The studio day cycle of interest here paired the principle *cognitively demanding work* with the mathematical routine Co-Craft Questions (Zwiers et al., 2017). Over Zoom, teachers participated in a series of three professional development meetings focused on *cognitively demanding work* and Co-Craft Questions. The language routine Co-Craft Questions is meant to engage students in communicating their reasoning by asking them to co-construct mathematical questions about a given context. Teachers first learned this routine in a pre-studio day Zoom session. Then, four of the teachers enacted a lesson using Co-Craft Questions over Zoom at their school during the studio day. One great advantage to using Zoom was that teachers for the first time observed one another implementing their lessons across school sites. During the final professional development day of this cycle, teachers examined student work, discussed their implementation of Co-Craft Questions, and shared challenges and successes.

Participants

Eleven teachers participated in our larger study, but we examined four focal teachers for this paper. The four focal teachers were interviewed before and after the Co-Craft Questions studio day cycle. Three of the four focal teachers were mathematics teachers: Mr. Ming, Mr. Huerta, and Ms. Parker. The fourth focal teacher, Ms. Lacrosse, was a special education co-teacher.

Data Collection and Analysis

We conducted two separate semi-structured interviews (Glesne, 2011) over Zoom with each of the four teacher participants to understand how they engaged their students, especially their MLs, in cognitively demanding work while engaging in mathematics. The pre-interview was conducted prior to the pre-studio day and the post-interview, following the post-studio day. Each interview was approximately one-hour long, was video recorded, and was transcribed. The interviews attempted to understand how well teachers provided MLs with rich language opportunities and access to mathematical content and reasoning. The interviews were divided into five parts: (1) teaching MLs in general; (2) experiencing mathematical language routines; (3) participating in studio days; (4) adjusting to remoting learning; and (5) attending to additional questions and comments.

Two researchers conducted several rounds of coding in NVivo. In the first round of coding, they independently open coded the transcripts. In the second round of coding, to categorize the data (Maxwell, 2013), they identified additional themes related to the following: (1) the five ML principles; (2) the Co-Craft Questions routine; and (3) the role of technology in remote instruction. Next, they used NVivo to produce comparative matrices (Yin, 2016).

Findings

We found that during the COVID-19 pandemic, teachers noted that their students participated more in mathematical discourse when they implemented mathematical language routines that were complemented by digital platforms. Teachers also shared successful conversations with their students in communal spaces in which both teacher and students were given opportunities to co-construct the learning environments together, intentionally intergrading funds of knowledge. Initially, each teacher indicated that their students were less likely to respond to language opportunities because of instructional changes associated with COVID-19. In response to this decrease in student participation, we identified two key themes in teachers' instructional practices. First, teachers used technology in the unfamiliar remote environment to implement mathematics language routines. Second, teachers recognized the importance of cultivating safe classroom communities, where students felt safe to ask mathematical questions and to discuss their responses. By using routines and technology, such as Co-Craft Questions with Pear Deck, teachers were able to elicit and display questions from their students. This allowed the class to review questions instantaneously, as a class collective, while making students feel comfortable to share their ideas privately, as well.

Using Technology to Implement Mathematics Language Routines in a Remote Environment

Teachers identified several ways they implemented mathematical language routines while simultaneously and strategically using technological platforms in remote learning environments. This allowed teachers to elicit sense-making and thoughtful responses from students, which they had found challenging in the new remote learning platform. Pear Deck, a Chrome add-on, allowed teachers to add interactive questions and formative assessments to their lessons. Mr. Huerta used Pear Deck in conjunction with Zoom and noted,

> For the first time this semester, it felt like…I get some insight on more than just quick math facts. That kids can respond in the [Zoom] chat or out loud, I get to see an actual constructed response from them [in Pear Deck] and having that space to like actually read it and then compare work with others. (01/12/21, 7:42-8:05)

Pear Deck made it seamless for Mr. Huerta to incorporate the language routine Co-Craft Questions into his remote instruction, "It could just be done at the beginning of every problem, and it could be…students typing. If it's on Pear Deck, it could be three kids sharing and people taking notes and conversing about it" (01/12/21, 15:51-16:06).
Routines and strategic use of technological platforms created a space for students to access mathematical texts and develop an understanding of rich mathematical language. Ms. Lacrosse explained that she also used Pear Deck with the language routine Three Reads to help students understand the language in the problems presented in class:

> We rip [the problem] apart, and we put [the problem] back together again in our Pear Deck slides. So, if we're doing something that is a word problem, we've really kind of broken it down to three or four sentences just so we can get it on the Pear Deck and start to then analyze it a little bit more. (10/12/20, 16:00)

Pear Deck provided user-friendly formatting to structure mathematical language routines and promote safe spaces for students' questions and broader student engagement.

Cultivating Safe Remote Classroom Communities

All four teacher participants valued safe classroom spaces where MLs could be supported with *disciplinary language supports* and engage in *opportunities for rich language production*. Mr. Ming explained, "I think you're able to develop a relationship with those students and to create a very safe and comfortable environment for them to go ahead and learn, and they feel comfortable making mistakes. I think that's first and foremost" (1/14/21, 23:24).

COVID-19 reshaped teacher perceptions of safe classroom spaces. For example, Ms. Parker shared that because some students had inequitable access to resources, such as the number of devices in their home, she limited the number of internet browser tabs students needed to open to participate in her class. Additionally, Mr. Huerta expressed that students in his classroom shared complaints of changing formats in their other classes, so he strived to provide consistency in the format of his class. Teachers perceived that their choices in presentation and platform correlated to students' responses and level of comfort expressed. Mr. Huerta highlighted this more clearly, explaining, "It's fascinating to see how many people will type on a Pear Deck, but won't type in a private chat on Zoom" (1/12/21, 36:42).

Discussion and Conclusion

We found that teachers strategically implemented mathematical language routines and technology to aid them in the construction of a safe and productive math learning environment in the midst of the COVID-19 pandemic. Teachers productively struggled through the pandemic with their students. By using mathematics language routines and technology platforms, teachers worked to increase the frequency of student responses, the depth of their mathematical responses, and the likelihood of persisting in *cognitively demanding work*. Complementary platforms to mathematical language routines, such as Pear Deck, provided safe spaces for students to articulate their questions and answers with peers. While strategic use of technology and mathematics language routines did not guarantee student engagement, our teacher interviews provided a deeper understanding of how teachers might effectively support some of our most vulnerable students in remote instruction.

EMERGENT SELF-REGULATION STRATEGIES OF AN UNDERGRADUATE FRESHMAN IN CALCULUS I: THE CASE OF ISAAC

Kyle R. Turner
University of Texas at Arlington
kyle.turner2@mavs.uta.edu

Keywords: Calculus, Affect, Emotion, Self-Regulation, and Undergraduate Education

Self-regulation learning strategies are defined as those “actions directed at acquiring information or skills that involve agency, purpose, and instrumentality self-perceptions by a learner” by Zimmerman and Pons (1986, pg. 615). Self-regulation can then be thought of as those skills or strategies used by students in an academic setting while attempting to synthesize and process new information, as well as how to maintain agency in one’s own learning. During the transition to undergraduate mathematics courses from high school mathematics courses such as pre-calculus or first semester calculus, freshman must navigate obstacles in their mathematics learning that may relate to the difficulty or pace of a college level mathematics course.

Using self-regulation strategies frameworks established by Wolters (1998) and Zimmerman and Pons (1986) as well as noting the transitional difficulties described by Gueudet (2008) and Sonnert et al. (2020) this poster aims to describe how first-year undergraduates use self-regulation strategies to adapt to challenges encountered in undergraduate mathematics courses.

This case study focuses on three interviews with a first-year undergraduate student taking Calculus I, Isaac. Isaac was one of three undergraduates who participated in interviews. He was enrolled at a large, urban research university in the Southwestern United States during Fall 2020. He and the two other interviewed undergraduates were selected based on their responses to a questionnaire that twenty-one undergraduates completed. The questionnaires focused on undergraduates’ educational background, demographic background, mathematical identity, use of self-regulation strategies, and expectations of college coursework. Invitations were sent based upon whether the students were first-year students and had attended high school within the last year and indicated strong performance in their past high school courses. Interviews focused on the use of self-regulation strategies during weekly in-class group lab activities. An audiovisual recording of the interviews was made. This recording was transcribed word-for-word by the researcher. The subjects were given a pseudonym to protect their identity.

After facing difficulty in an early midterm Isaac resolved to adapt his learning strategies to focus on some conceptual difficulties he recognized, such as problems involving graphs, as well as his general study habits in preparing for exams. After his first midterm Isaac resolved to spend more time on problems outside of class as well as speak to peers and instructors more when faced with difficulty. He more readily employed strategies as outlined by Zimmerman and Pons (1986) involving seeking assistance and self-evaluation by continuing lab activities past what was assigned and his attitude of persistence while facing obstacles promoted continued study aiding him in his success in a calculus course. This process produced positive results in his next exam scores so he continued using these strategies throughout Calculus I, confident that he would earn a high mark in the class. Other students may experience a similar cause for strategy development which may be generalized with further analysis. In the ongoing data collection and analysis, it will be explored how students’ self-regulation strategies interact with their mathematics identity and performance through general study habits and content-specific strategies, as well as how to encourage this development of useful self-regulation strategies for undergraduates that experience obstacles in their learning of mathematics.

A COMPLICATED RELATIONSHIP: EXAMINING THE EFFECT OF STRATEGY USE ON ACCURACY WHEN SOLVING MULTIPLE WAYS

Jeannette Garcia Coppersmith
Harvard University
jgarciacoppersmith@g.harvard.edu

Jon Star
Harvard University
jon_star@gse.harvard.edu

Strategy appropriateness lies at the core of flexibility (Star, 2005). Some problems can be completed using a so-called standard algorithm (e.g., Star & Seifert, 2006); other possible strategies may be better than the standard algorithm, where better may mean that the strategy is more elegant and/or better matched to the structural features of the problem. But what is the relationship between strategy appropriateness and strategy accuracy? Here we ask: (1) Are students more accurate when using standard approaches or better-than-standard approaches? (2) Is this relationship between accuracy and strategy appropriateness influenced by whether a problem is being solved for the first time or being re-solved?

A convenience sample of 450 high school students from 19 math classes participated in this study. Participants completed a two-part assessment where they were asked to solve five problems, each in two different ways. Responses were coded both for accuracy and type of strategy: standard, better-than-standard, and worse-than-standard. We fit a multiple regression model using the ordinary least squares regression technique and an interaction term to determine if the effect of strategy on accuracy depended on whether the student was resolving.

Our results indicate that while the standard approach was more related to accuracy as compared to the better-than-standard approach, this relationship differed by assessment part. For students' first strategy for solving each problem, the standard approach was related to a higher rate of accuracy compared to the better-than-standard approach $(t(3{,}044) = -6.728, p < .001)$. For students' second strategy, we found no significant difference in accuracy between the standard and better-than-standard approaches $(F_{1,3044} = 2.9, p = .0894)$. We also found a significant and positive interaction effect; the average effect of strategy on accuracy depended on assessment part $(t(3{,}044) = 5.901, p < .001)$. Finally, we find that the standard approach is more successful in Part 1 of the assessment compared to part 2 $(F_{1,3044} = 21.8, p < .001)$, while the above-standard approach is more successful in Part 2 of the assessment compared to Part 1 $(F_{1,3044} = 14.3, p < .001)$.

We interpret these results as suggesting that the standard approach is related to greater success in problem solving only when a student was solving a problem for the first time. However, when students are prompted to go beyond this strategy, they may be limited in the approaches they can apply successfully. It could be the case that the standard approach is more successful in part 1 because of students' greater familiarity with the standard algorithm as well as greater confidence employing this strategy. This combination of familiarity and confidence may not be the case for students who choose to employ better-than-standard approaches the first time they solve problems. This difference in order of approaches and the associated likelihood of obtaining accurate responses is a further area of study we recommend.

Chapter 8:

Professional Development & Inservice Teachers

UNDERSTANDING MATHEMATICS TEACHERS' COLLABORATIVE SENSEMAKING IN THE CONTEXT OF TEACHERS' LEARNING ECOLOGIES

Nadav Ehrenfeld
Vanderbilt University
nadav.ehrenfeld@vanderbilt.edu

Over the last two decades, researchers have portrayed quality professional development for mathematics teachers as collaborative and situated in teachers' instructional realities. However, empirical findings also point out various impediments to transforming teacher conversations into consequential learning. These findings illuminate the need to acknowledge additional resources that teachers bring to professional interactions and the need for ever more nuanced theories of teacher learning to inform teacher educators' work. Inspired by ecological models of learning, in this conceptual paper I work towards understanding teachers' collaborative sensemaking as part of broader teacher learning ecologies. I distinguish and name possible scopes and contexts for the study of teacher learning in conversations about instruction, and then identify directions for future research towards stronger connections between immediate and broader contexts.

Keywords: Learning Theory, Professional Development

Over the last two decades, many researchers have explored and documented ways to support teachers towards teaching rich mathematical content with extended student engagement, and more recently, with additional layers of responsiveness to the multiple cognitive, social, cultural and political dimensions of student learning. The resulting studies portray quality professional development (PD) as collaborative and situated in teachers' instructional context (Ball & Cohen, 1999; Borko et al., 2008; Horn, 2005; Horn & Garner, 2022; Kazemi & Hubbard, 2008). Here, I refer to these designs as Collaborative Sensemaking as Professional Development (CSPD). The situated nature of CSPD breaks away from prescription-based pedagogies that teachers often experience in typical top-down PD workshops (Kazemi & Hubbard, 2008), and its collaborative nature potentially counters the isolation that teachers often experience in schools (Lortie, 1975; Little, 1990). Other significant affordances of CSPD include providing teachers with opportunities to develop their adaptive expertise (Horn & Garner, 2022; Lefstein & Snell, 2013); supporting teachers in reconciling different perspectives on teaching (Ehrenfeld et al., 2020; van Es, 2012); and working towards more productive norms of participation in conversations about instruction (Horn & Little, 2010).

However, empirical findings also point out material, social, cultural, emotional, and cognitive impediments to transforming teacher conversations into consequential learning (Borko et al., 2008; Horn et al., 2017; Vedder-Weiss et al., 2018). For example, Horn & Kane (2015) provided evidence that limited engagement with rich conceptual resources in teacher workgroups results in limited learning opportunities, and vice versa. These findings illuminate the need to acknowledge additional resources that teachers bring to professional interactions and provide teachers with structures to reconcile these resources with local contexts. More generally, tensions between the potential and impediments for learning in CSPD underscore the need for ever more nuanced theories of teacher learning to inform teacher educators' work (Clarke & Hollingsworth, 2002; Horn, 2005; Horn & Garner, 2022; Opfer & Pedder, 2011).

Although researchers of teacher learning in conversations typically adopt sociocultural, situated and situative perspectives (Greeno, 2006; Lave & Wenger, 1991; Vygotsky, 1980)—all of which underscore the importance of context in interaction and learning—it is not always clear what contexts warrant careful attention, and which are overlooked. That is a theoretical and analytical gap central to this conceptual paper. As a review of teacher professional conversations by Lefstein et al. (2020) suggests, studies of teacher collaboration most often consider the immediate interactional context of learning, sometimes consider the institutional context of school and seldom acknowledge broader contexts, such as the multiple experiences teachers have in different settings external to school, or broader macro-level social structures. While some studies account for some of these aspects of teacher learning, there is nothing in the framing of sociocultural, situated, and situative perspectives that guides researchers towards being explicit and mindful of the contexts they account for and which they ignore.

Inspired by researchers of learning and development that take ecological perspectives (Bronfenbrenner, 1979; Erickson, 2004; Nasir et al., 2020), my overall goal is to understand CSPD environments in ways that account for the broader contexts of teacher learning ecologies, with a focus on the interactive impacts of multiple experiences in different settings, and social structures within which teachers work. Consequently, I ask *How can ecological models of learning inform research on mathematics teacher learning in CSPD settings?*

First, I discuss ecological perspectives on learning, with a focus on Bronfenbrenner's (1979) framework for studying the ecology of human development. Then, to distinguish and name possible scopes and contexts within teacher learning ecologies, I build on Bronfenbrenner's work and adapt it to the specific case of teacher learning. Finally, I move beyond distinguishing and naming contexts towards studying them as interrelated. In the final section I discuss how additional ecological models of learning (Cobb et al., 2018; Engeström, 2001; Erickson, 2004; Gutiérrez & Jurow, 2016; Horn et al., 2013; Hutchins, 1995; Nasir et al., 2020) can inform future research towards stronger connections between the immediate and broader contexts of teacher learning ecologies.

An Ecological Perspective on Learning

For the last four years, I have been part of a PD effort to support instructional growth among secondary mathematics teacher teams (Project SIGMa; Horn & Garner, 2022). Using the conceptualization of PD I introduced earlier, SIGMa would be considered CSPD, since it builds on teacher community and dialogue to respond to teachers' perceived instructional puzzles. Within this project, we learned about the teachers' personal and professional histories, their relationships with colleagues and students, and their approaches towards math teaching. Through these relationships, it became clear that the teachers' ongoing learning in the intervention was strongly related to other activities they participated in, such as workshops with our research partners, a professional development organization, ongoing conversations with colleagues, and their experiences in previous schools. This insight might seem obvious, but it stands in sharp contrast to the ways math teachers' professional learning in PD is typically examined within single activities or programs, with little to no attention to external settings and broader contexts.

Bronfenbrenner's Ecology of Human Development

Bronfenbrenner's (1979) framework provides a generalizable (Shelton, 2019) starting point for studying how teachers and their environments interact in professional development processes. Studying development "in context" could mean many things. Bronfenbrenner's call was not to study development "in context" in some general sense of development "in the real world" or "not in the laboratory" but rather to think about development in the specific context that is an ecological system, as he defines it (Bronfenbrenner, 1979; see also about his work in

Christensen, 2016; Shelton, 2019; Xia et al., 2020). It is hard to overstate the importance of this distinction for the study of teacher learning. As I mentioned, while researchers of teacher conversations often underscore the importance of context, they mainly consider the immediate local social situation and seldom acknowledge broader contexts. Considering broader contexts and their interactive impacts is essential for integrating issues such as power dynamics, class realities, and racial tensions more seriously into analysis of teacher conversation, and consequently, into teacher collaborative sensemaking.

Beyond the Microsystem

Bronfenbrenner's framework includes a collection of four nested structures of environment: microsystem, mesosystem, exosystem, and macrosystem. *Microsystems* represent the immediate settings in which the developing people engage in activities, relationships, and roles; all of which are directly influenced from participation in other settings. *The mesosystem*, rather than a layer that surrounds the microsystem, represents the relationships between two or more settings. For example, Bronfenbrenner discussed the case of mothers from two-parent families with part time jobs. Their partners might act as if they are full time mothers, and employers as if they are full time employees. The mothers themselves might experience the resulting frustration as parents, on the job, and more generally as human beings. (Bronfenbrenner, 1979, p. 212). In sum, participation in more than one setting has developmental consequences that are overlooked when we only attend to the immediate interactional context. *The exosystem* consists of settings in which the focal people of interest are not actively involved, but others who interact with them are. For example, for a child, if we consider the relations between home and school as a mesosystem, then the parents' workplace or social lives could be considered part of their exosystem, even if the child is not physically attending these settings. *The macrosystem* relates to the larger social and cultural structures within which development is taking place, including values, practices, resources, and the different types of identities they invite or discourage.

Interactive Impact of Multiple Contexts

According to reviews of literature by Tudge et al. (2009, 2016) many researchers wrongly see Bronfenbrenner's framework as a theory about the influence of context on development and use it to ask questions about the direct linear effects of individual factors (i.e., a "reductionist" or "mechanist" paradigm). In contrast, Bronfenbrenner's four nested structures of the environment are meant as a framework for exploring how different factors act synergistically towards multiplicative and non-linear outcomes. To adapt this perspective onto the realms of teacher learning, we would need to explore both the internal properties of CSPD settings themselves and how they gain their local meanings from their positioning in broader teacher learning ecologies.

Operationalizing Mathematics Teachers' Learning Ecologies

From a teacher perspective, teacher learning happens across time and settings, through a complex web of learning experiences. In contrast, a typical linear pathway perspective for teacher learning in PD assumes (often implicitly) that teachers attend PD where they develop their knowledge and beliefs, which, in turn, change their teaching practices and eventually improve students' learning (see Figure 1; Clarke & Hollingsworth, 2002). It too often focuses on the direct effects of PD interventions, where learning itself is an indicator of the effectiveness of specific curricula, programs, or core-features of PD activity (Goldsmith et al., 2014). This tendency within the field of math education reflects more general trends in research of teacher learning towards listing certain features of activity as optimal for teacher learning (e.g., Desimone, 2009). A binary perspective on features of PD as absent or present is problematic because it overlooks their specifications and interactions, which are highly consequential for teachers' learning (Opfer & Pedder, 2011). In response to such trends, many point out the lack of well developed theories that take into account more complex and nonlinear approaches towards professional development (Clarke & Hollingsworth, 2002; Horn, 2005; Opfer & Pedder, 2011).

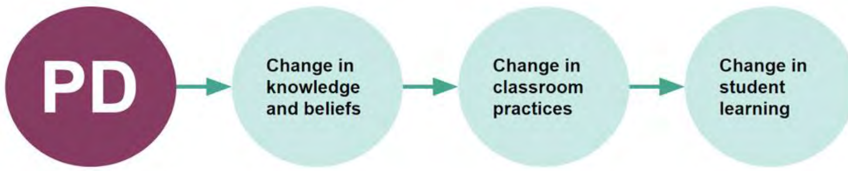

Figure 1: Linear Pathway Perspective (adapted from Clarke & Hollingsworth, 2002)

Inspired by Bronfenbrenner (1979) I suggest a framework for understanding teacher CSPD in the broader context of teacher learning ecologies. *The microsystems* included in this framework are the classroom, the settings of teacher collaborative sensemaking, informal teacher conversations, and other teacher learning settings such as PD workshops, conferences, organizations, and experiences in previous schools. *The school mesosystem* represents connections between classroom experiences, informal teacher conversations, and the focal collaborative and contextual PD setting. *The exosystem* represents connections to settings of teacher learning attended by one or more teachers or facilitators in the PD, but not necessarily by all (such as other PD workshops, conferences, organizations, and experiences in previous schools). *The macrosystem* represents the larger social and cultural structures within which the school operates, such as the school's neighborhood, or larger racial, ethnic, and civil structures. Figure 2 represents the suggested scope of an ecological perspective on teacher learning. Figure 3 represents possible contexts in the study of teacher learning in CSPD settings. Distinguishing and naming possible scopes and contexts for the study of teacher learning in CSPD settings can support researchers in being clearer about contexts they foreground and background in their design and analysis and for what reasons; in considering new aspects of learning that might be salient to their study; and in understanding the resources teachers bring to CSPD settings. The following vignette illustrates the framework as analytical lens for teacher conversations.

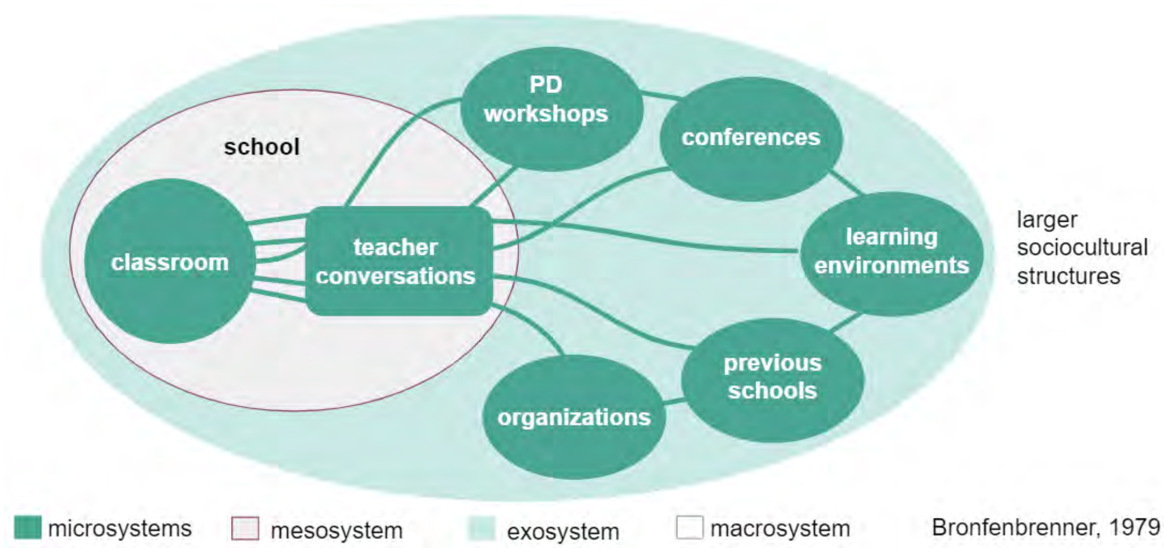

Figure 2: Suggested Scope of an Ecological Perspective on Teacher Learning in CSPD

Figure 3: Possible Contexts for the Study of Teacher Learning in CSPD

Vignette: Ezio and Veronica Discuss Grouping Strategies

To illustrate the analytical framework, consider the following vignette from Project SIGMa where two teachers discussed grouping strategies (for a careful analysis of this example see Ehrenfeld et al., 2020). In this conversation, the two teachers, Ezio and Veronica (pseudonyms), discussed Ezio's experiences in two different PD workshops: school-based Kagan training, where he learned about purposeful grouping (high and low achieving students in each group), and Park City Math Institute (PCMI), where he learned to group students randomly. Sharing his experience from the workshops, Ezio recalled how he first "did not agree" with PCMI random grouping. On the contrary, Kagan's purposeful grouping initially "made sense" to him. However, as the conversation progressed, Ezio and Veronica continued to make sense of these methods in light of their concern about tracking in their school. They discussed how purposeful grouping amplifies the consequences of tracking, in the shape of labeling kids as "dumb" or "awesome," while random grouping disrupts it. In addition, an interview with Ezio and Veronica revealed that they see tracking in their school as related to gentrification processes in their school's neighborhood. Their sense was that the principle was under pressure from newer and more affluent parents to increase tracking.

An ecological view of Ezio and Veronica's conversation highlights the following: First, teachers' opportunities to make sense of grouping strategies in the CSPD (microsystem), as an iterative process that involves experiments in the classroom (mesosystem) and experiences in two external PD workshops (exosystem). Second, it shows teacher agency with regards to both institutional structures of tracking (mesosystem) and broader social structures of gentrification (macrosystem) as structures to disrupt rather than to amplify. Third, it reveals other dimensions of the learning process, such as a trusting collegial relationship that affords ongoing inquiry into practice (microsystem). In sum, an ecological view of this example reveals learning in CSPD in the context of their broader learning ecologies (see Figure 4).

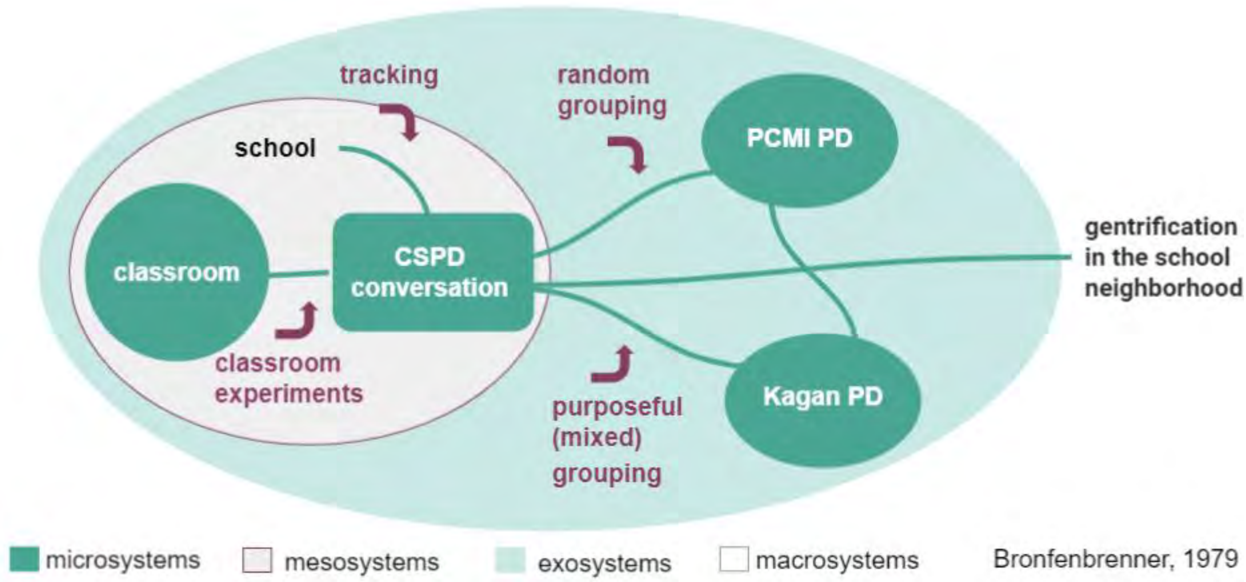

Figure 4: Suggested Scope of an Ecological Perspective on Ezio's CSPD Episode

My point is neither to diminish the value of research on the effects of specific activities (or certain features of activities) on teacher learning, nor to claim that every study of teacher learning must include all possible aspects of teachers' learning ecologies. Rather, I claim that (1) attempts to look at subsystems must be understood as partial (Opfer & Pedder, 2011) and (2) employing more complex perspectives on teacher learning would extend our ability to explain it and consequently to support teachers (Clarke & Hollingsworth, 2002; Horn, 2005).

Importantly, teachers do not experience scales and contexts as separated. In this sense, distinguishing and naming contexts should only be considered as a first step towards studying them as interrelated. In the next section I discuss how ecological models of learning can inform future research towards stronger connections between the immediate and broader contexts of teacher learning ecologies.

Future Research Directions: Connecting Immediate and Broader Contexts of Teacher Learning Ecologies

The claim that we need stronger theoretical connections between the immediate and larger contexts of teacher learning reflects more general calls to see interaction and learning both through a social microscope and a social telescope (Erickson, 2004). I will support this claim by looking at three examples of such calls. The first example comes from the recently published *Handbook of the Cultural Foundations of Learning*, wherein Nasir et al. (2020) conceptualize learning as "occurring along culturally organized learning pathways—sequences of consequential participations and transitions in learning activities that move (or do not move) one towards greater social recognition as competent in particular learning domains and situations" (p. 195). Nasir et al. made the overall claim that focusing only on local learning interactions limits our understanding of the cultural, relational, affective, and contextual nature of learning and their intersections with systems of power.

A second example comes from the work of Fred Erickson. In his book *Talk and Social*

Theory (Erickson, 2004), he likewise pointed out the need to better theorize connections between the immediate contexts of interaction and larger ones. Erickson discussed problems in contemporary social theories with regards to such connections, his main argument being that social theorists such as Foucault, Bourdieu, Gramsci and Fairclough are mostly showing “top-down” influences and are seldom attending to “bottom-up” or “inside-outside” ones. That is, they explain well how social order and structures of power are being reproduced by processes of socialization, normalization, hegemony, and the formation of discourses, but they fail to see the ways persistence and change of structures happens altogether by people in their everyday lives.

Along these lines, a third example is from the work of Gutiérrez and Jurow (2016). Conceptualizing social design experiments, Gutiérrez and Jurow extend traditions of design-based research and call for paying specific attention to ways participants reorganize their systems of activity to disrupt structural and systemic injustices. This emphasis is of particular interest to the world of mathematics education which is rife with normalized injustices and inequities (Chen & Horn, 2020; Louie, 2017). By building on their studies in the contexts of student leadership and food justice movement, Gutiérrez and Jurow (2016) describe different forms of learning, among them developing an understanding of oneself and other with relation to history and systems of power, increasing the capacity to use new conceptual tools, and giving rise to new forms of knowledge that develop across multiple contexts.

Tying the three examples back to the topic of mathematics teacher learning, I discuss how these and other ecological models for learning (Bronfenbrenner, 1979; Cobb et al., 2018; Engeström, 2001; Erickson, 2004; Gutiérrez & Jurow, 2016; Horn et al., 2013; Hutchins, 1995; Nasir et al., 2020) can inform research of teacher learning ecologies. Specifically, I identify three forms of investigations of learning that ecological models highlight (see Figure 5), and then “translate” them into three future directions for research of teacher learning.

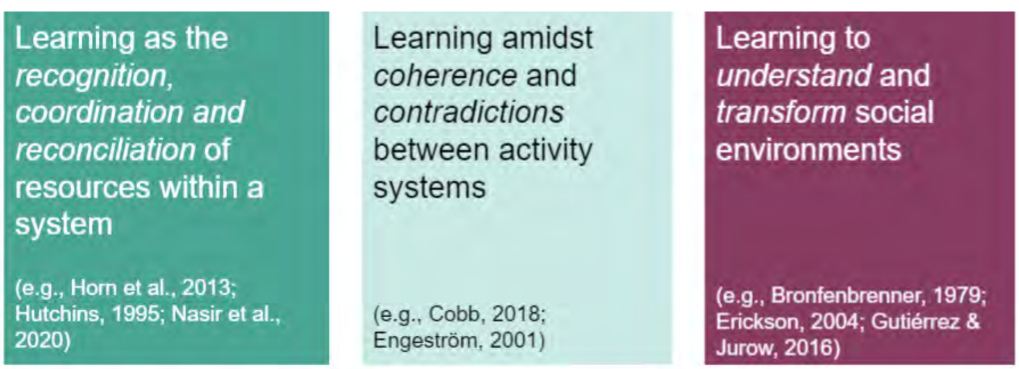

Figure 5: Ecological Forms of Learning Investigations

How do Teachers Reconcile Their Local Contexts With Circulating Resources?

Within the context of activity systems, a main form of learning is the recognition, coordination and reconciliation of resources (Horn et al., 2013; Hutchins, 1995; Nasir et al., 2020). Typically in research on math teachers’ learning, resource-centered approaches reflect the linear pathway perspectives (Figure 1), where instructional resources (e.g. practices, curricula, frameworks) are examined in the context of the PD interventions in which they are introduced (Sztajn et al., 2017). An ecological perspective on CSPD suggests the utility of a different resource-centered approach. In CSPD settings, as Ezio’s example illustrated, teachers themselves often draw on educational ideas that circulate across settings for their own sensemaking in their local contexts (Horn, 2005; Stengel, 1991). Indeed, I suggest that a critical aspect in the study of teacher collaborative learning is the articulation of mechanisms by which teachers reconcile local contexts with a range of circulating conceptual resources (Ehrenfeld et al., 2020).

What is the Role of Coherence and Contradictions in Teacher Learning?

In this section, I do not suggest that future research needs to decide whether coherence or contradiction are "better" for learning. Rather, I follow Opfer & Pedder (2011) and suggest that we should focus on causal explanations so that we understand under what conditions, why, and how teachers learn from coherence and contradictions between resources at hand. To do so, I compare and contrast Cobb et al.'s (2018) systematic perspective on teaching improvement efforts with Enge (2001) expansive learning. On the one hand, Cobb et al.'s (2018) systematic perspective on teaching improvement efforts specifically emphasizes coherence as conducive for instructional improvement towards ambitious and equitable math teaching. Others, such as Engeström (2001), describe contradictions as a force for learning. Engeström (2001) focuses on learning as constructing new practices that emerge from contradictions and hybridization (also Ehrenfeld & Heyd-Metzuyanim, 2019; Ward et al., 2011). We may hypothesize that coherence is more productive for normative and well-defined learning goals; whereas contradictions may be more productive for non-normative and disruptive trajectories.

How do Teachers Learn to Restructure Their Local Environment?

Bronfenbrenner's (1979) goal was to theorize the way people develop within and across changing settings "in both the immediate and more remote environment" (p. 11). He conceptualized human development as follows:

> Human development is the process through which the growing person acquires a more extended differentiated, and valid conception of the ecological environment, and becomes motivated and able to engage in activities that reveal the properties of, sustain, or restructure that environment at levels of similar or greater complexity in form and content. (Bronfenbrenner, 1979, p. 27, emphasis added)

In light of this definition, and in line with the argument that we need to better understand intersections between different contexts of teacher learning, I suggest that we need to investigate both separately and with relation to each other the processes by which teachers learn to reveal, sustain, and restructure their local environments, in particular, with relation to history and the disruption of harmful power relations (Gutiérrez & Jurow, 2016).

