referring to an hour as 1 unit of 60 minutes or 2 units of 30 minutes, or 6 of 10 minutes, or 12 of 5 minutes depending on the context. Partitioning refers to the ability to break down a unit into equal parts (Lamon, 1999).

When proportions are represented in fraction notation (ie. $\frac{a}{b}, \frac{c}{d}$, not *a*:*b*, *c*:*d*), the information is structurally represented where it can be manipulated algebraically in any given calculation process. It is important to remember that all of the four quantities (*a, b, c, d*) can each be equal to one (1) in a given situation, which is simply the multiplicative identity property as a proportion. This models a transfer and flexibility of thinking which is necessary to manipulate the proportion. Critical thinking is foundational to proportional reasoning, as it involves abstracting then possibly manipulating that information (depends on the situation).

Proportional reasoning situations can also be represented algebraically. Representing proportional reasoning situations algebraically involves a flexible understanding of the meaning variables such as representing a category, a known value, an unknown value, or a changing value (Moss & Lamberg, 2019) to represent a problem situation. Representing proportional reasoning problems algebraically involves the ability to model real world situations which is considered a main objective of algebra (Izsak, 2003; Kaput, 1999; Schoenfeld, 1992).

Algebraic Reasoning

Algebraic thinking involves engaging in reasoning and sense making (Kaput and Blanton, 2005, Swafford and Langrall, 2000). It is the ability to model quantitative situations by being able to represent relationships quantitatively (Driscoll, 2001). According to Driscoll (2001), algebraic thinking involves developing habits of mind to think about quantitative relationships such as the ability to organize information by discovering patterns, relationships, and rules. As these 'habits' are listed as a structure of steps, in essence, this too then is a procedural skill. When this is practiced in order to become a habit, it becomes a behaviorist model with the incentive of possibly developing a conceptual understanding at any given point in this habitual practice. However, algebraic reasoning is a practice with the distributive, commutative, associative, and identity properties of addition and multiplication, and its abstracted symbolic representation is used to denote the calculations which deliver the final analysis and result.

The cognitive process in algebraic thinking includes encoding information, then retrieving and manipulating it to produce a final representation—a function in the brain also known as working memory (Gluck et al., 2016). Reasoning algebraically with known, unknown, and changing values is an evident example of the working memory function in the brain, and multi-step reasoning problems require unitizing and managing the transitions as they are modeled, which are then abstractly denoted symbolically (or vice versa). Algebraic reasoning models the various stages which demonstrate one's depth of knowledge—a conceptual understanding of the mathematics in any given situation.

Method

Twenty-three K-8 teachers participated in four-week content based professional development in a western state and the data presented here is from a larger study. A pre and post test was administered at the beginning and end of the week-long institute. The week-long institute focused on developing teachers' understanding of fractions and proportional reasoning content and pedagogical knowledge. The following problem was analyzed in this study.

> *Jeff had one-fourth as much money as Peggy. Ed had twice as much money as Peggy, they counted their money and then gave $20 to one of their friends. If they now have a total of $84, how much money did they initially have. Write an equation for this problem and solve it.*

The data was coded based on strategies that teachers used in three categories, *evolving, emerging* and *effective* in proportional reasoning and algebraic thinking, as illustrated in Figure 1.

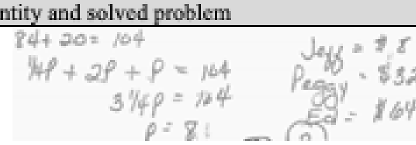
Score	Proportional Reasoning	Algebraic Thinking
1 *Evolving*	No Proportions, or no attempt	Variables used as labels, unable to model problem context problem and set up algebraic equation
		2 *Emerging*	Attempted to set up proportions, but has errors	Variable used to represent an unknown quantity and modeled problem but did not solve original problem
		3 *Effective*	Identified proper proportions correctly	Modeled problem using one variable as an unknown quantity and solved problem
		


Figure 1: Variables Rubric: Proportional Reasoning, Algebraic Thinking

In proportional reasoning, *effective* scores were able to identify the correct proportions. In this stage, participants were able to identify the unit (Peggy) creating a one-to-one relationship. They were also successful in demonstrating a correct ratio and partitioning understanding in forming the relationship between Jeff and Ed. For *emerging* scores, Peggy was correctly identified as the unit. However, for there was an incorrect partitioning or ratio relating Jeff or Ed to Peggy. For *evolving* scores, there was a lack of proportional understanding, in that there was

Olanoff, D., Johnson, K., & Spitzer, S. (2021). *Proceedings of the forty-third annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Philadelphia, PA.

no attempt to utilize a proportional relationship between Peggy, Jeff, or Ed. These strategies use a guess and check, and there was no clear demonstration of unitizing, partitioning or ratio concepts.

In algebraic thinking, *effective* scores were able to create an equation using one variable and correctly solve for all three values using algebraic properties of equality. For *emerging scores,* an equation was created using one variable, but was either not correctly solved or contained incorrect or missing proportions for either Jeff or Ed. For *evolving* scores an equation was used but contained multiple variables representing Peggy, Jeff and Ed or variables for Peggy, Jeff and Ed were identified but no equation was developed.

In full effect, an *effective* score in algebraic thinking includes correct referent units when presenting the solution. The presentation of referent units exhibits a thorough analysis and conceptual understanding of a problem, and demonstrate a focus on the unit that was manipulated in the problem. In this case a dollar symbol ($) was used to denote the referent unit in the rubric example. The role of referent units is for tracking information and changes between the known and unknown values.

A McNemar test (McNemar, 1947) was used to determine whether there was difference in proportion of participants classified as *non-effective (evolving & emerging)* and *effective* in both proportional reasoning algebraic thinking between the pre and post tests.

Results

The data revealed there was growth between the pre and post test in relation to teachers' ability to engage in proportional reasoning and algebraic thinking. In a paired t-test there was a significant difference in overall scores between the Pre ($M = 1.35$) and Post ($M=2.07$) scores, $p <.001$. This shows there was growth between the pre and post test (see Figures 2 & 3). This shows that overall, the professional development did have a positive impact on teachers' overall skill in a problem involving proportional reasoning and algebraic thinking.

The McNemar test (McNemar, 1947) revealed the following: In algebraic thinking the results were statistically significant *($p=.016$)* meaning there was a significant difference in the proportion of participants found to be *effective.* In proportional reasoning the results were statistically insignificant (*$p=.063$)* meaning that there was no significant difference in the proportion of participants considered to be *effective* in proportional reasoning between pre & post tests.

In an analysis of the pre and post tests, most teachers were able to set up the proportional reasoning aspect of the problem. However, they struggled modeling the problem algebraically using variables to solve the problem. More teachers initially struggled setting up an algebraic equation and solving the problem. While this was not the initial focus of this study, possible gaps of the teachers understanding in proportional reasoning are discussed.

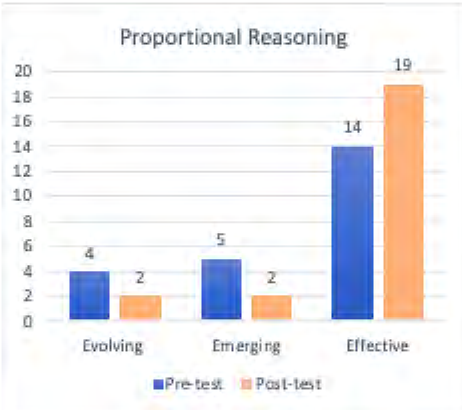

Figure 2: Proportional Reasoning Results

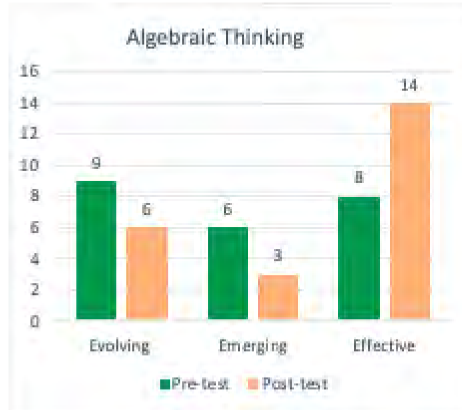

Figure 3: Algebraic Thinking Results

Discussion

The findings reveal that while there was improvement in the proportion of *effectiveness* in both proportional reasoning and algebraic thinking, the greatest gains and statistically significant results were in algebraic thinking. It was noted that some teachers initially struggled with proportional reasoning, and their ability to represent the multi-step proportional problem algebraically. These findings are consistent with other research findings that teachers struggle with conceptual understanding of proportional reasoning (Riley, 2010; Cohen, Templin & Labato, 2010; Weiland, Orrill, Brown & Nagar, 2019). The teachers that struggled with proportional reasoning were likely engaging in additive reasoning. Initially, many teachers had difficulty meaningfully modeling the proportional reasoning problem context using variables and equations. The ability to model and engage in algebraic reasoning is critical for understanding algebra (Izsak, 2003; Kaput, 1999; Schoenfeld, 1992). Algebraic reasoning involves being able to model the problem using expressions, equations, and variables. Specifically, it is helpful to distinguish between how variables are used such as labels or unknowns (Moss & Lamberg, 2019). Teachers who struggled with variables used them as labels to keep track of their thinking but were unable to set up an algebraic equation that involved proportional thinking. The post test results revealed that teachers became more proficient at solving a similar problem after they had engaged in professional development aimed at conceptual understanding of proportional reasoning and algebraic thinking.

More specifically, when setting up the initial proportions, teachers were able to effectively represent the proportions in one variable, which is foundational to the task to write an equation, and then solve it to answer the question. In further analysis, it was noted that all the participants in the *evolving* and *emerging categories* for algebraic thinking had a conceptual barrier in both unitizing and equality properties for proportional reasoning, whereby a one-to-one relationship allows for substitution in a problem, which then changes a multi-variable equation into a one-variable equation through properties of equality that is slated to be solved for first. Specifically, these participants were unable to identify Peggy as the unit and create a proportion or relationship between Jeff and Ed based on the unit (Peggy). In the *effective* category, it was noted that participants were successful in unitizing, creating a one-to-one relationship for Peggy, allowing for the multi-variable to be translated into a single-variable problem, using the correct proportions. See Figure 1.

This suggests that identifying Peggy as the unit algebraically may have been a barrier in setting up the algebraic equation in terms of one variable. An example of this gap in algebraic thinking can be found in the *evolving* score as in Figure 1. This shows there is an algebraic idea developing, with denoting the three people as three different variables are to be added. However, no further steps are taken to solve the equation (the final task) represented in three different variables.

In the *emerging score,* the teacher starts building an equation in one variable (p), there is a complete mid-stop and disconnect to a final presentation of an equation, which thereby demonstrates there is an incomplete understanding in relating the unit or one-to-one proportional representation that is necessary for the algebraic representation in the equation, ultimately limiting their ability to solve the problem. This is an example of when Driscoll's habits of mind used as a practice set of steps to foster algebraic thinking (2001) represents a classical conditioning model (a behavioral process) that may lead to habituation over time (response to a stimulus declines). However, either does not necessarily ascertain the development of the necessary conceptual understandings of the algebraic content and reasoning being presented.

Classical conditioning and the working memory in the brain (processing new and incoming information) are not directly related and have different neural underpinnings in the brain (Gluck et al., 2016). The latter has been found to predict the learning of underlying conceptual structures when connecting multiple pieces of information (Banas & Sanchez, 2012). Flexibility and transfer of thinking when connecting information are developed in the function of the working memory. The only flexibility in thinking shown *emerging* teachers' written response in levels, was in changing fractions into decimal representations. The process of identifying the unit in a problem that used a proportion and algebraic thinking was not a specific concept covered in the professional development. More research should be done to document the cognitive processes and relationship between the proportional reasoning unit and algebraic translation.

Given that this study was limited to a single math problem, more research is needed in teacher's knowledge and ability to translate a proportional reasoning problem into an algebraic equation to model and solve the problem. Furthermore, more research is needed to understand and develop best practices to support instruction and student thinking when encountering problems that involve both proportional reasoning and algebraic thinking. Additionally, in future professional developments, more attention needs to be spent in the cognitive process of unitizing in the proportional reasoning to determine whether it enhances teachers' ability to improve their algebraic thinking.

USING PROPORTIONAL TASKS TO EXPLORE TEACHERS' ABILITY TO MAKE SENSE OF STUDENT THINKING

Rachael Eriksen Brown
Pennsylvania State University Abington
reb37@psu.edu

Chandra Hawley Orrill
University of Massachusetts Dartmouth
corrill@umassd.edu

In this paper, we extend our previous work on challenges teachers face when engaging with proportional reasoning contexts to investigate two contexts that included four problems for middle grades teachers to solve as well as eight student solutions. Analysis included coding for correct solving of the problem as well as making sense of and determining reasonableness of the associated student work. Results indicate that making sense of student work was not dependent on correctly solving the problem. Determining reasonableness of student work was more challenging for our 32 participants. The think aloud interview, we argue, mimics responding to student thinking in a live setting. Implications for teacher knowledge as well as professional development and teaching will be discussed.

Keywords: Mathematical Knowledge for Teaching, Professional Development, Rational Numbers & Proportional Reasoning, Teacher Knowledge

Purpose

Proportional reasoning is an important mathematical concept for succeeding in K-12 math. However, not only students, but teachers, struggle with proportions (e.g., Akar 2010; Harel and Behr 1995; Post et al. 1988; Riley 2010). Teachers are often challenged to reason conceptually about proportions. Likely teachers, like their students, have an over-reliance on algorithms, like cross-multiplication, that leads to correct answers while not attending to multiplicative structures (e.g., Berk et al. 2009; Lobato et al. 2011; Modestou and Gagatsis 2010; Siegler et al. 2010).

Using Lamon's (2007) description of proportional reasoning as, "supplying reasons in support of claims made about the structural relationships among four quantities, (say a, b, c, d) in a context simultaneously involving covariance of quantities and invariance of ratios or products" (p.637-638) suggests the importance of teachers to identify what stays constant and recognize what varies in proportional relationships. One key idea is recognizing that a proportion is a multiplicative comparison and not an additive one (Lamon, 2007). In addition, teachers need to understand representations that highlight various components of proportional relationships, such as ratio tables and double number lines (Lobato & Ellis, 2010). Teachers need to understand how these representations support reasoning about the proportional structures.

One noted area of struggle is correctly identifying proportional reasoning situations and the tendency for students and teachers alike to use proportional reasoning in non-proportional situations (e.g., De Bock et al, 2002; Izsák & Jacobson 2017; Modestou & Gagatsis 2007). For example, De Bock and colleagues (2002) investigated students' persistent use of proportional thinking in a task focused on an area relationship. Of the 40 high school student participants in the study, 32 could not determine a correct answer even after being prompted with five scaffolds designed to highlight the area relationship. In our own work, we used a similar task, the Santa Task (see Figure 1), with middle grades math teachers and found several teachers were misled by the task. By the end of the task and our three scaffolds, only 13 of the 32 teachers correctly applied an area interpretation. Thus, this topic is challenging for teachers as well.

Santa Task		
A painter painted a 56 cm high Santa on the door of a bakery. He needed 6ml of paint. Now he is making an enlarged version of the same painting on a supermarket window using the same paint. This copy should be 168 cm high. How much paint will Bart need to do this?		
Scaffold 1: Compare favorite answers of 18ml and 54 ml	Scaffold 2: A student drew rectangles around both images	Scaffold 3: A student used easier numbers. For smaller picture used 1 tube of red paint and figured out larger would use 9 tubes of red paint.

Figure 1: Santa Task and student work

Given teachers need to not only work math problems correctly, but also make sense of students' work, we were interested in the relationship between teachers' abilities to solve the task and to make sense of sample student work on that task. We were also interested in their ability to determine whether the students' work was reasonable. We previously shared results of the Santa task analysis (Brown & Orrill, 2019). Our hypothesis was if teachers cannot solve a problem correctly, they are less likely to make sense of student thinking and less likely to determine if the solution is reasonable. Our Santa data suggest many participants could make sense of student thinking with or without solving the problem correctly; however, determining reasonableness was much more challenging when these participants had not solved the problem themselves correctly. Given this finding, we wanted to expand our focus to find out whether these trends stayed consistent across other items. Thus, we expanded our analysis to include the Milkshake task (see Figures 2-4). In this paper, we provide our analysis of both the Santa Task and the Milkshake Task. For each problem included in the tasks, we considered: (a) whether teachers engaged with students' reasoning and (b) whether they could determine the reasonableness of a student's approach. Our intent was to explore whether there was a connection between teachers' demonstrated content knowledge and their ability to make sense of students' reasoning in terms of how the student worked the task and whether the student's approach was a reasonable one. In our work, we define reasonableness to include determining whether the approach was mathematically viable or identifying the usefulness of a representation.

Perspective

Teachers facilitate students' interactions with mathematics in ways that allow them to develop meaning. Kilpatrick, Swafford, and Findell (2001) argue teachers decide when to allow students to struggle, ask questions, and provide guidance. Teachers also facilitate classroom discussions around key mathematical ideas. To do this well, teachers must engage with students' mathematical reasoning. *Principles to Actions* (NCTM, 2014) suggested teachers "elicit and use evidence of student thinking" (p. 10), including being able to assess student understanding in order to make instructional decisions.

While many have defined knowledge of teachers to include making sense of students' understanding (e.g., Shulman, 1986; Ball, Thames, & Phelps, 2008), little research has been done connecting teachers' understandings of mathematics to their understandings of students' ideas about mathematics. Rowland and colleagues' (e.g., Rowland, 2013; Turner & Rowland, 2011) Knowledge Quartet framework explores the connection between teacher content knowledge and how that knowledge is visible in teaching practice. Rowland (2013) wrote of the differences between the quartet and the Mathematical Knowledge for Teaching framework (Ball et al., 2008), "In the Knowledge Quartet, however, the distinction between different *kinds* of mathematical knowledge is of lesser significance than the classification of the situations in which mathematical knowledge surfaces in teaching." (p. 22). The Knowledge Quartet includes four dimensions: Foundation, Transformation, Connection, and Contingency. Foundation is teacher knowledge learned through schooling and professional development. The Transformation dimension is around using knowledge to support student learning in instruction. Connection addresses the coherent planning and teaching of mathematics. The fourth dimension is Contingency, a teacher's response to events in the classroom. This study addresses Contingency by investigating how a teacher reacts to unplanned student ideas about a task and how, if at all, that reaction relates to the teacher's ability to solve the same task.

Methods

In this study, we analyzed the data from the same 32 middle school teachers as in our previous work. The participants ranged from one to 26 years of experience. They were a convenience sample of middle school teachers from four states. Eight participants identified as male.

Milkshake Problem 2

Katrina wanted to make 3 cups of the recipe. How much of each ingredient did she need?

Student C:

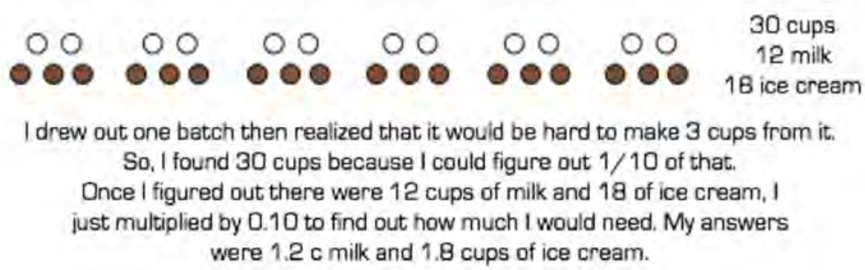

Figure 2: Milkshake Problem 2 and student work

Each participant completed a think-aloud interview that included the Santa Task and the Milkshake Task. The Santa Task was around the middle of the protocol and was inspired by De Bock et al's (2002) study. The Milkshake Task was inspired by the Orange Juice Task (National Research Council, 2001) and was at the end of the protocol. Teachers were asked to solve a mathematical problem and then respond to student work on the same task. Both tasks prompted the teachers to explain what the student was doing and whether it was reasonable. Figures 1-4 provide details about the two tasks. The Santa Task included one task with three different student solutions (we refer to these as Scaffolds 1-3). The Milkshake Task included three problems. Part 1 included two student solutions (Students A and B; Figure 3); Part 2 included one student solution (Student C; Figure 2); Part 3 included two student solutions (Team A and B; Figure 4). We considered in the verbatim transcript of each participant's interview (a) whether the participant's answer to the problem was correct; (b) whether the participant was able to make sense of each student approach; and (c) whether the participant identified the reasonableness of the approach. For participants who changed their initial solution, we analyzed only those responses that were given after the switch to correct reasoning. Transcripts were coded independently by each author and then discussed to reach 100% agreement.

Findings

Our intent was to determine whether there were relationships between participants' own mathematical thinking and their engagement with making sense of the students' thinking. Table 1 details the number of participants who solved each part correctly, were able to make sense of the student solutions, and were able to determine the reasonableness of the student solution process. The Santa problem was the more challenging problem for our participants to solve with only 13 solving it correctly. Of the three milkshake problems (Students A & B, Student C, and Teams A & B), the first was solved correctly by the majority of participants (97%). The second was solved correctly by 72% of participants, and the third was solved correctly by 88% of the participants.

Table 1: Coding for Santa and Milkshake Tasks

	Number of participants	Solved correctly	Able to Make Sense	Able to Determine Reasonableness
Santa Task				
Scaffold 1	32	12 (38%)	23 (72%)	12 (38%)
Scaffold 2	32	13 (41%)	26 (81%)	14 (44%)
Scaffold 3	32	13 (41%)	19 (59%)	10 (31%)
Milkshake Task				
Student A	32	31 (97%)	14 (44%)	16 (50%)
Student B	30*	29 (97%)	26 (87%)	27 (90%)
Student C	32**	23 (72%)	27 (84%)	23 (74%)
Team A	32	28 (88%)	27 (84%)	25 (78%)
Team B	30*	26 (87%)	17 (57%)	17 (57%)

*Data were missing for two participants for Student B and for two different participants for Team B.
**Only 31 people responded to the reasonableness question for Student C.

Overall, eight participants were able to correctly solve all four of the problems. Only three of those eight were able to both make sense of the student work and determine the reasonableness for all shared student work. Thus 9% of the participants (8 out of 32) were able to solve the problems correctly, make sense of and determine the reasonableness of all approaches.

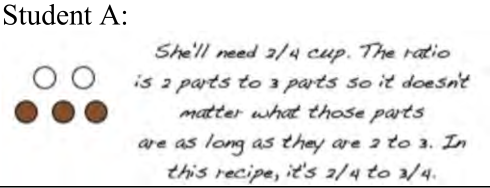
Another eight participants were able to solve one or two of the four problems correctly. Seven of these participants were able to make sense of student work on problems they did not solve correctly, but these same seven could not always make sense of the student work associated with the problem they did solve correctly. Thus, making sense of student work does not seem related to being able to solve the problems correctly. With respect to determining reasonableness, five of these eight participants had a harder time determining the reasonableness of the student work (the number of times they could determine reasonableness was less than the number of times they made sense of student work).

Looking only at the Milkshakes problems we can see that many participants solved the problems correctly and many were able to make sense of the student work and correctly determine reasonableness. However, we noticed that the responses for Student A and for Team B were markedly more difficult for these participants. Closer examination revealed that both of these student responses involved non-standard uses of common representations. For example, Figure 3 shows Student A using a common, discrete representation of the ratio two to three. In Student A's explanation, the reasoning applied to that representation used variable parts reasoning. That is, the student describes the idea that a ratio can be thought of as a fixed number of parts that can vary in size (see Beckmann & Izsák, 2015). Teachers who correctly reasoned about the student work often praised the approach as being "clever" (Charlotte), "wonderful" (Felicia) or "nice" (Greg). As Felicia so simply articulated, "I don't know why I didn't think about it, but basically, as long as she keeps the ratio to milk to ice cream as 2 to 3, it should work." For reasonableness, many teachers commented on the compatibility of the numbers. For example, Greg responded "This example was easier because you were given that she has three-quarter cups of ice cream. Therefore, each of those could equal one-fourth, and that was easy. If she was given two cups of ice cream, then you would have to figure out how to make the three circles equal to two, which would be a harder question for most students." These teachers not only solved this problem correctly but could make sense of Student A's work and reasoning. In correctly determining reasonableness they recognized the importance of the ratio remaining constant and often articulated when this strategy would be more challenging to use.

Milkshake Problem 1

Katrina wants to follow the milkshake recipe of 2 c milk and 3 c ice cream, but she only has ¾ c ice cream. How much milk will she need?

Student A:



Student B:

I used a ratio table to figure it out.

milk	2	1	1/3	1/6	3/6
Ice cream	3	1 1/2	1/2	1/4	3/4

Once I did that, it was easy to see that I'd need half a cu

Figure 3: Milkshake Problem 1 and student work

Team B, in Figure 4, used strips to demonstrate the ratios in the four recipes from Milkshakes Part 3. In this student work, we can easily see the ratios where each rectangle in the strip represents one cup. This representation is common, especially when students think more additively. The constant of proportionality is much harder to attend to in this representation. As seen in Table 1, only 17 out of 30 (57%) teachers could make sense of this work and determine whether it was reasonable. For example, Diana, in response to the question if this approach will always work, said no "Because I feel, I really feel like these students are simply counting their boxes and aren't taking into consideration the ratio." Participants who were able to determine reasonableness were able to articulate the potential pitfalls with this work and many suggested they would want to ask students a follow up question, such as when Ella said, "let's take the fractions five eighths and two thirds like those are one twenty-fourth apart. So if we were to draw those, I don't think students really could see which one is more chocolaty."

Milkshake Problem 3

Compare four milkshake recipes to determine which is the most chocolatey.

Team A: Team B:

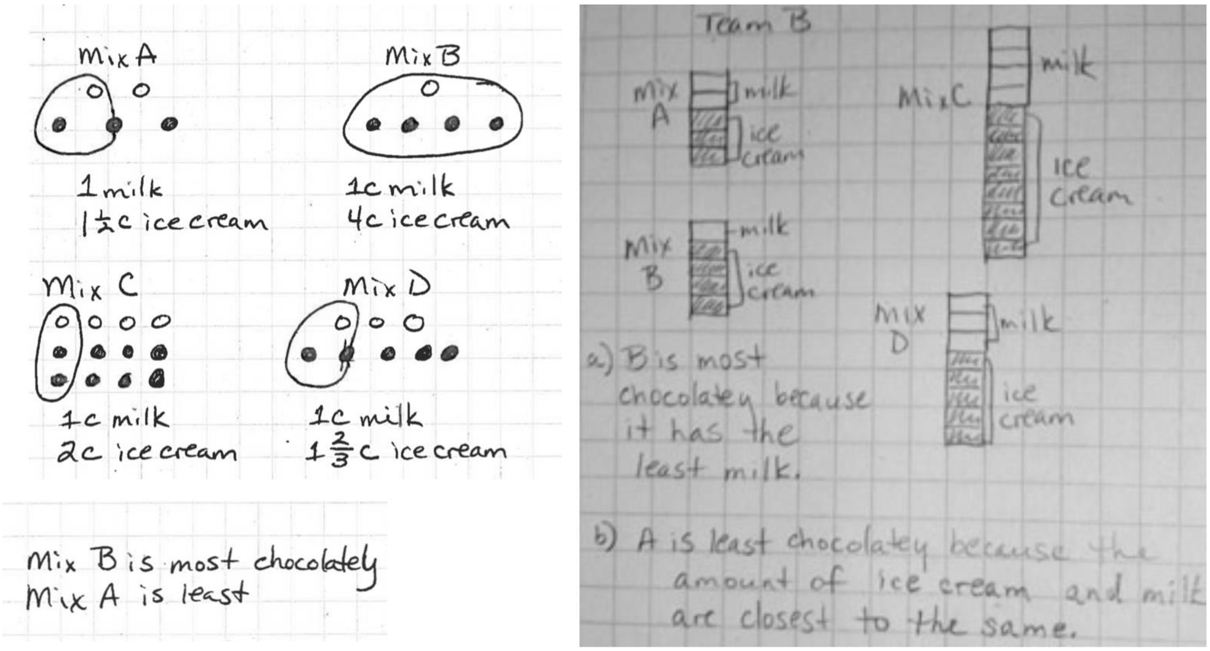


Figure 4: Milkshake Problem 3 and student work

Significance

These results contribute to the fields understanding of teacher knowledge, particularly using the Knowledge Quartet framework (Rowland, 2013) with practicing teachers (the Knowledge Quartet framework resulted from studies of preservice teachers). Our intent in this inquiry was to understand how teachers solve the problems and how they make sense of students' work, because those are both fundamental aspects of the work of teachers. We assert that evaluating seeing student work in an interview protocol is similar to seeing student work during an active lesson, only with the time constraints inherent in the classroom removed. Teachers need to make decisions about what a student is doing and whether it is a reasonable approach in order to respond in productive ways to students' work. The results from our participants indicate teachers, regardless of being able to solve a proportional reasoning problem themselves, can often make sense of what a student is doing to solve that same problem. Being able to determine the reasonableness of the approach appears to be more aligned with a teacher's ability to solve the problem correctly. Thus, Foundation and Contingency (2 of the four dimensions) may not result in the same teacher understandings used. The field should consider what teacher knowledge we are actually measuring.

In addition, these results suggest teachers are familiar with common representations, such as ratio tables. However, when common representations are used in unusual ways, such as our Student A and Team B examples, teachers have a harder time making sense of the work and determining whether it is reasonable. Thus, professional development providers and teacher educators should consider not only engaging teachers with these representations, but also engage them in considering unusual ways these representations could be used in productive and unproductive ways. This likely means, engaging teachers with the structures of the mathematics (e.g., attending to invariance and what remains constant) rather than using the representations.

It has been suggested that integrating reasoning and proof in mathematics teaching requires a special type of teacher knowledge – Mathematical Knowledge for Teaching Proof (MKT-P). Yet, several important questions about the nature of MKT-P remain open, specifically, whether MKT-P is a type of knowledge specific to teachers, and whether MKT-P can be improved through intervention. We explored these questions by comparing performance on an MKT-P questionnaire of in-service secondary mathematics teachers, undergraduate STEM majors, and pre-service secondary mathematics teachers. The latter group completed the questionnaire twice- before and after participating in a capstone course, Mathematical Reasoning and Proving for Secondary Teachers*. Our data suggest that MKT-P is indeed a special kind of knowledge specific to teachers and it can be improved through interventions.*

Keywords: Mathematical Knowledge for Teaching, Reasoning and Proof, Preservice and In-service Secondary Teachers

In recent years, there have been welcomed shifts in the research on teaching and learning of argumentation and proof towards increased focus on classroom-based interventions for supporting students' engagement with reasoning and proving (Stylianides & Stylianides, 2017). These studies have shown that students' opportunities to participate in proof-related practices such as generalizing, conjecturing, posing and critiquing arguments, are dependent on teachers' ability to design learning environments that foster such engagement and on teachers' ability to advance students' learning of reasoning and proof (Bieda, 2010; Cirillo, 2011; Martin, McCrone, Bower & Dindyal, 2005; Stylianides, Bieda & Morselli, 2016).

Given the critical role of the teacher in facilitating student engagement with reasoning and proving (Nardi & Knuth, 2017) and following Ball, Thames and Phelps' (2008) and Shulman's (1986) notion of Mathematical Knowledge for Teaching (MKT), several researchers have introduced the notion of Mathematical Knowledge for Teaching Proof (MKT-P). The latter has been posited as a special type of mathematical knowledge teachers need in order to carry out the work of teaching mathematics with an emphasis on reasoning and proving (e.g., Buchbinder & McCrone, 2020; Lin, et al., 2011; Lesseig, 2016; Stylianides 2011).

Although this line of research is fast growing, several key questions about the nature of MKT-P remain open. Specifically, it is unclear whether MKT-P is a type of knowledge that is specific to teachers of mathematics, or whether it should be viewed as general knowledge of mathematical content. If MKT-P can be shown to be distinctive to the act of teaching reasoning and proving, another important question is whether it is possible to facilitate the development of MKT-P through targeted interventions. Both questions have critical importance for preparation and professional development of mathematics teachers, yet, as far we know, the literature on this topic has been scant. Our study aims to provide some initial answers to both questions.

The study reported herein is part of a larger, NSF-funded 3-year design-based-research project (Edelson, 2002), which investigated how content and pedagogical knowledge of prospective secondary teachers (PSTs) developed as a result of their participation in a uniquely designed capstone course *Mathematical Reasoning and Proving for Secondary Teachers* (Buchbinder & McCrone, 2020). The design of the course and the MKT-P assessment instrument grew out of our conceptualization of MKT-P, described below. As we explored the growth of PSTs' knowledge in the course (our original research objective), we became intrigued by the specificity of the nature of MKT-P, which led to this current investigation. We administered the same MKT-P questionnaire to 17 in-service secondary mathematics teachers, 22 undergraduate STEM majors and 9 PSTs. These PSTs participated in the capstone course in Fall 2019. We hypothesized that the in-service teachers' performance would be quantitatively and qualitatively different from the other two groups. We also hypothesized growth in the PSTs' MKT-P as measured on the pre- and post-test questionnaires.

The Course: Mathematical Reasoning and Proving for Secondary Teachers

Our prior interest in proof and reasoning (Buchbinder, 2010; McCrone and Martin, 2009) and the current work with preservice mathematics teachers has culminated in our design-based research project in which we designed a capstone course *Mathematical Reasoning and Proving for Secondary Teachers* and studied the development of PSTs' knowledge in it (Buchbinder & McCrone, 2020). The course comprised four modules focused on the following proof themes: (1) direct reasoning and argument evaluation, (2) conditional statements, (3) quantification and the role of examples in proving, and (4) indirect reasoning. These topics are known to be particularly difficult to learn and to teach (e.g., Antonini & Mariotti, 2006; Stylianides & Stylianides, 2018).

Each module includes activities aimed to crystalize, connect and apply the PSTs' knowledge of proof and reasoning across a range of secondary mathematics topics. The *crystalize* activities aimed to help PSTs refresh their memory of a particular proof theme. The *connect* activities provided opportunities to connect PSTs' mathematical knowledge with knowledge of students' proof related conceptions and misconceptions. PSTs were then required to *apply* their knowledge in actual secondary classrooms by developing lessons related to a specific proof theme and teaching those lessons to small groups of middle school and high school students. Collectively these activities aimed to enhance PSTs' MKT-P.

Mathematical Knowledge for Teaching Proof Framework

Our conceptualization of MKT-P draws on Schulman's original framework (1986), with the broad categories of subject matter and pedagogical knowledge. Within these categories, we distill those elements that have particular relevance to teaching of reasoning and proving. We also drew inspiration from the existing MKT-P literature (e.g., Corleis et al., 2008; Lin, et al., 2011; Lesseig, 2016; Stylianides 2011), but ultimately developed our own comprehensive MKT-P framework. The framework distinguishes between three interrelated facets: Knowledge of Logical Aspects of Proof (KLAP), Knowledge of Content and Students specific to proving (KCS-P) and Knowledge of Content and Teaching specific to proving (KCT-P). KLAP describes elements of subject matter knowledge specific to proof, such as knowledge of valid and invalid modes of reasoning, knowledge of logical forms of proof, such as direct proof or proof by contradiction, knowledge of a range of accepted definitions, theorems and their proofs, knowledge of logical connections and relations, such as converse, inverse, bi-conditional, etc. The pedagogical content knowledge specific to proof is represented by two types: KCS-P and KCT-P. KCS-P includes knowledge of students' proof related conceptions and misconceptions such as a tendency to rely on inductive reasoning when attempting to prove general statements, or view counterexamples as mere exceptions. KCT-P describes knowledge of pedagogical strategies for supporting student learning of reasoning and proving, such as designing and enacting proof-related tasks, questioning techniques and providing instructional feedback on students' arguments.

The three facets of MKT-P are interrelated. For example, designing proof-oriented tasks (KCT-P) must take into account students' conceptions (KCS-P); and assessing the validity of students' arguments (KCT-P) requires robust knowledge of logical aspects of proof (KLAP). Distinguishing between the knowledge facets was useful for designing both the MKT-P questionnaire and the capstone course targeting MKT-P development.

Methods

Participants and Data Collection

The participants in the study were nine PSTs who participated in the capstone course in Fall of 2019, 17 in-service secondary mathematics teachers and 22 undergraduate STEM majors. All three groups completed the same MKT-P questionnaire, described below. The PSTs were seniors who had successfully completed most of their mathematical coursework, including a *Mathematical Proof course*, and at least one methods course, but had no prior classroom teaching experience. The PSTs completed the MKT-P questionnaire twice, at the beginning and the end of the course.

The in-service teachers were recruited through in-person presentations at local schools and professional development workshops. Of the 17 participants, five teachers were from the same school; the rest were from different schools or districts. Their teaching experience ranged from two to 25 years ($\bar{x}$ = 12.18, *SD* = 8.00). The teachers completed the Qualtrics Research Suite online version of the questionnaire and received $35 honorarium.

The 22 undergraduate STEM majors were recruited through in-person presentations in three sections of a *Mathematical Proof* course at the same university in which the capstone course was given. The group comprised 11 computer science majors, 9 mathematics majors, 1 mathematics education major and 1 philosophy major. Twelve participants were sophomores, eight juniors and two seniors. The questionnaire was administered in a paper and pencil version during the final weeks of the *Mathematical Proof* course and students received extra credit for this.

MKT-P Questionnaire

We developed a 29-item MKT-P questionnaire, with some questions having a common stem. Ten items were in the area of KLAP, 11 in KCS-P and 8 in KCT-P. The items spanned four proof themes: (1) direct proof and argument evaluation, (2) conditional statements and logical equivalence, (3) quantification and role of examples in proving, and (4) indirect proof, matching the four proof themes of the capstone course (Buchbinder & McCrone, 2020). The mathematical content was middle- to high-school level algebra, geometry and functions.

The KLAP questions were multiple-choice items with a box for justification. The questions called for detecting correct assumptions for a proof by contradiction, determining logically equivalent statements, recognizing circular reasoning steps in given proofs, and identifying counterexamples. The KCS-P questions were grounded in pedagogical context (Baldinger & Lai, 2019), describing classroom situations where students presented arguments for or against a particular conjecture. The participants were to interpret the students' arguments, assess their correctness on a 4-point scale and describe any errors or potential misconceptions (if any) they notice. The KCT-P items had a similar setup as KCS-P items, but instead of numeric assessment, the participants were asked to provide feedback to the hypothetical student, highlighting strengths and weaknesses of their arguments (see Figure 1 for a sample KCT-P item).

Mr. Briggs asked his students to prove the following statement: ***The sum of any two rational numbers is a rational number.***

Molly's solution:

Suppose r and s are rational numbers. By definition of a rational number, let $r = \frac{a}{b}$ where a and b are integers, and $b \neq 0$. Similarly, s is rational so let $s = \frac{a}{b}$ where a and b are integers, and $b \neq 0$.

Then $r + s = \frac{a}{b} + \frac{a}{b} = \frac{2a}{b}$.

Let $p = 2a$. Then p is an integer because it is the product of two integers.

Hence $r + s = \frac{p}{b}$, where p and b are integers and $b \neq 0$.

Thus, $r + s$ is a rational number by definition of a rational number. ■

i) Identify errors (if any) in the student's argument. If none, write "no errors".

ii) Provide feedback to the student, highlighting strengths and weaknesses of their argument.

Figure 1: Sample KCT-P item

Large-scale validation of the instrument was beyond the scope of our original research. Thus, we used expert validation with three mathematicians and one mathematics education expert, and tested the instrument for two years. Cronbach alpha for the entire MKT-P questionnaire was 0.892, with 0.81 for KLAP, 0.71 for KCS-P and 0.76 for KCT-P.

Data Analysis

For the quantitative data analysis, each KLAP item was scored out of 3 points: 1 point for correct choice and 2 points for correct explanation, or 1 point for partially correct explanation. The KCS-P and KCT-P items were scored on a 0-4 point rubric, with 0 points given to a mathematically incorrect response and 4 points to a correct answer that showed deep engagement with the student's argument (exceeding expectations). The research team developed the scoring rubric jointly, by analyzing about 20% of the data. Next, two researchers scored the rest of the data individually and met regularly with the rest of the team to reconcile any discrepancies. The Kappa scores for inter-rater reliability were 0.78 for KCS-P and 0.8 for KCT-P.

For each group: Teachers, STEM majors and PSTs, we calculated the mean total scores for the overall MKT-P. Since the number of items in each subdomain: KLAP, KCS-P and KCT-P, was different, we calculated the mean average score per subdomain per group. Using JMP® Pro statistical software version 15.0.0 we performed one-way ANOVA to determine whether the three groups differed statistically. In addition, we used Welch's Test for the presence of non-constant variance and Tukey-Kramer's Honestly Significant Difference Test for multiple comparisons. Since PSTs' pre and post-course scores are dependent on each other, we performed two separate analyses, once comparing the performance of teachers, STEM majors and PSTs' pre-course scores, and once comparing teachers, STEM majors and PSTs' post-course scores. In the rest of the paper, we use PSTs-pre and PSTs-post to denote this distinction. We also used matched pairs t-tests to compare PSTs-pre to PSTs-post performance.

To capture qualitative differences among the groups we used open coding and thematic analysis (Miles, Huberman, & Saldana, 2018; Yin, 2011). In particular, we coded for the use of first-person language in providing feedback to hypothetical students, and for the types of negative and positive appraisals of student arguments given by the study participants.

Results

The overall MKT-P performance of the three groups is shown in Table 1. The maximum possible score on the test was 86, suggesting that teachers' mean total was about 60%, STEM majors scored around 50% and PSTs went from 41% on the pre- to 70% total score on the post. The one-way ANOVA and the Welch's Test showed that the three groups: teachers, STEM majors and PST-pre are statistically different from each other ($p = 0.0219$). The difference was due to teachers scoring significantly higher than PSTs-pre ($p = 0.0379$). The differences between STEM majors and PSTs-pre or between teachers and STEM majors were not statistically significant. However, it is notable that while the maximum total score in the STEM majors' group was 66, four teachers had a total score above 75, meaning that the lack of significance can be due to the high variability of performance in the teachers' group.

Table 1: Overall MKT-P performance of the three groups

Group	No of participants	Mean Total Score	SD
Teachers	17	51.4	21.11
STEM majors	22	42.5	13.12
PSTs **pre**	9	35.4	7.59
PSTs **post**	9	59.7	11.23

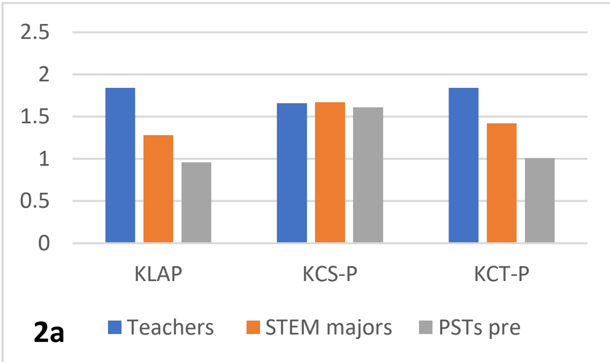
When comparing the mean scores of teachers, STEM majors and PSTs-post, the differences were still significant ($p = 0.0053$), but in this case, the difference was due to PSTs-post scoring higher than the other two groups. In particular, PSTs-post significantly outperformed STEM majors ($p = 0.0274$), but not the teachers ($p = 0.4319$).

The pairwise t-test comparing PSTs' pre and post-course performance revealed significant growth in overall MKT-P ($p < 0.0001$); the 95% confidence interval showing the average increase between 16 and 29 points. This outcome supports our assumption that MKT-P can be improved by targeted intervention, such as our capstone course, so much so that PST-post outperformed both the teachers and STEM majors.

Table 2 shows the results of the analysis broken down by MKT-P subdomains: KLAP, KCS-P and KCT-P. In this table, we calculated the mean scores for each domain, rather than total points, since the number of items (and points) in each domain was different.

Table 2: Performance of the groups by MKT-P subdomain

		KLAP		KCS-P		KCT-P	
Group	No	Mean Score	SD	Mean Score	SD	Mean Score	SD
Teachers	17	1.84	1.26	1.66	1.09	1.84	1.29
STEM majors	22	1.28	1.29	1.67	1.09	1.42	1.23
PSTs **pre**	9	0.96	1.17	1.61	1.01	1.01	1.12
PSTs **post**	9	2.15	1.15	2.04	1.03	1.97	1.22



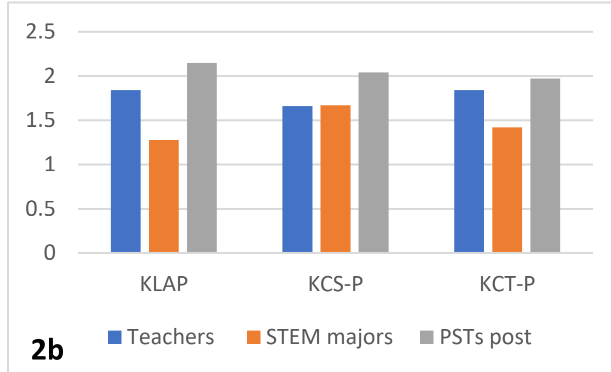


Figure 2 a & b: Performance of the groups by MKT-P subdomain

Figure 2 shows the same information as Table 1, but in a graphic format: Figure 2a (left) compares performance of teachers, STEM majors and PSTs-pre. Figure 2b (right) compares teachers, STEM majors and PSTs-post.

When comparing teachers, STEM majors and PSTs-pre, the analysis showed that there three groups differed significantly on KLAP ($p < 0.0001$) and KCT-P ($p < 0.0001$), but not on KCS-P ($p = 0.8843$). The KCS-P portion of the questionnaire intended to assess participants' ability to identify proof-related misconceptions. All three groups performed very similarly. We do not have an explanation for that, except that our KCS-P items probably measure mostly mathematical knowledge, despite their pedagogical framing. The PSTs performance on the KCS-P items improved significantly from pre to post ($p = 0.0013$), and was significantly higher than of teachers ($p = 0.0162$) and of STEM majors ($p = 0.0126$).

Considering the KLAP portion of the questionnaire, the teachers significantly outperformed both STEM majors ($p < 0.0001$) and PSTs-pre ($p < 0.0001$). This result is interesting since KLAP items measure pure mathematical knowledge. A closer analysis revealed that teachers were better than other groups at identifying logical forms such as converse and contrapositive and tended to use proper mathematical vocabulary. The PSTs' KLAP performance improved significantly on the post-questionnaire ($p < 0.0001$). The PSTs-post scored significantly higher than STEM majors ($p < 0.0001$) but not significantly higher than teachers ($p = 0.1343$).

A similar tendency was observed with respect to KCT-P portion of the test – items that called for identifying logical errors in student arguments and providing instructional feedback to the students. Not surprisingly, teachers significantly outperformed STEM majors ($p =0.0090$) and PSTs-pre ($p < 0.0001$). But when compared to PSTs-post, the PSTs closed the gap and scored very similar to the teachers, and significantly higher than STEM majors ($p = 0.0050$).

Qualitative Differences Between the Groups

The differences between the groups also had a qualitative nature, as revealed in the analysis of written feedback to hypothetical students' arguments on the KCT-P items. STEM majors tended to use third person language talking about the student work rather than addressing the student directly (contrary to the task requirements). STEM majors tended to compliment student work for brevity or clarity, focusing more on the presentation rather than on the content of the argument, e.g., "clear and appropriate assumptions, well ordered." Positive appraisals often merely reiterated the student's approach, e.g., "Anthony was smart in using variable *a* and *b* to help prove the conjecture." Despite praising the student, this comment shows neither analysis of nor engagement with the student's proof strategy.

In their critiques, STEM majors tended to point out that a student's argument did not constitute a mathematical proof but without clarifying the concern, e.g., "not proven enough," "isn't concrete enough to prove the statement." More substantive critiques referred to incorrect assumptions, e.g., "the student assumed their conclusion by saying the sum of two fractions is a fraction," and lack of generality, e.g., "there is no generality, it is only examples." Overall, STEM majors tended to focus feedback on the mathematical validity and form of a student's argument.

Alternatively, participants in the teacher group tended to speak directly to hypothetical students and focus their comments on students' conceptual understanding of the given problem. For example, "you show your strong understanding of what a rational number is and how to use variables to generalize a situation." Teachers' critiques of student arguments tended to focus less on the form and more on the mathematical validity of the arguments. Moreover, the critiques were often phrased as open questions, e.g., "can we look at this algebraically?" or "would your proof hold true if *r* and *s* were equal to different fractions?" or "is there a way to show this is true for all real numbers?" This rhetorical style of feedback shows teachers' concern for student understanding and engaging students in revisionary work.

The PSTs comments fell between the student-oriented feedback of the teachers and the mathematics-oriented feedback of the STEM majors. Some PSTs worded their feedback in the question format e.g., "How can you say that only numbers that satisfy Sam's conjecture are 2 and 0?" But the majority of PSTs used third person language and made mathematics-oriented comments, e.g., "Anthony made a valid argument by turning the numbers into a general expression." There were shifts towards more frequent use of first person language and question-posing feedback from pre- to post-questionnaire.

Discussion

The objectives of our study were to examine whether the Mathematical Knowledge for Teaching Proof, as measured by our MKT-P questionnaire, differs from pure knowledge of mathematical content. We hypothesized that if this knowledge is special to mathematics teachers, it would show as better performance on the MKT-P questionnaire when compared to STEM majors or PSTs. We also conjectured that it would be possible to facilitate MKT-P growth through a targeted intervention such as our capstone course *Mathematical Reasoning and Proving for Secondary Teachers* (Buchbinder & McCrone, 2020), which would be visible in improved PSTs' performance on the MKT-P questionnaire.

The data presented above supports both of our assumptions. The teachers outperformed STEM majors and PSTs-pre on the overall MKT-P, and on two MKT-P subdomains: knowledge of the logical aspects of proof (KLAP) and knowledge of content and students (KCT-P). The three groups performed similarly on the KCS-P portion of the questionnaire – items intended to assess knowledge of students' proof-related (mis)conceptions. This may be reflective of a limitation of our instrument, which did not discriminate between the different groups.

The fact that teachers outperformed PSTs-pre on almost every measure is not surprising; it is consistent with the general MKT literature (e.g., Phelps, Howell, & Liu, 2020). Our study adds to this literature by showing that the differences between prospective and practicing teachers appear also in MKT-P. The teachers also scored higher than STEM majors, whose knowledge of proof was fresh in their minds due to their enrollment in a proof course at the time of the study. This outcome may support our assumption that MKT-P is a special kind of knowledge, beyond mathematical content knowledge. Alternatively, this difference can be due to self-selection bias of the participants in the two groups of STEM majors and in-service teachers. Our study design does not allow distinguishing between these alternatives. Future studies should explore this issue.

Another support for our hypothesis about the special nature of MKT-P comes from the qualitative analysis of the feedback provided by the participants on sample student arguments. Particularly striking were the differences between teachers and STEM majors, while PSTs were somewhere between those two groups. The teachers' comments were characterized by a tendency to use first person language addressing the student directly, deeper engagement with a student's argument, attempts to gauge and advance student understanding through guiding questions and suggestions for revisions. On the contrary, the STEM majors' comments were characterized by the tendency to use third person language, focus on the form of the argument rather than its logical structure, critiquing student work for the lack of mathematical rigor but without explaining insufficiencies in student work. Thus, teachers' MKT-P is evident in their ability to provide feedback of higher potential for educative impact than STEM majors (Hattie, & Timperley, 2007).

Our second research question was whether MKT-P can be enhanced through intervention. Note that exploring *how* PSTs' MKT-P evolves throughout the capstone course, connecting the learning processes to the design features of the course and examining factors that promote or inhibit MKT-P development were the core objectives of our three-year long study. Presentation of these findings is beyond the scope of this paper. The significance of this paper is in comparing PSTs' pre- and post-course performance with other groups who may have similar characteristics to our PSTs. We do not see STEM majors or teachers as control groups in any sense. Comparing the MKT-P performance across all groups allows putting the observed changes in the PSTs' MKT-P into broader perspective, adding methodological strength to the simple pre-post design.

The data presented above show that STEM majors performed slightly better than PSTs-pre, although the differences were not statistically significant on any measure. Despite the fact that all PSTs had successfully passed the *Mathematical Proof* course in the second or third year of their program, prior to taking the capstone course, the proof-specific mathematical content was fresher in the minds of the STEM majors than of the PSTs. The course *Mathematical Reasoning and Proving for Secondary Teachers* provided the PSTs with opportunities to refresh and strengthen their proof-related content knowledge. More importantly, the course activities challenged the PSTs to connect this knowledge to teaching secondary mathematics by analyzing sample student arguments, providing feedback on hypothetical student work, planning proof-oriented tasks, enacting them in real classrooms and reflecting on their teaching. These types of activities help to bridge the gap between university-level mathematics preparation and the practice of teaching secondary mathematics (Grossman et al., 2009; Wasserman et al., 2018).

Our study concurs with that literature. After participating in the capstone course, the PSTs' MKT-P improved significantly both overall and in each subdomain. The PSTs closed the gap with in-service teachers on the overall MKT-P, KLAP and KCT-P, and scored significantly higher than the teachers did on KCS-P. The PSTs-post also performed significantly higher than STEM majors did on the overall MKT-P and on each of the MKT-P subdomains. Overall, these results support our hypothesis that MKT-P can be enhanced through intervention.

Our study is exploratory, small scaled and localized. In our data analysis, we utilized statistical techniques that are robust to small numbers of participants (see methods section). However, we make no claims to generality and the results should be interpreted as preliminary. Nevertheless, our study makes several notable contributions to the existing body of knowledge. We proposed an MKT-P framework and a questionnaire for assessing MKT-P at the secondary level, which spans four proof themes – key areas of difficulty with reasoning and proof, according to the research literature. The comparison of the MKT-P performance of in-service teachers, STEM majors and PSTs suggests that MKT-P, as measured by our instrument, is indeed a type of knowledge that is special to teachers, as opposed to other groups with presumably similar mathematical content knowledge. Finally, our study has shown that MKT-P can be enhanced by targeted intervention, such as our capstone course. This was evident in the significant improvement of PSTs' performance from pre- to post, and in comparison of PSTs-post scores with STEM majors and teachers. It would be important to replicate this study on a larger scale and with other, more diverse, populations.

CHARACTERIZING PROSPECTIVE SECONDARY TEACHERS' FOUNDATION AND CONTINGENCY KNOWLEDGE FOR DEFINITIONS OF TRANSFORMATIONS

One promising approach for connecting undergraduate content coursework to secondary teaching is using teacher-created representations of practice. Using these representations effectively requires seeing teachers' use of mathematical knowledge in and for teaching (MKT). We argue that Rowland's (2013) Knowledge Quartet for MKT, in particular, the dimensions of Foundation and Contingency, is a fruitful conceptual framework for this purpose. We showcase an analytic framework derived from Rowland's work and our analysis of 85 representations of practice. These representations all featured geometry. We illustrate examples of combinations of "high" and "low" Foundation and Contingency, and show results of coding juxtaposed with performance on an instrument previously validated to measure MKT. We describe the potential for generalizing this framework to other domains, such as algebra and mathematical modeling.

Keywords: Mathematical Knowledge for Teaching, Undergraduate Education, Preservice Teacher Education

Many secondary teachers find their undergraduate mathematical preparation disconnected from their teaching (Goulding et al., 2003; Ticknor, 2013; Wasserman et al., 2018; Zazkis & Leikin, 2010). The mathematicians who teach these teachers may want to connect content coursework to secondary teaching (e.g., Lai, 2019; Lischka et al., 2020; Ticknor, 2013). At the same time, mathematics faculty may lack the resources to say precisely what connections may be there, and how to give feedback to teachers regarding the connections (Lai, 2019).

In recent years, several groups have addressed this problem by developing (a) tasks for content courses where teachers create representations of practice, and (b) design principles for such tasks (e.g., lvarez et al., 2020; Wasserman et al., 2019). Mathematics faculty can now use these principles to create such tasks, but not necessarily to provide constructive feedback to teachers about their responses. To our knowledge, the field lacks frameworks for characterizing the mathematical knowledge in and for teaching (MKT) observable in representations of practice created by teachers, in ways that would support feedback. Such frameworks could position mathematics faculty to bridge mathematics and teaching more powerfully.

Our purpose is to characterize dimensions of MKT visible in teacher-created representations of practice, and to do so in a way that can potentially inform feedback to prospective teachers about their mathematical understanding and its use in teaching. In our work, representations of practice are snapshots of discourse used in responding to student contributions. Using such representations, created by prospective teachers, we asked: *What MKT is observable in teacher-created representations of practice?* We argue that Rowland's Knowledge Quartet framework for MKT is a productive analytic framework for analyzing representations of practice. We contribute a framework for observing "high" and "low" levels of knowledge in two dimensions of the Knowledge Quartet, namely, the Foundation and Contingency dimensions. Our corpus consists of teacher-created representations of practice featuring geometry from a transformation perspective. We conclude by considering how our work can generalize to other mathematical domains.

Conceptual Perspective

Mathematical Knowledge in and for Teaching (MKT)

Across the various literatures on MKT (e.g., Ball et al., 2008; Davis & Simmt, 2006; Heid et al., 2015; Rowland, 2013; Thompson & Thompson, 1994) and on mathematics learning (e.g., Daro et al., 2011; National Academies of Sciences, Engineering, and Medicine, 2018; Simon, 2006; Thompson, 2000), we have found ideas of Rowland and colleagues (2013, 2016), Simon (2006), and Thompson (2000) most generative for our work.

Among the four dimensions that compose Rowland's (2013) Knowledge Quartet framework for MKT, we focus on two: *Foundation* (knowledge and understanding of mathematical ideas, the nature of mathematics, as well as principles of mathematical pedagogy) and *Contingency* (the ability to respond to unanticipated events ranging from network outages to learners' alternative strategies). The remaining dimensions are *Transformation* (presenting ideas to learners) and *Connection* (cohering ideas over time). Foundation knowledge is observed through actions associated with the other dimensions, as well as in teacher talk outside of teaching (e.g., in a debrief of student teaching). Rowland, Thwaites, and Jared (2016) validated the use of this framework for identifying instances in student teaching at the secondary level where an observing teacher educator can infer the use of content or pedagogical content knowledge.

Rowland and colleagues used videos of teaching across multiple topics in multiple schools. We examined teacher-created representations of practice responding to a limited set of prompts. Hence, we found it useful to delimit and elaborate on Foundation and Contingency as follows. First, we delimited the Foundation dimension to knowledge of mathematics, because of our interest in content coursework. Second, the dependence of Foundation on *mathematical understanding* suggested that we be theoretically clear about a conception of mathematical understanding. We used Simon's (2006) characterization: mathematical understanding is the "learned anticipation of the logical necessity of a particular pattern or relationship" (p. 364). For instance, we consider understanding mathematical procedures to include relating that procedure to its underlying definitions or concepts, and to anticipate doing so when explaining procedures or troubleshooting a use of a procedure. Then, we delimited Contingency to the ability to integrate given student thinking into teacher talk. Finally, we used Thompson's (2000) notion of interacting reflectively to elaborate on integrating student thinking (cf. Ader & Carlson, 2018). When teachers interact reflectively, they interpret and leverage student thinking. When teachers interact unreflectively, they do not adopt the student's perspective.

Rowland and colleagues' work results in a framework for identifying instances where MKT may be used, but it does not result in a framework for characterizing levels of use such as would be useful for guiding an instructor to provide feedback to a teacher.

Teacher-Created Representations of Practice

In all assignments we analyzed, prospective secondary teachers created representations of practice based on a description of a teaching situation provided to them, where the teaching situation included various samples of student work. These representations of practice may be considered an approximation of practice in Grossman et al.'s (2009) framework, meaning that they are "opportunities for novices to engage in practices that are more or less proximal to the practice of a profession" (p. 2058).

Mathematical Context for Analysis

A transformation perspective is characterized by defining congruence and similarity via transformations (Usiskin & Coxford, 1972). The transformations critical to congruence and similarity are reflections, rotations, translations, and dilations. Across the two units in the materials used in this study, prospective teachers developed community definitions for reflection, rotation, translation, and dilation. Then, prospective teachers used these definitions to construct images of these transformations, as well as to determine whether two proposed figures can be connected by one of these transformations.

There were four prompts for creating representations of practice in the modules. Two prompts asked teachers to video-record themselves, and two asked teachers to write narratives. All prompts provided images of secondary student work and asked prospective teachers to respond in a way that would move students toward understanding connections between definitions and constructions of images of relevant transformations. All prompts provided the secondary level task that the sample secondary student work was responding to. Figure 1 shows images of student work from some of the prompts.

(Sample for prompt focused on rotation) As students are working on rotations of a flag, you observe two students with the following work completed.

Data & Method

Overview

To develop a framework for characterizing Foundation and Contingency knowledge in teacher-created representations of practice, we analyzed teacher-created representations of practice in two rounds of coding. The first round aimed to characterize three levels of Foundation knowledge using all representations of practice from the first year of data collection. The second round used a purposive sample from three years of data collection, as detailed below. In this round, we sought to streamline coding for Foundation and develop coding levels of Contingency. We focused on streamlining because we sought a framework that could be ultimately usable by mathematics faculty who may not be education researchers, and that could potentially generalize across domains. In the second round, our process for coding and reconciling for two levels each of Foundation and Contingency knowledge ("High", "Low") took an average of 10 minutes per coder, per representation of practice.

Sampling

Data were drawn from the *Mathematics of Doing, Understanding, Learning, and Educating for Secondary School*s (*MODULES*[2]) project, which has developed curriculum materials for content courses for prospective teachers in four content strands (algebra, geometry, statistics, and modeling). We analyzed prospective teachers' responses to tasks in the geometry materials. Data included more than 300 teacher-created representations of practice from 93 prospective teachers in different regions of the US. The first round of coding used 54 teacher-created representations (2 representations x 27 teachers) from the first year of data collection. The second round of coding used a purposive sample of 31 teacher-created representations of practice (4 representations x 7 teachers + 3 representations x 1 teacher). The purposive sample was selected to document the range of potential MKT. Among the 93 teachers, 61 had completed pre- and post-semester forms of GAST, an instrument validated to measure knowledge for teaching geometry at the secondary level (Mohr-Schroeder et al., 2017). After assigning "high-GAST" and "low-GAST" thresholds for each item, we narrowed the pool to 20 teachers, consisting of the top 10 teachers ranked by proportion of "high-GAST"-"high-GAST" pre-post item scores, and the top 10 teachers ranked by "low-GAST"-"low-GAST" pre-post item scores. Only 8 of these teachers had submitted all 4 representations of practice assigned in the modules. During analysis, we realized that one assignment was scanned incompletely. This resulted in our sample of 31 teacher-created representations of practice.

Analysis

To develop a framework for characterizing foundation and contingency knowledge, we first considered Rowland's (2013) descriptions and Weston and Rowland's (n.d.) elaborations of Foundation and Contingency dimensions. We then reflected on how these considerations may apply to the specific teacher-created representations of practice analyzed and, at the same time, how they may apply to other domains. To do this, we involved researchers with expertise in a variety of mathematical domains – such as mathematical modeling, algebra, and geometry – in our discussion. In both rounds, we were blind to pre/post-test scores; no coders scored the pre/post-tests. We created lists of characteristics of representations of practice demonstrating "High" and "Low" Foundation and Contingency knowledge. We used these lists of characteristics to classify representations of practice first individually, then reconciling differences collaboratively, following a constant comparison method (Strauss & Corbin, 1998).

Results

Characterizing Levels of Knowledge in Teacher-Created Representations of Practice

Our main result is a framework for characterizing levels of Foundation and Contingency knowledge in teacher-created representations of practice. This framework is shown in Figure 2. Codes from the second round of analysis, using the framework, are shown in Figure 3, along with those teachers' post-test scores.

In our full presentation, we illustrate characterizations of all four combinations of Foundation/Contingency (High/High, Low/High, High/Low, Low/Low) with teacher-created representations of practice in response to multiple prompts and discuss contrasts in knowledge observed in video and written representations of practice.

	FOUNDATION	CONTINGENCY
HIGH	Recognizes the logical necessity connecting the definition of a transformation to ways of constructing a transformation image *Examples:* ● Explains a method of construction by marking points on a preimage and then "applying the definition to each of the marked points" to obtain the image ● Reasons that an attempted image is incorrect by showing that it does not satisfy the transformation definition	Frames questions or explanations about connection between construction and definition in terms of students' thinking *Examples:* ● Directs attention to student work to understand the idea that all properties of the definition must be followed to produce a correct construction. ● Engages students in selecting locations in sample student work, and reasoning whether the definition is satisfied
LOW	Explicitly or implicitly treats the definition of a transformation as separate from constructing images, and/or demonstrates lack of understanding of definition *Examples:* ● Describes a method for constructing, and never mentions any definition. ● Provides incorrect definition	Does not integrate student thinking into explanation of connection between construction and definition *Examples:* ● Evaluates student work as "right" or "wrong"; does not cite work otherwise ● Provides a correct explanation that does not reference student work

Figure 3. Characterizations of knowledge observed in purposive sample, with GAST scores

In this paper, we illustrate two combinations of Foundation and Contingency knowledge (High/High, Low/High), using responses from one prompt. In this prompt, teachers were asked to write a narrative describing how they would "elicit student thinking about these reflections, with specific use of the two example students work, and move the class toward understanding connections between methods of reflection and the definition of reflection." The sample student work was shown previously in Figure 1. A class definition for reflection is given in Figure 4.

A reflection across a line L is a transformation that, for every point P in the plane: • $P' = P$ if P is on L • L is the perpendicular bisector of segment PP' if P is not on L.
Note: These materials teach prospective teachers the convention that P' refers to the image of a preimage P under the transformation discussed.

Figure 4. Version of class definition of reflection

Illustration 1: High Foundation-High Contingency

In our framework, the quality of Foundation knowledge is characterized by linking constructions to the definition, and the quality of Contingency knowledge is characterized by integrating student work into the work of connecting constructions and definitions. GMM302 was a representative case to illustrate High Foundation - High Contingency knowledge. GMM302 began their representation of practice:

> "To start, I would draw the student responses and our definition of Reflection on the board. [...] Pointing to the first response, [I would ask,] if we were to draw a line between the points P and the corresponding P's, what can we tell about the line segments made by P and P'? As students respond, I draw and make the corresponding changes to the figure on the board." (see Figure 5a).

Then, after describing some potential responses from students, GMM302 prompted students to link construction and definition: "What is it we know about our line of reflection in regard to our definition of reflection?" GMM302 then marked the angles (see Figure 5b), asked students questions to review the two defining properties of perpendicular bisectors (bisecting, and with perpendicular angles), and posed the question, "Since our main problem here is the angles, how might we approach this in a way that results in right angles instead?" Finally, after drawing a correct reflection (see Figure 5c) but without evaluating it as such to the students, GMM302 asked, "Looking at our new figure, does this hold true to the definition of a Reflection?" GMM302 concluded, after describing potential responses, "Yes, it does hold true. So, we know [segment] a' is the reflection of [segment] a across the given line." We characterized this response as High/High because GMM302 created tight connections from incorrect and correct images to the definition, positioned students to engage with these links, and did so while centering student work.

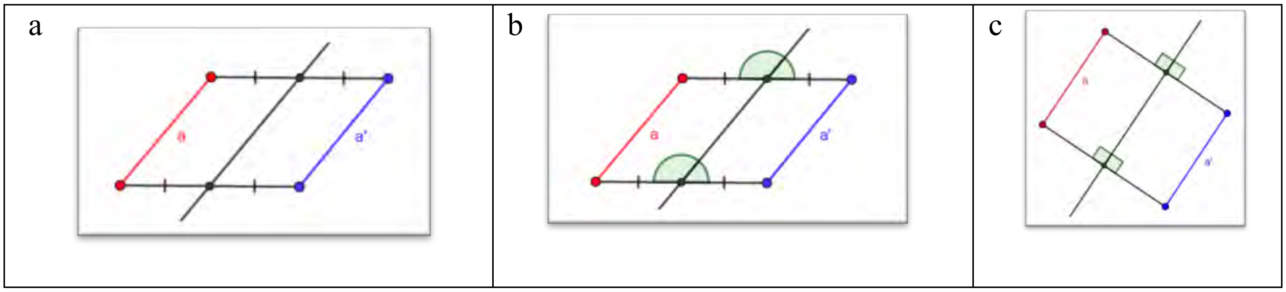

Figure 5. Board drawings proposed by GMM302 to link construction to definition

Illustration 2: Low Foundation-High Contingency

We chose participant GMM308 as a representative case to illustrate Low Foundation - High Contingency knowledge. GMM308 began their representation by analyzing the student work, and suggesting what may have been going on in the students' mind that led to these constructions.

> It looks as though they have drawn lines across the line of reflection from each point to the reflected point. I believe that they have thought that since it is reflected that the distance from the line of reflection is now opposite for each point (the point on top of the reflected image is the same distance as the point on the bottom of the pre-image and vice versa).

In this way, GMM308 exemplified the notion of interacting reflectively with student thinking (Thompson, 2000). GMM308 then described how the student work could be linked to the definition:

> I would use [Student 2's work] to discuss with students how this attending to some points of the definition, but not quite (sic). They have used the idea of the same distance from the line of reflection, but it was utilized incorrectly. I would use this to be able to discuss with students how this doesn't fully fit the definition of a reflection and how we can fix that. We would work as a class to improve the original reflection and make sure it fits all of the necessary components of the definition needed.

This representation of practice exemplified High Contingency knowledge because GMM308 identified how specific student work could be connected to the definition of reflection, especially the role of perpendicular bisectors. However, GMM308 did not articulate the reasoning about perpendicular bisectors precisely, and so we characterized the Foundation knowledge as Low. GMM308's analysis of Student 2's work was similar to their analysis of Student 1's work in that it did not articulate how precisely students might be able to determine whether an image and preimage could satisfy the definition of reflection.

Discussion

We analyzed teacher-created representations of practice in two rounds, resulting in a framework for observing Foundation and Contingency knowledge, characterizations of combinations of Foundation/Contingency levels, and the potential for comparing these characterizations to performance on an instrument previously validated to measure MKT. Previous research has identified dimensions of MKT (e.g., Rowland, 2013), conceptualized mathematical understanding (e.g., Simon, 2006), and unpacked teachers' actions to understand

and act on student thinking (e.g., Ader & Carlson, 2018; Thompson, 2000; Weston, 2013). These scholars grounded their work in videos of teaching and interviews. We synthesized previous research to contribute a framework for observing varying levels of different dimensions of MKT, applied to a pedagogy of teacher education, that of teacher-created representations of practice.

In evaluating the robustness of our framework, we consider the limitation of our data to four prompts for representations of practice in geometry, and the potential for our framework to generalize across domains. Our framework, as reported, is tailored to the use of definition to a particular concept of geometry, and derived from the analysis of a limited number of prompts. However, we see our framework as generalizable to mathematics more generally because of its underpinnings in the Knowledge Quartet (Rowland, 2013), mathematical understanding (Simon, 2006) and interacting reflectively (Thompson, 2000), all of which are intended to apply broadly to mathematics teaching and learning. Moreover, the centrality of definition to mathematics, as well as reasoning with definition or other assumptions (Kitcher, 1984), suggests the potential for adapting this framework to domains of mathematics with strongly structured logical systems, such as algebra. For instance, in place of linking definitions with construction methods, the framework could emphasize connecting definitions with common procedures or tests (e.g., ways to solve equations, vertical line test), and to what extent student thinking is centered in engaging with these procedures or tests. For domains such as mathematical modeling, which apply mathematics in phases of distinctive practices (e.g., Blum & Leiß, 2007), the framework could emphasize the rationale for each phase as well as anticipation of movement across phases, for instance, knowing that the proposal of a mathematical model can be followed by considering the real world or the results of the model, that that these phases can work together to refine one's model (e.g., Czocher, 2018).

We would be remiss to not issue caveats about the use of "levels" of knowledge. Most importantly, these characterizations, like other hierarchical characterizations in the literature (e.g., Ader & Carlson, 2018; Serbin et al., 2018), are not intended to be characterizations of teachers or their ultimate potential. Rather, we present these levels as descriptions of observable features of representations of practice that may be ultimately usable by teacher educators to guide formative feedback for prospective teachers. When the teacher educator is a mathematics faculty member, characterizing only an ideal may not be sufficient for helping that teacher educator articulate, for example, where a teacher might have involved student thinking more. A teacher educator could use the framework as a way to begin a dialogue with prospective teachers to support their growth. We believe that the risk of characterizing "levels" is outweighed by the potential benefit of supporting mathematics faculty members in seeing how to connect mathematics and teaching.

When we began this work, we had in mind conversations with mathematics faculty members as well as the research that indicates that mathematics faculty may want to connect mathematics and teaching, but do not know how. We also had in mind the mathematics faculty members that pilot our materials, which come in four domains: geometry, algebra, mathematical modeling, and statistics. We argue that attention to the dimensions of Foundation and Contingency are a fruitful framework for characterizing knowledge in teacher-created representations of practice. GMM308's representation of practice, and other examples of High/Low and Low/High combinations, illustrate that the dimensions of Foundation and Contingency can be viewed as separable, and therefore be distinct categories for feedback to teachers. Whereas Foundation knowledge might be a dimension that mathematics faculty find familiar, the Contingency dimension may be more foreign. We hypothesize that narrowing the scope of the unfamiliar to

Contingency, in the way that we have delimited it, may make it more accessible to mathematics faculty. If our hypothesis holds, then we will have a framework that can shape instruction and curriculum for mathematics content courses in many domains. Our future work involves testing the promise of this framework for building stronger connections between mathematics and teaching.

Acknowledgments

We are grateful to Lindsay Czap and Jenn Webster for scoring the pre- and post-tests, Cynthia Anhalt for generative discussion about the framework, and Catherine Callow-Heusser for advising us on sampling considerations. This research was partially funded by NSF #1726723 and #1726744.

There have been many efforts to measure pedagogical content knowledge with multiple-choice survey instruments, but little is known about how different types of items contribute. In this study, we examined interviews with 9 Grade 4 teachers to develop a deeper understanding of how teachers select pedagogical representations in the context of a survey assessment. Our analysis revealed two broad themes: representational justification (focused on how teachers interpreted features of the representation) and contextual justification (focused on how teachers considered their students and their own perspectives and experiences). These results indicated that content and pedagogical knowledge were highly intertwined in teachers' work on these tasks. However, the results also identify limitations for using this item type to measure teachers' pedagogical content knowledge in mathematics. Implications are discussed.

Keywords: Assessment, Elementary School Education, Mathematical Knowledge for Teaching, Rational Numbers.

In the time since Shulman (1986, 1987) first described pedagogical content knowledge (PCK) as an important part of the teacher knowledge base, the term has gain wide currency and accumulated a large body of scholarship. In mathematics education, perhaps even more than in other areas, concerted effort over the last two decades has been made to measure PCK and the related domain of mathematical knowledge for teaching (MKT) with survey instruments comprising multiple-choice items (Hill et al., 2005; Saderholm, et al., 2010).

Multiple choice teacher knowledge items are often written to measure specific categories within the domain of PCK or MKT, but the responses to a variety of different types of items all contribute to the same overall score on these instruments. Conceptualizations of teacher knowledge and psychometric results from several independent projects suggest that PCK and MKT are multidimensional constructs even though they have been measured primarily with unidimensional scales (Jacobson, 2017). Qualitative studies of teachers' written responses (Fauskanger, 2015) and teacher interviews (Lai & Jacobson, 2018) have revealed that teachers often draw on more than one category of knowledge when answering multiple-choice survey items. Even so, such items are still widely used because they provide an efficient means to assess teacher knowledge at scale.

MKT and PCK items often pair a specific mathematical topic with a pedagogical decision about that topic. Ball et al., (2008, p. 400) list 16 different "mathematical tasks of teaching" around which assessment items could be written such as, "evaluating mathematical explanations" and "modifying tasks to be easier or harder." Items on existing MKT and PCK instruments include a wide selection of these tasks of teaching, but little is known how well each type of task reflects teachers' knowledge. To investigate this issue, we designed a set of PCK items that share a single task of teaching: selecting pedagogical representations.

Theoretical Framework

In this study, we describe our efforts to use multiple choice survey items to efficiently assess teachers' knowledge of pedagogical representations, one of the two kinds of PCK described by Shulman (1986). Rather than framing our analysis in terms of PCK categories (and several different categorizations have been used in prior research), we ground our work with a foundational idea in one of Shulman's original articulations: PCK is an "amalgam of content and pedagogy", "the blending of content and pedagogy into an understanding of how particular topics, problems, or issues are organized, represented, and adapted to the diverse interests and abilities of learners" (1987, p. 8). This study is part of a larger project to design assessments of teachers' PCK and to link teachers' scores on these assessments to classroom teaching and student learning.

We focus on pedagogical representations because of their central importance in mathematics instruction. Mathematics is inaccessible by direct experience, hence, teaching and learning are necessarily mediated by representations (Bruner, 1966; Duval, 2006). Following Cai and Lester (2005), we make a distinction between solution representations used by problem solvers to make sense of a problem and communicate their solution to others and pedagogical representations which are "the representations teachers and students use in their classroom as carriers of knowledge and thinking tools" (p. 223). These two kinds of representations can overlap, but the critical difference is that teachers are uniquely responsible for curating the pedagogical representations available in their classrooms to ensure they are both mathematically accurate and comprehensible to learners (Cai & Lester, 2005; Leinhardt, 2001).

The dual nature of teachers' responsibility vis a vis pedagogical representation is aligned with the dual constituents of PCK understood as an amalgam of content and pedagogy. To select a mathematically accurate representation, teachers need to attend to the way features of the representation map to features of the problem situation and the underlying mathematical ideas. Content knowledge is implicated in this attention: for example, teachers must know to check that a representation which purports to show a fractional quantity is equally partitioned. Mathematical accuracy is necessary but insufficient. Teachers must apply their pedagogical knowledge to recognize which representations are unfamiliar or confusing for students and thus provide more hindrance than help. Teachers who coordinate their knowledge of content and pedagogy to select accurate, comprehensible pedagogical representations demonstrate PCK.

The research question which guided this study was, *To what extent do teachers' rationales for selecting a pedagogical representation reflect PCK versus other factors unrelated to PCK?*

Method

Item Design

We designed eight items (denoted Q1 – Q8) to assess Grade 4 teachers' proficiency in selecting pedagogical representations for fraction and decimal instruction. Each item consisted of a mathematics problem and two diagrams illustrating different pedagogical representations for the mathematics problem (see Figure 2). The mathematics problems were aligned with state standards for Grade 4 fraction and decimal topics. The pedagogical representations were based on interviews with teachers and teacher educators, a review of fraction and decimal literature in practitioner and research journals, and a review of student thinking and misconceptions with fraction and decimal topics. Teachers responded by indicating whether or not the representation in each diagram was useful for students who were learning to solve the problem (A, B, both, or neither).

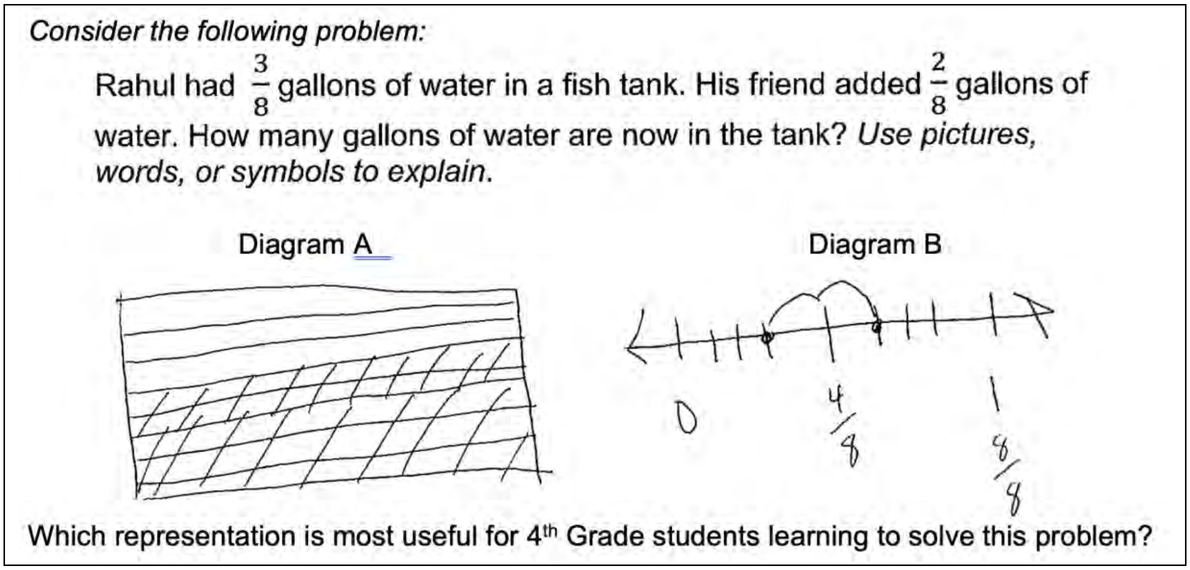

Figure 1. An example item for selecting pedagogical representations. Teachers could select A, B, both, or neither diagram.

The representations were designed with key features for teachers to notice that had either mathematical or pedagogical implications. All diagrams included representations of numbers in the problem, the solution, or both. The diagrams we intended teachers to endorse had representations that were both pedagogically warranted and mathematically accurate. Other diagrams that we intended teachers would not endorse included features that made them inaccurate or unclear.

We included one or more key features to make representations inaccurate. One inaccurate feature was using a representation that had a different sized whole for two fractions in a problem that were supposed to be commensurate. Another inaccurate feature had to do with the problem-representation alignment and focused on teachers' ability to distinguish between semantic equivalence of a problem and representation which can influence children's comprehension and the mathematical equivalence that an adult (but not a child) might use to solve a problem. For example, students would likely struggle to recognize a word problem describing 36 copies of 1/8 in a representation show 36 shared equally into eight groups, although an adult might use 36/6 as a way to compute 36 x 18. The third inaccurate feature was mathematical errors. For example, in one diagram we made a representation with a circle partitioned into non-congruent sections.

We also included key features to make diagrams unclear. (Although inaccurate representations are also unclear, here we describe features that are accurate but unclear.) One feature of unclear diagrams were representations that displayed the result instead of showing the process. For example, one unclear representation for a fraction comparison was an open number line with correctly labeled points but without any benchmarks or regular partitions by which order could be found. Another unclear feature was the alignment between the representation and common solution strategies students might use. For example, students often use a think addition strategy to solve change unknown subtraction problems. Teachers selecting a representation for a subtraction problem who were unaware of this strategy might inappropriately reject a representation that apparently showed addition. The third unclear feature was whether the representation illuminated or obscured a primary learning goal of the problem. Considering students who are learning how to add fractions with different denominators, a representation that already shows common denominators is less clear than a representation that also shows the original fractions.

Data Collection and Sample

Nine Grade 4 teachers (all White females), were selected from an economically and geographically diverse set of schools in a Midwestern State to complete a think-aloud item response interview. Teachers were in 7 different elementary schools across 5 different counties. Student eligibility for free or reduced lunch in these schools ranged from 8% to 85%, and enrollments of White students ranged from 64% to 98% across schools. Rates of students scoring at or above "proficient" levels on state mathematics tests ranged from 40% to 79% across the schools, with state school rankings ranging from the bottom 50% to the top 10%. This sample provided an opportunity to study the scope of teachers' thinking across a wide range of schooling contexts. Pseudonyms were used to report results.

Teachers answered the items and justified their representation selection. All interviews were video-recorded and transcribed. Because we limited interviews to 90 minutes and teachers varied in the time it took to discuss each item, not every teacher answered every item. Two teachers answered all 8 items, four answered 7 items, one answered 6 items, and two answered 5 items. In all, there were 60 item responses across all teachers. We used the selection (non/endorsement) and justification for each diagram (two diagrams per item per teacher) as the unit of analysis for this study. Thus, the size of the analytic sample was 120 diagram responses and the corresponding justifications.

Data Analysis

We first summarized teachers' responses and justifications with direct quotes (e.g., Vicky did not endorse Q1, Diagram 2 (a number line) because, "they [students] don't think about physical placement on the [number] line."). Then we conducted an inductive thematic analysis to analyze patterns in teachers' justifications, by reading the summaries and developing an initial codebook (Boyatzis, 1998; Rice & Ezzy, 1999). We then modified the codebook to remove ambiguities and overlapping codes. Two authors used a new codebook to iterate the code-reconcile-modify cycle until they arrived at a consensus on all codes. Once the codes were finalized, we reviewed each group separately considering to what extent the responses illustrated content knowledge, pedagogical knowledge, or an amalgam of the two.

Findings

Our analysis revealed two broad themes in teachers' response justifications: (1) some teachers based their justifications on the key features of the representation (as we had intended) and (2) some teachers based their justifications on contextual factors that teachers supplied from their own knowledge of students, the curriculum, and from their teaching experience. Among the 120 responses, responses were as likely to be justified based on features of the representation (*representational justification*; 56/120) as they were to be justified by non-diagrammatic concerns (*contextual justification*; 55/120). The themes were not strictly exclusive: 9 responses included both representational and contextual justifications. On some responses (18/120), teachers did not provide justification.

Representational Justification

Three subthemes emerged from the analysis of teachers' representational justifications. Teachers *interpreted key features*, *attended to some key features* of the diagram (while overlooking others), or *misinterpreted key features*.

Interpreted key features. In this subtheme, teachers noticed the key features of the representation and they endorsed (or did not endorse) a representation as pedagogically useful because of the mathematical or the pedagogical affordance of the representation in light of these key features (n = 41).

We considered teachers' interpretation reasonable if they noticed the key features and provided an explicit, coherent justification to support their non/endorsement of a specific diagram. For example, Sarah justified why Diagram 2 in Q1 was not useful by observing that:
Although the number line is a good measurement, you have no benchmark. The number line is very abstract for them [students] to say this is 3/8 without benchmarks such as one and a half. When denominators are different, the number line with benchmarks is still hard.
In this example, Sarah noticed that the number line did not have benchmarks, something we left out intentionally to make the representation unclear. (Note that this teacher also comments on student difficulty in her response, an example of contextual justification which is discussed in the next section.)

Similarly, Amy asserted that Diagram 2 in Q4 was not useful "because some of the kids are going to count the number of coins, not the value of coins". Another teacher, Vicky, said "Well, some of them might see so many pennies and say that [pennies] must be more than that [dimes]." We chose to use coins because values in this kind of representation are based on convention instead of an observable quantity like count, length, or area. This key feature makes the representation unclear for some students because it obscures a primary learning goal of the problem: the relationship between tenths and hundredths. These teachers closely attended to the key features of the representations and used these features to justify their non/endorsement of the representations.

Attended to some key features. In this subtheme, teachers paid attention to some key features of the representations while overlooking others (n = 12). For example, in Q1, Rose noticed that both diagrams (bar model and number line model) showed how large a fraction is compared to one whole: "We can see that 3/¾s getting closer to one whole on the number line..Ind of like a bar graph"; however, this teacher overlooked the absence of benchmarks on the number line. This situation also occurred when teachers endorsed mathematically inaccurate diagrams. For example, a set model representation in Q5 incorrectly added denominators, and both Brooke and Molly apparently overlooked this feature while asserting that this diagram would be useful for students.

Misinterpreted key features. This subtheme captured responses of teachers who noticed the key feature of the diagram but interpreted them incorrectly (n = 3). This code was prevalent for Q2, Q3, and Q5 because one of the options was designed to be mathematically inaccurate. For example, three teachers (Megan, Vicky, and Cathy) asserted the usefulness of a non-equipartitioned circle model (Q3, Diagram 1). Vicky said students "would be able to figure it out pretty easily and tell." Megan reasoned: "With the circle graph, that might give a little trouble…but I think they could see that this is a fourth out and this is a fourth out." Teachers noticed the representational feature but still considered the diagram to be useful for their students despite its inaccuracy.

Overall, responses in this category illustrated the potential for this kind of teacher knowledge task (selecting pedagogical representations) to assess teacher knowledge for using representations. Teachers who interpreted key features of the representations demonstrated pedagogical content knowledge whereas teachers of overlooked or misinterpreted key features did not.

Contextual Justification

The theme of contextual justification includes reasoning that influenced teachers' responses but had less to do with the features of the representations than with the teachers' own context and professional experience. Four subthemes emerged within the theme of contextual justifications: students' familiarity, students' competence, teachers' competence, and teachers' preference.

Students' familiarity. These non/endorsement responses were justified based on teachers' knowledge of students' familiarity with the representation (n = 30). Teachers used phrased like "used to", "have seen", or are "familiar with" while stating that their students' had a high degree or lack of familiarity with a representation. They used phrases like "never used" or "[they] haven'tcused those much" to indicate students' low degree of familiarity with a particular representation. In general, this category was not correlated with identifying inaccurate or unclear representations because key features were used to modify both frequently used (e.g., hundred grid) and less-frequently used representations (e.g., abacus) when we designed the items.

Students' Competence. Some teachers justified their diagram selection by anticipating students' competence (n = 13). Teachers justified their non-endorsement with statements, like, "They [students] don't think about physical placement on the line"," "number lines are very, very difficult for my fourth graders"," "even though Diagram 2 showed the whole, kids might not understand the pictures unless an explanation was given" and "the diagrams had too many things going on, which might be confusing to some students." sometimes, teachers selected a diagram over another by anticipating which one would be easier for their students (e.g., Laura chose Diagram 1 in Q7, stating "it might be easier to use [than Diagram 2]".)

Sometimes, teachers who were focused on students' competence seemed to neglect the pedagogical value of some representations that might be challenging to use, such as number lines. At other times, the anticipation of student struggle was associated with an unclear or inaccurate representation, and we could not determine whether these teachers may have had some tacit understanding of the problematic features of these representations. On the other hand, from our position as teacher educators, we found this stance towards selecting pedagogical representations concerning because it may lead to a classroom experience with only a very limited set of mathematical representations. Endorsements based on students' competence were weakly correlated with identifying inaccurate or unclear representations, and therefore can be taken as an indication of pedagogical content knowledge.

Teachers' competence. Teachers sometimes used their own anticipated competence with the representation to justify their selection (n = 7). In a typical example, Cathy explained why the abacus in Q6 would not be useful by stating "That one confuses me so I wouldn't even know how to explain it to my kids." Teachers also used phrases like "a little harder [for me] to understand" to explain why they thought the representation would not help their students.

Teachers' preference. A small number of teachers justified their selection based on their personal preference (n = 5). Teachers made statements such as "I like number line(s)" (Brooke, Q1) or "I am a fan of rectangle diagram(s)" (Sarah, Q1), usually without offering a rationale based on specific features of the representation. Only one teacher (Rose) justified their preferences based on the features of the diagram. Rose preferred Diagram 1 on Q2 because the zoomed-in portion of the number line representation allowed students to "see not only are tenths smaller than one but then each tenth is also broken down into smaller and smaller pieces." She continued "I haven't used this [number line with zoomed-in portion], but I like this." The teachers who made choices based on either their sense of competence or their preference often overlooked problematic key features, suggesting that both of the last two subthemes illustrate reasoning which was associated with a lack of pedagogical content knowledge.

Discussion

In this study, we examined interviews with nine Grade 4 teachers to understand how teachers select pedagogical representations in the context of a survey assessment. Our unit of analysis—a teacher's endorsement and justification of one diagram for one mathematical problem—provided a fine-grained tool to examine patterns in the variability across teachers and items. We present results that summarize 120 justification responses into two main themes with seven subthemes. These themes emerged from our analysis provide a comprehensive description of how teachers justified their decisions about the usefulness of specific pedagogical representations for particular mathematical problems.

Early in the analysis, we expected that responses involving representational justifications would provide opportunities for us to consider how content knowledge was used to select pedagogical representations, and that responses involving contextual justifications would help us understand how pedagogical knowledge was used. However, content and pedagogical knowledge were more intertwined in our data. As the example of dimes and pennies illustrates (Q4, Diagram 2), the largest subtheme—interpreted key features—involved some teachers who had made a sound, pedagogically-informed justifications for key features of representations which we had designed to be problematic. Similarly, contextual justifications sometimes provided information about teachers' content knowledge; the teacher who liked the zoomed-in number line representation did so because she saw how features of the representation mapped to important ideas about the content. These findings suggest that selecting pedagogical representations is an item type is well suited to engage teachers in reasoning that draws on pedagogical content knowledge.

This study offers researchers useful insights for developing and validating assessments of teachers' 'CK for selecting representations. For the most part, the interviews provided information about teachers' PCK that was aligned with what we would have inferred from their representation selection. However, the responses also illustrate the variety of reasoning that teachers used to justify their selection of pedagogical representations, including some justifications that were based on inaccurate mathematical thinking and inadequate pedagogical knowledge. An even larger number of responses were based on the teachers' personal experience and context, factors that are not related directly to the pedagogical content knowledge we aimed to assess.

The prevalence of justifications based on teachers' context and professional experience when selecting pedagogical representations is an important discovery because it highlights factors that are consequential to teachers' responses but are beyond the scope of survey item design. Every teacher sees the same text and inscriptions of an item, but these data reveal how the different experiences they have had with students, curriculum and their professional training provide a lens through which they interpret the task and their own response.

In practice, the best instructional decision when selecting a pedagogical representation will always depends on the context. A teacher with high knowledge may be able to use a new representation effectively, whereas a teacher with low knowledge may not be able to use a new representation without training. In such cases, it would be better for students to experience a familiar representation with mathematical accuracy than have the content misrepresented because of an unfamiliar representation. Even knowledgeable teachers' must balance the trade-off between the time and effort of investing in a representation that is unfamiliar to students and whatever pedagogical gains they anticipate once students have adopted the new representation. If the focus is on a new mathematical idea, then a familiar representation will help support student understanding, whereas an unfamiliar representation may impede students understanding by putting students in the position of needing to learn both the new mathematical idea and a new kind of literacy required to write and read with the new representation.

Can multiple choice survey items be designed that support valid inferences about teachers' PCK for selecting representations even though teachers' personal experience and context are equally salient as the key features of the representations in question? The responses that were justified by teacher's preference do not present a problem for this goal because they were generally aligned with low PCK. However, the remaining subthemes of contextual justification are all problematic to some degree. Responses based on the student competence subtheme are the least problematic, because these responses sometimes reflect PCK. On the other hand, these responses seem to come from a stance toward teaching and learning we find concerning because it might limit students' education experiences. Responses based on student familiarity—by far the most frequent contextual justification—are the most problematic, because these responses would reduce the accuracy of each item by adding noise to the signal. Noisy instruments are inefficient and must have more items to reach an acceptable level of reliability. If the noise could be mitigated through careful item design, it might be possible to build a trustworthy instrument to measure PCK for selecting representations. Addressing the important question of whether such a difficult task is possible is beyond the scope of this paper and will certainly require additional empirical work which we have begun to undertake.

The contribution of this study is to illuminate teachers' reasoning across a set of multiple choice teacher knowledge items of the same type: selecting pedagogical representations. Without a set of items with the same design focused on the same pedagogical decision and varying only in content (i.e., the mathematics problem, the representations, the key features), we could not have drawn generalizations about how teachers' reason about this type of item. In prior work, a PCK or MKT instrument might have had one or two items of this type among 20 to 30 items on an instrument, and interviews with teachers (e.g., Fauskanger, 2015) across a diverse set of items would not have supported the kind of discoveries we report about the range of teacher reasoning on a single type of question. We expect that there are important affordances and limitations of many other types of MKT and PCK items commonly in use that are not known because they have not been adequately investigated.

The data we have presented is drawn from a small qualitative study. The present study is focused on better understanding how teachers select pedagogical representations, and whether inferences about teacher knowledge can be drawn from multiple choice surveys about representation selection. The larger project engages in similar work for three additional kinds of pedagogical decisions. Further work is ongoing to examine whether these themes generalize to an independent sample of 40 preservice and inservice teachers.

EXPLORING THE PEDAGOGICAL CONTENT KNOWLEDGE FOR TEACHING FRACTIONS BETWEEN TWO IRANIAN EXPERIENCED TEACHERS

Maryam Zolfaghari
Kent State University
mzolfagh@kent.edu

Teachers' knowledge of teaching fractions and their ability to teach such a challenging topic plays an essential role in children's learning fractions. While some scholars have investigated teachers' pedagogical content knowledge for teaching (PCK) fractions, there is less attention on how PCK for fractions is operationalized by teachers of different nationalities. This study reports on initial efforts to understand how PCK for fractions operates between two expert teachers from Iran. Findings from interviewing these teachers suggests that the pedagogical reasoning of both teachers in confronting PCK-Fractions scenarios is similar. The implications of the commonalities in teachers' PCK-Fractions reasoning are discussed in the paper.

Keywords: Teacher knowledge, Rational Numbers & Proportional Reasoning

Teaching involves a set of highly professionalized skills. To acquire such skills, a teacher needs, among other things, to have sufficient content knowledge as well as the ability to apply such knowledge to students. Shulman (1986) named this intersection of teachers' subject knowledge and pedagogical knowledge as Pedagogical Content Knowledge (PCK). The PCK is the skill that teachers use to transfer the subject matter knowledge to facilitate student learning. Built on Shulman's notion of PCK, researchers have developed frameworks for it in different areas such as science (Van Driel et al., 1997; Halim & Meerah, 2002), literacy (Love, 2009), and physical education (Ayvazo & Ward, 2011). In their learning mathematics for teaching (LMT) project, Ball, Hill and others applied Shulman's construct into mathematics and created mathematical knowledge of teaching (MKT) framework (Ball et al., 2008; Hill et al., 2008).

Several studies have investigated the nature of teachers' understanding of students' reasoning. For instance, Peng and Lou (2009) examined the nature of mathematical misconceptions from both students' and teachers' perspectives. They found that teachers usually were able to identify students' errors, but they had difficulty interpreting the rationale underlying those errors. Sorto et al. (2014) investigated teachers' difficulty explaining students' reasonings and found that teachers mostly used a procedural explanation for interpreting students thinking and analyzing learners' errors. Rather, teachers are aware of students' errors in solving problems, but they usually fail to reason about those errors conceptually. Prediger (2010) called this ability to understand students' thinking a diagnostic competence. He explained that: "This notion is used for conceptualizing a teacher's competence to analyze and understand student thinking and learning processes without immediately grading them." (Prediger, 2010, p. 76)

Teachers' conceptual understanding of students' mathematical reasonings influences their classroom instructions and thus students' learning (Cai et al., 2016). Such conceptual understanding intertwines within other aspects of norms, culture, experience, knowledge of subject, and the whole instructional situation that a teacher lives in it (Herbst and Chazan, 2011). In order to have a more in-depth insight into how teachers understand students' reasoning, it is important to see how those elements integrate with teachers' interpretations (e.g., if any at all, they use the norms or their culture to interpret students' reasoning).

Given the importance of instructional situations, specifically the role of instructional and cultural norms in how teachers interpret students' reasoning and the importance of being familiar with the teacher's culture, this study aims to understand how experienced Iranian teachers understand students' reasonings of fractions. Therefore, in this exploratory study, I am addressing the following research question: How do experienced Iranian teachers understand students' misconceptions of fractions?

Method

For this exploratory study, two expert teachers participated from Iran. Iran has a centralized educational system. All K-12 educational textbooks are produced and published by the Ministry of Education. Therefore, all teachers across the country use the same textbooks as their main source of teaching the content. However, teachers are able decide on any text as supplementary material. The two participants, Dorsa and Roya, (pseudonyms) had experience teaching at upper-grade elementary schools for more than ten years. Both had experience teaching at upper-grade elementary schools for more than ten years.

The cognitive interview was selected as a technique of interviewing for this study. Both teachers were asked to read each scenario, then interpret each scenario, and lastly explain their rationale for their response to each item. For the interview, I used tasks of teaching, in the form of test items, from a PCK measure for fractions that were tested for content validity and reliability measures (Zolfaghari et al., in review). Each interview includes twelve scenarios: seven multiple-choice items and five multiple-response items. The items for the interview were adopted from a PCK measure for fractions. Initially, twenty questions were developed for the PCK measure for a pilot study (Zolfaghari et al., 2019). Considering the Iranian primary school knowledge and based on my knowledge of teaching mathematics in Iran, I finally selected 12 questions of the PCK measure and translated in Persian.

Analysis and Findings

Constant comparative analysis (CCM) was used to analyze the data (Lincoln & Guba, 1985). CCM is one of the qualitative analysis techniques that rely upon the systematic coding of the interview data alongside analyzing those codes to create a theoretical framework based on emergent themes (Ridolfo & Schoua-Glusberg, 2011). Guidelines provided by Ridolfo and Schoua-Glusberg (2011) were applied to analyze the cognitive interview data for this study.

The analysis began with line-by-line coding of the transcripts for all four interviews, considering the question in mind: how did the respondents answer to each PCK scenario interact with their backgrounds and culture? The findings' codes were organized to identify the analytic themes as well as the thematic categories that make up each theme.

Open coding

During the cognitive interview, I investigated the initial interpretation of teachers' responses to each PCK scenario. Respondents were probed on how they answer each 15 designed PCK scenarios and their explanation and rationale for their answers regarding their background (e.g., what item they think is the answer and why they select that item). While reviewing the transcripts, several key terms and notes were found. Interestingly, both teachers frequently use similar notes to answer each of the PCK scenarios. Those notes merge into several categories, including their reactions to atypical' strategies, their answers aligned with the intended answer, using self-experiences, citing books or curriculum, explicitly using correct/incorrect in their responses, explained their preferred strategies, showing interests in students' 'olutions. After gathering the above information from the transcripts, I used axial coding to refine those notes and clustered them to resolve any discrepancies among those categories and noticed the similarities (Ridolfo & Schoua-Glusberg, 2011).

Axial coding

Based on reviewing the initial codes, four categories emerged including: 1. Different attitudes toward atypical strategies, 2. Considering pieces of student's solution, 3. Methods of teaching fractions operations, 4. Referring to prior experience and textbooks. Following, I provide examples of how the teachers' answers were placed in those three categories.

The first category emerged because in some scenarios, the students' strategies was so atypical and made it difficult for both experienced teachers to interpret them. Such difficulty in interpreting students' strategies leaded the teachers to make opposed decision on either to accept them as or reject the entire strategy. For instance, when Roya was confronted on a scenario in which a student divided 12 circles into 4 groups to get 2/3 of 12, she admitted that the students' answer was right, however, she didn't accept it as "truly" correct because the strategy was not as clear and typical. In contrast, the other teacher admired a student's strategy and called it "smart work" and accepted it as a truly correct answer (see table 1 for teachers' quote to a scenario).

Table 1: Category #1[Different attitude toward atypical strategies]

	Dorsa' Quote	Roya's Quote
 **Four students were asked to shade 2/3 of 12 circles. Each student represented their answer differently. For each representation, select the best assessment.** Student uses whole number reasoning in a fraction context. / Student recognizes only familiar pictures of fractions. / Student correctly partitions the visual into equals part. II ① ② ③	"Wait, what did he do? …. oh, he divided into three, then colored two of each group. It is smart work. Nice.I am going to say he did his work accurately"	"he got the correct answer which would fit to what question asked, but his strategy is not. We always (in classroom) tell our students that for such problems they need to first divide the circles into three sections, then all the colored circles should be in a group and uncolored in another part. His representation of partitioning has problem."

The second category included when teachers considered a piece of students' 'nswers and interpret the entire strategy based on it. For instance, in the example shown in Table 2: the student used the strategy of regrouping to subtract a mixed number from a fraction, however, she did it inaccurately and get $3\frac{1}{7}$ instead of $3\frac{8}{7}$ and get the incorrect answer as a result. In examining her work, Roya interpreted the student's regrouping as a negligible mistake and said, "b"cause the hardest part of these scenario is knowing [that] there is a need to do regrouping and I think the student know it [how to regroup] … the computation is the student's problem… she just forgets to add a 1 part to the whole". This consideration of a partially correct solution was not always in favor of students and sometimes teachers ignored the correct piece of students' 'olution and rejected the whole of it (See table 2).

Table 2: Category #2 [Considering piece of student's solution]

	Dorsa' Quote	Roya's Quote
 **Julie was given the following problem:** $4\frac{1}{7}-\frac{3}{7}$ **Her work is shown below.** **Which statement(s) below appropriately describes Julie's reasoning?** *Select all that apply* ☐ Julie understands the need to regroup when subtracting certain mixed numbe and fractions. ☐ Julie understands how to regroup mixed numbers to include improper fractio ☐ Julie understands how to subtract two fractions with like denominators. ☐ Julie understands how to subtract two improper fractions.	"I can't tell if she understands to subtract two fractions, because she couldn't get the correct answer"	"and I think the student knows it [how to regroup] … she just forgets to add one part to the whole"

The third category included the teacher's approach of doing fractions operations. In PCK scenarios related to fractions operations (e.g., addition, subtraction, etc.), teachers used the expected norms of doing fractions operation.

Table 3: Category #3 [Method of teaching fractions operations]

	Dorsa' Quote	Roya's Quote
Ms. Weasley asked Wesley to tell her which two of these fractions is the smallest? $\frac{6}{7}$ or $\frac{7}{8}$? Wesley answered: They are equal because there is one piece missing $\frac{6}{7}$ and one piece missing from $\frac{7}{8}$. **Based on Wesley's answer, what is the best assessment of his reasoning?** ① Wesley is not considering the relative size of the two wholes. ② Wesley is not considering the relative size of the fractional pieces. ③ Wesley is not considering the relative size of either the parts or the wholes. ④ None of the above.	"nor nominators, neither denominators are not similar to each other…" then Dorsa started to mentally calculate the common denominator."	"even, as the boy said, one pieces missing… [as we know the rule textbook] if two nominators are same, then the fraction with smaller denominator is bigger"

The last category contains moments in which both teachers refer students' reasonings to their experiences or the textbooks. For instance, in a scenario that a student mistakenly wrote fourth in a denominator to change four to the fraction ($4 - \frac{6}{8} \ldots \frac{4}{4} - \frac{6}{8}$). Dorsa sighed and stated: "this is a common mistake that you would see every year.

Selective coding

Based on evidence from the above two steps, the unifying link between all patterns and categories was identified. The findings show the commonalities between teacher's approaches toward students' reasonings. In fact, both teachers used the same approach while they confront a same scenario. Interestingly, using the same approach of examining scenarios was independent from teachers' final decisions toward students' understanding of the concept. For instance, in a scenario of subtracting an improper fraction (see table 2), both experienced teachers used the same approach of *considering part of student's reasoning* to analyze student's reasoning. However, their decision in whether student understand the regrouping or not was different. Such commonalities observed across all themes within PCK scenarios. Indeed, both teachers used the same norm of reasonings while they interact with a similar situation. The norm that is defined as part of the instructional situation (Herbst and Chazan, 2011).

Conclusion

This study provides information about how two expert Iranian teachers interpret PCK fractions scenarios. The findings suggest the similarities across both teachers' approaches in terms of interpreting students' reasonings. Prior studies suggested the process of understanding students' misconceptions, interpreting and engaging to those misconceptions as the steps of teachers' work with students' reasoning (Peng & Luo, 2009; Prediger, 2010). This study provides evidence of some commonalities with teachers' approach to interpreting students' reasonings. Teachers' PCK has different aspects that are bounded by the schools' environment, culture, and other elements; however, some elements of the pedagogy aspect of teaching are common across teachers. Such similarities can play an important impact on PCK constructions. Future research is needed to compare more experienced teachers with more diverse nationalities.

TEACHERS' KNOWLEDGE RESOURCES FOR SOLVING PROPORTIONS

Chandra Hawley Orrill
University of Massachusetts Dartmouth
corrill@umassd.edu

Rachael Eriksen Brown
Pennsylvania State University Abington
reb37@psu.edu

In this report, we consider whether there are differences in the fine-grained understandings teachers use to reason about proportional situations. To examine these differences, we divided a group of 32 teachers into one of three groups based on their performance on the Proportional Reasoning LMT assessment. Then, we used a knowledge in pieces lens to analyze the teachers' performance on a series of proportional reasoning tasks. Based on that analysis, we were able to use Epistemic Network Analysis to determine which knowledge resources were most commonly connected for the groups of teachers. Implications for teacher development will be discussed.

Keywords: Teacher Knowledge; Rational Numbers & Proportional Reasoning, Cognition

Purpose of the Study

Proportional reasoning is a critical mathematical concept as evidenced by its status as a strand unto itself in the Common Core (National Governors Association & Council of Chief State School Officers, 2010). Despite this importance, students struggle with proportions (e.g., De Bock et al., 2002; Modestou & Gagatsis 2007) as do their teachers (e.g., Izsák & Jacobson 2017; Orrill & Brown, 2012). In this inquiry, we wanted to move beyond identifying whether teachers are able to solve proportions to understand what knowledge resources might be important for them to use in such solutions. To this end, we used the Learning Mathematics for Teaching Survey for Proportional Reasoning (LMT, 2007) as a proxy measure for teachers' proportional reasoning knowledge. We then divided the participants into three groups based on their LMT scores and examined each group's use of knowledge resources on a different collection of proportional reasoning items. We were interested in seeing whether there were differences in the knowledge resources used by teachers to solve proportion items based on their ability as measured by the LMT. Thus, our exploratory research question was: Are there different patterns of use in the proportional reasoning knowledge resources teachers used based on their LMT scores?

Theoretical Framework

This work relies on Knowledge in Pieces (KiP; diSessa, 2016; diSessa, Sherin, & Levin, 2006). KiP is a conceptual change theory that posits that knowledge exists as fine-grained understandings that work together *in situ* to allow people to make sense of their world. From this perspective, knowledge is comprised of pieces that are connected in a variety of different ways that allow them to be called upon for any given situation. Learning can occur through the development of new fine-grained understandings, refinements of existing understandings, or building connections between understandings, which allows that knowledge to be more readily accessed. KiP has a commonality with research on expertise in that both support the notion that expertise not only implies a person has more knowledge resources, but also that the ways in which those resources are connected differs from novices. Thus, attending to the connections between knowledge resources may be a useful way to understand teachers' knowledge.

In order to see the connections between knowledge resources, we rely on Epistemic Network Analysis (ENA; Shaffer et al., 2009). ENA is an analytical approach that focuses on the connections between knowledge resources. ENA presents a visual mapping of the knowledge resources that are used in connection with other resources along with information about the strength of that connection, as denoted by the thickness of the line, and the relative frequency of the use of each individual knowledge resource, as denoted by the size of the node.