Discussion

The overall goal of this conceptual investigation was to work towards understanding teacher CSPD environments in ways that account for the larger contexts of teacher learning ecologies. First, inspired by Bronfenbrenner's work, I suggested an ecological perspective for teacher learning and analytic framework for considering different contexts and scales in the study of teacher conversations. Second, inspired by a larger set of ecological models for learning, I suggested three future research directions for studying these contexts and scales as interrelated. Ultimately, such perspective would open new spaces for thinking about, seeing, and designing for ecological teacher learning in SCPD settings.

TRACING TAKE-UP ACROSS PRACTICE-BASED PROFESSIONAL DEVELOPMENT AND COLLABORATIVE LESSON DESIGN

Jennifer Valerio
University of Pennsylvania
valerioj@upenn.edu

This study explored how two professional development approaches to reforming math instruction with different mechanisms for fostering change might have valuable synergies when used in tandem to support ***take-up****, i.e., teachers' acceptance, adoption, and incorporation of ideas into practice. This investigation of Practice-Based Professional Development and Collaborative Lesson Design found that take-up was a recursive process that occurred across both PD types as teachers iteratively moved between building and deploying knowledge. Both overarching and practice-specific struggles occurred during enactment, triggering shifts back to knowledge building. Struggles associated with learning to facilitate productive struggle included making sense of student thinking, identifying and providing appropriate scaffolds without lowering the cognitive demand, and helping students move from intuitive to mathematical arguments.*

Keywords: Professional development, Teacher knowledge, Instructional vision

Introduction

Decades of research suggest that aligning math instruction with how children learn math involves prioritizing student sense-making and instructional activities that require mathematical reasoning and productive struggle (Stigler & Hiebert, 1999; Boaler, 2016). Research-based reform of math instruction therefore involves changing the way teachers teach, shifting from an "I do, we do, you do" model to responsive engagement with students and their ideas, as well as changing the types of learning activities that are used in classrooms, shifting from repetitive practice and closed questions to rich, worthwhile math tasks. The challenge lies in finding an approach to professional development (PD) that addresses changes to the "how" of teaching (teachers' instructional practices) as well as to the "what" of teaching (the lesson plans and instructional activities teachers use in their classrooms).

Objectives

This study explored how two PD approaches to reforming math instruction with different mechanisms for fostering change might have valuable synergies when used in tandem to support the translation of a reform-oriented vision of math instruction into practice. While ample research has focused on opportunities for learning that occur within communities of practice like those present in these PDs, I have focused specifically on individual teacher *take-up*, i.e., teachers' acceptance, adoption, and incorporation of ideas into practice, in an effort to address a gap in existing research spotlighted by Lefstein et al. (2020). This investigation of Practice-Based Professional Development (PBPD) and Collaborative Lesson Design (CLD) was aimed at helping to conceptualize and identify instances of *take-up* and was guided by the following research questions:

1. How do individual teachers demonstrate take-up of ideas?
2. What connections are there between individual teacher take-up of responsive teaching practices in PBPD and take-up that occurs in CLD?

Theoretical Framework

Teaching is a complex art that involves not only what the teacher is doing but also what the students are asked to do-— interweaving of instruction and curriculum. Professional development (PD) that addresses changing one without changing the other can create "problems of enactment," i.e., teachers who want to teach in a new way but lack either the curriculum resources or the teaching skills to enact this new vision (Kennedy, 1999). Ineffective PD drains precious resources of time and money while fostering little change in classrooms, so endeavoring to better understand how take-up of ideas from PD occurs is a worthwhile avenue of investigation.

Collaborative Lesson Design (CLD) focuses on changing teaching by improving the planning process and lesson plans teachers use to enact lessons. In this professional development model, researchers and teachers work together within a community of practice and within a local context to co-create and continually revise lesson plans based on reform priorities (Hiebert & Morris, 2012). It is assumed that the lesson design cycle, which consists of planning, enactment, reflection, and revision, is a high-leverage opportunity for teacher learning and that the use of CLD could surface core teaching practices and give teachers the opportunity to become skilled in these practices through induction and refinement in their own classroom context. The challenges that arise when using the CLD model, however, include the possibility that without any training in a new set of pedagogical skills, teachers may face the "problem of enactment" described by Kennedy (1999), i.e., vision change without the necessary skills to enact the new vision, making teachers unable to execute the lesson plans as the creators intend.

Practice-Based Professional Development (PBPD), by contrast, focuses on changing teaching through pedagogical training in enacting core teaching practices, i.e., specific instructional skills including launching problems and facilitating discussions (Grossman, 2018). This model assumes that pedagogies of enactment, including representation, decomposition, and approximation, (Grossman et al., 2009) are high-leverage opportunities for teacher learning and that practices such as discussion facilitation are applicable in any classroom setting. Further, PBPD also assumes that learning core practices provides an opportunity for teachers to rethink their lesson design for their particular context. Challenges arise, however, in the transfer of pedagogical skills to specific educational contexts, and a parallel "problem of enactment" may occur if vision change occurs without the necessary resources to enact it (e.g., if a teacher, equipped with facilitation skills for high quality math tasks finds herself working with a curriculum devoid of those tasks). In the absence of a supportive community of practice and reform-oriented teaching materials, teachers may struggle to put their teaching practices to use as practice-based educators intend.

Research on professional learning communities and generative discourse has proliferated over the past two decades (Lefstein et al., 2020). Often, the focus of this research is on opportunities for learning and there is an implicit leap of faith involved in connecting what occurs in these communities with individual learning and particularly with what occurs in individual teachers' classrooms. Situative theory, which attends to "how various settings for teachers' learning give rise to different kinds of knowing" (Putnam & Borko, 2000, p. 6), provided a theoretical foundation for this case study research. I examined evidence of take-up in PBPD and CLD settings in order to ascertain whether and how these opportunities for learning impacted individual teachers' classroom practices.

Context

The Responsive Math Teaching (RMT) Project a research-practice partnership between university researchers and 13 schools within a large under-resourced urban school district, engages K-8 teachers and instructional coaches in three years of professional development focused on utilizing worthwhile math tasks as a vehicle for responsive teaching and for fostering student productive struggle (Responsive Math Teaching Project, 2021a). Since this is a departure from traditional teaching practices, participants spend Year 1 experiencing responsive math teaching as *learners* in monthly Math Circle PDs before moving on to focusing on how to teach responsively in Year 2. Prior to the pandemic, Year 2 professional development primarily utilized practice-based approaches supplemented with individual coaching to help participants shift their math instruction to align with the RMT instructional model (Responsive Math Teaching Project, 2021b), which emphasizes reform priorities that include student sense-making, use of low floor/high ceiling tasks, and teachers acting as facilitators of both productive struggle and rich, responsive discussions. In response to the move to virtual instruction and requests from participants for curriculum support to supplement PD focused on responsive teaching, the RMT Project began incorporating CLD in the fall of 2020. Although the RMT Instructional Model includes seven components, this study focused on four: 1) Launching a Task, 2) Facilitating Productive Struggle, 3) Making Student Thinking Visible, and 4) Connecting to a Mathematical Goal. These are the four practices that were represented, decomposed, and approximated most often during RMT PBPD and the four components of lesson planning emphasized most consistently during the CLD sessions involving planning, reflection, and revision of lessons.

Methods

Participants

RMT professional development offered to Year 2 participants consisted of six 5-week cycles that included one practice-based professional development (PBPD) session and two collaborative, cross-school, grade-specific lesson design (CLD) sessions: a planning session followed by a reflection/revision session. I utilized a comparative case study approach, purposefully selecting 14 participants who attended PD sessions most consistently. These participants represented classroom teachers and math leads (grades 1-8) from 10 different schools. All participants taught primarily in a virtual environment with some hybrid instruction integrated at the end of the year. Some participants were recommended for RMT PD by their principals and others were simply volunteers. In this paper, I focus on one case from the study, chosen because it is both illustrative of the overall study findings and because the focal participant was the "best case" (Patton, 1987) in the sense that she was strictly a classroom teacher and not a math coach, was not at a school that received supplemental coaching from RMT researchers or RMT-trained school personnel, and attended all PBPD and CLD sessions.

Data Collection

Data collected and reviewed included videotapes, audio transcripts, and chat transcripts of PBPD and CLD sessions; observational field notes; participant journals; participant responses to feedback forms for each cycle; and participants' artifacts of practice in the form of video and audio recordings and student work samples. For each of the 14 study participants, data from all of the aforementioned sources were compiled chronologically on a spreadsheet, wherein color coding was used to differentiate between PBPD, CLD Planning, and CLD Reflection session data. Direct quotes from comments made in PD sessions and from journal and chat entries were captured verbatim and parenthetical descriptions were added to contextualize each quote, including journal prompts, facilitator questions that prompted the comment or summaries of the preceding discussion. During the data collection and compilation process, analytic memos were written for each PD session summarizing observations about both individual and group take-up.

Data Analysis

A pilot study focusing on Cycle 1 data for five teachers was conducted in fall 2020 to create and test data analysis tools. I used the practice grain size and terminology established by the Core Practice Consortium (Grossman, 2018, pp. 186-189) to develop of a list of *aspects*, component parts of larger practices, and *approaches*, actions taken by teachers when enacting an aspect of a practice, using both emergent approaches and approaches included in RMT coaching materials. This list was reviewed and further refined with input from three RMT research team members. Although the full list is too extensive to include here, the aspects and approaches for Facilitating Productive Struggle (FPS) are shown below in Figure 1.

Practice	*Aspects*	*Approaches*
Facilitating productive struggle (FPS)	Supporting learner thinking without lowering the cognitive demand	• Relaunching the task with students who can't get started • Using models, diagrams, or acting out to help a student get unstuck • Using questioning and/or annotation to help a student make sense of their own thinking • Determining how much support/scaffolding is just enough • Pointing out an approach that has helped another student or group get started • Providing "just in time" tools or supplies • Coaching mathematical participation by suggesting a "what would happen if" scenario • Coaching mathematical participation by asking a student to convince others
	Providing opportunities for collaboration	• Providing opportunities for students to work in pairs or small groups • Scaffolding collaboration by orienting students toward each other • Strategically pairing students with similar or complementary strategies
	Monitoring student work	• Monitoring group work for progress and group dynamics • Keeping track of strategies being used • Looking for / capitalizing on opportunities to assign competence • Finding ways to observe student work in progress in a virtual setting

Figure 1: Aspects and Approaches for Facilitating Productive Struggle

Inductive data analysis during the pilot study also resulted in the identification of 9 emergent *take-up manifestations*, i.e., ways in which participants demonstrated take-up, shown in Figure 2 below. Kazemi & Hubbard (2008) drew on Cook & Brown's (1999) earlier work to distinguish between "*knowledge* that is possessed and *knowing* that is deployed in action" (p. 429), a distinction I used to sequence the manifestations in order of the level of action they entailed, moving from knowledge building to knowledge deployment during enactment and finally to sustained integration into classroom practice.

Noticing	Expressing awareness of a practice aspect. May occur with or without identifying the pedagogical reasoning behind the practice aspect.
Agreeing	Affirming another's comment about a practice aspect.
Asking	Asking a question or expressing confusion about a practice aspect.
Suggesting	Recommending a way to incorporate or improve upon a practice aspect. May occur with or without advocacy.
Prioritizing	Expressing a belief that a practice aspect is important.
Raising a concern	Noting a lag between one's vision of a practice aspect and one's ability to enact it.
Enacting	Executing a practice aspect. May be evident in a teacher's description of a lesson or in lesson video or audiotape artifacts.
Critiquing	Making critical comments about one's own execution of a practice aspect or giving critical feedback to others, including suggestions for improvement.
Sustaining	Integrating a practice aspect into regular classroom instruction beyond the task-based lessons enacted as part of the CLD professional development.

Figure 2: Manifestations of Take-Up (shown from early to late stage by gray coloration)

Working chronologically, data for each participant was coded inductively on two levels (Miles, Huberman, & Saldana, 1994): first for practice aspect using the list of approaches in Figure 1 and then for manifestations of take-up. For example, a participant journal comment might have been coded for FPS aspect "Supporting learner thinking" based on the presence of the approach "Using a model to help a student get unstuck" and for take-up manifestation "noticing." This coding made it possible to trace the development of each practice aspect chronologically over the course of the year in order to identify *threads*, i.e., progressions from low level to higher level take-up. Using a mapping process borrowed from expansive learning research (Bal, Afacan, & Cakir, 2018) to visually display these chronological threads also surfaced the presence of *struggles*, i.e., recurrent dilemmas that hampered take-up progress across one or more cycles.

Summary memos were written for each participant for each of the four focal practices. These memos were compared to exit interviews for triangulation purposes. Data was also validated via member reflection sessions in order to engage participants as collaborative partners and to ensure that their perspectives were accurately represented (Creswell & Poth, 2018). Dialogic engagement with strategically selected thought partners was used on 4 occasions to refine study design and to perform validity checks on data analysis processes and findings (Ravitch & Carl, 2016).

Results

While a number of additional findings emerged from this data analysis, here I will focus on two: 1) Take-up is a recursive, iterative process during which teachers cycle between knowledge building and knowledge deployment in action; 2) Two different types of struggles emerged that triggered a shift from knowing in action back into the realm of knowledge building: *overarching struggles* and *aspect-specific struggles.* Four types of overarching struggles spanning multiple practices were observed: *vision preceding skills, skill development with incomplete vision buy-in, belief that a practice cannot be enacted with particular content or with a particular group,* and *difficulties enacting practices virtually.* In addition to overarching struggles, other struggles emerged that were unique to specific practice aspects. Here, I focus on struggles that emerged from the FPS aspect "Support learner thinking without lowering the cognitive demand." These struggles included *difficulty making sense of student thinking different from one's own solution strategy, difficulty identifying and providing appropriate scaffolds in real time without lowering the cognitive demand,* and *difficulty helping students move from intuitive to mathematical arguments.* To illustrate these findings, I will focus on Melanie, a fifth and sixth grade math teacher whose case is representative of the larger group.

Demonstrations of take-up over time

Tracing take-up threads across PD sessions enabled me to construct narrative accounts of how take-up occurs, often progressing from low level take-up evident in noticing and agreeing remarks to higher level take-up evident in enactment and critiquing over the course of a single PD cycle or across multiple PD cycles as shown in Figure 3 below.

Tracing Take-Up for Melanie	
PBPD	Take-up of FPS aspect *support learner thinking without lowering the cognitive demand* first occurs when Melanie **agrees** with a comment about the difficulty of responding to a student strategy that you don't understand when the student hasn't articulated it well.
CLD	This practice aspect resurfaces in the next CLD planning session, when Melanie **prioritizes** finding ways to support students who can't find an entry point to start the task, noting, "*This is going to be the bulk for me. I'll have 20% of my class who will be able to navigate this task, who will be interested or intrigued. But then I do fear for the children who are just like, 'I don't know what to do.'*" Melanie continues to pursue this topic by **asking** the group how to best provide support. When Melanie returns to the CLD reflection session, she recounts **enacting** this practice aspect with a student in her classroom and **critiques** her enactment because she feels that she funneled the student to her own solution strategy instead of trying to follow the student's thinking.
PBPD	Melanie continues to focus on this FPS aspect, which surfaces again in a subsequent PBPD as **noticing** that FPS involves providing stepping stones that are enough but not too much of a stretch for the student. During the same PBPD, Melanie analyzes the RMT Instructional Model and **notices** that to support learners appropriately, "*you need enough scaffolds..You need to know your learners and have scaffolds so that the struggle is productive. It's not just straight struggle.*" Melanie's **noticing** continues as she analyzes a video of a teacher executing FPS and is able to pick out effective support moves that the

	teacher used. She also **suggests** another scaffold that the teacher in the video could have used.
CLD	In the next CLD planning session, Melanie **suggests** a scaffold for the task and also **prioritizes** "*helping a student get unstuck without doing it for them*," noting that the scaffold should only be used if a student were struggling and should not be given to the whole class just in case. After **enacting** the planned lesson, Melanie **critiques** her enactment specifically in terms of how much support she provided to the students and **raises a concern** about the balance she is striking in her class between supporting students and doing the work for them. She notes, *I don't feel like my kids take risks anymore. When I say work on it..they just sit there and wait knowing that I'm going to pop over to my whiteboard and sort of draw something, and you know, help them out, and I actually think that they're right. So, I'm coming to this conclusion: I'm taking on too much of the load.* When Melanie shares a video clip of her lesson, she **asks** whether she had responded to a student question by giving too much assistance. As the group discusses her video, Melanie **agrees** with an alternative talk move suggested by the group. Moving beyond agreement, Melanie **prioritizes** supporting students by making an FPS "talk moves wall" behind her computer screen with post-it reminders of questions to ask that she can refer to during her instruction. Melanie later completes a feedback form on which she describes using questions from the RMT FPS framework to support students in explaining their thinking during her regular, daily instruction, a **sustained** effort to integrate this practice aspect into her teaching.

Figure 3: Example of a Narrative Constructed from Take-Up Tracing

Melanie's narrative above highlights a common overarching struggle I have termed *vision preceding skills.* Here, her competence enacting FPS lagged behind her vision of what FPS should look like, prompting iterative returns to knowledge building. Melanie's narrative also exemplifies *difficulty making sense of student thinking different from one's own solution strategy* which surfaced as funneling a student towards Melanie's own solution path rather than helping her make progress on her own. Also evident in Melanie's narrative was *difficulty identifying and providing appropriate scaffolds in real time without lowering the cognitive demand.* Struggle points in Melanie's narrative and the resulting shifts into forms of take-up associated with knowledge building are visually displayed in Figure 4 below.

As evident in Figure 4, struggles often surfaced during enactment and reflection, prompting a renewed effort to build knowledge in order to refine skills. Narratives such as Melanie's examined across multiple cycles made clear that take-up is not simply a linear progression from low level to high level but rather an iterative process across both PD contexts in which noticing, asking questions, and suggesting remain essential in fostering enacting and critiquing and ultimately in the honing of teaching practices.

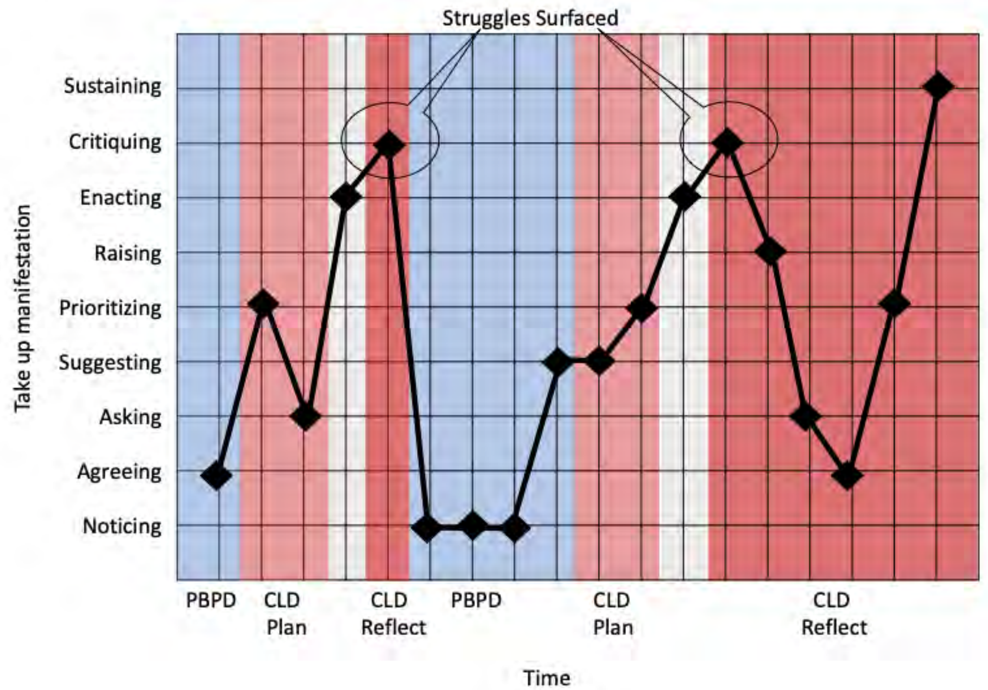

Figure 4. Melanie's Take-Up of FPS Aspect "Supporting Learner Thinking"

Discussion

Both take-up threads and their mapping made evident synergies between CLD and PBPD by highlighting instances when one form of PD provided opportunities for increased take-up of practice aspects originally taken up in the other. In early cycles, PBPD sessions focused on representation and decomposition of practices and most often fostered knowledge-building forms of take-up, including noticing, agreeing, and asking. Early on, suggesting, prioritizing, enacting and critiquing were primarily evident in CLD. CLD provided an early and consistent impetus to move beyond knowledge building and into knowledge deployment—beyond learning into experimentation, as 8th Grade teacher Leann noted, "*If we didn't need to do it for this [CLD Reflection Session], I might've not pushed myself to get it in.*" As the year progressed, however, and PBPD incorporated rehearsal and reflection on video artifacts, the types of take-up became more varied across both forms of PD. As learners focused their attention on specific practice aspects and specific struggles that emerged when enacting the practices, both PBPD and CLD sessions showed an uptick in the number of take-up manifestations across participants.

In my effort to focus on individual take-up, by no means did I intend to downplay the critical role played by the communities of practice formed within and across both types of PD. Discourse in each setting was not only generative but also fostered collective take-up in ways that were beyond the focus of this study. Instead, my intention was to shed some light on how participation in these communities impacted individual teachers' classroom instruction, a path less trodden in the field (Lefstein et al., 2020). Understanding how group and individual take-up intersect, with an eye towards classroom impact, remains an area in need of further investigation.

This study examined how mathematics coaches leverage written annotations to support professional discourse with teachers about important classroom events during synchronous debriefing conversations. Coaches and teachers created the annotations while asynchronously watching video of an implemented lesson as part of online video-assisted coaching cycles. More specifically, this project examined the extent to which a coach and teacher discussed the annotations during a debrief conversation in a coaching cycle. We present a rationale for needing new knowledge about the relationships between video annotations and professional discourse as well as the potential implications of such knowledge.

Keywords: Inservice Teacher Professional Development, Research Methods, Coaching

Coaching cycles have become a popular professional development activity to support teachers to plan for, implement, and reflect on ambitious instructional practices (Gibbons & Cobb, 2016). A coaching cycle typically consists of three parts including a coach and teacher collaboratively: (a) planning a lesson around specific learning outcomes for students and the use of instructional practices necessary to support student learning, (b) implementing the lesson and instructional strategies, and (c) reflecting on the success of the lesson using evidence of student learning and the teacher's use of new instructional strategies during a debrief conversation (Bengo, 2016; West & Staub, 2003).

Professional developers use video during coaching cycles for two primary reasons. First, video recording the lesson implementation, when paired with synchronous planning and debriefing conversations using distance technologies, allow coaching cycles to occur in a fully online space (Carson, Callard, Gillespie, Choppin, & Amador, 2019; Matsumura, Correnti, Walsh, Bickel, & Zook-Howell, 2019). Second, viewing video of one's own teaching has been shown to effectively support teachers to identify areas of improvement by providing a durable image of what occurred (Borko, Jacobs, Eiteljorg, & Pittman, 2008; Harlin, 2014; Rosaen, Lundeberg, Cooper, Fritzen, & Terpstra, 2008). Although using video during online coaching cycles has potential benefits, few researchers have examined how the content of what teachers and coaches notice during the viewing of lesson videos impacts debriefing conversations. Because the decisions made by a coach regarding how to facilitate coaching cycle conversations have been shown to significantly impact the learning opportunities of the teacher (Costa & Garmston, 2016; Heineke, 2013), this study examined the question, how do coaches and teachers discuss the annotations from lesson videos during debrief conversations within coaching cycles?

Theoretical Framing

Teacher noticing has become a common construct within research on mathematics teachers (Sherin, Jacobs, & Philipp, 2011; Star & Strickland, 2008). Teacher noticing describes the ability to sift through the many events taking place simultaneously within a classroom to identify important moments worthy of attention (Walkoe, 2015). The ability to notice what is important during complex classroom situations is a key characteristic of expert teachers (Berliner, 2001). In their framework, van Es and Sherin (2002) expanded the idea of professional noticing beyond simply identifying salient moments into three aspects: (a) identifying what is important during a teaching event, (b) reasoning about the event, and (c) making connections between this specific event and larger principles of teaching and learning. Productive teacher noticing also involves the ability to attend to and interpret student thinking so teachers can make decisions to respond in ways that positively impact student learning (Jacobs, Lamb, & Phillip, 2010; Miller, 2011).

A teacher or coach using an annotation to make their thinking public about a moment in a lesson video corresponds to the act of professional noticing (Amador, Carson, Gillespie, & Choppin, 2019). Furthermore, a teacher and coach have many choices throughout the annotation process, both about the events to mark as noteworthy and about how they communicate their thinking about these events of interest (Mason, 2011). Sherin (2007) adopted the term *professional vision* to emphasize the role of *selective attention* as a key subprocess of mathematics teachers' professional vision. Selective attention describes how a teacher focuses their attention given the many things happening within a single moment. In this study, we examined the interaction between the annotations (i.e. the highlighted moments) and what the teacher and coach discussed during the debrief conversation (e.g., their selective attention).

Related Literature

Several researchers have examined different aspects of the use of video within the specific context of online coaching cycles. Matsumura et al. (2019) found the use of video in online coaching cycles supported teachers to use new instructional practices, leading to improved student participation during class discussions. Gregory et al. (2017) argued that teachers involved in video-based online coaching cycles had improved student achievement, peer interactions, and a reduction in racial disparities. Both researchers made claims about the impact of video-based online coaching cycles, but neither articulated the ways in which viewing video supported professional discourse between a coach and teacher within the debrief conversations. Amador et al. (2019) examined the differences in the annotations created by coaches and teachers while watching lesson video within video-assisted online coaching cycles. They found coaches were more likely than teachers to focus on students and make connections within their annotations but did not explore the ways the coach and teachers made use of the annotations during the debrief discussion.

We explored the ways teachers and coaches took up the recorded noticing (i.e. the annotations) during a debrief conversation. Specifically, the study focused on how teachers and coaches used the annotations to conduct a debriefing conversation.

Methods

This study occurred within the coaching activity of a larger, fully online, professional development project created for middle school mathematics teachers working in rural areas (Choppin, Amador, & Callard, 2015; Choppin, Amador, Callard, Carson, & Gillespie, 2020). The project consisted of three parts: an online course, online teaching labs, and video-assisted online coaching cycles designed to improve teacher practices for implementing high cognitive demand tasks and facilitating mathematical discourse (Smith & Stein, 2011). Using a cohort model, 21 teachers from grades 5-8 participated in the project as part of two cohorts, each lasting two years. In the coaching cycle portion of the project, teachers were partnered with coaches using a content-focused coaching model (West & Staub, 2003).

Participants

This study focused on seven coaches and their assigned teachers who engaged in video-assisted coaching cycles in the professional development project. Each coach was assigned one or two cohort teachers, resulting in nine coach/teacher pairings. Data were collected from the debriefing conversations of the coach/teacher pairs in addition to the annotations created by the coach and teacher when watching the lesson video prior to the discussion.

Context: Video-assisted Coaching Cycles

The goal of each video-assisted coaching cycle was to support participating teachers to successfully implement productive discourse practices (e.g., Smith & Stein, 2011) discussed during the online course and teaching labs. Each coaching cycle followed the same structure and utilized both synchronous and asynchronous activities (see Figure 1). First, the coach and teacher participated in a planning discussion using video conferencing technology, Zoom, focused on a lesson proposed by the teacher. Guided by the content-focused coaching model, participants collaboratively analyzed the mathematical lesson goals, the tasks used in the lesson, the anticipated student strategies, and the instructional practice goals for the teacher (West & Staub, 2003). Following the planning meeting, the teacher video- and audio- recorded the teaching lesson using Swivl Technology (automated video camera and recording). After the lesson was taught, the coach and teacher asynchronously watched and annotated the lesson video. Annotations were written comments about the contents of the lesson video. The coaching cycle concluded with the coach and teacher engaging in a forty to sixty minute debrief discussion that utilized the annotations to reflect on the lesson.

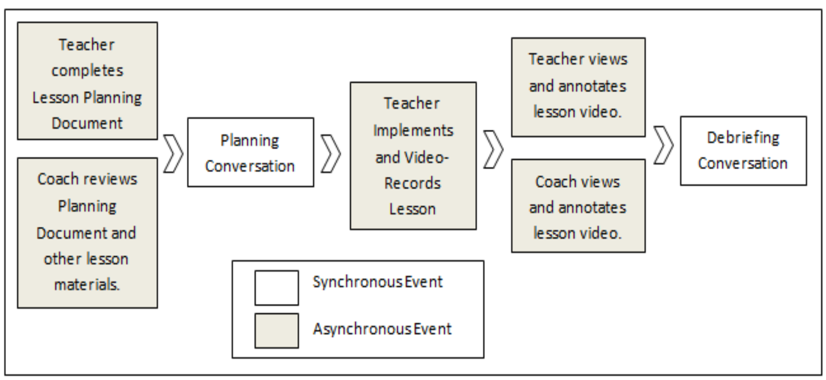

Figure 1*:* Video-assisted coaching cycle process

Data Collected

We analyzed the video annotations created by the coaches and teachers and the corresponding debriefing conversations from the third coaching cycle for nine coach-teacher pairs. The third coaching cycle was selected because it allowed the teachers and coaches time to become accustomed to each other and the video-assisted coaching process (Matsumura, Bickel, Zook-Howell, Correnti, & Walsh, 2016). Using the third coaching cycle data resulted in the analysis of video annotations from nine video-recorded lessons and the nine corresponding debrief conversations. All nine debrief conversations were video-recorded using Panopto screen-capture and then transcribed. Transcripts were parsed into stanzas which including the coach's discursive move and/or the teacher's discursive move about a particular topic (Sa , 2013). A single video annotation served as the unit of analysis.

Data Analysis

The data analysis process began with the researcher entering annotation data into a spreadsheet. This data included: the annotation text, the author of the annotation, the number of the annotation in the full set, and the timestamp connecting the annotation to a specific moment in the lesson video. The researcher then watched the video of the debrief conversations from the third coaching cycles and read the transcriptions of the conversations.

To identify instances when coaches and teachers discussed the annotations during debrief conversations, two binary variables were created to code the presence of a written annotation within an instance of verbal discussion. Both variables were assigned a code of yes or no for each annotation. The first variable, *indicated connection to annotation*, described instances when the coach or teacher clearly indicated that their verbal statement connected to a written annotation. The second variable, *verbatim use of annotation,* described instances when the verbal statement of the coach or teacher matched the written language in the annotation verbatim. If the coach or teacher explicitly indicated their verbal statement connected to an annotation or if a verbal statement matched a written annotation verbatim, there was reliable evidence that an annotation had been taken up in conversation. In instances when indication was coded no and it was debatable if a significant portion of an annotation matched a spoken statement verbatim, the researcher used the video of conversation to consider the context. In these ambiguous instances, if the annotation was present on the coach's screen at the time of the spoken statement, such instances were coded as verbatim. If the annotation was not on the coach's screen at the time of the spoken statement, such instances were coded as not verbatim.

An annotation was considered to have been discussed in the conversation if either variable was coded yes, since the presence of either variable provided a reliable indication that the written annotation influenced the discussion. If both indication and verbatim were coded no, the annotation was considered not to have been discussed in the conversation (see Figure 2). A single annotation could have been discussed multiple times throughout a conversation. Therefore, each time an annotation was brought into the conversation, the annotation was coded using the two variables and labeled as a new instance of annotation discussion.

Annotation considered present in the debriefing conversation. (green)

Annotation considered not present in the debriefing conversation. (red)

		Verbatim Does the spoken statement of the coach/teacher match language from the annotation verbatim?	
		Yes (Verbatim)	**No (Not Verbatim)**
Indication Does the coach/teacher clearly indicate (via spoken language or through technology features such as sharing a screen) that their verbal statement connects to an annotation?	**Yes (Indication)**	*Verbatim with Clear Indication*	*Not Verbatim with Clear Indication*
	No (No Indication)	*Verbatim with No Indication*	*Not Verbatim and No Indication*

Figure 2: Coding scheme for determining the presence of an annotation during debriefing conversations.

To illustrate the coding process with these two variables, an example is provided. Coach Alvarez created an annotation, "And what did you learn about students' understanding? How did this inform your lesson?" During the debriefing conversation, Alvarez said,

> I wondered then, again at 7:35, just what you thought about what you learned about students understanding, from the warmup, and then how that informed your lesson. Were there takeaways that you had from the warmup that made you think differently about your lesson?

Because Alvarez explicitly mentioned the timestamp of the annotation, she provided a clear indication her question was connected to the annotation. Therefore, indication was coded as yes. Alvarez also included the phrases "learned about student understanding" and "how that informed your lesson" in her verbal questions. Therefore, verbatim was also coded as yes.

If an annotation was considered to be discussed within an instance of the conversation, four additional codes were applied to each instance of annotation discussion to gain further insight into the research question. First, we coded for who initiated the conversation about the annotation, the coach or teacher. Second, we coded for who created the annotation. Third, we recorded the stanza number from the transcript in which the instance of annotation discussion began. Fourth, we recorded the stanza number from the transcript in which the discussion of the annotation ended. Coding the starting and ending stanzas for an instance of annotation discussion allowed us to analyze the length of discussion about an annotation and to determine if a single annotation was discussed multiple times throughout the conversation.

As an example of this coding process, coach Lowery created the annotation, "What do other people think about what he just said about using the difference of 5? His point highlights the relationship and bears repeating by another voice (preferably a peer before the teacher)." In stanza 12 of the debrief transcript, coach Lowery initiated conversation about this annotation. The discussion about the annotation continued until the end of stanza 13 when the conversation moved to a topic not contained in the annotation. In stanza 16, teacher Fernandez initiated additional conversation about this annotation which continued until the end of stanza 17. Therefore, the researcher recorded two instances of annotation discussion for this coach-created annotation; one initiated by the coach with a starting stanza of 12 and an ending stanza of 13 and the second initiated by the teacher with a starting stanza of 16 and an ending stanza of 17.

Findings

In total, we analyzed 308 annotations the nine coach/teacher pairs created during nine debriefing conversations. Of this total, coaches created 158 annotations and teachers created 150 annotations. In analyzing the extent coaches and teachers talked about the annotations, the process revealed 96 of the 308 annotations were taken up, resulting in an average of 10.7 annotations discussed per conversation. Because some annotations were discussed more than once during a conversation, 110 instances of annotation discussion were identified resulting in an average of 12.2 instances of annotation discussion per conversation (see Table 1). However there existed variability between the coach/teacher pairs with respect to their verbal uptake of written annotations. For example, coach Braithewhite and teacher Summers had only three instances of annotation discussion about three separate annotations despite collectively creating 50 annotations prior to the conversation. Conversely, coach Bishop and teacher Parsons had 23 instances of annotation discussion about 21 separate annotations after creating 23 total annotations prior to the discussion. This suggests differences in how these coach/teacher pairs interpreted the role of the annotations during video-assisted coaching cycles. This finding also highlights a range for the number of annotations that can be discussed within a single debrief conversation.

Table 1: Annotation Discussion Counts by Coach/Teacher Pair

Coach/Teacher	Annotations Created	Annotations Discussed	Instances of Annotation Discussion
Alvarez/Graham Marks	59	11	13
Bishop/Parsons	23	21	23
Bishop/Wise	14	9	12
Braithewhite/Summers	50	3	3
Hale/Swanson	47	9	11
Lowery/Fernandez	25	11	15
Riess/Larson Waters	27	10	10
Riess/Sandoval	23	5	7
Whilton/Morrison	40	15	16
Average	34.2	10.7	12.2

To further examine the extent coaches and teachers talked about the annotations during debriefing conversations, the percentage of transcript stanzas containing instances of annotation discussion were calculated. The number of stanzas containing an instance of annotation discussion was divided by the total number of stanzas in the conversation. For example, the Bishop/Wise conversation transcript contained 40 stanzas. Instances of annotation discussion occurred during stanzas eight and nine and in stanzas 18 through 29. Therefore, 14 of the 40 total stanzas (35.0%) contained instances of annotation discussion. When this analysis was done for all 364 stanzas within the nine debrief conversations, 41.4% of stanzas contained an instance of annotation discussion. This finding indicated annotations were taken up in debrief conversations but were not the sole focus on conversation since less than half of the stanzas contained instances of annotation discussion. Similar variability also existed when comparing the percentage of stanzas containing instances of annotation discussion between different coach/teacher pairs. For example, in the debrief conversation transcript between coach Whilton and teacher Morrison, 62.5% of the stanzas contained instances of annotation discussion. However, for coach Hale and teacher Swanson, only 20% of the conversation stanzas were found to have instances of annotation discussion.

Table 2: Instances of Annotation Discussion within Conversational Stanzas

Coach/Teacher	Total Number of Stanzas in Conversation	Number of Stanzas Containing an Instance of Annotation Discussion	Percentage of Stanzas Containing an Instance of Annotation Discussion
Alvarez/Graham Marks	37	23	62.2%
Bishop/Parsons	67	30	44.8%
Bishop/Wise	40	14	35.0%
Braithewhite/Summers	25	4	16.0%
Hale/Swanson	40	8	20.0%
Lowery/Fernandez	41	20	48.8%
Riess/Larson Waters	43	14	32.6%
Riess/Sandoval	31	12	38.7%

Whilton/Morrison	40	25	62.5%
Average	40.6	16.7	41.1%

Analyses also explored whether coaches or teachers were more likely to initiate conversation about the annotations. Coaches initiated conversation about the annotation more frequently than teachers. Of the 110 instances of annotation discussion, 91 (82.7%) were initiated by the coach and only 19 of the instances (17.3%) were initiated by the teacher. This finding was consistent across coach/teacher pairs as the coach initiated more than 70% of instances of annotation discussion for seven of the nine pairs.

Annotations coaches created were discussed more frequently than those teachers created despite the fact that roughly half of the annotations for the nine coach/teacher pairs were teacher created. Of the 110 instances of annotation discussion, 74 (67.3%) focused on coach-created annotations compared to only 36 of the instances (32.7%) focused on teacher-created annotations. This trend was found within instances of annotation discussion initiated by both teachers and coaches. Of the 19 instances in which teachers initiated discussion about annotations, 13 of these instances (68.4%) focused on coach-created annotations. Of the 91 instances when coaches initiated discussion about annotations, 61 of these instances (67.0%) focused on coach-created annotations. When combining the findings about initiating annotation discussion and the creator of the annotations, coaches initiating conversation about coach-created annotations was the most common occurrence with 61 of the 110 (55.5%) instances of annotation discussion meeting these criteria. The least common occurrence was teachers initiating conversation about a teacher-created annotation. This occurred in only six of the 110 (5.5%) instances of annotation discussion (see Table 3 for additional information).

Table 3: Comparison of Annotation Discussion Initiation and Annotation Authorship

	Instances of Discussion about Coach-Created Annotations	Instances of Discussion about Teacher-Created Annotations	Total
Instances of Coach-Initiated Annotation Discussion	61 (55.5%)	30 (27.3%)	91 (82.7%)
Instances of Teacher-Initiated Annotation Discussion	13 (11.8%)	6 (5.5%)	19 (17.3%)
Total	74 (67.3%)	36 (32.7%)	110 (100%)

These findings suggest coaches were more likely to initiate conversation about the annotations and tended to discuss annotations they created. These findings highlight that coaches exerted significant influence regarding the selection of annotations to discuss and focused on annotations containing their own ideas about the lesson.

Discussion

Findings from this study contribute to existing literature on coaching in three ways. First, prior studies have claimed that the use of video within coaching cycles held the potential to improve teaching practices (e.g., Gregory et al., 2017; Matsumura et al., 2019). However, prior studies did not provide any description about how the coaches and teachers took up the lesson video and annotations during conversations, leaving the actions of both coaches and teachers within the activities unknown. For professional development providers wishing to successfully implement video-assisted coaching, the findings from this study partially fill this crucial gap by highlighting a range for the number of annotations discussed within a single debrief conversation. This knowledge may support both teachers and coaches in selecting a limited number of focal annotations from a larger set when preparing for a debrief discussion. Additionally, findings about the percentage of stanzas containing annotation discussion also may support coaches and teachers to prepare for reflective discussions, which often are constrained by a limited amount of time. For example, this study revealed that even in extreme cases, less than two-thirds of the stanzas contained annotations discussion and eight of the nine coach/teacher pairs discussed 15 or fewer annotations within a single conversation. Thus, when given a fixed amount of time for a debrief conversation (commonly constrained by school logistics such as the length of a preparation period), these findings may support a coach and teacher to set realistic goals regarding how much of their conversation could be dedicated to annotation discussion.

Second, these findings contribute the existing literature about variability of coaching actions within coaching cycles. Prior studies have shown the actions of coaches when engaging teachers in conversation can vary significantly (e.g., Heineke, 2013; Sailors & Price, 2015). This study extends these claims about variability of coaching actions to the ways in which coaches take up annotations during debriefing conversations. The large range found in both the *number of annotations* discussed in the debriefing conversations and the *number of transcript stanzas* containing instances of annotation discussion suggest significant variability in the ways the coach leveraged the annotations to catalyze discussion. This variability may be due to different interpretations about the role of the annotations to support teacher learning. For example coach Braithewhite and teacher Summers created 50 annotations prior to the debriefing conversation. Yet, only three of these annotations were discussed with 16% of the transcript stanzas containing instances of annotations discussion. Conversely, coach Bishop and teacher Parsons created 23 annotations prior to the debrief discussion and discussed 21 of these annotations. In this case, 44.8% of the stanzas contained instances of annotations discussion. These differences suggest coach Bishop and coach Braithewhite may have held different views about how to use the annotations to initiate productive reflective opportunities for teachers. Such differences may have significant impact on teachers because diversity in the actions of coaches has been shown to influence learning opportunities of teachers (Heineke, 2013; Sailors & Price, 2015). Although these findings cannot be directly used to make claims about teacher learning, they do suggest teachers such as Parsons and Summers had different learning experiences when engaging in reflective discussion about video annotations.

Third, the finding that coaches initiated more annotation discussions than teachers and the tendency of coaches to initiate conversation about their own annotations connects to claims made by Mosley Wetzel and colleagues (2017) regarding implications of power within coaching conversations. They argued a coach holding a formal position of power is often perceived as being more accomplished and knowledgeable than the teacher. Therefore, the actions of the coach and their position of power may have implications for a teacher's learning experience. Akin to coaches positioning themselves as the authority through the use of *directive* discourse moves versus positioning the teacher as the authority through the use of a *reflective* discourse moves (e.g. Ippolito, 2010), coaches tendency to initiate conversation about their own annotations and the infrequency of teachers initiating conversations about their own annotations raises new questions about the power dynamics within video-assisted coaching cycles.

Specifically, if the goal of written annotations is to support teachers to verbally reflect on their practice, should coaches strive to position teachers to more frequently initiate conversation about their own annotations? Or, is it more beneficial for teachers to have coaches initiating conversation about coach-created annotations? Future research should examine these questions regarding how the differences in the ways coaches use annotations during debrief conversations impact teachers' learning experiences.

PROFILES OF TEACHERS' EXPERTISE IN PROFESSIONAL NOTICING OF CHILDREN'S MATHEMATICAL THINKING

Victoria R. Jacobs

vrjacobs@uncg.edu

Susan B. Empson
University of Missouri
empsons@missouri.edu

Noticing children's mathematical thinking is foundational to teaching that is responsive to children's thinking. To better understand the range of noticing expertise for teachers engaged in multiyear professional development, we assessed the noticing of 72 upper elementary school teachers using three instructional scenarios involving fraction problem solving. Through a latent class analysis, we identified three subgroups of teachers that reflected different profiles of noticing expertise. Consideration was given to the noticing component skills of attending to children's strategy details, interpreting children's understandings, and deciding how to respond on the basis of children's understandings. We share theoretical and practical implications for not only the three profiles but also our choice to explore separately two versions of deciding how to respond (deciding on follow-up questions and deciding on next problems).

Keywords: Teacher Noticing, Professional Development, Elementary School Education

Our work is aligned with a vision of teaching that is responsive to children's mathematical thinking. In this vision, teachers attend to and pursue the substance of children's ideas and important mathematical connections within those ideas (Richards & Robertson, 2016). This type of responsive teaching builds on research on children's mathematical thinking and connects to numerous policy recommendations, but has proven challenging to achieve (Cai, 2017; National Council of Teachers of Mathematics, 2014; National Research Council, 2001).

Efforts to support teachers in achieving this vision have included attention to core practices of teaching (Grossman, 2018; Grossman et al, 2009; McDonald et al., 2013). We focus on one of the core practices—teacher noticing—that has been researched extensively in mathematics education (for compilations, see Schack et al., 2017; Sherin et al., 2011). Although multiple conceptions exist, *teacher noticing* fundamentally refers to how teachers focus their attention and make sense of what children say and do so that teachers' instructional responses are productive.

We chose to focus on teacher noticing of children's mathematical thinking, with an awareness that this type of noticing is only one of many that teachers must use to be successful. Examples of noticing research with different foci include curricular noticing (Amador et al., 2017), racial noticing (Shah & Coles, 2020), and noticing of participation and status (Kalinec-Craig, 2017; Wager, 2014). We view these different types of noticing as potentially mutually supportive in that using one focus as a starting point can provide entry into other types of noticing. In this study, we foreground noticing children's mathematical thinking as foundational for teaching that is responsive to children's thinking—one can only be responsive to what one has noticed. Further, research has shown that teachers usually do not gain this expertise solely from teaching experience (Copur-Gencturk & Rodrigues, 2021), but it can be learned (see, e.g., Casey & Amidon, 2020; Lee, 2019; Roth McDuffie et al., 2014; Schack et al. 2013; Simpson & Haltiwanger, 2017; van Es & Sherin, 2008).

Our conception of teacher noticing comes from our earlier work on professional noticing of children's mathematical thinking in which we identified three component skills: (a) attending to children's strategy details, (b) interpreting children's understandings reflected in their strategies, and (c) deciding how to respond on the basis of children's understandings (Jacobs et al., 2010). This final skill—deciding how to respond—refers to teachers' intended responses because teacher noticing is invisible, happening prior to teachers' observable responses. The three component skills are conceptually and temporally linked, and in the midst of instruction, they often occur almost simultaneously. They are not ends in themselves, but collectively are foundational for making productive instructional responses that build on children's thinking.

In this study, we extended our earlier work by identifying profiles of noticing expertise that include consideration of teachers' expertise with each of the component skills. By better understanding how teachers in multiyear professional development (PD) take up and engage in the complex practice of teacher noticing, we should be better able to support them in developing this expertise. Thus, we investigated the following research question: *What meaningful profiles of teachers' expertise in professional noticing of children's mathematical thinking exist among teachers engaged in multiyear PD?*

Methods

The data were drawn from a larger PD design study in which the goals included building a model of teaching that is responsive to children's mathematical thinking (Empson & Jacobs, 2021, these proceedings). In this paper, we focus on one instructional practice in the model—professional noticing of children's mathematical thinking—and use teachers' responses to a noticing assessment to identify profiles of expertise across the component skills.

Participants

We assessed the noticing expertise of 72 upper elementary school teachers—68 classroom teachers (grades 3–5) and 4 teaching specialists (instructional facilitators, resource teachers, etc.)—who had voluntarily enrolled in our PD. The teachers (64 females and 8 males) were generally experienced, with their teaching experience ranging from 2 to 36 years ($M = 11.8$).

To develop our noticing profiles, we purposefully studied teachers who were at different points in our 3-year PD and worked in a variety of contexts. Specifically, data were collected during one school year when teachers were at the end of their first ($N = 22$), second ($N = 26$), or third ($N = 24$) year of PD. Teachers worked in 3 districts in a state in the southern United States. The districts had varied instructional histories in that all administrations had endorsed teaching that was responsive to children's thinking, but for different amounts of time. Further, teachers were drawn from 36 schools that reflected a range of student demographics. Across the schools, students who qualified for free or reduced-cost lunch ranged from 10%–98% ($M = 59.7\%$) and students classified as Limited English Proficiency ranged from 2%–85% ($M = 33.3\%$). Student race and ethnicity classifications also varied. White students ranged from 6%–85% ($M = 49.6\%$), Hispanic students ranged from 4%–81% ($M = 34.8\%$), Black students ranged from 0%–20% ($M = 4.3\%$), Hawaiian and Pacific Islanders students ranged from 0–31% ($M = 5.4\%$), and students with race and ethnicity classifications of "other" ranged from 0%–14% ($M = 6.0\%$).

Professional Development

Our PD consisted of more than 150 hours of face-to-face workshops offered over 3 years, and the overall goal was to help teachers develop expertise in teaching that is responsive to children's mathematical thinking, with special emphasis on the teaching and learning of fractions (Jacobs, Empson, Pynes, et al., 2019). Key resources included research-based frameworks of children's mathematical thinking (Carpenter et al., 2015; Empson & Levi, 2011) and research-based frameworks of instructional practices, such as noticing children's mathematical thinking (Jacobs et al., 2010) and questioning to support and extend children's mathematical thinking (Jacobs & Ambrose, 2008; Jacobs & Empson, 2016).

Noticing Assessment

We captured teachers' noticing expertise using a written assessment that was structured around three instructional scenarios in which teachers had opportunities to notice children's thinking linked to fraction story problems. The scenarios were conveyed via authentic, strategically selected artifacts of practice—a classroom video, a set of children's written work, and a video of a teacher's conversation with one child. We chose the three scenarios because we wanted to capture teachers' noticing expertise throughout the multiple facets of their work.

For each instructional scenario, teachers responded, in writing, to prompts linked to the component skills of noticing children's mathematical thinking (see Table 1). Note that we included two prompts for the final skill of deciding how to respond. We chose to keep separate the prompts (and scores) for deciding on follow-up questions and deciding on next problems because the two categories of deciding how to respond are conceptually distinct, and we wanted to better understand their relationship to teachers' overall noticing expertise.

Table 1: Writing Prompts for the Noticing Assessment

<table>
<tr><th colspan="2">Noticing Component Skills</th><th>Sample Writing Prompts</th></tr>
<tr><td colspan="2">Attending to children's strategy details</td><td>Please describe in detail what you think each child did in response to this problem.</td></tr>
<tr><td colspan="2">Interpreting children's understandings</td><td>Please explain what you learned about these children's understandings.</td></tr>
<tr><td rowspan="2">Deciding how to respond on the basis of children's understandings</td><td>Deciding on follow-up questions</td><td>Imagine that you are the teacher of these children and you want to have a one-on-one conversation with one of them. Which child would you choose? Describe some ways you might respond to their work on this problem, and explain why you chose those responses.</td></tr>
<tr><td>Deciding on next problems</td><td>Imagine that you are the teacher of these children. What problem or problems might you pose next? What is your rationale?</td></tr>
</table>

Scoring

Each teacher received 12 noticing scores—4 scores for the noticing component skills within each of the 3 instructional scenarios. Drawing on our past research (Jacobs et al., 2010), scoring was done holistically on a 0–2 scale indicating the extent to which we had evidence for teachers' engagement with children's mathematical thinking: lack of evidence (0), limited evidence (1), or robust evidence (2). We double-coded all data (in a blinded format) and interrater reliability for all 12 noticing scores was 80% or higher. Discrepancies were resolved through discussion.

For the attending-to-children's-strategy-details score, we looked for inclusion of mathematically significant details such as how children used drawings to represent and partition quantities, how they combined fraction amounts, or how they described amounts using fraction names or notation. For the interpreting-children's-understandings score, we did not seek a single best interpretation but instead looked for an emphasis on what children understood (versus did not understand) and reasoning that was consistent with and grounded in the children's strategy details. For the deciding-on-follow-up-questions score, we did not seek a single best set of follow-up questions but instead looked to see if the questions and rationales were reasonable, meaning that they were consistent with the children's strategies and understandings. We also looked to see if the questions centered children's thinking not only by asking about details *inside* their existing strategies (Jacobs, Empson, Jessup, & Baker, 2019) but also by leaving room for children's ways of thinking (versus funneling children toward a particular strategy or answer [Wood, 1998]). For the deciding-on-next-problems score, we did not seek best next problems but instead looked for problems that were consistent with teachers' rationales. We further looked to see if the rationales linked to children's understandings and left room for children's thinking.

Findings

Our goal was to identify profiles of noticing expertise across the noticing component skills. We began by determining that the internal consistency for the noticing assessment was adequate, as indicated by Cronbach's alpha of .77. We then conducted a latent class analysis to empirically identify subgroups of the 72 teachers displaying similar patterns of responses across their 12 scores—4 scores for the noticing component skills within each of the 3 instructional scenarios. We considered the response patterns for these subgroups as profiles of teachers' expertise in professional noticing of children's mathematical thinking. Our goal was not to "label" teachers but instead to better understand variation in teachers' expertise in this practice.

We considered a 3, 4, and 5-profile solution, and we chose the 3-profile solution based on (a) the lowest Bayesian Information Criteria goodness-of-fit statistic (Schwarz, 1978), (b) conceptually interpretable profile patterns, and (c) sufficient sample sizes for comparison among profiles. We then assigned each teacher to the profile for which they had the highest probability based on their response pattern across the noticing assessment. The 3-profile solution generated ordered profiles that we labelled *Accomplished Noticing* ($N = 14$), *Mixed Noticing* ($N = 33$), and *Emerging Noticing* ($N = 25$). The profile means of teachers' overall noticing scores (computed as a mean of their 12 scores) reflected this ordering: 1.42, 0.98, and 0.61, respectively. Our assessment design allowed us to further characterize the expertise associated with each profile in terms of the noticing component skills, and we were especially interested in whether mean scores were above or below a score of 1—the midpoint in our 0–2 scale that indicated limited evidence of engagement with children's mathematical thinking (see Figure 1).

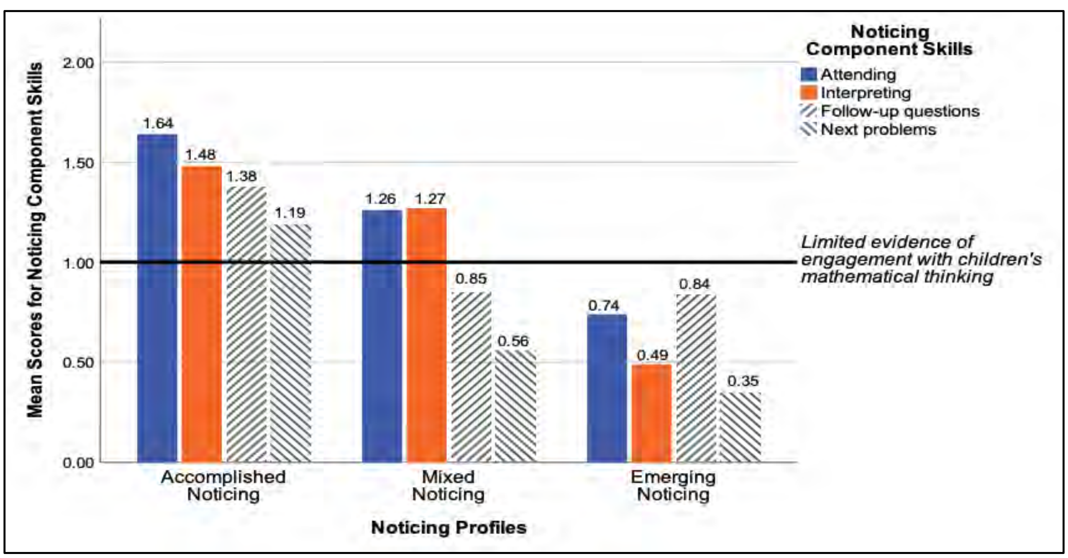

Figure 1: Mean Scores for Noticing Component Skills by Noticing Profile

The *Accomplished Noticing* profile was characterized by consistently strong expertise, with all mean scores above 1. For these teachers, expertise in attending to children's strategy details was their strongest skill and deciding on next problems was the skill for which they showed the most room for growth. The *Mixed Noticing* profile was characterized by a split performance, with mean scores above 1 for attending to children's strategy details and interpreting children's understandings, and mean scores below 1 for the two deciding how-to-respond skills. Thus, these teachers had developed substantial expertise in making sense of children's strategies, but they were still learning what to do with that information in terms of an instructional response. Finally, the *Emerging Noticing* profile was characterized by consistently weak expertise, with all mean scores below 1. However, their pattern of means scores showed that they were beginning to notice the details of children's thinking and pose follow-up questions about those details, but that they particularly needed support in making sense of what those details meant in terms of children's understandings and how to craft problems that built on those understandings.

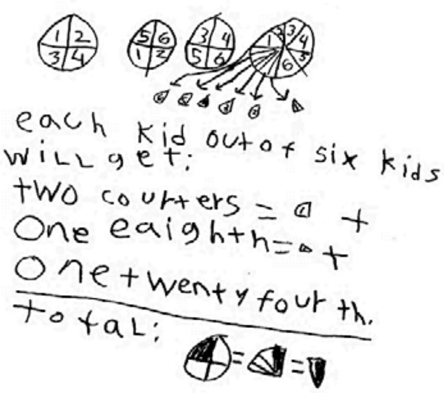
We also noted two major patterns across the profiles. First, the mean score for deciding on follow-up questions was higher than the mean score for deciding on next problems for all three profiles, reinforcing the importance of our separate consideration of these two categories. A related finding was that the mean score for deciding on next problems was the lowest score for all three profiles, which is consistent with earlier findings documenting this skill's challenging nature (Jacobs et al., 2010, 2011). Second, the mean score for attending to children's strategy details was one of the top scores for all profiles, suggesting the foundational role that details play in teachers' ability to make sense of and build on children's thinking (Jacobs & Spangler, 2017).

Figure 2 illustrates this second pattern for a teacher with an *Accomplished Noticing* profile. We share samples of her responses linked to Joy's written work for the pancake problem. Joy had a correct solution with a non-traditional final answer—she used words and pictures of fraction pieces (rather than fraction symbols) and did not combine her amounts into a single total. All sample responses were scored as robust evidence of engagement with children's mathematical thinking. For attending to children's strategy details, the teacher richly described Joy's strategy, highlighting details such as multiple partitions (4ths, 8ths, and 24ths) and why Joy might have made those partitions. For interpreting children's understandings, she focused on what Joy *did* understand, drawing on Joy's strategy details of (a) repeated halving, which is a common strategy for young children (Empson & Levi, 2011), and (b) correctly naming a fractional amount (1/3 of 1/8) which is challenging for many children. For deciding on follow-up questions, she made extensive use of strategy details, asking Joy how she partitioned, how she named the 1/24th-size pieces, and whether she had a sense of the amount each child would receive. She consistently centered Joy's thinking, and even her last question that moved beyond Joy's strategy to explore other possible partitions left room for Joy's thinking (versus funneling it toward the teacher's thinking). For deciding on next problems, she posed the same problem with new numbers that built on Joy's initial strategy that involved fourths (and repeated halving). Her rationale drew on this strategy detail to anticipate Joy's new strategy, and problem numbers were chosen strategically—9 pieces (for 9 sharers) cannot be reached by partitioning into fourths thereby making visible whether Joy could partition differently, such as by the number of sharers.

Across this teacher's responses for the component skills, strategy details were visible and integral to her reasoning. In contrast, for responses with scores of limited evidence or lack of evidence, we saw progressively less attention to strategy details in the initial strategy descriptions and throughout the other component skills. At times, teachers even focused on changing the child's strategy to one that they preferred.

<table>
<tr>
<td colspan="2">Joy's Strategy for the Pancake Problem

The teacher has 4 pancakes to share equally among 6 children. How much pancake does each child get?



</td>
</tr>
<tr>
<td>*Attending to Joy's strategy details*</td>
<td>Joy drew her 4 pancakes and cut them into 1/¼ I believe she did that because she is comfortable with 1/¼ When she reached her last pancake, she realized 1/¼wouldn't get each person a pancake piece. I think she then divided it into 1/8s. Again, I think 1/¼and 1/8s are comfortable for her. After she numbered 6, she realized she had 2 pieces left so she divided the last two 1/8s into 6 pieces. I believe she counted the pieces as if thirds were in each 1/8 to come up with twenty-fourths.</td>
</tr>
<tr>
<td>*Interpreting Joy's understandings*</td>
<td>**…** Joy has a good grasp of repeated halving (or fourth-ing). She continued to use 1/¼and 1/8s until she was able to solve the problem. She was however able to identify what [1/3] of 1/8 was. That impressed me and would be a question I'd pose to her.</td>
</tr>
<tr>
<td>*Deciding on follow-up questions for Joy*</td>
<td>• Can you tell me what you did? (To understand the thinking behind the work)
• Why did you split the first 3 pancakes into 4 pieces? (To understand the rationale, to see if she saw the relationship with the people)
• Tell me about the last pancake. (I want to see what she was thinking when she split this pancake)
• You wrote here 1/24. Can you show me 1/24 in the picture? How do you know that is 1/24? (What thinking was behind this decision to split the pieces? What understanding does she have about it?)
• Do you know how much the kids will get altogether? (Can she add her pieces?) Is it more than 1/½r less? More than 1 or less?
• Is there another way to split the pancakes? (Does she see the connection now?)</td>
</tr>
<tr>
<td>*Deciding on next problems for Joy*</td>
<td>*The teacher has 5 pancakes to share equally among 9 children. How much pancake does each child get?*

… I was curious to see if Joy would start with 1/¼and divide the pancakes into smaller pieces to solve the problem.</td>
</tr>
</table>

Figure 2: Sample Responses Linked to Joy's Strategy (*Accomplished Noticing* Profile)

Discussion

We began this study with the assumption that all participating teachers had strengths as teachers. They chose to engage in our PD to enhance their teaching by learning about children's mathematical thinking and its pivotal role in instruction—learning about noticing children's mathematical thinking was a piece of that learning. By assessing teachers' noticing expertise and empirically identifying three profiles of expertise, we hoped to better understand how teachers were taking up and engaging in this practice so that we could better support their development. We purposefully chose to assess teachers with varying amounts of PD because we know that teachers learn, and implement what they learn, at different rates, and we wanted to capture as much variety as possible. Our findings replicated our earlier work (Jacobs et al., 2010) in new grade levels (upper elementary grades versus primary grades) and with new mathematical content (problem solving with fractions versus problem solving with whole numbers). We also extended this work in two main ways: (a) elaboration of the deciding-how-to-respond component skill, and (b) identification of profiles of noticing expertise.

Elaboration of the Deciding-How-to-Respond Component Skill

In our earlier work, we introduced the inclusion of the deciding-how-to respond component skill in teachers' noticing of children's mathematical thinking, and we explored either decisions about follow-up questions or decisions about next problems, but not both together (Jacobs et al., 2010, 2011). In this study, we asked teachers to make both decisions for each instructional scenario so that we could compare teachers' engagement with children's thinking in the two categories of deciding how to respond with the same set of children's strategies. We found that teachers consistently showed more expertise when deciding on follow-up questions than when deciding on next problems, and this relationship held for each of the three profiles. This finding may reflect how teachers often have little experience deciding on next problems that build on children's understandings, and they may even wonder if they have the freedom to craft their own problems (or adjust existing problems) given the widespread, systemic use of resources such as pacing guides and mandated textbook materials.

In short, we would encourage the theoretical bifurcation of deciding how to respond because teachers engaged differently with each category, and both are important to teachers' work. We would also suggest including opportunities to practice both categories in PD, with an awareness that deciding on follow-up questions may initially be more accessible. Gaining expertise in posing these follow-up questions has other benefits as well because these questions can serve as leverage points for teachers' learning. Follow-up questions not only provide teachers with information about a specific child's thinking, but over time they also help teachers increase their understanding of children's mathematical thinking in general (Franke et al., 1998, 2001).

Identification of Noticing Profiles

Each profile had strengths and room to grow, and thus they provide snapshots of developing expertise. Theoretically, the profiles extend our earlier work in which we characterized expertise in each component skill but did not provide a conceptualization for how the skills might work together differently for individual teachers (Jacobs et al., 2010). Our profiles provide this conceptualization and suggest that teachers in different profiles may need different types of support (see also, Munson, 2020). We provide some initial suggestions for customization.

Teachers with an *Accomplished Noticing* profile demonstrated strong expertise across component skills, but still with room to grow. Focusing on challenging examples—complex or ambiguous strategies—could provide these teachers with opportunities to refine their expertise (Jacobs, Empson, Pynes, et al., 2019). Teachers with a *Mixed Noticing* profile demonstrated some expertise, with more expertise in attending to children's strategy details and interpreting children's understandings than with the two deciding-how-to-respond skills. Focusing on typical and straightforward strategies could provide these teachers with opportunities to easily make sense of children's strategy details and related understandings so that they could concentrate on how to build on these understandings with follow-up questions and next problems. Teachers with an *Emerging Noticing* profile had substantial room to grow in all component skills, but their mean scores for attending to children's strategy details and deciding on follow-up questions were relatively higher. Focusing on typical and straightforward strategies could provide these teachers with opportunities to solidify their ability to recognize strategy details and generate follow-up questions. Further, providing access to research on children's mathematical thinking could help them begin to interpret children's understandings reflected in strategy details, learn how those understandings are likely to develop, and consider next problems to support this development.

In addition to providing insights for PD, our profiles provide a starting point for conversations about teachers' developmental trajectories with respect to noticing expertise. However, caution is warranted given that our data are not longitudinal. Assuming that teachers are moving toward an *Accomplished Noticing* profile, the question is whether the other two profiles represent two separate paths or a single, connected path. Specifically, one possibility is that, as teachers learn about children's mathematical thinking, some may develop skills consistent with an *Emerging Noticing* profile and others with a *Mixed Noticing* profile, and then each group follows a different path toward an *Accomplished Noticing* profile. Another possibility is that, as teachers learn, they move from an *Emerging Noticing* profile to a *Mixed Noticing* profile and finally to an *Accomplished Noticing* profile in a single, connected path. We have some evidence to suggest that this second possibility may be more apt.

We looked at the relationship between the number of years of PD that teachers completed and their noticing profile. Teachers who had completed 1, 2, and 3 years of PD were found in all three profiles, but the distribution varied as one might expect with a single, connected path for development—there were more teachers who had 3 years of PD with an *Accomplished Noticing* profile and more teachers with only 1 year of PD with an *Emerging Noticing* profile. In fact, the membership of the two profiles were essentially mirror images of each other. The *Accomplished Noticing* profile had 7%, 36%, and 57% of teachers who had completed 1, 2, or 3 years of PD respectively, whereas the *Emerging Noticing* profile had 56%, 36%, and 8% of teachers who had completed 1, 2, or 3 years of PD respectively. The *Mixed Noticing* profile was in-between, with a more even distribution. These findings support earlier findings that teachers usually do not gain expertise in noticing children's mathematical thinking from teaching experience alone, but it can be developed with sustained time and support (Jacobs & Spangler, 2017).

Final Thoughts

We provided an initial exploration into profiles of teachers' expertise in professional noticing of children's mathematical thinking. The profiles we identified differed in terms of the overall expertise demonstrated and in the constellations of strengths and needed areas of growth related to the noticing component skills. Not only do these profiles help us better understand the construct of professional noticing of children's mathematical thinking, but they also form a basis for customizing PD to support growth in teachers' noticing expertise. Overall, the profiles increased our appreciation for the complexity of noticing expertise and raised our awareness that teachers may display inconsistent expertise across the component skills as they are learning.

Mathematics education needs measures that can be used to research and/or evaluate the impact of professional development for constructs that are broadly relevant to the field. To address this need we developed the Priorities for Mathematics Instruction (PMI) survey consisting of two scales focused on the constructs of Explicit Attention to Concepts (EAC) and Student Opportunities to Struggle (SOS) – which have been linked to increased student understanding and achievement. We identified the most critical assumptions that underlie the proposed interpretation and use of the scale scores and then examined the related validity evidence. We found the evidence for each assumption supports the proposed interpretation and use of the scale scores.

Keywords: Instructional Activities and Practices, Teacher Beliefs, Measurement

Teacher beliefs are important predictors of classroom practice (Stipek, Givvin, Salmon, & MacGyvers, 2001). The field of mathematics education needs measures of teacher beliefs that are broadly applicable and useful across multiple research studies (e.g., for comparisons), and linked to student learning outcomes of value to the field (e.g., student achievement). In many cases, this has led to development of surveys to assess the degree to which teachers hold beliefs aligned with preferred approaches to mathematics instruction. However, teachers' beliefs are just one aspect of a complex system affecting teachers' instructional practices (Leatham, 2006), and though survey scores may be associated with implementation, the competing priorities of teachers instructional practice have important effects on classroom practice. There is a need for a survey about mathematics instruction that describes teachers' beliefs while foregrounding the competing priorities teachers must consider when making instructional decisions.

Our interest in developing a survey stems for our involvement in multiple K-12 teacher professional development (PD) projects with a goal to influence teachers' beliefs about particular instructional strategies. We value our collaborations with teachers and the competing priorities they weigh while making instructional decisions (e.g., limited time vs. a desire for building both conceptual and procedural fluency). Therefore, we wanted a survey that does not devalue the knowledge teachers have about their contexts, and that gives us the ability to understand and use a broader perspective to support use of effective instructional practices. In particular, our survey is aimed to be applicable and useful for examining the impact of PD on teachers' beliefs and implementation across our PD projects, and with scales that recognize teachers' priorities without explicitly privileging particular instructional strategies.

Perspectives

Our instrument development work is framed through two perspectives. We first describe the theoretical framework for effective mathematics instruction from which our survey scales are based. We then draw from modern validity theory, explaining our choice to use an argument-based approaches to validation.

Theoretical Framework for EAC and SOS

Our perspective on effective mathematics instruction centers on Explicit Attention to Concepts (EAC) and Student Opportunity to Struggle (SOS), which come from Heibert and Grouws' (2007) synthesis of literature regarding classroom practices connected to increases in student conceptual understanding and mathematics achievement. EAC refers to instructional practices involving public noting of connections among mathematical facts, procedures, and ideas, while SOS occurs when students expend effort to make sense of mathematics or figure something out that is not immediately apparent. Recently, Stein, Correnti, Moore, Russell, and Kelly (2017) investigated the relationship between EAC, SOS, and student achievement across a large group of teachers. They found students in classrooms with high EAC and SOS performed higher on mathematics achievement assessments of both conceptual understanding and skills efficiency. Based on the extensive literature base, the connections to student achievement, and the likelihood for broad applicability, we used the constructs of EAC and SOS as the starting place to develop our survey scales.

Our goal was to identify and situate the EAC and SOS constructs in contrast to common competing priorities for instructional focus. Studies of traditional mathematics instruction highlight beliefs among teachers that emphasize ways in which beliefs about learning and context factors relate to teachers' choices to prioritize mastery of procedural skills (Philipp, 2007) and identify a need to 'funnel' tasks to reduce cognitive demand (Peterson, Fennema, Carpenter, & Loef, 1989). We label this set of priorities as Single Methodological Focus (SMF) and Highly Scaffolded Content (HSC), respectively, and situate them as contrasting priorities to EAC and SOS.

Argument-Based Validation

Modern validity theory has been articulating and promoting the idea of instrument validation through the lens of argumentation for many years (Cronbach, 1988, Kane, 1992, Messick, 1995), culminating in recommendations for argument-based validation in *The Standards for Educational and Psychological Testing* (AREA, APA, NCME, 1999, 2014). While a variety of approaches to argument-based validation have been articulated, there is not one generally accepted approach (Carney, Crawford, Siebert, Osguthorpe, Thiede, 2019). Therefore, we use the recommendations from *The Standards* (AREA, APA, NCME, 1999, 2014) and Kane (1992, 2001, 2016) to guide our work.

Validity involves the degree to which the score interpretation for proposed uses is supported by theory and evidence[1], and validation involves constructing and evaluating arguments related to the score interpretation for proposed uses (AERA, APA, NCME, 2014). Therefore, the articulation of the score interpretation for proposed uses must be the first step in validation (Kane, 2001, 2016). The argument is further developed by articulating the assumptions that underlie the score interpretation and use (AERA, APA, NCME, 2014). Once the assumptions have been articulated, it is incumbent upon the instrument developers to gather evidence to investigate the most critical or suspect assumptions first (Kane, 2001, 2016).

The goals of this paper are to (a) articulate the score interpretations for proposed uses for two survey scales we have developed, (b) articulate the most critical or suspect assumptions that underlie the score interpretations for proposed uses, and (c) examine evidence in relation to those assumptions. We see this work as an initial step in the iterative cycle of instrument development and validation, with the goal of others using the scales and continuing to gather evidence in support of, or to refute, the assumptions that underlie the score interpretation for proposed uses.