Methods

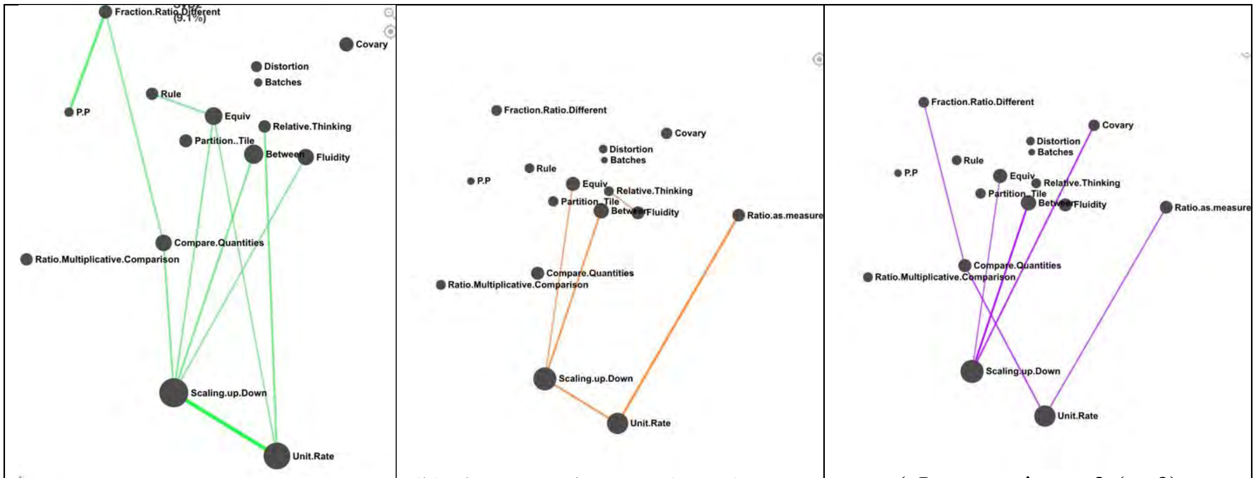
We consider a convenience sample of 32 middle grades mathematics teachers from four states. The participants ranged from one to 26 years of experience. Eight participants identified as male.

Participants completed two task-based interviews. One interview was completed using a LiveScribe pen, which recorded markings on the paper as well as participants' spoken words. The other interview was a 90-minute video-recorded clinical interview. Tasks asked participants to make sense of student work or other teacher's mathematical observations as well as to solve novel proportional situations. Both interviews were transcribed verbatim and analyzed by at least two members of the research team. Each utterance was coded for the presence of knowledge resources in participants' reasoning based on a set of 26 codes for teaching proportional reasoning (Weiland et. al, 2020). For this analysis, we focused on subsets of the codes to help us better understand how the teachers were reasoning.

Using ENA (https://www.epistemicnetwork.org/), equiload graphs were generated showing the ways in which participants used two or more knowledge resources together. The equiload graphs show each knowledge resource as a node. The lines connecting the nodes indicate that two resources were used in the same utterance at least two times. Thicker lines indicate more co-occurrences of resources. Using ENA, the mean of a participant's equiload is used to place that participant in the space generated by ENA. Participants are located within the field of codes based on the relative frequency of co-occurrences between codes. All of the equiload graphs in this paper represent the average equiload for the group of participants, rather than one single participant.

Findings

To understand how teachers reasoned about the proportional reasoning items, we first considered the teachers' use of the full set of knowledge resources we had identified for reasoning about proportional situations (see Weiland et. al, 2020 for more information). To determine whether there were differences in patterns among our participants, we grouped them into three groups: those who scored below 0 on the LMT (n=3), those who scored above 0 but less than 2 on the LMT (n=20), and those who scored above 2 (n=9). We then used the ENA tool to plot the group "average" interactions for each of these groups using only 16 codes that were related to proportional reasoning knowledge resources. These included structural codes, such as attending to the between measure space relationship, as well as codes more focused on solving proportions such as applying a rule. Based on that analysis, we were able to generate the equiloads shown in Figure 1.



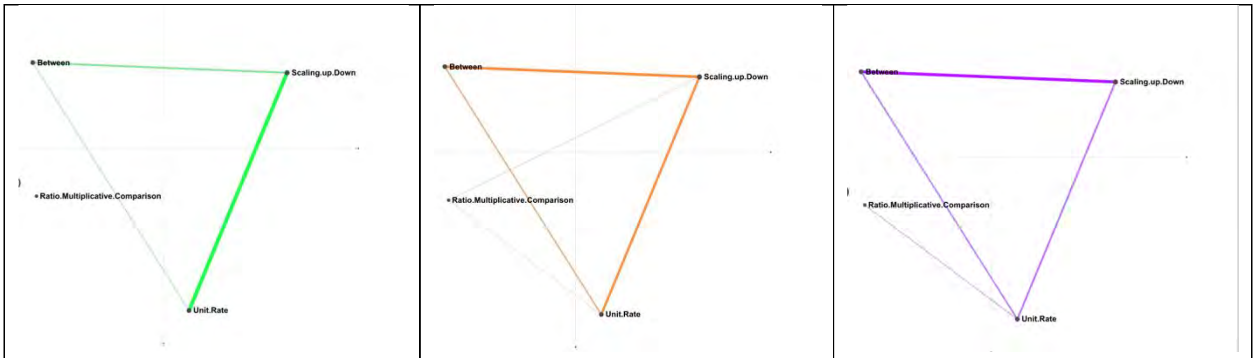
Those scoring < 0 (n=3) (b)Those scoring 0-2 (n=20) (cIose scoring > 2 (n=9)

Figure 1. Equiloads of 16 proportional reasoning knowledge resources for each group of participants.

These ENA maps show considerable differences in the knowledge resources that were used in combination by the different groups. The two lower-scoring groups, for example, often used scaling up and down (that is, applying a scalar to find an equivalent ratio) and using unit rate together to solve tasks. However, in the highest-scoring group, that connection was no longer a factor. Instead, the teachers in the highest group tended to group scaling ideas with equivalence, between measure space reasoning, and covariation. This suggests a strong attention to structural characteristics rather than different solution paths. A second difference we noted between these groups was that the lowest-scoring participants used more combinations of knowledge resources (as seen in connecting lines) as compared to both stronger-scoring groups. Our hypothesis is lower-scoring teachers have many of the same knowledge resources as higher-scoring teachers; however, they may have not developed as many connections between and among those knowledge resources. Therefore, they may not see the commonalities between tasks to cue the use of particular resources. That is, stronger teachers have more organized, and therefore more accessible, knowledge resources.

Because we noticed differences between the three groups of teachers and particularly noted the interaction between unit rate reasoning and scaling, we wondered how different the groups might look if we focused only on a small number of knowledge resources focused on key structures for proportions. To this end, we narrowed the codes for which we were analyzing to 4: unit rate, using multiplicative comparisons, scaling up and down, and reasoning about the between measure space relationship. We selected these four because they get at the heart of proportional relationships: the constant of proportionality, the invariant nature of proportions, and the multiplicative nature of proportions.

In this analysis (see Figure 2), there is an interesting progression in which the lowest-scoring participants again show a strong reliance on using unit rate and scaling up and down together. In the middle group, we saw our first signs of attention to the multiplicative relationship. That group also started to place more emphasis on the relationship of between measure space reasoning and scaling up and down, which suggests attending to both the constant of proportionality (the between measure space constant) and the maintaining of equivalence through using a scale factor. Finally, in the highest-scoring group, the co-occurrence of multiplicative reasoning and unit rate becomes stronger and the connection of between measure space and scaling up and down becomes more dominant (meaning these participants used both resources to solve tasks more frequently).



(a) Those scoring < 0 (n=3)	(b)Those scoring 0-2 (n=20)	(cIose scoring > 2 (n=9)

Figure 2. Equiloads of 4 key structural knowledge resources for each group of teachers

Implications

This study is important because it starts to unpack teacher content knowledge in ways that highlight differences among the ways in which teachers reason about proportions. This begins to uncover differences between teachers who have various levels of success with the LMT that could be addressed in professional development. For example, the findings in Figure 2 strongly suggest that more focus on reasoning about proportions in multiplicative ways would be a fruitful approach for all teachers in professional development. Similarly, this analysis demonstrates that all teachers have a strong set of knowledge resources as shown in Figure 1, but that they draw on them in different combinations. By understanding these combinations, we can create tasks that help teachers further develop their connections between knowledge resources in productive ways that highlight the structure of proportional relationships.

THE PARAMETER IN TEXTBOOKS A DOCUMENTAL ANALYSIS

Luis Enrique Hernández
CINVESTAV
luisenri.hernadez@cinvestav.mx

Claudia Acuña-Soto
CINVESTAV
claudiamargarita_as@hotmail.com

Parameters are not explicitly mentioned in textbooks from elementary school to higher education to solve Systems of Linear Equations (SEL) with infinite solutions, these almost always present methods to solve square systems with unique and numerical solutions, although later the parameters appear and are addressed in the undergraduate level but are introduced in an ambiguous manner which makes it difficult to understand its nature, its potentiality and proper use.

Keywords: Algebra, Algebraic Thinking, Parameters, textbooks.

Background

Parameters were introduced by Viète (1540 - 1603) to distinguish different types of variables, while in Mathematics Education they have eventually been interpreted as: *"…variables which are replaced by constants where at least one other variable remains*" (Šed . At the same time, they have been considered as a special type of variable, as Drijvers (2001) points out where *"The parameter can be considered a metavariable: the a in y=ax+b, it can play the same roles as an 'ordinary' variable, such as a placeholder, an unknown or changing quantity, but it acts on a higher level than a variable" "p.2).* The parameter is considered here as a second order variable, because they can make vary what is already varying, as Ursini & Trigueros (2004) point out, where they assume the role of unknown or related variable, depending on the situation.

The use of parameters for their later professional use can initially be addressed with SEL that have infinite solutions, so we are going to investigate the treatment of parameters in the school taking as a source of information the institutionally recommended textbooks, in order to know the basis on which the parameter could be proposed as a control variable, which includes both the treatment as a variable and as a constant.

Theoretical Framework

From the textbook format point of view, O'Keeffe (2013) suggests that the analysis of a book should consider: *content, structure, expectations, and language*. Concerning the structure of the textbook it is established that it increases or decreases the comprehension of the textbook, which suggests that the succession and connections between the elements of the textbook should be carefully analyzed. Textbooks are the result of a certain way of thinking about the contents that are in fact considered important to teach in the classroom and how they should be teaching.

In this case, we will address the mathematical content in textbooks associated with the parameters and analyze aspects related to the dominant procedure and their presence in relation to infinite solutions from high school to undergraduate level.

Methodology

In this study we carried out a documentary research on the textbook contents in order to detect the way how SEL solutions are presented and how parameters are introduced in the case of infinite solutions. For this purpose, we have reviewed some of the syllabi of different levels of mathematics education in Mexico with respect to SEL, their solutions and the treatment of parameters in these materials, for which we have chosen some representative secondary, high school, and undergraduate institutions to analyze the textbooks recommended in such materials.

The syllabi and sample textbooks we reviewed were as follows:

- **Basic level**: Current syllabus recommended by the Secretaría de Educación Pública SEP (2017) in it is recommended: (1) Trigueros et al (2019), (2) Bosch & Meda (2018), (3) Riva Palacio & Santana;(2019), (4) Martínez & Contreras, (2019) and finally the text of (5) Block, García & Balbuena (2019).
- **High School:** The syllabus of the Dirección General del Bachillerato (DGB,2018) and the UNAM corresponding to the Escuela Nacional CCH. Recommends: (6) Miller, Heeren & Hornsby (2013).
- **Undergraduate level:** The Linear Algebra texts recommended by the Faculty of Sciences of the UNAM and by the Division of Basic Sciences and Engineering of the UAM recommend: (7) Espinosa et. al. (2004) and for science we review the books by (8) Hoffman (1971), (9) Curtis (1984) and (10) Rincón (2006).

In order to carry out the analysis of the contents, we chose those we considered representative, so we will now discuss the text productions at the secondary (1-5), high school (6) and undergraduate levels (7-10), analyzing 10 texts in total.

Results and data analysis

The review performed on the content of the textbooks suggests that there are certain constants among them, which refer to 1) The shape and size of the systems, 2) A dominant type of algebraic procedure, 3) The type of solutions associated to the SEL and finally, we will see any mention of the parameters to deal with infinite solutions in the books analyzed, aspects that we will summarize below.

- The middle school books (1-5) present 2x2 square systems; use of solution methods by equality, substitution; dominant method: elimination; unique and numerical solution; no mention of parameters.
- The high school book (6) uses square and rectangular SEL, although his solution of this case is not addressed; solution methods by equality, substitution, and elimination; dominant method: elimination; numerical and infinite solution; no mention of parameters.
- The undergraduate books (7-10) address square and rectangular SEL; the same methods and Gaussian elimination is added; the case in which there is no solution is incorporated; dominant method: Gaussian elimination; regarding the apparition of the parameter, two cases out of four mention a change of variable, one presents it as a variable and finally in the last one its nature is not clarified.

The analyzed books' contents show that the predilection of the authors of secondary and high school textbooks is directed to the treatment of SEL squares of order 2x2 and 3x3, while in the undergraduate level, rectangular SEL are incorporated, which will give rise to infinite solutions that are eventually solved.

In all the cases analyzed, the texts rely on the development of multiple procedures to determine that the solution is unique and numerical, while the infinite solutions are almost not addressed and it seems that these solutions cannot be found because this problem is discarded and the books do not promote interest in them, nor do they lay the foundations to calculate them through the figure of the parameters.

Concerning the introduction of the parameters in the SEL, we observe that they appear functionally to the tertiary level when the infinite solutions of the SEL are attended to.

We found that in some texts it is used as a special type of sign (Hoffman, 1971; Curtis, 1984), while in others it is assigned the role of a constant (Espinosa et. al., 2004), in both cases an explanation of these facts is omitted, which generates confusion.

In the following we present excerpts from the textbook by Espinosa et. al. (2004) that support the above:

La última matriz está en su forma escalonada reducida, ya no se puede reducir más, de donde obtenemos:

$$x + \frac{5}{8}z = \frac{3}{2}$$
$$y - \frac{9}{16}z = -\frac{1}{4}$$

despejando x, y

$$x = \frac{3}{2} - \frac{5}{8}z$$
$$y = -\frac{1}{4} + \frac{9}{16}z$$

luego x, y dependen de z, si $z = t$, $t \in \mathbb{R}$, tenemos

$$x = \frac{3}{2} - \frac{5}{8}t$$
$$y = -\frac{1}{4} + \frac{9}{16}t \; ; \quad t \in \mathbb{R}.$$
$$z = t$$

Es decir, el sistema de ecuaciones tiene una infinidad de soluciones ya que para cada valor de t habrá un valor para x, y, z.

En esta parte se dan ejemplos de sistemas de ecuaciones lineales donde se determinan valores de constantes para que el sistema tenga o no solución.

15) Obtener el valor de λ para que el sistema de ecuaciones:

$$2x + y = 6$$
$$x + \lambda y = 4$$

tenga:

a) Solución única.

b) Infinidad de soluciones.

c) Carencia de solución.

Figure 1: Parameter use in SEL (Espinosa et. al. 2004, P.17 & 25)

On the left side of Figure 1 we observe an SEL with more variables than equations, which justifies the use of the parameters for its solution, but in the text there is no explicit mention of it, your presence is justified through a sentence that says: *". "I can't be reduced anymore."* and then they search for a "*variable*" that is defined as usual and the parameter *t* is introduced, accompanied by another sentence that says: *". "Ien x and y depend to z , if z = t"* "hat strictly is not justified and then it do not seems to be any rules to know how and when it should be used. The phrases that accompany the activity seem more like a kind of story, of which we do not know when and why we must use it, despite the mention of dependence, which involves specific conditions for this to be carried out.

When we avoid an explanation, we may generate a misconception particularly when one variable is simply substituted for another, in this case $z = t$, leading to possible doubts about the procedure, e.g., why z should be equal to t and not x or y, this procedure seems to be part of an apparent substitution ritual that avoids presenting the parameters and their properties explicitly.

On the other hand, on the right side of Figure 1 we observe a particular situation of SEL treatment, in which the parameter is initially introduced as a constant named λ, but never is clarified. This type of practice promotes the idea, as in the previous case, that the type of letter indicates the difference between the variables as well as of its role and the proper operation.

Another use to the parameter is the fragment of Hoffman's'(1971) work in Fig. 2, where the parameter appears as a substitution of a variable (x_4) for a literal (c), as is mentioned in the phrase *"... "t is evident that if we assign any rational value c to x_4 we obtain a solution ..."* the first obstacle that we observe is to affirm that the substitution *"i" is obvious"*, as if this were the only possible way to do it, so again we have a substitution like a ritual in which implicit indications are not given, such as the fact of choose x_4 as the variable to solve due it appear at the right hand, therefore it should be used to make the substitution.

EXAMPLE 5. Suppose F is the field of rational numbers, and

$$A = \begin{bmatrix} 2 & -1 & 3 & 2 \\ 1 & 4 & 0 & -1 \\ 2 & 6 & -1 & 5 \end{bmatrix}.$$

$$\begin{bmatrix} 0 & 0 & 1 & -\frac{11}{3} \\ 1 & 0 & 0 & \frac{17}{3} \\ 0 & 1 & 0 & -\frac{5}{3} \end{bmatrix}$$

The row-equivalence of A with the final matrix in the above sequence tells us in particular that the solutions of

$$\begin{aligned} 2x_1 - x_2 + 3x_3 + 2x_4 &= 0 \\ x_1 + 4x_2 \qquad\quad - x_4 &= 0 \\ 2x_1 + 6x_2 - x_3 + 5x_4 &= 0 \end{aligned}$$

and

$$\begin{aligned} x_3 - \tfrac{11}{3}x_4 &= 0 \\ x_1 \qquad + \tfrac{17}{3}x_4 &= 0 \\ x_2 \qquad - \tfrac{5}{3}x_4 &= 0 \end{aligned}$$

are exactly the same. In the second system it is apparent that if we assign any rational value c to x_4 we obtain a solution $(-\frac{17}{3}c, \frac{5}{3}, \frac{11}{3}c, c)$, and also that every solution is of this form.

Figure 2: The parameter presence as a C-value (Hoffman, 1971, p.9)

In this case, the parametric solution is made explicit in the following lines: *". "Id also that every solution is of this form* $\left(\frac{-17c}{3}, \frac{5}{3}, \frac{11c}{3}, c\right)$" and despite the fact that every solution can be written with this expression, the statement is incomplete since the form of the solution set depends on the variable that we are working with and it is also ambiguous because the solution set is unique, but not the expression to determine it, besides the fact that the solution must be $\left(\frac{-17c}{3}, \frac{5c}{3}, \frac{11c}{3}, c\right)$.

Finally, let us analyze an excerpt from the book by Miller, Heeren & Hornsby (2013), in Figure 3.

The infinite solutions here are presented meant of the idea of linear dependence, this is made explicit in the sentence: "*T“e set of ordered pairs of a system of dependent equations is written as a set of ordered pairs that expressing x in terms of y...*" ”nd in the procedure where any of the variables involved in the problem is declared. An action that can confuse students when they do not know yet this type of resource that consists of clearing one of the variables *(x)* and then presenting the solution set by means of the expression $\frac{y-2}{4}$ in the first entry of the ordered pair associated to the solution set and the second by *y,* in this procedure the *x* disappears and then is found again in the next line without warning. Again, we have a change in the nomenclature without apparent justification and with the features of a substitution ritual as part of the procedure.

Final Discussion

In this inspection of the secondary school textbooks, we observed that the contents deal exclusively with SEL squares of 2 and 3 dimensions with emphasis on unique and numerical solutions from which we can infer that the language and the teaching expectation is directed to the exercise of the procedures to acquire algebraic language skills.

Regarding the treatment of parameters in university textbooks, we observe that they are used as constant or variable as convenient, which makes that their function be seen as informal by the student or that depends on the situation, this treatment prevents their nature.

The square dimension of the systems studied at this level is extended to rectangular ones, which requires the use of parameters to find the solution set, they are treated indirectly through phrases like: *"w“ can't’clear anymore"* ”r *"i“ is evident that if we assign any rational value c to* x_4 *we will obtain a solution ... "* “hat seem more like a warning to use them, rather than an explicit and normed procedure, which takes the form of a ritual in which variables are substituted when the conditions are same like commented it and in the same way they are presented in the texts. Therefore, we find that the language associated to the parameters is ambiguous and these

Este enunciado verdadero, es decir, $0 = 0$, indica que la solución de una ecuación también es solución de la otra, de modo que el conjunto solución es un conjunto infinito de pares ordenados. Las dos ecuaciones son dependientes.

El conjunto solución de un sistema de ecuaciones dependientes se escribe como un conjunto de pares ordenados expresando x en términos de y, como se muestra a continuación. Se elige cualquier ecuación y se despeja x. Nosotros seleccionamos arbitrariamente la ecuación (3).

$$-4x + y = 2 \qquad (3)$$

$$x = \frac{2-y}{-4}$$

$$x = \frac{y-2}{4} \qquad \text{Se multiplica por } \tfrac{-1}{-1}.$$

El conjunto solución se expresa como

$$\left\{\left(\frac{y-2}{4}, y\right)\right\}.$$

Los pares ordenados del conjunto solución se pueden obtener seleccionando valores de y y calculando los valores correspondientes de x. Por ejemplo,

$$\text{si } y = -2, \text{ entonces } x = \frac{-2-2}{4} = -1$$

y la solución es el par ordenado $(-1, -2)$. ■■■

Figure 3: SEL with infinite solutions (Miller, Heeren & Hornsby, 2013, p.380).

are only highlighted as auxiliary bridges that we allow to write the solutions in very particular cases, they leave aside the role of this type of variables play in the solution, which causes that they are not considered as part of the procedure, but as a story for the general expression, but not as a mathematical resource.

Given the most recent need for virtual teaching, many mathematics teacher educators have taught pre-service teachers with virtual manipulatives, which often stood in for physical manipulatives. This brief considers the theoretical framing for pre-service teachers' actions with physical Cuisenaire rods before considering benefits and limitations virtual Cuisenaire rod features afford when making such a transition to virtual Cuisenaire rods. In particular, we seek to consider the theoretical question: what is gained and lost when trying to replicate preservice teachers' 'se of physical Cuisenaire rods with virtual Cuisenaire rods?

Keywords: Preservice Teacher Education, Mathematical Knowledge for Teaching, Rational Numbers, Mathematical Representations

In response to the COVID-19 pandemic, many mathematics teacher educators are trying to promote productive struggle while transitioning from teaching with physical manipulatives to teaching with virtual manipulatives. If we are trying to prepare teachers to teach with physical manipulatives, to what extent can we replicate that use with use of virtual manipulatives? Motivated by Herbst and Chazan's (2017) call for subject-specific theories of mathematics teaching, we focus on the specific mathematical goal of conceptualizing fractions as measures—that is, of understanding fractions as the result of coordinating mental actions of partitioning, disembedding, unitizing, iterating, and splitting (Wilkins & Norton, 2018)—and on one specific manipulative, Cuisenaire rods. Cuisenaire rods are constructed of wood or plastic, of size 1cm by n cm, for n=1 to 10. Each rod length is represented by color (i.e., orange rods = 10 cm in length, red rods = 2 cm in length). They have been used for decades to teach arithmetic (Aurich, 1963; Egan, 1990) and fractions (Robinson, 1978; Wallace, 1974). We examine Affordance theory (Gibson, 1979) and Units Coordination theory (Steffe & Olive, 2010) to theorize how features of virtual Cuisenaire rods support teaching fractions as measures.

Theoretical Framing

To frame this discussion, we integrate an ecological affordance theory for virtual manipulatives (Gibson, 1979) with a constructivist theory of fractions learning (Steffe & Olive, 2010). Moyer-Packenham and Westenskow (2013) constructed an interrelated framework with five different types of affordances with virtual manipulatives that explain learning effects. *Focused constraint* (1) is the degree to which features focus and constrain students' attending to particular mathematical aspects of the manipulatives. *Creative variation* (2) allows students opportunities to experiment with mathematical ideas in creative and novel ways. *Simultaneous linking* (3) promotes students to link actions, dynamic/static pictures, and/or symbols simultaneously. *Efficient precision* (4) describes the degree of fidelity of particular dynamic objects and mathematical properties of manipulatives. *Motivation* (5) involves affective qualities students express in manipulatives use. We wondered how these affordances may benefit or limit preservice teachers' (PSTs) construction of fractions as measures.

Steffe and Olive (2010) describe a theory for children's construction of fractions as measures via a reorganization of mental operations for constructing whole number concepts. Units are constructed through children's external activity before becoming internalized (imagined actions) and then interiorized (able to anticipate relationships between levels of units). *Partitioning* involves projecting a "composite unit into a continuous whole to create equally sized parts within the whole" (Wilkins & Norton, 2018, p. 2). By *disembedding*, students are able to take "parts out of a whole as separate units while maintaining their relationship with the whole" (p. 2). Students evidencing *iterating* repeat a "unit of length or area to produce a connected whole" (p. 2). By coordinating three levels of units (i.e., unit fraction, composite fraction, referent whole) students are able to conceptualize a fraction larger than the whole.

Fraction Development with Physical Manipulatives

We first consider features of physical Cuisenaire rods as a PST solves the fractions task, "if the purple rod is ⅔, what rod represents ½?". The student first locates the purple rod and places it on the desk. Next, the student places her fingers on the rod in a "cutting" motion (see Figure 1a). The student explains that she is partitioning the rod to determine the unit fraction (⅓). After determining the red rod is equal to ⅓, the student then iterates the red rod three times to construct the referent whole (see Figure 1b). Finally, the student determines a green rod iterated twice represents two halves. One of these two halves is then placed alongside the purple rod to illustrate the relationship between ⅔ and ½ (see Figure 1c).

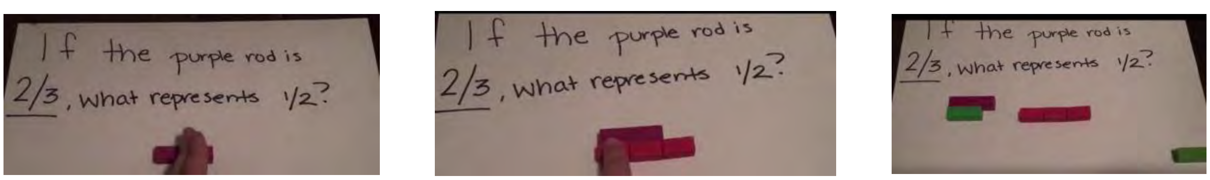

Figure 1a (left), b (middle), c (right): A Preservice Teacher's Activity with Cuisenaire Rods.

When PSTs engage with physical Cuisenaire rods, partitioning is constrained because individual blocks cannot be broken into smaller parts. We theorize that this constraint would encourage iterating, which is critical for understanding a fraction as a measure. The proportional relationship between blocks affords students a "guess and check" strategy; PSTs who do not immediately choose the correct rod are able to choose rods a bit smaller or larger in length due to the accuracy of their solution, allowing multiple access points.

Fraction Development with Virtual Manipulatives

When considering PSTs' potential engagement with virtual Cuisenaire rods when solving fraction tasks, we sample five virtual Cuisenaire rods. In this examination, we compare features of each virtual tool and determine possible affordances these features may promote in PSTs (see Table 1). When reviewing the tools, it seems clear that there were features that were similar between virtual Cuisenaire rods (e.g., grid features, ability to overlap or not) and features that varied (e.g., pen tool, organization of rods by length). To examine these features relative to potential affordances, we consider each feature individually.

Grid and proportional relationships. When virtual Cuisenaire rods have a grid and rods are organized in proportional order, it removes the necessity to partition and iterate because the unit and referent whole length are measured with the grid or illustrated with the relationships. These features afford PSTs simultaneously linking between measured lengths and the rods. Conversely, we argue these features might also afford PSTs' efficient precision when solving fraction tasks. Thus, PSTs may not actively partition and iterate with virtual tools with these features but provide accurate solutions to fraction tasks.

Table 1: Comparison of Virtual Cuisenaire Rods

Labels. When reviewing labels, we considered how PSTs might be afforded with simultaneous linking between whole numbers (cm length) and proportional relationships between rods. For example, a fraction measurement task might state that the “red rod equals ½”; this might present the PST with conflicting values between fractions and whole numbers if the red rod is labeled “2” in the virtual manipulative. Again, these simultaneous links between whole numbers and rods remove the necessity to partition and iterate. These links may inhibit PSTs from considering rods with this feature as representing fractions and flexible units.

Rotation of rods. Some virtual Cuisenaire rods had the option to rotate rods from horizontal to vertical and vice versa and some do not allow rotation. Often measurement models for fractions use horizontal orientations. By allowing rotation of the rods, we believe PSTs are afforded creative variation. This variation may allow PSTs to change the orientation of the models to one that most often aligns with their understanding of measurement. It is unclear how this may provoke or prevent iteration and partitioning.

Overlap of rods. Many virtual rod tools allow for these rods to overlap. For example, a rod 3 cm in length might overlap another rod 2 cm in length, resulting in a rod 4 cm in length. Again, we believe this feature affords PSTs creative variation. In this case, creative variation has the possibility of representing inaccurate lengths than the physical rods may represent. Additionally, this feature may discourage iteration because the PSTs’ actions do not represent full copies of units. This feature may also afford PSTs’ focused constraint because they need to continually attend to the length each rod represents to prevent rods from overlapping. Thus, this feature may have benefits for supporting knowledge for teaching a fraction as a measure.

Pen tool. Only one of the virtual manipulatives reviewed had a built-in pen tool. We believe this feature affords PSTs’ simultaneous linking, creative variation, and efficient precision. These three affordances would promote sequential partitioning and iterating activities because they would have to construct segmenting marks, simultaneously link these marks to their actions, and use these links to attend to the mathematical precision of a potential solution.

Blocks easily draggable. All virtual manipulatives had features, which allowed individuals to drag blocks across the screen with traditional mouse-driven devices and multi-touch devices. We determined this feature afforded PSTs’ creative variation and simultaneous linking because they were given creative opportunities to explore mathematical ideas while also linking their actions to the placement of the rods. This affordance has the potential to mimic iteration in similar ways that physical manipulatives afford PSTs.

Conclusions

In conclusion, our theoretical framework and examination of virtual manipulative features suggest that the Math Bars virtual Cuisenaire rod tool has features which allow PSTs’ the ability to turn on and off grids, turn on and off labels, rotate rods, overlap rods, rely on proportional ordering of rods, and draw with a pen tool. Many of these features are helpful because mathematics teacher educators can specify which features afford PSTs to partition and iterate. Conversely, the proportional relationships feature also limits these actions. The Number Blocks virtual Cuisenaire rod tool does not have this proportional relationship feature but uses labels which also provide simultaneous links between whole number symbols and rods. The Cuisenaire Environment and Maths Bot tools do not provide a pen tool, but features such as a grid, labels, and proportional relationships can be turned off. Moreover, this tool features overlapping rods if users do not attend to the precision of the rod’s length. Thus, these tools may benefit PSTs’ active engagement when constructing fractions as measures. Given the limited space this paper provides, we wonder which affordances are often beneficial and/or limiting when PSTs evidence and construct fractions. Additionally, larger questions center on how frameworks may change when blending theoretical frames.

MATHEMATICAL KNOWLEDGE FOR TEACHING FORMATIVE ASSESSMENT: RECOMMENDATIONS FOR MATHEMATICS TEACHER EDUCATORS FROM A META-AGGREGATION

Rachael Kenney	Michael Lolkus	Yukiko Maeda
Purdue University	Purdue University	Purdue University
rhkenney@purdue.edu	mlolkus@purdue.edu	ymaeda@purdue.edu

*Qualitative research explores the complexity of teaching and learning, but there are barriers to using qualitative findings to inform practice/policy. We see a critical need to integrate finding*s *across qualitative studies to develop synthesized, actionable recommendations for mathematics teacher educators. Using a meta-aggregation of 11 qualitative studies, we investigated how teacher educators' mathematical knowledge for teaching can inform their support of formative assessment practices in secondary mathematics classrooms. Synthesized findings led to nine lines of action that we provide as recommendations for mathematics teacher educators.*

Keywords: Assessment, High School Education, Research Methods

Mathematics teacher educators play a key role in connecting theory into practice when it comes to using formative assessments (FAs) to inform instructions in secondary mathematics classrooms and supporting teachers' development of effective FA practices. In this study, we used meta-aggregation, a qualitative research synthesis method, to understand how mathematics teacher educators' (MTEs) pedagogical content knowledge (PCK) informs their work with mathematics teachers on FA practices in secondary classrooms. From our results, we generated \nine actionable recommendations for MTEs who work closely with teachers to connect research to classroom FA practices. Our research questions are:

- What is needed in terms of MTEs' PCK to support teachers' collection and use of FA data to move student thinking forward in secondary mathematics?
- What recommendations can we make for secondary MTEs to connect teachers' 'CK to their development of FA practices?

Theoretical Framework

As a part of classroom assessment, FA is a crucial component of instructional decision-making and developing students' mathematical thinking (Black & Wiliam, 2009). FA is a complex set of "informed actions" (Andrade & Cizek, 2010; Black & Wiliam) concerned with identifying and understanding what and how students are thinking (Black & Wiliam; Looney, 2005; McManus, 2008). Collecting FA data often permeates the various interactions that teachers have with learners as they discuss, listen to, and observe mathematical thinking in the classroom.

In order to identify and assess students' mathematical understandings, it is essential for secondary mathematics teachers to have extensive knowledge of mathematics content, how it connects to student thinking and learning across the broader mathematics curriculum, and how it informs pedagogical practice (Gotwals et al., 2015). In other words, effective FA practices are connected to teachers' PCK. MTEs can support teachers development of PCK as it relates to their FA practices; but knowing how to facilitate this development also requires MTEs to develop and reflect on their own teaching knowledge (Borko et al., 2013; Carney et al., 2019). In this paper, we report research-based recommendations for MTEs who are supporting teachers' FA practices to move students' thinking forward.

Method

Qualitative Synthesis as a Methodology in Mathematics Education

Qualitative research studies play a critical role in education as they push the field "beyond process–product research toward considering the complexities and nuances significant for understanding factors that influence outcomes" (Thunder & Berry, 2016, p. 334). The wide range of qualitative methods and the nature of the findings, however, make it difficult to integrate findings across studies. Recently, meta-aggregation has gained attention as an effective methodology for bridging research findings to practice (Aromataris & Munn, 2020). It is a specific type of qualitative synthesis intended to treat findings from individual studies as *data* for analysis to derive a new theory or interpretation from the original findings. The aim of meta-aggregation is specifically to inform lines of action that are directly and immediately applicable to decision-making practices (Lockwood et al., 2015). This method is well suited to our objective of linking practice and research and generating recommendations for how MTEs can best prepare teachers to use FAs to move students' thinking forward.

Data Collection

In a meta-aggregation, the research question drives the search for qualitative studies to include in the synthesis. Before searching for existing studies, we set criteria for consideration in the search. Our data collection steps are described as follows.

Locating and sampling studies. The target population of studies for our meta-aggregation were qualitative studies that explored FA practices of secondary mathematics teachers. To be included, we set criteria that a study should: (a) be empirical, qualitative research; (b) target United States secondary mathematics students, teachers, and classrooms; (c) investigate in-service teacher's FA use; and (d) meet the criteria for reporting quality through a critical appraisal. We searched using multiple databases (e.g., Google Scholar, JSTOR, PsychINFO). From abstracts, we identified 47 potential studies for inclusion, but excluded 36 after screening for not meeting inclusion criteria.

Appraising reporting quality of identified studies. We used a critical appraisal form with 23 appraising questions to evaluate the sufficiency of reported information of each of the remaining potential study and to enhance the credibility of our results (Lockwood et al., 2015). All 11 identified studies met the criteria for reporting quality and were included for the meta-aggregation (these are indicated with an * in references), comprising three journal articles and eight dissertations. These *primary studies* provided the data for our analysis which includes verbatim extracts from the studies and authors' interpretation of results (Lockwood et al., 2015).

Qualitative Synthesis

After extraction, there are three steps for analysis. For clarity, we use *claims* below to refer to the data we pulled from the primary studies, and we use *findings* to refer to the results of our own data analysis of these claims.

Step 1: Rating extracted claims. We considered authors' claims to be unequivocal (no room for debate), credible (open to challenge) or unsupported (when no evidence backed authors' statements). Our four-person research team worked to find coding consistency and discussed any challenges encountered. Through this process, we identified 656 claims as credible or unequivocal, and 79 as unsupported across 11 studies. Coding was conducted using NVivo.

Step 2: Categorizing and synthesizing codes. We used descriptive coding (Saldaña, 2013), assigning a word or short phrase from each claim to describe the key idea, and then sub-coding (Miles & Huberman, 1994) to reduce the number of descriptive codes and organize the codes for further analysis. We next analyzed portions of data with an extended thematic statement (Saldaña) to identify conceptual commonality (Hannes & Lockwood, 2011; Major & Savin-Baden, 2010). Finally, we used provisional coding (Saldaña) to look within each of 23 themes to see if we could identify connections among our data and PCK framework. We wrote synthesis statements for each theme individually, and reviewed and finalized as a whole research team.

Step 3: Generating lines of actionable recommendations. The final step of the analysis was to translate the synthesis statements to actionable recommendations. We first independently developed a recommendation for each synthesis statement. Then, the developed recommendations were compared until we reached full consensus among team members.

Results

The results below detail our meta-aggregation findings and actionable recommendations for MTEs to (a) support secondary mathematics teachers' development of specific FA practices that they can implement as part of their daily instruction and (b) develop, enact, and reflect on *their own* teaching knowledge to effectively facilitate PD around FA.

Synthesis of MTE's Knowledge of Teachers

Mathematics teachers at all levels of experience benefit from ongoing, differentiated professional development. It is important for MTEs to understand secondary teachers' prior teaching experiences (as a teacher and a learner) with FA as well as their current FA strategies. Unpacking these things could be established through teacher interviews, small group discussions, or classroom observations. Understanding teachers' dispositions and levels of self-efficacy in their mathematical content knowledge and PCK is also critical, as a lack of confidence in themselves as mathematics teachers and a fear of not understanding students' mathematical thinking will hinder effective use of FA for learning. Developing an environment that positions teachers as autonomous partners in learning is shown to improve teachers' sense of self-efficacy with FA. Resulting lines of action are shown in Figure 1.

Unpack Prior and Current Experiences. Recognize that teachers have prior experiences engaging their students in FA. Use teachers' experiences to build common vocabulary, norms, and practices.	**Unpack Affective Factors.** Work with teachers to identify levels of confidence in themselves as mathematics teachers and their dispositions, beliefs and values related to FA practices in the secondary classroom.	**Support Individual Practices, Preferences and Needs.** Differentiate PD and instructional support to meet mathematics teachers' 'iverse needs related to the implementation of effective FA strategies.

Figure 1. Recommendations for MTEs: Focus on knowledge of teacher-learners.

Synthesis of MTE's Knowledge of Content and Curriculum

Targeted instructional support/professional development can lead to positive changes in teachers' understanding of short- and long-cycle assessment use, regardless of their years of experience. Teachers use FA for a variety of purposes including: (a) assessing student's proficiency of mathematics content; (b) evaluating whether students "got it" or not and how instruction should be adjusted; (c) understanding student thinking and reasoning; and (d) assessing students' engagement and attitude. Teachers used different types of FAs in terms of its nature, occurrence, format, and strategy. Thus, when teachers are learning about FA, it is important for them to develop their own definition of FA, to understand the purposes that FA can serve in a mathematics classroom, and to identify the factors that may influence FA practices in their classrooms. When teachers know the broad goals of FA for specific mathematical topics, they are better prepared to alter instructional plans in response to FA data to move students' thinking forward. Figure 2 shows three lines of action for MTEs to consider in relation to curriculum when facilitating experiences that support secondary mathematics teachers' FA practices.

Understand the Purpose for FA	**Understand Conditions for FA.**	**Use Learning Objectives and Trajectories**
Ask teachers to unpack multiple purposes of FA as they engage in FA practices. Build a collective understanding that all can relate to, internalize, and incorporate into practice.	Understand the complex thinking that accompanies FA, and support teachers' understanding of the factors that influence their choice of FA tools and strategies.	Work with teachers to look across grade levels, follow the curricular trajectory of mathematical topics, and explore trajectories in students' thinking on related learning targets.

Figure 2. Recommendations for MTEs: Focus on knowledge of PD content and curricula.

Synthesis of MTE's Knowledge of Teaching

Teachers benefit from observation and written feedback on their FA practices from instructional leaders or peers who have the knowledge and ability to provide differentiated support for teachers' diverse needs regarding FA practices. With the implementation of FA, teachers learn to attend to diverse student thinking, different learning approaches, and their understanding of specific content area, difficulties, and challenges students face in learning mathematics. Therefore, teacher's self-reflection, self-evaluation, and self-regulation of their own learning and teaching effectiveness are critical to identify their strengths/weaknesses around supporting students and building confidence in their teaching. Thus, ongoing internal and external supports for teachers' learning and use of FA practices is beneficial.

Develop Teachers' 'elf-Efficacy with FA	**Recognize Teachers' Roles as Learners**	**Provide Ongoing Instructional Feedback and Support.**
Develop authentic collaborative mathematics learning spaces where the MTE is a facilitator, not authority, in the development of FA practices to build teachers' 'elf-efficacy with FA.	Examine how decisions guide and are guided by FA. Collaboratively analyze how FA informs which type of adjustments could be most productive for a given situation. This can support teachers' applications of past learning to a new group of students in a similar setting.	Create and sustain a system for ongoing instructional support with coaches and peer teachers. Engage teachers in observing and analyzing their own and others' 'A practices and providing focused reflection or feedback on target goals.

Figure 3. Recommendations for MTEs: Focus on knowledge of teaching

Discussion and Conclusions

Effective use of FA in secondary mathematics classrooms involves a complex set of practices. When considering teachers' varying experiences and beliefs related to FA, supporting teachers to engage their students in FA is equally complex. Our meta-aggregation highlights the importance for MTEs to reflect on multiple components of their own PCK when working with secondary mathematics teachers to offer customized, ongoing and differentiated support for all levels of secondary mathematics teachers regardless of their experiences with FA practices. Our findings and nine lines of action recommendations motivate a call for using needs-driven PD

(Marra et al., 2011) for supporting FA practices. Teachers who receive targeted instructional support demonstrate improvement in their knowledge and use of FA core practices. We recommend that help secondary teachers practice FA as a normal, integrated component of instruction instead of as a stand-alone construct. Our synthesis also illustrates the potential of qualitative synthesis methodology for generating empirical-based practical knowledge directly applicable for future PDs and classrooms.

ARTICULATING THE UNARTICULATED: PROSPECTIVE SECONDARY MATHEMATICS TEACHERS' NARRATIVES OF PROOF WITHOUT WORDS

Xiaoheng Yan
Simon Fraser University
xkyan@sfu.ca

This paper reports a preliminary analysis of prospective secondary mathematics teachers' diagrammatic reasoning and understanding of visual proofs. The data comprises responses to a task in which participants were asked to articulate how a given claim was proven through diagrams and to compose a dialogue between two students and a teacher about the proofs. The findings show that the participants' approaches to articulate "the unspoken" of the diagrams greatly differed; their pedagogical preferences to teach the same mathematical content were also distinct. The unspoken and unarticulated, from prospective teachers' perspective, were different from what was anticipated.

Keywords: Visual proofs, Diagrammatic reasoning, Prospective secondary mathematics teacher, Teacher knowledge

If linguistic representation is sequential and linear, then diagrammatic representation is planar (Larkin & Simon, 1987). In both geometric and algebraic proofs, figures and diagrams are often created and used not only in presenting a problem, but also in illuminating a solution (e.g., Alsina & Nelsen, 2010; Brown, 1999; Nelsen, 1993, 2000). In proof construction, in particular, visual means are much more than an aid to understanding; they can be resources for discovery and justification, and even for proving (Arzarello, Micheletti, Olivero, & Robutti, 1998; Giaquinto, 2007). Researchers in mathematics education have noticed content and structural distances between informal argument and acceptable proof (Garuti et al., 1998, Pedemonte, 2001, 2007). While acknowledging the formal and informal approaches to proof as different ways of thinking, recent studies suggest an optimal approach that simultaneously uses logic and visualization (Nardi, 2014; Zazkis, Weber, & Mejia-Ramos, 2016). This study uses the suggested approach to investigate prospective secondary mathematics teachers' understanding of visual proofs. Particularly, the paper focuses on prospective secondary mathematics teachers' narratives of visual proofs that the sum of an integer and its reciprocal is at least two.

Theoretical Framing

Visual Proofs

The concept of visual proof, as Davis (1993) stated, is an ancient one. Azzouni (2013) emphasized the use of geometric content presupposed in visual proofs as it allows an experience in 'seeing' the proofs in question and seeing that the result is true. From a philosophical perspective, visual representations can be seen as adjuncts to proofs, as an integral part of proof, or as proofs (Hanna & Sidoli, 2007). A *proof without words* (PWWs) is such an example of the latter case. These proofs use pictures or other visual means to communicate a mathematical idea, statement, equation, or theorem (Casselman, 2000; Gierdien, 2007). More importantly, a *proof without words* offers insights into how one might begin to go about proving it true (Nelsen, 2000). With an emphasis on the provision of visual clues to the viewer, many *proof without words* in Brown (1999) and Nelson's (1993) work exhibit an interesting conservative element in mathematics and grant opportunities to promote and develop visual mathematical thought

(Azzouni, 2013; Gierdien, 2007; Stupel, Sigler, & Jahangiri, 2019). Recent studies on *proof without words* suggest that the relationships embedded in a good diagram represent real mathematics awaiting recognition and verbalization (e.g., Katz, Stupel, & Segal, 2016; Stupel, Sigler, & Jahangiri, 2019).

Diagrammatical Reasoning

On the one hand, what makes visual representation and diagrammatic reasoning effective is the directness of its interpretation – the capacity a user has to read off key features of the target structure from the appearance of the diagram (Stenning & Lemon, 2001). On the other hand, diagrammatic reasoning is also considered deceptive, particularly when it causes one to treat an apparent relationship as being valid in general. Due to its particularity, a diagram has been considered a heuristic device (Radford, 2008), a useful instrument for the discovery, formulation, and intuitive comprehension of a proof. Even though diagrammatic reasoning seems insufficient to fulfill a justificative role in proof, Kidron and Dreyfus (2014) suggest that mathematical justification takes into account the learner's point of departure with its intuitive thinking, visual intuitions, and verbal descriptions, rather than starting from formal mathematics.

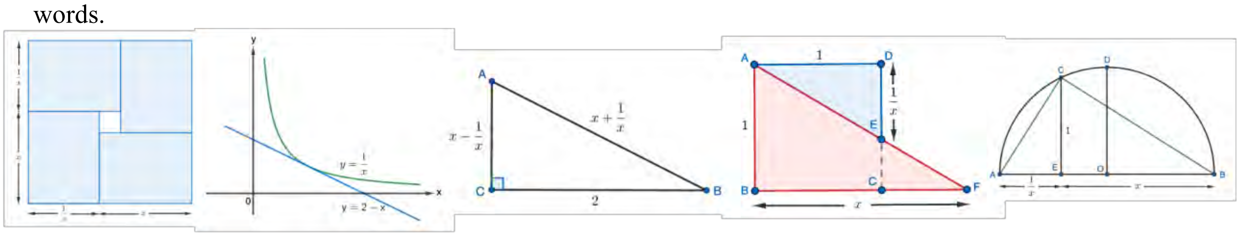
In the interest of using graphical arguments to support proof construction, Nardi (2014) found that some teachers used graph-based argumentation as part of the learning trajectory towards proof construction. Zazkis, Weber, and Mejia-Ramos (2016) further suggested that writing a proof based on a graphical argument could engage prospective teachers in elaborating and syntactifying that leads to a verbal-symbolic proof.

Method

Participants were 22 prospective secondary mathematics teachers enrolled in a mathematical content course as a part of their undergraduate teacher education programe. The goal of the course was to examine secondary mathematics from an advanced standpoint, to broaden the understanding of key topics by drawing connections among various topics and representations. The means towards this goal is intensive problem-solving experience, followed by reflection.

The Task

1. **Articulating.** The five diagrams below all illustrate "the sum of a positive number and its reciprocal is at least 2. Please choose TWO diagrams out of five and articulate how the two diagrams prove the claim in your own words.



2. **Script-writing**. Based on your articulation of the two diagrams you have chosen, write an imaginary dialogue about them between you (the teacher) and two students. Please start the dialogue with the prompt below.

Frank: I tried to add a positive number and its reciprocal. Look what I found… I sense that this must lead to something groundbreaking.

$$3+\frac{1}{3}=3\frac{1}{3},\ 2+\frac{1}{2}=2\frac{1}{2},\ 1+\frac{1}{1}=2,\ \frac{2}{3}+\frac{3}{2}=2\frac{1}{6},\ \frac{4}{5}+\frac{5}{4}=2\frac{1}{20},\ \dots\ \frac{100}{101}+\frac{101}{100}=2\frac{1}{10100}$$

Francis: How do you know?

Teacher: …

Figure 1. The Task

The participants were given five visual proofs of $x + \frac{1}{x} \geq 2$ for $x > 0$, selected from Nelsen (1993). The task consists of two parts: 1) select two out of five diagrams and articulate how they prove the claim; 2) write an imaginary dialogue between two students and a teacher based on the prompt (see Figure 1). The first part of the task was designed for prospective teachers to draw on their mathematical content knowledge; the second part, their pedagogical considerations regarding visual proofs. The imaginary dialogue is also referred to as a "scripting task" to explore and strengthen teacher knowledge while considering instructional situations (e.g., Zazkis & Kontorovich, 2016; Zazkis & Herbst, 2018). In analyzing participants' articulations and scripts, three themes emerged regarding "the unarticulated": 1) the extra bit, 2) the minimal value, and 3) the algebraic approach. This brief report focuses on the first two themes for discussion.

Preliminary Findings

The majority of the participants selected two out of five visual proofs to articulate, while a handful of participants attempted to explain all five proofs. The frequency of distribution of selected proofs can be found in Table 1. More than two-thirds of the participants selected proof 1 and 2; about half of the participants selected proof 3; one-third, proof 4; and 5 participants chose proof 5. In this paper, our preliminary analysis focuses on the first two proofs: the "square" proof and the "function" proof.

Table 1: Frequency of distribution of selected proofs

	Proof 1	Proof 2	Proof 3	Proof 4	Proof 5
Diagram					Total	15	14	10	7	5

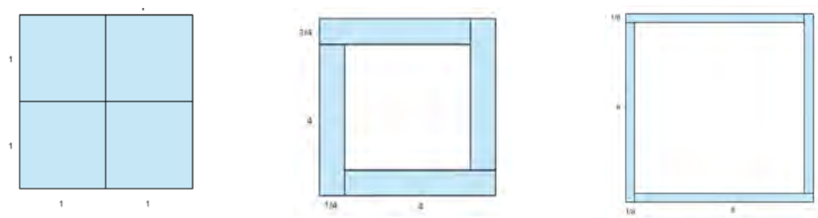
The Unarticulated – The Extra Bit in the "Square" Proof

When asked to articulate the "square" proof, the participants attended to the dynamic that is evident yet implicit in the diagrams. For example, Dave's approach to explaining the "square" proof focused on a discussion between the two student-characters around "the extra bit":

Frank: Okay, how do we know that the "1/x + x" by "1/x + x" square is bigger than the 2-by-2 square?
Francis: Well, because we can compare it to the original.
Frank: Hmm… what happens if we keep taking bigger and bigger x values?
Francis: Nice sketch… the inner square gets bigger too. But the area of the blue-shaped rectangles is still 4.
Frank: Oh, so that means $(x + 1/x)^2 \geq 4$…
Francis: ..Iich means $x+1/x \geq 2$!



The discussion took an empirical approach to test out the area changes of the inner square when the value of x changes. To reach the result that "$1/x + x$" by "$1/x + x$" is greater than 4, three examples were drawn to illustrate when x increases from 1 to 4 to 8, the side-length of the inner square consequently increases from 0 to 15/4 to 63/8, which leads to the changes of the area of the outer square from 4 to 4+15/4 to 4+63/8 to support the result $(x + 1/x)^2 \geq 4$. In a similar light, Judy's script focused on losing the extra bit to explain $(x + 1/x)^2 \geq 4$.

Teacher: The area of this square must be greater than 4 because we also have this little square in the middle to consider.
Francis: So then, the sum of $x + 1/x$ must be greater than 2.
Teacher: Exactly! Now notice that when $x = 1$, the area of the square is exactly 4.
Frank: Yes because the side length will be 2 and we will lose that middle center square.
Teacher: So then, $x + 1/x$ can also equal 2.

One distinction between Dave's and Judy's scripts lies in the fact that different characters participated, generated, and led a discussion. In Dave's script, the teacher-character was absent, while in Judy's, the teacher-character led the discussion. This indicates different pedagogical preferences of prospective secondary mathematics teachers when discussing the same mathematical content.

The Unarticulated: The Minimal Value of the "Function" Proof

Regarding the minimal value of the "function" proof, the majority of the participants focused on the instance when $y = \frac{1}{x}$ and $y = 2 - x$ intersect. For example, in Brian's script, the teacher character pointed out that the minimal value could be obtained when the graphs of the two functions touch. Carol noted that $y = \frac{1}{x}$ lies above $y = 2 - x$ for $0 < x < 1$ and $x > 1$, indicating that $x = 1$ was a "special" point. "Lying above" was interpreted differently by Mike: "We want to consider the 'area' where $1/x$ is larger than $2 - x$, which from the graph is always true except for $x = 1$." By 'area' he referred to the space below the curves even though the area below $1/x$ is unclosed.

In contrast, Niaj approached the minimal value of $x + \frac{1}{x}$ by differentiating $f(x) = x + \frac{1}{x}$ and identifying the zeros of the differentiated function:

Now let $f(x) = x + \frac{1}{x}$. If we differentiate $f(x)$ then,

$$f'(x) = 1 - \frac{1}{x^2} = 0 \Rightarrow x^2 - 1 = 0 \Rightarrow (x+1)(x-1) \Rightarrow\ x = 1 \; or \; x = -1$$

Since x is a positive number, when $x = 1$ we will have a minimum value: $f(1) = 1 + \frac{1}{1} = 2$. Thus, the sum of a positive number and its reciprocal is at least 2.

Discussion

This study explores prospective secondary mathematics teachers' understanding of visual proofs and their pedagogical considerations. All visual proofs, in one way or another, contain the unspoken or unarticulated elements that can be verbalized and articulated. The task consisting of five visual proofs was designed for prospective secondary mathematics teachers to create their narratives of proof without words. The preliminary analysis of the data indicates that the participants' approaches to articulate "the unarticulated" of the diagram greatly differed and that their pedagogical preferences to teach the same mathematical content were also distinct. While some participants read and interpreted diagrams in compelling ways, others focused on non-geometric approaches, shying away from diagrammatic reasoning. This speaks to Davis's (1993) observation that despite the importance and usefulness of the visual proofs, it was overshadowed by the rise of formal logic. Further investigation and a more in-depth analysis would shed more light on how prospective secondary mathematics teachers approach, interpret, and articulate visual proofs.