Methods

Instrumentation

Structure of the scales. As mentioned in the section Theoretical Framework for EAC and SOS, we wanted to structure our survey scales to recognize the most likely competing priorities for these constructs. We set up these competing priorities along a continuum for each construct. One continuum contrasts Explicit Attention to Concepts (EAC) with Single Methodological Focus (SMF), which prioritizes a compartmentalized approach to mathematics instruction that focuses on teaching one important mathematical idea and/or procedure at a time, often in an attempt to reduce student confusion between different approaches to solving problems. This approach is often manifested in classroom practice by asking students to correctly apply a particular procedure to a set of problems. A second continuum contrasts Student Opportunity to Struggle (SOS) with Highly Scaffolded Content (HSC), which prioritizes a gradual increase in complexity of mathematics, with scaffolding for students to move from relatively easy to more challenging ideas and procedures. This approach is often manifested in classroom practice by teachers breaking down students' work into progressively more challenging tasks, with the teacher providing explanations as needed, so students can gradually build fluency.

Using the two continuums as underlying constructs, the Priorities for Mathematics Instruction (PMI) survey has two scales focused on teachers' prioritization of beliefs - *PMI: SMF-EAC beliefs* and *PMI: HSC-SOS beliefs*. Each survey item starts with a common stem and presents instructional practices representative of the two ends of the target continuum. Respondents select one of six positions to describe the relative priority they place on the competing statements. See Figure 1 for the directions at the start of the survey and an example item highlighting the continuum:

Survey Directions: Each item asks you to choose between two statements. Both have value, and you may believe both are important to your teaching. Nonetheless, we ask you to choose one over the other. That is, please position the slider to indicate which statement you believe has greater priority in terms of your perspective on teaching mathematics. The further you move the slider to one side or the other, the greater priority you give that statement.

Survey Item: Students are more likely to succeed in math when they can:

Apply a particular method to solving similar math problems	•—•—•—•—•—•	Make connections among math topics
SMF	*-2.5 2.5*	*EAC*

**The information in italics is provided for reference and is not part of the item.*

Figure 1. Example of directions and an item for the PMI: SMF-EAC beliefs scale.

Interpretation and Use. The *PMI: SMF-EAC beliefs* and *PMI: HSC-SOS beliefs* scale scores (calculated as an average of the responses within the scale) can be interpreted in the following way. A score above 0 indicates beliefs more closely aligned with EAC or SOS practices, respectively. The closer the score gets to 2.5, the more closely the beliefs align with EAC or SOS. A score below 0 indicates the beliefs more closely align with SMF or HSC practices, respectively. The closer the score gets to -2.5, the more closely the teacher's beliefs align with SMF or HSC. A score near 0 indicates the teacher tries to balance the competing beliefs in their instructional priorities. The *PMI: SMF-EAC beliefs* and *PMI: HSC-SOS beliefs* scale scores can be broadly used by professional developers to examine beliefs relative to these constructs, inform professional development activities, and evaluate the effectiveness of PD activities in regards to their impact on teachers' beliefs related to EAC and SOS.

Critical Assumptions. Once the interpretation and use are clearly stated for an instrument, it is incumbent upon the developer to investigate the underlying assumptions (AERA, APA, NCME, 2014). The initial focus should be on the assumptions that are the most critical to demonstrate or the most likely to fail (i.e., are most suspect) (Kane, 2001). We have identified the following assumptions as particularly critical in our initial investigation of the interpretation and use of the *PMI: SMF-EAC beliefs* and *PMI: HSC-SOS beliefs* scale scores. For all instruments, there is an assumption that the operationalization aligns with the construct(s) theorized structure (assumption 1). For instruments such as the PMI survey where use is proposed (a) across a variety of professional development projects, the assumption is that the construct is broadly relevant to a mathematics education audience (assumption 2), and (b) related to measuring growth, the assumption is the instrument is sensitive enough to detect growth in an individual or group (assumption 3). Lastly, for instruments such as the PMI survey where social desirability of the response is a potential unintended factor, the assumption is social desirability is not impacting the scores (assumption 4).

Instrument Administration

Data Collection. The survey was administered to teachers participating in programs offered by a single K-12 math PD center in the Pacific Northwest. The programs are diverse in format, content, and duration, ranging from content-focused workshops to multi-year collaborative projects. There are clear differences in approach across the three PD groups [Blinded for Review]: Program 1, Program 2, and Other. Program 1 is a state-mandated 3-credit course in which K-12 educators build mathematical knowledge for teaching with a special emphasis on increased awareness of EAC and SOS, Program 2 is a federally-funded teacher-researcher alliance of Grades 6-8 teachers with an emphasis on adapting EAC and SOS strategies for their classroom practice, and the Other programs incorporate EAC and SOS ideas in their design, but not as the primary emphasis. Surveys were administered online via email invitation just before participating in the PD (pre, $N = 645$) and again (depending on program timing) 2 to 8 months later (post, $n=321$). Data collection spanned July 2019 to February 2021, with paired post/pre-response rates differing by PD group (Program 1: 48/107 (45%), Program 2: 78/106 (74%), Other: 195/432 (45%)).

Analysis

Statistical analyses of the survey response data was conducted in the statistical software package *R* (R Core Team, 2020), following recommendations for scale development by Jackson, Gillaspy, and Purc-Stephenson (2009). This included inspection of item response distributions, estimation of the bivariate correlational structure, and confirmatory factor analysis (CFA) using the *lavaan* software package (Rosseel, 2012). Missingness assumptions were evaluated under Little and Rubin's recommendations (1989), with iterative multiple imputation (van Buuren & Groothuis-Oudshoorn, 2011) used to augment incomplete responses (6.7%) without introducing bias into the fitted factor model. Evaluation and reporting of CFA model fit and parameter estimates followed guidelines by Cabrera-Nguyen (2010), with emphasis on indications of construct validity given the space restrictions of this report. Potential differences in pre-post PMI beliefs across subsamples were assessed using standard inferential statistical procedures (e.g., descriptive summaries, plots, ANOVA).

Results

Operationalization Aligns with Theory (Assumption 1)

The internal structure of the pre-responses were analyzed via a two factor CFA model using maximum likelihood estimation, with the eight EAC items loaded onto a latent "eac" factor, and the seven SOS items loaded onto a latent "sos" factor. The two factors were standardized (mean 0, standard deviation 1) and assumed to be correlated. The estimated model converged in 19 iterations with 31 free parameters, with indicators suggesting good fit between the theoretical model and the observed structure (model $X^2(89) = 304$, null $X^2(105) = 3228$, AIC $= 30140$, BIC $= 30279$, RMSEA $= .06$, CFI $= .93$, TFI = .92, SRMR $= .04$) with no areas of local strain and statistically significant factor loadings (all z $> 10, p < .0001$). Similarly, the model exhibited strong convergent and discriminant validity with standardized factor loadings strictly between 0.4 and 0.8 (see Figure 2). Follow-up principle component analysis identified no indications of cross-loadings (suggesting strong convergent validity), and the correlation between eac and sos beliefs (0.71) was below 0.80, suggesting strong discriminant validity. The evidence of model fit provides support for the unique operationalization of SOS to HSC and EAC to SMF as a continuum.

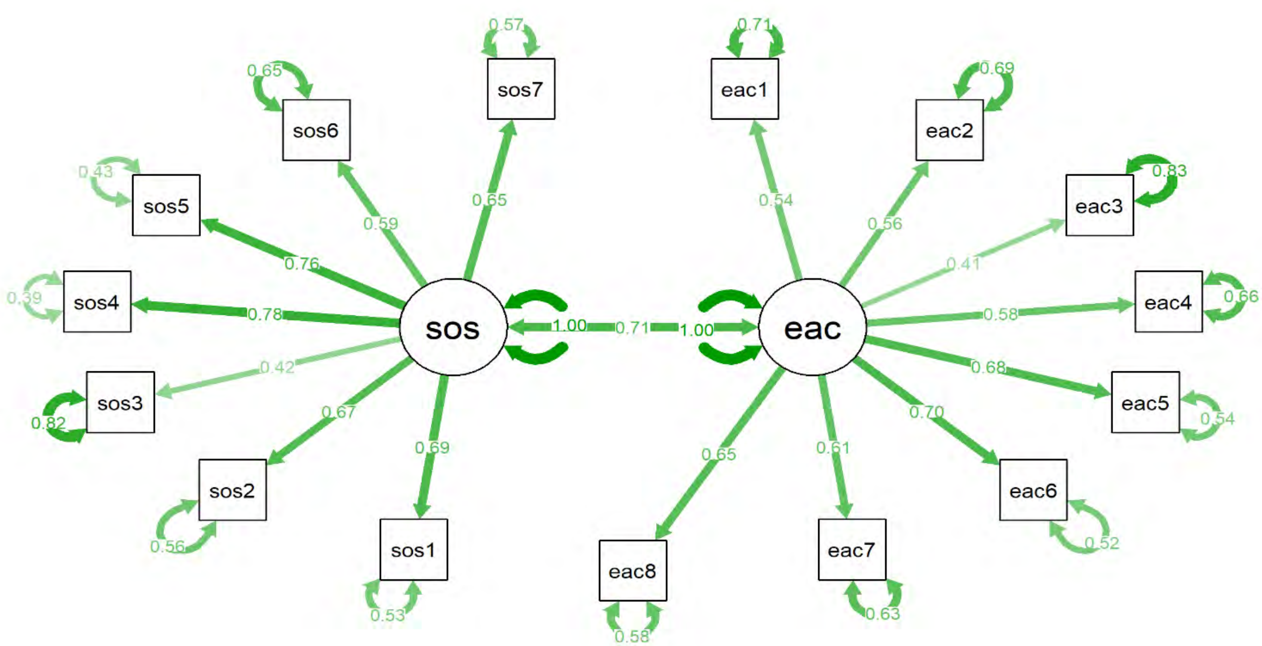

Figure 2. Standardized estimates for two-factor CFA model of EAC and SOS beliefs.

Broad Relevance (Assumption 2)

In addition to the theoretical argument establishing broad relevance and applicability of EAC and SOS across mathematics education settings (see section Theoretical Framework for EAC and SOS), the pre-distributions of PMI scale scores across the PD groups supports Assumption 2. Though each group differed in contextual variables, they had similar initial distributions of EAC and SOS belief scores (Table 1), this indicates the scales are likely to be broadly useful across different PD groups and settings.

Table 1. Distributions of EAC, SOS, and PMI Quadrants by PD Group

		EAC		*SOS*		*PMI Quadrants*			
Group	*n*	M	SD	M	SD	EAC&SOS	SMF&SOS	SMF&HSC	EAC&HSC
Program 1	107	0.1	0.8	0.0	0.9	41%	9%	36%	13%
Program 2	106	-0.2	0.8	-0.1	0.7	32%	16%	48%	4%
Other	432	0.0	1.0	0.0	1.0	43%	7%	40%	10%

Sensitivity to Group and Individual Changes (Assumption 3)

Figure 3 supports the potential for the PMI survey to detect change in teachers EAC and SOS beliefs. The chart illustrates how teachers in each PMI quadrant shifted in the post assessment, including a general pattern of small changes among teachers who began in the EAC&SOS quadrant, while teachers in the other quadrants showing increased variability in their post scores while generally shifting toward EAC&SOS. The ability to detect differential growth based on pre-PD scale scores indicates utility of the survey for detecting group and individual changes.

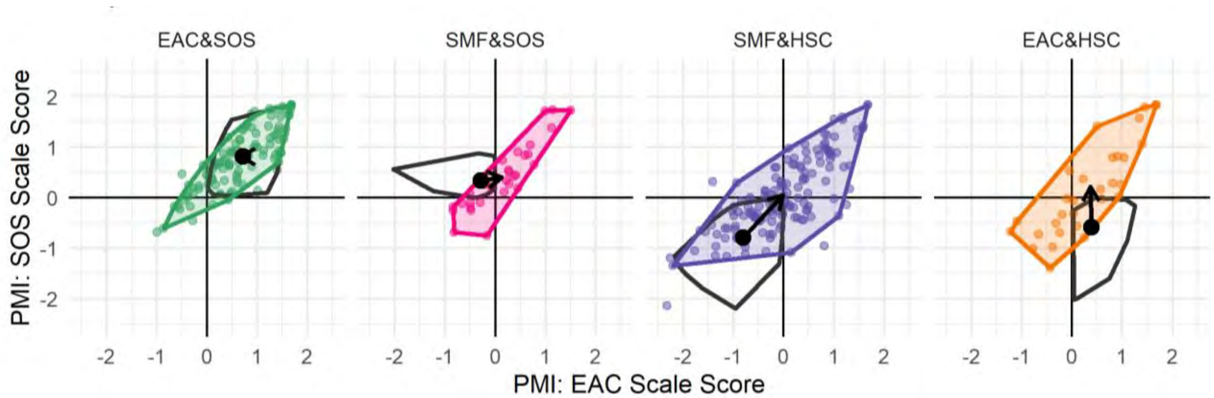

Figure 3. Post EAC and SOS scores, split by pre PMI Quadrant.
(Polygons capture the middle 90% of points by group, arrows indicate mean change.)

Figure 4 illustrates pre-post changes across the PD groups in EAC and SOS. The chart demonstrates substantial shifts toward prioritizing EAC and SOS among teachers in the Program 1 group. The ability to detect differential growth across PD contexts supports this proposed use.

Olanoff, D., Johnson, K., & Spitzer, S. (2021). *Proceedings of the forty-third annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Philadelphia, PA.

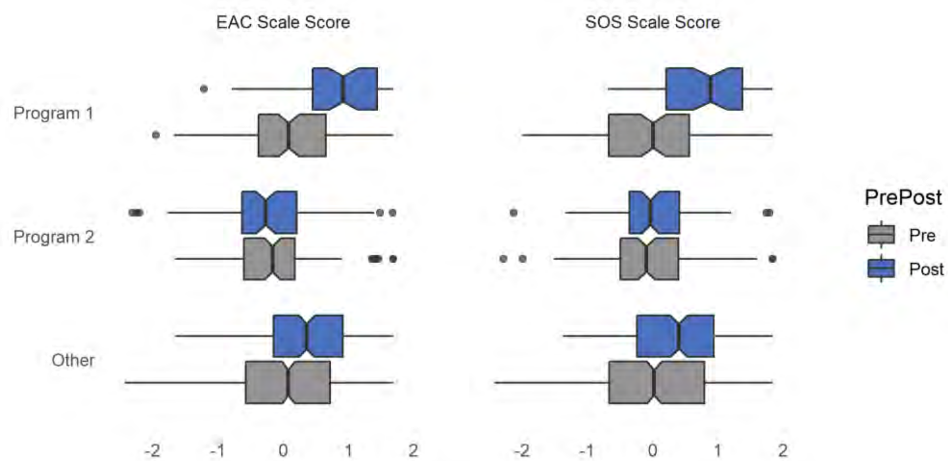

Figure 4. Pre and post distributions of EAC and SOS beliefs by PD Group. (Non-overlapping central notches indicate statistically different group medians.)

Social Desirability Response Bias (Assumption 4)

The paired pre-post EAC and SOS scores suggest minimal risks of social desirability response bias at the individual or group levels. Though teachers tended to shift toward the EAC&SOS quadrant after participating in PD (see Figure 5), the magnitudes and directions of those shifts varied greatly, with greater variability within groups than across. This variability supports the assumption that the social desirability of the response options is not obvious to respondents following PD that includes a focus on EAC and SOS.

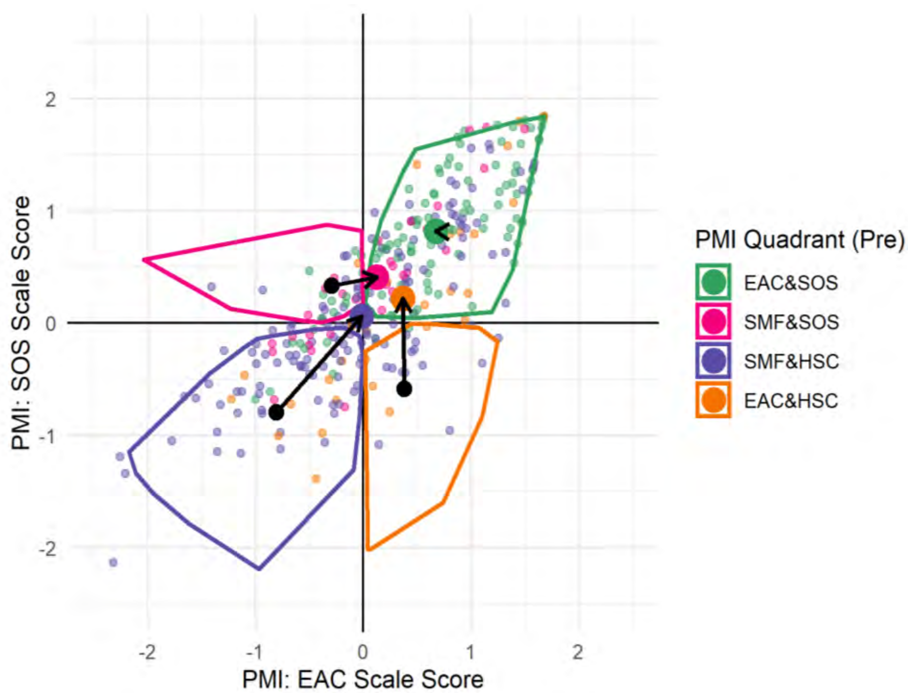

Figure 5. Post EAC & SOS Scores by Pre PMI quadrant. (Polygons capture the middle 90% of points in each group, arrows indicate mean changes.)

Olanoff, D., Johnson, K., & Spitzer, S. (2021). *Proceedings of the forty-third annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Philadelphia, PA.

In addition, pre-post changes in EAC and SOS beliefs differed across the PD groups, with substantial changes in Program 1 (EAC: M = 0.8(SD = 0.9), SOS: 1.1(1.0)), insignificant changes in Program 2 (EAC: 0.0(0.8), SOS: 0.1(0.6)), and moderate changes in Other (EAC: 0.4(0.8), SOS: 0.5(0.8)). As shown in Figure 6, changes in PMI Quartiles differed significantly across the PD contexts. All three PD contexts included information about why EAC and SOS are important for classroom practice, and Program 2 in particular emphasized engaging in activities that make use of EAC and SOS in the classroom. However, there was significant variability in the amount of change in EAC and SOS across PD contexts with Program 2 having the least change and most focus on EAC and SOS. This evidence of variability across PD contexts supports the assumption that social desirability in favor of EAC and SOS is not impacting responses to the survey items. If it were, we would have expected the Program 2 scores to have shifted to reflect this bias.

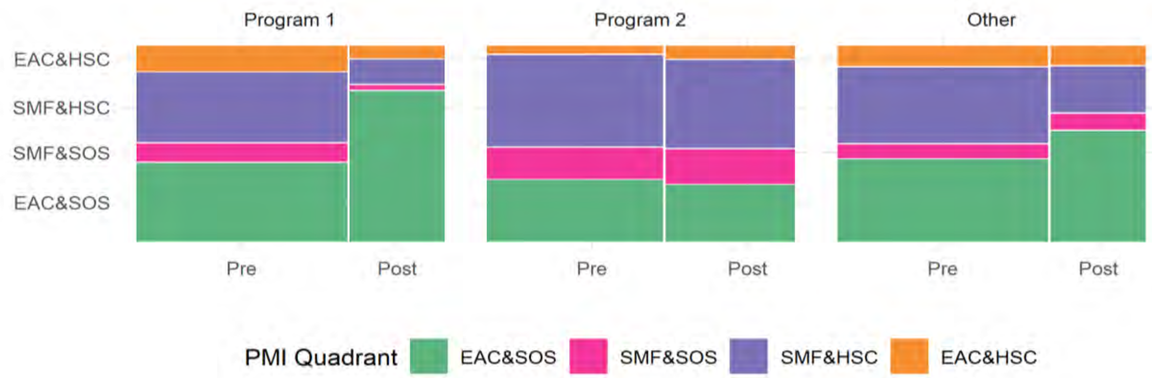

Figure 6. Pre-post changes in distributions of PMI quadrants across PD Groups.

Discussion

Instrument validation is an iterative process. This work presents an initial set of evidence for the interpretation and use of the PMI survey scale scores for *PMI: SMF-EAC* beliefs and *PMI: HSC-SOS* beliefs. Following the recommendations of the *Standards* (AERA, APA, NCME, 2014) we stated the interpretation and use of the two survey scales and identified the most critical assumptions to investigate. In particular, we investigated the following assumptions, and examined the associated evidence.

- The operationalization aligned with our theory (assumption 1). The CFA indicated a good fit which provides support for the unique operationalization of SOS to HSC and EAC to SMF as separate continuums of competing priorities.
- The survey scales scores are broadly relevant to the mathematics education community (assumption 2). The grounding of the scales in the work of Hiebert & Grouws (2007) and Stein and colleagues (2017), in addition to the finding of similar measures of center, variability and quadrant percentages across PD contexts, provide evidence in support of this assumption.
- The survey scales are sensitive enough to identify group and individual changes (assumption 3). The evidence of scale score changes from the perspective of both the pre-PD quadrant and three different PD contexts provides support for this assumption.

- Social desirability did not impact post survey responses (assumption 4). The strongest evidence in support of this assumption is that Program 2 participants – where the primary focus of the PD is EAC and SOS – had the least changes in pre-post scale scores.

Taken together the evidence in support of the four critical assumptions provides an important initial investigation into the interpretation and use of the PMI survey scale scores. We see this evidence as sufficient for recommending the use of the survey scales more broadly within the mathematics education community and hope that others will make use of the instrument and conduct additional validity investigations.

It is important to note a few key limitations. We did not complete a full investigation of the validity argument. There are additional assumptions that need to be examined and as the survey is used we anticipate others might have additional interpretation and use ideas that expand upon what was stated here. These would require further investigation. Finally, this work occurred during the COVID-19 pandemic, which likely impacted survey responses in complicated ways.

Note

[1] The Standards explicitly state "It is incorrect to use the unqualified phrase "the validity of the test" (p. 11)."

Supporting teachers to facilitate discussions with argumentation is as complex as the practice of facilitating argumentation itself. In this paper, we describe how a community of teachers and one teacher within this community made sense of facilitating argumentation. We use the construct of problems of practice as an indicator of teachers' sensemaking and learning. We contend that problems of practice are highly situated within teachers' contexts. The teachers identified participation as a broad problem of practice for facilitating argumentation and we identify three aspects of participation salient for teachers. Moreover, we show how Amanda, one of the teachers recontextualizes these problems to her thinking and practice.

Keywords: Professional Development, Teacher Knowledge, Teacher Educators, Reasoning and Proof

Whole class discussions that focus on mathematical argumentation are central events of inquiry-oriented environments (Staples & Newton, 2016), and important for promoting conceptual understanding and developing mathematically proficient students (Osborne et al., 2019; Rumsey, 2012). Mathematical argumentation engages students collaboratively in a process where they make claims and justify them using reasoning that is based in disciplinary practices and in their existing knowledge and cultural and linguistic resources. Argumentation-based discussions, however, are uncommon in U.S. classrooms (Cazden, 2003). Studies of teachers' roles and responsibilities in these socially and intellectually demanding environments highlight various teaching practices that support mathematical argumentation (Lampert, 2001; Staples, 2007). However, this research also suggests that implementing these complex practices is not trivial. Teachers must judge how to elicit and respond to student thinking and how to facilitate students' engagement with each other's ideas around disciplinary content. Problems of practice are endemic to this work and how teachers understand them and what they do to address them reflect pedagogical reasoning that is deeply embedded in their context, students, and professional knowledge. In this paper, we investigate problems of practice emerging from a community of elementary teachers engaged in a practice-based professional development (PD) focused on facilitating mathematical argumentation. We also describe how one teacher in this community, Amanda, contextualizes these problems in her practice.

Problems of Practice

Problems of practice (PoPs) have been a focus of teacher education research. Lampert (2001) wrote extensively about problems of practice based on teaching mathematics over the course of a year in a fifth-grade classroom. Using a zooming metaphor, she described teaching as a complex web of relationships involving the teacher, students, and content on different levels. It is within these relationships she argued "problem spaces" lie. She elaborated, "the problem space in which the teacher works is full of ideals to be realized, full of worthy destinations… In the actuality of teachers' work, however, the practices intended to realize these ideals are often incompatible" (p. 447). Thus, PoPs arise through these contradictions. Ghousseini (2015) framed these contradictions in "the way a teacher holds and deploys knowledge and coordinates instruction can constrain or promote what students can do with the content. Similarly, students and content can both constrain and open up what the teacher can do to teach, hence rendering the relationships inside the instructional triangle as both sources of problems of practice and resources for solving them" (p. 338). In other words, when teachers draw on a set of knowledge, beliefs, and identities to manage their practice, most often, their visions are reshaped by contextual factors.

Building on this work, we view a problem of practice as teachers' perceived misalignment between idealized instruction and actual instruction as normalized by a community. This misalignment can be manifested through teachers' interactions expressed as "troublesome, challenging, confusing, recurrent, unexpectedly interesting, or otherwise worthy of comment" (Horn & Little, 2010, p. 189). This view is based on a number of assumptions. First, it foregrounds teachers' perceptions instead of the researchers given that problems of practice emerge from knowledge-in-practice where "teacher learning hinges on enhancing teachers' understandings of their own actions—that is, their own assumptions, their own reasoning and decisions, and their own inventions of new knowledge to fit unique and shifting classroom situations" (Cochran-Smith & Lytle, 1999, p. 267). Second, this view assumes that PD is geared towards developing and leveraging teachers' knowledge in practice-based contexts, where teachers may learn about and from practice, with support from "more knowledgeable others" such as university professors, PD facilitators, or cooperating teacher mentors. In fact, it is through such experiences that we can understand the genesis of teachers' idealized instruction. Third, this view acknowledges the social aspect of teaching—although teachers teach largely individually, problems of practice can be embedded in broader principles and visions of teaching when they are normalized by colleagues and other stakeholders (Horn & Little, 2010). Research on teachers' framing of problems of practice has painted a picture of teachers' reasoning as collaborative sense-making situated in contexts of particular schools and districts, rather than purely cognitive individual acts that educators deploy (Thompson et al., 2015).

Teacher Learning and PoPs

We view teacher learning through a situative perspective where teachers' engage in ongoing sensemaking and reasoning in a community of practice, using various types of available conceptual and practical resources and tools and/or representations. This view of teacher learning guided our PD structure which we elaborate in a later section.

Professional development, especially highly adaptive, collective professional development, supports teachers' sensemaking. Following Schwarz et al. (2020), we view sensemaking as "wrestling with ideas, language, experiences, and perspectives to figure out how and why the world works; sense-making means proactive engagement in understanding the world by generating, using, and extending scientific knowledge within communities" (p. 1-2). As teachers make sense of their practice, such as through discussing and resolving PoPs, "they can come to know their practice in a way that enables them to construct meaning, make inferences, and solve problems" (Lampert, et al., 2015, p. 349). When teachers work together to address PoPs, they develop their ideas, knowledge, practice, and identities as well as their evolving commitments about what it means to teach, learn, and engage in collective inquiry. Together they are able to generate knowledge including "how decisions are made, how strategies are selected, how disparate instances are connected to one another, how subject matter is conveyed, and how new occurrences are understood and framed" (Cochran-Smith & Lytle, 1999, p. 268). They consider problems of practice in particular situations, "intentionally and introspectively examining those situations, and consciously enhancing and articulating what is tacit or implicit."

When the design of professional learning allows for the coevolution of participation between classroom practice and PD (Kazemi & Hubbard, 2008), individual teachers have the opportunity to recontextualize PoPs normalized in a community to their personal practice. Recontextualization is "a process of disembedding, re-embedding, and change" of discourse from one social context to another (Ensor, 2001, p. 297). This is important within professional learning communities. Even though PoPs may bring the community into a shared problem space, when embedded into teachers' practice, they are likely to change when teachers render them as part of familiar practice or their vision of practice (Horn & Little, 2010). Recontextualization as a process affords insight into teachers sensemaking beyond the setting of PD.

In this paper, we examine what PoPs emerge in a professional learning community and how they get recontextualized in a teacher's practice. Specifically, we will address:

1. What are the problems of practice identified by a group of teachers learning to facilitate discussions with argumentation?
2. How are the PoPs recontextualized in one teacher's practice?

Professional Development Structure and Focus

We co-designed and co-facilitated a PD environment called Learning Labs (LLs) focused on facilitating students' practices of argumentation. LLs are organized to (1) be adaptive and responsive to local communities, (2) involve ongoing collaboration and inquiry, and (3) consist of cycles of investigation, enactment, and reflection (Lampert et al 2013; Kazemi et al 2018). Each LL included four phases: new learning, planning, enactment, and debrief (Kazemi et al., 2017). The new learning phase focused on an analysis and discussion of artifacts of practice, such as a video clip, to unpack the nature of productive argumentation. Lab members collaboratively prepared a lesson to enact in one of the teachers' classrooms during the planning phase. In the enactment phase, they facilitated the lesson. As the lesson progressed, teachers would pause instruction to discuss instructional decisions using a routine called Teacher Time Out (Gibbons et al., 2017). During the debrief, lab members discussed insights from the enactment and set goals for argumentation in their own classrooms. Such a model of PD falls within Koellner & Jacobs's (2014) description of adaptive models where we are responsive to "the goals, resources, and circumstances of the local PD context. These models are based on general and evolving guidelines rather than specific content, activities, and materials" (p. 51).

We designed LLs to support teachers to facilitate classroom discussions focused on argumentation. We frame argumentation as constructing a reasoned case for why a mathematical statement or claim is logical or true and deemed acceptable by the community, in this case, other students and the teacher(s) (Knudsen et al., 2018; cf., Toulmin 1969). Researchers have produced substantial reports on argumentation (and proof, a closely related concept) but most reports are focused on student conceptions and classroom-based research more than teacher knowledge and development around facilitating argumentation (Stylianides et al., 2016). In the sparse work on PD focused on learning to facilitate argumentation, researchers used models drawing on representations and in some cases approximations of practice (Grossman and McDonald, 2008).

For instance, Osborne et al. (2019) in a practice-based PD used classroom videos to support teachers in adopting a more dialogic approach to teaching and fostering argumentation from evidence. They identified a specific set of instructional practices to foster students' argumentation from evidence, which were modeled by PD leaders. They also tested an approach to support teacher learning in the form of a practicum where teachers had multiple opportunities to enact, collaboratively investigate, and refine their practices. While such PD models ground teacher learning in the context of practice, they do not clarify the nature of teachers' sensemaking and how the adaptive PD affords insight into how it unfolds over time.

We facilitated LLs at Lockwood Elementary which is situated in an urban area in the Midwest region of the United States. In 2018-2019, the school served 443 students. The demographic make up includes 10% Asian, 10% Black, 40% Hispanic, 32% White, and 7% identifying as two or more races. Moreover, 13% of students were labelled as "students with disabilities, 56% as "economically disadvantaged," and 41% as "limited English proficiency." We began our LLs in January of 2019. Across the LLs at Lockwood, two university-based mathematics educators worked with four third-grade teachers, a fourth-grade teacher, three fifth-grade teachers, two school-based mathematics instructional coaches, and a retired mathematics instructional coach who worked at Lockwood. Most of this group identified as white and the rest as people of color. We focus half of our analysis on one member of the LL. Amanda, a White teacher certified in bilingual and elementary/middle school education with more than 10 years of experience teaches fifth-grade mathematics in both English and Spanish as part of a Dual Language Immersion program (DLI) where native Spanish and native English speakers were placed in the same class with instruction in both Spanish and English.

Data and Analysis

We collected video and audio recordings and field notes from eight LLs spanning one and a half school years. In addition, we conducted teacher interviews at the beginning of the project (Fall 2018) and at the end of the first and second school year (Summer 2019 & Spring 2020) where we asked teachers about their conceptions of discussions, argumentation, and equity. Between LLs, instructional coaches conducted video-stimulated recall interviews (VSRIs) related to teachers' attempts to facilitate argumentation in their own classrooms.

Analyzing LL PoPs

Analysis consisted of multiple phases to identify PoPs relevant to argumentation and how they emerged. We first identified instances where teachers highlighted "classroom interactions experienced as troublesome, challenging, confusing, recurrent, unexpectedly interesting, or otherwise worthy of comment" (Horn & Little, 2010, p. 189). Two authors then condensed these instances into PoPs exhibiting similar concern or comments in the context or argumentation. We also distinguished between one-off comments and comments contributing to a PoP. In order for a comment to contribute to a PoP the contribution had to normalize an existing PoP (e.g., a teacher connecting another teachers' similar experiences or concerns in their own), discussing potential reasons for a PoP, or relating the PoP to a teaching principle (see Horn & Little, 2010).

Analyzing Amanda's PoPs

To analyze Amanda's recontextualization, we first needed to understand how Amanda made sense of teaching in general. To do this, we analyzed her three teacher interviews. We looked for general principles that Amanda held by finding instances where she made sense of a set of experiences (e.g., her instruction with multilingual students) or general principles of teaching. From this, we identified her idealized version of teaching. One researcher then analyzed her

VSRIs and participation in LLs and looked for experiences where Amanda expressed misalignment with her practice and idealized practice. These, similar to the previous analysis, were collapsed into PoPs and were mapped back to the set of PoPs constructed in LLs in order to see how Amanda's PoPs related to those discussed in LLs. This allowed us to describe what Amanda felt as familiar to the group's sensemaking. We acknowledge there is more complexity in recontextualizing than the directionality we are present i.e., Amanda recontextualizations PoPs constructed from LLs, but space limitations only allow us to present one direction.

Results

We found PoPs related to argumentation to be primarily focused on participation processes. Teachers generally agreed that argumentation and discussions are important mathematical practices; however, they viewed the ideal classroom discussion focused on argumentation entailed students participating in discussions. Thus, the three PoPs we identified in the LL were couched in social processes to get students to participate, mostly thought talk, and engage in other students' ideas. We also describe one PoP from Amanda and how it relates to her practice.

Learning Lab PoPs

As the teachers made sense of experiences of teaching with argumentation in LLs, they identified PoPs centered around the social aspect of argumentation—particularly participation and their role in it. Because of the adaptive nature of the PD, these concerns became a strong focus of the group and we structured experiences in the PD provided teachers the opportunity to investigate the relationship of participation and argumentation (see Kazemi et al, 2020).

Teacher involvement. Teachers were broadly interested in making sure their involvement in discussions were minimal. Ideally, teachers wanted students to have autonomous conversations where they would step back from directing the discussion; however, they found themselves constantly stepping in to ask questions and push on new ideas when students did not immediately contribute to the discussion. A desire to decrease teacher involvement related to a school-wide commitment to student-centered mathematical learning.

Decreasing teacher involvement was constantly normalized as teachers provided different accounts of similar sentiments. Christina recounted a few times she wanted students to carry on autonomous conversations by either moving to the back of class or averting her gaze while students were talking about each other's ideas. Others also provided accounts of how they decreased involvement when eliciting students' ideas. For instance, Alyssa described wrestling how she could revoice student ideas but also having students revoice. The teachers further specified the problem by indicating teacher involvement usually occurs when students are given free rein of the conversation, such as during turn-and-talks, where students may talk about tangential mathematical or off-task topics. Several teachers added more dimension to this problem by discussing revisions to the nature and causes of this PoP. Karla thought there is a difference in values—teachers viewed math talk communities as important, yet students did not see the relevance yet. Christina thought one potential reason is because she acknowledges how she tends to make assumptions about students' thinking.

Value of students' ideas. Teachers realized when students participate in discussions, they are put in an emotionally vulnerable position. Ideally, teachers wanted to make classrooms a space where students felt comfortable and confident in sharing their ideas. However, they found that many students were complacent to be silent, letting others share ideas they assumed would be correct. Some teachers described students who had something to contribute but were uncomfortable sharing their ideas with the whole class because instruction was provided in a language different from their home language, especially in DLI classrooms.