TRANSFORMING AN ELEMENTARY TEACHER'S CONCEPTUAL UNDERSTANDING OF MATHEMATICS THROUGH COACHED PRODUCTIVE STRUGGLE AND REFLECTION

Asia Franks
Fordham University
afranks2@fordham.edu

Alesia Mickle Moldavan
Fordham University
amoldavan@fordham.edu

Keywords: Teacher Knowledge, Mathematical Knowledge for Teaching, Elementary School Education

Providing professional coaching opportunities to explore mathematical content and pedagogy can assist teachers in improving their conceptual understanding of mathematics (Association of Mathematics Teacher Educators, 2017; National Council of Teachers of Mathematics, 2000, 2014). With COVID-19 prompting a transition to remote learning, some teachers lacked access to professional coaching and shifted their pedagogical practices to rote learning. Recognizing the implications of this paradigm shift has encouraged teachers to rethink their own conceptual understanding of mathematics and how they might improve their teaching using meaningful tasks, manipulatives, problem-solving techniques, and child-friendly vocabulary (Appova & Taylor, 2020). This study reports on an elementary teacher's effort to improve their conceptual understanding of division through professional coaching used to elicit productive struggle and reflection when solving standard-aligned tasks. The following research question was examined: How does intellectual preparation through professional coaching encourage teachers to reflect on their conceptual understanding of mathematics and rethink their pedagogy?

This study used a participatory action research approach where one of the researchers acted as a professional coach to facilitate three intellectual preparation sessions with a 5th grade co-teacher in the Northeast. Intellectual preparation was defined as one-on-one coaching pre-instruction focused on solving standard-aligned tasks to improve conceptual understanding and identifying best practices for teaching the targeted concept. The coaching included conversations around content, pedagogy, and student learning, which evident in other studies improves teacher reflection and practice (Russell et al., 2020). Given that the researchers relied on the teacher's view of intellectual preparation, a social constructivist theory grounded this study (Creswell & Poth, 2018). Data collection included session observations regarding the teacher's observed conceptual understanding and the teacher's written reflections after each session. Data was analyzed using in vivo and descriptive coding techniques to recognize themes (Saldana, 2016).

We report on three themes that provide insight on how the teacher transformed their conceptual understanding to improve their pedagogy through coached productive struggle and reflection. The first theme addressed the teacher's realization of the importance of using appropriate mathematical terminology and child-friendly language to guide conceptual understanding. This is echoed in his statement: "I now see importance in thinking about the language that is necessary for teaching a specific concept conceptually." The second theme emphasized a new understanding of how models (e.g., tape diagrams) can be used to aid in visualizing abstract ideas. The last theme highlighted the teacher's efforts to use multiple problem-solving methods to make connections. After solving the standard-aligned task, the teacher was able to articulate the connection between a model and an algorithm. This research signifies how teachers can transform their conceptual understanding of targeted concepts with the aid of productive struggle during professional coaching to improve one's practice.

PRESERVICE TEACHERS' MATHEMATICAL KNOWLEDGE FOR TEACHING: FOCUS ON LESSON PLANNING AND REFLECTION

Bima Sapkota
Purdue University
bsapkota@purdue.edu

Keywords: Mathematical knowledge for teaching, Preservice teacher education, Instructional activities and practices, Lesson planning

Mathematics preservice teachers (PMTs) often take mathematics content courses in the Department of Mathematics and education courses within the College of Education, which limits PMTs' opportunities to learn how to apply content knowledge in their teaching (Burton et al., 2008; Wasserman et al., 2019). Because Mathematical Knowledge for Teaching (MKT; Ball et al., 2008) offers a framework with six MKT domains to explore how content knowledge is associated with mathematics teaching (Thomas et al., 2017), PMTs would benefit from attention to MKT-related dispositions and language. In this study, I provided opportunities for secondary PMTs, enrolled in a mathematics methods course, to engage in the following activities: planning, implementing, reflecting on, and discussing lessons; and reflecting on and discussing the six MKT domains. Utilizing a collective case study approach (Yin, 2017) and content analysis methods (Schreier, 2012), I investigated the following research questions: (a) Which MKT domains were evidenced in PMTs' lesson plans? (b) How did PMTs describe MKT domains in their lesson plan reflections? Data for the study were PMTs' lesson plans and reflections.

Initial findings indicated that three MKT domains, *Common Content Knowledge (CCK)*, *Knowledge of Content and Teaching (KCT)*, and *Knowledge of Content and Curriculum (KCC),* were evidenced in PMTs' lesson plans. For example, *KCT* was evidenced through PMTs' selections of instructional strategies while *KCC* was evidenced when PMTs built their lessons on students' prior knowledge. However, these domains were not evidenced in many lesson plans because some PMTs included generic teacher and student actions without connecting those actions with the content of their lessons. For example, one PMT, in her lesson plan, offered that she will "check students' understanding of the material and reflect on it." Here, the instructional strategy involved the PMT's plan for addressing students' understandings without anticipating what those understandings could be and how they plan to address those. PMTs most often highlighted *KCT* in the second data set (lesson plan reflections), describing why they included specific instructional strategies in their lesson plans. *Horizon Content Knowledge* was the least discussed domain in PMTs' reflections, which was not evidenced in their lesson plans. When PMTs were prompted to reflect on how their content knowledge contributed to lesson planning, they often mentioned that knowledge helped them to choose several mathematical strategies without specifying them. Further, PMTs acknowledged that they could not anticipate students' unconventional strategies during lesson planning, indicating that PMTs were able to reflect on *Knowledge of Content and Students* even though it was not evidenced in their lesson plans. Overall, even though some domains were evidenced in PMTs' lesson planning, PMTs tended to pay less attention to mathematics content while planning and reflecting on lessons. Thus, PMTs would benefit from content-specific instructional activities that require them to explicitly utilize their content knowledge in several aspects of teaching because such activities potentially assist them in exploring and utilizing the content knowledge for rich mathematics teaching.

Conceptual Framework

Measures of teacher mathematical knowledge are notoriously difficult to develop (e.g., Orrill et al., 2015). This is in part because of the multidimensional nature of teacher knowledge. As part of two separate projects being undertaken by this research team, we have attempted to write assessments of teacher pedagogical content knowledge (PCK) in the area of proportional reasoning. Building from Shulman's (1986) conceptualization of teacher knowledge as comprised of content knowledge, pedagogical knowledge, and PCK, we have attempted to write items that capture only PCK. To this end, we endeavored to write items that measure PCK to teach proportions separate from the knowledge needed to solve proportions. The specific topics focused on analysis of student work, assessment of student understanding, planning for teaching, and issues of implementation (e.g., Smith & Stein, 2018).

The purpose of this poster is to report on findings from our development efforts. In prior papers, we have reflected on some of the challenges in writing items to measure teachers' specialized content knowledge (e.g., Orrill et al, 2015). In this paper, we reflect on our analysis of think-aloud interviews to identify what we have learned about the development of PCK items for proportional reasoning.

Methods

Data were collected on two assessments, one tied to an online course and the other being developed for broader use. As part of the item validation process, five in-service middle school teachers were interviewed for the first assessment and 11 were interviewed for the second. Teachers' responses to each item were analyzed to determine whether the item was measuring the intended knowledge as well as whether the item was interpreted by teachers as intended.

Findings

In this poster, we will report on some of our main findings related to the development of PCK items. These include teachers' reactions to the items, elements that obscure the measurement of PCK, and other observations about the interaction of CK and PCK.

JAPANESE TEACHER INSTRUCTIONAL CIRCLES

Matthew Melville
University of Delaware
Melbob@udel.edu

Keywords: Professional Development, Mathematical Knowledge of Teaching, Teacher Knowledge

Introduction

Interest in Japanese mathematics teaching has been motivated through their high achievement scores in international mathematics assessments (e.g., TIMSS). Lesson study is perhaps the most influential idea from the study of Japanese mathematics education. This mode of professional development has been widely studied and implemented in adapted versions in various countries (Fujii, 2013). Lesson study implementation outside of Japan has had mixed results (Doig, Groves, & Fujii, 2011). Miyakawa & Winslow (2019) argue that Japanese lesson study cannot be fully understood without understanding the entire "infrastructure" of work and development of a Japanese teacher. One part of this "infrastructure" that can support teachers' ability to engage in lesson study is *teacher instructional circles*.

Teacher instructional circles are widely unknown in the field of mathematics education. Therefore, the goal of this study is to provide an in-depth look at the purpose of these teacher instructional circles in the instructional system of Japan. Specifically, I was guided by the research question: *How do teacher instructional circles support Japanese teachers in the development of high-quality instructional plans during lesson study?*

Methods

Data Collection

To answer my research question, I used an ethnographic approach to collecting data. I participated in three different teacher instructional circles in three different areas in Japan. I collected data through participant observations, interview with members of the instructional circles, collection of artifacts, and self-journaling as my understanding of this professional development opportunity changed. I triangulated my data through member checks to make sure that the things I observed were accurate.

Data Analysis

Data analysis was done through an open coding approach. I began with the idea about the purposes of teacher instructional circles developed from my own experience, then added, tested, and refined categories as they emerged from the data analysis of observations and interview data.

Findings

I found that there are two types of teacher instructional circles, namely *study meeting (benkyoukai)* and *research meeting (kenkyuukai)*. The purposes and goals of these meetings vary however, the main focus is to improve teachers' understanding of student thinking, and to deepen their understanding of the mathematics they are teaching. Teacher instructional circles are adaptable to different teaching cultures, thus lending a possible support to countries attempts to implement lesson study. Even if lesson study is not the overall goal, teacher instructional circles provide an interesting alternate to current professional development programs.

PSYCHOMETRIC ANALYSIS OF 2019 KNOWLEDGE FOR TEACHING EARLY ELEMENTARY MATHEMATICS (K-TEEM)

Xiatong Yang
Florida State University
xy15@my.fsu.edu

Gizem Solmaz
Florida State University
gs19j@my.fsu.edu

Robert Schoen
Florida State University
rschoen@lsi.fsu.edu

Keywords: Assessment, Mathematical Knowledge for Teaching, Research Methods

Introduction

Hill and Shih (2009) presented a compelling argument for improvements in quantitative research methods in mathematics education. The quality and usefulness of quantitative research rests on high-quality measurement practices (APA, AERA, & NCME, 2014). In this poster, we present a method for examining the structural validity (Flake et al., 2017) of the 2019 Knowledge for Teaching Early Elementary Mathematics (K-TEEM), a web-based assessment of mathematical knowledge for teaching (MKT) at the early elementary level (Ball et al., 2008; Schoen et al., 2017; 2019; 2021).

Methods

The 2019 K-TEEM test serves as a pretest measure for a randomized controlled trial of a teacher professional development program based on Cognitively Guided Instruction. Teachers of grades K–2 completed the web-based assessment in spring 2019.

Analysis

Using methods based on both classical test theory and item-response theory, we went through the following process: missingness in data, dimensionality analysis, model fit and selection, item and test analysis, person-ability estimates, reliability estimates, and equating posttest to pretest scores.

Results

The sample size was 645. Item-level analysis suggested that 31 out of 32 items were adequate. Reliability estimates indicated that the test was useful for group-level analyses and was reasonably well aligned with the MKT of the population of interest.

Discussion

The process used for analysis and scoring of the K-TEEM can present a model for researchers in mathematics education to use as they increase the methodological rigor of their measurement practices.

Math Processes

SUPPORTING MIDDLE-SCHOOL STUDENTS' DEVELOPMENT OF EMERGENT GRAPHICAL SHAPE THINKING

Teo Paoletti
University of Delaware
teop@udel.edu

Julien Corven
University of Delaware
jcorven@udel.edu

Allison Gantt
University of Delaware
agantt@udel.edu

Emergent graphical shape thinking (Moore & Thompson, 2015) is a way of reasoning that is critical across numerous STEM fields. However, evidence indicates that the underlying component ideas for emergent thinking are underdeveloped in school mathematics education (e.g., Thompson & Carlson, 2017), and few studies directly report on students' development of this way of thinking. We present the results of a teaching experiment conducted with eighth-grade students to support stable meanings for emergent graphical shape thinking. We focus on the in-the-moment meanings expressed by a pair of students as they engaged in a sequence of tasks that we conjecture could support stable meanings for constructing and interpreting graphs.

Keywords: Algebra and Algebraic Thinking, Middle School Education, Learning Trajectories and Progressions

Across STEM fields, constructing and interpreting graphs is a crucial skill (e.g., Glazer, 2011; Potgieter et al., 2008). For instance, in a study looking at the use of graphical representations across numerous science textbooks and practitioner journals, Paoletti et al. (2020) determined that, at least implicitly, an individual must engage in *emergent graphical shape thinking* (hereafter emergent thinking) to interpret most graphs in these sources. Moore and Thompson (2015) defined emergent thinking as conceiving a graph simultaneously in terms of "what is made (a trace) and how it is made (covariation)" (2015, p. 785). Specifically, with a conception of a point as a multiplicative object, a student can conceive of a graph in terms of an emergent, progressive trace generated by the point's movement and dictated by the covarying quantities' magnitudes represented on the axes. The resulting graph represents the tracking of the two quantities' simultaneous covariation. Although there is some evidence that students in grades 6-12 can engage in emergent thinking in-the-moment (e.g., Ellis et al., 2015; Johnson, 2015), other research suggests that pre-service (e.g., Moore & Thompson, 2015; Moore et al., 2019) and in-service (e.g., Thompson et al., 2017) mathematics teachers in the United States often do not reason emergently in tasks designed to elicit such reasoning. Therefore, there is a need to examine how to productively support students in developing emergent thinking.

In this report, we address the research questions: *How do two eighth-grade students develop meanings for graphs that entail emergent thinking?* To investigate this question, we conducted a teaching experiment (Steffe & Thompson, 2000). In this report, we examine the work of two eighth-grade students as they completed the *Faucet Task* (Paoletti, 2019). Prior to this, we define components of emergent thinking to help readers understand how the task could support students' developing meanings for graphs. We then describe the in-the-moment meanings (Thompson, 2016) the two students developed as they engaged in the task. Finally, we share the results of a task developed by Thompson et al. (2017) that the students completed after the instructional sequence to determine whether such meanings may have become part of the students' stable meanings for constructing and interpreting graphs.

Components of Emergent Thinking

Covariational Reasoning and Multiplicative Objects

Several researchers (see Thompson & Carlson, 2017, for a review) have explored ways in which students' covariational reasoning can support them in developing productive meanings for various mathematical ideas. Researchers have contended covariational reasoning is developmental (Carlson et al., 2002; Saldanha & Thompson, 1998). Initially, a student is likely to coordinate two quantities by thinking "of one, then the other, then the first, then the second, and so on" (Saldanha & Thompson, 1998, p. 299) until the student has developed an operative image of covariation that entails a relationship between quantities that results from imagining both quantities being tracked for some duration. Saldanha and Thompson (1998) elaborated:

> [Covariational reasoning] entails coupling the two quantities, so that, in one's understanding, a multiplicative object is formed of the two. As a multiplicative object, one tracks either quantity's value with the immediate, explicit, and persistent realization that, at every moment, the other quantity also has a value. (p. 299)

Saldanha and Thompson's use of *multiplicative object* stems from Piaget's notion of 'and' as a multiplicative operator (the Cartesian product). Thompson et al. (2017) noted, "A person forms a multiplicative object from two quantities when she mentally unites their attributes to make a new attribute that is, simultaneously, one and the other" (p. 98). Hence, covariational reasoning entails understanding the simultaneity of two quantities' values in relation to each other.

Reasoning in a Coordinate System

To represent and coordinate two conceived quantities, students can construct a coordinate system (Lee, 2016; Lee et al., 2020). In the Cartesian coordinate system, once a student has conceived that quantities' magnitudes can be represented via line segments, the student can consider changes in the lengths of these segments, oriented orthogonally on horizontal and vertical axes, as the situational quantities covary. With such a coordinate system in mind, a student can then conceive of a point as a multiplicative object (Lee, 2016; Lee et al., 2020; Thompson, 2011) that simultaneously represents the two covarying quantities via the two segments' magnitudes. Such a meaning is a prerequisite for reasoning about (or imagining) a graph as representing an emergent trace of a point representing covarying quantities.

Setting and Methods

The middle school where the study took place serves a diverse student population (over 75% students of color) in the northeastern United States. We conducted the teaching experiment in an accelerated eighth grade math class with eight students who had completed high school level Algebra I and Geometry courses. The experiment occurred over five days in June after administration of the Geometry end-of-course assessment. The first author, who was not the students' normal teacher, served as the classroom teacher-researcher (TR).

All portions of the teaching experiment were video- and audio-recorded. The two focus students for this study, Kendis (female, African American) and Camila (female, Hispanic), were a pre-established group in the class. During the instruction, Kendis and Camila used a Chromebook computer to view and manipulate interactive applets and recorded their work on paper worksheets and a dry-erase board. To analyze this data, we watched the videos to identify occurrences providing insights into each student's in-the-moment meanings for constructing, interpreting, or representing quantities and relationships between quantities (Thompson, 2008).

Additionally, we collected data from the *uv*-Task described in Thompson et al. (2017) one day after the instruction concluded. In the *uv*-Task, a coordinate system is shown, and bolded segments representing quantities *v* and *u* (on the horizontal and vertical axes, respectively) vary as the animation plays. (The animated task can be seen at http://bit.ly/CovaryMagnitudes.) Consistent with Thompson et al.'s (2017) methods, we gave participants a paper with a set of axes and the initial segments representing *v* and *u* shown, and the animation was played six times. The students were asked to sketch a graph that depicted the value of *u* relative to the value of *v* (see Figure 1 (left) for an accurate graph). Using the rubric from Thompson et al. (2017) shown in Figure 1 (right), we independently coded the student responses on the shape of the sketched graph (92% interrater reliability). Although the *uv*-Task was not explicitly designed to measure emergent thinking, we contend imagining the graph as the trace of the (imagined) point corresponding to the endpoints of the two segments as they covary is required to produce a more accurate graph shape; we infer scoring a 2 or higher is likely indicative of a person engaging in emergent thinking.

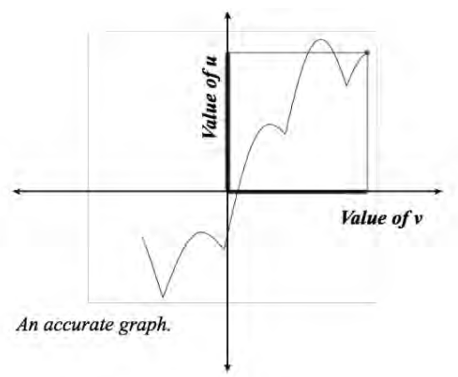

Table 4. Scoring rubric for Dimension B, shape of teachers' sketched graphs (SSG).

Level B4a:	The graph has four local minima in ascending order and three local maxima in ascending order*
Level B4b:	The graph begins decreasing, is generally increasing, has at least 2 local extrema, and has these points of inflection: – 6 if graph starts concave up and ends concave up – 7 if graph starts concave up (down) and ends concave down (up) – 8 if graph starts concave down and ends concave down
Level B3a:	The graph has 6 or 8 local extrema with minima in ascending order and maxima in ascending order.
Level B3b:	Same as B4b except that the graph has one too few or one too many points of inflection given the way the graph starts and ends.
Level B2:	The graph is generally increasing and has 2-5 or 9-12 local extrema, ignoring ascending order.
Level B1:	The graph has no more than 1 local minimum and is otherwise monotonically increasing.
Level B0:	The graph does not fit any of the above levels.

* By ascending order, we mean that from left to right each local minimum's *y*-coordinate was greater than the previous one, and likewise for each local maximum's *y*-coordinate.

Figure 1: (left) The accurate graph and (right) the scoring rubric for shape of the sketched graph on the *uv*-Task (Thompson et al., 2017).

Kendis and Camila's Development of Emergent Thinking

In the sections that follow, we present evidence that Kendis and Camila developed in-the-moment meanings for graphs that entailed emergent thinking. We first present evidence of their construction of component meanings to highlight how this thinking developed.

Constructing Quantities and Reasoning Covariationally

Critical to thinking emergently is conceiving of two covarying quantities. To help students construct quantities situationally, the TR presented the class with a GeoGebra applet (https://www.geogebra.org/m/rdxkrwek) intended to represent a faucet with hot and cold knobs (Figure 2). The TR directed students to use sliders to represent turning each knob on or off; changing the sliders changes the representations of amount of water (width of the rectangle below the faucet) and temperature (color of the rectangle). We intended for students to reason about the changing amount of water and temperature as two quantities to coordinate.

Figure 2: Screenshots of part one of the *Faucet Task* (turning cold water on).

The TR asked, “What are some of the things that this applet is trying to represent?” Camila stated, “the more to the right you dragged [the slider], the wider it [the rectangle below the faucet] got.” Kendis added that the width of the rectangle represents “how much water comes out of the faucet.” When the TR drew students’ attention to the changing colors of the rectangle, Kendis volunteered that the color represented “temperature,” and she explained that turning each knob outwards (cold on and hot off) would result in lowering the water temperature. Kendis’s responses demonstrated that she conceptualized two situational quantities.

Next, to support the students in coordinating two covarying quantities, the TR asked students to make predictions for what would happen to the amount and temperature of the water in four scenarios, assuming that both the hot and cold knobs start halfway on. Each scenario consisted of turning one knob either all the way on or off. By making predictions for changes in both amount and temperature of water in each scenario, we provided students opportunities to coordinate simultaneous changes in two quantities and thereby understand the simultaneity of the two quantities changing as a multiplicative object. As evidence of such reasoning, when asked what would happen if the hot knob were turned all the way off, Kendis responded, “the water is going to get colder, and it’ll be less [water].” Kendis’s response explicitly described changes in the magnitudes of both quantities, indicating her meaning that the quantities simultaneously covary.

Constructing and Using a Coordinate System

The next prompts were designed to develop two ideas related to constructing and using a coordinate system: using line segments to represent quantities and understanding a point in a coordinate system as a multiplicative object. These components support emergent thinking.

Using line segments to represent quantities. In the next prompt, students accessed a revised applet that included (a) a vertical (graduated, but unlabeled) thermometer (colored red) to represent the water temperature and (b) a horizontal pink line segment that corresponded to the width of the rectangle that represented the water stream (Figure 3, left). The positioning of the segments as vertical and horizontal was designed to foreshadow the creation of a coordinate system using segments to represent quantities’ values on the vertical and horizontal axes.

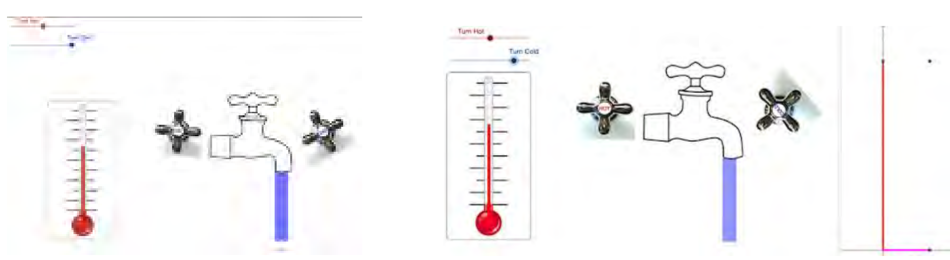

Figure 3: Screenshots of (left) part two and (right) part three of the *Faucet Task*.

The TR then asked students to describe how the segments varied for the same four knob-turning scenarios as before. Our goal was to provide opportunities to connect the lengths of the segments to the previously established quantities. To exemplify the productivity of such opportunities, consider a dialogue about turning the cold knob off between Camila and the TR:

Camila: Um, you turn the cold to the left, and then the temperature will increase, and the red line will get longer because of that. And the pink line will be shorter. [*TR asks Camila to repeat.*] The red line is going to get longer.
TR: It's going to get longer? Why?
Camila: Because you're eliminating the cold water, so the hot is left, and the hot water increases the temperature.
TR: [*TR restates what Camila said.*]…[A]nd then the pink segment's going to go?
Camila: It's going to get shorter.
TR: It's going to get shorter because there's going to be?
Camila: Less water overall.

In this dialogue, Camila connects changes in the quantities in the situation (temperature and amount of water) to changes in the lengths of the corresponding line segments, indicating that she understood the segments as representing the situational quantities. Further, we note Camila readily transferred this reasoning when presented with the segments on the coordinate system.

Understanding a point in a coordinate system as a multiplicative object. Shortly after the previous exchange, the TR showed students a new applet. This applet included a coordinate system with the pink segment (representing amount of water) positioned along the horizontal axis, the red segment (representing temperature) positioned along the vertical axis, and a point with position corresponding to the endpoints of both segments (Figure 3, right). The TR directed students to describe the motion of the point as they explored the applet to provide an opportunity to conceive of relationships between the point's movement and variations in both segments.

While working as a pair, Camila and Kendis had the following conversation with the TR:

TR: So how is this point moving around the screen?
Camila: In accordance with the…
Kendis: [*moves fists horizontally back and forth*]
TR: In accordance with what?
Kendis: The, the temperature… [crosstalk]
Camila: [crosstalk] Temperature.
Kendis: …and the, and how much water was coming out.
TR: With both?
Kendis: [*nods and gestures a vertical line with hand*] It stays in line with both of them.

We interpreted Kendis's reference to "both of them" as the segments representing amount of water and temperature. We inferred that Kendis's horizontal gesture was intended to show that the top endpoint of the temperature segment and the point on the coordinate system formed a horizontal line (and similar for the vertical gesture and the amount of water segment). We infer Kendis understood that the point's movement was dictated by the two quantities' magnitudes represented by segments; the point served as a multiplicative object in the coordinate system.

Using the same applet, the TR told students to investigate a point's movement in several scenarios. Responding to a scenario starting with both knobs turned halfway on, and asked to predict how the quantities will change when they turn hot all the way on, both Kendis and Camila related segment lengths to the situational quantities. Kendis stated:

> Yeah, this is going to go up [*traces finger along the vertical axis from the origin upward beyond the length of the red segment]*… more temperature…. [*traces finger along the horizontal axis from the origin to the right beyond the length of the pink segment*] It's going to move to the right and up.

In response to Kendis's reasoning, Camila used the Chromebook to do a Google Image search for a compass and produced a drawing (reproduced in Figure 4a). We infer that Camila interpreted the described action ("move to the right and up") as occurring simultaneously, and the diagonal line segment represented her understanding of the point's movement.

Indicative of not yet explicitly connecting the coordinate point to the situational multiplicative object she had constructed earlier, Kendis initially disagreed with Camila's representation, stating:

> [I]t's going this way [*traces right along the horizontal axis, as in (1) in Figure 4b*] and, look, it's going to stay in a line with [the red segment], so it's just going to move over and up [*traces from the point to the right a short distance (2) and then up (3) in Figure 4b*].

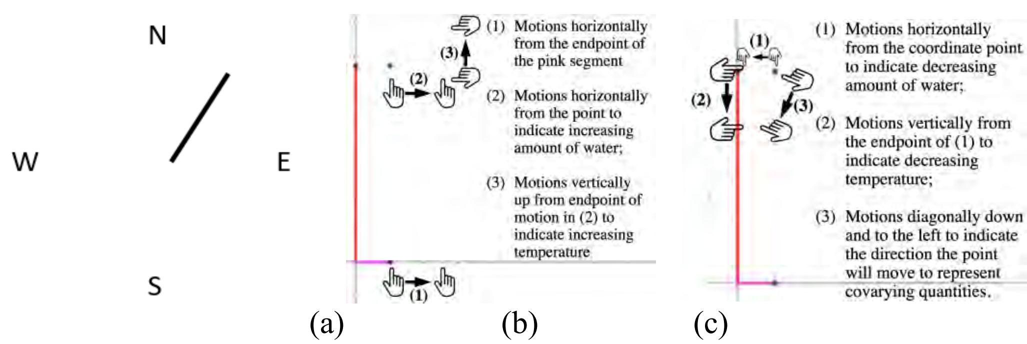

Figure 4: (a) Recreation of Camila's drawing. (b, c) Recreations of Kendis' hand motions.

Although both Camila and Kendis understood where the point would end up relative to its starting position, they conceptualized the point's movement differently. Consistent with the developmental nature of covariational reasoning (Saldanha & Thompson, 1998), Kendis initially conceived of the changes in the underlying segments as sequential (the point would move to the right, then up) as opposed to the simultaneous movement Camila had described.

As the pair continued to discuss the scenarios, evidence emerged that Kendis also began to explicitly connect the motion of the point with the simultaneously covarying situational quantities. For instance, when predicting the point's movement when the two knobs start halfway on and the hot knob is turned off, Kendis described "[the red segment]'s gonna go down, and then [*points to the horizontal axis*] it's less water also so it's gonna go diagonal [*making a diagonal cutting motion with her hand*]." Immediately after this, Kendis silently engaged in a series of movements. She first motioned horizontally to the left from the point as if indicating a decreasing amount of water (indicated by (1) in Figure 4c), then motioned down as if indicating a decreasing temperature of water ((2) in Figure 4c). Critically, and differing from her earlier activity, after these two motions, Kendis lastly motioned diagonally down-and-to-the-left ((3) in Figure 4c) to indicate that the point would move in such a way to reflect the simultaneous variations of the two segment and quantities magnitudes. We took this as evidence of Kendis's formation of a multiplicative object.

Reasoning Emergently and Interpreting Graphs in Multiple Ways

For the final activity in the *Faucet Task*, the TR provided students with several graphs that we told them resulted from turning the knobs. The TR asked students to determine what position each knob was in initially and what action(s) occurred. It is important to note that the graphs were undirected (i.e., no starting or ending point was identified). Thus, each graph had at least two possible interpretations. Through this activity, we intended to provide students the opportunity to reason emergently by interpreting (at least) one possible trace of the graph.

As the pair discussed the actions that would produce a graph (Figure 5 (left)) that was moving "down and to the right," Camila reasoned that the action was turning the cold knob on. She stated, "It's going down in temperature and to the right, so it means you're increasing water, and it's going down, so it means you have to be adding cold water." Camila's reasoning moved between imagining the tracing of a point on the graph, the underlying quantities and how they covary, and the action in the situation. We infer she was reasoning emergently.

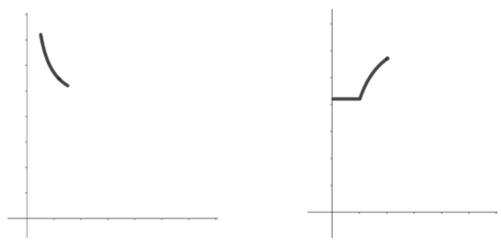

Figure 5: Two trace graphs the TR asked students to interpret.

Kendis and Camila did not independently consider that more than one action could produce the same graph. However, during the class discussion of Figure 5 (left), another group described an interpretation of the graph as turning the cold knob off (reading the graph from right to left). Once the discussion revealed that reading the graph as a trace from right to left could be produced by a different action that would result in the same final graph, Camila was able to apply this idea to describe two different possible productions of the graph in Figure 5 (right):

Camila: First step is to turn the cold on, then turn the hot one on.
TR: [T]hey're both starting completely off, turning cold on then turning hot on…. [S]o in terms of the two quantities, how did you know that was [*trails off*]?
Camila: Well, it continued to go to the right, so it means [the amount of water]'s increasing in quantity, and then, after the second transition, it's going up in temperature, which means you're going to be adding hot water. So, the first one we started off as cold adding it, and then we had to add more of hotter temperature.
TR: … Could there be another way this plays out?
Camila: Hot water off.
TR: Hot water, so you start with both of them on, turn hot water off get to here…
Camila: And then the cold is at halfway and then you could also turn it off.

We take Camila's independent description of two different action sequences that would produce the graph as strong evidence that she was engaging in in-the-moment emergent thinking.

uv-Task Results

As shown above, the work on the *Faucet Task* provided evidence of Kendis and Camila developing in-the-moment emergent thinking. We hypothesized that repeated experiences with such thinking in different contexts would allow emergent thinking to become part of the students' stable meanings for constructing or interpreting graphs. The remaining sessions of the teaching experiment provided students with seven additional opportunities to construct and five additional opportunities to interpret graphs in different tasks and contexts. We use the results from the *uv*-Task (Table 1) to provide some evidence that such opportunities were productive for both Kendis and Camila, as well as their classmates, in developing stable meanings (Thompson, 2016) for constructing and interpreting graphs that entail emergent shape thinking.

Table 1 presents the results of US secondary mathematics teachers as reported in Thompson et al. (2017) and our participants' results on the *uv*-Task. We interpreted a score of 0/IDK ("I don't know") on this task as no evidence of employing covariational reasoning, a score of 1 as evidence of employing gross covariational reasoning (Thompson & Carlson, 2017), and a score of 2 or greater as evidence of employing some level of emergent reasoning. Kendis and Camila each received a score of 2 for the shape of their sketched graphs (see Figure 6). These scores, which exceeded the performance of over 70% of US mathematics teachers in the Thompson et al. (2017) study, indicated to us that Kendis and Camila may have developed emergent thinking as a component of their stable meanings for constructing or interpreting graphs, as evidenced by their ability to apply such reasoning in an unfamiliar, decontextualized situation.

Table 1: Scores on the Shape of Sketched Graph Rubric for the *uv*-Task

	0/IDK	*1*	*2*	*3*	*4*
US teachers (n = 121)	65 (53.7%)	22 (18.2%)	11 (9.1%)	14 (11.6%)	9 (7.4%)
8th graders (n = 8)	2 (25.0%)	0 (0.0%)	4 (50.0%)	1 (12.5%)	1 (12.5%)

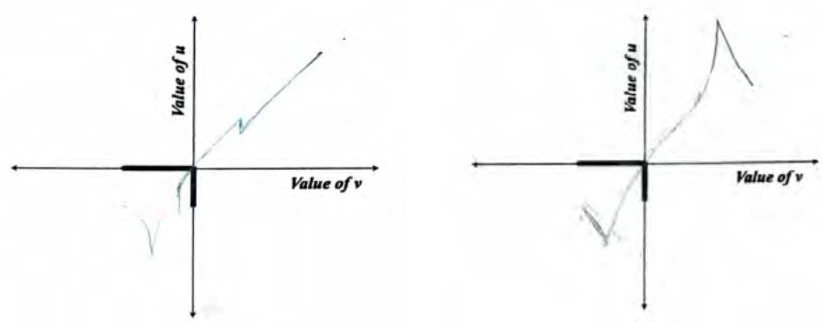

Figure 6: (left) Camila's graph and (right) Kendis's graph in response to the *uv*-Task.

Conclusion

Addressing our research question, we described two students' activity as they engaged in an instructional sequence that emphasized aspects of covariational reasoning (Thompson & Carlson, 2017) and reasoning within a coordinate system (Lee, 2016; Lee et al., 2020) to support them in developing emergent thinking. We highlight that despite individual differences in students' in-the-moment meanings during instruction, each student demonstrated evidence of stable meanings that entailed emergent thinking by the end of the study; each student conceived graphs as "what is made (a trace) and how it is made (covariation)" (Moore & Thompson, 2015, p. 785). We add to the literature by providing a proof-of-concept that at least some middle school students can develop emergent thinking as part of their stable meanings for graphs.

Although our quantitative results present students' performance on a task relative to a sample of U.S. mathematics teachers (Thompson et al., 2017), we do not intend for comparisons to be drawn between these populations. Rather, we intend to provide a frame of reference that conveys the non-trivial nature of constructing meanings that entail emergent thinking. Our study demonstrates that a purposeful learning progression can develop eighth-grade students' stable meanings for graphs via emergent reasoning; we conjecture other populations (e.g., teachers) could develop comparable meanings if provided similar opportunities.

We acknowledge that the small sample size and the use of an accelerated math class limit the generalizability of our findings. Given the importance of emergent thinking as a way of interpreting graphs across STEM fields (Paoletti et al., 2020), it is critical to continue to investigate ways to develop such meanings throughout school mathematics education.

HARMONY AND DISSONANCE: AN ENACTIVIST ANALYSIS OF THE STRUGGLE FOR SENSE MAKING IN PROBLEM SOLVING

This work seeks to understand the emergent nature of mathematical activity mediated by learners' engagement with multiple artifacts. We explored the problem solving of two learners as they aimed to make sense of fraction division by coordinating meanings across two artifacts, one being a physical manipulative and the other a written expression of the standard algorithm. In addressing the question, "How do learners make sense of and coordinate meanings across multiple representations of mathematical ideas?" we took an enactivist perspective and used tools of semiotics to analyze the ways they navigated the dissonance that arose as they sought to achieve harmony in meanings across multiple representations of ideas. Our findings reveal the value of such tool-mediated engagement as well as the complexity of problem solving more broadly. Implications for learning mathematics with multiple artifacts are discussed.

Keywords: Problem Solving, Mathematical Representations, Learning Theory, Technology

Hiebert and Grouws (2007) synthesized evidence from a number of studies to argue that the conceptual learning of mathematics is associated with teachers' and students' "explicit attention to the development of mathematical connections among ideas, facts, and procedures" (p. 391). Much research has been done regarding the ways in which teachers can support students' engagement with multiple representations. What is less well understood is the process by which multiple representations of a concept can be leveraged and connected in order to contribute to learners' meanings of the referent of those representations.

Findings from an enactivist analysis of strategy development in mental mathematics contexts suggest that the nature of the processes at play are dynamic, emergent, and contingent on "an ongoing loop" (Proulx, 2013, p. 319) of interactions between the problem and the solver(s). Since sense making results from problem solving, and since problem solving is dynamic, emergent, and contingent (Proulx, 2013), it follows that sense making should be, as well. Moreover, sense making is inextricably linked to the material and symbolic tools that mediate its learning (Artigue, 2002; Verillon & Rabardel, 1995). Following this line of inquiry, we consider what an enactivist analysis might reveal about the processes at play in mathematical meaning making as it develops through the complex interplay of signs and meanings (Maffia and Maracci, 2019) associated with learners' engagement with multiple representations. Thus, this work seeks to address the following question: *"How do learners make sense of and coordinate meanings across multiple representations of mathematical ideas?"* We do so through an analysis of the mathematical activity of two learners as they aim to make sense of fraction division mediated by two representations: the flip-and-multiply algorithm for fraction division and a physical manipulative designed for learners' engagement with fraction concepts.

Theoretical Framework

This study is grounded in the enactivist theory of cognition, which asserts that: "1) perception consists in perceptually guided action, and 2) cognitive structures emerge from the recurrent sensorimotor patterns that enable action to be perceptually guided" (Varela, Rosch, &

Thompson, 1992, pp. 172-173). Thus, cognition, or active knowing, is not some "outward manifestation of some inner workings" (Davis, 1995, p. 4), but rather a dynamically co-emergent phenomena that arises and is brought forth (Maturana & Varela, 1987) through one's goal-directed, "embodied (enacted) understandings" (Davis, 1995, p. 4). In Davis's (1995) adaptation of Maturana and Varela's (1987) words, "*Knowing* is *doing* is *being*" (p. 7).

By viewing knowing in the interactivity of learners, the enactivist perspective offers an alternative to a view of knowledge as the static accumulation of facts and ideas that one may select in response to a problem at hand. Instead, "to know is to respond adequately; it is a situated doing that emerges through the interaction of the organism (e.g., a student, a researcher) and [their] environment" (Maheux & Proulx, 2015, p. 212). But fit is more than that. We use *harmony* to emphasize that fit is an internally "felt dimension of experience" (Petitmengin, 2017, p. 144) that drives problem solving. This drive toward a harmony of goals and actions is theoretically linked to the concepts of structural coupling and structural determinism.

Structural coupling is the process associated with the Darwinian concept of co-evolution, whereby an organism and its environment co-adapt through recursive and repeated inter-actions (Maturana & Varela, 1987). As they do so, the organism and environment experience mutual structural changes so that the fit between them is dynamic. Moreover, this fit is contingent upon unique histories of recurrent interactions and structural changes (Maturana 1988, as cited in Reid & Mgombelo, 2015, p. 175) that are determined by the organism's own structure, a phenomenon referred to as *structural determinism* (Maturana & Varela, 1987). Proulx's (2013) analysis of students' emergent problem-solving activity is committed to this concept as it assumes that a problem solver's strategies are determined by the solver's own way of making sense.

We take this enactivist perspective on mathematical activity as knowing-in-action to investigate the emergent problem solving of two learners as they aim to understand fraction division by finding harmony in meanings across what for them are recurring and competing interpretations in the various elements of two artifacts: 1) the flip-and-multiply algorithm for fraction division, and 2) a manipulative that one of them designed for engagement with fraction concepts. Maffia and Maracci's (2019) concept of *semiotic interference* is used to analyze these dynamic, emergent, and contingent (Proulx, 2013) interactions with the two artifacts. This concept, framed within the Theory of Semiotic Mediation (Bartolini Bussi & Mariotti 2008) relies on Peirce's (1998) triad of sign relations to analyze how meanings emerge from the translation of personalized signs into new signs and eventually into generalized mathematical signs.

According to Peirce, a *sign* is a triadic relationship among a *representamen* (the perceivable part of a sign), an *object* (what the sign stands for), and an *interpretant*, which Presmeg (2006) describes as follows: the "interpretant involves *meaning making*: it is the result of trying to make sense of the relationship… [between] the object and the representamen" (p. 170, emphasis added). Thus, semiotic interference becomes useful for analyzing the process of meaning making across multiple artifacts whenever "the interpretant of a sign whose object belongs to the context of [one] artifact is translated by a student in a new sign whose object belongs to the context of another artifact" (p. 3-58). That is, as the two learners aim to "make meaning" by negotiating their interpretations of signs across the orange and the algorithm, each of the artifacts affords them with differing semiotic potentials (Bartolini Bussi & Mariotti, 2008) for the emergence of a relationship between the personal use of the artifact and mathematical meanings associated with the artifact and its use. Semiotic interference provides a window into their chaining of signs (Presmeg, 2006; Bartolini Bussi & Mariotti, 2008) as they negotiate these interpretations in order to converge upon a meaning for fraction division. In this sense, meaning making is understood as emergent phenomena arising from this “complex interplay of signs” (Maffia & Maracci, 2019, p. 3-57). We thus frame the activity of problem solving from an enactivist perspective and leverage tools of semiotics to depict the evolution of meaning making to better understand how learners make meaning through the coordination of multiple representations of mathematical ideas.

As a critical point of clarification, “representation” in the Peircean sense is a thing perceived by a learner, and that is the meaning we will be using throughout the remainder of this paper. What the field of mathematics education terms a “representation” (e.g., tables, graphs, symbolic expressions) is what we will refer to as an “artifact.”

Methodology

This project is part of a larger study that aims to test and refine the hypothesis that a pedagogically genuine, open-ended, and iterative design experience centered on the Making (Halverson & Sheridan, 2014) of a physical manipulative for mathematics learning would be formative for the development of practicing and prospective mathematics teachers’ (PMTs’) inquiry-oriented pedagogy. Data collection for this study took place across several semesters of a graduate-level mathematics course for PMTs at a mid-sized university in the northeastern United States. For the project reported here, we took a revelatory case study approach (Yin, 2014) in order to determine what an enactivist perspective might reveal about the phenomena involved in the problem-solving activity of “Dolly” and “Lyle” (both pseudonyms).

Dolly was a participant in this larger study; she is a participant-researcher on this project. She calls the tool she designed a “fraction orange” (Figure 1, left), and in designing it, she aimed to create a tool with affordances for the exploration of fraction concepts. The orange is a sphere partitioned into two hemispheres; one hemisphere is further partitioned into fourths, eighths, and sixteenths of the whole; the other into sixths and eighteenths.

Figure 1: The Orange and the Algorithm

The manipulative Dolly created and the thirteen-minute problem-solving interview she conducted with Lyle are artifacts of her participation in the larger study. They also constitute the data for this case study. Three researchers on this project, including Dolly, enacted interpretations of data both individually and in collaborative dialogue. Dolly’s role as both participant and researcher offers validation by permitting a strengthening of the interrelationship between a research context and its participants.

We undertook the analysis by transcribing the recorded video and analyzing the “verbal utterances through line-by-line analysis of the transcripts; stud[ying] body language and intonation by viewing video tapes...; and in511andeng] mathematical forms and objects from the participants’ actions, utterances and notations” (Simmt, 2000, p. 154). Specifically, we focused our analysis on the particular interactions where Dolly and Lyle aimed to coordinate meanings for fraction division in the manipulative and in an algorithm that presumably substantiates those meanings (Malafouris, 2013). As we take our learners’ activity to be driven by an evolutionary imperative to maintain harmony through their problem solving, we used the enactivist concepts of structural coupling and structural determinism to analyze these inter-actions. And in order to analyze their emergent and recursive processes of meaning making across multiple representations, we employed Peirce's (1998) triad of sign relations and Maffia and Maracci's (2019) concept of semiotic interference to refine the analysis.

Results

Given the duration and non-linearity of Dolly and Lyle's problem solving, space constraints only permit us to share selected excerpts uniquely revealed by enactivist and semiotic lenses that elucidate critical moments in their emergent mathematical activity. As a note for the reader, Dolly and Lyle only make use of the hemisphere of the Fraction Orange that is partitioned into fourths, eighths, and sixteenths. In our analysis of their activity, unless otherwise indicated, all fraction pieces are named as Dolly and Lyle do, that is, as if that hemisphere of the orange is the whole.

Embarking on a path of problem solving

We set the stage for the presentation of these findings at the beginning of Dolly's interview with Lyle. Dolly poses the problem, ½ ÷ ¼, on paper alongside her fraction orange. Lyle chooses the pen and paper, performs the flip-and-multiply algorithm: $\frac{1}{2} \div \frac{1}{4} = \frac{1}{2} \times \frac{4}{1} = \frac{4}{2} = \frac{2}{1}$, and declares his answer to be 2. We interpret this application of the standard algorithm as a structurally determined action informed by a lived history of structural coupling with traditional school mathematics, where a *knowing* of fraction division as the execution of an algorithm and the answer it yields was deemed *good enough* to "survive." It constituted what Lyle needed to do to achieve harmony within his mathematics learning environment.

Next, Dolly directs Lyle's attention to the orange and asks, "Can you show me with this?" With two artifacts affording them differing semiotic potentials, both Dolly and Lyle set off to navigate a complicated interplay of signs literally at (their) hand. As we will observe, they experience semiotic interference (i.e., meaning making through the enchaining of these signs) as they pursue a non-linear path of problem-solving activity punctuated by moments of what we refer to as either *harmony*[1], a pleasing fit, or *dissonance*, a displeasing conflict or lack of fit. The cognitive/affective underpinnings of these terms is intentional, because cognition from an enactivist perspective is synonymous with *effective* action.

First dissonance

This exchange captures the first moment of dissonance as Lyle responds to the task Dolly posed to him and as the two learners realize that their understandings of fraction division do not harmonize across the two artifacts.

> Lyle: A half divided by a quarter… <*removes what he considers to be a half piece*> a half divided by a quarter <*points to the fourth pieces inside of the half*> is four.
> Dolly: <pointing to the algorithm and the answer on the page> But that's not what you got.
> Lyle: Uh oh. <*Lyle pulls out the fourth pieces from the half pieces and looks back and forth between the paper and the orange. His gaze then shifts more rapidly between the two artifacts, and the timbre of concern in his voice grows as he continues*.> Uh oh. A half divided by a quarter. Why doesn't that work?

In analyzing this excerpt, we first point out that we are able to observe Lyle's embodied knowings of mathematics precisely because those actions *are* his knowings. They are not inferences of *a priori* knowledge possessed internally; they are only "discovered in action" (Malafouris, 2013, p. 174). In our observations of his interactions with the orange – selecting, removing, gesturing, and communicating about pieces – we can see that the tool mediates new affordances for Lyle's actions. In this first moment, these new affordances evoke an emergent sense of dissonance, which is evident in Lyle's puzzled utterances and frantic glances – somatic markers (Damasio, 1996, as cited in Brown & Coles, 2011) of his negative affective response to seemingly conflicting interpretations of the same mathematical idea. We take these actions to indicate that his knowing of fraction division as expressed through the algorithm is discordant with his knowing of fractions and division as he perceives them in the fraction orange. This experience of semiotic interference between the two representamens (the orange and the algorithm) catalyzes an embodied drive to find harmonized meaning between them, an essential motivation for their problem solving.

The messiness of multiple representations

This next exchange features an extended moment of semiotic interference that is a particularly complicated one for Lyle and that we suggest speaks more broadly to the complexity that is characteristic of meaning making through the connections of multiple representations (Lesh et al., 1987; Hiebert & Grouws, 2007). Dolly and Lyle, motivated by a desire of sense making, strive for harmony in meanings between the orange and the algorithm as they evaluate the expression, ½ ÷ ¼.

Dolly: Here's our half. <*She picks up the half piece and confidently places it next to the algorithm on paper. Lyle points to the piece and looks back to the paper*.> And how many quarters go into a half?

Lyle: <*Looking at the orange*> Two. <*shifting his attention to the paper*> Four. <*shifting his attention back to the orange, and then again back to the paper*> Is that half of a quarter, though? It's half <*pointing to the ½ on the paper in the expression, "½ ÷ ¼"*> of a quarter. <*pointing to the ¼ on the paper*> It's not half of a whole thing. <*As he says, "whole thing," he circles the "4" of the* $\frac{4}{1}$ *in the flip-and-multiply part of the equation on his paper.*>

Dolly: It's a quarter of a half, right? <*Lyle looks at the orange, back at the paper, and back at the orange*>

Lyle: <*with uncertainty*> Yeah?

Dolly: How many quarters of a half are there? <*pauses and laughs*> Why is this so hard?

Through Dolly and Lyle's varied interpretations of both fractions and fraction division in relation to the orange and the algorithm, we observe expressions of semiotic interference. Through their words and gestures, we see Dolly begin by enacting her knowing (interpretant) of "a half" (object) in the orange (representamen) and physically placing the piece on the paper, as if to propose a common meaning between the two by creating a physical bridge between the piece of the orange and the symbolic form of the fraction on paper. She interprets the posed problem, ½ ÷ ¼, as "How many quarters go into a half?" – an interpretation that is for Dolly both meaningful and actionable. Lyle, referencing the orange and evoking his own meanings of both one quarter and one half, determines that two quarter pieces fit into a half piece and (correctly) answers, "2." Immediately thereafter, however, he shifts his attention to the algorithm on the page, and possibly seeing $\frac{4}{1}$, he changes his answer to "4." Doing so provokes dissonance in the pair's meaning-making process, since the outcomes of what Lyle had enacted with the orange did not match what he had enacted with the algorithm. We conjecture that this shift from "2" to "4" was provoked by Lyle's prior knowing of fraction division as the execution of an algorithm, and as a result, he seems to privilege the algorithm over the orange as an anchor of certainty against which his own reasoning is measured.

Next, Lyle aims to resolve the dissonance he experienced as he produced two different solutions to the posed problem. Turning back to the dividend (½) and quotient (¼) in the problem, he seems set on finding a harmonious interpretation of the "whole thing" (object) across both artifacts and wonders yet again just what ½ ÷ ¼ means.

In our interpretation, Lyle's actions are directed at finding harmony across three instances of dissonance: 1) His expression, "Is that half *of* a quarter, though?" [emphasis added] corresponds to a (mis)interpretation of fraction division as one fractional part *of* another; 2) Lyle's ongoing endeavor to identify the whole in his interpretations of fractions – including the utterance, "It's not half of a whole thing" as he repeatedly circles the "4" on the paper – is an indication that he has yet to settle on what that whole is; and 3) His contemplative circling of the "4" could indicate that the number is a perceived point of both importance and confusion resulting from the actions of the flip-and-multiply algorithm. Dolly's utterance, "Why is this so hard?" is an expression of the messiness of engagement with multiple representations and what it feels like for her and Lyle to find themselves amidst spirals of semiotic interference across different *artifacts* (the orange, the algorithm), their wonderings about *objects* (e.g., What is a whole? What is division? What is $4/1$?), and the *relationships* between artifacts and objects across signs (e.g., What is the whole across these different representations?, What does ½ ÷ ¼, mean, and how does it relate to an enactment of "How many quarters go into a half?" with the orange?).

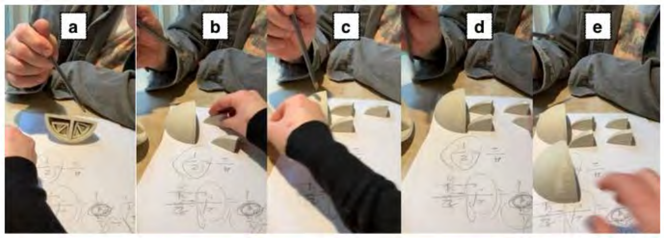
A crowning achievement

In this next excerpt, we present what appears to be a crowning achievement for Dolly and Lyle in their search for harmony in meanings for fraction division mediated by two artifacts. By enchaining signs across pieces of the orange and elements of the algorithm, more specifically by translating interpretations of parts of the orange to interpretations of quantities in the algorithm (i.e., $4/2$ and $2/1$), they have just made sense of those quantities. Next, they engaged in similar sense making in order to find interpretations for the ½ and ¼ in the posed problem, ½ ÷ ¼.

> *Dolly: <referring to the expression, ½ ÷ ¼>* We wanna take a half of one and divide it by a quarter of one, right?
> *Lyle:* Yes.
> *Dolly:* Take a half of one and divide – oh, that's what it is!
> *Lyle:* It's 2.
> *Dolly:* We wanna take this <points to the half piece of the orange> and see how many of those <*now pointing to quarter piece*> fit in there <*points to the half piece again. Then, with confidence:*> And that's why our answer is 2.
> *Lyle:* Yes.
> *Dolly:* There's still two halves in a whole, 'cuz this <*the expression, ½ ÷ ¼*> is in regards to a whole. <*rephrasing*> This is in regards to 1. So a half of 1 divided by a quarter of 1 is 2, because 2 quarters fit into 1 half. Or <*returning to the expression,* $\frac{4}{2}=\frac{2}{1}$> 4 quarters fit into 2 halves.

Lyle: Yeah.

In this excerpt, we observe the meaning Dolly makes of the expression, ½ ÷ ¼, by enchaining interpretations of ½ and ¼ in light of the measurement meaning of division she and Lyle enacted earlier, as well as the meanings they enacted for $\frac{4}{2}$ and $\frac{2}{1}$ in the algorithm. Next, Lyle re-enacts the interpretation for himself.



Figures 2a - –e: Lyle re-enacts Dolly's understanding of "$4/2 = 2/1$."

Lyle: <*pointing to ½ on the page:*> So this is half of a whole <now pointing to ¼ on the page.> and this is a quarter of a whole. <*Next, he turns his attention to the orange (Figure 2a) and points to the half piece resting on the paper. He mutters quietly as if he's reassuring himself:*> Half of a whole. <*Next, he takes his pencil and points to each quarter piece in a sweeping motion of the pencil across each piece*:> Quarter of a whole <*Then, pointing to the two quarter pieces, he continues:*> is 2. <*Thus, he appears to be establishing that the number of quarter pieces he's identified – 2 – is the answer to the posed problem, ½ ÷ ¼*>.
Dolly: <*pointing to the 2 quarter pieces*> Yeah, 'cause there's two quarters of a whole.
Lyle: Yeah, that makes sense.
Dolly: 'Cause there's two of these <*She pulls out the quarter pieces and sets them next to the half piece (Figure 2b)*.> for every one of these <*she says as she touches the half piece*>.
Lyle: <*with a sigh, perhaps of relief*> Yes.
Dolly: Or there's four of these. <*She takes the quarter pieces out of the other half piece.* >
Lyle: <*points to the half piece and extends Dolly's thinking (Figure 2c*)>: For two of those.
Dolly: <*revoicing Lyle*> For two of those. <*As she speaks, she aligns all of the quarter pieces as well as the second half piece on the page (Figures 2d and 2e*).>

As if to establish his own meanings for fraction division and its coherence in representations across artifacts as Dolly has just done, Lyle uses the pencil in his hand to re-enact a physical bridge between the elements of the problem (½ ÷ ¼) and the pieces of the orange. He utters "half of a whole" as he points to the ½ on paper, and "quarter of a whole" as he points to the ¼. Then he repeats these phrases on the other side of the bridge he's establishing: "half of a whole" as he points to the half piece, and "quarter of a whole" as he points to the quarter piece. We interpret this activity as a matching of his interpretation of half of a whole and quarter of a whole in the symbolic representations (½ and ¼, respectively) to the representations he's identified in the orange (the half piece and the quarter piece, respectively). These embodied epistemic actions seem to reify the harmony that has finally emerged from recursive interactions that culminate in an enchaining of signs signifying the sense he and Dolly have made. This reification can be viewed as a newly coupled structure of fraction division for Dolly and Lyle, one that offers a stark contrast to the structurally determined response to fraction division that they enacted at the outset of their problem-solving activity. That is, rather than performing a rote algorithmic process as fraction division, they actually come to do (be/know) fraction division and enchain multiple mathematical signs in order to do so.

Concluding Discussion

This work set out to address the question, *"How do learners make sense of and coordinate meanings across multiple representations of mathematical ideas?"* We did so by analyzing Dolly and Lyle's sense making of fraction division through the complex interplay of signs and meanings that emerged from their engagement with multiple representations. In particular, we analyzed problem-solving interactions that were driven by an imperative to *make sense* of the complicated ideas of fraction division mediated by both an algorithm and a "Fraction Orange" manipulative. The course of their moment-to-moment activity beckoned us to leverage an enactivist framework for its stance on interactions *as* knowing, and for its appreciation of the doing of mathematics as a recursive, nonlinear, unfolding, embodied activity influenced by a system's lived history and its ongoing strive for *fit*.

In analyzing the iterative cycles of harmony and dissonance experienced by Dolly and Lyle, the analytic concepts of structural coupling, structural determinism, semiotic interference, and fit enabled us to discern valuable insights into learners' activity as they navigated multiple representations of mathematical ideas. In particular, structural coupling and determinism enabled a particular focus on the co-constitution that takes place between the individual and their environment through dialectic interactions that result in action-as-knowing. Dolly and Lyle's structural couplings with traditional school mathematics became apparent to us as they navigated felt experiences of harmony and dissonance throughout their drive for fit. For quite a while, they struggled to establish and maintain coherence in meanings across representamens (artifacts, symbols), objects (mathematical ideas), and interpretants (their own meanings of relationships between artifacts and ideas) at hand. Eventually, their dissonance gave way as they established harmony by enchaining meanings across signs through interactions with multiple representations of the complex network of mathematical ideas involved in fraction division. Ultimately, this harmony made way for deep (and felt) ways of doing/knowing mathematics.

The implications of this finding for practice are in recommendations for pedagogical and material resources that enable, support, and honor this sort of loosely structured problem-solving activity to occur in mathematics classrooms. On this point, we wish to re-emphasize that it was this activity that was fundamental to Dolly and Lyle's learning and not their assimilation of a path constructed by others. As Proulx (2013) reminds us, students' paths of problem solving emerge in interactions with the environment and are contingent on their particular mathematical structures and interactions. "Average" paths and tools presumed viable for sense making simply cannot be determined *a priori*. Rather, tools should be provided that are responsive to students' creative and agentive efforts at sense making as they lay down their own path while walking (Varela, 1987). And it is only in such walking that learners can define and refine their own authoring of mathematical ideas and meanings, and find confidence as a mathematical doer with membership in a classroom community.

Note

[1] We use the word *harmony* in a sense similar to Mariotti and Montone's (2020) concept of *synergy*, to denote "the emergence of a phenomenon of semiotic interference [that] fosters the

evolution of signs in an effective semiotic chain," which is an indication of a "deepening and weaving [of] the semiotic web" of mathematical meaning (p. 113).

This report documents how one undergraduate student used set-based reasoning to reinvent logical principles related to conditional statements and their proofs. This learning occurred in a teaching experiment intended to foster abstraction of these logical relationships by comparing the predicate and inference structures among various proofs (in number theory and geometry). We document the progression of Theo's emergent set-based model from a model-of the truth of statements to a model-for logical relationships. This constitutes some of the first evidence for how such logical concepts can be abstracted in this way and provides evidence for the viability of the learning progression that guided the instructional design.

Keywords: mathematical processes, reasoning and proof, advanced mathematical thinking

Teaching logic for the purpose of supporting students' apprenticeship into mathematical proving imposes fundamental challenges regarding how the content-general relationships of logic can be operationalized within students' reasoning about particular mathematical concepts. Scholars affirm that this requires that logic be understood in both its syntactic and semantic aspects (Barrier, Durand-Guerrier, & Blossier, 2009; Durand-Guerrier, Boero, Douek, Epp, & Tanguay, 2012). In other words, students must be able to reason about the form of statements and arguments as well as the way they refer to mathematical objects. Previous studies find that logic taught syntactically often does not foster understandings that are useful in context (e.g., Hawthorne & Rasmussen, 2014), and textbooks downplay the referential aspects of logic (Dawkins, Zazkis, & Cook, 2020). How then are students to abstract logical relationships that generalize across contexts and yet interface with their meanings for particular concepts? How do such logical understandings become functional for comprehending mathematical proofs?

In our ongoing investigations of these questions (Dawkins, 2017, 2019; Dawkins & Roh, 2020), we have found that set-based reasoning can provide a unifying structure by which students abstract key logical relationships. Set-based reasoning is propitious for student thinking and it provides a clear means by which students can interpret statements about very different topics as being in some sense the same (Hub & Dawkins, 2018). We claim the two questions above can be answered by guiding students to formulate logical understandings by comparing interpretations and generalizing their reasoning about mathematical texts in particular contexts.

In this report, we share a case study that illustrates one student's pathway to reinventing some basic logical principles of conditional statements: proof by universal generalization, converse independence, and contrapositive equivalence. As we shall explore, Theo's construction of these new logical relationships depended on his coordination of two ways of thinking: properties defining sets of objects and proofs showing implications between properties as relating such sets. Our teaching experiment methodology (Steffe & Thompson, 2000) allows us to provide a detailed account of Theo's learning process, rooted in his meanings and activity (Piaget & Garcia, 1991; Thompson, 2013). This account of a student abstracting logical relationships is a novel contribution to the literature. We analyze the episode using the emergent models framework to document the emergence of a new mathematical reality (Gravemeijer, 1999), namely that of content-general logical structure rooted in set relationships. We highlight Theo's learning pathway to demonstrate the viability of the learning progression, which closely matched what we intended in the instructional design.

Conceptual Analysis of the Logic of Conditionals

In our prior teaching experiments (Dawkins, 2017; Hub & Dawkins, 2018), we guided students to reinvent logical principles by comparing their interpretations of mathematical statements of the same logical form. In this experiment, we extended this task sequence by asking students to read theorems paired with 2-4 proofs each and to determine whether each proof proved its associated theorem. We encouraged students to associate to each property the set of objects that makes it true (*reasoning about predicates*, Dawkins, 2017). This allowed them to formulate generalizable truth-conditions for the statements and generalizable interpretations of the proofs. In this section, we shall present a conceptual analysis (Thompson, 2008) of these set-based understandings to clarify what we intended students to learn.

Each theorem was a universally quantified conditional: "For any [$x \in S$], if [$P(x)$], then [$Q(x)$]." We use brackets since the statements/proofs that students saw always had particular objects and properties in these slots (e.g., "For every integer x, if x is a multiple of 6, then x is a multiple of 3" and "For all quadrilaterals $\blacksquare ABCD$, if $\blacksquare ABCD$ is a rhombus, then it is a parallelogram"). Each proof was either a direct proof, a proof/disproof of the converse, a proof by contraposition, or a proof/disproof of the inverse (see Table 1). No proofs contained errors. All the proofs (as opposed to disproofs) used universal generalization. The principle of universal generalization (Copi, 1954) states that a proof regarding an arbitrary particular justifies the claim for the whole set of such objects. Choosing such an arbitrary particular is conventionally expressed using the imperative "let" and assigning a property to an object. The argument that follows must depend only on that property and thereby the argument will carry to all objects with the property (Alcock & Simpson, 2002). Such proofs that "property P implies property Q" justify a subset relationship: the set of objects with P is a subset of the set of objects with Q. This is the truth-condition for such conditional statements, which we refer to as the *subset meaning* (Hub & Dawkins, 2018). Such statements are false when there is an object with property P and not property Q. To connect the subset meaning to proofs, students must relate chains of inference to the underlying sets of objects. Proofs establish implication relationships among properties, which are tantamount to containment relationships between the sets of objects with the properties. Counterexamples show lack of set containment and property implication.

Notice that the direct proof of a conditional and the proof of its converse (if both possible) deal with the same two sets of objects. They prove two facts about those sets: the Q's contain the P's and vis-versa. In this case the two sets are equal, meaning the exact same objects have the two properties. Since not every implication involves two equal sets, these two proofs are taken as independent (the converse proof does not prove the original theorem). However, the contrapositive proof is understood to prove the theorem as the contrapositive statement is equivalent to the original theorem (arguments for this will appear in the results section). Since we expected students to abstract these structures from reading statements and proofs, we purposefully maintained a parallel structure to the proofs. The disproofs are somewhat oddly stated, but we intended for them to match the same first-line/last-line structure to help students associate each proof to the statement it is normatively understood to prove or disprove.

Table 1: Forms of proof presented for comparison

Direct proof	Converse proof	Converse disproof	Contrapositive proof	Inverse disproof
Original theorem	"For any [$x \in S$], if [$Q(x)$], then [$P(x)$]."	"For any [$x \in S$], if [$Q(x)$], then [P(x)]."	"For any [$x \in S$], if not [$Q(x)$], then not [P(x)]."	"For any [$x \in S$], if not [$P(x)$], then not [$Q(x)$]."
Proof: Let x have property P. … Thus, x has property Q.	Proof: Let x have property Q. … Thus, x has property P.	Proof: Let x have property Q. x could be a. a does not have property P.	Proof: Let x not have property Q. … Thus, x does not have property P.	Proof: Let x not have property P. x could be a. a does have property Q.

Guided Reinvention and Emergent Models

Our instructional sequence was inspired by the Realistic Mathematics Education design heuristics of guided reinvention and emergent models (Freudenthal, 1991; Gravemeijer, 1999). Guided reinvention entails providing students with experientially real situations they can easily imagine and from which they might elaborate key mathematical ideas. The emergent models heuristic describes how students may first develop a *model-of* the situation. They then elaborate the model by applying it to new situations until the model becomes a new body of understanding apart from the situation(s) it interpreted. The model then becomes a *model-for* reasoning about new problems and concepts. The model's elaboration for mathematical exploration constitutes the establishment of a *new mathematical reality* for the student. The key distinction between model-of and model-for is the extent to which the structure of the model reflects the original situation or alternatively comes to take on its own internal meaning for the student.

To apply these tools to teaching logic to undergraduates, we first wondered what kind of experientially real activity would lead students to perceive questions about logical structure. Logic generalizes across language and proofs, which led us to engage students in comparative reading of statements and proofs of parallel form. By focusing them on set structure, students can develop a *model-of* how each statement refers to sets of objects (reasoning about predicates) and what it means for conditional statements to be true and false (in terms of set relations). By considering how this set structure repeats across various statements and proof texts, students may extend their *model-for* reasoning about content-general logical relationships.

Context independence is a key aspect of how we study students' models. Students often draw the contrapositive inference in a particular context. For instance, they may infer that since all multiples of 6 are multiples of 3, a number that is not a multiple of 3 cannot be a multiple of 6. While this relates to a logical principle, it is not a *logical understanding* for that student if they only apply it locally. We call an understanding *logical* to the extent it generalizes across contexts. Only content-general understandings will support students in reasoning about the logical relationship between *any* conditional statement and its contrapositive statement/proof.

Methods

As part of a grant project developing constructivist models of students' learning of logical principles through guided reinvention, we conducted 8-12 session teaching experiments with pairs of undergraduate students recruited from Calculus 3 classes at two large public universities in the United States. The site for this study's data is a Hispanic Serving Institutions (HSIs). Students volunteered to participate and completed a screening survey to verify that they did not already know the target concepts to be taught (see Roh & Lee, 2018). The experiment featured in this paper was conducted remotely once per week over Zoom using OneNote as a shared space for reading and writing. The two participants chose the pseudonyms Theorem (which we abbreviate as "Theo" for clarity) and Phil. The lead author served as the teacher/researcher and the other three authors acted as outside observers (Steffe & Thompson, 2000). Each session lasted between 60 and 90 minutes and participants were compensated monetarily for their time.

This experiment consisted of an intake interview with a pre-test, nine instructional sessions, and an exit interview with a post-test. During the exit interview, we asked students to choose how they wanted to be identified in terms of their ethnic and gender identities and how those identities were significant for their mathematics learning at university. Theo identified himself as a white, non-Hispanic male. At the time of the study, he was in his first year of university as a finance and mathematics double major. He described himself as "passionate" about mathematics. Phil, an engineering technology major, identified himself as a Hispanic male. The two students worked productively and respectfully together, though they generally operated in parallel rather than interactively. We focus on Theo in this report because of the clear evidence of his progression toward our learning goals. Our models of other students' learning progressions will appear in other reports. Theo constitutes a clear existence proof for our intended learning path.

Consistent with teaching experiment methodology (Steffe & Thompson, 2000), the research team continuously made conjectures about the two students' understandings and tested those conjectures through questioning and iterative task design. The research team met once or twice between sessions to analyze and plan for subsequent sessions. All sessions were recorded on at least two or three screens: the interviewer screen that moved between pages in OneNote and two screens dedicated to capturing Theo and Phil's pages respectively. All main study sessions were transcribed. Our retrospective analysis drew upon field notes, transcripts, and compiled video.

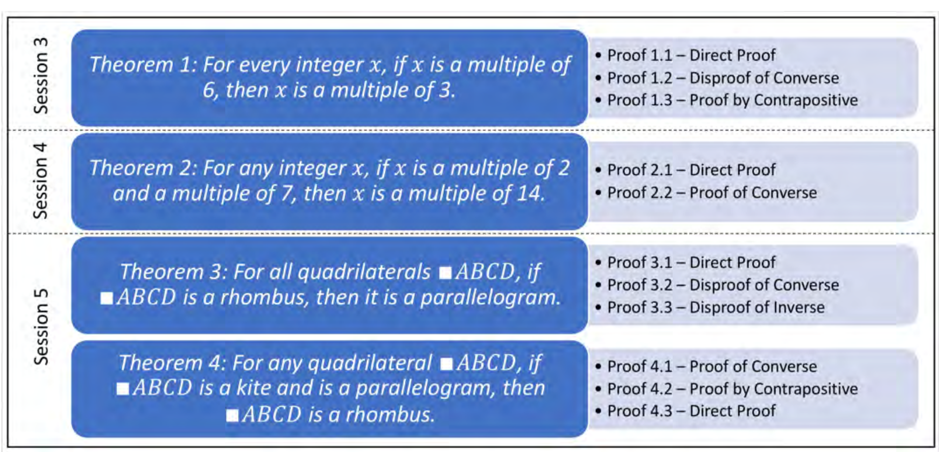

Figure 1: Sequence of proof reading tasks.

Teaching Progression

In the first two instructional sessions of the experiment, Theo and Phil read sequences of universally quantified conditional statements and considered the relationships between the sets of objects that made the if-part true and objects that made the then-part true (hereafter the "if-set" and "then-set"). We intended them to formulate the *subset meaning* (see Conceptual Analysis) for such statements and the conditions for a counterexample. In the next three sessions, they read theorems and proofs as shown in Figure 1. Theorems 1-4 were chosen to intentionally vary the relationships between the underlying sets (proper subset in 1 and 3; set equality in 2 and 4) and to vary the mathematical context (number theory in 1 and 2; geometry in 3 and 4). In the sixth session, which is the last featured in this report due to space limitations, Theo reviewed all of the theorems and proofs and his decisions about which proved the associated theorems. We call this the Comparison Task. We sought for him to systematize the relationship between the logical form of the proof and whether it proved the given theorem (evidence of a model-for logical reasoning that generalizes across context).

Results

Developing Set-Based Meanings (Days 1-2)

In the intake interview, Theo read a direct proof, inverse proof, converse proof, and contrapositive proof of the claim "For any integer x, if x is not a multiple of 3, then $x^2 - 1$ is a multiple of 3." He affirmed the direct proof proved the theorem and denied that the other three did. His rejection of the converse proof was based on whether the middle section of the argument worked, not based on its reverse order from the theorem. Productively, he showed early evidence of associating an equation such as $x = 3k + 1$ to a set of values (*reasoning with predicates*).

On the first day of instruction, once Theo and Phil had assigned truth values to all the given conditionals, the interviewer asked the students to explain the relationship between the if-sets and then-sets. Theo initially drew a diagram showing the then-set as a circle nested within the circle for the if-set. He then thought about a specific statement (Theorem 1) and revised his answer to say, "Because if you think of it, one to 100, that'd'be more multiples of 3. So that's the larger set in these multiples of 6. That's a subset." Over those first two days, the pair came to confirm this interpretation of the set relationship for true conditional statements. They also agreed that a conditional was false whenever an element of the if-set was outside the then-set.

Theo generally represented complement sets using separate circles rather than the inside and outside of a given circle. In reasoning about Theorem 1 and its contrapositive statement, Theo drew three circles that corresponded to the equations $x = 3k$, $y = 3k - 1$, and $z = 3k - 2$. This reflects a common tendency to replace negative categories with a positive description (Dawkins, 2017). He then drew a smaller circle inside the x circle to represent the multiples of 6. This pattern of representing a partition by separate circles persisted throughout the experiment.

Reading Number Theory Proofs (Days 3-4)

During the third and fourth teaching sessions, Theo eventually adopted normative answers as to whether each proof proved the associated theorem based on his set-based reasoning developed in the first two days. At the beginning of Day 3, the interviewer asked Theo to summarize what he had learned the previous two days. He reported:

> It's true if the statement, if it exists inside then or is the same size as then… If the condition exists outside of the parameters of the then statement. Like if it goes beyond the bubbles or diagrams that we created, if it extends beyond it then that's when it's not true.

We note two things about this explanation. First, Theo acknowledged that either the if-set may be contained in the then-set or they may be equal. Second, he referred to the parts of the statement as having physical extension in space and being contained by one another. This constituted his initial model-of interpreting statements by which he determined whether conditional statements were true or false. Each part of the statement corresponded to a group of objects and those objects could be imagined as taking up a region enclosed by a closed curve.

Theo affirmed that Proof 1.1 (direct) proved Theorem 1. He did so focusing on the steps within the proof, not the order from first to last line. He denied Proof 1.2 (converse), saying:

> I don't agree with this theorem [sic] because we're trying to say that if it's a multiple of six then it's a multiple of three, not if it's a multiple of three then it's a multiple of six. It kind of goes into what we were saying last week, if the condition falls outside of the realm of all possibilities and the then statement, then it doesn't hold up, it's not true.

In the first part of the quote, Theo restated Theorem 1 as what "we're trying to say" and contrasted it with what Proof 1.2 is addressing, which he articulated as the converse conditional. He thus attended to the order of the theorem and the first/last-lines of the proof in order to distinguished the meaning of the theorem from what the proof accomplished and to show conflict between the two. He then elaborated what the proof (which presents the counterexample 15) proved: that the if-condition for the converse "falls outside the realm" of the then-statement. He thus shifted back into the language of sets of objects as spatial regions.

Both Theo and Phil agreed that Proof 1.3 (a proof by contraposition) proved Theorem 1. They had read the theorem and contrapositive statement on Day 1 and then noted then that the contrapositive should be true based on the fact that all multiples of 6 are multiples of 3. It is worth noting that Proof 1.3 contains 19 lines and explores how a number having a remainder of 1 or 2 when divided by 3 means it has a remainder of 1, 2, 4, or 5 when divided by 6. The interviewer invited Theo to draw a diagram for how he understood the proof to ascertain how he was making sense of the complex case structure.

> Int: Okay. Can y'all try to use the diagrams that we were using the last two times we met? We have this kind of meaning for what the theorem says in terms of the group of multiples of 3 covering the group of multiples of 6. Can y'all try to explain to me how is it that Proof 1.3 proves it using that idea?
>
> Theo: I think you got to look at, it would be the pattern of all the non-multiples of three and you could be like, 1, 2, 4, 5, 7, 8. And you have that subset of numbers, and then you have the other subset that's three and obviously they're not in each other. However, the multiples of six does not exist inside the non-multiples of three. It only lives inside the multiples of three… It's talking about the subspace when x is not a multiple of three [see Figure 2], which is going to be this whole range of numbers on the left side. And basically, it proves that there exists no of this smaller subset that's on the right side, the blue circle that exists in the non-multiples of three, not even like a cross over even.

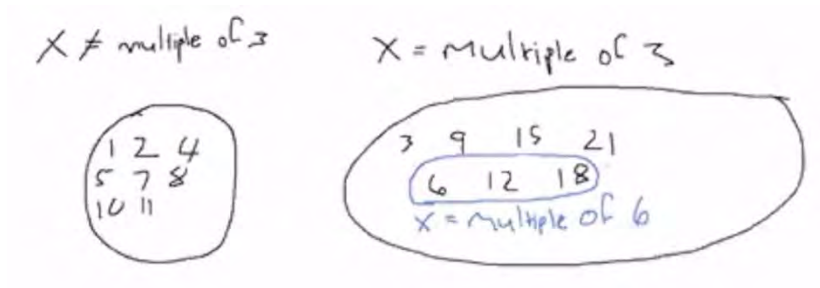

Figure 2: Theo's diagram for Proof 1.3

In this argument, Theo justified Proof 1.3 using what Hub and Dawkins (2018) called the *empty intersection meaning*, namely that "if x is not a multiple of 3, then x is not a multiple of 6" is true because there is no overlap between non-multiples of 3 and multiples of 6. While this is distinct from the subset meaning developed on the first two days, it supported Theo in perceiving symmetry between Proof 1.1 and Proof 1.3. He explained, "[Proof] 1.3 shows that the [multiple of 6] circle doesn't exist in the circle of non-multiples of three, while proof 1.1 would show it exists in the circle with multiples of three." By this point he was comfortable treating the complement of multiples of 3 as a category. However, his notation and reasoning in some sense expressed that x was *not in the set* of multiples, rather than saying it *had the property* of being a non-multiple. His empty intersection meaning similarly negated the "element of" relation, not the property of being a multiple of 6. We have found this preference common, meaning students often avoid treating a negative property as constituting a predicate (Dawkins, 2017). Theo's justification is similar to the arguments Yopp's students produced for how contrapositive proofs eliminate counterexamples (Yopp, 2017).

During Day 4, Theo affirmed Proof 2.1 (direct) and denied Proof 2.2 (converse). He did so using an analogy to Theorem 1 and Proof 1.2 (converse), desiring consistency. He explained:

> In this case, the if and the then are the same set. But, if you switch them around in a set where they're not the same, then it doesn't necessarily work out that way. In this example, it works out, but switching the if and then doesn't necessarily mean it will work out every time.

This argument marks a key development in Theo's thinking because his model-of the set structure allows him to make an analogy between Theorem 1 and Theorem 2 that determines how the proofs do or do not support the theorems. In Dawkins and Roh (under review) we discuss a prior study participant who similarly recognized the analogy, but she denied that it held force. That participant perceived that the difference between subset situations and equal set situations meant the proof relationships for Theorem 1 do not apply to Theorem 2. It is unclear why Theo took a different interpretation. Still, it shows how his set-theoretic model had become a model-for reasoning about more abstract relationships between theorems and proofs. However, we learned in the next sessions that his model still carried some contextual dependence.

Reading Geometry Proofs (Day 5)

Recall that our operating definition for a student's understanding as being logical is that it generalizes across semantic content. Theo's use of his set-theoretic model showed that to some extent he was attending to logical structure on the number theory tasks. In contrast with his prior reasoning, on Day 5 Theo affirmed that a Proof 4.1 (converse) proved the theorem and he denied that Proof 4.2 (contrapositive) did so. Initially Theo and Phil judged that Proof 4.2 was irrelevant to Theorem 4. Though Phil later developed an indirect argument for why Proof 4.2 supported the theorem, neither judged that it proved. Theo also had trouble applying his subset meaning to this theorem because he represented the if-set (kite and parallelogram) using two overlapping circles to show what is shared between the two properties. He then identified that the conclusion (rhombi) existed in the overlap, which led him to imagine the then-set as nested within the if-set. We hypothesize that the three-set structure and the more complex nature of negating the hypothesis kept Theo from structuring these theorem/proof pairs as he had on previous tasks.

Comparison Task (Day 6)

On Day 6, we presented Theo with all of the theorems and proofs from the previous three sessions along with his decision about whether each proof proved the theorem or not. We asked him to look for patterns among the proofs, his decisions, and how the proofs did or did not prove the associated theorem. He began by grouping all the direct proofs and affirming they all proved their associated theorem: "You start by saying like, okay, we have this if, it meets such criteria and then like, it continues on to conclude, okay, this criteria can be put inside this larger space." He initially placed Proof 4.1 (converse) in this group, and then removed it since it started with "the then." He then grouped the first three (dis)proofs of converse, omitting Proof 4.1. Later he decided to move Proof 4.1 into that group. When asked about his claim that Proof 4.1 proved the theorem, he decided to change his decision "to be consistent." He explained the pattern among the proofs that proved the theorem: "We're going to have to start by looking at the smallest subspace, I'm saying for the other yeses (sic), excluding 1.3, because that's doing it from the other way. But proving the converse doesn't necessarily prove the theorem."

Theo grouped all the rest of the proofs (inverse and contrapositive) together as not direct or converse. We explain this in terms of his set-based model, which operated with the structure of if-sets, then-sets, and everything else. Since his model did not include the complement of the if-set, he did not distinguish the order of inverse and contrapositive. Theo's groupings demonstrate how the structure of the proofs reflected the structure of the sets, not the statements per se.

The interviewer asked Theo to explain again his argument for why Proof 1.3 proved, which he did in terms of his empty intersection meaning. The interviewer then asked him to apply the same argument to Proof 4.2. Upon considering he decided Proof 4.2 proved, explaining:

> Because I think when we do it like the same way in 1.3, we're saying, okay, it has this property that it's a non-rhombus. And if it's not a rhombus, it either exists in the space that, like we don't have to look at it like is not a kite or is not a parallelogram… So it's basically saying that the non-rhombi don't have properties of both… Which is basically saying that the space where they have both of the properties is rhombi.

By adapting his empty-intersection argument, Theo began to construct contrapositive equivalence as a logical concept rooted in his set-based model-for reasoning about proofs.

Discussion and Conclusions

We proffer this account of Theo's learning as an account of how logical understandings can emerge from set-based reasoning about the structure of conditional statements and their proofs. We argue that Theo's ability to see necessity in logical relationships (e.g., converse proofs cannot prove for consistency) and to generalize logical arguments (e.g., applying his empty intersection argument from Proof 1.3 to Proof 4.2) as evidence that his set-theoretic model constituted a new mathematical reality for *reasoning about logic* (Dawkins & Cook, 2017).

To further illustrate what was involved in Theo's learning, we highlight some shifts in Theo's ways of talking about the statements and categories in the statements. First, he became comfortable talking about negative categories such as non-rhombus. Second, he shifted rather fluidly between using a) set language interpreted as spatial regions such as "smallest subspace," b) property language such as "meets such criteria," and c) syntactic/temporal order language of "if," "then," and "start." In this way, Theo coordinated quantification, property relations, and statement syntax to give meaning to these complex proof texts. What is more, these understandings allowed him to perceive theorems/proofs about number theory categories and geometric categories as the same, since they all shared set-theoretic structure. We conjecture that developing negative categories and exploring how properties stand for whole classes of objects are essential parts of his construction of a logic of conditional statements and proofs.

We began with questions about how students' understanding of logical relationships can interact with their content-specific reasoning. We claim that Theo's learning progression provides an actionable answer to this question. Specifically, logical concepts can be reinvented in context via the emergence of set-based models for the truth and falsehood conditions and the structure of mathematical proofs. Ongoing work is seeking to understand other students' pathway to these abstractions to create generalizable learning sequences for undergraduate students' introduction to mathematical proving.

We report findings from an investigation of one teacher's instruction as he guided students through the proofs of 21 theorems in a Grade 8 Honors Geometry course. We describe a routine involving four distinct phases, including Setting up the Proof and Concluding the Proof. Results from an end-of-course proof test are also presented to attest to the effectiveness of the teacher's approach. By engaging with descriptions of the theorem-proving routine, one can learn about different strategies that may support students to learn to prove theorems, such as asking students to put forth claims in the form of conjectures or other statements that they believe are true and seeking justifications for these claims as well as sanctioning a theorem once proven.

Keywords: Reasoning and Proof, Geometry and Spatial Reasoning

Purpose of the Study

In 1994, Alan Schoenfeld noted: "Proof is not a thing separable from mathematics, as it appears to be in our curricula; it is an essential component of doing, communicating, and recording mathematics" (p. 76). Yet, despite the fact that reasoning and proving are considered central to the discipline of mathematics, and geometry is typically the place in the school mathematics curriculum where proof is taught, the teaching of proof in school geometry has been considered to be a failure in almost all countries (Balacheff, 1988). Acknowledging this failure, Battista (2007) posed the question: "How can proof skills best be developed in students?" (p. 888). To address this question, in this mixed-methods study, we focus on the development of proof skills with respect to the "instructional situation" (Herbst, Nachlieli, & Chazan, 2011) of proving theorems. Proving theorems is an activity that differs from doing proofs of "configurations" (Herbst & Miyakawa, 2008, p. 470) whereby students are typically provided with "Given" information, a "Prove" statement, and a figure to go along with the proof. Research conducted by Otten and colleagues (Otten, Gilbertson, Males, & Clark, 2014; Otten, Males, & Gilbertson, 2014) suggested that U.S. textbooks primarily engage students in proving configurations rather than theorems. This is a problematic situation if one agrees with Schoenfeld's (1994) argument that proof is an essential component of doing mathematics.

Because we agree with Reid and Knipping (2010) who suggested that recommended changes to how teachers teach proof must be based on detailed understandings of how teachers currently teach proof, we designed a study that involved spending significant time in teachers' classrooms. After determining that the students of one of the teachers in the study, who we call Shane, were outperforming other teachers' students in seemingly similar courses on an end-of-course proof test, we observed 22 of Shane's lessons during the 2018-2019 academic year. For this paper, we posed the following research question: *How did a teacher whose students were overall* *"successful" on an end-of-course proof test teach his students to prove theorems in geometry?* We operationalize what is meant by "successful" in subsequent sections of this paper.

Theoretical Framework

In order to frame the purpose of the study, justify the study methodology, and focus and guide the reporting and discussion of the results (Cai et al., 2019), we review three areas of literature. We first describe past results from the end-of-course assessment used in this study. Next, we describe research on "doing proofs" in U.S. geometry classrooms to support the need for the study. Last, we highlight research-based competencies for proving to frame the findings.

Students' Past Performance on an End-of-Course Proof Test

In Senk's (1985) paper titled, *"How Well Do Students Write Geometry Proofs?"* Senk described some of her research instruments and summarized some key findings from her (1983) dissertation. Senk's (1985) research question was: To what extent do secondary school geometry students in the United States write proofs similar to the theorems or exercises in commonly used geometry texts? Her results were part of the larger Cognitive Development and Achievement in Secondary School Geometry (CDASSG) Project. To answer her research question, Senk administered three forms of the CDASSG end-of-course proof test. Each form contained six items. The first item required students to fill-in-the-blanks of a two-column proof. The second item required a translation from a verbal statement to an appropriate "figure," "given," and "to prove." The last four items required students to write full proofs (Senk, 1985). Senk administered the CDASSG assessments to 1520 students in 74 classes from 11 schools in five states in 1981. Each item was scored on a four-point scale, and students were considered "successful" if they scored at least 3 out of 4 possible points. Students scored a 3 if their proof steps followed logically from previous ones but contained minor errors. Overall, Senk (1985) concluded that only about 30% of students in the full-year geometry courses that covered proof reached a 75% mastery of proof (i.e., were "successful" on the test overall). Senk also concluded that proofs of textbook theorems were difficult for many students. For example, only 32% of students were successful in proving the theorem that the diagonals of a rectangle are congruent, and 34% of students scored a 0 on this proof. A common error was citing the theorem in the proof (i.e., using circular reasoning). Across the three forms, an average of approximately 13% of students were successful on all six tasks with only 3% of students receiving perfect scores on all six.

"Doing Proofs" in U.S. School Geometry

Building on the past work of Lampert (1993) and Schoenfeld (1986, 1988, 1989) who documented the role that proof has traditionally played in classroom teaching and learning, Herbst and colleagues examined both students' and teachers' perspectives on what "doing proofs" is like in American high school geometry classrooms. Herbst and Brach (2006) reported findings from 29 interviews with 16 students in five categories: Statements, Initial Conditions, Concepts, Targets of the Work of Proving, and The Work of Proving. Several findings from Herbst and Brach's study are relevant to this study, especially students' claims that:

- It is customary that the "given" and prove" will be specified in the problem statement,
- Students are rarely asked to prove theorems, and
- The first thing in proving is to mark the givens on the diagram.

Herbst's and colleagues' (2009) study of teachers' views outlined a set of 25 norms for the instructional situation of "doing proofs," including the following norms about the division of labor - the teacher or textbook is responsible for:

- Establishing the givens in terms of properties of a figure represented in a diagram, and
- Providing a diagram that fairly represents the objects to be used in the proof.

The 25th norm was that every single statement or reason is produced in a handful of seconds. Overall, this research demonstrates that when "doing proofs" it is the teacher, not the students, who seems to carry much of the cognitive load.

Developing Competencies for Proving

Cirillo and colleagues' research has focused on understanding the conditions in which teachers currently teach proof in geometry with the ultimate goal of improving the teaching and learning of proof (see, e.g., Cirillo & Hummer, 2019). After observing that the classroom teachers with whom she worked were unsure about how to teach proof and were particularly unclear about how to *begin* teaching proof, Cirillo et al. (2017) developed a pedagogical framework for teaching proof based on the research literature and classroom observations. The pedagogical framework decomposes proof so that understanding of the larger goal (i.e., doing proofs) can be built up sequentially by teaching particular sub-goals of proof over time. The sub-goals of proof included in the framework that are particularly relevant to this study include: Knowing Geometric Concepts, Conjecturing, Working with Diagrams, Drawing Conclusions, Understanding Theorems, and Understanding the Nature of Proof. Particularly relevant competencies, which are nested within the sub-goals, include: Being able to turn a conjecture into a testable conditional statement; knowing how to read a diagram and understanding what can and cannot be assumed from a diagram; using axioms, postulates, definitions, and theorems to draw valid conclusions from some "Given" information; and being able to identify the hypothesis and conclusion of a conditional statement and then writing particular "Given and "Prove" statements, typically making use of a generic figure (see the full framework in Cirillo & May, 2021). Many of these competencies were also observed in Cirillo and Hummer's (2021) smartpen interview study in the work of students who were "successful" in completing proofs during the clinical interviews. For example, the following competencies were observed in the work of students who were successful with the proofs - students: productively attended to the "Given" information; used the diagram as a resource; identified warrants as postulates, axioms, definitions, or theorems; and attended to important details in their proofs.

Methods

In this paper we share results from a sub-study of a larger study focused on improving the teaching and learning of proof in secondary geometry. The larger project, *Proof in Secondary Classrooms* (Cirillo, 2015-2020), is a mixed methods study that took place in the mid-Atlantic region of the United States. Here, we focus on a subset of participants from the larger study who did not receive the study treatment (i.e., they were in the control group).

Context and Data

Across the three years of the sub-study, with the help of the research project staff, six teachers who taught a total of 464 Grade 8 Honors Geometry students administered Senk's (1983) CDASSG assessment at the end of the school year. It is important to note that prior to adopting the CDASSG for our study, through an alignment analysis, we concluded that the

CDASSG was, in fact, well aligned with current standards and textbooks being used in the study classrooms. The assessments were scored, and results were analyzed each summer. Beginning in Year 1 of the test administration, we noticed that, in comparison to the other sections of Grade 8 Honors students, one teacher's students consistently scored higher on the CDASSG assessment. More specifically, we noticed that in Year 1, the students (n=43) of the teacher, who we call Shane, earned a mean score of 19.05 out of 24 possible points on the six-item proof assessment (i.e., 79%); whereas the Grade 8 Honors Geometry students (n=129) in other teachers' classes earned a mean score of 8.5 out of 24 (i.e., 35%). Upon noticing this, we became interested in observing Shane's teaching, and we asked to observe his proof-focused lessons. Consequently, we conducted 22 classroom observations in one section of Shane's Grade 8 Honors Geometry course during the 2018-2019 school year. We requested that Shane invite us in when he first introduced proof up until and including lessons focused on quadrilateral proofs.

Qualitative Data Analysis

Phase 1: Identifying a reduced data set. The research team initially watched and developed timelines of the 22 classroom observation videos. These timelines identified the portions of the class that were dedicated to various classroom activities such as whole-class work, seatwork, and going over homework; within each activity, researchers included descriptions of the content covered. Of the 22 observations, we identified 11 observations where theorems were proved in the whole-class setting. Within these 11 observations, a total of 21 theorems were proved, comprising of approximately 6 hours and 23 minutes of video data. Transana Multiuser 3.32d (Woods, 2020) was used to transcribe and create a collection of video clips of each theorem-proof (i.e., proofs of actual theorems rather than "configurations" (Herbst & Miyakawa, 2008) including the Pre-Proof activities). The video clip collection was then further analyzed.

Phase 2: Identifying themes. The research team watched all 21 video clips of the whole-class theorem-proofs, as well as any related activities conducted prior to the theorem-proof (i.e., pre-proof activities) and looked for patterns within these data. We identified three distinct activities that occurred during the teaching of theorem-proofs: Setting up the Proof, Making and Justifying Claims, and Concluding the Proof.

Phase 3: Coding the themes. We developed codes to further analyze the three activities. Codebooks for each activity were developed using constant comparative analysis (Boeije, 2002). The codebooks were continuously revised and improved as each activity was coded in teams of two. Each pair of researchers independently coded at least 3 of the 21 theorem-proofs for their specific activity. After achieving above 80% interrater agreement (i.e., 90% for Setting Up the Proof, 92% for Making and Justifying Claims, and 92% for Concluding the Proof) and reconciling differences, coders worked independently to code the remaining data.

Quantitative Data Analysis

To provide further information about Shane's students' performance on the end-of-course CDASSG proof assessment in comparison to other similar students' performance on the same assessment, we analyzed results from two particular items of the CDASSG. More specifically, we focused on results from Senk's CDASSG Items 4 and 5. These two items were selected because across all three forms of the CDASSG, the items were similar in nature and explicitly required students to write full proofs. In particular, each form of the test included a proof of a theorem for one of the two items (e.g., the measures of the angles of a triangle sum to 180° or the diagonals of a rectangle are congruent), and the second item was a configuration proof involving triangle congruence. Following Senk, we report the percentage of students who were "Successful" and "Not Successful" on these items, where "Successful" means that students scored at least 3 out of 4 points on the item. Results across three years of the study are shared for Shane's Grade 8 Honors Geometry students and for all other Grade 8 Honors Geometry students in the study who were also in the control group (i.e., did not receive the project treatment).

Results

We share findings from five related analyses. We begin by exploring the four parts of Shane's theorem-proving routine: Pre-Proof: Making and Justifying Claims; Setting up the Proof; During-the-Proof: Making and Justifying Claims; and Concluding the Proof (see Figure 1). We then share additional quantitative data from the Grade 8 Honors Geometry student assessment results. This last finding is included to provide evidence of the effectiveness of Shane's approach to teaching proof. We begin by describing the two Making and Justifying Claims activities since they are closely related to one another.

Figure 1: Shane's Routine for Proving Theorems

Making and Justifying Claims in Pre-Proof and During-the-Proof Activities

We considered student-generated claims and justifications that were made both during "Pre-Proof" activities, which preceded Setting up the Proof, as well as "During-the-Proof," which followed Setting up the Proof. We only considered claims and justifications that were made by the students, rather than the teacher. Claims that were truly generated by the students without teacher support were made 44% of the time, and claims that were generated by the students as a result of question-and-answer exchanges between Shane and the students occurred 56% of the time. Throughout all 21 whole-class discussions of the theorem-proofs, Shane used the word "believe" 130 times, asking questions such as: "What do you *believe* is true?," "Do you *believe* it's always true?," and "Do you have a reason for why you *believe* that?"

Pre-Proof Claims and Justifications. Pre-Proof activities included exploring definitions to better understand the geometric objects involved in the proof (e.g., developing or stating definitions of isosceles triangles or parallelograms) and making claims that were sometimes unsupported and considered to be conjectures or were valid conclusions that could be drawn from a proof assumption. Across the 21 theorems, we identified 28 claims made during the Pre-Proof activities. Three of these claims were related to establishing a definition of the geometric object centrally involved in the proof. Fifteen of the claims were conjectures that would ultimately be considered "worth proving;" that is, the students conjectured the proof idea through a discovery process led by Shane prior to the Setting-Up-the-Proof activity that followed. Two of the 28 claims were generated through a combination of some assumption that could be made about a diagram and a postulate (e.g., AB + BC = AC by the Line Segment Addition Postulate). The remaining eight claims were conclusions that could be drawn from the premise of the proof. For example, if Shane presented some quadrilateral ABCD that was assumed to be a parallelogram (i.e., eventually the proof hypothesis or "Given" statement), then students would state a valid claim that the two pairs of opposite sides of the quadrilateral were parallel. The justification for this claim would be the definition of parallelogram. By engaging students in a routine that involved Pre-Proof activities focused on claims and, where applicable, justifications, Shane provided students with opportunities to explore or "experience" mathematical objects (Schoenfeld, 1986) and develop conjectures prior to working on proofs about those objects.

During-the-Proof Claims and Justifications. Four codes were developed for Claims and Justifications made During the Proof. Across the 21 theorems, we identified 60 student-generated claims made during the proof. The first code, which was related to stating the proof assumption and justifying it by "Given" only occurred once. We hypothesize that this aspect of proving needed to be carried out only once so that students would understand this proof requirement. The next two activity codes were similar to activities that occurred during the Pre-Proof. There were 11 instances of students stating claims that were conclusions drawn directly from the "Given" statement. The justification for such claims was typically the definition of the mathematical object that was the subject of the theorem (e.g., definition of parallelogram), but, at times, it was also appropriate to use a theorem about the mathematical object to justify a claim made directly from the "Given" statement. Also, similar to an activity described above, there were six claims generated through combinations of a postulate and an appropriate assumption that could be made about the diagram. The majority of student-generated claims (n=41) were related to the statements and reasons that followed once the initial conclusions were drawn from the hypothesis and any valid, relevant assumptions made about the diagram were identified.

Setting up the Proof

Setting up the Proof involved a range of activities including: working with the theorem as a conditional statement, developing the "Given" and "Prove" statements, and developing or working with a diagram for the proof. During the Setting-up-the-Proof activities, Shane attended to different aspects of setting up the proof, working on different competencies across the 21 theorems, over time. For example, for 8 of the 21 theorems, rather than providing students with the conditional statements of the theorems to be proved, Shane drew from the conjectures students developed during the Pre-Proof activities. Since these conjectures were often written using "everyday language," such as "Opposite sides of a parallelogram are congruent," when Setting up the Proof, Shane led discussions that supported his students to identify the assumptions (or hypotheses) in the conjecture (e.g., [If] a quadrilateral is a parallelogram) as well as the conclusions of the conjecture (e.g., [then] the opposite sides are congruent). For 11 of 21 theorems, students were not provided with the "Given" and "Prove" statements but rather had to participate in developing them during the whole-class discussions. For 6 of 11 of these theorems, students also played a role in generating the particular figures that would be used in the proof. Six of the 21 theorems proved during the observations were converses of other theorems that the class had also proved. Thus, it is unsurprising that discussions about the truth values of the converses of six of the theorems occurred. Last, for 12 of 21 of the theorems, a figure was provided for the students, but it was not marked. For example, for parallelogram proofs, Shane had pre-populated parallelograms labeled ABCD on his advanced organizer, but for each of the theorems, the diagrams still needed to be marked to reflect what students knew to be true from what they determined to be the "Given" information. Across the 21 theorems, by modifying what information was provided and what Shane left blank for the students to develop, Shane provided students with opportunities to develop different competencies needed to set up the proofs.

Concluding the Proof

Across the 21 theorem-proofs, Shane's facilitation of Concluding the Proof activities included three noteworthy features. For 9 of the 16 theorems that did not have "names" such as The Midpoint Theorem or the Base Angles Theorem, Shane concluded the proofs by developing a shorthand version of the theorem that students could use moving forward. For example, Shane suggested that students could write "⊥ lines → ≅ Adjacent ∠s" rather than writing out the full text of the theorem: "If the two lines are perpendicular, then they form congruent adjacent angles." Referring to the shorthand notation, Shane stated, "Your options are either to write something like this, or you may just write the whole thing." Second, for 12 of the 21 theorems, Shane restated or rephrased the theorem after the class proved it, typically in a way that seemed intended to foster an understanding of what the class had just proved. For example, after proving the converse of the Isosceles Triangle or Base Angles Theorem, Shane stated: "So if you do have a pair of angles that are congruent in the triangle, it does imply that the sides opposite them are congruent, which implies it is an isosceles triangle." Last, upon completing 9 of the 21 theorem-proofs, Shane explained to students or reminded them that once a theorem was proven, it could be used in future proofs. For example, after writing shorthand notation for the third of four parallelogram theorems that they would prove that day, Shane asked his students, "So now we have how many properties of parallelograms we can use?" After establishing that they had three theorems plus the definition of parallelogram, Shane asked students to prove the fourth theorem of the day and reminded them: "Remember now, we, you can use any properties that we have already proved. So now you can use everything except for the one you're trying to prove." In doing so, Shane established that once a theorem was proved it could be used to prove other theorems; he also reminded the students not to engage in circular reasoning.

Proof Assessment Results

As explained in the Methods section, we calculated results for two of the full-proof items from Senk's (1983) CDASSG assessment that were administered in this study. For two groups of students - Shane's Grade 8 Honors students and Grade 8 Honors students who had teachers other than Shane (i.e., "non-Shane") - we calculated the numbers and percentages of students who were "Successful" (i.e., scored at least a 3 out of 4 points) on *both* Items 4 and 5, on *either* Item 4 or 5 but not both, and on *neither* Item 4 nor Item 5. As can be seen in Table 1, there were large differences between the results of the two groups of students. Acknowledging that the student populations for the two studies differed, as another point of comparison, in Senk's (1983) study, approximately 43% of students were successful on Item 4 and approximately 37% of students were successful on Item 5. Percentages of success for the same items in our study were 77% and 84% for Shane's students, respectively, and 30% and 25% for non-Shane students, respectively. This is noteworthy given that the students in this sub-study were all Grade 8 Honors students, whereas the students in Senk's study included a population of Honors and non-Honors students.

Table 1: Student Assessment Results for Shane's Students Compared to Other (Non-Shane) Grade 8 Honors Students

	Number (%) of Students *Successful on both 4 & 5*	**Number (%) of Students *Successful on either 4 or 5, but not both***	**Number (%) of Students *Successful on neither 4 nor 5***
Shane's Students (n=128)	83 (64.8%)	40 (31.3%)	5 (3.9%)
Non-Shane's Students (n=336)	53 (15.8%)	78 (23.2%)	205 (61.0%)

Discussion and Conclusions

As noted by Herbst and Miyakawa (2008), while all theorems have proofs, in U.S. geometry classrooms, not every theorem is proved. The study reported here is significant in that it describes a routine for proving theorems - an activity that is apparently lacking in many U.S. classrooms. Furthermore, our assessment results provide evidence that the strategies employed by Shane seemed to be reasonably effective given that nearly two-thirds of Shane's students were successful on the two full-proof tasks analyzed for this study. It is interesting to note that the percentage of Shane's students who *were successful* on both proof items analyzed (about 65%) is very close to the percentage of students from non-Shane classrooms who *were not successful* on either proof task (61%). One limitation of this study, however, is that due to space constraints, we did not report more sophisticated statistical analyses controlling for various factors, and we did not determine statistical significance when taking these factors into account.

In contrast to reports by Cirillo and colleagues (2017), who noted that proof is often taught in a show-and-tell manner, we saw evidence that, in Shane's classroom, students were expected to make claims and provide justifications for their claims. This was evident in the way that Shane continuously asked students questions about what they *believed* to be true during the 21 theorem-proof episodes. Summing together codes from the Pre-Proof and During-Proof activities, it is also noteworthy that, within the data set of 21 theorem-proofs, we identified a total of 19 instances of students drawing conclusions directly from the hypothesis of the theorem. This is important because drawing valid conclusions from the proof assumptions has been identified as an important competency in proving, particularly for *beginning* a chain of reasoning, a skill in which many students struggle (Senk, 1985; Cirillo and Hummer, 2019, 2021). Also, there were 8 instances, in total, of students generating claims through a combination of a postulate and an assumption about the diagram. Cirillo and Hummer (2019) pointed out that making valid assumptions about diagrams is an under-recognized, but important proof competency.

Across the three features Shane incorporated during the Concluding the Proof activity, one important take-away is that these activities often seemed to accomplish what Herbst and Miyakawa (2008) identified as "sanctioning" the theorem, which involves explicitly declaring it as having that label. Shane sanctioned theorems by restating them, establishing shorthand notation for writing them, and acknowledging that they could now be used in future proofs.

Herbst and colleagues (2006, 2009) provided evidence which suggests that teachers heavily control the work of proving in American classrooms. Although, as evidenced by the data, through his question-and-answer exchanges to support students' development of claims, and through the ways Shane scaffolded the Setting up the Proof activities by alternating which competencies students had opportunities to practice while proving any one theorem, Shane did seem to provide students with more opportunities to authentically engage in proving theorems than research suggests is typical. To start, in contrast to the claim made by Herbst and Brach (2006), that students were not expected to prove theorems, Shane *did* expect his students, not only to prove theorems, but to heavily participate in proving them. For numerous theorems, Shane also expected students to participate in sketching their own diagrams and in determining the "Given" and "Prove" statements from the conjecture or the conditional statement. Thus, in contrast to the teachers from Herbst and colleagues' (2009) study, Shane did, in fact, seem to expect his students to carry a good deal of the cognitive load. To be clear, we are not suggesting that we disagree with the norms put forth by Herbst and colleagues. Rather, we mention these norms to demonstrate that Shane's approach seems to be unusual, and, given his students' test results, is worthy of examination. One question that this study raises is related to how effective Shane's teaching approach would be with a non-Honors student population. In other words, would Shane's approach work well for heterogeneous groups of more "typical" students?

Acknowledgement

We would like to thank Sharon Senk for allowing us to use her research instruments for this study as well as Shane for participating in this study. We also thank undergraduate researcher Emma Brown for supporting this work. The research reported in this paper was supported with funding from the National Science Foundation (DRL #1453493, PI: Michelle Cirillo). Any opinions, findings, and conclusions or recommendations expressed in this material are those of the authors and do not necessarily reflect the views of the National Science Foundation.

TEACHER FEEDBACK AND AUTHORITY DURING INSTANCES OF STUDENTS' PROVING

Mitchelle M. Wambua	Samuel Otten	Kimberly Conner
University of Missouri	University of Missouri	University of Northern Iowa
mwqdd@umsystem.edu	ottensa@missouri.edu	kianderbionner@uni.edu

Teacher feedback during the process of students' proving is important to consider because proving is often challenging for students, requiring feedback and support. Additionally, feedback has implications for authority and agency, which are constantly being negotiated. We examined the authority dynamics evidenced in a teacher's feedback actions while students proved geometry claims. By analyzing audio and video recordings of classroom proving discussions, we found that various teacher feedback types position either the teacher or students as authorities with regard to providing and validating mathematical ideas. We provide suggestions for research and practice with respect to teacher feedback and authority in proof instruction.

Keywords: Proving, Authority, Classroom Discourse, Instructional Activities and Practices

Introduction

Mathematics proving has long been considered a central component of secondary students' mathematics (Schoenfeld, 1994; Stylianides et. al., 2017) because, among other reasons, it is useful as a process through which students make sense of and communicate mathematical knowledge (de Villiers, 1999; NCTM, 2000). Despite the significance of proving in mathematics learning, research evidence shows that secondary school students struggle with constructing and understanding proofs (Chazan, 1993; Harel & Sowder, 2007; Shongwe, 2020). This tension highlights the need to examine how teachers can support their students in learning this important yet difficult concept. Scholars have studied some teacher practices like the careful enactment of proof tasks (Bieda, 2010) and teacher moves (Martin et.al., 2005) to support students' learning of proving. The present study builds on the work of these researchers by examining how teacher feedback practices can support students' as they learn to construct a proof.

Teacher feedback is defined as the information provided by a teacher to students about their performance or understanding (Dempsey, et al., 1993; Hattie & Timperley, 2007) and is known to support student learning in a variety of ways. Feedback provides information that learners can use to confirm, reject, or modify prior knowledge (Fyfe et al., 2015), increases student motivation, and acts as a guide for what students should do to make progress towards the learning goals (Hattie & Timperley, 2007). Hattie and Timperely, however, caution that the effectiveness of feedback depends on the type of feedback and the way it is given, adding that feedback by itself may not have the power to initiate student action because students can accept, modify, or reject teachers' feedback.

Beyond academic performance, another way to examine the power of feedback is by focusing on how it promotes or hinders student authority in classroom learning. Powerful classrooms are ones where students provide the ideas that drive classroom discourse (Engle & Conant, 2002). Such classrooms are characterized by students having opportunities to talk elaboratively (Soter et al., 2008) and actively participate in the class by taking up positions of authority (Engle, 2012; Otten et al., 2017). Students' authority and active participation in classroom proving are important because they allow for student ownership of the proving process with students learning to make and justify conjectures (Otten et al., 2020) without relying on the teacher to always tell them what to do. In other words, feedback can be a way for a teacher to support a student and spur them forward or focus their attention without explicitly directing their actions. For these reasons, the present study considers authority in the context of students' proving, with the object of study being the teacher's feedback actions.