The teachers normalized the PoP by recounting when students felt confident sharing their thinking with each other and in whole group discussions. For example, teachers shared accounts of students who shared ideas with a partner were asked to share their thinking with the whole class, but showed reluctance or resistance to sharing with the whole class. Teachers revised this problem of practice to consider how the activity itself encouraged or discouraged students from seeing their ideas as significant and the risk involved in sharing with others. Karla shared how in choral counts, "more kids would participate because we were part of a whole… So if I wasn't sure if my next number was correct I could say it a little bit quieter and then I would notice it if I was not with the group". Teachers generalized the PoP to principles of teaching, based on what moves would support students to see their thinking as meaningful within class discussion. The teachers wanted students to connect to their feelings on what it means to share and create space for vulnerability, recognizing that they can make mistakes and sharing an idea does not have to be an entire solution to the problem. For example, Melissa and Lea highlighted that making mistakes is part of being human and that mistakes can often help others learn. Similar to how the teachers talked about a math talk community for the sake of decreasing teacher involvement, the teachers talked about how a math talk community can create an environment where students feel comfortable sharing ideas. Towards the end of the LLs, Christina talked about how the environment (or math talk community) can be both nourishing and nurturing to better bring about student talk.

Students' engagement with peers. Teachers wanted to know how they could support students to have productive conversations with their peers. In teachers' classrooms, students were used to mathematics lessons in small groups while LLs were conducted in whole groups. Teachers recognized the challenge in how students engaged with their peers in this environment. Building on the first PoP, teachers were interested in making sure autonomous conversations were productive. The teachers continually returned to revise the problem of student engagement with peers and its possible causes. Olivia highlighted how students want to take ownership and connect with each other's ideas, but teachers need to be explicit on what it means to share your work with others. Revisions of the question lent elements of complexity, considering the experiences and needs of individual students. Teachers discussed the power of listening to others as a form of engagement, the implications of diverse language needs, and what it means when students are not socio-emotionally ready to explain their thinking to a partner. Addressing this problem within principles of teaching heavily relied on the use of turn and talks and teachers being explicit in particular questions or expectations of what it means to share with others. Alyssa and Lea shared how teachers can ask questions about students explaining another student's thinking or adding on to an idea proposed by a different student as a form of engaging students with each other. The growth in how students connected with one another individually in turn and talks and eventually in the whole group showed a greater number of students listening to and learning from one another. Karla noted in LL6 that there was more accountability for students in large group discussions as they engaged with each other's ideas.

Amanda's Recontextualization

Amanda's view of discussions with argumentation, like her peers, hinged on having students being able to participate in discussions. In making these PoPs more familiar to her practice, she strongly envisioned these discussions to be "equitable" in order for argumentation to occur. She viewed equitable discussions as students viewing their ideas as valuable as others and autonomously participating in discussions equally; however, in her classroom, students are not contributing to discussions equally especially when she reflected on her experience with emergent bilinguals in the DLI classroom. Thus, one of her PoPs is to support these students to talk at the same rate as their peers in order to achieve equitable participation.

Amanda frequently stated equitable participation as the ideal discussion to facilitate argumentation. During interviews, Amanda expressed equity as "feeling that each student in the classroom matters equally and what they have to say matters as much as anybody else in the classroom." She also expressed her role as "responsible for keeping discussions equitable" and try to "draw out maybe students that aren't talking as much, um, to give, like to privilege their voice a little bit more because they don't have that experience all the time." She also said she used drawing sticks where students' names are on sticks and Amanda draws a random student's name. During LLs, Amanda said one of her goals for equitable participation is how she can support students to join in on discussions particularly during whole-class discussions where she notices that students are comfortable sharing with a partner but not to the whole class. She viewed whole-class discussion as important for empowering students, "what feels good is honoring each student's perspective and having them communicate their ideas about math in front of the whole class is empowering to every student."

Whenever Amanda talked about her class or looked closer at her class during VSRIs, she notes the misalignment between her goal of equitable participation. She notes those larger societal inequities at play. For example, she notes gender during a VSRI, "I can see it's still not where I want it to be in this lesson. It seems like the boys, when they're in mixed gender pairs, the boys seem to talk a lot more. So yeah, just being more conscious of that and finding ways that they can participate. In front of everybody." More importantly, she consistently drew from her experience as one of the bilingual teacher at the school who taught in DLI classroom and noted students' home language as an inequity feeding into discussions, "I think English dominant students tend, I don't know, tend to feel more power in the school system for some reason, and they just tend to dominate space wherever they are..Spanish speaking students in summer school [where majority of students speak Spanish]… become a lot more lively and active and participate in the discussion." Amanda noted that because of this inequity, she felt "responsible for keeping the discussion more equitable and trying to draw out maybe students that aren't talking as much—to give privilege to their voice a little bit more because they don't have that experience all the time." Her goals for future work centered around cultivating equitable whole class discussion and to build a math talk community where equitable participation happens.

We largely saw Amanda's PoP of equitable participation as a recontextualization of PoPs from LLs. Amanda expressed part of equitable participation is students' seeing their contributions as valuable. During LLs, Amanda shared that one sticking point for discussions is figuring out how Amanda can build up students' ideas as valuable in order for them to share during whole-class discussion. In order for students to participate, Amanda needed students to view their ideas as valuable, especially for emergent bilinguals. If they are valued, then students may participate more. She commented, during a VSRI, about how an interaction supported a student. She noticed student M, who she said does not normally participate, talking with her partner and nodding along as her partner built on what student M said. Amanda queried, "I'm curious about whether you know it's a language thing or she doesn't have that much language to explain it" but because her partner participates more in discussion, Amanda saw this interaction as reaffirming her and her ideas. Amanda's PoP also was a recontextualization of students' engagement with each other. Amanda noted students needed to view each other peers' as valuable, noting that if students engage with each other's ideas during discussions, students will build more confidence in sharing their ideas, in turn, participating more. She shared that she provided students with sentence stems in order for students, especially those needing language support, to be able to begin and carry on discussions with others.

Discussion and Conclusion

In this paper, we identified PoPs related to discussions with argumentation constructed by a group of elementary school teachers. PoPs are important for teachers' sensemaking because it provides them with a shared space to identify parts of practice they would like to work on. Because the shared space is tied to the contexts and experiences of the teachers, PoPs are also highly situated and are a reflection of the values of the community. At Lockwood, the teachers' saw an ideal classroom situation where students would almost independently carry deep mathematical conversations; however, in most teachers' classrooms, this was not the case. Thus, the three PoPs—reconsidering their position in discussions, valuing students' ideas, and supporting student-to-student interaction— allowed the teachers to map out how to improve their practice in order to better facilitate discussions with argumentation. We also described the relationship between one teacher's PoP and those brought up in LLs. Amanda saw equitable participation as the ideal space for discussions with argumentation, related to two of the PoPs brought up in the LLs. Her idea of equitable participation can be drawn from her values and her experiences as one of the bilingual educators teaching in a DLI classroom in thinking about equitable participation where she wanted to see all students talking at a similar rate.

There are some conclusions and implications we draw from this report. This work highlights the importance of the work of PD in supporting teacher learning. We structured LLs to be highly responsive to teachers' ideas and practice; thus, our PD design provided space for teachers to wrestle with supporting students' participation in discussions with argumentation. This does not mean teachers did not concentrate on components of argumentation as identified in the literature (e.g., claim-making, providing data, establishing warrants). In fact, teachers saw participation and argumentation as intimately tied together and were attuned to aspects of argumentation in LLs and designed tasks to support argumentation; however, the teachers elevated participation as a critical component for argumentation to occur. This marks a strong movement from knowing that an idea exists to knowing how to bring that idea to life (Mason, 2002). Such PD experiences not only support teachers in wrestling issues close to their practice but also provide teacher educators the opportunity to think alongside teachers and construct powerful experiences.

We also saw PoPs brought up in this group were situated. In a community of teachers, shared experiences provide material for teachers to construct PoPs rooted in these experiences and thus, they make sense and solve these problems together. In our case, teachers generally agreed with the work on participation that needed to be done to facilitate discussions with argumentation. They were all committed to honoring students thinking and creating communities where students can deeply talk to one other about mathematics. Having this group, can support teacher learning. As Mason (2002) asserted, "real change also requires the support of a compatible group of people whose presence can sustain individuals through difficult patches, and who provide both a sounding board and a source of challenge for observations, conjectures, and theories" (p. 144). Further, any work that needed to be done would be constrained and supported by the contexts the teachers were in as seen in Amanda's work. As a teacher attuned to the language needs of her students, Amanda saw some inequities, particularly with language, in her classroom connected them with the PoPs brought up in the group. Her recontexualization of the group's PoPs was framed through, what she called, equitable participation, making something in one context, familiar in another. Further work needs to be done to examine the other direction (i.e., how teachers contribute to community PoPs). It is through this collective sensemaking in context that teachers learn—that we cannot refer to teacher learning as acquiring declarative knowledge, but rather as sensemaking from practice to change practice.

LESSON STUDY: SUPPORTING SECONDARY TEACHERS' PERSEVERANCE TO ENGAGE WITH STUDENT THINKING

Jenifer Hummer
West Chester University of
Pennsylvania jhummer@wcupa.edu

Teachers often struggle to attend to student thinking in ways that facilitate students' conceptual understanding of mathematics. This struggle is particularly evident in the context of teaching mathematical modeling. Lesson study has supported teachers' engagement with student thinking. Hence, this qualitative study investigated how lesson study and the "Five Practices for orchestrating mathematical discussions" (Stein et al., 2008) supported three secondary teachers' engagement with student thinking while they implemented mathematical modeling tasks. The findings revealed how the teachers: anticipated valid and emerging student responses, used the five practices to advance student thinking, and focused on student thinking to refine lesson plans. These findings indicated that the teachers were supported by an integration of the Five Practices and lesson study in the context of teaching mathematical modeling.

Keywords: Professional Development, Instructional Activities and Practices, Modeling

Increased awareness of student thinking can improve teaching (e.g., Fennema et al.,1996). When teachers attend to student thinking they can be prepared to facilitate rich discussions (Stein et al., 2008). However, mathematics teachers have struggled with attending to student thinking (e.g., Smith & Stein, 2018). As a further complication, teachers have struggled to attend to student thinking while implementing complex mathematical modeling tasks (e.g., Thomas & Hart, 2013). Due to these challenges with teaching mathematical modeling, researchers (e.g., Ang, 2013; Kuntz et al., 2013) recommended that teachers receive professional development (PD) on implementing modeling, such as lesson study (see Turner et al., 2014).

Lesson study consists of four essential activities: Curriculum Study, Lesson Planning, Teaching and Observing, and Debriefing. Outside of modeling contexts, researchers found the activities and goals of lesson study naturally supported teacher learning, and improvement of teaching (e.g., Lewis et al., 2009). These outcomes were influenced by a focus on student thinking (Murata, et al., 2012; Stigler & Hiebert, 1999).

Because each phase of lesson study is guided by student thinking, this study, situated in the context of teaching mathematical modeling, employs a framework to support teachers to engage with student thinking through student discussions. Stein et al. (2008) proposed Five Practices (5Ps) written about in *Five Practices for Orchestrating Productive Mathematics Discussion* (Smith & Stein, 2018). The 5Ps are as follows: 1. *anticipating* likely student responses to challenging tasks; 2. *monitoring* students' actual responses to the tasks (while students work in pairs or small groups); 3. *selecting* particular students to present work during whole-class discussions; 4. *sequencing* student responses to be displayed in a purposeful order; and 5. *connecting* different students' responses to each other and to key content ideas.

Hence, the aim of this study was to investigate how teachers engaged with student thinking as they worked to improve their teaching through lesson study in the context of teaching mathematical modeling. The lesson study team consisted of one university researcher, the author of this paper, and three secondary teachers who completed two cycles of lesson study. The following question guided the research: *In what ways does teachers' participation in lesson study support their engagement with student thinking while teaching modeling?*

Research Methods

The participants were three mathematics teachers who taught in a vocational high school with a diverse student population in the mid-Atlantic region of the United States (all names are pseudonyms). At the time of the study, Ms. Dain was a second-year teacher. Next, Ms. Maronis, a former engineer, had six years of teaching experience. Lastly, Ms. Denvers had 21 years of teaching experience. The researcher served as a "knowledgeable other" and facilitator by providing curriculum materials, relevant practitioner articles, and guiding discussions during meetings. During the summer, after an introduction to lesson study and a curriculum study, the teachers planned a two-day lesson. Each of the enactments took place in the fall, about six weeks apart in the following order: (1) Ms. Dain, (2) Ms. Denvers, (3) Ms. Maronis. The teachers observed each other teach the lesson and debriefed after enactments (2) and (3).

All meetings, lesson enactments, and debrief sessions were video and audio-recorded and transcribed. To maximize opportunities to analyze how the participants engaged with student thinking, and to reduce the data, only transcripts centered around specific tasks were analyzed. Specifically, the tasks were open-ended and could have a variety of valid responses. Figure 1 includes examples of tasks that were selected for the data analysis. Day 1 Task 1 provided opportunities for students to develop various state apportionment methods. Day 2 Task 1 allowed for exploration of Thomas Jefferson's state apportionment method. Using themes from the literature and data, the transcripts were analyzed using constant comparative methods (see Strauss, 1987). Then final codes were organized into categories aligned with the Five Practices (i.e., anticipating, monitoring, selecting, sequencing, and connecting).

Day 1 Task 1: For simplicity, imagine that a newly formed country wishes to copy the U.S. House of Representatives. This new country has just 100,000 people split up into only four different states, listed in the table below.

State	Population
A	15,000
B	17,000
C	28,000
D	40,000

A. If the new country plans on having 25 representatives in its House of Representatives, how many should each state receive?
B. What if they plan to have only 17 representatives?
How did you calculate how many representatives each state should receive? Did you use the same method for both 25 and 17 representatives?

Day 2 Task 1: Watch the video on the Jefferson method, apply the Jefferson method for 25 representatives. Link: https://tinyurl.com/SGJefferson Use the tables to apply the Jefferson method.

Jefferson's Apportionment for 25 Seats

State	Population	Calculation	Number of Seats
A	15,000		
B	17,000		
C	28,000		
D	40,000		

Why did Jefferson use this method?
What are the differences and similarities between the Jefferson Method and the Hamilton Method?

Figure 1: Example Tasks from the Lesson on State Apportionment Findings

The findings are organized according to teachers' engagement with student thinking through the 5Ps during each lesson study activity: Planning, Enacting, and Debriefing the Lesson.

Planning: Anticipating Multiple Responses; Advancing Thinking; Purposeful Sequencing

Because the teachers had solved the tasks and had considered multiple approaches to each task, they were able to anticipate *multiple student responses*. In the context of teaching mathematical modeling, it was also important for the teachers to acknowledge that modeling tasks can have more than one correct approach. For example**,** in addition to considering multiple student responses, Ms. Maronis acknowledged for state apportionment methods, "there's not really a right or wrong answer."

In their planning, the teachers intended to *advance student thinking* through judicious telling (Lobato et al., 2005). For instance, when Ms. Maronis and Ms. Denvers discussed how to support students with Day 1 Task 1. They both discussed how to "steer" students without "taking the steering wheel." In their efforts to avoid "telling," teachers also planned advancing questions such as these suggested by Ms. Denvers: "What's the purpose? What do you have to accomplish by doing this?; How do you know when to stop guessing?" By asking these questions, the teachers hypothesized that students might reflect on their work or think about next steps.

In planning to sequence various student responses and support student understanding, the teachers planned to show *simple strategies before complex strategies*. Also, the teachers added connecting questions for the whole-class discussion (see Figure 4). By adding these questions, they planned to support students in making connections and building on one another's thinking.

Student Response Sequencing	Questions to ask during share-out:
First: Guess and check weighting method Second: Percentage method & rounded to get too many or too few representatives Final: Rounded and ended up with the right number of representatives (compare two groups that rounded differently)	What do you notice about each method? What are the pros and cons of each method? What are your revisions for your initial responses?

Figure 4 Teachers' Planned Sequencing for Day 1 Task 1

Enacting: Advancing Student Thinking and Purposeful Sequencing

As the teachers monitored student thinking, they used student responses to *advance student thinking* by asking *assessing questions* and using *judicious telling*. Although the teachers did not explicitly plan assessing questions, the teachers planned to use judicious telling (Lobato et al., 2005). Thus, asking assessing questions was a natural first step. Then, based on the planning, the teachers chose their next move. For example, during the second lesson enactment, in a discussion between Ms. Denvers and her student, Sam, about Day 2 Task 1, Ms. Denvers started the discussion by asking the following assessing questions: "I would like to see is yours exactly the same? Tell me exactly what you did." Then Sam guided Ms. Denvers through his written work.

For whole-class discussions, the teachers selected and sequenced student responses from *simple to complex* and *connected* student responses. As an example, Ms. Dain sequenced the responses as planned. Then she *connected* student responses, as illustrated in the following transcript for Day 2 Task 1, by encouraging students to engage in discussions with each other.

Ms. Dain Why did your group decide to take away the representative from State A…?

Jamal …you can't have .55 for a person and we didn't know what to do. And we think that's what, we didn't know any other way to do it. If we add all this together it made 17.

Ms. Dain I think Alisha wants to add to the question I just asked.

Alisha Well, my group, did the [approach] that you said, but we just looked at the decimal numbers and we chose the lowest one that could be rounded…

Ms. Dain Excellent, I heard other groups saying that too…

In this case, Jamal was unsure of his group's methods, so Alisha jumped in to validate their method. Ms. Dain then connected Alisha's response to other groups' responses.

Another theme that emerged was that the teachers *adapted to unanticipated student responses* so that the responses would still be sequenced from *simple to complex* approaches. Ms. Denvers encountered an unanticipated and unique approach and chose to share the response as one of the complex responses. In the transcript, Ms. Denvers asked *connecting questions* and encouraged students from other groups to explain Jake's approach.

Ms. Denvers Anybody have any thoughts about what those calculations are able to achieve?...

Kelsey He has 100,000/15,000, uh 6.666.

Ms. Denvers … What would that mean? … What's'that 6 and 2/3 represent? Kelsey Is it because a certain portion out of the whole will go into each? Ms. Denvers And that will give you 25/6 and 2/3, right? Jake, can you tell us?...

Jake So, the uh, the size of the state compared to the size of the overall population.

Ms. Denvers So that sounds like what Kelsey was saying right?

Although this student response was unanticipated, Ms. Denvers was able to adapt how to sequence the approach and Ms. Denvers was prepared to facilitate a future discussion about it.

Debriefing: Modified Tasks and Enhanced Anticipated Responses

The lesson study team used evidence of student thinking collected during observations to *modify tasks* and revise the lesson plans. For instance, during the first debrief session, after Ms. Dain taught the lesson, the group acknowledged that the student responses for the Day 1 Launch were not aligned with a learning goal about students developing their methods for state apportionment. Thus, the teachers decided to *modify* the task (see Figure 5). As a result, the student responses in subsequent lessons were specific and better aligned to the learning goal.

Version 1: Launch/Warm Up (10 minutes)	**Version 2: Launch/Warm Up (10 minutes)**
How might you arrange a system so that each state is represented fairly? What obstacles do you think might be present?	If you were in charge of determining how many representatives each state in the United States should have, what information would you need. How would you use that information? What obstacles do you think might be present?

Figure 5 Modification to the Day 1 Launch

The teachers also used their observation notes to *refine anticipated student responses*. During the debrief meetings they used their observations of student response to add specific details to the student responses. In addition to refining anticipated student responses, the teachers *enhanced* anticipated responses by adding student responses that surfaced during each lesson enactment. For example, the teachers used detailed notes to add Jake's method, discussed earlier, to the lesson plan for Day 1 Task 1. This type of focus on student thinking provided opportunities for teachers to improve the lesson plans for future enactments.

Discussion and Conclusions

The findings of this study provided insight into how lesson study can influence teachers' engagement with student thinking. For one, contrary to previous studies the teachers in this study engaged with student thinking in productive ways such as anticipating multiple student responses (e.g., Thomas & Hart, 2013). Then to make use of multiple student responses, the teachers planned and executed judicious telling (see Lobato et al., 2005) and asked questions that could support student thinking. Finally, also contrary to previous studies (e.g., Stein & Smith, 2018), these teachers purposefully planned and executed the selecting and sequencing of student responses from simple to complex approaches. The participants in this study further planned and executed the connecting of student responses. By planning how to select, sequence, and make connections, these teachers were prepared to engage with student thinking in ways that could support students to engage in complex tasks. Finally, the debrief sessions, focused on student thinking, supported the improvement of the lesson plan. Also, a main implication, needing future research, from this study, suggests that as recommended by Turner et al. (2014), lesson study and the 5Ps have the potential to support teachers when implementing mathematical modeling.

Acknowledgments

Many thanks to the teacher participants and the University of Delaware for dissertation funding.

AN EXPLORATION OF COACH-TEACHER INTERACTIONS DURING MODELING

Evthokia Stephanie Saclarides
University of Cincinnati
saclares@ucmail.uc.edu

Jen Munson
Northwestern University
jmunson@northwestern.edu

Drawing on six coach-teacher dyads' interactions (n=295) across 25 lessons, this study examines the foci and depth of coach-teacher modeling interactions. Qualitative analyses revealed six types of coach-teacher interactions, and two levels of depth that take into account the extent to which reasoning about content, pedagogy, and students was made evident during coach-teacher interactions. Implications for future research as well as practice are provided.

Keywords: Professional Development, Instructional Leadership, Classroom Discourse

A growing body of research examines what coaching activities and coach-teacher interactions are most productive for supporting teacher learning of complex teaching practices (Gibbons & Cobb, 2017; Saclarides & Lubienski, 2021). One such coaching activity is modeling (Gibbons & Cobb, 2017), where the coach embodies the teacher role to demonstrate a pedagogical practice to support the observing teacher's learning. And yet, modeling involves far more than performing instruction while teachers observe; to support teachers in making sense of the modeled lesson, coaches must make visible the complex reasoning work involved in enactment through professional interactions. By providing teachers with a window into the ways that more knowledgeable others reason pedagogically in the moment, teachers' learning opportunities may be enhanced. Doing so is a central tenant of the teacher education pedagogy of modeling (McGrew et al., 2018). This type of talk during teaching is not unprecedented (Gibbons et al., 2019; Munson & Dyer, 2020), but how it might look during a modeled lesson has not yet been explored.

The focus of coach-teacher talk circumscribes the learning opportunities created for teachers. Talk that addresses student thinking, disciplinary content, or pedagogy could be venues for teachers to learn about professional practice (Russell et al., 2020). While talk that addresses logistics, such as timing or classroom management, may be less oriented to teacher learning (Horn et al., 2017). Our conception of modeling points not just to the importance of coach-teacher talk about content, pedagogy, and students being *present*, but to the role of its *depth*. Depth of talk, or the degree to which talk engages with pedagogical reasoning, reflects teacher learning opportunities (Horn et al., 2017). When teachers moved beyond reporting what did or will happen in classrooms (low depth) to addressing how or why those events might unfold (high depth), they opened learning opportunities by exposing their pedagogical reasoning for collective consideration. Prior research on depth examined this construct in the context of extended professional interactions, where the unit of analysis was often a teacher meeting (Horn et al., 2017). Depth in brief interactions, such as during modeled lessons, has yet to be characterized. In this study, we examine the coach-teacher interactions in six dyads during modeled lessons to explore: 1) What are the foci of coach-teacher interactions; and 2) During conversations about content, pedagogy, and students, what depth of coach-teacher interactions is possible?

Method

Setting and Participants

This study took place in two different public school districts, Midtown and Southampton, where all coaches had full-time release from teaching, did not evaluate teachers, and reported directly to their building principals. We partnered with four coaches (Beth, Jade, Meg, Latoya), and six elementary teachers (Barbara, Brianna, Lindsey, Michelle, Mackenzie, Jennifer).

Data Source and Analytic Technique

Twenty-five modeled lessons (24-75 minute range, 45 minute mean) were observed, audio recorded, and transcribed. All transcripts and accompanying field notes were read to identify coach-teacher exchanges during modeling, which we define as subsequent turns of talk. Then, complex exchanges that included multiple ideas were parsed into exchanges that focused on a single topic. This led to the identification of 295 coach-teacher exchanges about a single topic (mean of 12 exchanges per lesson) across the 25 modeled lessons.

An open coding process (Creswell, 2013) was used to inductively develop codes for the focus, or topic, of each exchange. Codes and definitions were refined until all exchanges were reflected in six focus codes. We then isolated exchanges that centered on content, pedagogy, and students (n=60), and inductively developed *depth* codes to attend to the reasoning that was evident. *Low-depth* interactions were characterized by observations without reasoning or evidence, while *high-depth* interactions included reasoning or evidence, making thinking public.

All codes were mutually exclusive and assigned at the exchange-level. After coding was complete, data were analyzed to tabulate percentages for all codes for each coach-teacher dyad, as well as across all data. Last, matrices were created to detect patterns within and across dyads.

Findings

Foci of Coach-teacher Interactions

Analysis of 295 exchanges across 25 lessons yielded six distinct foci of coach-teacher interactions during modeled lessons (see Table 1).

Table 1: Foci of Coach-teacher Interactions

Coach-teacher dyad	n	Logistics	Building Relationships	Performative Praise and Discipline	Joint Teaching	Discussing Content and Pedagogy	Noticing Student Thinking	Other
Meg-Michelle	83	50%	2%	35%	0%	1%	10%	3%
Meg-Mackenzie	65	51%	24%	8%	0%	10%	7%	1%
Jade-Jennifer	17	19%	12%	14%	15%	22%	20%	0%
Beth-Barbara	26	32%	8%	0%	0%	20%	41%	0%
Beth-Brianna	42	44%	25%	0%	0%	23%	8%	0%
Latoya-Lindsey	62	37%	2%	3%	4%	22%	31%	1%
Mean	49	39%	12%	10%	3%	16%	20%	1%

Logistics. When engaged in logistics conversations, the dyads discussed issues that arose from the coach teaching in a classroom not her own, such as materials (Coach Latoya: "Do they have markers?"), technology functionality (Coach Beth: "Does your eject button work?"), and attendance (Coach Beth: "Ms. Barbara, are you missing a student?"). Logistics conversations were the most prevalent topic across all data, making up 39% of the coach-teacher interactions.

Building Relationships. When building relationships, the dyads displayed their partnership through, for example, greeting one another (Coach Latoya: "Hey ladybug..how are you?"); apologizing (Coach Beth: "Sorry, it's just been kind of a crazy morning"); complementing one another (Coach Beth: "You're so good and I am a forgetter"); or commiserating (Coach Beth: "I even got here early this morning. I just can't seem to get it all together.") Across all dyads, building relationships conversations made up 12% of interactions.

Performative Praise and Discipline. Performative praise and discipline interactions featured public, emotive conversations between dyads for which students were the intended audience. The dyads either praised students' academic or behavioral efforts or expressed their frustrations or disappointment in students' behavior. For instance, at the end of her modeled lesson, Coach Jade publicly complimented the fourth grade students' behavior: "[Teacher Jennifer], you've done such a lovely job with them! This may be my favorite class ever!" Across all dyads, performative praise and discipline conversations made up 10% of interactions.

Joint Teaching. When engaging in joint teaching, the teacher shared moments of brief, public teaching with the coach that involved interacting with both the coach and students. For instance, Coach Jade asked students to find a spot on the rug so that they were seated in a square. Teacher Jennifer took this opportunity to incorporate the lesson's vocabulary; she interjected, raised her voice, and looked directly at Coach Jade while saying, "Or, make the *perimeter* of the rug." Acknowledging Teacher Jennifer's contribution, Coach Jade replied, "Thank you, Teacher Jennifer." Across all dyads, joint teaching interactions were rare (3%).

Discussing Content and Pedagogy. When discussing content and pedagogy, the dyads talked about the content featured in the lesson or pedagogical dilemmas that surfaced during instruction. For instance, while Teacher Jennifer was playing a subitizing game with a small student group, Coach Jade prompted the teacher to more quickly flash the dot cards to encourage automatic recognition: "You can flash it [cards] for like 1, 2, 3, and then turn it [over]. So, you don't want them [students] to count it. You want it to be instant." Overall, discussing content and pedagogy made up 16% of interactions.

Noticing Student Thinking. While noticing student thinking, the dyads shared their noticings about how students grappled with the content, made predictions about how students might engage with the lesson's content, discussed their perceptions of student affect, and set student growth goals. For instance, during one modeled lesson, Coach Beth shared her observations with Teacher Barbara about two students: "But I think that there was great success right here with Oscar and Juan. They are super clear about where their model and their problem…have the same link, right? So, they were actually able to write…this is the 10 times 6 part." Overall, interactions focused on noticing student thinking made up 20% of the data.

Depth of Coach-teacher Interactions

There was substantive variation in the depth of coach-teacher talk about content, pedagogy, and students (see Table 2).

Table 2: Depth of Coach-teacher Interactions

		Discussing Content and Pedagogy		Noticing Student Thinking	
	n	Low Depth	High Depth	Low Depth	High Depth
Coach Meg-Teacher Michelle	9	100% *(1%)*	0% *(0%)*	37% *(4%)*	63% *(6%)*
Coach Meg-Teacher Mackenzie	5	24% *(2%)*	76% *(8%)*	100% *(7%)*	0% *(0%)*
Coach Jade-Teacher Jennifer	5	29% *(6%)*	71% *(15%)*	100% *(20%)*	0% *(0%)*
Coach Beth-Teacher Barbara	7	0% *(0%)*	100% *(20%)*	0% *(0%)*	100% *(41%)*
Coach Beth-Teacher Brianna	9	42% *(10%)*	58% *(13%)*	0% *(0%)*	100% *(8%)*
Coach Latoya-Teacher Lindsey	25	21% *(5%)*	79% *(18%)*	28% *(9%)*	72% *(22%)*

Note. In each cell, the first percentage indicates the percent of coach-teacher talk at a particular depth for the foci of discussing content and pedagogy and noticing student thinking. The second parenthetical percentage indicates the percent of all the given dyad's talk at that depth.

Low-depth coach-teacher interactions about content, pedagogy, and students lacked reasoning and did not provide evidence to support statements made. Typically, one partner restated students' actions, named mathematical content, or stated mathematical procedures. In the absence of reasoning, we argue that fewer teacher learning opportunities were available.

High-depth coach-teacher interactions were marked by reasoning, as the coach and/or teacher elaborated on the process or the justification for their observations or decisions regarding content, pedagogy, or students. Typically, one partner justified their pedagogical decision making, provided reasoning behind their interpretations of student work, discussed their plans to implement pedagogical strategies or activities, or made conceptual mathematical connections visible to one another. In the presence of such reasoning, we argue that high-depth interactions open up rich opportunities for teacher learning. To illustrate, the following interaction took place while Coach Latoya modeled instruction in Teacher Lindsey's fourth grade classroom. Students had been independently working on a fair sharing fractions task, and the dyad came together during students' work time for the following 23-second, high-depth exchange:

Lindsey: So, even if they're not ready and they don't have it—

Latoya: But then they could talk with people at their [table], and that's the reason why I wanted to keep giving them independent time. Because I didn't want them to feel like somebody else is talking them through their thinking.

Lindsey: Right. And what if they're still, after five or 10 minutes they still don't have anything?

Latoya: Right. With the model, they should have something.

Above, Latoya provided a justification for her pedagogical decision to have students first grapple with the task independently before working in groups. Furthermore, when Lindsey raised concerns about students who may not have any work recorded, Latoya assured Lindsey that students should have something recorded, providing the reasoning that they were permitted to use manipulatives and pictorial representations.

Discussion and Implications

This study found six types of coach-teacher interactions during modeled lessons. We propose that four interaction types (joint teaching, logistics, performative praise and discipline, relationship building) lay the foundation for the model to occur by attending to logistics, materials, and the coach-teacher relationship. These kinds of interactions do not, however, open up opportunities for teacher learning about content, pedagogy, and students. Interactions focused on discussing content and pedagogy and noticing student thinking moved beyond discussing necessary mechanics to create learning opportunities about the work of teaching. Our analysis of the depth of coach-teacher talk found that when discussing topics of potential teacher learning, even brief interactions could include reasoning.

This study has implications for both practice and research. Our results serve as existence proof that coaches do not need to wait until after the lesson to engage teachers in high-depth interactions, and that such moments can happen as instruction unfolds in the presence of students. Furthermore, coaches need opportunities to learn how to engage teachers in high-depth interactions about content, pedagogy, and students during instruction. Future research is needed to explore the kinds of coach-teacher interactions that are possible against different disciplinary backdrops, as well as the contextual factors that enable and inhibit coaches as they seek to engage teachers in high-depth interactions during modeling.

THE INFLUENCE OF POSITIONALITY ON COACHES' OPPORTUNITIES FOR PROFESSIONAL LEARNING

Britnie Delinger Kane, PhD
The Citadel
britnie.kane@citadel.edu

Evthokia Stephanie Saclarides, PhD
University of Cincinnati
saclares@ucmail.uc.edu

Content-focused coaching is highly complex work, yet little is known about how coaches develop expertise needed to support teachers. This discourse analysis explored one group of elementary mathematics coaches' learning opportunities while collaboratively engaging in mathematics. Drawing on video and interview data from coaches and their district leader, our analysis highlights that coaches' discursive positioning influenced the types of coaching expertise they were able to develop while engaging collaboratively in mathematics. Implications for future research and practice are discussed.

Keywords: professional development, instructional leadership, classroom discourse

Effective coaching requires multiple forms of expertise, including disciplinary knowledge, pedagogical knowledge, as well as a professional coaching vision (Kane et al., 2018); however, little research has explored how instructional coaches develop these forms of expertise. Because *doing the math* has—for at least two decades—been recommended as a support for teachers' development of specialized disciplinary knowledge (Gibbons & Cobb, 2017), we were interested in how *doing the math* might support mathematics coaches' development of coaching expertise.

Because the research base on coaches' learning from *doing the math* is still in development, we extrapolate from findings about teachers' learning to better understand how *doing the math* might support coaches. In *doing the math,* educators are positioned as students in mathematics classes and asked to engage in inquiry with rich tasks that could be solved using multiple solution strategies. *Doing the math* has been found to support teachers to experience mathematics as a field in which knowledge is constructed—not received and reproduced—for the first time (Schifter & Fosnot, 1993). This is a foundational realization if one is to teach mathematics ambitiously (Windschitl, 2002). In addition, *doing the math* can support teachers to consider the mathematical strategies students might use and to discuss how they, as teachers, might guide and refine students' strategy use and selection (Borko et al., 2011).

Conceptual Framework

Building from Greeno and Gresalfi (2008), as well as a growing body of work on teachers' professional learning (e.g., Horn et al., 2017; Horn & Kane, 2015), we highlight that coaches' professional learning opportunities—like teachers'—are always influenced by the affordances and constraints of the contexts in which coaches learn. From this perspective, individuals' identities and positionalities within particular groups – that is, how they position themselves and how others position them – are an integral aspect of the ways in which individuals come to learn and to be accepted members of particular communities of practice (Lave & Wenger, 1991). Coaches' professional learning opportunities are thus shaped by the structure of professional development activities, how members are positioned within these activity, available tools and resources, histories of participation within particular groups, predominant topics and modes of talk, and the ways in which particular problems of practice are framed. Viewing coaches' professional learning opportunities through this lens allows us to analyze systematically how the design of the activity structure *doing the math* opened up particular foci for coaches' professional learning while constraining others.

Methods

Setting and Participants

Using a best case sampling logic (Yin, 2009), we selected one group of 12 elementary mathematics coaches from a district we call Hamilton. Hamilton coaches were a best case, because they met regularly (twice a month for 8-hour sessions) to participate in collaborative *doing the math* sessions. This group was especially notable because they worked together to solve cognitively demanding (i.e., "rich") tasks and held one another accountable for comparing and contrasting multiple mathematical solution strategies. All of these practices feature prominently in the literature on ambitious instruction in mathematics. These coaches reported to the building principal, were released full-time from teaching, and did not evaluate teachers.

Data Source and Analytic Technique

This analysis rests on two main data sources: transcribed video recordings of coaches' ongoing professional development sessions (n=6) and 15 semi-structured interviews conducted with a subset of coaches and the district administrator. We began by coding for two discursive moves, which have been identified in previous literature as central to educators' opportunities for professional learning (Horn & Kane, 2015): *epistemic claims* (assertions about what is true about students, teaching, mathematics, or coaching) and *representations of practice* (descriptions of classroom life focused on students, teaching, mathematics, or coaching). Coding was completed at the turn level, and utterances were coded multiple times as appropriate. This round of coding revealed qualitative differences in the ways that epistemic claims and representations of practice were used to make sense of mathematics, students, teaching, coaching, or any combination thereof, depending on whether participants spoke from the positioning, or footing (Goffman, 1974), of a student of mathematics, a teacher or mathematics, or a mathematics coach. Thus, in our second round of coding, we focused on which of those three roles participants took up. We used linguistic ethnographic methods (Rampton et al., 2015) to analyze the positionality from which coaches spoke, analyzing what opportunities for professional learning these positionalities made available about mathematics, students, teaching, and coaching. Last, we triangulated our findings using interview data from a subset of coaches.

Findings

When coaches spoke about mathematics, they were positioned as learners engaged in the process of doing mathematics over half of the time (435/791), which makes sense, since coaches were participating in *doing the math* sessions. Forty-three percent of the time, when coaches talked about mathematics, they did so from the positioning of a teacher. The frequency with which coaches spoke of mathematics from the positioning of teacher is notable, given that none of these coaches were teachers of record at the time of this study, although some coaches did teach an intervention course during the school day. Only six percent of the Mathematics codes were spoken from the position of coach, meaning that coaches were rarely positioned as coaches, despite that this data set is one in which, ostensibly, coaches met to learn about coaching.

From Student to Teacher of Mathematics. Hamilton coaches consistently shifted from a positioning as a participant in mathematics to a positioning as a teacher, which opened up opportunities for Hamilton coaches to make connections between their own mathematical thinking and instructional adaptations they might make in order to better support students. For instance, during a meeting in February of 2019, Hamilton coaches discussed a task which required participants to read a recipe and decide how they could cut a block of cheese into 36 pieces which were under half an ounce each. After the group had engaged with the task themselves, they had decided that "There are a lot of directions" (Facilitator Beth) and that the task would be a "reading comprehension activity" (Coach Lauren). Facilitator Beth then shifted the group's positioning from practitioners to teachers of mathematics, asking: "[W]hat might be something that you do to the problem itself to make it maybe more accessible?"

Coaches took up the positioning of teachers, discussing instructional adaptations such as breaking the problem up (Coach Maya), putting steps on index cards (Facilitator Beth), and giving students a "context for what was actually happening," since many students do not cook (Coach Lola). In this way, *doing the math* supported coaches to consider multiple instructional adaptations to use with rich tasks.

***Doing the Math* Supports Empathy for Students.** *Doing the math* also led coaches to take up an empathetic stance toward students. In the following excerpt, coaches discussed their own experience of engaging with the task and connected that experience to ideas for other instructional adaptations:

> Lola: 'Cause I cook, and I was reading this and finding myself checking out…You know, like I don't want to know all that. [CROSSTALK]
>
> Kaci: When I saw about cutting the cheese into 36 pieces I was like, yeah, next recipe.
>
> Beth: Yeah. Yes. Same… So that leads me to another thought. Simplify the wording, the numbers, the tasks. Simplify the amount of instruction for kids. Take away, like you said: "I'm a baker, I cook, and I was checking out."
>
> Lola: Right.
>
> Beth: You saw the number 36 and was like, nope! So already—we're adults.
>
> Lauren: So I checked out at dissolve yeast in warm water.
>
> Lola: I don't yeast. I don't yeast. [LAUGHTER]
>
> Lauren: I was like, I'm gonna go to another question.

Here, again, coaches presented their own thinking as practitioners of mathematics before making explicit connections between their own experience of *doing the math* and students' potential affective and academic responses to the tasks: "You saw the number 36 and was like, nope! So already—we're adults." In this way, Facilitator Beth introduced an empathetic stance toward students, and coaches then suggested a number of instructional approaches that could proceed from this understanding of students' thinking.

Interview data validates that being positioned as practitioners of mathematics supported Hamilton coaches to empathize with students. Three of the four coaches we interviewed highlighted *doing the math* as central to their learning, noting that it led them to more carefully consider their mathematical thought processes (i.e., specialized disciplinary knowledge) and to empathize with students. As Coach Lola pointed out in her year-end interview:

> I love the math, doing math, and I think it just is always good to get back in that being the learner…[It's] probably the most helpful thing that we do…because we're all learning the

> content part, but we're also putting ourselves in the, you know, position of students to remember, you know, what that feels like. (March 13, 2019)

Thus, *doing the math* supported coaches to empathize with students and to devise instructional adaptations in light of that empathy.

Coaching as a Rare Focus of *Doing the Math*. However, *doing the math* sessions rarely opened up opportunities for coaches to discuss issues related to the work of coaching. Across our data set, coaches discussed mathematics from the standpoint of a coach in only 6% of the total utterances devoted to mathematics (50/1961). When coaches spoke from the positioning of a coach, they most frequently discussed how they might support teachers, usually by sharing rich tasks and other resources with teachers (27 utterances); teachers' resistance to rich tasks (19 utterances); described teachers' success (2 utterances); and described school-level or administrative work (2 utterances). Interview data corroborated that coaches' participation in doing the math encouraged them to make rich tasks available to teachers. However, apart from these references, coaches did not elaborate in interviews about how *doing the math* influenced their coaching. This is perhaps unsurprising, given the infrequency with which Hamilton coaches spoke from the positioning of coaches or directly discussed coaching.

Discussion and Implications

Implications for the field include that coaches may value opportunities to collaboratively do mathematics, as it may support them to empathize with students' thinking and to think through instructional adaptations. Thus, our analysis demonstrates that findings about the usefulness of *doing the math* for teachers' professional learning also extend to coaches. Yet, findings also highlight that we must carefully attend to how coaches are positioned within activity structures (e.g., *doing the math*), since positioning coaches as teachers of record may truncate coaches' learning opportunities about coaching. Given the complexity of coaching, coaches need support not only in content and content-specific pedagogies, but also in developing a professional coaching vision. By attending to how coaches are positioned while *doing the math*, coaches might be supported to link their discoveries from when they were positioned as practitioners of mathematics to those that arose when positioned as teachers, and—finally—to those that arise when positioned as coaches. In this way, *doing the math* has the potential to help coaches develop empathy for both students and teachers. We look forward to future research that will undoubtedly clarify and refine the ideas we present here.

TEACHER SELF REPORT FRAMEWORK FOR MAKING TEACHING VISIBLE

Teruni Lamberg
University of Nevada, Reno
Terunil@unr.edu

Linda Gillette Koyen
University of Nevada, Reno
gillette@unr.edu

The Whole Class Discussion Framework (Author, 2019; Author, 2020) was administered pre and post PD. Specifically, teachers self-reported their teaching practice as it related 1) the design of physical space, 2) classroom routines, 3) lesson planning and 4) the whole class discussions. The meaning of these categories was explicitly addressed in the professional development that teachers participated in. The pre and post data were compared, and the data revealed that there were shifts in every category. The greatest shifts took place on how they facilitated whole class discussions. Implications for using this tool for teachers to professionally notice their practices to refine teaching, and for professional developers to make decisions to adapt PD are discussed.

Keywords: Teacher Noticing, Teacher Education, Professional Development

Theoretical Framework

The challenge of teacher professional development is to ensure that teachers refine their classroom practice to improve student learning. Even though many teachers engage in professional development, teachers often struggle to implement these ideas into their teaching practice (Borko, 2004). This is because the new ideas that they learn in the professional development that align with the Common Core (CCSSM, 2019) Standards for Mathematical Practice, does not align with more traditional approaches in teaching. Therefore, teachers struggle to figure out how to implement standards-based approaches into their existing routines. This is because most of what teachers do in planning and organizing for teaching becomes routinized and invisible (Author, 2003).

Teaching is a complex endeavor and therefore removing the complexity of teaching into isolated parts such as learning how to ask great questions without addressing how asking questioning fits supporting student learning, limits teachers' ability to transfer PD into the classroom (Opfer & Pedder, 2011; Van Driel and Berry, 2012). This example, can be thought of as a car engine. If you remove the battery, the engine does not work.

Therefore, a consistent pedagogical framework to support teachers to connect theory and practice along with time to learn and refine practice is needed (Heller at. al, 2012; Opfer & Pedder, 2011). The Whole Class Discussion Framework (Author, 2019; Author, 2020) was used as a tool for teachers to self-reflect to make their teaching practices visible and document shifts in practice. This study investigated what teachers reported as their teaching practice after they participated in a content and pedagogy based summer institutes that explicitly discussed aspects of the framework with regard the design of classroom environment, classroom routines, lesson planning and discussions. In addition, we investigated what ratings teachers self-reported after they had a whole academic year to implement the ideas that they learned to determine shifts in practice.

Methodology

Twenty-seven teachers participated in a yearlong content and pedagogy based professional development aimed at supporting teachers to implement the Common Core Standards (CCSSM, 2010). This was part of a larger study that was implemented in a Western State. The professional development was designed using the PD design outlined in Author, (2020). The participants were in-service teachers from several school districts who taught grades K-8th. The Whole Class Discussion Framework (Author, 2019) was administered at the end of a weeklong professional development and at the end of the school year. The weeklong professional provided teachers with content and pedagogical knowledge and explicitly addressed the aspects of the Whole Class Discussion Framework. Twenty-seven teachers completed the pre-survey and 23 teachers completed the post survey. The mean for each category of the framework was calculated and the differences between the pre and post survey means was determined to identify the change that took place in the mean scores. The scale was between 0 - 4.0

Findings

The pre and post surveys revealed that the teacher practice shifted in all areas of the whole class discussion framework (See Table 1).

Table 1: Teacher Reported Shifts in Practice

	Pre-Survey	Post Survey	Change
Design of Physical Space	2.26	3.17	0.91
Classroom Routines			
Routines for Discussion	2.36	3.17	0.81
Routines for Communication	2.32	3.35	1.03
Routines for listening	2.21	3.04	0.83
Lesson planning			
First Level	2.21	3.04	0.83
Second Level	1.93	2.83	0.90
Third Level	2.00	3.00	1.00
Whole Class Discussion			
First Level (Making thinking explicit)	2.00	3.09	1.09
Second Level: Analyzing Thinking	1.79	3.78	1.99
Third Level: Making big ideas explicit	1.79	2.91	1.12

The pre and post survey data indicate that teachers changed how they designed the *physical space* in the classroom for productive discussions and thinking. The initial mean was 2.26 and shifted to a mean of 3.17. The classroom routines involve what teachers do to prepare for discussions. This involves giving student time to think, work in small groups, and using representations and tools. When teachers started the professional development, the *routines for discussion* was a mean of 2.26. Many teachers did not think about what they needed to do to get students to prepare for discussions by thinking through the problem and engaging in problem solving. The mean shifted to 3.17 in the post survey. The *routines for communication* involved creating a classroom environment where students felt safe to express their ideas respectfully. This involved communicating in a manner so that the whole class could understand what was being shared. This means explaining their thinking and reasoning using gestures and representations. Teachers became mindful of creating a classroom culture for communication after the PD. The mean shifted from 2.21 to 3.04. The *routines for listening* involved creating norms for student expectations to listen to each and reflect on what is being shared. The mean shifted from 2.21 to 3.04.

Teachers were exposed to *Three Levels of Lesson Planning* with a focus on interconnections and sequencing. *The First Level of Planning* involves thinking about the standards and the "big ideas" that students need to learn. This process involved looking at the big picture and getting a sense of what students were expected to learn throughout the year. The initial mean was 2.21 and the post survey mean was 3.04. The *Second Level of Planning* involved looking at the unit and planning how to implement a lesson. This involved taking into account prior knowledge and sequencing lessons and tasks to support mathematical connections. Many teachers did not think about the sequencing of lessons and considering how to take into account student prior knowledge when planning lessons. This category had a low score of 1.93 prior to implementing ideas from the professional development and a mean score of 2.83 after the professional development. The *Third Level of Planning* involves adapting the lessons while teaching based on student reasoning. The pre-survey mean score was 2 and the post survey mean score was 3. Lesson planning was an area that scored lower than the rest of the categories.

Teachers were exposed to *Three Levels of Sense Making* to facilitate mathematical discussions so that students can make mathematical connections. The First level involves *making thinking explicit*. In other, words getting students to share their thinking. Teachers indicated pre-survey a mean score of 2 which increased to a mean score of 3 post PD. The *Second Level of Sense Making* involves having students analyze each other's solutions. This process involves looking at the structure of mathematics and strategies students used to identify similarities and differences in ways of thinking. Many teachers reported that they did not do this. The mean pre-survey score was 1.79 and the post survey score was 3.78. This mean that many of the teachers were beginning to go beyond having students share their thinking but digging deeper to think about the similarities and differences. The growth was 1.99. This was a huge shift in their practice. The *Third Level of Sense Making* involved thinking about abstraction to make the big mathematical ideas and strategies explicit so that students could transfer what they learned to new situations. There was significant growth in this area. The pre-survey score was 1.79 and the post survey score was 2.91. There was a growth of 1.12 in the mean.

Discussion

Teachers identified areas of strengths and growth and rated themselves critically in the pre and post teacher self-reported survey. A non-threatening environment was created to support learning in the PD sessions. This was critical for teachers to feel comfortable to honestly rate themselves to reflect on their teaching. The goal was to make teaching visible to the teachers and to have a tool (Author, 2020) that the professional developers could use quickly to make decisions to focus on areas of emphasis. The PD design and the professional development that was implemented is outlined in Author, (2020).

Prior to administering the framework, it was important to ensure that teachers all understood what the framework measured. The weeklong PD explicitly focused on various aspects of the framework, that involved the physical design of space, classroom routines, lesson planning, and whole class discussions (Author, 2019). They got the opportunity to learn math themselves and reflect on their learning experiences as it related to the aspects of the framework. They got to watch and analyze videos on various aspects such classrooms that used the *Three Levels of Sense Making* against discussions that only sharing took place. Teachers were given an opportunity to plan as they learned content and pedagogical content.

The framework identifies the complexity of teaching (Opfer & Pedder, 2011; Van Driel and Berry, 2012) and makes it possible for teachers to pinpoint their strengths and weaknesses. Furthermore, the aspects of the framework are aligned with the process of organizing for teaching and facilitating lessons in the daily work of teaching.

Therefore, the Whole Class Discussion Framework (Author, 2019; Author, 2020) served as a useful tool for teachers to think about the complexity of teaching and to make practices visible through self-reflection. Understanding this complexity and how everything is connected is an important part of shifting practice (Opfer & Pedder, 2011; Van Driel and Berry (2012). This is an important part of making teaching visible to shift practice. In addition, the framework is a useful tool for professional developers to quickly assess areas of strength and growth and plan professional development to meet the needs of teachers. The whole class discussion framework integrated multi-dimensions of teaching as suggested by Bransford, Brown, and Cocking (2000). The pre and post survey made it possible to identify areas of shifts and where teachers struggled the most and grew the most. This framework served as a performance tool that teachers could continuously use independently or with others to make teaching visible to improve teaching.

BUILDING "SMALL WORLDS" IN ONLINE PROFESSIONAL DEVELOPMENT WITH EVIDENCE-BASED NOTICING AND WONDERING

Anthony Matranga
California State University San Marcos
amatranga@csusm.edu

Jason Silverman
Drexel University
j657@drexel.edu

Understanding how to design online professional development environments that support mathematics teachers in developing mathematical and pedagogical knowledge is more important than ever. We argue that productive social and sociomathematical (SM) norms have benefits for teachers learning mathematics in online asynchronous collaboration and that particular patterns in interactions can create context for the emergence of such norms. We employed social network analysis to compare the emerging social networks of two iterations of an online asynchronous professional development course focused on functions to understand whether particular scaffolds can support the emergence of specific patterns of interactions. Results suggest that evidence-based noticing and wondering can impact the "small world" properties of a social network and associated potential for the emergence of social and SM norms.

Keywords: Professional Development, Online and Distance Education, Teacher Knowledge, Noticing and Wondering

Objectives and Purposes

Our work focuses on the design of online professional development environments that support teachers in collaboratively developing mathematical and pedagogical knowledge. One challenge associated with such design endeavors is moving mathematics teachers from "show and tell" to collaboratively building mathematics knowledge together (Stein, et al., 2008) by participating in productive social and sociomathematical (SM) norms (Cobb et al., 2001). We argue that there can be a connection between the evolution in particular patterns of teachers' interactions in online asynchronous collaboration and potential for the emergence of social and SM norms. The current paper documents evidence-based noticing and wondering (EB-NW) scaffolding the emergence of these particular patterns of interactions in mathematics teachers' online asynchronous collaboration, where the focus of collaboration was on developing foundation reasoning skills for understanding the concept of function.

Theoretical Framework

Social norms and their mathematics-specific counterpart SM norms – accepted and expected regularities in mathematical dialogue – have benefits for collaborative mathematics learning in both face-to-face (Clark et al, 2008) and online mathematics teacher professional develop. Such norms can guide generative and collaborative mathematical activity that includes explaining and justifying one's reasoning, communicating the meaning of mathematical ideas, and critiquing colleagues' mathematical reasoning (Elliot et al., 2009; van Zoest et al., 2012). As such norms emerge, they create conditions for teachers learning to make contributions to collaborative mathematical activity that align with these generative forms of participation (Cobb et al., 2001). Further, teachers participating in productive norms provides them with experiences learning mathematics in a discourse-centered environment and these norms can become tools for building similar norms in their own classes (Clark et al., 2008; Tsai, 2007). Thus, it is important to understand how to support the emergence of norms in online professional development settings –

a setting that can be scaled to increase the impact of professional development on teachers' mathematics instruction.

Mathematics teachers accessing and engaging with their colleagues' mathematical reasoning is important for the emergence of social and SM norms in online settings. A key difference between building norms in face-to-face and online settings is how one gains access to or listens to their colleagues' ideas (Dean & Silverman, 2015). In face-to-face settings, teachers can listen to a mathematics conversation simply through proximity to others; in online asynchronous collaboration, researchers must define "listening" in a different way (e.g., see Wise et al., 2013). In our work, we define listening as explicit interaction with colleagues' mathematical reasoning by reviewing and responding to another's post. Because of the publicity and permanency of teachers' contributions to online asynchronous collaborative environments, reviewing and responding to another's post can include extended reflection on a specific way of reasoning in the post. Therefore, an individual's mathematical reasoning in an online environment can become a scaffold that supports others in learning to engage in generative contributions and/or interactions in the online space. Regularities in mathematical reasoning can emerge when mathematics teachers are reflecting on, taking up, and trying out their colleagues' mathematical reasoning. This process can result in specific ways of reasoning becoming more visible in an online space (Borba et al., 2018), which increases the potential influence of specific reasoning on collaborating teachers' future use of reasoning (Lave & Wenger, 1991) – if they are interacting with colleagues' in the online space.

Small world networks can create context for interaction and, ultimately, the emergence of social and SM norms in online professional development settings. The concept of a small world - what is commonly thought of as the "six degrees of separation" between any two people in the world - is often applied to studies of social networks. Formally, a small world is a sparsely connected social network - – set of nodes (people) and edges (an interaction between two people) - with both high local clustering and short paths of connections between individuals in the network (Watts, 1999). In the context of online asynchronous collaboration via discussion boards, a social network with a minimal average path length means that mathematics teachers are accessing and engaging with a large proportion of their colleagues' mathematical reasoning. We argued above that access and engagement with mathematical reasoning can create context for the emergence of social and SM norms because of the potential for specific ways of reasoning to diffuse through the network. Therefore, we argue that the "small worldness" of mathematics teachers' social network is an indicator of the potential for emerging social and SM norms in online asynchronous collaboration.

Further, we argue that EB-NW can scaffold the emergence of small worlds. Noticing and wondering is receiving increasingly more attention in the literature (e.g., Dobie & Anderson, 2020). We are currently engineering a virtual assessment environment that scaffolds a specific type of noticing and wondering – EB-NW, which is noticing and wondering that is explicitly connected to a colleagues' thinking. The environment enhances typical online asynchronous discussion forum conversations by scaffolding EB-NW with two key design features: a selection tool that allows teachers to highlight specific aspects of colleagues' mathematical reasoning and a commenting tool that supports noticing and wondering that is explicitly connected to the selections (the evidence). Our past work has documented the effectiveness of the environment to support teachers in engaging with the details of their colleagues' mathematical reasoning and providing generative feedback that moves beyond a focus on the correctness of their colleagues' solutions (Matranga et al., 2018). Further, we have found that teachers are less likely to provide one another evidence-based and generative feedback when online asynchronous collaboration is scaffolded by discussion forums (Matranga, 2017). Thus, we argue that technologically scaffolded EB-NW can increase the proportion of interactions in an online asynchronous collaborative setting that include mathematics teachers' explicitly engaging with colleagues' mathematical reasoning, thus enhancing the small world*ness* of a social network and associated potential for emergent norms.

Methods

We investigated the small world properties of mathematics teachers' evolving social network in two iterations (C1 and C2) of an online asynchronous professional development course focused on understand the behavior of functions. The course includes eight weekly problem-solving modules, each featuring a set of mathematics tasks and scaffolds to support participant engagement with the mathematics and interaction with colleagues. The modules included an initial period of individual problem solving and then a period specifically devoted to peer-to-peer collaboration. The two iterations of the course differed only by the collaboration scaffolds provided – the first utilized traditional discussion boards (C1), while the second utilized the virtual assessment environment designed to scaffold EB-N&W and mediate teachers' collaboration and interaction (C2). Our research question is: How does participants' engagement with and access to colleagues' mathematical reasoning differ between C1 (n = 16) and C2 (n = 23)? In particular, we seek to understand if one course and associated scaffolds more effectively support participants' engagement with and access to colleagues' mathematical reasoning.

Social Network Analysis (SNA), an analytical tool that can be used for quantifying patterns in interactions (Light & Moody, 2020), and statistical analysis was used to examine and compare the extent to which the networks exhibited small world properties. Accordingly, we modeled C1 and C2 as a set of nodes (participants) and directed edges connecting nodes (a response from one participant to another). We used the SNA metric of network efficiency to examine the small world properties of the network because this metric can provide insight into the extent to which network members are accessing and engaging colleagues' mathematical reasoning (Latora, & Marchiori, 2002). Specifically, network efficiency is quantified by counting the minimum number of edges required to connect one colleague to another. The individual degrees of separation for each pair is used to calculate the network efficiency by summing across all pairs and normalizing results. Network efficiency ranges between 0 and 1, where 0 is a minimally efficient network (a completely disconnected network) and 1 is the most efficient network (a fully connected network - the smallest possible world). We extracted participant interactions (358 for C1; 385 for C2) from the courses, generated cumulative interactional datasets for each week of the courses (e.g., the week two data set from C1 included interactions from week 1 and week 2 of C1), and then imported the data into UCINET to assess the network efficiencies.

SNA measures are highly sensitive to the number of nodes in the network (Wasserman & Faust, 1994). Therefore, in order to compare the two courses and interpret our results, following Opsahl et al. (2017), we modeled 50 different hypothetical networks with the same number of nodes (participants) as the courses under investigation but with edges (interactions) randomly distributed between pairs of nodes. The mean efficiency of these hypothetical networks, referred to as the *average random graph network efficiency* (RGNE), allowed us to compare the observed network efficiencies from each week of C1 and C2 to RGNE for each week of each course, where engagement with and access to mathematical reasoning was randomly distributed throughout the network. This included verifying that the network efficiencies of each set of 50 hypothetical networks were normally distributed and then calculating significance levels by comparing the observed network efficiency from each week of each course to the corresponding RGNE.

Results

Table 1 presents results for the observed network efficiency (O), the RGNE, and the corresponding p-values when comparing the observed network efficiencies to the RGNE. In both courses, the network efficiencies increased throughout the course, which is expected because participants had increased opportunities to access and engage with colleagues' reasoning as the course progressed. The network efficiency of C1 remained larger than C2 throughout the course. Further, the network efficiency of C1 was significantly lower than RGNE for weeks 3-8 *($p <$ 0.05)*, while the network efficiency of C2 was not significantly different from the RGNE for weeks 1-7. However, the network efficiency for C2 was significantly lower than RGNE after week 8.

Table 1: Week by week observed network efficiency, RDNE, and p-values

	Wk1	Wk2	Wk3	Wk4	Wk5	Wk6	Wk7	Wk8
O-C1	.140	.321	.431	.465	.528	.570	.613	.630
O-C2	.055	.138	.301	.366	.395	.444	.537	.548
RGNE-C1	.112	.336	.489	.534	.577	.623	.646	.664
RGNE-C2	.054	.113	.276	.377	.416	.472	.549	.564
***P* - –1**	0.129	0.374	0.015	0.001	0.003	1.1E-06	3.2E-06	3.2E-09
***P* - –2**	0.396	0.221	0.289	0.351	0.235	0.097	0.191	0.026

Discussion

The results of the analysis indicate that for the majority of the course (week 3-8), C1 had a significantly lower network efficiency than would be predicted by the RGNE, while the network efficiency of C2 was not significantly different than the RGNE. Watts and Strogatz (1998) note that a small average path length (i.e. higher efficiency) is one characteristic of randomly generated graphs and, as a result, the C2 network has small world characteristics. This result provides evidence that C2 (scaffolded by technologically supported EB-N&W) more effectively supported participants' engagement with and access to colleagues' mathematical reasoning throughout the "meat" of the course, increasing the likelihood for social and SM norms to emerge. Implications of this study include (1) the design of online teacher professional development environments with scaffolds that support teachers in connecting their N&Ws to evidence in their colleagues' reasoning when providing feedback, and (2) a methodology that can increase the scale of rigorous SNA studies of collaborative professional development, from examining single implementations of professional development to comparing multiple iterations of the same professional development as well as across professional development programs (Borko, 2004). Our plans for future research include expanding the current results to examine the specific social and SM norms that emerged in C1 and C2 as well as the specific role of EB-NW in scaffolding the emergence of norms.

HIGH SCHOOL TEACHERS' THINKING ABOUT THE LIMIT CONCEPT

Beste Güçler
University of Massachusetts Dartmouth
bgucler@umassd.edu

Facilitating meaningful discourse is a component of supporting productive struggle. To facilitate meaningful discourse in their classrooms, teachers need to be aware of and reflect on their own mathematical discourses and communication. This study examines one pre-service and seven in-service high school teachers' thinking about the limit concept in a calculus content course they took as part of their professional development. The course focused on eliciting teachers' discourses on limits and make them explicit topics of discussion and reflection to support teacher thinking and communication. The results indicate that the approach has the potential to support teacher thinking and increase awareness of their mathematical discourses and communication. The study concludes that it is important for teachers to engage in productive struggle to use it as a practice in their own classrooms.

Keywords: Calculus, classroom discourse, communication, professional development

Introduction

Supporting productive struggle is a component of mathematics teaching and facilitating meaningful discourse is a critical aspect of supporting productive struggle (Boston et al., 2017). It is unlikely for teachers to facilitate meaningful discourse in the classroom unless they are aware of and reflect on their own mathematical discourses. This work focuses on high school teachers' discourses on the limit concept with a focus on their thinking in a calculus content course designed to elicit their discourses on limits and then make them explicit topics of discussion and reflection to support thinking and classroom communication.

Limit is a foundational concept of calculus that presents major challenges for students and teachers (e.g., Masteroides & Zachariades, 2004; Williams, 1991). Students often think about limit as a dynamic process rather than a mathematical entity (a number) obtained at the end of that process, leading to challenges in thinking about the formal aspects of limits. This issue is referred to as a process-product or a process-object duality inherent in limits through its dynamic and static realizations (e.g., Gray & Tall, 1994; Güçler, 2014). Some other student difficulties about limit include thinking about limit as a *bound* (Cornu, 1991; Williams, 1991), as *unreachable* (Williams, 1991) and assuming that *limit implies continuity* (Bezuidenhout, 2001). Students' realizations of limits can differ from their mathematical definitions of limit, leading to confusions about the concept and its representations (Güçler, 2014; Tall & Vinner, 1981).

Although teachers can flexibly move between different realizations of limits, the associated changes in their discourses can remain tacit for the students in the classroom (Güçler, 2013). Teachers can enhance classroom communication and facilitate meaningful discourse by explicating their discourses and talk about the different assumptions shaping different realizations of the limit concept (Güçler 2013; 2014). To create such a classroom environment, teachers need to be aware of different contextual realizations of limits and their own discourses about the concept. The study uses a discursive lens to answer the following question: How do eight pre- and in-service high school teachers think about limit in a calculus content course that promoted the elicitation, discussion, reflection, and explication of their discourses to support thinking and mathematical communication?

Theoretical framework

This study uses Sfard's (2008) communicational approach to cognition, which highlights the sociocultural origins of human development and views thinking as communicating with one's self. From this perspective, mathematics is characterized as a discourse – a form of communication that can be distinguished by its word use, visual mediators, routines, and endorsed narratives (Sfard, 2008). Word use refers to the ways in which participants use mathematical words in their discourses. Visual mediators refer to all the visuals generated and used for the purposes of mathematical communication. Routines are the meta-level rules that characterize the patterns in participants' discourses. Endorsed narratives are the utterances describing mathematical objects and their relationships the participants consider as true. In this study, the focus is on high school teachers' word use and endorsed narratives about limit in the form of definitions and the potentially implicit aspects of their discourses on limits. A fundamental assumption of the study is that teachers' awareness of and reflections on their own discourses on mathematics does not only support their thinking and communicating, but also generating meaningful discourse in their own classrooms.

Methodology

The focus of the study was to elicit teachers' discourses on limits and make their discourses explicit topics of discussion and reflection in the classroom. The activities used in the classroom were developed based on research on student and teacher difficulties about limits and the research highlighting the tacit aspects of the discourse on limits to expose teachers to different realizations of limits. The goal was to use the classroom activities to bring forth and reflect on teachers' discourses to support their thinking on limits, which could then help them support the thinking of their students.

The participants were one pre-service and seven in-service high school teachers taking a content course in calculus as part of their initial licensure program or professional development. Except for the pre-service teacher, who had no prior teaching experience besides calculus tutoring, the participants' teaching experiences ranged between 4 –12 years. The researcher was the instructor of the course. The data for this work consisted of an initial survey given to teachers at the beginning of the course and 3 video-taped classroom sessions (each lasting 2.5 hours) on limits. The classroom sessions were transcribed. The transcripts were examined with a focus on teachers' word use (particularly with respect to the process-object duality of the limit concept), endorsed narratives about limit (in the form of definitions), and the assumptions shaping their word use and narratives.

Results

In the initial survey, which was administered during the first week of the course, the teachers were asked to define what a limit is in their own words. Table 1 shows the teachers' responses to the initial survey. All the names used in the study and pseudonyms; Steve was the only pre-service high school teacher in the course.

Table 1: Teachers' definitions of limit in the initial survey

Carrie	[1] A value that is approached but not necessarily reached.
Fred	[2] As an input gets very large or very small, the function approaches a particular

	value.
Lea	[3] Restriction
Martin	[4] The point to which a function no longer adheres to the same rule.
Milo	[5] An interval of data options
Ron	[6] Looking at a function at a specific point from both sides of the function
Sally	[7] As the x values approach certain values, the function approaches the limit.
Steve	[8] As an equation or function approaches a specific point (or increases/decreases) the limit is a point in which the function approaches.

Table 1 indicates that not all teachers provided a mathematically accurate definition for the limit concept ([3], [4], [5]). Some teachers referred to limit as an object (a value [1], a point [4,8], an interval [5]), whereas others talked about the dynamic process of obtaining a limit ([2], [6], [7], [8]). Carrie's response indicated that she viewed limit as *unreachable* [1] and Lea seemed to refer to limit as a *bound* [3] demonstrating that some of the teachers showed difficulties about limit mentioned in the literature. It was unclear how Martin and Milo thought about limits. Martin referred to limit as a point where a function does not adhere to the same rule [4] whereas Milo seemed to think of confidence intervals in his response [5].

The elicited discourse in the classroom provided more information about how teachers thought about limit and clarified some of their responses in the initial survey. The classroom discussions about limits started with an activity where teachers were asked to define limit in their own words (a) using one word, and (b) using as many words as they wanted. They were then asked to elaborate on their responses and reflect on their definitions in terms of their similarities and differences. The one-word definitions of limit ("A limit is a….") generated by the teachers were: boundary, unreachable, constraint, value, approach, convergence, exists/does not exist. When teachers were asked to elaborate, Carrie said "I think of limit as the value you approach. We sometimes attain it; it is a value" indicating that she viewed limit as a value that can be attained and did not realize limit as unreachable, which was different than her response in the initial survey, where she argued that the value would not necessarily be reached [1]. Fred said "you can't go beyond it; it is like a bound or constraint" and "you don't ever get to the limit", indicating that he viewed limit as a *bound* and *unreachable* – views that were not apparent in his response in the survey [2]. Ron, when talking about the word approach, said "you approach the graph, the function and say where is your function? So, you approach from the left and right, where does the function approach? The function may or may not be defined at that point." When asked what a limit is, he replied "it is the approaching". Ron's discourse indicated that he realized that discontinuous functions could have limits and limit is the dynamic process of approaching. He also seemed to think about limit visually since he consistently used the word graph when talking about limits throughout the class. Steve, building on Ron's discourse, elaborated on his word convergence by saying "I see it as the same thing as approaching; it is just I am more used to hearing convergence. As you are approaching infinity, you are trying to see what value this function converges to". Here, Steve referred to limit as a value through a dynamic view of limit involving approaching and convergence. Sally elaborated on her words exists/does not exist by saying that "in algebraic problems, and depending on which way you are approaching, sometimes the limit exists and sometimes it doesn't".

The teachers then generated three definitions of limit using any number of words as they wanted:

Carrie: A limit of a function as x approaches a is the value that the function approaches as x gets very close to a. $f(a)$ may or may not be equal to the limit value.

Fred: The limit is the function output as the input value of x approaches a value resulting in a convergence of a specific value.

Lea: Limit is a specific value a function approaches but will never reach.

Carrie's definition indicated that she did not hold the view *limit is the function's value* and her realization was based on a process view of limit resulting in a value as the limit. Fred adopted the word "convergence" used by Steve in his definition and his definition was also based on a process view through dynamic motion while referring to limit as an object (function output). Yet, his views of limit as a *bound, unreachable,* and *constraint* were not evident in his definition. Lea's definition referred to limit as a value based on a dynamic process view while also retaining the realization that limit is *unreachable.*

Although these discussions did not completely reveal all aspects of teachers' discourses when thinking about limits, they revealed that many teachers showed the student difficulties about limit highlighted in the literature. The teachers' discourses indicated that—even when they referred to limit as a value—their realizations of the concept were mainly based on the process view of limit through dynamic motion, where the function approaches a value as the x approaches a specific point. The discussions showed that the teachers were not aware of the process-object duality inherent in the concept. There was also no indication in the teachers' discourses that they were aware of the static view about limits consistent with the formal definition of the concept. This activity showed that teachers' realizations of limit could be varied and fragmented, providing a mathematically correct process view definition, but at the same time having the many mathematically incorrect realizations of limit such as viewing it as a *bound* or *unreachable*. Teacher responses during the activity also suggested that the assumptions teachers hold in their realizations and definitions of limit may remain tacit, especially if those assumptions are not explicitly spelled out in their definitions. The discussion ended with the explication of and reflection on the assumptions and metaphors inherent in the teachers' discourses about the definitions as well as those not mentioned by the teachers (e.g., limit as a process, limit as an object, metaphor of motion through the dynamic view, metaphor of discreteness through the formal view).

Space constraints do not allow elaborating on all the classroom activities in detail or demonstrating the development of the teachers' thinking throughout the course, but those results indicate that activities tailored to elicit teachers' discourses on limits, encourage reflection on their discourses and the tacit assumptions shaping their discourses have the potential to support teacher thinking, learning, and enhance communication in the classroom.

Discussion and Implications

The results of the study suggest that making teachers' discourses explicit topics of discussion and reflection in the classroom supported their thinking and communication about the limit concept. The teachers learned about and increased their awareness of the tacit aspects of their discourses and such awareness is necessary for them to communicate mathematical ideas effectively and facilitate meaningful discourse (a component of supporting productive struggle).

The pedagogical approach used in the study helped teachers realize their own struggles with the limit concept, which can help them better anticipate student difficulties—another component of supporting productive struggle in the classrooms (Boston et al., 2017). The study demonstrates the importance of engaging teachers in productive struggle in the context of teacher education to prepare them to support productive struggle in their own classrooms. The discursive inquiry, explication, and reflection demonstrated in this study can be useful for teachers to model, adopt, or adapt similar approaches in their own teaching practice to facilitate meaningful discourse and support productive struggle.

The EnCoMPASS project (Emerging Communities for Mathematical Practices and Assessment) at Drexel University has produced a web-based software tool for the assessment of student work. This paper discusses research on the impact of this tool on teachers' attitudes toward engaging with students in the software environment. The tool supports teachers adopting a more dialogic perspective towards learning and teaching through cycles of problem solving, discussion and mathematical development. It is suggested that the tool aids teachers' transition toward this more interactive approach to teaching mathematics while also acknowledging and addressing concerns about the time it takes to engage in more detailed dialogue and thinking about mathematics with their students.