Theoretical Framing

Our view of proofs is guided by the work of de Villiers (1999), who viewed proofs as a tool to accomplish several purposes such as verification, explanation, communication, and intellectual challenge. These purposes are not solely for individuals but function within a classroom community in which teachers have a dual duty to represent the discipline of mathematics as a more knowledgeable other while also honoring students as learners of mathematics and attending to their needs (Stylianides, 2007). We connect these ideas to teacher feedback which can be a tangible act through which a teacher responds to students' learning needs while also representing mathematics in an authentic way.

Proving in a classroom community inculcates a discourse, during which patterns of interaction and authority dynamics are continuously established and negotiated (Otten et al., 2017). For example, teachers and students may negotiate what definition(s) and format(s) to use during classroom proving and there may be a negotiation over whether a proof is sufficiently complete or clear. During classroom negotiations, the person or object in authority is the one who takes the lead while others follow (Pace & Hemmings, 2007). Using this definition, we view the person in authority as the one who leads the proving discourse by deciding what ideas are foregrounded and validated.

Teacher's feedback may either maintain the authority of teachers or position students in authority of leading the proving discourse. We investigated the authority dynamics manifested during teacher feedback by examining both the focus and purposes of the feedback. In terms of focus, Hattie and Timperley (2007) outline that teacher feedback may focus on task correctness, students' processing of information and/or students' motivation. Dempsey and colleagues (1993) on the other hand delineate various feedback types that play different purposes (e.g., providing correct answers, probing students to think towards the correct answers, among others) during classroom learning. To this end, we ask two key questions:

RQ1) What feedback types does a teacher provide students during classroom proving?

RQ2) How is authority manifested in the feedback types used by this teacher?

Method

Setting and Participants

Data for this study came from a larger teaching experiment that explored a non-traditional way of introducing proof to secondary students. The teaching experiment involved students using tasks and strategies that attended to the generality and purpose of proofs rather than direct instruction on the specific techniques for constructing arguments (Conner, 2018). The third author was the instructor in this teaching experiment that involved ten students (7 females; 3 males) enrolled in an accelerated 9th grade mathematics course at a rural, public school in the Midwest United States. Prior to the study, these students had not received any high school Geometry or formal proof instruction, although reasoning and justification had been a part of earlier mathematics courses. The teaching experiment consisted of 14 sessions (ap539anderb28–38 minutes each), with students primarily working on tasks in three small groups. This study focuses on Sessions 11-13, when students were engaged in conjecturing and proving claims about specific classes of polygons and whether or not they are all similar (e.g., “all squares are similar”). The instructor used non-traditional instructional practices because she hoped to share authority of proving with students by actively engaging them in both the discourse and practice of reasoning-and-proving and she intended for students to see the purpose of deductive reasoning instead of relying on teacher authority to direct them to use deductive rather than empirical reasoning when constructing proofs.

Data Sources and Analysis

As part of the larger study, all classroom discourse was audio and video recorded with recorders at each of the three groups as well as focused on the full class setting. Students’ written work was also collected. Selected sections of the classroom discourse (i.e., when there were interactions between the teacher and students) were transcribed and coded using MAXQDA software. We coded for oral teacher feedback given during both whole-class and small-group discussions. For this report we are not including instances of student-to-student feedback, although this did occur.

Data analysis comprised three phases of coding. Phase one involved flagging any instance of teacher-to-student discourse that contained (or functioned as) feedback to the students about their performance, understanding, or directing them toward or away from a solution path. We tried to be overly inclusive in this flagging of teacher feedback. In phase two we coded for feedback types based on the works of Dempsey and colleagues (1993) and Hattie and Timperley (2007):

- *Knowledge of results feedback* - –informs learner whether their strategy or answer is correct or incorrect (e.g., “that is a good guess, but it is not correct”).
- *Knowledge of correct response feedback* - –informs the learner what the correct strategy or answer is (e.g., “the angles of an equilateral triangle are all the same size”).
- *Elaborated feedback on correct response* - –gives explanations for why the student’s response is correct and/or directs students to relevant materials or information that could strengthen the response (e.g., We can label the angles of a square with a representation of 90 degrees because the angles are always going to be 90 degrees).
- *Elaborated feedback on incorrect response* - gives explanations for why the student’s' response is incorrect and/or directs them to relevant materials or information that could lead to a correct response (e.g., “what you provided is a conditional statement, but it’s not a conditional statement for squares being similar”).
- *Questioning feedback* - –poses questions to respond to students’ strategy or answer with the questions functioning as an indicator of correctness or incorrectness (e.g., “[Student X] said that isosceles triangles are similar. What do you all think?”).
- *Revoicing feedback* – Uses a restatement of students’ strategy or answer to respond to students with the restatement functioning as an indicator of correctness or incorrectness *(*e.g., “[Student Y] just gave us a counterexample. He said …”).

The *questioning* and *revoicing* feedback codes were not in the prior literature but emerged from our analysis because these teacher moves, in some instances, functioned as a form of feedback to students. Note, however, that not all teacher questions nor all instances of teacher revoicing were necessarily feedback. For example, to start Session 11, the teacher asked students to read the task description then revoiced what the students read. In this context, this question and revoicing did not indicate to the student any information about their performance and was thus not coded.

Finally, in phase three, we coded for mathematical authority dynamics using our definition of authority. We examined the authority at play for each instance of coded feedback by asking the following questions: Who provided the mathematical ideas that were the focus of the discourse? Who critiqued or validated the correctness of the mathematical ideas? And who confirmed or rejected the completeness and correctness of proofs? We considered these questions with respect to the teacher and to students collectively (not individual students). We then considered patterns across instances in terms of the authority for each feedback type. Multiple authors analyzed the data and met regularly to clarify and reconcile coding differences.

Findings

The classroom proving discourse was marked by various feedback types, with questioning feedback being the most common. Table 1 shows the number of instances of each feedback type and the predominant authority figure for each feedback type.

Table 1: Authority Figure(s) and Number of Instances for Various Feedback Types

Feedback Type	Number of Instances	Predominant Authority Figure
Knowledge of results	9	Teacher
Knowledge of correct response	12	Teacher
Elaborated feedback for correct response	9	Student
Elaborated feedback for incorrect response	5	Teacher
Questioning feedback	24	Student
Revoicing feedback	13	Student

Authority dynamics in the feedback were two-fold. There was authority in terms of who provided mathematics ideas that propelled the classroom proving, and authority in terms of who validated the correctness of the proofs. Our findings show that *knowledge of results*, *knowledge of correct response*, and *elaborated feedback for incorrect responses* positioned the teacher as authority whereas *questioning feedback*, *revoicing feedback*, and *elaborated feedback for correct responses* positioned students as authority.

Feedback Types that Position the Teacher as Authority

Knowledge of results feedback positioned the teacher as the mathematical authority with regard to deciding whether students' responses or their steps within the argument they were formulating were mathematically correct. Moreover, through *knowledge of correct response* feedback, the teacher positioned herself in authority of both providing what counted as true responses and the ideas that moved the proving process forward. For example, consider the excerpt below from a whole-class discussion at the start of Session 12 when the teacher was introducing conditional statements.

T: To start off, does anyone remember anything about conditional statements? We talked about them when we were doing the diagrams? No? Okay.

S: They were true sometimes but not all the time, right? They were not for sure things.

T: That would be a good guess, but no. That is not what it is (*chuckles*). A conditional statement is just a statement that is written in a certain form. It is written in the form 'if something, then something. (*Writes the statement if _ then _ on the white board.*)

Here, a student attempted to give the definition of a conditional statement, and the teacher gave *knowledge of results* feedback, "that is not what it is." In this case, the teacher positioned herself in authority of determining that the students' response was incorrect. The teacher then went on to provide *knowledge of correct response* feedback on what the correct response was by saying, "A conditional statement is just a statement that is written in a certain form." Again, the teacher claimed authority in giving the correct response and also providing the definition which would be used later in proving activities.

Later in this class as the students were attempting to use the earlier given definition of conditional statements to prove that 'all squares are similar,' the teacher gave *knowledge of results, knowledge of correct response*, and *elaborated feedback for incorrect response*, again positioning herself as the mathematical authority. See the discussion below:

T: Can anyone take a stab at writing our statement 'all squares are similar' into a conditional if-then kind of format? (*Looking at student S1 specifically*) You want to take a stab?
S1: ..If all the angles on a square are 90 degrees, then they are all the same.
T: So that is a conditional statement, an if-then, but it is not a conditional statement for squares being similar. So, what could we--, what did we assume to be true when we were proving our statement about the squares being similar? What did we start off with?
S2: That they were similar?
T: That is what we are trying to prove. So, we did not start off with that.
S3: That they have four 90 degrees angles?
T: So that is actually a property of squares. So, we just started with, "if we have squares."

When Student 1 gave a guess of how to write a conditional statement for all squares being similar, the teacher used both *knowledge of correct response feedback* and *elaborated feedback for incorrect response* to tell the students why their response was incorrect ("that is a conditional statement ..It it is not..Ir squares..."). Here the teacher positioned herself in authority, determining what a correct conditional statement for all squares being similar would be. The teacher then rephrased the question by asking, "What did we start off with?" Again, when two students gave the responses "they were similar" and "they have four-90 degrees angles," the teacher gave *elaborated feedback*, wherein she did not explicitly tell the student that their responses were incorrect but rather elaborated the incorrectness by explaining that the responses were what needed to be proved or just "a property of squares." Finally, the teacher gave *knowledge of correct response feedback* by stating that "we just started with, 'if we have squares.'" In this way, the teacher assumed authority in validating the correctness of what the class "start[ed] off with" and in providing the correct response.

Feedback Types that Position the Students as Authority

Feedback that was in the form of *questioning*, *revoicing*, and *elaboration of correct responses* tended to position the students in authority of providing correct responses and ideas that moved the classroom proving discussion forward. For instance, see the discourse below when students were attempting to come up with conjectures for similar polygons at the beginning of Session 11:

S1: Is a circle a polygon?

T: Huuh. That was the question over there too. (*Asking the whole class*) Okay. Quick question. Is a circle a polygon?
S2: Yes.
S3: No.
S4: It has no defined sides.

In this case, the teacher avoided taking authority by giving the students the correct answer, and instead used *questioning* and *revoicing feedback* simultaneously by posing the same question to the whole class, thus positioning all students in authority of offering thoughts and potentially deciding as a group what they thought the correct answer to be. Indeed, a whole-class discussion continued until all students seemed to agree that circles are not polygons.

A similar authority dynamic happened in another instance during a small-group discussion in Session 11 when students were attempting to formulate a conjecture about specific triangles that are similar. One student asked the teacher, "All equilateral triangles are similar because they have 90 degrees--, no, which one has a 90-degrees angle?" The teacher responded using both *questioning* and *revoicing feedback* by re-asking the question to the other students in that group, "which one has 90 degrees?" again positioning students in authority of deciding together what could count as correct responses.

The prior examples involved shared authority as students clarified the scope of what they should consider in their proving process. The teacher also used *elaboration feedback on correct responses* in addition to *questioning* and *revoicing feedback* to position the students in authority of providing ideas that would propel the proving discourse forward. For example, see the excerpt below from Session 13 when the whole class was discussing how to label two squares before proving that they are similar.

T: Now, you all had a couple of different ways of correctly labelling this diagram, so we are going to talk about it. But first of all, let's talk about the angles (*the teacher has two unlabeled squares on the board*). What do we know, or how do we label the angles of our square?
S1: Put a box.
T: Put a box. And what does the box represent or tell us?
S2: 90 degrees.
T: 90 degrees. Now why can we label it 90 degrees instead of using like a letter?
S3: It's always going to be 90 degrees.
T: It is always going to be 90 degrees, because we are talking about squares.

In this example, the teacher started by giving a general *elaboration feedback* on students' previous correct work of labeling diagrams and invited them to share what they did. During the discussion, the teacher used both *revoicing feedback* to foreground what the students said and did so in a way that seemed to indicate the students were correct, and the teacher used *questioning feedback* (e.g., what "the box" means in angles and why we label squares using a "box") to solicit ideas from the students. This way, although the teacher was guiding the discussion, she centered students' responses, thus sharing with them the mathematical authority of giving ideas that propelled the classroom proving discourse.

Discussion and Conclusion

This study aimed to determine the teacher feedback types given to students during classroom proving and to examine the authority dynamics of the various feedback types. The teacher gave a variety of feedback types that positioned either the teacher or the students as mathematical authorities. The feedback types that tended to position the teacher in authority were those where the teacher gave verdict on the correctness of students' responses and where the teacher provided the students with the correct responses that moved the proving discourse forward. The feedback types that positioned the students in authority were mostly through questions that probed students to think deeper or questions that invited students to respond to each other's ideas and hence develop a shared notion of how the classroom proving process might continue.

It is our view that the variety of teacher feedback maintained a balance of authority between the teacher and students. This form of balance is worthwhile to consider because although it may be viewed as ideal for students to have more agency, giving entire authority to students is not always feasible, especially when they are learning formal proving for the first time (Otten et al., 2020). There are times when it is rational for the teacher to take up the role of the more knowledgeable other by providing corrective guidance to students. For example, there are incorrect or unproductive ways to turn the conjecture "all squares are similar" into a conditional statement and these could have negative implications for the proof the students were about to construct.

Our study contributes to the ongoing efforts to support teachers in sharing authority with students as a way of enhancing students' meaningful learning of math and active participation (Engle, 2012; Otten et al., 2020). Sharing authority in areas like proving may seem challenging due to the inherently complex nature of teaching and the difficulties students experience with learning proofs (Chazan, 1993; Harel & Sowder, 2007; Shongwe, 2020). We nevertheless encourage teachers to enact feedback practices that invite students to share in the authority of mathematical ideas to encourage students to become more adept at conjecturing, making arguments, and critiquing the arguments of others. Elsewhere, we encourage teachers to share authority gradually and strategically with students (see Otten et al., 2020) in the spirit of maintaining the dual role of teaching in a classroom community (Stylianides, 2007). Our findings in this study show that questioning feedback could be another strategy for sharing proving authority with students.

Finally, using feedback as a lens for viewing questioning is another way to think about the literature on questioning. Questioning has been documented as a teacher practice that is essential in promoting active student participation (Black et al., 2003). When used as teacher feedback, questions can invite students to take up authority of their own learning and that of their peers. Through questions, teachers can assess student thinking but also provide implicit feedback guiding them towards the learning goal. Good questions spur students to confirm or modify their prior thinking, detect errors and correct them without the teacher explicitly telling them the correct answer. Questions also serve to invite students to respond to and critique each other's arguments, thus promoting rich classroom proving discussions. For example, when the teacher re-asked a student's question on whether circles are polygons back to the class, the students held a discussion until they agreed that circles are not polygons. Future research might document the differential outcomes between a teacher providing directive feedback and questioning feedback, with questioning feedback not only having the possibility of promoting shared authority but also being aligned with the kinds of discourse that we hope to be common in the proving process.

Acknowledgments

We thank the students for their participation in the study and for allowing us to learn so much from them. This work was supported by the National Academy of Education and the National Academy of Education/Spencer Dissertation Fellowship Program.

This study examines how joint exploration is established and maintained among students and the teacher in secondary mathematics classrooms. We use the theoretical perspective of positioning to conceptualize joint exploration as involving the negotiation and coordination among participants to position students with epistemic agency and authority. Using a constant comparative method, we use classroom video data of two episodes containing joint exploration and closely analyze the shifts in epistemic positioning within them. We find that shifts in epistemic positioning, especially when students position one another with epistemic authority, help to support continued joint exploration. We also find that the teacher can play an important role in decentering themselves as the epistemic authority.

Keywords: Classroom Discourse, Problem Solving, Instructional Activities and Practices

Mathematics education reform has long called for students to collaboratively engage in the broad array of mathematical practices and reasoning used within the discipline (NGA & CCSSO, 2010; NCTM, 1989). To be authentically engaged in the discipline of mathematics, students should have opportunities to exercise epistemic agency and authority, which focus on their role in taking on the work of knowledge building. Epistemic agency goes beyond the idea of conceptual agency in mathematics, related to developing solution strategies and meaning of concepts (Cobb et al., 2009), by recognizing the roles students play in making decisions about the process by which ideas are constructed (Damsa et al., 2010; Stroupe, 2014). Specifically, this vision involves students making decisions as a part of mathematical inquiry or exploration, such as which mathematical questions and problems are worth pursuing or which approaches to take in investigating them. Within the context of a classroom community, these decisions are often made as joint negotiations between teacher and students (Krist, 2020). As many mathematics classrooms provide little opportunity for students to exercise joint epistemic agency and authority, it is crucial to better understand how teachers and students interact in ways that position students as active participants, particularly during mathematical explorations.

In this paper, we examine *joint exploration* in secondary mathematics classrooms when the teacher is present by analyzing the epistemic positioning of participants. It aims to answer the following research questions: *How are episodes of joint exploration established and maintained in a secondary mathematics classroom? What social and/or epistemic roles do teachers and students play, and how do these roles shift throughout the episodes?*

Exploration as a Form of Mathematical Activity

Exploration, or investigation, is an important aspect of knowledge generation across a wide range of disciplines, with disciplinary distinctions made in the methods for how this exploration is taken up. Exploration is centered around mathematical questions, ideas, or problems that are not sufficiently known and thus represent an intellectual need to be fulfilled (Harel, 2001). As such, exploration involves jointly orienting toward inquiry as a fundamental component of the work (Keifert & Stevens, 2019). Furthermore, processes by which questions, ideas, or problems are framed, clarified, and made investigable are an integral part of mathematical exploration. For example, research has examined students' problem posing in mathematics (Cai et al., 2015; Silver 1994) and the activities involved in problematizing in science learning (Suárez, 2020; Phillips et al., 2018). In addition to activity orienting toward an intellectual need, exploration also involves the investigation and potential closure around whether that intellectual need is fulfilled (Keifert & Stevens, 2019). These activities could include stating what is known and not known, offering suggestions of next steps, monitoring and reporting on the status of the activity to the group, and confirming a solution, among others. Thus, mathematical exploration provides a context for students to actively engage in many types of productive disciplinary work (Engle et al., 2002) for the purpose of fulfilling an intellectual need.

We focus on *joint* exploration, highlighting the instances in which students and the teacher participate collaboratively. This focus helps uncover the interactional and political dynamics involved in establishing and maintaining opportunities for exploration, given that it is not normative for mathematics learning to incorporate it. Thus, we claim that joint exploration likely necessitates re-negotiating the roles and participatory structures of traditional classroom contexts that distribute the social and intellectual authority and agency to students, rather than residing solely with the teacher (Ko & Krist, 2019). To investigate these complex interactions related to epistemic agency and authority, we apply the theoretical lens of positioning.

Positioning Theory as a Theoretical Lens

Positioning theory considers both social and intellectual roles and authority in analyzing interaction. It highlights the interactional nature of activity, which is afforded and constrained by normative possibilities of the authority and responsibilities associated with different roles (Davies & Harré, 1990). From this theoretical lens, participants in activity take up roles or positions, which afford them specific ways of acting and recognition among participants. These positions are flexible and can shift over time. Shifts tend to indicate important moments of activity because they typically involve participants negotiating and coordinating roles.

This theory has been recently used in analysis of discourse in mathematics classrooms in ways that help highlight the role of identity and power in micro-interactions among students and the teacher (Herbel-Eisenmann et al., 2017). For example, research on epistemic positioning (i.e., positions related to knowledge and its creation) in mathematics classrooms has identified two main positions students and the teacher commonly take up during mathematical activity: 1) a *knower* who provides mathematical information and 2) an *actor* who performs an action doing mathematics (DeJarnette & González, 2015; Lo & Ruef, 2020). Within these positions, participants can take on primary or secondary roles depending on whether they provide or request the activity to be completed. In a traditional classroom structure, the teacher is often in a position of authority as a primary knower, viewed by the students as the conduit of disciplinary knowledge. This traditional relationship between teacher and students can be conceived of as an inherent asymmetry in authority over knowledge, as well as bearing the responsibility for controlling the conversation (Mercer & Dawes, 2008).

In particular, we hypothesize that the presence of the teacher could both support and constrain students to be actively involved in joint exploration. The teacher could help facilitate collaborative work, model many disciplinary practices, and position students with epistemic authority to take on intellectual roles in exploration. However, the teacher may also be positioned as a knowledgeable disciplinary expert and authority, such that students could rely on the teacher to fulfill any intellectual need rather than take up exploration. Furthermore, we hypothesize that when a teacher seeks to create opportunities for students to participate in exploration, the inherent asymmetry of the teacher-student dynamic would need to be challenged by positioning students in roles that are associated with intellectual and social authority.

Methods

For this study we analyzed two comparative episodes drawn from a large classroom video dataset (Dyer, 2016). Below we describe the data, episode selection, and analysis of the episodes.

Data and Episode Selection

We use classroom video data from one focal teacher, Mrs. Perry, from a class with grade 10 and 11 students. Mrs. Perry was selected because her lessons contained a large amount of time with students working in small groups and previous research has documented that Mrs. Perry's teaching practice is responsive to student thinking (Dyer & Sherin, 2016). We believed that both of these factors would make it more likely for joint exploration to occur with the teacher present.

Data from Mrs. Perry's classroom included 10 videotaped 100-minute lessons, filmed approximately every week for the final three months of school, which corresponded to about a quarter of her lessons during that time period because her school used block scheduling. Video was collected from three different angles and separate audio was captured for each group of students. We selected two lessons, one from each of the first two months, from different units of instruction on 1) trigonometric functions, and 2) exponential and logarithmic functions.

We selected two episodes of joint exploration, one from each lesson. These episodes were identified by watching video of the two selected lessons and identifying potential instances of joint exploration as a sensitizing concept (Blumer, 1954) in which the teacher was physically present. We defined instances of joint exploration as the collaborative activity of investigating disciplinary questions and ideas among students and/or teachers through interaction. Thus, our analytic criteria specified that instances must have (a) at least two participants contribute substantively, intellectually or socially, to the group's sensemaking activity, and (b) participants seek to construct new knowledge related to a content idea or question to fulfill an intellectual need. We selected two contrasting cases based on the different types of participation from the teacher in each of these episodes as we hypothesized the teachers' participation would have a large influence on how episodes of joint exploration are established and maintained.

Episode Analysis

We used a constant comparative method (Strauss & Corbin, 1990) that involved constructing rich descriptions of the of the epistemic positioning for each of the episodes. We bounded episodes by starting with the teacher approaching the student(s) and ending with the teacher leaving the students to interact with another student group. We created transcripts of each episode, which we used in tandem with the video and audio records in all subsequent analysis. Two authors independently wrote descriptive accounts of the positioning with the aim of highlighting salient aspects of the epistemic positioning that occurred. These descriptions considered: Who is seeking knowledge? Who (or what) is being sought for knowledge? What is an individual's level of certainty about the knowledge? Who confirms the knowledge as certain?

We used the descriptive accounts of positioning to identify portions of the episodes in which the positioning of a participant in interactions shifted. We considered a shift in epistemic positioning to be: (1) an individual changing from expressing certainty to uncertainty (or vice versa) about a piece of information; (2) an individual being newly sought as a source of information or (3) a change in who confirmed information as valid.

Results

We present two contrasting episodes from the same classroom that we identified as instances of joint exploration and report shifts in epistemic positioning that we identified in each episode.

Episode I: Solve a Cosine Equation using a Graph

The first episode involves a group of three students, Ellie, Nick and Theo, and the teacher, Ms. Perry, jointly exploring a task that she provided to the class. This task asked students to solve the equation $-15=20\cos(30x)$ for the portion of the function shown in the provided graph (Figure 1, left), where x is measured in degrees. Using the inverse cosine function to solve the equation yields one solution (*x »* 4.62). Students could then use the graph and the period of the cosine function (12) to find the remaining three solutions (*x »* –4.62, 7.38, 16.62) by locating the x-values of the points of intersection of the function and the line $y = -15$ (Figure 1, right).

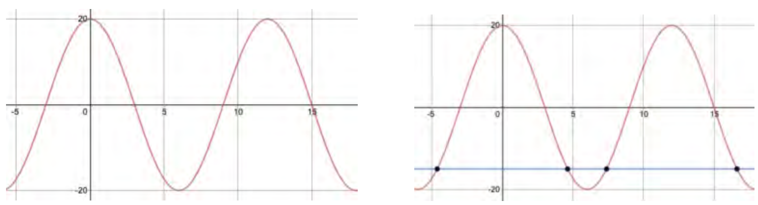

Figure 1: Solve a Cosine Equation Graph Provided (left) and its Solutions (right)

This episode involves joint exploration, as Ellie, Nick, Theo and Mrs. Perry (teacher) work collaboratively to find the remaining solutions. Each participant contributes by posing questions about the task, offering solution strategies, or directing the next steps of the activity. These questions, strategies, and directions are taken up by others to advance the search for remaining solutions. We present three main shifts in epistemic positioning that served to establish and maintain joint exploration below.

Ellie positions Nick as having epistemic authority. This exchange begins the episode of joint exploration. The first shift occurs when Ellie looks to Mrs. Perry to confirm her solution, who is standing up to leave. As Mrs. Perry leaves momentarily, Ellie then turns to Nick to confirm her answer of 4.61.

Ellie: Yes, I don't know if I'm right, is this right? (*moves paper towards Mrs. Perry who stands up to briefly leave group, turns to Nick*) What did you get Nick?

Nick: I got 4.62, 16.62

Ellie: Yesss (*exclaims, holds both fist in the air*). Wait, I just got 4.61. (*Mrs. Perry returns*)

Nick: You're supposed to find all this, just one more. All you have to do is add the period…

Ellie: But how do you make that into like an equation so I can solve it?

Nick: (*Stands up, leaning over Ellie's work across from him*) You don't necessarily, … put it into the equation. What you can do… knowing that this is going to be repeating over and over again … so say you want here… you would add this to 12.

Ellie seeks confirmation for her answer on the task and first looks to Mrs. Perry. When she leaves, Ellie instead turns to Nick to confirm her answer, indicating a shift in Nick's epistemic position. Ellie cheers as Nick gives an equivalent answer to hers, but then questions him when he lists a second answer. Ellie continues to ask Nick questions and he continues to fulfill his role as a source of information, offering an explanation of how to find the other solution.

Mrs. Perry shares epistemic authority. The second shift involves Mrs. Perry sharing epistemic authority with the students in the group by re-positioning herself as one who gives directives without giving mathematical information. By re-positioning herself, she shares her epistemic authority with the students and helps sustain the joint exploration in this exchange. When Mrs. Perry re-enters the conversation, she continues to generally redirect Nick, Theo, and Ellie to the graph, rather than providing a clear next step.

Mrs. Perry: Well, where's the one, what x does that say? (*pointing to Nick's work*)
Nick: 4.61, I got 4.62 because I rounded.
Mrs. Perry: Can you like find that, mark that on the x-axis where that is?
Nick: That would be about, let's assume, here (*writing on paper*)
…
Mrs. Perry: Maybe you should mark that on there, like you were about to, because maybe that will help you to think about, okay, how can I?
Nick: Because I know you can add to the period to get this
Mrs. Perry: Okay so that will get you that one, so you could at least get that one by adding the period and we just have to figure out how to get the other two.

Mrs. Perry's moves to re-position herself to the students include clarifying which x value the students are referring to and directing them to mark that value on the x-axis. Mrs. Perry does affirm Nick's proposed solution of adding the period to the first solution to find a second solution. Then, she summarizes what is left to find, the remaining two solutions, rather than providing more specific epistemic guidance. These moves position the students to continue the exploration independent of Mrs. Perry as the epistemic authority.

Theo and Nick position each other as having epistemic authority. The third shift occurs while Mrs. Perry is still with the group when Theo enters the conversation and begins to work with Nick to find the other solutions. Nick and Theo shift to position each other as sources of information. This shift also maintains the joint exploration. As Nick poses the question of how to find the remaining solutions, in addition to 4.62 and 16.62, Theo offers ideas that Nick takes up.

Nick: How would you solve for that one, though?
Theo: You would add 12
Nick: When you're adding 12, you're just going through an entire period, 6 you're going through half a period
Theo: Yes, which wouldn't work because it's a cosine..I, could you add the three? Possibly?
Nick: A fourth of the period?
Theo: Yeah.
Nick: Let's find out! (*typing into calculator*) No, that's not what I wanted..Ipe!... There we go, that's another one.

When Nick asks, "how would you solve for that one, though?" Theo responds with an answer, although it is restating the strategy Nick was employing, adding one period (12) to the first solution. This continues the joint exploration between Nick and Theo as they search for a way to find the remaining two solutions. Theo proposes a strategy of adding 3, which Nick reframes as "a fourth of the period" and proceeds to test out using a calculator. Nick reports back as he continues to use the calculator and eventually seems to have success. Nick and Theo, together take up the epistemic authority shared with them to find the remaining solutions. Theo's offer of a possible strategy and Nick's uptake of this strategy maintain the exploration of the episode, which ends when Nick finds another solution.

Episode II: "Is there a Natural Logarithm that is equivalent to *e*?"

This episode involves a student, James, posing a problem that he created. James calls for the teacher's'attention while she is at his group and asks whether there is a number whose natural logarithm is equivalent to e (it is $e^e \approx 15.15$, whose natural logarithm is e), which does not appear to be directly from the homework they discussed immediately before.

We consider this episode to be an instance of joint exploration among Mrs. Perry, James and a third student, Sergey, seated beside James. Each participant contributes intellectually (with information) or socially (with directives) to answer the question posed by James. Further, the participants are all not certain of their proposed answers right away. We present three main shifts in epistemic positioning that served to establish and maintain joint exploration below.

Mrs. Perry's initial release of epistemic authority. Mrs. Perry's initial reaction to James' question involves a change in epistemic positioning that serves to establish joint exploration. This shift involved a release of epistemic authority by Mrs. Perry.

James: Is there, I've just been messing around a little bit. Is there a natural log that is equivalent to *e*? (*looking at calculator, then looks up at Mrs. Perry, resting head on hand*) Like 15 point something?

Mrs. Perry: (*slowly*) Is there a natural log that is equivalent to *e*? (*pauses, steps back,*) You mean like, you take the natural log of something and you get *e*? (*looking at James, who nods*) Is that what you mean? (*pauses, puts hand up to mouth and then brings it down*) Ahhh so... (*leans slightly back briefly writing in the air*)

The interaction begins with James positioning Mrs. Perry as an epistemic authority, asking her this question and looking to her for an answer. Notably, James does have an accurate estimate to answer his question when he poses it. Yet, he is not certain and looking to Mrs. Perry as a source of epistemic authority to confirm his hypothesis of the existence of a natural logarithm that is equivalent to *e*. This is followed by Mrs. Perry restating James' question, pausing, and stepping back to lean backward, away from James and Sergey. Mrs. Perry's words and movement seem to suggest that the answer is unknown to Mrs. Perry, in contrast to being positioned with epistemic authority. By pausing to consider the question, Mrs. Perry creates an opportunity for James and Sergey to take up the intellectual authority within the conversation.

James' re-positioning of Sergey and himself as epistemic authorities. As Mrs. Perry shifts away from being an epistemic authority, James and Sergey position each other as epistemic authorities. In response to James' question, Sergey joins the conversation and affirms the existence of such a value, continuing the exploration.

Sergey: I mean, yeah, cuz it'd be a power.
James: of *e*, right? (Mrs. Perry: yeah)
Sergey: Would it just be 1? (*looking at James*)
James: It would be *e* to the power of *e* (*looking at Mrs. Perry*)…
Sergey: So the log, log base *e*
James: Oh, log of *e* to the *e* (*pauses*) is *e*? (*looking at Sergey, laughs*) Wait a second, is that right? Lemme check. (*picks up calculator*)
Mrs. Perry: Well wait, write it down, write it down. I can't think right. I have to see it.

bending down to table, leaning over student work) So,
James: I'm wondering, so I think we just figured out that (*writing*) log base *e*..It would be ln of *e* to the *e*. Okay. So, what's wait. Does that, does that work?
Mrs. Perry: That seems right. Log (*looking at work*)
James: Let's try that so (*typing into calculator*)
Mrs. Perry: Waaait no (*long pause, bends head all the way forward*)

Sergey supports James in exploring his question. He first affirms that such a value would exist, explaining that "it would be a power [of *e*]". Sergey initially offers 1 as a solution, which James quickly disregards. Sergey is undeterred, however, in contributing information. Sergey reminds James that he is interested in the natural logarithm (base *e*), rather than the common logarithm, and reorients James to this in several instances, which James acknowledges and takes up. Notably, James shifts his gaze from Mrs. Perry to Sergey, indicating a shift from positioning Mrs. Perry as an authority to Sergey as supporting his exploration. James begins to talk through his hypothesis that "log of *e* to the *e* is *e*" and uses the calculator to confirm his proposed solution, re-positioning himself as an epistemic authority. Rather than rely on Mrs. Perry for confirmation, James uses a calculator to confirm his solution.

James' and Sergey's epistemic authority begins to equalize. With Mrs. Perry still present, James and Sergey continue to take up the epistemic authority and their authority relative to each other appears to equalize. This can be seen as they reach an answer they are both satisfied with.

James: *e* to the *e* to the 1. Yeah, fifteen point, yeah, there it is. And then log of that is *e*
Sergey: No (James: Just kidding) natural log of that (*looking at James' work*)
James: (*mumbles*) ln. Yeah, my bad.
Sergey: Yeah
James: Yeah

At first, Sergey joins the conversation with lower epistemic authority than James: he offers 1 as a solution, which James disregards. Here, James acknowledges Sergey's contribution about it being the natural log (or log base e) rather than log and readily accepts by saying "yeah, my bad.". Their mutual affirmations of "yeah" at the end of this episode indicate that they are confident in their solution and acknowledge each other's confirmation as well, indicating a similar status of epistemic authority. At the conclusion of the exploration, Sergey and James arrive at a solution they were both satisfied with, without any affirmation from Mrs. Perry.

Comparison of Two Episodes

In both episodes, exploration is initiated by a student asking, or attempting to ask Mrs. Perry a question and request information. In episode one, this is initiated when Ellie asks Mrs. Perry if her work is correct and in episode two, when James poses his question to Mrs. Perry. Mrs. Perry's responses in both, either briefly leaving, or restating the question, are a shift away from her being positioned as the epistemic authority and coincide with the start of joint exploration.

In both episodes, joint exploration is maintained by two shifts in positioning: (1) Mrs. Perry, the teacher, redistributes authority by re-positioning the students as capable of seeking the answer, and (2) the students (Nick and Theo in Episode I and James and Sergey in Episode II) position themselves and each other as epistemic authorities in the situation, as they both exchanged ideas among each other, and took up the ideas offered.

The extent to which Mrs. Perry releases epistemic authority to the group, however, differs between episodes. In episode one, Mrs. Perry supports the students in working through the assigned task by directing Nick to mark his solution at a particular place on the graph and giving the status of the group's work. In doing so, Mrs. Perry shares some of the epistemic authority with the students yet still seems in command of the material as she guides the students toward the next step, implying she holds the solutions to the task. However, in the second episode, Mrs. Perry appears to release her epistemic authority almost entirely after James asks a question to which she does not immediately know the answer. The moment when Mrs. Perry says, "wait no" as she leans her head down, effectively bowing out of the conversation, appears to be when she fully releases her epistemic authority, as James and Sergey are not deterred by her refutation. Rather, they continue toward their solution in spite of her lack of direction or affirmation.

In both episodes, joint exploration ends when a student or students become the ones to determine whether knowledge was correct or incorrect, without confirmation from the teacher. This is particularly notable that students are able to resolve their own uncertainties in the presence of the teacher, yet without relying on the teacher as the source or confirmation of knowledge as valid. Additionally, as students worked to resolve their own uncertainty, students in both episodes utilized calculators as tools to verify their proposed solutions. While the student had to determine what to input into the calculator, and how to interpret the output, the calculator appeared to positioned by students as an authority for validating of knowledge.

Discussion and Conclusion

These episodes are encouraging as they suggest that joint exploration can happen in secondary mathematics classrooms with the teacher present. In fact, our findings suggest that the teacher's actions may be helpful to establish and maintain joint exploration. In both episodes, joint exploration was initiated by students while the teacher was present, with the teacher acting in ways that implicitly decenter herself as the epistemic authority and primary knower. It is not clear that this was the teacher's intended purpose in leaving the group briefly or expressing hesitation in response to James' question. However, it appears to have that result as Ellie redirects her question to Nick. Neither involves explicit or obvious positioning, such as the teacher directing the group investigate a question or asking how the group might figure it out. This suggests that the teacher's role in fostering joint exploration can be subtle. Future research could explore the possibility of whether teacher moves that more obviously and explicitly decenter herself as the authority can also be present when joint exploration is established.

The findings also show the teacher positioning students in more obvious and explicit ways while maintaining joint exploration. For example, the teacher takes stock of what solutions they know, frames the group's work as needing to figure out the other solutions, and restates a student's question with more clarity. These actions do not position students to provide information they already know about the problem in order to answer or solve a question, which would reflect the "knower" position in the literature (Gonz lez & DeJarnette, 2015; Lo & Ruef, 2020). Instead, these findings suggest that an additional position of "explorer" or "investigator" that better characterize the positions subtly implied by the teacher, which are taken up by students during the episodes of joint exploration. Future research could investigate whether coding schemes for positions of participants in groupwork (e.g., González & DeJarnette, 2015; Lo & Ruef, 2020) can be extended to distinguish between knowers, actors, and explorers.

We note that both of these episodes seem to be rich instances of productive disciplinary engagement (Engle & Conant, 2002), including mathematical sensemaking, reasoning, and a variety of mathematical practices. Future research could conduct an analysis of students' engagement with mathematical content and practices, and its relationship to positioning, in episodes of joint exploration. As previous research has done in relation to social positioning in collaborative groupwork in mathematics (e.g., Langer-Osuna, 2016), this line of future research could examine how different mathematical engagement may be afforded to different group members, potentially due to how they are positioned by other members in the group.

In this paper, we report on a study in which we investigated the outcomes of an immersive, 90-day, island-based semester-program that utilizes a place-based curriculum. Using interviews we investigated students' 'endencies to engage in sense-making (drawing on realistic considerations) in the context of story problems. Our findings suggest that such programs may not be enough to support students in unlearning the norms regarding the suspension of sense-making associated with doing story problems in school.

Keywords: Informal Education; Problem Solving; Problem-Based Learning

In this paper, we investigate the outcomes of an immersive, 90-day, island-based semester-program that utilizes a place-based curriculum. Program faculty leveraged the local culture and geography to help students connect their disciplinary learning and the broader world. The program's mathematics classes are focused on equipping students with the fundamentals of statistical and mathematical analysis needed to work problems about various sustainability and research projects of local significance.

Theoretical Framework

While place-based efforts in mathematics education are still emerging (Showalter, 2013), the foundations of such work are not new. Research on *ethnomathematics* (D'Ambrosio, 1985) demonstrates the role of context in student learning—sensitizing scholars to the differences between school mathematics and street mathematics (e.g., Carraher, Carraher, & Schliemann, 1985). Similarly, research on *funds of knowledge* (e.g., Civil, 2007) demonstrates how school mathematics tends to privilege institutionalized forms of knowledge over those drawn from students' lived experiences.

The *suspension of sensemaking* literature (e.g., Silver, 1993; Schoenfeld, 1991) has demonstrated ways that the story problem genre in particular, is woefully inadequate for eliciting students' realistic considerations—demonstrating that students often do not proffer realistic considerations when confronted with story problems. In that work, researchers illustrate children's tendencies to answer a question like, *A captain owns 26 sheep and 10 goats. How old is the captain?*, with nonsensical solutions like 36 (obtained by adding 26 and 10, see Baruk, 1985).

In an effort to resolve this, scholars have investigated the potential of curricular and instructional interventions (e.g., *Realistic Mathematics Education* (RME)—Van den Heuvel-Panhuizen & Drijvers, 2020) for shifting the story problem genre offered in schools—creating more realistic, interesting, and context-driven problems (Gerofsky, 1996). These efforts have demonstrated the potential for educational interventions for improving students' proclivities for mathematical sense- making (Verschaffel & De Corte, 1997).

Semester programs provide a fertile environment in which to test the value of a more fully-operational model of place-based curricula on student sense-making. Thus, this paper seeks to answer the question: What evidence of mathematical sensemaking can be observed in students' responses to story problems during their participation in such a program?

Methods

To investigate this question, we engaged 17 of the 51 students enrolled in the program in a 30-minute interview. Teachers recommended students of varying skill levels for interviews, and parent consent was obtained before proceeding. Students who participated received a $15 gift-card. In these interviews, we asked students to solve three story problems (see Table 1), drawn from the suspension of sense-making literature.

Table 1: Story problems administered in second half of interview

Problem	Rope Problem	Runner Problem	Bruce & Alice Problem
Problem Text	A man wants to have a rope long enough to stretch between two poles 12 meters apart, but only has pieces of rope 1.5 meters long. How many of these would he need to tie together to stretch between the poles?	John's best time to run 100 meters is 17 seconds. How long will it take him to run 1 kilometer?	Bruce and Alice go to the same school. Bruce lives at a distance of 17 km from the school and Alice lives at 8 km. How far do Bruce and Alice live from each other?
Expected Answer	8 pieces	170 seconds	9 km or 25 km
Realistic Answer	More than 8 pieces	More than 170 seconds	Between 9 and 25 km

Three criteria guided the selection of problems: The problem (1) required mathematics we could be reasonably assured that all participants would have prior experience with, (2) resembled the kinds of problems that could appear in high school curricula, and (3) had prior results reported for similarly-aged students, without intervention—useful for informing our expectations regarding the proportion of students likely to demonstrate realistic reactions (see Table 2).

Table 2: Percentage of students demonstrating realistic reactions to the given problems across four studies

	Rope Problem	Runner Problem	Bruce & Alice Problem
Study 1 (n=100)	12%	6%	N/A
Study 2 (n=67)	6%	3%	N/A
Study 3(n=75)	0%	3%	3%
Study 4 (n=45)	2%	7%	2%

Study 1: Greer (1993)—reported on 100 students between the ages of 13 and 14 years old from Northern Ireland; Study 2: Reusser & Stebler (1995)—reported on 67 students between the ages of 10 and 12 from Switzerland; Study 3: Verschaffel et al (1994)—reported on 75 students between the ages of 10 and 11 years old from Belgium Study 4: Yoshida et al (1997)—reported on 45 students in 5th grade from Japan.

We coded students' answers to the story problems (using their written and verbal response) using four of the five categories outlined by Verschaffel et al. (1994): Expected Answer (EA), Technical Error (TE), Realistic Answer (RA), No Answer (NA). The fifth category outlined by Vershaffel et al., Other Answer (OA), did not emerge in our analysis of the data. We also examined the transcript/video containing explanations students provided for indications of sense-making (hesitations, criticizing the problem, qualifiers) and augmented the five categories with a "+" if any such indications were found, and with a "-" if not. For example, in the Runner Problem, an EA- was used to code student responses that simply multiplied 17 by 100 to get 1,700 seconds; while EA+ was used if such responses were accompanied by reasoning like the following:

> But then again, you probably can't run that kilometer because if it's his best time to run 100 meters then you probably can't maintain that time for a full kilometer. But I feel like the number is 170, so I'm going to go with 170.

Results

Table 3 provides an overview of students' reactions to the three problems with the final row providing a summary of all the Realistic Reactions (RR)—combining categories with a "+". The percentage of students with realistic reactions is somewhat underwhelming for the first two problems, given that similar percentages have been reported in other studies of similarly-aged students without intervention (see study 1 from Table 2 conducted with 100 13 to 14 year olds).

Table 3: Number (percentage) of students' (n=17) according to various reactions to the problems

Answer Category	Rope	Runner	Bruce & Alice
EA+	0 (0%)	1 (6%)	8 (47%)
EA-	13 (76%)	13 (76%)	7 (41%)
TE+	0 (0%)	0 (0%)	1 (6%)
TE-	1 (6%)	1 (6%)	0 (0%)
NA+	0 (0%)	0 (0%)	0 (0%)
NA-	0 (0%)	1 (6%)	0 (0%)
RA+	3 (18%)	1 (6%)	1 (6%)
RA-	0 (0%)	0 (0%)	0 (0%)
RR	3 (18%)	2 (12%)	9 (59%)

We are less certain how to make sense of the larger percentage of RR responses in the final problem. One possibility is students' exposure to the triangle inequality in high school geometry gives them routine ways for thinking about the problem. Another is the back-to-back administration of problematic items may have sensitized students to the need to pay attention to context. Yet, we find it perplexing that such a large percentage of students engaged in these kinds of mathematical experiences gave EA+ type responses—unwilling to assert a realistic answer; choosing instead to say things like, "I'm just going to say it's nine kilometers," even after showing some signs of sense- making by asking questions like, "Do they live on the same side of the school?" or "Do they live like on—is this school between them or is this school like, are they both—Like would Bruce walk by Alice's house if he were walking to school?"

Discussion & Conclusions

These results are challenging to interpret. While one interpretation casts doubt on the impact of mathematical activities like those afforded at this semester program on students' propensities to make sense of problem situations, another casts challenges this genres' viability for gauging students' propensity to make sense. This echoes a concern expressed by others (e.g., Gerofsky, 1996, 2010). We suggest a third interpretation: this genre of items may not work well for gauging students' propensity to make sense *in this kind of supplementary program.* This interpretation draws on two premises: (1) the radically different organization of students' mathematical activity in such a program could be seen by students as something wholly different from the kinds of things valued and expected in school mathematics, and (2) the representation of the context in these problems evokes something closer to the norms of school and in this way may be at odds with students' experiences in the program. Premise one suggests that students may view the kinds of mathematical practices developed and used in such a program as not being applicable to the mathematical work expected of them back in their sending school. Premise two suggests to students that the story problem presented to students in the context of this interview "looks" like school, rather than like the work they have been doing in the program, and they respond accordingly.

Authentic problem posing and inquiry often leaves its users with more questions than answers. This is no less true in research as it is in mathematics classrooms. The ease with which students in this semester program reverted to the kinds of persistent, well-rehearsed routines of playing school when primed with a school-like story problem surprised us, which suggests the norms of school may be quite challenging for students to unlearn. We are interested in investigating ways to support students in developing the kinds of awareness and agency that would enable them to both question and challenge norms of schooling that may be unproductive for their learning. Such work would have important implications for supporting students to leverage the knowledge and experiences they gain in supplementary, out-of-school programs.

UNDERSTANDING GENERALIZATION THROUGH THE LENS OF MATHEMATICAL WORK SPACES

Xiangquan Yao
The Pennsylvania State University
xzy73@psu.edu

This study applied the theory of Mathematical Work Space (WMS) to examine learners' mathematical work in generalization activities. Data analysis suggested that the theory of MWS provided a useful tool to examine the quality of learners' mathematical work in the process of generalizing and to identify the obstacles encountered in this process.

Keywords: Advanced Mathematical Thinking; Learning Theory; Problem Solving

Generalization, both as a process and a product, plays an important role in mathematics teaching and learning. It has been argued that making, representing, justifying, and reasoning with generalizations are crucial components of mathematical thinking and should be at the heart of mathematics activity in school (Kaput, 2008). To help learners become more proficient at constructing, justifying, and reasoning with mathematical generalizations, it is important to understand the nature of mathematical work they engage in these processes. Rivera (2013) argued that learners' generalizing activities are sophisticated and influenced by inferential processes, kinds and sources of generalization, types of structures, ways of attending to structures, and modes of representing generalizations. The emphasis on the nature of inferential process and mathematical structures is implied in many categorizations of forms of generalization (e.g., Mason, Burton, and Stacey, 2010). There is also empirical evidence that semiotic representations mobilized in the process of generalizing mediate what is generalized and how generalization is produced, expressed, and validated (Wilkie, 2016). In addition, the study of mathematics learning in dynamic environments has shown that the use of mathematical tools mediates mathematical thinking processes. Therefore, the study of learners' mathematical work in generalization activities has to be framed in a way that simultaneously considers the mobilization of representations, the use of mathematical tools, and the use of chains of inference. Building on Duval's cognitive model of geometric reasoning (Duval,1998) and the theory of instrumental genesis (Artigue, 2002), the theory of Mathematical Work Spaces (MWS; Kuzniak & Rauscher, 2011; Kuzniak, Tanguay, & Elia, 2016) provides such a theoretical lens for examining the mathematical work of individuals when they engage in generalization activities.

Elements in the Theory of Mathematical Work Spaces

Building on the idea that mathematics work depends on the specific mathematical content under consideration and the individual's cognitive activity, the theory of MWS considers both the epistemological and cognitive aspects of mathematical work. The epistemological aspect concerns about the nature of mathematical knowledge and its historical development while the cognitive aspect is about how individuals as cognitive subjects acquire, develop and make use of mathematical knowledge in their practice of the discipline. The theory of MWS argues that mathematical meaning is constructed as a process of bridging the epistemological and cognitive planes through genetic development. The theory describes semiotic genesis, and instrumental genesis, and discursive genesis as the three dimensions of genetic development, which highlights the roles of representation, mathematical tool, and system of reasoning in mathematical work.

The theory of MWS uses three vertical planes to describe the interrelationships among the three geneses. The *Sem-Dis* plane describes the connection between the semiotic genesis and the discursive genesis of proof, which is critical for developing mathematical work that goes beyond the simple iconic perception of a sign. Within the Sem-Dis plane, the semiotic dimension is given priority when visualization and perception dominate mathematical work. In contrast, the focus is on the discursive dimension when a formal proof is deductively carried out with the heuristic help of visual representations. The *Ins-Dis* plane conjoins the instrumental genesis and the discursive genesis. It arises typically when instrument-supported exploration or experimentation is performed regarding one or several well-defined mathematical statements. The instrumental dimension dominates when conclusions are empirically drawn from data given by instruments while supported by inductive reasoning. On the other hand, mathematical work can strongly rely on the discursive dimension but gradually be constructed from steps that are supported by instrumented experimentations and exemplifications. The *Sem-Ins* plane connects the semiotic genesis and the instrumental genesis, which enables the production and transformations of representations for the purpose of shaping the conceptualization and understanding of a particular notion.

Although originally developed to analyze learners' mathematical work in the context of geometry, the theory has recently been used to study teaching and learning in other mathematical content, such as function (Miranda et al., 2016) and mathematical analysis (Delgadillo &Vivier, 2016) and mathematical thinking processes, such as problem solving (Santos-Trigo, et al., 2016), arithmetic and algebraic thinking (Hitt et al., 2016), and proof (Richard et al., 2016). Given its emphasis on the role of representation, tool, and system of reasoning in mathematical work, it is reasonable to ask the following question: To what extent can learners' mathematical work in generalization activities be analyzed and characterized by the theory of Mathematical Work Spaces? This study aimed to answer this question.

Methodology

The data for this study was collected from a series of task-based interviews that were a part of a larger research project aimed to investigate preservice secondary mathematics teachers as learners and teachers of mathematical generalizations. The task-based interview was chosen to obtain knowledge about individual preservice teacher's processes to generalize mathematical ideas and the mathematical knowledge resulting from those processes. Figure 1 is a task used in the interviews. The task included a GeoGebra file that allows its user to change the dimensions of the rectangle by sliding m and n. The participants were eight junior undergraduate preservice secondary mathematics teachers. Four are men and four are women. They were selected based on voluntary participation. Each participant spent about 45-60 minutes solving the above task. Each participant's interactions with the task were screen-recorded

Interior Crossings

In the rectangular grids below, the diagonal touches the interiors of some of the squares in the grid. For example, in the 5×2 grid, the diagonal intersects the interiors of 6 squares. In the 4×6 grid, the diagonal crosses through the interiors of 8 squares. In general, in an $n \times m$ rectangular grid of squares, a diagonal would pass through the interiors of how many squares in the grid?

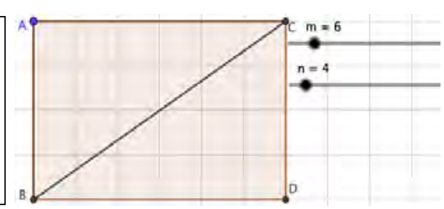

Figure 1. One task used in the interview

All the recordings were transcribed, resulting in annotated transcripts including what was said by the interviewer and a participant, a description of actions taken with the GeoGebra, and screenshots of work. Generalization attempts in each interview were then identified. These generalization attempts served as anchor points to understand what came before a generalization was articulated and what came after it. The mathematical work in these generalizing attempts was analyzed, focusing on its semiotic genesis, instrumental genesis, discursive genesis, and the transitions among the three geneses. A mathematical activity was coded as semiotic genesis when a participant created, manipulated, interpreted, or connected mathematical representations, as instrumental genesis when a participant relied on his/her use of GeoGebra to conduct experimentations, make observations, or confirm conjectures, as discursive genesis when a participant justified a generalization based on property and structure other than perception and empirical data. One activity might be supported by multiple geneses. The obstacles to making and justifying generalizations were also analyzed from the perspective of the three geneses.

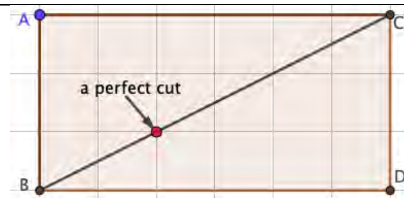
Results

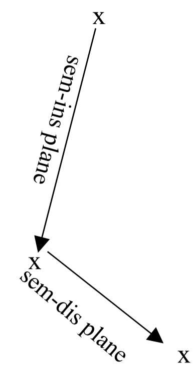
Data analysis has shown that the theory of MWS provided a useful tool to examine the quality of learners' mathematical work in the process of generalizing and to identify the mental blocks encountered in the process of making and justifying generalizations.

The process of generalizing can be triggered by various sources (e.g., visual perception, numerical pattern, analogy, experimentation with technology, and inherent structure) and result in different forms of generalization (e.g., empirical and structural generalizations). The quality of mathematical work produced in the process of generalizing is determined by the extent to which the work can support the construction, refinement, and justification of a generalization. This study has shown that mathematical work that led the participants to construct and justify a generalization often mobilized all three forms of geneses. This suggests that productive generalizing practices often involve purposeful creation and transformation of semiotic representations, skillful use of mathematical tools, and formation of a chain of reasoning. Although the use of dynamic software might trigger an individual to first conduct experimentations with technology or to manipulate dynamically-linked representations, it is important to note that a generalization attempt could start from any one of the three geneses and then move back and forth among the three geneses.

Speaker	What is said and done with GeoGebra	Sem	Ins	Dis
Jordan	When it's a rectangle it has to be at least m, or whichever one is bigger.			x
Intvr.	Okay.		ins-dis plane	
Jordan	(Sliding m and n to create a 6×3 rectangle) so this case is exactly 6, but I think that's probably because it's intersecting perfectly.	x		
Intvr.	What do you mean by intersecting perfectly?		sem-dis plane	

Jordan	Okay, like right in here (pointing to a "perfect cut" in the 6×3 rectangle). When I stretch it out (sliding m and n to create a 7×3 rectangle) it doesn't have those nice cuts. So, the diagonal is going to cut through more squares. Like here it starts with 7 because it has to go across, but then it has to make steps down. So it has to go all the way across and it has to go down two intersections. So would it be like m plus n minus 1? … 1,2,3,4,5,6,7,8,9. So that's nine. So I think in the case where it has no perfect intersections I think it will cut through m plus n minus 1 where m is the greater side.
Intvr.	Why is it m+n-1?
Jordan	So, I'm just thinking in this case it obviously has to go through at least m to get to the other side of the rectangle. But it also has to jump down two. Yeah, it has to jump down two, n-1.





The above short excerpt demonstrates the mobilization of all three forms of geneses and the associated vertical planes in the process of constructing and justifying a structural generalization. In this excerpt Jordan first reasoned that the number of interior crossings is at least the maximum of m and n because the diagonal has to first go across the rows or columns. The GeoGebra-generated diagram in the case of the 6×3 rectangle drew Jordan's attention to the "perfect cut" in the diagram. Jordan used the existence of "perfect cut" to reason why the number of interior crossings was exactly 6 in this case, although he had not yet established a numerical relationship between the number of "perfect cuts" and the number of interior crossings. By sliding m and n, Jordan then created a contrasting case (a 6×3 rectangle) where no "perfect cut" existed and observed that the diagonal had to pass through 7 columns and make 2 steps down. Based on this observation, Jordan made a generalization that when there is no "perfect cut" the number of interior crossings would be $m + (n - 1)$, where m is the number of steps to go across and $(n - 1)$ is the number of steps to go down. More importantly, his justification of the formula was based on a structure in the diagram rather than empirical results. Later, Jordan made use of his idea of "perfect cut" and further generalized that for any rectangular grid the number of interior crossings would be $m + ((n - 1) -$ the number of "perfect intersections"). The to-and-fro movements among the three geneses contributed to Jordan's productive work to generalize.

Obstacles to generalize can arise at different stages of the process of generalizing. These obstacles might include the difficulties to, for example, observe a useful numerical pattern or property, express a generalization with mathematical language, and formally justify a generalization. The study has shown that these obstacles to generalize can be identified and characterized through the lens of the three geneses. Certain blockages arose when one genesis and its associated vertical planes were absent in the process of generalizing. For instance, the absence of a particular way of seeing and manipulating mathematical signs (e.g., numbers, diagrams, and algebraic symbols) might lead to a blockage in a learner's process of generalizing; the lack of a particular technique for using a mathematical tool might hinder the construction of a specific generalization; and the inability to reason with and justify a mathematical idea might result in generalizations that are purely based on numerical patterns.

Discussion and Conclusion

In the past a few decades researchers have categorized generalizations based on different criteria. For instance, based on the status of cognitive schema in a generalization, Harel and Tall

(1991) differentiated between expansive generalization and reconstructive generalization.

fler's (1991) distinction between empirical generalization and theoretical (i.e., operative) generalization was based on the types of abstraction involved in generalization. The differentiation between empirical and structural generalization (Mason et al., 2010) is based on a learner's attentiveness to mathematical structures. The essential role of the three geneses in generalization activities suggests that learners' generalizations might be categorized based on the genesis that dominates the mathematical work in the process of generalizing. High-quality mathematical work in generalization activities requires the mobilization of all three geneses. It often involves purposeful creation and transformation of semiotic representations, skillful use of mathematical tools, and formation of a chain of reasoning.

Obstacles to generalize arise when one or more genesis are absent in generalization activities. In order to support learners to overcome a mental block in the process of generalizing it is important to first analyze the specific type of genesis that is missing and then identify pedagogical actions that are likely to mobilize the genetic development. Expanding the notion of instrumental orchestration (Drijvers et al., 2010), we might use semiotic orchestration and discursive orchestration to characterize teacher's pedagogical actions for guiding students' semiotic genesis and discursive genesis, respectively. Examples of these actions of orchestration include analyzing possible roles of semiotic representations, artifacts, and systems of reasoning, and their arrangements in a task environment, and deciding the schemes and techniques to be developed and established by the students in each genesis to be successful in problem solving.

Mathematical modeling is new to many teachers, especially in the United States. To complement studies of the effectiveness of professional learning programs, we use retrospective methods to elicit modeling teachers' perceptions of experiences that contributed to their capacities to understand mathematical modeling and to facilitate students' mathematical modeling experiences. Empirical evidence suggests a trajectory along which teacher understanding of mathematical modeling and the teaching of it might develop. Results inform the design of teacher professional learning activities as well as advance inquiry in mathematical modeling teaching and learning.

Keywords: Modeling, Mathematical Knowledge for Teaching

Mathematical modeling (MM) has been an essential element of many careers, the base of many technological advances, and a part of university mathematics curriculum for decades. Not surprisingly, mathematics education practitioners and researchers identify MM as important in K-12 education (e.g., Blum & Ferri, 2009) and elaborate its potential for school and college students (e.g., Garfunkel & Montgomery, 2019). MM also is an object of increased interest world-wide (e.g., Hankeln, 2020). Yet, many K-12 teachers historically have not integrated MM in their instruction (e.g., Schmidt, 2011), and MM has received little attention in teacher preparation programs (e.g., Lingefjärd, 2007). A growing body of literature (e.g., Anhalt & Cortez, 2016; Chapman, 2007; Fulton et al., 2019) offers insights into how teachers learn to model mathematically and to facilitate their students' MM activity. However, design research and studies of the effects of professional learning sessions take substantial time. In this study, we use theoretical and methodological lenses to listen to teachers' voices about what experiences matter and thus both complement existing work and yield immediate insights to inform professional learning design. Using retrospective methods framed by an adult learning theory, we ask: *What are secondary mathematical modeling teachers' perceptions of experiences and events that contributed to their capacities to understand mathematical modeling and to facilitate students' mathematical modeling experiences?*

Background

Literature in mathematical modeling (MM) includes theoretical discussions of what MM is (e.g., Kaiser & Sriraman, 2006) and offers numerous definitions of MM (Cirillo et al., 2016). We take the view that MM "is a process that uses mathematics to represent, analyze, make predictions or otherwise provide insight into real-world phenomena" (Garfunkel & Montgomery, 2019, p. 6). Developing insights into complex real-world phenomena requires knowledge of the phenomena and mathematical knowledge to model the phenomena and gain insights. Throughout this process, students (and teachers) encounter cognitive obstacles (Galbraith & Stillman, 2006).

In addition to deep knowledge of MM, teachers need knowledge about how to successfully facilitate their students' modeling (e.g., Blum & Ferri, 2009; Cai et al., 2014). Despite decades of studies of teacher knowledge and professional development in traditional areas of school mathematics (e.g., algebra, rational number, function, proof) (e.g., Jacobs & Spangler, 2017; Strutchens et al., 2017; Sztajn et al., 2017), a question that has not been answered adequately is what experiences help teachers of MM to develop such knowledge.

A shift from familiar problem solving to MM requires "a new set of teaching and learning skills" (Herget & Torres-Skoumal, 2007, p. 385). Beyond encountering obstacles associated with learning MM, teachers face such perennial challenges as limited teaching time (e.g., Blum & Niss, 1991). Unproductive teacher beliefs about mathematics and modeling (e.g., Gould, 2013; Zbiek, 2016) further challenge teachers' work. Recent studies suggest that completing a short MM module or a teacher preparation course can offer teachers opportunities to experience the MM process and deepen foundational understandings of the process (Anhalt et al., 2018; Cetinkaya et al., 2016; Jung & Newton, 2018) and to develop foundational ideas for teaching MM (Cetinkaya et al., 2016). However, these same researchers acknowledge a need for significantly more knowledge about how to develop experiences that facilitate the development of effective teachers of MM (e.g., Cetinkaya et al., 2016). Our theoretical perspective elaborates teacher knowledge and our methods underpin an alternative way to identify learning experiences.

Theoretical Perspective

Transformative learning theory (Mezirow, 1985, 1991, 2000) provides our theoretical grounding. An adult learning theory based in constructivism, transformative theory involves *meaning schemes* made up of an individual's specific knowledge or beliefs and *meaning perspective* as interconnected webs of assumptions and expectations among clusters of meaning schemes. Transformative learning occurs through *transforming meaning schemes* or *transforming meaning perspectives*. New, revised, or transformed meaning schemes typically arise through an individual's reflection on the content and process of problem solving (Mezirow, 1991). Meaning perspective transformation occurs through an accrual of transformed meaning schemes or in response to a triggered disorienting dilemma that precipitates critical reflection on presuppositions when current problem-solving processes do not provide resolution to the dilemma at hand (Merriam & Caffarella, 1999). Critical reflection involves reflecting on the premises of problem solving, that is, questioning the importance of or the validity and utility of the problem-solving content and process, often while engaging in rational discourse with others (Cranton, 2006; Mezirow, 1985). Conditions conducive to teachers' perspective transformations include dissatisfaction with current practices, occurrence of disorienting dilemmas, critical examination of beliefs, support and freedom to pursue alternatives, support and opportunity to engage in rational discourse, readiness for change, and openness to alternative perspectives (Cranton, 2006; Cuddapah, 2005; Merriam, 2004). Understanding teachers' perceptions of their experiences means exploring their recollections with respect to dilemma triggers and conditions.

Methods

To understand the nature of the conditions around the experiences that teachers perceived as contributing to their evolving understanding of MM and how to facilitate MM with students, we use a phenomenological methodology (Moustakas, 1994; Vagle, 2018). Because participants must have experienced the phenomenon (Moustakas, 1994) of learning to do and teach MM, we recruited teachers who met criteria for experience in doing and teaching MM. They (a) have experience in facilitating MM, (b) are committed to teaching MM, (c) have participated in professional development on MM at the national level, and (d) have served as leaders in MM teaching (e.g., led MM professional development, produced MM curriculum materials). The purposeful sample consisted of five teachers from across the United States.

We employed established retrospective techniques that minimize recall effects (Eisenhower et al., 19911). The teachers completed and submitted event history calendars (EHCs) (Morselli et al., 2019) and critical incident descriptions (CIs) (Eisenhower et al., 1991). EHCs aided teachers in accurately and completely reconstructing past events related to teaching and learning MM; CIs helped them to highlight significant events related to their professional development. Teachers also provided resumés. A first semi-structured interview elicited individuals' feelings about and experiences with the phenomenon (learning and teaching MM) under study (Seidman, 2006). It was conducted via Zoom with each teacher to reconstruct finer details of experiences detailed in EHCs and CIs (Seidman, 2006). A second Zoom interview was held to capture recollections of experiences not mentioned previously and for member checking of our evolving interpretations.

Our analysis of teachers' documents and interviews followed systematic procedures recommended for analysis in phenomenological studies (Vagle, 2018) and used by Peters (2014). Both interviews were videorecorded, transcribed, and annotated prior to analysis. Each researcher began by viewing the first interview videos followed by a line-by-line reading of the transcript while highlighting text and making margin notes. We created chronological listings of experiences that teachers identified as contributing to their capacities to understand MM and to facilitate students' MM experiences, as well as teachers' perceptions of characteristics that helped or hindered their development (Cuddapah, 2005). We sought evidence of transformative learning as well as evidence that transformative learning did not occur. For each teacher, after examining and discussing each researcher's notes and observations for the first interview, we crafted questions for the teacher's second interview. We then followed the same process to analyze the second interviews. We used constant comparison (Glaser & Strauss, 1967) in subsequent readings and discussions to identify emerging themes in the data to help us understand the teachers' experiences in learning of MM and its teaching and how the teachers described the experiences as shaping their current understanding of MM and the teaching of it.

Findings

As the five teachers recounted experiences that they perceived as helpful to their capacity to understand or facilitate MM, they reported similar kinds of experiences (e.g., professional conferences, conversations with colleagues, modeling problems that were of particular interest to them, reading coaching guides for MM competitions). Our findings are not the teachers' or our assessment of their experiences and events but rather an articulation of themes regarding what they experienced as triggers and described as valuable characteristics of their experiences.

Dilemma triggers common to all of the teachers included MM problems that interested them and supportive spaces in which to work on MM problems and to consider teaching MM. Triggers often challenged teachers' sense of what mathematics is, how one does mathematics, and what teaching is. Triggers often arose in engagement with others, in-person or through listening or reading. Importantly, triggers could be found in MM experiences and in experiences that were not explicitly about MM. For example, opportunities to use multiple representations and explore student thinking were noted as triggers for important early experiences.

The triggers connected to one or more conditions for learning. Karen twice participated in a MM competition as a high school student and engaged with teammates in MM problem solving. However, it was her experience in a college MM course that was a trigger to open her to doing MM. The college course presented a problem that interested her (what makes the "best" cookie) and provided a safe space to explore the problem and offer ideas about how to pursue it. She wrote in her EHC, "my world view of what math is was in constant disequilibrium and expanding each day but I had a strong basis to support me." In engaging with science and technology teachers during a summer workshop that required them to share lessons, Dwayne discovered that science teachers did wonderful demonstrations to inspire scientific ideas and formulas but did not pursue the mathematics behind the formulas. This trigger was about "bringing mathematics to life" and consistent with the "conversations" that he has with his students about variables and assumptions about real world phenomena that were at the heart of models in math problems. Teresa was interested in making math more "fun" for her students and readily looked for new problems and activities. Following presentations by other teachers at a professional conference, she examined her beliefs about students and became open to pursuing alternative lesson approaches as she realized she could trust her students' abilities to work with less-structured problems. Viv's dissatisfaction with her own practice as she realized students were offering only weak references to measurement error when they were asked to critique their models and encouragement offered by an expert MM teacher to engage in conversation led her to seek a lunch-time conversation with the expert teacher to explore specifically how to facilitate testing and revising models.

Each trigger was wrapped in opportunity for critical reflection and rational discourse, with readiness for change as a disposition. Opportunities fell short of being transformative when these features were absent. For example, a mandate from Phil's school system to implement problem-based learning (PBL) activities could have encouraged him to engage in MM. It fell short as he was informed by an administrator that his attempt at PBL fell short, with no opportunity for rational discourse. In contrast, when he had the opportunity to engage in conversation with others at a national MM workshop about a food waste problem that resonated with his social justice lens, Phil engaged in MM and shared that he found "a new way of thinking mathematically."

Our data analysis suggests a tentative pattern in experiences contributing to teachers' growth as modelers and teachers as they grow in five knowledge areas: MM, students, social nature of mathematics, curriculum, and contexts. Prior to learning what MM is, teachers have experiences that draw their attention to the usefulness of multiple linked representations and alternative strategies in solving mathematics problems and teachers encourage students to use alternative means to solve problems situated in real-world contexts. Greater engagement in MM and the teaching of MM occurs as teachers present problem statements that are open to different interpretations and prompt a variety of assumptions and variables. Teachers initially engage students in discussions that link aspects of the context with identified mathematical ideas, in the spirit of mathematizing to connect mathematical properties and parameters to situation conditions and assumptions (see Zbiek & Conner, 2006). Teachers become increasingly trusting of students and open to different interpretations of the problem and eventually to different questions and thus to different mathematical approaches for a single real world context. The last and most difficult part—perhaps due to the confines of time, grading, and school curriculum expectations— is the testing and revision of models in the spirit of settling on a model that, though imperfect, is appropriate to answer the real-world question that drove the MM activity.

Concluding Thoughts

This exploratory study reveals triggers and conditions of experiences that teachers perceive as helpful to their MM doing and teaching capacity. Our analysis also yields a potential trajectory along which teachers develop understandings of MM doing and teaching. The results offer insights into how teachers can be better supported in learning and doing MM.

A CASE OF A STUDENT USING DIAGRAMS WHILE READING A PROOF

Kristen Vroom
Oregon State University
vroomk@oregonstate.edu

Tenchita Alzaga Elizondo
Portland State University
halzaga@pdx.edu

Reading proofs is a significant part of mathematicians' and undergraduate mathematics students' work and is often viewed as challenging for students. Viewing the act of reading proof as a form of problem-solving, we investigated the different ways that a student analyzed and refined his diagram as he made sense of a proof. We found that (a) the student analyzed his diagrams in different and important ways and (b) that his diagrams could be viewed as a series of refinements in which the diagram evolved into a more descriptive representation of the formal proof. We argue that his diagram usage supported his proof comprehension.

Keywords: Reasoning and Proof, Mathematical Representations, Problem Solving, Advanced Mathematical Thinking

Reading proofs is a significant part of mathematicians' practice (Weber & Mejia-Ramos, 2011) and is a key aspect of mathematics students' university studies. However, the literature suggests that the practice is challenging for students (e.g., Selden & Selden, 2003; Weber, 2010). An important part of comprehending proofs is making sense of the mathematical objects introduced and the role they play in the logical argument. Research has shown that students may not understand the complex ways that these objects are used in proof (Lew & Meija-Ramos, 2019) potentially impeding their ability to fully comprehend the proof. We conjectured that supporting students to use diagrams would help with proof comprehension for two reasons. First, it is a productive tool for mathematicians' 'eading activity (Mejia-Ramos et al., 2012), and second, creating such diagrams necessitates attention to mathematical objects. In this paper, we report on a case of a student using diagrams in several distinct ways, answering: In what ways can a student analyze and refine their diagrams as they make sense of a proof?

Theoretical Perspective

Zazkis et al. (1996) introduced the Visualization/Analysis (V/A) model that assumes visualization and analysis work together in problem-solving. The model describes the thinking as beginning with an act of visualization, V_1 (e.g., constructing a diagram) and then is followed by an act of analysis, A_1 (e.g., comparing what is illustrated in the diagram to the given problem). A_1 then leads to a second act of visualization, V_2. As this cyclic process continues, the problem solver gains more understanding of the problem, and ideally, ends with solving the problem. Stylianou (2002) elaborated the model by describing categories of analysis that they observed mathematicians engaging in as they solved problems: (a) inferring additional consequences, (b) mathematical elaboration, (c) imposing a new goal, and (d) monitoring statements. We note that there are important differences in the problem-solving that the V/A model emerged from and the problem-solving that our students are engaged in. For instance, Zazkis et al.'s (1996) model emerged from students making sense of listing the elements of a particular dihedral group and calculating the product of two such elements. We view our students as engaging in problem-solving in the sense that they are investigating the prover's logical argument for a given claim (answering questions like: Why is a particular line true? How does the proof-structure organize a logical argument for the validity of the claim?). We take an individual view on this socially embedded activity in order to make sense of the thinking that the diagrams afforded a student.

Methods

This study is part of a larger project that aims to create inquiry-oriented curriculum materials for Introduction to Proofs courses. Our data comes from a design experiment (Cobb & Gravemeijer, 2008) with a pair of students, Piper and Neal. The primary goal of the experiment was to test and refine proof comprehension tasks to later incorporate into the course curriculum. Two teacher-researchers met with Piper and Neal on Zoom for multiple teaching sessions, each lasting 1.5 hours. During the sessions, the participants and teacher-researchers worked on a collaborative online whiteboard (i.e., Google Jamboards). Each session was recorded, capturing both the students' gestures and their markings on the whiteboard in real-time. A content log was created after each session, including the full transcription and pictures of tasks and students' work. Between each session, the teacher-researchers and another researcher on the project team discussed what happened in the previous teaching session and refined the upcoming session plan.

Statement:
Let $s \in \boldsymbol{R}$ be an upper bound for a sequence $\{x_n\}$. Suppose for every $\varepsilon > 0$, there exists a $k \in N$ such that $s - \varepsilon < x_k$. Then s is the least upper bound of $\{x_n\}$.

Formal version of the proof:
(1) Let s be an upper bound such that for all $\varepsilon > 0$, there exists $k \in N$ satisfying $s - \varepsilon < x_k$.
(2) By way of contradiction assume t is an upper bound of $\{x_n\}$ such that $t < s$.
(3) Let $\varepsilon^* = s - t$.
(4) Then, there exists $k^* \in N$such that $s - \varepsilon^* < x_{k^*}$.
(5) But, this means that $x_{k^*} > s - \varepsilon^* = s - (s - t) = t$ which is a contradiction.
(6) Therefore, s is the least upper bound of $\{x_n\}$.

Figure 1: Statement and proof that students were asked to read.

Data for this study comes from the second session when we noticed that the students leveraged diagrams in seemingly meaningful ways to make sense of the statement and proof given in Figure 1. In this report, we focus on investigating Neal's diagram usage as he read the proof. To begin this analysis, we first re-read the content logs and re-watched the corresponding video, searching for and making sense of acts of visualizations and acts of analysis. Analyzing these acts was an iterative process in which the two authors together identified visualizations, described Neal's analysis, compared and contrasted these descriptions to Stylianou's (2002) categories, and refined working definitions for the type of analysis we observed. We cycled through the data multiple times until our refined definitions captured the agreed-upon understanding of Neal's analyses. See Table 1.

Table 1: Definitions for Acts of Analysis

Act of analysis	Definition	Observable Evidence
Inferring	When the student searched the diagram to extract information about the proof.	Evidenced by the student's attention to a diagram followed by communicating (words or written) new information.

Elaborating	When the student connected how information from the diagram is used in the proof.	Evidenced by the student communicating (words or written) the utility of the information in the proof.
Monitoring	When the student compared the diagram to their current understanding of the proof or the proof itself.	Evidenced by the student referencing both lines in the proof and (parts of) their diagram.
Imposing goal	When the student identified information about the proof to add to their diagram.	Evidenced by the student altering their diagram.

Results

Prior to the following episode, the students interpreted the statement and created a diagram as they explained their thinking. After the students read the proof privately, the teacher-researcher prompted them to explain their thinking. The students expressed that they understood that the proof was by contradiction but were still unpacking the details. In response, the teacher-researcher suggested that they “relate this proof to the pictures that you drew before”. Neal then offered the first visual (see Figure 1-V_1), which was essentially the picture he created when making sense of the statement.

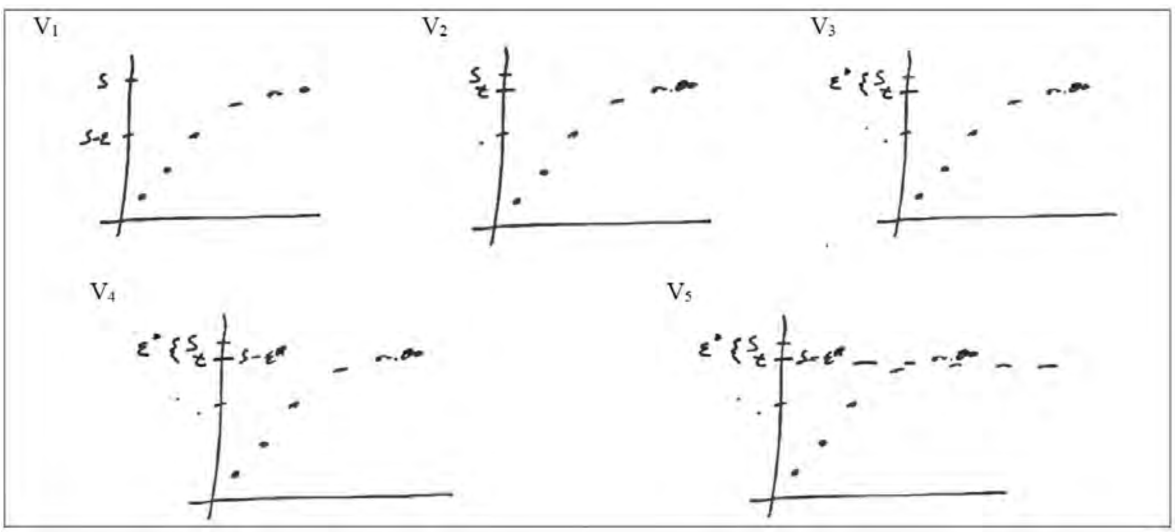

Figure 2. Neal’s Diagrams

Analyzed V_1 by inferring, elaborating, and imposing goal (A_1)

After Neal offered V_1, he said, “So I think I see that, like, I get the conclusion I get that the idea here is that x_k one of these guys [pointing to later terms in the drawn sequence] is greater than t which is our like fake upper bound.” Neal extracted from the diagram that there were sequence terms greater than $s - \varepsilon$ (*inferring*). Then, he explained the later terms were going to be used to show that there was some sequence term x_k greater than a “fake upper bound” t (*elaborating*). Neal identified that a “fake upper bound” t could replace the $s - \varepsilon$ (*imposing* *goal*) creating V_2 (see Figure 2-V_2). V_2 included a key mathematical object of the proof, an upper bound of $\{x_n\}$ that was less than s.

Analyzed V_2 by monitoring and imposing goal (A_2)

Neal then turned to the proof, explaining "…And we're gonna let $\varepsilon^* = s - t$ [referring to line 3]. Which should be this little area [pointing to the distance between s and t in V_2]." Neal compared the third line of the proof to his diagram (*monitoring*) and then identified that he could add ε^* to their diagram (*imposing goal*) creating V_3 (see Figure 2-V_3). V_3 depicted another key mathematical object, ε^*, a particular distance from s.

Analyzed V_3 by monitoring and imposing goal (A_3)

Neal read the first three lines of the proof, pausing after each line to point to the information in his diagram (*monitoring*). Then he read Line 4 multiple times, pointing to ε^* in V_3 and then indicated, "Well, this would be $s - \varepsilon^*$[pointing to t in V_3]" (*imposing goal*) suggesting that ε^* in V_3 did not explicate that $t = s - \varepsilon^*$. He then created V_4 by adding $s - \varepsilon^*$ to his diagram (see Figure 2-V_4). V_4 explicated the relationship between $\varepsilon^*, s,$ and t; if ε^* was the distance between s and t, then $t = s - \varepsilon^*$.

Analyzed V_4 by elaborating and imposing goal (A_4)

Next, Neal attempted to connect how $s - \varepsilon^*$ in his diagram was used in the proof (*elaborating*) by explaining: "And that means that x_k…" then paused for several seconds and added a horizontal line at $t = s - \varepsilon^*$ (*imposing goal*) to create V_5 (see Figure 2-V_5). The presence of the horizontal line in V_5 highlights a relationship between the sequence terms and t.

Analyzed V_5 by elaborating and monitoring (A_5)

Neal tried again to communicate the utility of $s - \varepsilon^*$in his diagram (*elaborating*). To do so, he also compared the diagram to his current understanding of the proof (*monitoring*), explaining:

> So I think the idea here, $s - \varepsilon < x_k$, so that's'right, any ε we choose. [...] Since ε is just greater than zero, we can kind of choose any ε for $s - \varepsilon$. We say t being our fake upper bound and is less than s. The difference there, we can call ε^*. That's'valid for $s - \varepsilon$, we know that there's'some $x_k > s - \varepsilon^*$, which means $x_k > t$ and that contradicts what we've said. Okay, I'm'there.

Here, Neal explained how $s - \varepsilon^*$in V_5 is used in the proof (*elaborating)*: First, he pointed to the assumption in Line 1 that 'for all $\varepsilon > 0$, there exists $k \in N$ satisfying $s - \varepsilon < x_k$' (*monitoring*). Then, he noted how their fake upper bound ($t = s - \varepsilon^*$) gave them an instance that satisfied the necessary conditions saying, "The difference there, we can call ε^*. That's'valid for $s - \varepsilon$." And then explained how $t = s - \varepsilon^*$ lead to the contradiction (*elaborating*). At this point, Neal seemed satisfied with his understanding of the proof ("Okay, I'm there.")

Discussion and Conclusion

In the above episode, Neal built a diagram in multiple steps in which each visualization (V_n) was followed by some analysis of the visualization (A_n). We described the different ways that he analyzed his diagrams as: inferring, elaborating, monitoring, and/or imposing goal. By engaging in this analysis, Neal's initial diagram evolved into a more descriptive representation of the formal proof in that each iteration of the diagram included more information than the previous. We argue that Neal's analysis and following diagram refinements supported his proof comprehension in the sense that it supported his awareness of the mathematical objects and the nuanced ways they were used in the prover's logical argument. Each act of visualization was motivated by Neal gaining awareness of mathematical objects and the potential role they played in the proof and how his diagram could better capture the objects (*imposing goal*). He gained this awareness by comparing mathematical objects introduced in the proof with the objects in his diagram (*monitoring*) and/or making connections to how these mathematical objects were used in the logical argument (*elaborating*). In this way, Neal's diagram usage gives us important insights for how we might support students in using diagrams to comprehend proof.

PRESERVICE TEACHERS' LEARNING ABOUT ELEMENTARY STUDENTS' MATHEMATICAL REASONING

Marta T. Magiera
Marquette University
marta.magiera@marquette.edu

Hyejin Park
James Madison University
park33hx@jmu.edu

We report on a study with 23 preservice teachers (PSTs) preparing to teach grades 1-8 who were engaged in analyzing a series of student-generated arguments for evidence of student mathematical reasoning (MR). We examined PSTs' assessment of student MR prior to and after instruction designed to support PSTs' understanding of how expert-like reasoning might look like in elementary mathematics classrooms. Prior to the intervention, PSTs interpreted and assessed students' MR looking for evidence of isolated reasoning actions (e.g., adapting, exemplifying, representing). After the intervention, rather than assessing student reasoning in terms of the presence or absence of specific reasoning actions, PSTs analyzed the identified reasoning actions on the continuum from less to more expert-like. We discuss the intervention and the specific nature of PSTs' assessment practices before and after class activities.

Keywords: Reasoning and Proof, Assessment, Teacher Education – Preservice

Introduction

Mathematical reasoning (MR), interpreted broadly as "the process of drawing conclusions on the basis of evidence or stated assumptions" (NCTM, 2009, p. 4), is fundamental to doing mathematics. MR involves "developing and communicating arguments" (Loong et al., 2017, p. 6) and takes many forms, from informal explanations and justifications to formal deductions and inductive observations. MR is often described in terms of reasoning actions such as analyzing, exemplifying, generalizing, conjecturing, inferring, adapting, investigating why, explaining, representing, evaluating, or justifying (e.g., Australian Curriculum Assessment and Reporting Authority, 2015; Clarke et al., 2012; Jeannotte & Kieran, 2017; Lannin et al., 2011).

Students show a wide range of mathematical expertise within any mathematics classroom and demonstrate varying levels of readiness for mathematical content. It is likely to expect then that students also demonstrate different levels of reasoning abilities in a typical elementary mathematics classroom. Preservice teachers (PSTs) preparing to teach elementary school mathematics need experiences that can help them make sense of different ways elementary students might reason. To promote and support students' reasoning skills, PSTs need the capacity to attend, understand, analyze, interpret, and assess students' MR. They also need to understand how disciplined expert-like mathematical reasoning can look like in the elementary mathematics classroom. In this paper, with a focus on PSTs preparing to teach elementary grades mathematics, we examine the following research question: *To what extent instructional intervention focused on MR facilitates PSTs' assessment of students' MR?*

Conceptual Framework: Assessing Students' Mathematical Reasoning

We drew on descriptions of students' reasoning skills delineated by the NRICH team at the University of Cambridge (NRICH, 2014). The NRICH team illustrated five levels of mathematical sophistication in elementary students' reasoning skills and described student's reasoning skills on a continuum from less to more expert-like. We used their descriptions to design the Student Reasoning Assessment Tool (SRAT) (see Table 1) to support PSTs' thinking about reasoning actions as PSTs analyze student-generated arguments. Our goal was to bring PSTs' attention to different reasoning actions, specifically justifying and generalizing, and bring their attention to a wide variety of student reasoning skills from novice to expert-like.

Table 1: Student Reasoning Assessment Tool (SRAT)

Levels	Descriptions of elementary students' reasoning levels
L0	The student tells what he or she did
L1	The student attempts to provide some reasoning (not necessarily relevant, complete, or valid) for what he or she did
L2	The student provides a chain of reasoning, which is incomplete, insufficient, or invalid, to support the assertation
L3	The student provides a chain of acceptable valid reasoning in support of the assertion; the argument is at best partial
L4	The student provides an exhaustive acceptable chain of valid reasoning in support of the assertion; the argument can be accepted as proof

Methods

Participants and Study Context

Participants were 23 PSTs enrolled in a semester-long mathematics content course for elementary education majors, *Algebra and Geometry for Teachers*. The course supported PSTs in developing conceptual understanding of mathematical ideas essential to the grades 1-8 mathematics curriculum. Throughout the semester, PSTs were engaged in analyzing, interpreting, and assessing students' MR about fundamental mathematics concepts in grades 1-8 mathematics. Figure 1 gives an overview of the class intervention.

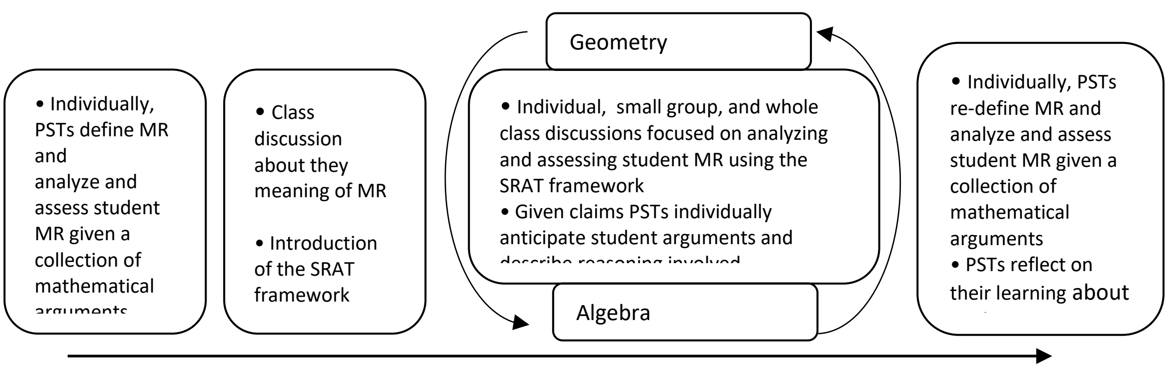

Figure 1: An Overview of the Instructional Sequence

Data and Data Analysis

We analyzed PSTs' written analyses of student arguments for evidence of MR (n = 69) and PSTs' reflections on their learning about MR (n = 23). We coded PSTs' responses for the specific reasoning actions that PSTs recognized in student arguments. The five codes and their descriptions below were derived from the existing literature on students' and teachers' MR (e.g., Clarke et al., 2012; Jeannotte & Kieran, 2017).

- Adapting: Recognizing what mathematical facts or properties students used to develop their arguments

- Justifying: Recognizing whether students validated their statements/claims
- Exemplifying: Recognizing how students used examples to reason about a given claim
- Generalizing: Recognizing whether students reasoned beyond particular cases
- Representing: Recognizing modes of representations students used to express their reasoning

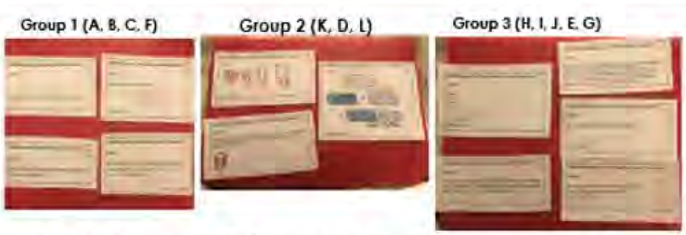
We then looked for patterns within and across PSTs' responses before and after being introduced to the SRAT and examined changes in the nature of PSTs' assessment practices. Finally, we used open coding (Hatch, 2002) to analyze PSTs' reflections and identify the impact of class activities on PSTs' learning about student MR.

Results

The analysis revealed vast differences in PSTs assessment of students' MR with and without the SRAT. Figure 2 includes a summary of PSTs' assessment practices prior to and after the intervention. In Figure 3, we illustrate the discrete emphasis in PSTs' assessment practices prior to class activities, with an excerpt from one of the participants (PST 17). The discrete approach of the assessment of student MR is evident in the provided explanations.

Assessment Foci	
Initial Assessment without SRAT	**Assessment with SRAT**
Assessing MR from less to expert-like (Developmental perspective) (4PSTs, 17%)	Assessing MR from less to expert-like (Developmental perspective) (23 PSTs, 100%) • Explicit attention to generalizing and justifying and delineating between the evidence of no justification, invalid or incomplete justification, valid but incomplete justification, valid and full justification, evidence of no generalizing, an attempt to provide generalization, and establishing generalization. • Delineating the quality of student justifications and generalizations focusing on how students used representations in their justifications, what specific mathematical ideas, properties, or definitions provided the basis for student justifications, and whether examples students used were generic or specific.
Discrete emphasis on the presence or absence of specific reasoning actions (19 PSTs, 83%) • Exemplifying: Paying attention to the use of examples (17 PSTs, 74%) • Representing: Paying attention to the use of mathematical symbols (15 PSTs, 65%) or pictorial representations (13 PSTs, 57%) • Adapting: Paying attention to whether to use similar mathematical ideas, properties, or definitions (8 PSTs, 35%)	

Figure 2: PSTs' Assessment of MR without and with SRAT



Group 1: In all of these examples, the students showed us that adding even numbers together always equals an even number by showing different even numbers added together.

Group 2: In this group, all the students made illustrations to demonstrate why adding even numbers is always even. All of these illustrations show some type of grouping.
Group 3: [In] all of these examples [students] …generated equations to support the argument that adding even numbers always equals an even number. For these equations, you should be able to plug in any even number, and it should work in the sense that the answer will also be an even number.

Figure 3: Example of PSTs' Assessment Practices Before Using the SRAT (PST 17)

At the end of the semester, the same PST recognized changes in the mathematical sophistication of student arguments and differentiated among ways in which students A, B, C, and F used examples to support their claims (yellow codes) (See Figure 4 below). PST 17 recognized that Student F reasoned about the sum of any two-digit numbers more generally by exploring sets of possible one's digits in the sum. PST 17 also noted that Student F's reasoning was not exhaustive to provide a proof-like argument generated by Students E and I.

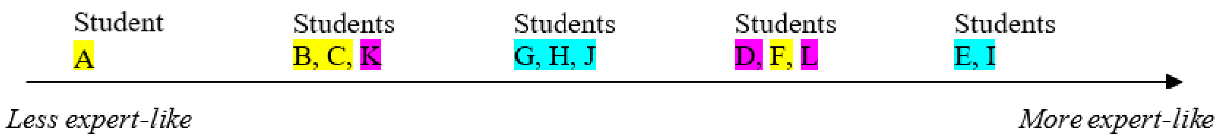


Figure 4: PST 17's Assessment Practices with the SRAT

When reflecting on their learning about MR from the class activities, PSTs commented on gaining awareness about different reasoning actions (11 PSTs, 48%), developing sensitivity for assessing progression in MR rather than taking a "discrete" approach (e.g., correct or incorrect) in their assessment of student MR (10 PSTs, 43%), seeing the benefits of SRAT in assessing their own MR (7 PSTs, 30%), and recognizing the need for instructional focus on MR in the mathematics classroom and their future work with students (5 PSTs, 22%).

Summary and Conclusion

Our work contributes to the research on MR by exploring how engaging PSTs in analyzing student-generated arguments for evidence of MR impacts PSTs' thinking about MR and their assessment practices focused on students' MR. Our results show that exposing PSTs to a broad range of students' mathematical arguments and reasoning increases PSTs' awareness of different reasoning actions. By providing PSTs with the framework for thinking about student MR developmentally (SRAT) we contributed to PSTs' understanding of MR on a continuum from less to more expert-like. At the beginning of the semester, almost all of our PSTs interpreted student reasoning in a discrete way by focusing on the presence or absence of isolated reasoning actions, particularly exemplifying, representing, or adapting actions. Using the SRAT as a guide for analyzing student reasoning, PSTs shifted their assessment practices to focus on justifying and generalizing actions and have begun considering the evidence of student MR on a continuum from less to more expert-like. In addition, our results also revealed that the SRAT and class activities positively affected PSTs' confidence in assessing students' MR, helped them reflect on their own reasoning skills, or develop a vision of their future practice with a focus on MR.

Our study provides important insights for mathematics teacher educators about supporting PSTs' learning about elementary students' MR. PSTs who learn to recognize and assess student reasoning actions along a progression from less to more expert-like can be more effective in helping their students become more sophisticated mathematical thinkers. Loong and colleagues (2013) advocated that teachers need a strong understanding of reasoning actions to be effective in promoting MR in their mathematics classrooms. In our study, the SRAT framework provided a scaffold for PSTs' learning about and assessment of student MR. This framework needs to be tested in future research with more diverse groups of PSTs and contexts.

THE EMERGENCE OF STUDENTS' COLLECTIVE PROVING ACTIVITY

Tenchita Alzaga Elizondo
Portland State University
halzaga@pdx.edu

While working with peers is seen as valuable for mathematical learning, this practice is understudied with undergraduate students in proof-based courses. I investigated how collective activity emerged among three students working on a proving task. Results show that as part of their collective activity, the group had to collectively create and coordinate multiple aspects of proof. I argue that this coordination was a critical component to their ability to move forward in their collective proving activity.

Keywords: Advanced Mathematical Thinking, Classroom Discourse, Reasoning and Proof

The claim that mathematical learning can be supported by working with peers has been repeatedly backed by literature (e.g., Francisco, 2013; Stahl, 2006). In the case of proof-based courses, research has also pointed to the benefits of engaging in social interactions during proving activity (Balacheff, 1991). However, literature specifically focused on students' collective activity in proof-based courses is slim (Ottinger, 2019). By studying how students work together to engage in proving activities, we can gain insights into how to support their learning in the classroom. The purpose of this study is to provide a detailed analysis of students' collective activity when working in groups on proving tasks. Specifically, it aims to answer the question: How does collective proving activity emerge among students working with peers in an Introduction-to-Proof course?

Theoretical Perspective

This study draws on the work of Martin and colleagues' (Martin et al., 2006; Martin & Towers, 2015) collective mathematical understanding framework. The framework is based on improvisational theories and focuses on the dynamical process of in-the-moment collective mathematical activity. Taking a sociocultural perspective, the emergent mathematical activity is how Martin and colleagues view collective mathematical understanding as developing. Martin and Tower (2015) identified three key types of collective mathematical activity that groups engage in as part of developing this understanding. These are: *Collective Image Making (CIM)*, *Collective Image Having (CIH)*, and *Collective Property Noticing (CPN).* The term image is used to represent any ideas that the learners might have about the specific topic at hand. These are considered to be primarily mental representations and it is the sense-making that happens surrounding these representations that constitutes the image (Martin & Towers, 2009). Students' progression through these stages is not meant to be linear but instead is comprised of a forward and backwards progress. When working at an outer stage, a group might encounter a problem that signals to the limits of their current image. When their image is challenged, students may *fold back* to an inner stage taking with them their newfound knowledge from the outer stage (Martin, 2008). I view students' proving activity as a form of problem-solving (Weber, 2005) and for this study, I use the stages of this framework, along with the concept of folding back, to frame the students' problem-solving process that makes up their collective proving activity.

Methods

This study was part of a larger, ongoing project with the goal of developing a modular inquiry-oriented Introduction-to-Proof curriculum and instructor support materials. Data for this study comes from a whole-class implementation of these curriculum materials in a university Introduction-to-Proof course. Content for the course was split between a group theory and real analysis context throughout the term. This course was offered remotely with synchronous meetings using video conferencing technology (i.e., Zoom). In line with inquiry-oriented instruction, the curriculum is designed to regularly engage students in small group work and as such, was rich in opportunities to study students' collective proving activity. Zoom breakout rooms were used to structure small group work where students used collaborative technology (e.g., Google Docs) to engaged in collective activity. Every time students worked in small groups I entered a breakout room with one group acting as an observer. Occasionally students directed questions to me, at those times I would take on an instructor role. Screen recordings were used to capture activity on Zoom and any collaborative technology that was being used in real time.

I used Powell et al.'s (2003) methodology for capturing students' mathematical reasoning to structure my analysis. First, I identified *critical episodes* that would undergo further analysis. These were episodes that featured groups working particularly well together, for example, by discussing and debating ideas often. For each critical episode, I developed multimodal transcripts (Hoffman, 2019) to capture all student interactions as accurately as possible. This study focuses on one critical episode in which three students; Justin, Abigail, and Alison worked together to collectively write a proof of what the class called the Sudoku Property of group Cayley tables. The Sudoku Property referred to the fact that for each row and column of a group's Cayley table, every group element appears exactly once (i.e., it exists and is unique). The results presented here focuses on the students' work in regards to the uniqueness part of the proof. I analyzed this episode by re-watching the video data and reading transcripts to identify the students' activity in relation to each stage of Martin and Tower's (2015) framework. This was an iterative process in which I first went back and forth between the data and framework to identify and develop descriptions of each stage of the framework. Through this process I found evidence of CIH, CIM, and folding back. With these descriptions (see Table 1), I coded segments of the transcript and interpreted these segments according to the surrounding context. I used these coded segments and interpretations to create an illustrative narrative of the students' emerging collective activity.

Table 1: Descriptions of Each Stage of Collective Activity

Collective Activity Stage	Description
Collective Image Making	When students offer up and/or discuss (but not yet take up) ideas for how to approach different parts of the proof.
Collective Image Having	When students agree on a direction and work on writing out a proof or give instructions to a peer for what to write in a way that is not challenged.
Folding Back	When an intervention is introduced that makes students' question and reexamine their approach/current train of thought.

Preliminary Results

After the instructor introduced the Sudoku Property and outlined two goals of the proof, the instructor sent the students into breakout rooms to work on the proof. The three students in this episode started working on the first part, proving uniqueness, with Alison offering a strategy:

Alison: Okay. So, we're like, kind of doing a proof by contradiction.
Abigail: (reading from the worksheet) Part One, show that each element appears at most once in each row. Suppose symmetry B showed up twice.
Alison: So, if symmetry B showed up twice, and we would have like Q being another symmetry. And I don't know, W being another symmetry, which means Q and W would have to equal the same thing. (As she speaks, she writes AQ=B and AW=B on the Google Doc.) They would have to be equivalent. Is that what we're getting at?

Abigail and Justin then agreed with this approach. Here the group began making an image of how to approach and structure the proof (*CIM*). Alison proposed a contradiction argument that assumed two symmetries Q and W composed with A would both result in the same symmetry B. With the lack of rebuttals regarding using a contradiction argument, the students at this point collectively had an image of their proof that centered on how it should be structured (i.e., by contradiction) (*CIH*).

While attempting to forward collectively to carry out their image of the contradiction proof, Justin introduced a question motivating the students to *fold back* to *CIM*.

Justin: What would the explanation part of it be. How does this prove that it's at most once?
Abigail: Well, well put- Because? Because, um, if? Well, because you wouldn't. So, on the top here (referring to the Cayley table), you only have like, each one shows up one time. So, if Q and W are identical, which they would be in this case, then-
Alison: there would be redundancy?
Abigail: Well, yeah, they would- that just wouldn't happen. Like they wouldn't show up more than once.
Alison: We just need another way to say all that.
Justin: Yeah, like I'm saying, I think this is right, is just with proofs we have to make sure to get that across. I just want to try to make sure that we can do cause I think it makes sense, is that we're supposed to- […], when you multiply the two different symmetries, that they're supposed to be unique symmetries? Right? I don't remember if that's something we explicitly said. So, I don't know if I can reference that. So, I'm trying to figure it out.

In order to complete the proof, Justin suggests that they need an "explanation part" which would outline why their argument showed that there is at most one solution. The group's inability to answer this question forced them to *fold back* to a *CIM* stage. At this stage, the students' CIM was focused on a different aspect of the proof, they were working to develop an understanding of *why* their proof worked (why they could assume distinct symmetries) rather than reexamining their understanding of how to approach the proof (i.e., by contradiction).

The episode continued with the members discussing the properties of Cayley tables, hoping these properties could provide insights to why their proof worked (*CIM*). Alison intermediately attempted to move their collective image making forward by connecting it to their task of explicitly writing the explanation that Justin originally suggested they needed. For example, consider the following exchange:

Alison: We have to find a way to say that there's a finite amount of symmetries. There are a finite amount of symmetries, right? There's just a bunch of different actions you can take to get each one?
Justin: A finite amount of non-redundant symmetries, I think.
Alison: Then let's say something like that, just to get that out of the way. Know what I mean?
Justin: Does it help us in any way?

The group continued to struggle to move forward to a *CIH* stage of their proof given that they had yet fully come to an understanding of why their approach works. The students eventually put this conversation on pause after the instructor added a comment on their Google Doc suggesting they justify each step in the proof they already had written down.

After addressing the instructor's comments, Abigail and Alison suggested moving on to the second part of the proof (i.e., proving existence). This indicates that they were satisfied with their proof and assumed that the group had completed a collective image of their proof. Justin on the other hand, did not see their proof as complete, stating "We didn't finish the first one is the only thing too." Justin suggested needing a statement for why their argument works to which Alison agreed stating "Yeah, like a conclusion." Justin's statement initiated the group to *fold back* to a *CIM* stage briefly to develop an image of what their final proof should include. With Alison's confirmation, and a lack of rebuttal from Abigail, Justin offered to complete that task (*CIH*).

Almost immediately upon entering the *CIH* stage, Justin encountered a problem which acts as a catalysis for the group to *fold back* again when he asks the "Do we want to agree on that there's supposed to be only unique- Each of the ones we're multiplying by have to be unique symmetries, meaning that Q and W can't be the same?". This comment brought the group back to the problem of why their argument worked (why they can assume distinct elements). The group again failed to move forward with their *CIH* due to not forming an understanding of one aspect of their proof. At this point, they decided to reach out to me and acting as a teacher, I informed them that they could assume the elements in their table were unique from each other. With this assurance, the students quickly checked in with one another and seemed to all agree on why their proof worked, marking a moment when they collectively had an image of their proof (*CIH*). At this point the students were able to successfully complete the problem.

Discussion and Conclusion

As part of their problem-solving process, the students in the above episode worked together to create an image of their uniqueness proof by developing a collective understanding of two related ideas: 1) what the proof should look like and how it should be structured (i.e., how to write the formal proof) and 2) the concepts underlying the proof (i.e., why their argument was valid). Moreover, even though the group was able to progress to the *CIH* stage of the proof by using the second idea, their inability to develop a collective understanding of why their argument worked (the first idea), often caused them to *fold back* to the *CIM* stage. It was not until the students developed a collective understanding of why their argument worked in relation to how they structured the proof, that they were able to successfully move forward with a collective image and complete the task. Thus, the preliminary results presented here suggest that to make progress in their collective proving activity, students need to 1) make explicit why and how they can prove their claim and 2) be able to coordinate those two aspects of their proof. The students in this episode were able to support one another in making progress to develop a rich image of the proof that they might not have gotten on their own. It is possible that without this activity the students might have instead struggled to work together. Further analysis will explore if a similar phenomenon occurs with other groups and with different proving activities.

CONJECTURE OF THEOREM STATEMENTS AND THEIR PROOFS BY ANALOGY: THE CASE OF ANDREW

Michael D. Hicks
Texas State University
Mh1653@txstate.edu

Construction of proofs by analogy with previously constructed proofs is a ubiquitous strategy in abstract algebra due to the existence of several structural similarities between algebraic structures. Examples found in textbooks suggest that such proofs by analogy are straightforward. However, it is unclear how students make sense of these proofs by analogy. This preliminary report explores one student's process of producing conjectures for theorem statements and their respective proofs in ring theory by analogy with what they knew from group theory. In particular, I analyze the student's analogical reasoning with the use of the ARM framework (Hicks, 2020) to make inferences about their analogical proof activity. Results indicate that Andrew reasoned more productively when spontaneously reasoning by analogy, while he lacked confidence in analogous statements and proofs that were prompted by the interviewer.

Keywords: Advanced mathematical thinking, reasoning and proof, undergraduate education

Proof construction and comprehension is essential to undergraduate mathematics (Mejia-Ramos, Fuller, Weber, Rhoads & Samkoff, 2012). One proof approach is to generate a proof by analogy with a previously proven statement. Examples of proof by analogy are ubiquitous in abstract algebra due to the existence of several commonalities between the structures of group and ring theory by way of their historic development (Hausberger, 2018). For instance, consider the following quote from Gallian (2010): "The next three theorems parallel results we had for groups. The proofs are nearly identical to their group theory counterparts and are left as exercises" (p. 283). An underlying assumption is made in this quote: because the relevant analogous proofs are found in group theory, they are meant to be straightforward and do not require a proof written in the book. However, of the three theorems being referred to in this quote, one is the first homomorphism theorem for rings, a theorem that is hardly considered trivial in an introductory course in abstract algebra.

It is unclear to what extent students appreciate the apparent simplicity in suggesting that a theorem about a new context is obvious by analogy with a previously known theorem. Matters may become especially complicated when considering the potential lack of coordination between what students, their teacher, and the discipline may accept as an appropriate establishment of new knowledge (Solomon, 2006). In order to better understand students' analogical proof construction and comprehension, this preliminary paper seeks to answer the overarching question: *How do students leverage theorems and proofs in group theory to conjecture theorems and construct proofs by analogy in ring theory?*

Theoretical Framing

I utilize the Analogical Reasoning in Mathematics (ARM) framework (Hicks, 2020) as a foundation for describing analogical reasoning in this paper. In particular, ARM describes analogical reasoning as a process of comparing similarity and difference between two domains: collections of knowledge (of varying size and scope) of mathematical content. For example, one could reason about the domain of group alone, or about the domain of group theory taken as a whole. Analogies are formed by mapping content from a source domain to a target domain. The source is typically the domain that is known to the individual, while the target is the domain to be understood. Analogical reasoning is operationalized as: (1) mapping and non-mapping activity involving the source and target domains; (2) attention to similarity and difference between the source and target; and (3) the foregrounding of a domain during reasoning. In addition, ARM also outlines several specific analogical activities characterized with the three dimensions described above and suggests a categorization for the different types of mathematical content to be attended to during analogical reasoning. I outline these activities in the methods.

Consistent with ARM, I interpret student mathematical activity through the lens of the Actor Oriented (AO) perspective (Lobato, 2012). Several existing frameworks make assumptions of what an appropriate analogy entails (e.g., subrings in ring theory are the appropriate analogy for subgroups in group theory, and anything else is false). The adoption of the AO perspective in this study allows for an examination of student analogical reasoning that may or may not adhere to the established or accepted analogies one might expect.

Methods

The data in this study was collected as part of a larger study investigating how students might reason by analogy in the context of abstract algebra between structures in group theory and ring theory. In the larger study, five 60-90-minute-long interviews were conducted with each of four students who had previously taken a course in group theory: three undergraduates mathematics majors, and one graduate student in mathematics education. In this preliminary study, I explore the activity of the graduate student, Andrew (a pseudonym), as he conjectured about three theorems in ring theory by analogy with the following theorems in group theory:

A) The subgroup test.
B) Suppose phi is a group homomorphism from a group G to a group H. Then the image of a subgroup of G is a subgroup of H.
C) Given a group G, the set of cosets {gH | g is an element of G} is a group under the operation aH * bH = abH if and only if H is a normal subgroup of G.

The given task differed based on the focal statement. For Theorem A, Andrew was only asked to develop a structure in ring theory analogous to subgroups and attention to the subgroup test itself was a spontaneous development by Andrew. During this task, Andrew was given full freedom to generate an analogous theorem and proof with no intervention from myself. For Theorems B and C, Andrew was first provided the theorem itself and asked to generate an analogous theorem in ring theory. After formulating his conjecture, he was then given a proof of the theorem in group theory, asked to analyze the proof in group theory, and then consider how to prove his conjectured statement in ring theory.

Transcripts were produced for each of Andrew's interviews and the sections in which Andrew developed ring theoretic analogies with the three above statements were analyzed in this study. In particular, the relevant sections of transcript were segmented by attending to shifts in analogical activity and mathematical focus. To each segment, the Analogical Reasoning in Mathematics (ARM) framework was used to assign codes describing the analogical activity as well as the mathematical content central to the analogical activity. These codes can be found in Table 1. I present the results of this process in the next section.