Keywords: Problem Solving, Professional Development, Technology, Teacher Knowledge

Introduction

EnCoMPASS (http://mathforum.org/encompass) is an NSF-funded project that is focused on creating an online community of teachers that supports and encourages the use of students' mathematical work – particularly detailed and structured analysis of students' work – to inform instruction. As a central part of the project, the EnCoMPASS tool, was developed to support teachers to shift from the assessment of the "products" of student work toward a process-oriented approach involving interaction with students around mathematics. The EnCoMPASS Tool is a web-based software environment focused on the assessment, analysis and support of student mathematical problem solving. We argue that the EnCoMPASS tool disrupts the normative tendency for teachers to focus on what students know and correct answers. Instead, it provides a scaffold for teachers to look carefully at student work, selecting specific evidence from that work, and using that evidence to begin the process of dialogue with students about mathematical thinking and ideas. Built into the EnCoMPASS tool is the Noticing & Wondering (N&W) framework that was developed and promoted by the Math Forum to encourage teachers to focus on the evidence from the work that student have produced. N&W also scaffolds teachers as they begin a process of dialogue with students about how students' ideas and understandings are developed and supported by those noticings and wonderings.

The EnCoMPASS tool is designed to collect student work and allows a teacher to identify and highlight potentially significant excerpts from the student work and comment on selected text or "selections". These selections can then be sorted and categorized into a number of folders that allow for quick categorization of the work of multiple students and for teachers to easily look at the aggregated work in the folders. In addition, teachers can craft feedback to a student, or the students in a particular folder, to push their mathematical thinking further. Through a process of iterative design testing of the tool with teacher collaborators, the N&W framework was integrated into the tool to scaffold teachers in their efforts to comment upon selections from the student work and organize the work into folders with the selections connected to their N&W comments.

In this segment of our research, we have attempted to understand how the EnCoMPASS tool helped to disrupt traditional norms mathematics teaching, as recognized by the participants, and further, helped teachers see the value of taking students ideas seriously and beginning a conversation with those students about the mathematics. The research questions guiding this work are: 1) How does the EnCoMPASS tool support teachers to engage in a processual approach to mathematics?, 2) What does the shift toward process look like in this context?, 3) What forms of teacher reflection are produced through the EnCoMPASS tool and the Noticing & Wondering scaffold?, 4) How does the tool support a continued dialogue with students?

Theoretical Framework

Researchers at the EnCoMPASS project see mathematics as part of people's everyday lives. Many of the math problems used come from everyday life and they remind students and adults that doing math is part of what we all do. Everyday problems remind us that math is about the practice of problem solving. And problem solving involves understanding situations, assumptions and includes conversations with others. Thus, mathematics is a communicative and social process. Finally, the result of working out problems and talking with others about that work results in mathematical thinking. The way for all people, students and teachers alike, to get better at math is to improve their mathematical thinking.

Central to this practice is the relationship between conversation, interaction and thought. Several philosophers and social scientists have pointed out that thinking, learning and knowledge production are social phenomena (Peirce, 1931; Bakhtin, 1981). Sfard (2008), bringing together the work of scholars such as Dewey (1938), Vygotsky (1978, 1986) and Wittgenstein (1953) claims that communication and cognition are flip sides of the same coin and that our traditional ideas about knowledge acquisition are incorrect. Knowledge and what we call learning, are communicative acts and necessarily social. She coined the term commogition to underscore that communication and cognition are social and intersubjective. To Sfard (2001), mathematical development involves being assimilated to a new discourse akin to the ways that Lakoff & Johnson (2003) talk about how metaphor is used to expand understanding in general.

These ideas are compatible with the notion of sociomathematical norms and mathematical identity (Cobb, Gresalfi,& Hodge, 2009; Boaler & Greeno, 2000). Teachers must be immersed in a discourse of mathematics, but they also need to be able to help students move to use these new signifiers before they are fully able to understand the mathematical objects they represent (Horn & Kane, 2015). Students and teachers must then find themselves in a discourse community where problem solving and mathematical practice is part of the norms of that social group (Gresalfi & Cobb, 2011). Being a member of that discourse community leads in a dialectical way to more conversation and more thought and deeper forms of knowledge and understanding (Bannister, 2015). Lave & Wenger (1991), for example, note that it is impossible to distinguish the learning from the context within which the learning takes place.

We can think of the traditional norms of math education, where students and teachers focus on using the right procedures and getting the right answer as a scaffold to this more complex process of building mathematical knowledge. The problem with that scaffold is that it reifies the process and the product and only aids the development of and only values mathematical thinking in a limited way. The EnCoMPASS tool, and the N&W model built into it, was designed to provide a more productive scaffold. For the purposes of this paper N&W allows teachers to notice things about student work, wonder what the student was thinking and where that thinking could go. This scaffold them allows the teacher to begin a dialogue with the student about their ideas and move both the teacher's thinking about the students' understanding and the students' mathematical thinking forward.

The EnCoMPASS tool not only allows N&W to move a conversation and a process forward, but it also productively disrupts the normative practices and assumptions in mathematics education (Figure 2 above). The online tool allows the conversation about mathematics to slow down and not move so quickly toward correct answers.

Disrupting traditional norms of the mathematics classroom (Yackel & Cobb, 1996) then makes room for a more process-oriented approach. The notion of productive disruption has been used in other contexts by other education researchers (Hall, Stevens & Torralba, 2002; Ma, 2016). What is consistent in those contexts and ours is the idea that we are disrupting existing norms and assumptions in order to have a productive effect on the conversation and thinking of a group of people. The scaffold the tool provides support for teachers and as a result they attempt to engage in a more organic conversation about the math centered on the student's thinking. In this way it mitigates against teachers' anxiety about not having enough time.

Methods and Data Sources

Because the goal of this analysis is to look closely at the ways in which teachers interact with student work in the EnCoMPASS environment discourse analysis was used (Gee, 2014). Data sources for the discourse analysis came from several teachers who were enrolled in a graduate education program at Drexel University and were using the EnCoMPASS tool as part of the work they did in a course focused on student problem solving and student thinking. There were a total of 18 middle or high school teachers enrolled in the course. Several different kinds of text-based data sources were subject to an interpretive and iterative analysis. In the course, teachers first highlighted selections from student work with the EnCoMPASS tool. They then commented upon these selections by making a noticing about the highlighted selection and/or a wondering about the selection. For our analysis we paid attention to what was highlighted, the kind of commentary the teacher made (noticing or wondering) and then the content of the comment.

Additional data included teachers' reflections upon their experience using the tool, using the noticing and wondering framework and the process of taking students ideas seriously. These comments were also analyzed using an interpretive and iterative analysis. At the point this data was collected, students had used the EnCoMPASS tool, as a sometimes option tool, in assignments/class for over 6 months.

Data Analysis

In our data, we see teachers who are working with the EnCoMPASS tool attending closely to the students' mathematical work. They are more likely to respond to specific aspects of student solutions. In follow up interactions with teachers, we observed three important characteristics. First, teachers noted the importance of slowing down their interactions with students and how the N&W approach allowed her/him to see things in the student work. Second, we saw evidence of teachers asking the student what they were thinking, wondering about connections the student was making. The teacher was moving toward a more dialogic approach to working with this student on mathematics, placing emphasis on continued and generative mathematical conversation and not just evaluation of correctness. Teachers also noted that much of this work was not part of their "initial instinct[s]" about this student's thinking. In addition, we saw that the EnCoMPASS tool and the N&W framework encouraged shifts in their practice. Teachers would compare their solutions to the problem with those of their students. The teachers also discussed how the N&W framework really forced them to think about what the students were doing and to ask questions about what the students were thinking. One teacher noticed that the value of the software tool was not only to help the process of dialogue with the student, but also the tool helped organize the teacher's thinking and perhaps aided efficiency.

Discussion

As we can see, from the brief summary of examples in the data, the EnCoMPASS tool allows teachers to use student work and student thinking as the starting point for pedagogically purposeful conversations with students. Evidence indicates teachers believing this work has enabled shifts in their instructional practice and the value they found in these student-centered instructional practices. Of course, not all students respond to these prompts. But the nature of the prompt is to disrupt a more normative response and reorient the teacher toward dialogue about mathematics and thinking rather than the assessment of correct strategies and correct answers. We can see further from some of the responses, that in order to reflect on what the student is doing it is natural to reflect on what one did to work with the problem – a process referred to as double reflection (Shumar, 2017). Double reflection can be a critical attitude and practice in the building of mathematical knowledge for both the teacher and the student. It enables teachers' changing orientations toward problem solving, student engagement and making the focus process not production, allowing the teacher to more naturally move toward the dialectical process of practice-talking-thinking.

Significance

The analysis here demonstrates that the EnCoMPASS tool and the N&W scaffold helps to move teachers toward an interactive stance with students around the doing and talking about mathematics. The tool has helped move them toward paying close attention to their own mathematical work and has transformed how the look at student work and student assignments. There are suggestions here for future research. We suggest that this tool and way of working will help teachers deal with unique situations and more unusual responses on the part of students. This should help teacher take advantage of opportunities to help students make insights and advance their thinking. The tool moves everyone from reified notions about being good at math toward genuine dialogue. Our contention is that this should make both students and teachers better mathematical thinkers. Looking at how to assess teachers and students as mathematical thinkers is a next step in the research.

HOW ADJUNCT INSTRUCTORS' PERCEPTIONS ABOUT IMPLEMENTING RESEARCH-BASED MATHEMATICS CURRICULUM MAY INFLUENCE THEIR PROFESSIONAL DEVELOPMENT NEEDS

Zareen G. Rahman
James Madison University
rahmanzx@jmu.edu

When planning professional development (PD) for adjunct instructors the PD developers should be mindful of the diverse experiences and needs of adjunct instructors. Developing PD that is one-size-fits-all may not work for all adjunct instructors. In this study the diversity of 3 adjunct instructors' experiences is highlighted prior to and in the initial stages of implementing a new research-based Precalculus curriculum. This work draws from a larger study (Rahman, 2018) about adjunct instructors' experiences navigating a new mathematics curriculum.

Keywords: Undergraduate Education, Curriculum, Professional Development

Teachers play an important role in implementing research-based curricula that aim to prepare and retain STEM students (Ball & Cohen, 1999; Cohen & Ball, 1999; Ellis, 2014; Remillard, 2000). They often find implementing such curricula challenging (Thompson & Carlson, 2017) and must be supported (Ellis, 2014; Remillard, 2000; Thompson & Carlson, 2017). It must be noted that the needs of teachers varies based on their situation. For example, adjunct instructors, who are part-time, non-tenure track faculty at the college- and university-levels have their own sets of challenges and constraints (Pepin, 2014). In the United States, adjunct instructors are increasingly being employed by institutions of higher education (Mason, 2009; Curtis, 2014; Green, 2007), often receiving less pay than full-time faculty (Gerhart, 2004). Their increased presence in higher education classrooms emphasizes the need to understand their experience, especially as it connects to their students' learning (The Delphi Project, 2012). Specifically, it's important to understand the professional development (PD) needs of adjunct instructors.

Literature Review

PD for part-time faculty is important because regardless of their appointment type, all faculty members are valuable to an institution (Gappa, Austin, & Trice, 2007). With support, faculty can continue to be effective and strengthen the quality of their instruction, research, and outreach (Leslie & Gappa, 2002; Gappa et. al, 2007). Teacher learning takes place within a context and it is important to recognize the environment within which learning takes place (Putnam & Borko, 2000). Teachers benefit from PD when it is connected to their own contexts (Lave & Wenger 1991, Greeno et al. 1996, Borko 2004). Effective PD has four parts: design, teachers, facilitators, and context in which the teachers function (Borko, 2004). Participants must find the PD relevant to their context and connect with other members of their community (Desimone, 2009). Further, the design of effective PD must include teachers as co-designers of the learning experience to ensure that the PD is relevant to their learning needs (Timperley, 2011).

When designing programs to support adjunct faculty, it is important to keep their needs in mind. Adjunct faculty needs to feel like they are a part of the intellectual life of the institution (Gappa et al., 2007; Lyons, 2007). In addition, adjunct faculty require continued PD, recognition for good work (Lyons, 2007), and access to resources needed to fulfill their responsibilities (Gappa et al., 2005). Administrators should learn about adjunct instructors' specific PD needs

(Green, 2007; Gappa et al., 2007) as their working conditions and lack of PD opportunities can influence student learning (The Delphi Project, 2012). Research on mathematics adjunct instructors is scarce, in particular research about adjunct instructors implementing research-based mathematics curricula. To this end the research question for this study was: *How did three adjunct instructors' perceptions about a new research-based mathematics curriculum influence their engagement with professional development?*

Theoretical Framework

To answer the research question, the study used the teacher engagement, challenge, & opportunities for learning framework (Rahman, 2018). The framework allows for analysis of teachers' learning opportunities emerging from challenges they face while engaging with curricular resources. The framework was developed to analyze teachers' engagement with curriculum resources where engagement includes teacher actions such as planning, implementing, collaborating and reflecting. The engagement between teacher and tool can be viewed in light of their actions. This engagement and the challenges the teachers face have the potential for their learning. For this paper the engagement between the adjunct instructors and the curriculum as mediated through the professional development was analyzed.

Methodology

I used case study methodology (Yin, 2009) to answer the research question. This research took place at a midsized university in the northeastern United States within a department of mathematical sciences. The study was part of a larger course coordination effort for Precalculus. As part of this effort a new research-based curriculum was adopted (*Pathways to Calculus*). The instructors teaching the course participated in a 2 day summer PD prior to their first semester of implementation. The summer PD was led by the curriculum developers. The instructors also had access to hour long, weekly online PD sessions for continued support. These online sessions were facilitated by a faculty member or a doctoral student in the Mathematics Education program. During the meetings, the instructors had a chance to ask questions, share their classroom experiences and seek advice. The course coordinator for the course provided the instructors with a pacing guide, syllabus, and common assessments.

Data was collected during Fall 2016 and Spring 2017 semesters and included semi-structured interviews (Merriam, 2002), audio recordings of PLC meetings, and classroom observations. Data was transcribed and analyzed using elemental methods to develop an initial set of codes, and then pattern coding to further categorize the data (Salda a, 2009).

For all three participants, it was their first time teaching Precalculus using the *Pathways to Calculus* curriculum. The three participants are as follows:

Caleb (Pseudonym) taught at several institutions at the time of the study. He was a Ph.D. student in Mathematics Education at the institution where the study took place. He had 18 years of high school and college teaching experience, and had taught Precalculus 10 times prior to this study. He had an undergraduate (Accounting) and a master's (Mathematics Education) degree. Michael (Pseudonym) had only taught Precalculus at the college level with no experience teaching at the K-12 level. He worked as an accountant at the time of the study. He received his undergraduate (Mathematics) and graduate (Mathematics, Education concentration) degrees from the institution where the study took place and felt comfortable in the department. Justin (Pseudonym) had taught Precalculus at the high school level, working as a full-time teacher for over ten years. He had an undergraduate degree in Mathematics and received his master's degree (Mathematics, Pure and Applied concentration) from the institution where the study took place. He taught accelerated Precalculus at his high school at the time of the study.

Findings

Caleb – A Case of Self Professional Development

Caleb perceived the new curriculum as an opportunity to learn and was enthusiastic about improving his teaching practice. His engagement with the new curriculum was marked with proactive decision making and planning to challenge as well as support his students.

Caleb perceived the summer PD and the ongoing online PD as learning resources. He actively engaged in the summer and weekly PD, and also drew upon the curricular resources as a guide. For example, the design of tasks in the online homework portal that provided a piece of the problem first, then guided the students to build on their own responses. Caleb shared that he recognized what the curriculum developers were trying to achieve by having the students struggle through the problems and guiding their learning. Caleb was seeking his own PD and actively learned from all the resources available to him. Even though implementing a curriculum that emphasized student engagement was challenging, he embraced this challenge and shared, "My challenges are part of my own professional development" (Interview 1, Spring 2017)

As the semester progressed, his vision of the curriculum itself broadened. After implementing the curriculum for two semesters, he had a better sense of the curriculum's goals, the big ideas to be discussed in class, as well as the recommended pedagogy.

Michael – Using PD to Solve Problems

Michael's engagement with the PD focused on fixing immediate problems his students faced. He perceived the curriculum as beneficial for the students but he also had concerns about the emphasis on conceptual understanding. At the beginning of the first semester Michael shared that his students were struggling with the investigations. He attributed this difficulty to his students' prior experiences in a mathematics classroom. He reasoned that students were used to a classroom that required them to master procedures instead of developing conceptual understanding. One of his challenges was, "Getting the kids onboard!" (Interview 1, Fall 2016) He reported realizing early on in the first semester that his students were not used to investigating concepts in the classroom, or being attentive to the use of precise language. According to Michael, familiarizing himself with the new curriculum and getting his students on-board were his main challenges when implementing the new curriculum. His plan was to guide the students through their challenges in problem solving. In his experience, having a guided approach worked for students to understand concepts and develop problem solving strategies.

For Michael his collaboration with his colleagues during the weekly online meetings played a big role in supporting him. Michael asked questions, shared concerns about students or pacing of the course. He actively participated in the summer and weekly PD during both the semesters. Over the course of the two semester Michael's teaching practice and his challenges with the students remained the same but he had a better understanding of the curriculum and its goals.

Justin's Engagement – PD as Inspiration for Creating Instructional Resources

Justin's engagement with the curriculum, exhibited a focus on developing his own instructional materials. Justin saw the new curriculum as a learning opportunity for himself. He perceived the instructional materials themselves as possible tools to facilitate his students' learning and the problems in the curriculum resonated with Justin.

Participation in the summer workshop allowed Justin to get an overview of the new curriculum, the investigations, and pedagogical suggestions. Justin was receptive to the new curriculum and appreciated its focus on developing students' conceptual understanding of Mathematics. As he started to implement the curriculum, he experienced challenges such as, encouraging student discourse, student participation and engagement. He shared, "I think there is a little resistance..We're having kids do work together in a group that really aren't used to that so they naturally fight it!" (Interview 2, Fall 2016) Justin blamed his lack of experience teaching at the college level for his students' lack of engagement in the classroom. He explained that he spent a large portion of each class to motivate his students. He felt that his students were demotivated by the problems and he wanted them to be persistent.

Justin rarely relied on the weekly meetings to ask questions or share his concerns. He attended most of the meetings during the first semester but seldom attended them during the second semester. He found support in another adjunct instructor whom he talked to regularly. Justin knew him from outside of the university setting and reached out to him for advice. In terms of his engagement with the PD, after the summer workshop he found the weekly meetings beneficial during the first semester but not so much during the second semester.

Discussion and Conclusion

I described three adjunct instructors' experiences engaging with PD as they implemented a research-based mathematics curriculum. The instructors engaged with the PD guided by their own needs. While Caleb was motivated to learn from the curriculum, not all adjunct instructors might have the time or the motivation to struggle through their challenges like him. For both Michael and Justin their student challenges posed a more immediate need than a possible long-term goal of improving their teaching practice. Instructors' current or future goals might not be aligned with learning new teaching practices, especially if this means challenging their students.

When developing effective PD for adjunct instructors it is crucial to keep in mind the factors impacting their teaching experience. For all three adjunct instructors, being an adjunct instructor was not their only occupation. With other responsibilities and resulting time constraints, the online format of PD was accessible. It was a form of support during the first semester because all three instructors shared the need to learn about the curriculum. During the second semester their needs changed as they had implemented the curriculum once and knew what to expect. For example, Caleb continued to be proactive and reflected on his students' past experiences to develop more effective lesson plans. Michael played a supportive role in the weekly meetings and shared his experience, and Justin's attendance in the meetings dwindled during the second semester. Interview data revealed that Justin's needs were no longer being met by the weekly online PD. He wanted to develop instructional materials and actively collaborate to design learning resources but the PD focused on trouble shooting curriculum implementation challenges and sharing student experiences. PD is beneficial for teachers when it is aligned with their goals and needs. Further, the design of the PD did not include the adjunct instructors as active co-designers of the PD. Surveying the instructors about their PD needs and learning goals can aid the PD designers in aligning the sessions to meet the instructors' needs.

When designing PD for adjunct instructors it is essential to be mindful of the diversity of their learning needs, their conflicting schedules, their prior knowledge about mathematics pedagogy and experience teaching at the K-12 or college level. It is also important to include their voice in the decision-making process when deciding the type and focus of PD activities.

MAKING SENSE OF MULTILINGUAL LEARNER PRINCIPLES AND MATHEMATICS LANGUAGE ROUTINES THROUGH STUDIO DAY PROFESSIONAL LEARNING

Sarah A. Roberts
University of California, Santa Barbara
sroberts@education.ucsb.edu

Cameron Dexter Torti
University of California, Santa Barbara
cdextertorti@ucsb.edu

Julie A. Bianchini
University of California, Santa Barbara
jbianchi@ucsb.edu

We studied 11 high school teachers' reflections of their experiences in a professional learning project organized around five principles of effective mathematics instruction for multilingual learners and mathematics language routines (MLRs). We examined how teachers' ideas about these principles developed using the MLRs across four studio day professional learning cycles. Using open-coding, we analyzed pre-studio day and studio day reflection responses to understand how teachers' understanding of the MLRs and principles developed, looking for patterns in individual teachers, individual routines, and across all routines and teachers. We found that teachers discussed sentence frames less often as a method for attending to their multilingual learners; identified that the MLRs were an organizational method their students could use; and, finally, noted they could use multiple modes of communication with MLRs.

Keywords: Professional Development; Equity, Inclusion, and Diversity

The population of multilingual learners continues to increase in US schools, with over 10% of students in K-12 settings identified as multilingual learners (National Center for Education Statistics, 2020). Teachers often find it challenging to engage multilingual learners in rich mathematical work, such as that associated with the *Common Core State Standards for Mathematics* (National Governors Association Center for Best Practices, Council of Chief State School Officers [NGA Center, CCSSO], 2010), as few teachers have had professional learning experiences that are mathematics and multilingual learner-specific (Ballantyne et al., 2008). Additionally, the field is lacking in research around professional learning that attends to mathematics and multilingual learning (de Araujo et al., 2018). To fill both these practice and research gaps, we studied a two-year professional learning opportunity organized around mathematics language routines (MLRs) and five principles of effective mathematics instruction for multilingual learners. We examined how teachers' ideas of these principles developed using the MLRs across four studio day professional learning cycles (Von Esch & Kavanagh, 2018). This study answered the following research question: How did teachers' understanding of using MLRs to enact five principles of effective multilingual learner instruction develop as they participated in studio day cycles of professional development?

Theoretical Framework

This study is organized around two complementary theoretical ideas: key principles of reform-based instruction for multilingual learners and MLRs, both of which are meant to engage multilingual learners with content in meaningful ways. The five principles of reform-based instruction (see also Roberts, 2021) are understood as reinforcing and overlapping with one another. For the first principle, *build on and use multilingual learners' funds of knowledge and resources* (Moll et al., 1992; Moschkovich, 2002), teachers identify, celebrate, and use the knowledge and skills students, their families, and their communities bring to the classroom. With the second principle, *provide multilingual learners with cognitively demanding work* (Stanford Graduate School of Education, 2013), multilingual learners have the opportunity to engage in cognitively rich activities and assignments often reserved for English-only students (Iddings, 2005; Planas & Gorgorió, 2004). In the third principle, *provide multilingual learners opportunities for rich language and literacy exposure and practice* (Khisty & Chval, 2002; Lee et al., 2013), teachers engage multilingual learners in the language of mathematics by creating opportunities for students to receive comprehensible input through listening and reading and to produce comprehensible output through speaking and writing. The fourth principle, *identify disciplinary language demands and supports for multilingual learners* (Aguirre & Bunch, 2012), involves teachers' attending to language demands and implementing appropriate scaffolds so that students can read disciplinary texts, as well as share their ideas and reasoning. The fifth principle is *create a safe classroom* and allows for intellectual risk-taking (Luria et al., 2017), where everyone is part of a community of learners and free to learn (Hernandez et al., 2013).

These five principles provide the foundation for MLRs (Zwiers et al., 2017). These routines support students' productive engagement with cognitively rich mathematics content (Kelemanik et al., 2016). Routines empower students to focus on their learning, because they allow for sense-making of challenging mathematics and for building important mathematical thinking habits—providing more students with access to important mathematics ideas. Examples of MLRs include Stronger and Clearer and Co-Craft Questions. Teachers can use these routines specifically with multilingual learners to amplify, assess, and develop their mathematics thinking and language simultaneously (Kelemanik et al., 2016; Zwiers et al., 2017).

Methods

Our study was situated in a school district in California that included a substantial number of multilingual learners. As introduced above, teachers participated in a two-year professional learning program organized around multilingual learner mathematics studio days (Von Esch & Kavanagh, 2018), developing and studying lessons focused on one multilingual learner principle and one MLR for each of the four studio day cycles.

Context: Studio Days Enactment of Multilingual Learner Principles and MLRs

Teachers participated in three professional development meetings in each studio day cycle (in person during the first year and over Zoom during the second year). Each cycle paired one multilingual learner principle with one targeted MLR (e.g., *funds of knowledge* with Stronger and Clearer). During the pre-studio day, teachers learned about the multilingual principle and MLR and prepped a lesson to implement. Teachers then enacted this lesson at their schools during the studio day, with teachers observing each other's implementation. During the final day of the cycle, the post-studio day, teachers examined student work to assess studio day lessons, shared challenges and successes, and considered implications for their future practice.

Participants

Eleven high school teachers participated in the study. Two teachers were in their first year of teaching, four had 1-4 years of teaching experience, and five had 10-19 years of teaching experience.

Data Collection and Analysis

Teachers completed Google Form reflections about their understanding and implementation of the MLRs and multilingual learner principles as well as their general thoughts on the studio day experiences. For this paper, we focused on two questions from these forms: (1) "[MLR] will support emergent multilingual students engaging in [multilingual learner principle] in my class by…" from the pre-studio day; and (2) "[MLR] is intended to support multilingual learners in their work with [multilingual learner principle]. How well do you think the routine accomplished this today?" from the studio day. From our four studio day cycles, we collected four sets of these two questions. To analyze teachers' responses to the above identified questions, we used open-coding (Yin, 2016) and looked for patterns in the pre-studio day and studio day responses. We compared pre-studio day and studio day coding to make sense of teachers' understanding of the MLRs and the principles, looking for changes in individual teachers, individual routines, and across all routines and teachers.

Findings

Overall, we found that the principles and routines came into clearer view for the teachers after they were able to see the MLRs in each other's classrooms. In comparing teachers' responses to the pre-studio day and studio day, we found that there were three key themes that illuminated this development among teachers. First, teachers mentioned sentence frames less often as a method for attending to their multilingual learners. Second, teachers identified MLRs as a structure or organizational method that their students could productively use. Finally, teachers noted they could use multiple modes of communication with their students when implementing the MLRs.

Decreased Mention of Sentence Frames

Teachers described the use of sentence frames to engage multilingual learners in two of the four cycles of studio days. In both of these cycles, three teachers mentioned this as linked to a principle (*rich language opportunities*, *funds of knowledge*) and MLR (Clarify, Critique, and Correct; Stronger and Clearer) in the pre-studio day forms, but only one did so in the studio day forms. As a project, we would link sentence frames to the principle *disciplinary language support*, however, it is not surprising that teachers would see sentence frames as supporting other principles. Sentence frames are both a common multilingual scaffold that teachers use and we had built this scaffold into most of the MLRs, to model using specific sentence frames with specific content. In her initial pre-studio day mention of using sentence frames with *rich language opportunities* and Clarify, Critique, and Correct, Ms. Frasca noted, "Sentences frames…[are an] easy 'entry' point (just a list of what they have seen). [It] is a way to support these students." Here, providing these sentence frames was described as an entry to the content. Ms. Frasca was also one of the teachers who identified use of sentence frames in her *funds of knowledge* and Stronger and Clearer pre-studio day, sharing succinctly that she would leverage multilingual learners' funds of knowledge "using the sentence frames." It is possible this was a go-to method for attending to multilingual learners for Ms. Frasca.

While several teachers mentioned sentence frames initially in their pre-studio day reflections, in contrast, only one teacher mentioned sentence frames in their studio day reflections. Ms. Parker noted in her studio day on *rich language opportunities* and Clarify, Critique, and Correct, "I love the sentence frames and leading questions. They really help students begin to formulate coherent arguments." In this case, Ms. Parker's attention to sentence frames was closely connected to the routine itself: She was having students construct viable arguments using the frames (MP.3; NGA Center, CCSSO, 2010).

MLRs Provided Structure and Organization

The MLRs provided structure and a form of organization (i.e., *disciplinary language support*), according to the teachers, again in two of the four cycles of studio days (*disciplinary language support* with Three Reads; *rich language opportunities* with Clarify, Critique, and

Correct). For Three Reads, the teachers recognized this structure similarly both in the pre-studio day and in their studio day reflections, while more teachers mentioned this structure in the pre-studio day than in the studio day for the Clarify, Critique, Correct MLR. This might indicate that the role of this structure was more central to the actual implementation of the Three Reads MLR, than to the Clarify, Critique, and Correct MLR. In Mr. Bakula's pre-studio day reflection, he shared that this MLR helped multilingual learners access disciplinary language by "modeling the thought process they should be engaging in every time they approach a problem. It also helps de-construct the problem into more easily-digestible chunks." Similarly, Ms. Scott explained on the pre-studio day that Clarify, Critique, and Correct helped students "organize their thinking and break down the process of looking at another person's work and forming their own thoughts/critiques/compliments and then giving them the opportunity to implement these ideas mathematically." This MLR provided disciplinary language support structures for students to access text, although teachers noted the importance of actually making the routines routine in their classrooms for students to take advantage of these structures.

Potential Use of Multiple Modes of Communication

The teacher participants shared that three of the four routines provided opportunities for multiple modes of communication (i.e., *rich language opportunities*). The MLR missing, Three Reads, could also include modes of communication in theory, however, it was simply not one that teachers highlighted. For the Clarify, Critique, and Correct and the Stronger and Clearer MLRs, teachers mentioned multiple modes of communication more in their studio day reflections than in their pre-studio day reflections, possibly indicating that seeing the MLRs in action provided more context for eliciting *rich language opportunities* or more ideas for how to execute such opportunities. Teachers illuminated that the Clarify, Critique, and Correct MLR allowed for revoicing (i.e., *disciplinary language support*), as well as "moving students forward to read, write and talk more in class," according to Ms. Frasca. Mr. Bakula shared that the Co-Craft Questions MLR allowed students to use "math-specific academic language." Our final routine, Stronger and Clearer, Ms. Lacrosse explained, "Taught students how they could build on their communication skills they bring to class…. They can build on it by listening to other students' points of view and acquire language that might be richer, stronger, and clearer."

Discussion and Conclusions

Our 11 teacher participants came to understand the MLRs as structures that helped students organize their thinking mathematically and linguistically. They recognized they could use these structures to provide disciplinary language scaffolding and rich language opportunities during their instruction, supports that included and went beyond sentence frames, perhaps a nascent type of multilingual learner scaffold. While they initially noted familiar practices, like sentence frames, after being in each other's classrooms as part of the studio day cycles, teachers' frames of reference appeared to expand to include wider notions of how to engage their multilingual learners. Their understanding of using the MLRs appeared to grow clearer. In summary, the studio day cycles provided teacher participants opportunities to develop a broader repertoire of understanding how to implement the MLRs and multilingual learner principles. Providing meaningful instruction for multilingual learners and compelling professional learning for their teachers remains important; this study provides an example from which we can draw.

THE IMPACT OF AN IMMERSIVE TEACHER PROFESSIONAL DEVELOPMENT PROGRAM BASED ON EXPLORATORY NUMBER THEORY

Chris Norris-LeBlanc
Harvard Graduate School of Education
norrisleblanc@g.harvard.edu

Jon Star
Harvard Graduate School of Education
jon_star@gse.harvard.edu

In the literature around high quality professional development (PD) opportunities for teachers of mathematics, immersion, duration, collaboration, and a focus on content have emerged as some of the key factors which lead to impactful experiences. Despite knowing which attributes are associated with effective PD, only a small number of programs are rigorously studied or evaluated. This multi-year qualitative study investigated a professional development program – PROMYS For Teachers (PfT) – which immerses teachers in a 7-week intensive summer program in exploratory number theory. Through three case studies with participating teachers, the authors sought to understand the key dimensions of PfT and the impact that it has on participants. Findings show that while PfT can elicit changes in teachers' relationship to mathematics and teaching practice, a lack of clear program goals leads to varied outcomes.

Keywords: Professional Development, Advanced Mathematical Thinking, High School Education, Mathematical Knowledge for Teaching

Theoretical Framework

In the literature around high quality professional development (PD) opportunities for teachers of mathematics, immersion, duration, collaboration, and a focus on content have emerged as some of the key factors which lead to impactful experiences. Experiences which have these attributes ask teachers to engage in the process of actively doing mathematics with other professionals on a regular basis over an extended period of time (Loucks-Horsley & Matsumoto, 1999) (Darling-Hammond et al., 2017).

Of particular interest in this nexus is the content focus of PD opportunities. The field has, at best, a tenuous understanding of the kind of content that mathematics teachers should focus on in PD in order to improve their practice. This is particularly true for teachers of secondary mathematics and for content beyond the scope of their curriculum (Ball & Hill, 2009).

While some programs choose to focus on content which teachers might be expected to teach at some point in their career, other programs use more advanced content beyond the scope of the high school curriculum in an effort to engage teachers meaningfully in immersive, challenging, and deep mathematical experiences.

These programs – like many other professional development programs for teachers in the US – have not been rigorously studied or evaluated. (Borko, 2004; Hill, 2009) The present study is a multi-year qualitative investigation into the PROMYS for Teachers program at Boston University and the impact that it has on teacher participants. There have been two previous scholarly investigations into PfT since its inception in the 1990s, both resulting in doctoral dissertations. The first (Abel, 2010) asked how participation in PfT impacted teachers' conceptions of student learning. (Abel, 2010, p. 257). The second (Matthews, 2014) asked questions quite similar to those of the current study: what is the nature of the PROMYS experience and are teachers' beliefs and/or teaching practices influenced by the program? Ultimately, both previous investigations found that PROMYS had little impact on teachers' beliefs and practices. However, in both instances, the researchers brought measurement tools to the table which didn't necessarily align with the outcomes one might expect from the program. By taking a more open-ended and qualitative approach to data collection – and by looking for emerging themes from a mixture of recorded classroom observations, semi-structured interviews, and ethnographic field notes – the current study aims to more thoroughly document the potential impact of the PfT program.

Methods

For this study, the authors utilized a mix of ethnography and case-studies. An initial offer to participate in the study was made via email to the entire incoming cohort of first-year teachers. Four teachers responded and three of them ultimately agreed to be participants. Participants were compensated with a stipend of $500, half of which they received at the beginning and half of which they received once their participation was complete.

Ethnographic data was compiled by visiting the program site an average of 1.5 days per week throughout the summer. During these visits, the first author would sit through lectures, participate in activities, and often simply sit quietly and observe. Case study data was collected through one-on-one interviews and recorded classroom observations. The study design entailed interviews and classroom observations before the program to establish a baseline for each teacher, interviews and observation during the program to track participants' experiences, and follow-up interviews and classroom observations to see how, if at all, PfT impacted teachers' relationship to mathematics, ideas about teaching, and classroom practice.

PROMYS For Teachers: History and Program Structure

The PROMYS (Program in Mathematics for Young Scientists) organization was originally founded at Boston University in 1991. PROMYS engages high school students, pre-service teachers, and active teachers of mathematics in an exploratory course in number theory.

While the PROMYS program for teachers (PfT) has undergone shifts over the years, the content and fundamental approach has remained remarkably similar. Throughout 7 weeks in the summer, pre-service and in-service teachers come to the Boston University campus Monday through Friday for 7-8 hours each day to do mathematics. Largely, each day is organized around solving a set of open-ended problems in number theory. As a direct result of the fact that problem-solving sessions make up the vast majority of teachers' time in the program, their nature and structure comprise the vast majority of the PfT experience. The structure and ethos of these problem-solving sessions can be characterized by the following ideas: a) learning new ideas and content is best done through exploration and discovery, b) while there is no explicit demand for people to work in teams, an ethos of collaboration is encouraged, c) there is no inherent value in working on easier or harder problems, d) while hints and help are readily available from program admins, answers are not, and e) assessment is entirely intrinsic.