Table 1. Analogical Activity Codes

Code	*Description*
Recalling	Recalling or remembering content about one domain, usually the source.
Distinguishing	Identifying differences between the source and target domain.
Associating	Identifying similarities between the source and target domain.
Exporting	Mapping (almost) exact content from the source to the target; often associated with assuming that domains are completely similar with respect to some content.
Importing	Purposefully selecting content from the source to map to the target domain; discriminately forming similarities rather than assuming content is similar.
Extending	Viewing one structure as being grounded within another and establishing the new structure by "decorating" the old.
Adapting	Making changes to content to account for differences found between domains.
Elaborating	Expanding on what is known about a domain, usually the target.

Results

Andrew's Conjecturing of Theorems by Analogy

Andrew's approach to conjecturing theorem statements by analogy varied depending on the theorem. For Theorem A, Andrew spontaneously recalled the subgroup test and considered what a subring test would entail on his own. In particular, Andrew had previously distinguished the structure and structural properties of group and ring (by noting that rings have two operations, and that multiplicative inverses need not exist) and leveraged these differences to make an adaptation to create the subring test: unlike subgroups, subrings required the property that the set was closed under the multiplicative operation.

While Andrew spontaneously produced the analogous theorem statement of Theorem A, he was provided the theorem statements for Theorems B and C and then asked to produce the analogical statement. In contrast to Theorem A, Andrew made conjectures for analogies to Theorems B and C in ring theory that closely resembled their counterparts in group theory. This is strongly evidenced by the following quote where Andrew conjectured a theorem statement in ring theory analogous to Theorem B above:

> I'm gonna let R and S be rings and let phi be a ring homomorphism. I'm literally just replacing the words. I mean, this is my best guess then phi of R is a subring… Right, yeah. Replace group with ring. Replace homomorphism with ring homomorphism and replace subgroup with subring.

Thus, Andrew's approach to generating an analogous statement for Theorem B was to replace the names of structures in group theory with their relevant analogues in ring theory. This same strategy was employed for producing an analogous statement for Theorem C, although Andrew briefly alluded to what might be different: "Yeah, right now I'm just replacing group with ring, and normal subgroup with normal subring. I am worried about dealing with the two operations, though." (I note here that Andrew was unaware of the definition of ideal when engaging with this task. Thus, the appearance of "normal subring" does not indicate that he was ignoring ideals as a suitable replacement for normal subgroups.) Unlike the subring test, Andrew did not consider the need to attend to any differences when formulating these theorems.

Andrew's Consideration of Proofs by Analogy

In addition to making conjectures about analogical theorems in ring theory for Theorems B and C, Andrew was also given proofs of the group-theoretic statements to analyze before considering the proof of his conjectured statement for rings. Andrew directly leveraged these provided proofs to organize his thinking of a potential proof for his analogically conjectured theorems. Consider his thinking about proving his conjectured analogue to Theorem B: "So really I think you can take this proof and just add a last little paragraph proving that phi of R is closed under multiplication. That would prove this theorem." Thus, Andrew considered the proof of his analogous theorem in ring theory as being an extension of the proof provided to him. While Andrew considered what might change, he claimed that there were only menial differences or changes to be made (e.g., "But I think you can scrap the first line..It's one of those things where it's not necessary, but it's not useless.") and doubled down on his belief of the analogous proof being an extension of the given proof:

> What part would I change? Maybe I would take the, the second paragraph and say next we check that phi of G is closed under each group operation and do each proof there. But yeah, I mean, it's really just an extension of this proof. This could be like a lemma for it.

Despite spontaneously establishing the subring test by analogy with the subgroup test, Andrew never presented a full proof of his conjecture; instead, creating the test by analogy appeared to be sufficient. Similarly, Andrew never went on to construct full proofs for the analogues to Theorems B and C either and once again relied on the analogy. However, Andrew was less confident in the analogues to Theorems B and C and their potential proofs:

> Well rings can do weird stuff… So there's a chance that I'm not considering something. Yeah, I feel like this is right, but I wouldn't be that surprised if… this actually isn't right.

Thus, Andrew maintained an awareness that his analogically conjectured statements and his strategy for constructing their proofs through analogy were perhaps insufficient or flawed.

Discussion

From these examples, it would appear that Andrew was more willing to create a meaningful (to him) analogous statement for the theorem that he spontaneously generated: he recalled the subgroup test without prompting, and the subring test he produced was a result of an adaptation to account for differences he had previously identified himself. In contrast, Andrew simply exported the theorem statements he was given in group theory in order to generate his conjecture for theorems in ring theory. Thus, it may be more productive to provide students an opportunity to spontaneously reason by analogy when possible.

In addition, Andrew appeared to be more confident in the validity of the subring test which he spontaneously produced. By contrast, when Andrew exported the statements of the theorems that were provided to him to formulate analogues to Theorems B and C in ring theory, he was not quite as confident in the viability of the analogous statements or their proofs. These preliminary results indicate that there is perhaps a disconnect between the apparent simplicity of formulating analogous proofs suggested in mathematics textbooks, and what students themselves view as being simple and straightforward analogies.

Further research can greatly refine these preliminary results on how students might productively conjecture theorem statements and construct proofs by analogy by observing the analogical proof activity of several students on a variety of tasks. Specifically, further research is needed to determine the balance between: (a) when and how it is productive for students to attempt spontaneous production of theorems and proofs by analogy, and (b) when and how students can productively leverage pre-existing statements and proofs to reason by analogy.

MIDDLE SCHOOLERS' USE OF REPRESENTATIONS IN PROBLEM-SOLVING AROUND SLOPE

Allison Gantt
University of Delaware
agantt@udel.edu

In this study, I examine how the construction and use of representations might relate to the learning process in a problem-solving task involving slope. I report on one task-based interview with an eighth-grade student who had not yet engaged in formal study of slope to explore this relationship. Specifically, the construction of a graph coincided with a shift in the student's problem-solving approach, which I operationalize as the student's use of a representation. I discuss the implications of these moments in generating opportunities to learn.

Keywords: Algebra and Algebraic Thinking, Cognition, Mathematical Representations, Middle School Education

Representational activity is an important part of making sense of mathematical ideas and solving problems, particularly in the context of *slope*, or constant rate of change, in linear relationships. As learners work to conceptualize slope, meaningful construction and interpretation of graphs and tables, in particular, have been viewed as intertwined with robust conceptual understanding (Adu-Gyamfi & Bossé, 2014; Ellis et al., 2018; Peck, 2020; Zaslavsky et al., 2002). This study seeks to explore how students' representation construction might be leveraged in problem-solving involving slope. In this paper, I will address the following research question: *How does an eighth-grade student use her own constructed representation(s) to problem-solve about slope in a linear relationship prior to significant instruction on the topic?*

In the sections that follow, I will first present a conceptual framework for my constructs surrounding representation. Then, I present one case from a larger task-based interview study ($N = 2$) with the goal of developing a preliminary conjecture about how representations may be involved in the initial discovery of slope concepts. I conclude with a discussion of implications for opportunities to learn about slope through representations in problem-based environments.

Representations and Mathematical Thought

This work follows Stylianou (2011) in defining a *representation* as "a configuration that stands for something else" (p. 266). While internal representations are inaccessible to a researcher, this study focuses on learners' external representational activity, which includes expressions in both visual and discursive mediums (Goldin & Kaput, 1996). In this report, I seek to explore how a learner's own external representational activity may come to influence their internal representational schemes, as identified through shifts in external expressions.

Representations can lend themselves to different cognitive purposes for learners. While structural conceptions act as static mental objects (such as the perspective of slope as a measured quantity), operational conceptions are more dynamic (such as the process of calculation of slope, Sfard, 1991). Stylianou (2011) applied this theoretical distinction to a study of representations in mathematical problem-solving with both experts and middle-school students. In this account, learner-generated representations functioned statically when employed to understand a problem, record key information in a problem, or present an idea. Representations functioned dynamically when applied to explore a problem, evaluate an idea, or negotiate an understanding. In this report, I operationalize student *use of a representation* if they constructed a representation of the problem or strategy and interacted with it dynamically, per Stylianou's (2011) characterization.

Methods

Setting and participants

To examine external representational activity during a problem-solving task involving slope, I conducted a semi-structured, task-based interview (Maher & Sigley, 2020; Mejía-Ramos & Weber, 2020) with two students enrolled in a general eighth-grade mathematics course. The following report features only the case of one student, Marie (a pseudonym), as her interview involved the most marked strategic shift in *representational use*.

Marie was identified by her teacher for this project as a student who met but did not exceed grade-level performance standards (as measured through standardized test scores, course grades, or both) and was known or inferred to be comfortable with sharing her mathematical ideas out loud through Zoom video. Marie attended a public school in the northeastern United States that was approximately 70% White, 14% Hispanic or Latino, 6% multiracial, 5% Black or African American, and 5% Asian American. Marie, age 13, identified as female and White. She had not yet engaged in in-depth study of linear relationships at this point in the year. However, she and her classmates had been briefly introduced to the concept of slope as a geometric ratio for the purposes of reasoning with similar triangles.

Data collection and analysis

Marie was interviewed for 60 minutes via a recorded Zoom session to complete a problem-solving task involving slope. I recorded audio, a video focused on the student and their scratch work, and a screen capture of each student's live interaction with the Desmos-created task. The task was designed to encourage students' construction of tables and graphs in their problem-solving, as these representations were known to have prior meaning for the students in their instructional context. I introduced the task as one central question with several related prompts:

> Two friends go to the candy shop. They each pay for their baskets and collect their candy. The first friend buys 3 pounds of candy and spends a total of \$30.50 for the candy and the basket. The second friend buys 7 pounds of candy and spends a total of \$68.50 for the candy and the basket. How much are the friends paying for each pound of candy that they buy?

In each interview, I first asked students to solve the problem using any strategy to identify the price per pound (or the slope of this linear relationship). I then requested that the student construct three representations to solve the problem in the following order: 1) a visualization of their initial strategy, 2) a table, and 3) a graph. In cases 2 and 3, I also asked the student to explain if the representation had shifted their initial thinking about the task.

Explanations of thinking during problem-solving in conjunction with student reflection around that thinking aided in my identification of *representational use*. Representational use was determined if 1) the student explained how a constructed representation helped them to think about the problem differently, or 2) novel features of the mathematical strategies emerged compared to previous solution strategies. To support the determination of representational use, I developed a coding structure to first identify the mathematical strategies that occurred during discussion. Given the novelty of conceptions for slope to these students, I developed the coding scheme emergently yet also informed by related literature (i.e., Lobato et al., 2003; Peck, 2020) and prior experience. Ultimately, the codes of *price per pound as division* and *price per pound as* *difference* became salient strategies in Marie's interview. These codes are defined in the results that follow.

Results

Starting strategies: Marie representing the price per pound as division

Marie's initial strategies to solve the problem were classified as views of the *price per pound as division*. She described her preliminary ideas as follows:

> So the first thought, I was like, hm, maybe the basket's 50 cents, because they both have 50 cents. But, I think we might have to do some division to figure out, like, how much each pound is, so [trails off].

Though she described the potential role of the cost of the basket, Marie began to solve the problem by dividing the amount of money that the first friend spent by the number of pounds that were purchased. She repeated this strategy with both pairs of values, reaching a price per pound of $10.16 for the first friend and then $9.78 for the second. When I asked Marie why she thought she might be getting different results for these divisions, she responded, "Maybe they got different kinds of candy or, I'm not sure." Marie did not reach a conclusion for the price per pound, but she constructed a visual to support how she envisioned her general strategy of distributing one friend's total (in her example, $14, which was not a value from the problem) across the number of pounds (in her example, 3 pounds, represented by circles, Figure 1).

Figure 1: Marie's constructed representation of price per pound as division.

The theme of *price per pound as division* continued when Marie represented her thinking in a table (Figure 2). Still without a satisfactory solution from her initial approach, Marie resorted to dividing other values in the table (such as 7 and 3) to "see if there's, like, a relationship with like any of the numbers." Marie continued to focus on divisions (though now different divisions) as she constructed a table, but she again did not reach a value she identified as the price per pound.

friend 1	friend 2
3	7
30.50	68.50

Figure 2: A recreation of Marie's table representation.

Representational use: Marie representing the price per pound as difference

Marie's reasoning about *price per pound as division* began to change to *price per pound as difference* when prompted to construct a graph. Therefore, I describe Marie's construction of a graph as a case of *representational use*.

While constructing a graph, Marie drew a point to represent each friend. She connected each point horizontally and vertically to the x- and y-axes. She then explained her new strategy as a need to calculate the difference between costs: "So I'm going to try and count, um, like, this amount [creates Figure 3] um, where the green line is, like, from, from where the 68 is to where the, from where the top line is to the bottom line."

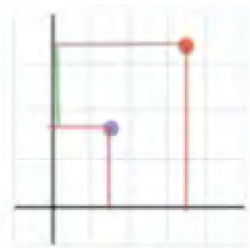

Figure 3: Marie's revised graph that connects points to axes; includes green segment to measure distance.

I asked Marie about her choice to construct this green line in the context of the solving the problem around the cost per pound:

> Hm. Um, I think it could, like, tell, like, um, the difference between, um, 30.50 and 68.50. Uh, I just had a thought. Maybe I could subtract those two numbers, so [types on calculator] 68.50 minus 30.50, yeah 38, hm. I wonder if that has to do with anything. So I just thought like, hold on, so I'm just going to write down the word 38 [writes "38" and circles it on paper], the number 38 in case I need it, so I remember it. I think I'm going to try like 7 divided by 38 [types on calculator] or no, 38 divided by 7.

Though the graph was the final representation with which Marie worked, reasoning involving the *price per pound as difference* emerged for the first time in her activity. However, despite this new idea, Marie still did not reach a solution for the price per pound by the end of work on the problem. In fact, when Marie was given a choice at the very end of the activity to try any final strategy to attempt a solution, Marie returned to her initial calculations of price per pound through division of each friend's total cost by the number of pounds purchased, still trying to reason through why these had given her different amounts. In reflection at the end of the activity, however, Marie described that the graph had shifted her conceptions during the activity:

> [The graph] kind of helped me to like, see the different, like, I don't know what the word is like the, the like, farness away of each dot, of each um, like number kind of, it, like, showed me like the difference.

Though Marie did not integrate her new reasoning around the *price per pound as difference* together with her previous strategies around *price per pound as division*, Marie described that the graph supported her to visualize a different element of the problem ("farness away"). This shift was unique to her work with a graph, thereby classified as *representational use*.

Discussion and Directions for Future Research

This research provides insight into the process of *representational use* in problem-solving with slope prior to significant formal instruction on the topic. Marie's initial reasoning had focused on a *price per pound as division* through her own representations and a table. However, Marie used her graph and uniquely adopted a new strategy of *price per pound as difference*. Though a graph became a dynamic representation (Stylianou, 2011) for Marie in this case, this trajectory is not assumed to be universal. Indeed, different representations led to different shifts for each of the two students in the interview study. I conjecture that moments of students' representational use could present potential opportunities to learn when accompanied by instruction and interaction outside of the task-based interview setting. Future research could explore how representational use is connected to conceptual development for slope over time.

FROM NUMBER LINES TO GRAPHS: A MIDDLE SCHOOL STUDENT'S RE-ORGANIZATION OF THE SPACE

Halil I. Tasova
CSU, San Bernardino
halil.tasova@csusb.edu

Kevin C. Moore
University of Georgia
kvcmoore@uga.edu

We report on developmental shifts of a middle school student's (Ella) graphing activity as we implement an instructional sequence that emphasizes quantitative and covariational reasoning. Our results suggest that representing quantities' magnitudes as varying length of directed bars on empty number lines supported Ella re-organizing the space consistent with a Cartesian plane.

Keywords: Algebra and Algebraic Thinking, Cognition, Representations and Visualization

Constructing and interpreting graphs represents a "critical moment" in middle school mathematics for its opportunity to foster powerful learning (Leinhardt et al., 1990). Students, however, experience a number of challenges (e.g., conceiving graphs as picture of situation, event phenomena, literal motion of an object) in interpreting graphs (see Johnson et al., 2020 for a summary of these challenges). One potentially promising way to support students to develop productive meanings for graphs is to emphasize the role of seeing a graph as an emergent trace of how two quantities' measures vary simultaneously (Moore & Thompson, 2015). Although numerous researchers have investigated students' ability to interpret and construct graphs by plotting points and scaling axes, using slope and y-intercept, incorporating embodiment-based learning opportunities, and connecting with the other forms of multiple representations of functions, far fewer researchers have focused investigating how students construct graphs as emergent traces of quantities' covariation. Thus, we investigate the following questions: What ways of thinking do middle school students engage in graphing activities intended to emphasize quantitative reasoning? How can modeling with a quantitative reasoning approach support students' ability to develop productive and powerful ways of graphing?

Theoretical Framework: Quantitative Reasoning

This study focuses on middle school students' graphing activities involved in reasoning with relationships between quantities in real-world situations. We use *quantity* to refer to a conceptual entity an individual construct as a measurable attribute of an object (Thompson, 2011). In this study, we demonstrate ways in which students make sense of quantitative relationships in dynamic events and in graphs by reasoning with quantities' *magnitudes* (i.e., the quantitative size of an object's measurable attribute) independent of numerical values.

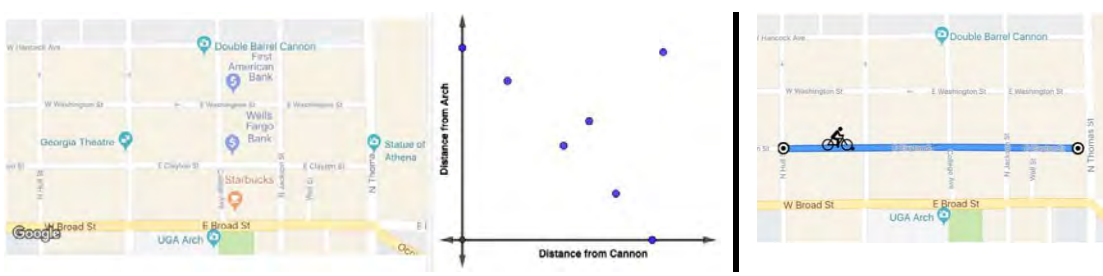
In the context of graphing, a relationship between two quantities is often represented in a coordinate system. Lee (2017) pointed out that researchers and educators have often taken coordinate systems for granted in students' graphing activity. Until recently, researchers did not question the importance of constructing a coordinate system because most researchers did not view it as a mental structure that students needed to construct (Lee, Moore, & Tasova, 2019). Furthermore, the idea of representing quantities' values or magnitudes on number lines is often taken for granted in students' construction of coordinate systems (and, in turn, in students' graphing activities), which is problematic because the construction of a plane requires conceiving of two number lines and using them to create a two-dimensional space (Lee, Hardison, & Paoletti, 2018). Thus, in this study, we investigated the nature and extend of students' abilities to represent varying quantities' magnitudes on number lines, and whether/how those abilities influence their construction of coordinate systems and graphs.

Methods

This study is situated within a larger study that examined four seventh-grade students' graphing activities in a teaching experiment (Steffe & Thompson, 2000) that occurred at a public middle school in the southeast United States. This study focuses on Ella's meanings for graphs and her developmental shift of those meanings over the teaching experiment.

Ella participated in 6 teaching sessions each of which last for approximately one-hour. Data sources included video and transcripts of each session that captured her exact words, gestures, and drawings. We conducted a conceptual analysis in order to understand her verbal explanations and actions and develop viable models of her mathematics (Steffe & Thompson, 2000). Our analysis relied on generative and axial methods (Corbin & Strauss, 2008), and it was guided by an attempt to develop working models of Ella's thinking.

Before conducting the teaching experiment, we developed an initial sequence of tasks each of which was designed with a dynamic geometry software and displayed on a tablet device (see https://www.geogebra.org/m/w9n4hn7r for digital versions of the tasks). *Downtown Athens Task* (DAT) includes a map with seven locations highlighted and labeled (see Figure 1a). We also present a Cartesian plane whose horizontal axis is labeled as Distance from Cannon (DfC) and vertical axis is labeled as Distance from Arch (DfA). Seven points are plotted without labelling in the coordinate plane to represent the seven locations' DfA and DfC (see Figure 1a, right). We asked students what each of these points on the plane might represent with an intention to observe their spontaneous responses and to explore students' meanings of points.



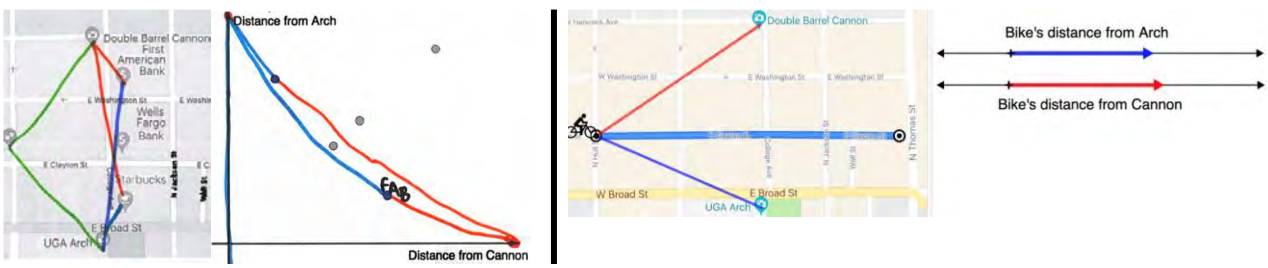
(a) (b)

Figure 1. (a) Downtown Athens Task (b) Downtown Athens Bike Task

In *Downtown Athens Bike Task* (DABT), we present the students with the same map of Downtown Athens highlighting a straight road (i.e., Clayton St.). We asked students to graph the relationship between the bike's DfA and DfC as the bike moves at a constant speed back and forth along the road. We also designed numerous tasks where students engage with quantities' magnitudes represented by varying length of directed bars placed on empty number lines (also called *magnitude lines*, see Figure 2b). The length of directed bars on the magnitude lines vary according to the bike's movement in the map. We conjectured that this representation might help students when they move to the two-dimensional space to represent two quantities by a single point in a coordinate plane. Note that we call the line "empty number line" in order to emphasize magnitude reasoning as opposed to numerical or value reasoning.

Results

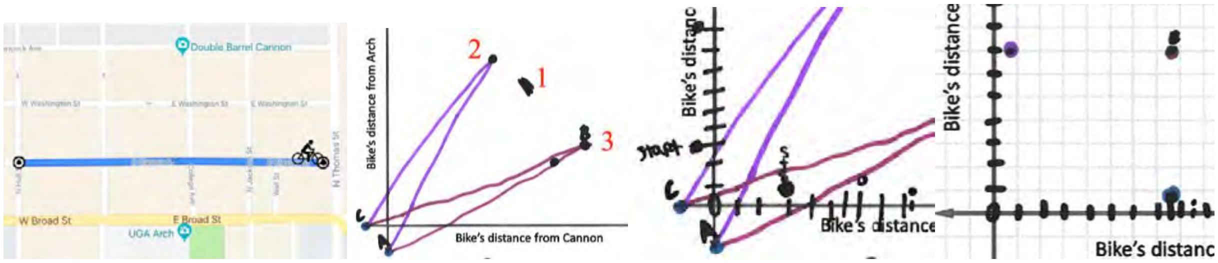
Initial meanings of the points and the organization of the space. We illustrate Ella's initial meanings by using her activity during DAT. Ella assimilated points in the plane as a location/object, however, her meanings were based in focusing on object's quantitative properties. After conceiving Arch and Cannon physically located on each axis as implied by the labels (see orange dots on each axis in Figure 2a), Ella made sense of the rest of the space by coordinating the radial distances between "places" on the plane and Arch and Cannon on each axis. For example, Ella labeled a point as "FAB" on the plane (see Figure 2a) to indicate First American Bank, and she conceived the point as FAB based on the orange and blue line segments that she drew on the plane. She stated, "the orange is shorter, and the blue is longer… [*referring to the orange and blue line segments on the map*] over here, like the same thing." Ella perceived FAB is closer to Cannon and farther from Arch in the map as well as in the plane. Therefore, we infer that Ella's meanings of the points included determining quantitative features of an object in the situation (i.e., its DfA and DfC as indicated by segments) and subsequently preserving these quantitative properties via the location of a point in the plane.



(a) (b)

Figure 2. (a) Ella's bipolar coordinate system, (b) DABT with magnitude lines

Representing a quantity's magnitude on an empty number line. In order to aid Emma in developing particular meanings for representing quantities in Cartesian plane, we engaged her in a dynamic tool that represented quantities' magnitudes as directed bars of varying length (see Figure 2b, right). We first wanted to get insights to how Ella could conceive this representation. While moving the bike to the right from its position seen in Figure 2b (red segment in the map and the corresponding red bar on the line were hidden at the moment), we drew Ella's attention to the fact that the right end side of blue bar on the magnitude line was moving to the left (indicating the bike's DfA was decreasing from our perspective). Ella determined that the bike's DfA is decreasing while moving the bike to the right in the map. She explained "it [*pointing to the blue bar*] is gonna get smaller because distance is smaller on the number line too." Moreover, Ella labeled the starting point as "zero." From this activity, we infer that Ella conceived the length of the blue bar on the magnitude line as a representation of the bike's DfA.



(a) (b) (c) (d)

Figure 3. (a) Map showing the bike's position when questioned, (b) Ella's graph, (c) marks and dots on axes, and (d) points in the plane.

Graphing bike's DfA and DfC. After Ella engaged with the magnitude line activity, we asked her to sketch a graph to represent the bike's DfC and DfA using a given piece of paper with two orthogonal axes. Ella re-organized the space different than her earlier actions in the teaching experiment (see Figure 3b vs. Figure 2a). For example, Ella conceived Cannon at very left side of the horizontal axis (labeled C) because "farther it is here [*sweeping her finger to the right from left over the horizontal axis*] means that farther it is from Cannon." This may show that Ella's re-organization of the space was an implication of her engagement with the magnitude line activity. Ella still assimilated the dot she drew in the plane as the bike (labeled B, #3 in Figure 3b) whose location was determined by coordinating the radial distances between the bike's DfA and DfC. Note that Ella wanted to change the location of the dots (see her earlier attempts in Figure 3b with the numbers showing the order in which she drew) "because it [the dot labeled as B] is like farther away from Cannon than it is Arch."

Ella's shift. Note that Ella plotted only one point on the plane (see Figure 3b), although the prompt was to graph the relationship as the bike traveled. We asked her whether her graph (i.e., the dot she plotted) illustrated the relationship between the bike's DfA and DfC as we animated the bike—the length of the bars on the magnitude lines also varied accordingly—in the tablet screen. She said no. Ella claimed, "I probably could have put a number line right here [*referring to the axes of the plane*]" to show how the bike's DfC and DfA changed as it moved. To illustrate this, she plotted tick marks on each axis in conjunction with tick marks plotted on the magnitude lines. She added dots near certain (and somewhat arbitrary) tick marks on each axis (see black dots in Figure 3c) to represent certain states of bike's DfA and DfC as the bike changed its location. During this activity, Ella did not focus on her purple line segments or the points that she drew earlier in the plane (see Figure 3b). She only worked on the axis to represent each quantity, and she did not plot points in the plane to represent them simultaneously. So, we repeated the same task with grid paper to see if she could join those quantities in the plane. By describing "this is what I did earlier" referring to her latest activity, Ella began plotting a dot on each axis to show the bike's DfA and DfC (Figure 3d). Then, she plotted a point in the plane "where those two [*tracing the pen in the air from the dots on each axis to the dot in the plane horizontally and vertically, respectively*] would meet up if they have like a little line." When asked to explain what that point represented to her, Ella said, "that is where the bike is." We infer that Ella seemed to establish a way to represent two quantities in her newly organized space as a single point; although she seemed to conceive the point that she plotted in the plane as the physical location of the bike.

Discussion

In this study, we illustrated different ways a student's graphing activity involved representing quantitative relationships. These examples illustrate alternative meanings of a coordinate system and coordinate points. Ella initially assimilated the points on the plane in relation to the physical objects that appear in the situation, and her meanings for points were based in quantitative properties (i.e., magnitudes from a fixed point). Ella conceived the length of the bar on the magnitude line as a proxy for the quantity that she conceived in the situation (i.e., the bike's DfA). In doing so, she conceived a constrain regarding how to represent the variation of a quantity on a magnitude line (e.g., only left and right on a horizontal line). Thus, she organized the space accordingly in later activities when considering two-dimensional space (see her shifts along Figure 2a, Figure 3b, and Figure 3d). Our results illustrate that explicit attention to quantities in the situation and mapping those quantities' magnitudes onto the empty number lines supported Ella's re-organization of the space consistent with a Cartesian plane.

This paper reports a case study of the feedback practice of one professor (Dr. X) in an abstract algebra course and the utilization of the feedback by four students from the class on three proof assignments. During interviews, Dr. X provided the rationale for each piece of feedback and described her general feedback practices. The students provided their interpretations of the feedback during interviews and were given a chance to revise the proofs to gauge whether they learned from the feedback. Dr. X wrote comments on her students' proofs to make them think, to correct notational or logical errors, or to address misinterpretations. Dr. X provided feedback even when no points were deducted. Students were generally able to successfully revise their proofs by addressing Dr. X's feedback.

Keywords: Advanced Mathematical Thinking; Classroom Discourse; Reasoning and Proof

Proof proficiency is an integral component of many upper-level mathematics courses. Many faculty members report spending considerable time and effort providing feedback to students on their proofs (Moore, 2016) and try to be thoughtful about their feedback practices (Weber, 2004; Lew, Fukawa-Connelly, & Mejía-Ramos, 2016; Miller, Infante, & Weber, 2018). However, this is under-researched at the collegiate level (cf., Speer, Smith, & Horvath, 2010).

Moore (2016) found that mathematics professors tend to focus on logical validity, clarity of writing, fluency of writing, and conceptual understanding when grading proofs. However, professors are rather subjective when grading proofs, often awarding vastly different scores for the same proof (Miller et al., 2018; Moore, 2016). Furthermore, professors report giving different scores based on students' past performances or the professor's interpretation of the error (Lew & Mejia-Ramos, 2019; Miller et al., 2018; Moore, 2016).

Additional research indicates that students are often unable to fully understand the feedback they are given (Byrne, Hanusch, Moore, & Fukawa-Connelly, 2018; Lew et al., 2016). This is not unique to mathematics; undergraduate students in many disciplines are often unable to fully interpret the comments instructors leave on their work (cf., Higgins, Hartley, & Skelton, 2001; Norton & Norton, 2001; Vardi, 2009). Byrne et al. (2018) found that students can fully revise direct edits on proofs without understanding the rationale for the feedback.

This project seeks to understand a professor's feedback practices in abstract algebra, and the students' reactions to the feedback. Our research questions are: (a) What are the professor's feedback practices on students' abstract algebra proofs when viewed through the commognitive framework? and (b) Can students revise their proofs successfully after receiving this feedback?

Theoretical Framework

Sfard's (2008) commognitive framework offers the tools to discuss detailed aspects of teaching and learning (Nardi, Ryve, Stadler, & Viirman, 2014) by adopting a participationist perspective towards human learning. Learning mathematics is the process of becoming a member of a mathematical discourse, which is distinguished by its *word use*, *visual mediators* (i.e., diagrams), *narratives*, and *routines* (Sfard, 2008). Narratives include definitions, proofs, and theorems. *Routines* are repetitive patterns (Sfard, 2008), which are governed by *object-level rules* and *meta-level rules* (or simply *metarules*). Object-level rules are the narratives about regularities in the behavior of objects of the discourse (Sfard, 2008), whereas *metarules* are patterns in the activity of the participants when trying to produce and substantiate object-level narratives (Sfard, 2008). In this study, *a proof* is a narrative that is produced by following certain routines and endorsed by those with authority. *Proving* is embedded within a commognitive social context (mathematical discourse) that puts emphasis on the activity.

Object-level learning is detected by the expansion of the discourse, such as extending the vocabulary, constructing new routines, and producing new endorsed narratives (Sfard, 2008). *Meta-level learning* is characterized by changing one's metarule of the discourse (Sfard, 2008), including knowing the *how* and *when* of a routine in a discourse (Ioannou, 2018).

For analyzing the students' proof revisions, we employed an analysis framework inspired by Conrad and Goldstein's (1999) strategy. We define a successful revision to be one that integrates the feedback in a way that improved the quality of the proof, even if some errors remained.

Methodology

Participants

The participants in this study were the course instructor (Dr. X) and four students from an undergraduate abstract algebra course at a large R1 university in the United States. Dr. X was an Assistant Professor and had a research specialty in Commutative Algebra and Lie Algebras. The students, recruited voluntarily, were three seniors, and one first-year graduate student. All four students had previously taken proof classes, so they were familiar with the general process of writing proofs.

Materials

Three problems assigned by Dr. X were intentionally chosen from three main topics (groups, subgroups, and isomorphisms) among the abstract algebra course assignments:

1. Let L be the set of positive real numbers. Define a binary operation $\heartsuit$ on L by $a \heartsuit b = a^{\log b}$. Determine if $(L, \heartsuit)$ is a group.
2. Let G be a group and let H be a subgroup of G. Let x be a fixed element of G. Define $xHx^{-1} = \{xhx^{-1} \mid h \in H\}$. Show that xHx^{-1} is a subgroup of G.
3. Show that $U_{26}/\langle 5 \rangle \simeq Z_3$.

Dr. X graded and provided feedback for each proof, as was her normal routine. We collected graded proof productions from each student (without Dr. X knowing who participated in the study). All collected proofs were rewritten for the purpose of confidentiality since they were shown to Dr. X during the meeting with her.

Procedures

We conducted two types of interview: interview with each student and interview with Dr. X. One of the researchers met with each student three times throughout the semester. During the interviews, students were asked to provide their interpretations of the feedback and answer general questions about feedback. Moreover, if Dr. X deducted points, the students were asked to revise the proof, explain what they changed, and identify how they used Dr. X's feedback. The revisions were not graded by the instructor, but they were evaluated by two of the researchers to judge whether the revisions were successful.

Two of the researchers met with Dr. X. During the interview, we asked Dr. X to offer her rationale for each piece of feedback on all 12 student proofs, along with insight into her more general process for providing feedback and her proof feedback practices. Note that all the students' 'roofs were rewritten by one of the researchers to hide students' identities, but the structure of the original proofs and feedback was maintained. All interviews were analyzed using an inductive approach, with the codes and themes derived from reading the interview transcriptions (Braun & Clarke, 2006).

Results and Discussion

Professor's Feedback Practices

Comments that prompt students to think. Dr. X wanted students to think when reading her comments. She highlighted this by probing students' understanding, bringing their attention to material from lecture, explicitly asking them to think about a part of their proof again, and encouraging the students to revise their proofs and discuss their revisions with her outside of class. For example, on Problem 2, Student A claimed that as a group in its own right, the subgroup H "must contain the identity element e" Dr. X left feedback indicating that Student A should elaborate and think this through, explaining in the interview, "I said all subgroups contain the identity element of G and particularly $\mathrm{e_H}$ equals $\mathrm{e_G}$, and I wanted them to think why that's'true." Another example of this type of prompting was found in the feedback on Student D's proof of Problem 1. Dr. X wrote "think again" to direct the student to think about Student D's assertion that every element of L had an inverse. In addition to the comment "think again", Dr. X also provided a hint on Student D's proof to focus the student on a counterexample.

In terms of general feedback practice, Dr. X stated, "I want them to see if their thought-process is properly transferred into the paper." Furthermore, she expressed that, at times, she wants students to "think" about the feedback and the problem, revise their proofs, and seek more feedback, sometimes asking students to turn the problem in again. Commognitively, such feedback prompts students to build a mathematical discourse with themselves. Dr. X intentionally avoided indicating what was wrong and how to fix it, leading the students to identify and correct what was wrong, helping the students improve their understanding of each topic and expand their own discourse.

Comments related to object-level learning. Dr. X provided much feedback on notation and quantifiers. This feedback was often provided in the form of direct edits, such as: crossing out multiple instances of H and writing xHx^{-1}; adding logical quantifiers; and other direct phrases conveying additional mathematical norms. With such feedback, Dr. X did not normally deduct points, stating, "if the ideas [are] there, if they don't use some time to write the right notation, I don't take points off, but then I say, 'look, your notation here should have been this.'" We did, however, find one instance where such an error received a substantial deduction.

Several times, Dr. X edited the students' proofs to add quantifiers. For example, on Student D's proof that $(L, \heartsuit)$ satisfied the associative law, Student D wrote: "Thus $a\heartsuit(b\heartsuit c) = (a\heartsuit b)\heartsuit c$, and so $(L, \heartsuit)$ has the associativity property," and Dr. X provided the direct edit "$\forall$“$, b, c \in L$" right after "$a\heartsuit(b\heartsuit c) = (a\heartsuit b)\heartsuit c$." Dr. X viewed this as a clarity issue and did not deduct points, but she did convey mathematical norms to the students through her feedback. In all, we found that Dr. X provided most of her feedback on object-level learning (logical reasoning, notation, and quantifiers), but this emphasis was often not accompanied by point deductions.

Comments related to meta-level learning. We found that there were two places where Dr. X would always deduct points: (1) for not showing non-emptiness when applying the subgroup test, and (2) for not ensuring that the subgroup is normal when working on quotient groups. In such cases, Dr. X explicitly noted what was missing. For example, she wrote to Student B that "you should also check that $xHx^{-1} \neq \emptyset$. $xHx^{-1} \neq \emptyset$ because $\mathrm{e_G} \in H$ and hence $x\mathrm{e_G}x^{-1} \in xHx^{-1}$." Viewing these commognitively, both of these errors are routines governed by metarules: the metarules of performing the subgroup test, and the metarules of quotient group construction. Ioannou (2018) suggested that "not addressing non-emptiness indicates that students are probably not aware of its importance due to problematic metalevel learning in the context of group theory" (p. 130). In a similar manner, not showing the normality of the subgroup could be an indication of deficient meta-level learning. The importance of awareness of routines and meta-level learning was punctuated by Dr. X's consistent deduction of points.

Revision Analysis

The four students successfully revised six out of eight revision attempts. Student B's unsuccessful proof of Problem 1 did not address all the relevant feedback items, neglecting to include the prerequisite sub-proof of 10 as the identity element of L. The student said that she would have included all four group axioms, including the missing sub-proof, if the revised proof was to be produced for Dr. X and not the study. However, by calling such portions "redundant," the implication may be that the student did not view the missing portion as logically necessary, but rather as satisfying the desires of a professor to see students' knowledge of group axioms on display. This highlights how feedback can fail to have the intended effect on a subsequent proof revision when a student filters the feedback and weighs its importance. In contrast, Student C received similar feedback and chose to include proofs of all necessary axioms. From a commognitive perspective, the metarules established for the classroom did not fully promote aspects of meta-level learning necessary to internalize which portions of the proof are logically necessary.

The other unsuccessful revision resulted from problematic meta-level learning of the metarules for normal subgroups, on Problem 3. Specifically, Students C and D needed to defend the *normality* of the subgroup $\langle 5 \rangle \subset U_{26}$. On this matter, Dr. X provided an essentially the same comment to both students. Student C provided incorrect justification to show the subgroup is *normal*, while Student D produced a correct proof. This could be due to students' preferences of the type of feedback and students' preexisting knowledge. A small nudge in the right direction may be just what one student needs to bridge the gap for internal discourse and complete a revision successfully, but that same nudge may be more frustrating than helpful for another student. This suggests that the notion of *effective feedback* might be very contextual and depends on many aspects involved in the feedback process. On Problem 2, Dr. X used a more direct approach with explicit corrections, which resulted in successful revisions from all students.

Conclusion

Dr. X wrote comments on students' proofs to prompt them to think, to indicate notational errors, or to illustrate misconceptions and logical errors. Point deductions were not the only reason for feedback. In fact, some of Dr. X's most pointed comments on significant inaccuracies (such as logical errors) came with little-to-no point reductions. Furthermore, Dr. X always deducted points and provided feedback relating to meta-level learning when students did not fully address the non-emptiness condition for a subgroup or did not establish that the subgroup is normal before articulating why a quotient group is isomorphic to $\mathbb{Z}_3$.

Having students revise proofs is a way to gauge whether students have properly interpreted the feedback, as seen in this study. However, understanding the error and professor's feedback did not imply that students could successfully revise their proofs. This result complements the earlier work by Byrne et al. (2018), which found that producing a successful revision does not imply that the student has fully understood the professor's feedback.

Quantitative and covariational reasoning (QCR) are foundational to productive conceptualizations of functions, and especially to properties belonging to first and second derivatives. Through the lens of QCR, we explore how derivatives and rates of change might influence mathematical model construction. Drawing on sessions from an exploratory teaching experiment with an undergraduate STEM major, we illustrate reasoning with non-normative conceptions of derivatives that is consistent and robust and conjecture how this reasoning impacts model construction.

Keywords: modeling, calculus, mathematical representations, undergraduate mathematics

Many STEM disciplines rely on mathematical models to convey meaning. The kinds of models studied in advanced mathematics and STEM coursework regularly feature first and second derivatives, sometimes in relation to a single independent variable and sometimes in relations among themselves. Thus, relational properties among these quantities like dependence, directionality, and coordination-of-change take on additional importance when considering students' meanings for the models that recruit these quantities. It is yet to be understood how the manner of quantification of specific quantities may constrain covariational reasoning and subsequently the kinds of scenario-based conditions modelers may carry forward into their models. The purpose of this paper is to examine the interface of quantification and covariational reasoning about the first and second derivative.

Theoretical Perspective and Empirical Background

Researchers have elaborated theoretical constructs such as quantitative reasoning and covariational reasoning (QCR) for explaining, predicting, and extending students' thinking in the presence of variation (Thompson & Carlson, 2017) while at the same time, studies of mathematical modeling processes have been incorporating methods capable of accounting for modelers' QCR (e.g., Czocher & Hardison, 2021). By *mathematical model*, we mean a conceptual system accessible through the modeler's mathematical expression of locally meaningful representational systems for real-world phenomena. Coordinating two varying quantities and attending to relationships among them is *covariational reasoning* (Carlson et al., 2002). It presents as patterns of reasoning that compares quantities, combine them through operations, trace their changes, rates of changes, and intensities of changes (Johnson, 2015). According to Carlson et al. (2002), covariational reasoning passes through five levels of development based in the individual's imagery of the dynamics and relative to a task scenario. Each level corresponds to increasingly sophisticated mental actions while retaining the nature of mental actions associated with all lower levels: MA1 – *dependence* of one variable on another, MA2 – *direction* of change of one variable with changes in the other, MA3 – *amount* of change of one variable with changes in the other, MA4 – *average* rate-of-change of one variable with uniform increments of the other, MA5 – *instantaneous* rate-of-change of one variable with continuous changes in the other (Carlson et al., 2002). Jones (2016) studied students' conceptions of second derivative and concavity, elaborating on the covariational reasoning levels. He argued that, if one considers rate-of-change in a quantity as the dependent variable, then reasoning about concavity can be recast as mental actions MA4_1 (dependence of rate of change on independent variable), MA4_2 (direction of change in the rate of change with respect to the independent variable), and MA4_3 (amount of change in the rate of change with changes in independent variable). Conceptualizing mental actions 1, 2, and 3 applied to variation of rate-of-change along with mental actions 4 and 5 applied to variation in the base variable foreshadows ways of thinking reported in by Jones (2019), where participants conflated the magnitude of rate of change with its directionality.

Taken together, the literature points toward students' quantification as an explanatory mechanism for their modeling activities and especially toward the quantitative and covariational relationships students formulate as a basis for the graphical or symbolic expressions they create to communicate those relationships. Our methodology, described below, is borne out from these considerations as we seek to understand how an individual conceives of relations among time, a quantity, and a rate-of-change of that quantity and the models occasioned by those relations. We address the question: How does quantification of the first and second derivative influence covariational reasoning and what might be its collective impact on model construction?

Methods

Data comes from two task-based interview sessions drawn from exploratory teaching experiment with an undergraduate STEM major, Azure, focused on uncovering how to leverage and extend students' quantitative reasoning for the purpose of creating and expressing mathematical models of real-world scenarios. The sessions treat the Ice Melt Task, which presents a set of scenarios where ice is placed in contrasting environments. The participants are asked to distinguish among magnitude and sign of volume and rate of change of volume. Follow up questioning occasioned consideration of pairwise covariational comparisons of time, quantity, and rate of change of quantity, and to communicate properties of those conceived relationships through graphs and symbolic representations. Data analysis first sought instances of Azure's reasoning consistent with Jones's (2016, 2019) conceptual descriptions of concavity and where he made comparisons to physics concepts like velocity. We then catalogued the situationally-relevant quantities Azure imputed to the scenario, applying Czocher & Hardison's (2021) quantification criteria. Finally, we analyzed the instances identified in the first pass by examining the mental actions (MA1-MA5; MA4_1-MA4_3) and levels of covariation (CL1-CL5) the relevant pairs of quantities (identified in the second pass) permitted (Carlson et al., 2002; Jones, 2016).

Results

In total, Azure imputed 5 quantities with situational references relevant to the research question: Volume (amount of ice), Ambient Temperature (temperature of environment surrounding ice), Rate of Change of Volume (absolute change in volume between two distinct times; ice), Rate of Change (of Rate of Change) of Volume (rate at which ice melting), and Time (the indefinite continued progress of existence and events). Additionally, Azure quantified *slope* without a situational referent that nevertheless had a meaningful referent in his graphing activity. We discuss his non-normative situational referents for the rates of change below.

Azure described volume of ice in different scenarios in interesting ways, for example an iceberg in the ocean has a small/positive volume while ice in a cup has large/positive volume. He demonstrated coordination of V, volume of water, and time t through mental action (MA) 1 and covariational reasoning level (CL) 1. For example, he drew the graph in Figure 1, which along with his explanations suggested that as t changes, so must V. He was aware that V would decrease as time increased. In the next session, he stated that ice volume would decrease as time changed. In the tasks, he argued for a negative directionality between changes in V across two points in time, evident in his graphs in Figure 1. Thus, he evidenced MA2 for volume and time.

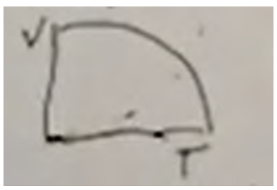

Figure 1: V-t graphs for Ice Melt, first session (left) and second session (right)

However, Azure did not extend his coordination of the direction of V with t in an anticipated way. Azure asserted that dV/dt would be positive or zero for the scenario-based conditions of the Ice Melt Task, for example, an iceberg in the ocean was said to have a small/positive dV/dt, and though he established that the direction of change of V with respect to t depended on ambient temperature, he did not evidence thinking that the rate-of-change of V with respect to t would change sign dependent upon ambient temperature. We interpret he coordinated dV/dt and t through MA1, MA3, MA4 and CL1, CL4. Azure did successfully and consistently coordinate direction of change of the magnitude of dV/dt, and so it is unclear whether 'credit' for MA2 should be given, according to the covariational reasoning framework. Specifically, he sketched Figure 2 (left) to represent an ice cube dropped into a hot cup of coffee. His figure shows dV/dt above the t-axis, with a positive sign, but he stated that the rate-of-change of volume was decreasing. He explained, "the slope of volume versus time graph is the magnitude of the dV/dt", suggesting that he associated slope with the directional coordination of V and t (MA2) but that he associated magnitude of dV/dt, which is always positive, with the rate that V changes with respect to t (also MA2, but for magnitude). Further complicating Azure's covariational reasoning, and our interpretations of it, was his quantification of rate-of-change of volume with respect to time. He defined rate-of-change of volume with respect to time as "the comparison [of volume] between two different points in time." Thus, he conceived rate-of-change as a displacement, an always-positive quantity. This would offer some confirmatory support to him when checking his own reasoning about the sign of dV/dt, or at the least, would not be a source of cognitive conflict in his reasoning with dV/dt.

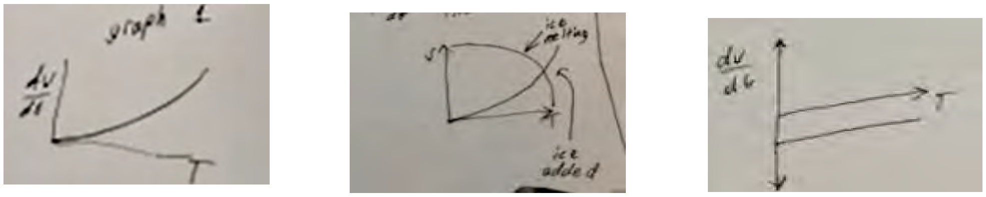

Figure 2: dV/dt-t graph for Ice Melt first session (left), V-t graphs for ice melting and ice added (middle), dV/dt-t graph for Ice Melt second session (right).

Azure evidenced imagery of amount-of-change of volume and rate-of-change of volume changing with respect to time. He stated that the rate-of-change of volume would be positive and increasing with respect to time. Azure drew two curves on the same V-t axes (Figure 2, middle) and stated, “either one of these, depending on how the problem is worded” would be correct, which suggests, similar to Jones (2019) argument, that the different quantifications of derivative can clash. Because Azure conceived of rate-of-change as always positive, the same dV/dt-t graph could represent either increase or decrease in volume. He explained that rate-of-change being positive either means that the volume is increasing (so ice is being added) or volume is decreasing (ice is melting). He noted there was no way to tell from the graph which scenario was modeled; he would need more information about the ambient temperature of the room and if water were available to re-freeze.

Azure supplied evidence that he could coordinate the amount of change of rate-of-change with change-in-time. In one instance, he argued “if it [dV/dt] is horizontal, regardless of if it’s above or below the x-axis [t-axis], it [volume] is changing. But if the V-t graph is anything but a straight line, if it’s one of these lines (indicating Figure 2 middle), the steeper this curve gets, the more dV/dt-t graph is a straight line up or down.” Working from Figure 1 (right) and Figure 2 (right), he appealed to a quantification of steepness of the graph (here the “situational referent” is figurative material in the graph). He referred to the steepness property of the V-t graph as an indicator of how closely dV/dt-t graph should resemble a vertical line. These latter instances are indicative of Jones’ extended MA4_1 and MA4_3. Azure attended to multiple attributes of volume, so it was difficult to clearly attribute MA4 and MA5 to his reasoning. He conceived negative rate-of-change of volume as equivalent to positive rate-of-change of volume when absolute “change between the initial state and the final state” are the same.

Discussion and Conclusions

Azure adeptly coordinated both change and change-in-change with time and was able to coordinate change and change-in-time with one another, by appealing to graphical properties, real-world reasoning, and without evidencing MA4 and MA5 for the V-t covariation. This observation supports Jones (2019) arguments. Azure’s conception of derivative was associated with multiple attributes of a situational referent. Sometimes dV/dt meant absolute change in volume across two times and at others meant changing intensity of that change. His conception of instantaneous rate-of-change corresponded to imagery of steepness of slope of the V-t graph, for an arbitrary time. Despite his non-normative conceptions and meanings for symbolic notation, his reasoning was consistent and correct when thinking through relations between change, rate-of-change, changes-in-change for volume and time, especially when illustrated graphically. However, his conceptions would be counterproductive for deriving models represented with arithmetic operations. Because he did not distinguish between freezing/melting graphically, he would not be able to use the graphs or his covariational reasoning to validate symbolic models and may come to inadequate conclusions about the validity of his models. We hypothesize that developing an (adequate to Azure) symbolic relationship as a model under these conditions would be challenging because of conditions he implicitly or explicitly imposed, like asymptotic behavior of the derivative directly caused by non-directionality covariation between the quantity of interest and time.

This study investigated high school Math I teachers' methods for cultivating learning spaces in remote environments, and how teachers enriched language opportunities for multilingual learners (MLs) to engage in cognitively demanding work. Eight teacher interviews, from the 2020-2021 academic school year, were analyzed using two complementary theoretical ideas: key principles of reform-based instruction for MLs and mathematical language routines. We found that when teachers co-constructed math lesson with students building on their funds of knowledge while embedding digital platform(s) the mathematics language routines were complimented, and the learning environment fostered more active engagement. This research attended to the students' and teachers' productive struggle of during the COVID-19 pandemic and how mathematics language routines and technology supported their work.

Keywords: Diversity, Equity, High School Education, Inclusion, Professional Development, and Remote Instruction

National Public Radio recently reported that some parents expressed concern regarding their children's socialization and communication skills caused by a lack of peer interaction and learning during the COVID-19 pandemic (Kamenetz & Uzunlar, 2021). Many teachers have shared their struggles of having to quickly adapt and apply practical remote instruction techniques to increase student engagement during COVID-19. Before the pandemic, teachers already had difficulty engaging multilingual learners (MLs) in rich mathematical work (Iddings, 2005; Planas & Gorgorió, 2004). For these reasons, it is imperative to apply best instructional practices within distance learning classrooms, particularly for MLs. Our research question was: How did high school mathematics teachers cultivate safe learning spaces to encourage rich academic discourse for MLs to engage in cognitively demanding work in a remote environment?

Theoretical Framework

This study was organized around two complementary theoretical frameworks: key principles of reform-based instruction for MLs and mathematical language routines. Both frameworks helped teachers think about ways to engage MLs with content in meaningful ways. The five key principles to engage MLs in mathematical work reinforced and overlapped with one another. The first principle, *build on and use MLs' funds of knowledge and resources* (Moll et al., 1992; Moschkovich, 2002), has teachers identify, celebrate, and use the knowledge and skills students, their families and communities bring to the classroom. In the second principle, *provide multilingual learners with cognitively demanding work* (Stanford Graduate School of Education, 2013), teachers are expected to focus on the Common Core State Standards – Mathematics

(NGA Center, CCSSO, 2010) and provide MLs with the opportunity to engage in the same kinds of activities and assignments often reserved for students who are not MLs (Iddings, 2005; Planas & Gorgorió, 2004). The third principle provides MLs *opportunities for rich language production* (Khisty & Chval, 2002). Teachers provide comprehensible input through listening and reading, as well as opportunities for comprehensive output through speaking and writing. The fourth principle is to identify *disciplinary language supports for MLs* (Aguirre & Bunch, 2012). Teachers attend to those aspects of language that might prove challenging for all students, including MLs, and provide adequate scaffolding for students to both interpret and produce language (Aguirre & Bunch, 2012). The fifth principle is to *create a safe classroom* that allows for intellectual risk-taking (Luria et al., 2017), where everyone is part of a community of learners and where everyone values collaboration (Choike, 2000). A safe classroom is a place where students are free to learn regardless of their race/ethnicity, social class, or linguistic background (Hernandez et al., 2013).

These principles provide the foundation for mathematical language routines (Zwiers, et al. 2017), structures that support students' productive engagement with content, and supply them with tools they can regularly return to when completing mathematical tasks (Kelemanik et al., 2016). Routines provide opportunities for students to gain access to challenging mathematical content and build important mathematical thinking habits to engage in cognitively demanding work. Teachers can use routines specifically for MLs to amplify, assess, and develop their mathematical thinking and language simultaneously (Zwiers et al., 2017).

Methods

This study was situated in a California school district where teachers participated in a two-year professional learning program organized around four cycles of studio days (Von Esch & Kavanagh, 2018). Teachers developed, implemented, and studied lessons that focused on one ML principle and one mathematical language routine during each studio day cycle. The first two cycles were conducted in person: the second two, through Zoom.

Studio Days Enactment of a ML Principle and Mathematical Language Routine