These structures and practices are, in the frame of education theory, oriented toward a constructivist, inquiry and/or discovery-based approach to the teaching and learning of mathematics. This kind of framing, though, is almost entirely absent from any documentation or official descriptions of the program. Furthermore, despite being a program for teachers, there are no workshops, classes, or structured discussions about teaching and teachers aren't directly instructed in any teaching techniques or curricula relevant to their classes. In the following sections, data from each case study will be used to grapple with precisely how a program with such loose goals might ultimately have an impact on teachers' beliefs and practices.

Results

Changes in Teachers Beliefs and Practices

The following two categories emerged thematically as areas in which all three teachers demonstrated noticeable changes during and after their summer at PfT.

Reigniting and Reforming Relationship to Mathematics. Although each of the three teachers came into PfT with widely diverging backgrounds in mathematics, all of them experienced shifts in their relationship to the discipline throughout and after the program.

For Grace, a teacher who came into the program with an unusual amount of skill and interest in mathematics, the most impactful changes in her relationship to the discipline were realized through the low stakes structure of the daily problem-solving sessions. In an interview midway through the summer, Grace mentioned that she hadn't previously seen mathematics as a thing that could be done without time constraints, assessments, and clear goals in mind. The process of working on problems without any due dates or consequences was new to her and made her realize that she could have a very different relationship to the discipline than she previously imagined.

Jordan, on the other hand, said that this was her first experience doing mathematics where she had to figure out how to solve problems on her own. Of her time as an undergraduate student, she said that she has never "experienced the maximum potential" of her brain and that with this experience, she was able to retain concepts and understand them on a deeper level. Ezra echoed these feelings, saying that while her mathematical work in high school and college could be mostly characterized by trying to replicate what she saw being done in class, online, or in a textbook, this was her first experience "not having anything but myself, my own mind." Both Ezra and Jordan also found the summer to be an empowering experience in terms of the way they viewed their own competency within the discipline. For Ezra, immersing herself in a challenging experience filled with a lot of unknowns was intense, especially because by the end of the summer, a lot of the content still felt muddy and uncertain. However, she found value in this struggle and the ownership that she was able to take over her ideas.

Particularly important about these observations is that while each teacher started in a very different place in terms of mathematical comfort and knowledge, they all had experiences which positively changed their relationship to the subject.

Attention to Inductive Learning Through Pattern Hunting. All three teachers who spent their summer at PfT came back to their classrooms and introduced problems and activities which had a common thread: asking students to learn content through induction and pattern hunting rather than through direct instruction or deductive reasoning. Prior to their summer at PfT, none of the teachers expressed in interviews that this was an important or useful pedagogical tool and there was no evidence of this kind of practice during observations. After the summer, none of the teachers explicitly mentioned this as a new instructional tool, but all three of them either referenced this kind of approach in an interview or demonstrated it during an observation.

In two of the three of Grace's classes which were observed after her summer at PfT, pattern noticing played a central role in how students were expected to understand the key objectives or theorems from the lesson. In the first lesson, Grace was teaching a lesson about the first derivative test for local extrema. Rather than tell students what to look for to confirm the results of the test, Grace would elicit student input about the sign of the derivative on either side of the point. During the first example, she said "keep an eye on this, how the sign is changing, it might be useful." As the lesson went on, Grace explicitly used the language of pattern hunting, telling students to "look for a pattern in how the sign is changing – how does that relate to the shape of the function?"

While the day that Jordan's classroom was visited didn't include an activity which involved an inductive or pattern-hunting process, when asked whether she took anything from PfT and applied it to her teaching, she described a lesson which fits into the pattern seen in Grace and Ezra's classrooms. In a lesson about graphing quadratics, Ezra described giving her students dozens of examples of different equations of the form $ax^2 + bx + c$. Rather than show students specific examples and explain to them how different values of a would impact the graph of the function, Ezra asked students to look at a number of graphs and try to find a pattern between the changing value of a and the way that the graphs looked.

This idea that one should learn mathematics by noticing patterns and formalizing them is heavily represented in the structure of the number theory problem sets that teachers worked on over the summer. It is therefore perhaps not surprising that teachers took this away from the program. While this attention to pattern hunting and logical induction is a noteworthy finding, it also belies another important part of the PfT experience and the ethos of the program: like learning mathematics, the program seems to suggest that learning to teach is a process that can be done through pattern hunting. The limitations of this are discussed in the next section.

The Limitations of Inductive Learning for Teacher PD

While the findings above represent real and important changes in teachers' beliefs and practices, interviews and observations also demonstrated a number of areas in which things either stayed the same or, in some cases, actually changed in a way that seemed in opposition to the ethos of PfT. For instance, observations after the summer revealed that other than in Ezra's Geometry classroom, traditional teacher-led classroom structure prevailed. More than the other two teachers, Grace took a more varied set of instructional practices from PfT. In addition to the themes mentioned above, Grace also allowed students to choose which problems they wanted to work on and only graded the ones they did – a practice taken directly from PfT. However, despite the strong ethic in PfT that ability and knowledge should not be hierarchically applied to how and what a student learns, Grace ultimately felt like most of the practices which she learned at PfT were only truly appropriate for more advanced students. Although Ezra completely redesigned her Geometry class to align with more constructivist and induction-based approaches, she also mentioned in an interview that participation in PfT had given her the confidence to give students who didn't complete assignments on time zeros in her gradebook without worrying about their reaction. This practice seems directly opposed to PfT's ideas about grading.

A common theme running through each of these stories that without being given specific ideas about how the pedagogy of PfT might relate to their classrooms – or even being given structured space or time in the program to contemplate this relationship for themselves – each of the teachers was left to their own devices to take what they could from the program.

Conclusions and Discussion

Through these case studies and our time observing teachers' experiences with PfT, it is clear that the program has an impact on the way that teachers relate to the field, their beliefs about themselves, their beliefs about teaching, and ultimately their teaching practice. In fact, some of the changes mentioned above could be described as transformative. However, it seems like PfT as an organization approaches the notion of teacher learning in the same way that it approaches the notion of mathematics learning: discovery, induction, and pattern hunting. In this context, it is difficult for teachers to take actionable steps back to their classrooms.

SHAPING THE PROFESSIONAL GROWTH OF MATHEMATICS FACULTY WHO TEACH PROSPECTIVE SECONDARY TEACHERS

Professional development (PD) that supports faculty in teaching courses for prospective secondary teachers, especially courses focused on mathematical knowledge for teaching, are largely absent from higher education, despite the need to improve instruction in these courses. This study examines a novel PD program whose structure was inspired by rehearsals (Lampert et al., 2013). We analyzed PD discussions throughout the year using an instructional triad framework, and we interpreted the PD structure using Clarke and Hollingsworth's (2002) Interconnected Model for Professional Growth. We suggest that a rehearsal-inspired pedagogy offered opportunities for faculty growth in attending to student contributions.

Keywords: Mathematical Knowledge for Teaching, Undergraduate Education, Professional Development

Recent policy documents agree that secondary mathematics teacher preparation must attend to developing teachers' mathematical knowledge for teaching (MKT) (Conference Board of the Mathematical Sciences, 2012; Association of Mathematics Teacher Educators, 2017). Although there is promise in simulating practice to develop teachers' MKT in ways that coordinate mathematical and pedagogical sensibilities (Biza et al., 2007; Stylianides & Stylianides, 2010), such tasks are uncommon in undergraduate content courses for pre-service secondary teachers (Lai & Patterson, 2017). To expand opportunities for developing MKT in content courses, the project Mathematics of Doing, Understanding, Learning, and Educating for Secondary Schools (MODULE(S^2)) has developed curricular materials for Algebra, Geometry, Modeling, and Statistics undergraduate content courses for prospective secondary teachers. To support enacting these materials, MODULE(S^2) provided a year-long professional development (PD) program for mathematics faculty. This PD included activities inspired by teaching rehearsals (Lampert et al., 2013; Ghousseini, 2017), and aimed to support attending to prospective teachers' thinking.

In this study, we drew on the MODULE(S^2) data to examine: *How does a rehearsal-inspired pedagogy shape the interactions among mathematics faculty during a professional learning experience?*

Theoretical Perspective

Throughout this paper, *student* refers to a prospective secondary mathematics teacher, and *instructor* refers to a mathematics faculty member. Following Lampert (2001) and Cohen, Raudenbush, and Ball (2003), we model instruction as attention to relationships formed between instructors, students, and content. In this view, learning occurs as students work to develop, understand, and strengthen their relationship with content and each other; meanwhile, instructors enact their practice through relationships with content and with students, in addition to their relationship with student learning whereby they attend to and are influenced by the student-content relationship.

Following Clarke and Hollingsworth (2002), we view professional growth as “an inevitable and continuing process of learning” (p. 947). They conceptualized teacher professional growth as an “Interconnected Model” of dynamics among four domains: the Personal Domain (i.e., a teacher’s individual knowledge and beliefs), the Domain of Practice (i.e., all forms of professional experimentation), the Domain of Consequence (i.e., inferred outcomes of instructional decisions), and the External Domain (i.e., entities outside the teacher’s self). They argued that professional growth, such as that shaped by PD, can be represented through “change sequences” of reflection and enaction.

Teaching rehearsals can shape teachers’ professional growth (Ghousseini, 2017; Lampert et al., 2013). Initially conceived to support novice K-12 teachers, rehearsals provide opportunities to “simulate and analyze manageable chunks of interactive teaching before enacting them with students in classrooms” under the guidance of knowledgeable practitioners (Ghousseini, 2017, p. 188), followed by a collaborative debrief discussion. We hypothesized that rehearsal-inspired experiences could provide opportunities for professional growth for mathematics faculty, particularly in developing capacity for attending to student thinking.

Data and Method

Design of Rehearsal-Inspired Experiences

The PD for the instructors teaching with the MODULE(S^2) materials spanned the summer prior to teaching and the academic year. A cornerstone of the PD was a series of *rehearsal lessons*: in the summer, each piloting instructor planned a lesson from the materials and then taught the other instructors, who took on the role of acting students. To assist the instructors in planning their rehearsal lessons, the facilitators provided a planning guide with prompts intended to support attending to student thinking. Facilitators video-recorded the lesson and immediately played the recording to all participants. During the viewing of the recording, facilitators provided instructors an observation guide framed toward noticing student thinking in the rehearsal. The video viewing was followed by a facilitator-led debrief.

During the academic year PD, the instructors continued to meet over Zoom with project facilitators. Prior to each meeting, one instructor shared a video recording of a MODULE(S^2) lesson that they implemented in their own classroom with the rest of the group. To begin a meeting, a facilitator prompted the group by asking open-ended questions (e.g., “How are things going?”) so that instructors shaped the focus of meetings. Conversations addressed debriefs of the video recording of the participant’s lesson, the materials themselves, and instructional experiences that the participants wished to reflect on. In contrast to the debriefs of recorded lessons during the summer portion of the PD experience, the debriefs of recorded lessons during the academic year did not follow particular structures or prompts.

Participants and Data Sources

We focus on one group of three instructors who implemented the Algebra strand of MODULE(S^2) materials. During the summer, they participated in three teaching rehearsals --one for each of the instructors to act as the instructor. During the academic year, they participated in five facilitated meetings, which included debriefs of recorded lessons. The three debriefs of the summer teaching rehearsals were video recorded and were each approximately ten minutes in length. The five meetings during the academic year were also video recorded and ranged from

30-90 minutes each. The transcriptions of these eight recorded debriefs and meetings serve as our data source for this study.

Analysis

The authors used an instructional triangle as an analytic tool. An example of this coding is shown in Figure 1. We have highlighted how these interactions would have been coded in the transcript for these portions. "Teacher" refers to instructors of content courses and "students" refers to prospective teachers.

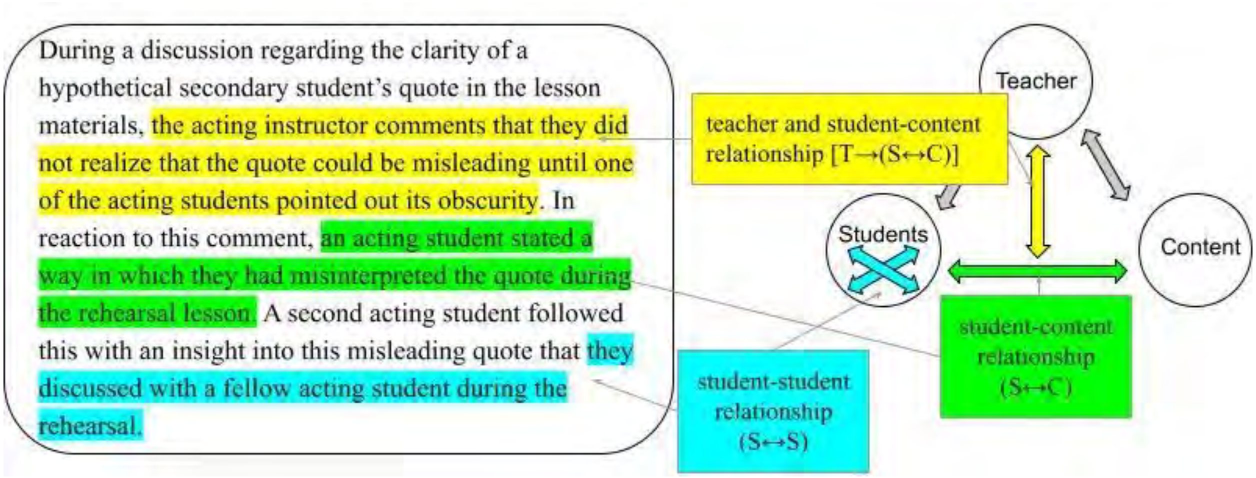

Figure 1: Vignette with categories of interactions highlighted

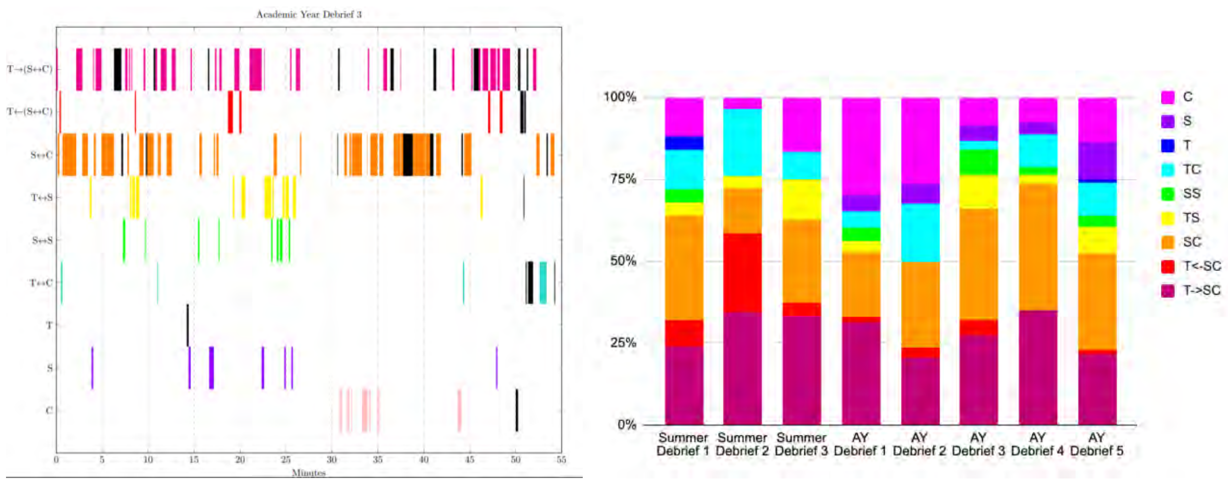
To understand the role of the PD structure in shaping the interactions between the participating faculty members, we utilized the Interconnected Model of Professional Growth. Specifically, we identified how the materials and activities utilized in the PD operated within the model's four change domains and provided opportunities for reflection and enactment. With these results, we produced a change sequence representative of the opportunities for growth offered by this PD.

Results

Mathematics Faculty Attention to Students and Content

We created visualizations for all eight debriefs and meetings, one of which is displayed in figure 4(a). The horizontal axis represents the time at which a statement referring to instruction is made, and the vertical axis represents to which particular instructional relationship a statement is referring. Statements about instruction made by instructor participants are shown as a colored block whose horizontal length indicates for how long that particular instructional relationship was being referenced. Statements about instruction made by project facilitators are colored black and indicate length similarly.

As is the case for all eight debriefs, this example displays a high density of statements referring to the student-content relationship (S↔C) and the relationship between the teacher and the student-content relationship [T→(S↔C)]. (Again, "teacher" refers to a mathematics faculty member, and "student" refers to a prospective teacher.) To further investigate this density of codes, the frequency counts for each instructional relationship code are plotted in a stacked bar graph in Figure 4(b). This stacked bar graph reveals that, for all of the eight debriefs and meetings, half or more of the instructional relationships being referred by instructors and facilitators were to the student-content relationship (S↔C) and the relationship between the teacher and the student-content relationship [T→(S↔C) and T←(S↔C)]. The frequency of references to instructional relationships related to the student-content relationship suggests that instructors maintained a focus on student thinking throughout the entire PD experience.



(a) **(b)**

Figure 2: (a) Visualization of the third debrief during the summer portion of the PD and (b) Stacked bar graph of the frequencies of each code during the eight debriefs

The PD Experience as a Change Sequence

In the space allowed in this brief report, we present only a summary of the results of our analysis of the PD structure using the Interconnected Model of Professional Growth. Our data suggested two change sequences: one for the summer PD structure and one for the subsequent academic year PD structure. Each change sequence used all four change domains and was based on numerous opportunities for enaction and reflection.

We offer two illustrative examples. First, during the summer portion of the PD experience, instructors were given rehearsal planning guides that focused on aspects of student thinking to scaffold the planning of their rehearsal lessons. Planning their rehearsals using these resources were instances of instructors enacting from the External Domain to the Domain of Practice. Second, throughout the academic year, instructors were encouraged to discuss both the practices of the instructors whose lesson has been video recorded as well as their own practice. Reflection on practice that supports prospective mathematics teachers' thinking, whether it be their own or another participant's, are instances of an instructor reflecting from the Domain of Practice to their Personal Domain.

Opportunity for Professional Growth

This study shows promise for adapting and translating the concept of rehearsals to the context of faculty who teach undergraduate mathematics courses. Because mathematics learning is supported in classrooms where there is attention to learners' thinking about the content (e.g., Learning Mathematics for Teaching Project, 2011), this could mean that leveraging an adapted rehearsal pedagogy during PD of mathematics faculty teaching content courses for prospective secondary teachers could support the future teachers' development of MKT. In the case of MODULE(S^2) materials, because the materials connect mathematics and teaching in ways that are designed to promote MKT, this means that centering teaching on student thinking means centering teaching on student development of MKT.

COMPARING ELEMENTARY MATH SPECIALISTS' BELIEFS WITH THEIR PEERS

Maria Stewart
University of Missouri
mntkd@umsystem.edu

Corey Webel
University of Missouri
webelcm@missouri.edu

This study's purpose is to explore how Elementary Math Specialists (EMS) teachers' practice-based beliefs differ from their peers, especially regarding situation-specific, self-reported practices. Likert-scale survey data were compared to teacher responses to situation-specific questions where teachers were asked to explain how they would respond to various mathematics classroom situations. This approach allowed the researchers to compare self-reported beliefs with practice-based beliefs, building on prior research. Two findings from this study are: (1) EMS teachers were more likely to believe that conceptual understanding should come before instruction and (2) teachers who exhibit more confidence about doing mathematics and more security in their teaching of mathematics are more likely to engage in practices like having students share and discuss multiple strategies and delaying the teaching of standard algorithms.

Keywords: elementary school education, teacher beliefs, affect, emotion, beliefs, and attitudes

Mathematics teachers hold beliefs about mathematics, learning mathematics, teaching mathematics, and their own ability to do mathematics, and these beliefs play an important role in how teachers plan, implement, and assess their instruction (Swars, Smith, Smith, Carothers, & Myers, 2016; National Council of Teachers of Mathematics [NCTM], 2014; Ambrose, Clement, Philipp, & Chauvot, 2004). For example, Peterson, Fennema, Carpenter, and Loef (1989) found that teachers who reported beliefs such as "the natural development of children's mathematics ideas should determine the sequence of topics used for instruction" (p. 7) were more likely to engage their students in mathematical word problems which required reasoning and problem solving. Based on these relationships, many preservice and in-service teacher education programs are designed, in part, to influence what teachers believe about mathematics teaching and learning.

One category of such programs is focused on developing Elementary Math Specialists (EMSs), content experts who serve in a variety of roles to support mathematics instruction (de Araujo et al., 2017). Research has found that EMS programs can have positive impacts on teachers' beliefs, such as shifts towards a cognitive orientation (i.e., implementing cognitively demanding tasks) and increases in levels of teacher efficacy (Swars et. al., 2016). Many such studies are based on Likert-scale survey data and produce general conclusions about clusters of beliefs, but some surveys, like the Integrating Mathematics and Pedagogy (IMAP), are designed to probe teachers' reasoning around their actions in specific situations. We find the IMAP to be a relatively untapped resource for exploring in more granular detail the ways that beliefs are enacted in practice (i.e., "practice-based beliefs"). In this paper, we focus specifically on some of the pedagogical situations contained within the IMAP and explore how general belief clusters might relate to decisions EMSs and their peers make regarding these situations. Our research questions are: (1) How are EMS teachers' practice-based beliefs different than their peers? (2) What relationships exist between teachers' attitudes and these practice-based beliefs?

Theoretical Framework

Beliefs are defined as "psychologically held understandings, premises, or propositions about the world that are thought to be true" (Phillip, 2007, p. 259). Some beliefs about teaching and mathematics are more beneficial for teachers and students than others. For example, in *Principles to Actions,* NCTM (2014) shares a list of productive and unproductive beliefs which impact effective mathematics teaching. Productive beliefs are related to engaging students in tasks that promote reasoning and problem solving (NCTM, 2014). Since beliefs can be productive or unproductive, it is important to find ways to help teachers shift toward more productive beliefs.

Teachers' beliefs are generally grounded in their prior experiences and evolve through reflection on new experiences (Beswick, 2012; Giboney Wall, 2018; Raymond, 1997; Vace & Bright, 1999), especially those experiences which challenge existing beliefs. For example, beliefs can change when teachers experience and reflect on unexpected results within their classroom (e.g., students providing rich mathematical explanations or exhibiting excitement about engaging in mathematics). Reflection is key because beliefs can be tacit; that is, teachers may have beliefs that guide their behavior they are not aware of, or that they are unable to articulate directly. Such beliefs can be identified by exploring how teachers respond to specific classroom scenarios (e.g., Joram, 2007). One way to help teachers transition to more productive beliefs is to encourage them to examine ways that their practice may be in tension with their stated beliefs (Boyd & Ash, 2018; Vace & Brith, 1999). In addition, the role of teachers' attitudes (how teachers feel about doing and teaching mathematics) can influence their practices (Philippou & Christou, 1998; White, Perry, Way, & Southwell, 2005/2006). Specifically, more positive attitudes towards a concept or action tend to be taken up more than negative attitudes towards a concept or action (White et. al., 2005/2006). Thus, understanding how teachers' beliefs relate to their attitudes may help us to understand why they enact certain teaching practices more than others.

Methodology

Context

The data for this paper were drawn from a funded study investigating differences between graduates of a 24-credit Elementary Mathematics Specialist program and their peers teaching at the same schools and grade levels. Previous findings showed that EMSs had significantly different beliefs than their peers (Webel et al., 2018; Webel et al., under review). An exploratory factor analysis (EFA) had reduced 38 items from a survey developed by White and colleagues (2005/2006) to 4 clusters of teacher beliefs: Constructing (10 items, mathematical knowledge is constructed), Computing (7 items, knowing mathematics is mostly about knowing how to compute the right answer quickly), Security (14 items, security in teaching mathematics), and Confidence (7 items, confidence in doing mathematics). Analyses had revealed significant differences between EMSs and their peers for each of those factors. Specifically, EMSs had higher scores for Constructing, Confidence, and Security, whereas nonEMS teachers had higher scores for Computing. In this paper, we explore relations between these scales and individual items in the 2012 Horizon and Integrating Mathematics and Pedagogy (IMAP) surveys to examine relationships between these general beliefs and attitudes and specific reported practices.

Data Collection

This study included 61 elementary teachers, of whom 28 were EMS. Data was collected from three different surveys. The first survey was a web-based assessment which originated as part of the Integrating Mathematics and Pedagogy (IMAP) project (Ambrose, Philipp, Chauvot, & Clement, 2003). The survey consists of 9 sections, each with multiple parts, for a total of 46 questions, which includes elementary level, open-ended questions set in classroom contexts, including videos. Those items were used to identify teacher beliefs in 7 areas. For the purposes of this study, we focus on IMAP item 3.3, in which participants were shown five student strategies for solving a multi-digit addition problem, 149 + 286. The strategies included 1) a manipulative approach using base 10 blocks, 2) the standard United States algorithm for addition, 3) left to right addition (sometimes called the "intermediate algorithm"), 4) combining the same units (with a minor computation error), and 5) a compensating approach in which 149 was temporarily rounded to 150. The teachers were then asked, "Consider the strategies on which you would focus in a unit on multidigit addition. Over a several-week unit, in which order would you focus on these strategies?" We chose to focus on this item because of the direct connection to practice and, when comparing EMS and nonEMS teacher responses, we found a significant difference in their ordering of the five strategies.

The second belief survey was designed by White and colleagues (2005/2006). This survey consisted of 18 Likert scale items from 1-strongly disagree to 5-strongly agree. The questions in the survey included statements like, "mathematics is computation" and "being able to memorize facts is critical in mathematics learning." Also from White et. al. (2005/2006) we utilized a teacher attitudes survey. The survey consisted of 20 Likert-scale items related to teachers' attitudes towards mathematics and teaching mathematics, such as, "mathematics makes me feel inadequate" and "I'm quite good at mathematics."

The final survey that was utilized to understand teacher beliefs was the 2012 Horizon Survey (Banilower, Smith, Weiss, Malzahn, Campbell, & Weis, 2013). We looked at teacher responses to items in three sections of the Horizon Survey. The first part of the survey, which focused on beliefs, consisted of 11 items which participants responded to on a 5-point Likert scale ranging from a 1 (strongly disagree) to a 5 (strongly agree). Questions included "teachers should explain an idea to students before having them investigate the idea." The second section asked participants to rate their emphasis on eight instructional goals ("Learning test taking skills/strategies") on a 5-point Likert scale ranging from 1 (none) to 5 (heavy). The third section, related to frequency of current practices, included 15 5-point Likert scale items ranging from 1 (never) to 5 (all the time), with items such as, "explain mathematical ideas to the whole class."

To address RQ1, we started by identifying significant differences between how EMS and nonEMS teachers responded to IMAP survey item 3.3. We then looked for significant differences on the White and colleagues (2005/2006) and Horizon (2012) survey items. This process allowed us to limit which items we wanted to examine further; we only examined items that had a significant difference between EMS and nonEMS teachers. We then explored relationships between beliefs and specific reported practices for each group, including the situation described in the IMAP item. To address RQ2, we calculated correlations between each item on the pedagogical goals and self-reported practices scales (Horizon) and the factor scores on the attitudes survey (White et al., 2005/2006) to compare how teachers who exhibited more or less confidence in doing mathematics and security in teaching mathematics answered questions about specific teaching practices (Horizon and IMAP). We also looked at how teachers' attitudes related to their responses on Item 3.3 (see below) from the IMAP survey, comparing means via *t*-tests for teachers who responded differently.

Results

Differences in Teacher Beliefs

One primary theme from our analysis was that EMSs were more likely than their peers to believe it is important for students to develop conceptual understanding of mathematical concepts before they learn mathematical procedures. On IMAP question 3.3, when asked to say which of the five strategies they would focus on first in a unit on multi-digit addition, 100% of EMSs chose a strategy which employed the use of base-10 blocks to model the place value of the digits in the problem. When asked to justify their reasoning, one EMS teacher wrote, "I would first have students use manipulatives to make sure they understood the concept of adding and had a good grasp on place value." This teacher's ordering of student representations, along with most EMSs, moved from concrete to abstract with 60% of EMSs choosing the standard algorithm as the last approach they would show to students. In contrast, 33% of nonEMS teachers chose to share the standard algorithm last and 12% chose to share it first. A focus on conceptual understanding prior to teaching procedures was not only represented in teachers' practice-based, situation-specific beliefs but also in their self-reported beliefs. In the Horizon (2012) survey none of the EMSs agreed with the survey question, "Teachers should explain an idea to students before having them investigate the idea" as compared to 34% of nonEMS teachers. Additionally, on the White et. al. (2005/2006) survey 11% of EMSs agreed with the statement, "mathematics is computation" as compared to 42% of nonEMS teachers. These examples taken together show that EMSs believe conceptual understanding should serve as a foundation for procedural fluency and that their self-reported beliefs aligned with their practice-based beliefs.

Teacher Attitudes and Reported Practices

In general, correlations between attitudes and reported practices revealed that teachers who expressed more confidence in their mathematical ability were significantly more likely to report engaging in class discussions ($r = 0.26$, $p = 0.06$) and to focusing on a wider variety of mathematical representations and solution strategies when responding to the situation on IMAP item 3.3. Teachers who expressed more security with regard to their teaching of mathematics were similarly more likely to report having students compare and contrast their strategies and solutions ($r = 0.25$, $p = 0.06$), and justify their reasoning ($r = 0.30$, $p = 0.03$). On IMAP question 3.3, teachers who felt less secure in their mathematics teaching were more likely to share the standard algorithm with their students first, second, or third (such teachers had an average security rating of 3.77). Teachers with higher security scores were more likely to share the standard algorithm later or not at all (such teachers had an average security rating of 4.12, a significant difference, ($t(29) = 1.84$, $p = .03$). This suggests that teachers who feel less secure in their mathematics teaching might feel less comfortable with nonstandard solution methods.

Discussion and Implications

In this study we sought to build on previous research that focused on EMS teacher beliefs by closely examining how teachers held beliefs were represented their practice-based and situation-specific, self-reported beliefs. Not only did the researchers find that EMS and nonEMS teachers' beliefs about mathematics, teaching, and learning were different but it was also confirmed that teachers self-reported beliefs were aligned and reflected in their practice-based beliefs. This adds to the previous literature, which only shared generalized results about teacher beliefs without exploring how those self-reported beliefs were enacted in situation-specific scenarios.

Additionally, limited research has been done comparing EMS and nonEMS teacher beliefs. Finally, this study connects teacher attitudes with teacher beliefs and self-reported practices.

Future research might take this work a step further by comparing self-reported and practice-based beliefs with classroom observations to understand the more tacit beliefs that teachers might hold. The findings of this study present a way of exploring teacher beliefs through a variety of lenses which allows for a more robust understanding of teacher beliefs. This understanding could help teacher educators to present elementary teachers with any disparities between self-reported beliefs and practices-based beliefs, which could lead to changing beliefs.

Being able to notice students' mathematical thinking during teaching (in-the-moment noticing, IMN) impacts the quality of instruction. Also, noticing students' mathematical thinking and reflecting on the activities of teaching after instruction (post-instruction noticing, PIN) is important for teachers' long-term professional development. We explored the relationships between IMN and PIN by examining the data from seven elementary in-service teachers engaged in a professional development program. By analyzing 33 coaching videos and post-coaching conversations, we found that teachers' IMN did not align with their PIN, and PIN tended to be of lower quality than IMN. We discuss implications for future research and practice.

Keywords: Teacher In-the-Moment Noticing, Teacher Post-Instruction Noticing, Teacher Professional Development

Introduction

Noticing students' mathematical thinking during instruction is an essential component for "highly individualized and responsive instructional tactics" (Thomas et al., 2017, p. 6). We refer this kind of noticing (noticing during instruction) as in-the-moment noticing (IMN) (Cross Francis et al., 2021). Additionally, reflecting on instruction with a focus on students' mathematical thinking after the lesson helps teachers identify meaningful and problematic aspects of students' thinking that can inform subsequent instructional practices (Sherin et al., 2011). We refer to this kind of noticing, which occurs after instruction, as post-instruction noticing (PIN) (Cross Francis et al., 2021).

Research findings support that high level IMN helps teachers in making strategic choices about adapting their instruction, hence, acts as a central factor in high-quality instruction (Thomas et al., 2017; Walshaw & Anthony, 2008). As such, high quality teaching would be, at least in part, the result of high-level IMN. Subsequently, if a teacher demonstrates high level IMN, then they would have access to relevant knowledge and skills, which theoretically would inform high PIN. However, despite this apparent connection, the link between IMN and PIN has been understudied. In this study, we examined the alignment and misalignment between teachers' IMN and PIN. We aimed to answer: What are the alignment patterns between elementary teachers' in-the-moment noticing and post-instruction noticing levels?

Theoretical Framework

In-the Moment Noticing (IMN)

High-level IMN supports meaningful instructional decision-making that facilitates students' learning (Ayalon & Hershkowitz, 2018; Thomas et al., 2017). The skills encompassed in IMN – attending, interpreting, and responding to students' mathematical thinking – are essential for teachers to differentiate their instruction and support students effectively. However, these noticing skills can hardly be accessed directly. As Jacobs et al. (2010) proposed,

> We suggest that, before the teacher responds, the three component skills of professional noticing of children's mathematical thinking – attending, interpreting, and deciding how to respond – happen in the background, almost simultaneously, as if constituting a single, integrated teaching move… (p. 173).

Additionally, as Schoenfeld (2011) argued "what you see and don't see shapes what you do and don't do" (p. 228), so we can infer teachers' noticing activity from observing students' and teachers' in-the-moment interaction. Therefore, strong facilitation of students' engagement with high frequency of use of students' thinking, close attention to students' learning difficulties, and facilitation of student substantive contributions, serve as indicators of high-level IMN.

Post-Instruction Noticing (PIN)

Researchers (e.g., Amador et al., 2017; Sherin & Van Es, 2009) have focused on investigating PIN to understand what and how teachers observe, how they interpret the gathered information, and how professional developers can support teachers in this process. Research on noticing found that teachers' PIN skills help teachers in identifying significant student contributions (Leatham et al., 2015). Furthermore, PIN skills can be improved through professional development (PD) (Sherin & Van Es, 2009; Star & Strickland, 2008). Different from IMN, PIN via watching videotaped lessons offers teachers fruitful opportunities to observe and attend to students' thinking as they can pause the video, replay interesting and meaningful instances, and spend time making sense of students' mathematical thinking. This suggests that teachers will have more opportunities to notice students' thinking than during actual instruction.

Methods

Context

This study was conducted within a PD program designed to collaboratively work with elementary teachers on improving their MKT and instructional practices. The data were collected from the coaching intervention, termed as Holistic Individualized Coaching (HIC) (Cross Francis, 2019), implemented during the second year of the PD. During each coaching cycle, teachers engaged in conversations with the coaching team to plan their lesson (pre-coaching conversations) and to discuss the taught the lesson (post-coaching conversations). For the post-coaching conversation, the teachers were asked to select three videoclips they considered useful for improving instruction from the videotapes of their taught lessons to discuss with the coach.

Participants

Seven elementary teachers participated in this study. They taught across three different schools that served high populations of minoritized students with over 50 percent of students qualifying for free/reduced lunch. Table 1 includes additional information about the teachers.

Table 1. Demographic Data on Participants

	Bo	Liv	Avi	Mia	Kai	Joy	Sky

Data Sources and Analysis

Instructional videos. Instructional videos were used to determine instructional quality and the level of instructional quality was used as a proxy for IMN. Each teacher was involved in five HIC cycles. We analyzed 35 (seven teachers times five cycles) coached lesson videos using the Mathematical Quality of Instruction instrument (MQI) (see Hill et al., 2008). We specifically used three IMN related items from the *Whole Lesson Codes* section: i) Teacher Uses Student Ideas (USI); ii) Teacher Attends to and Remediates Student Difficulty (RSD); and iii) Lesson Contains Common Core Aligned Student Practices (CSP). The items were scored from 0 to 5 (0 – not present, 1 – low, and 5 – high) and the average scores of items were used to indicate teachers' levels of IMN. We assigned the average score of 0 to 1.6 as low level, 1.7 to 3.3 as medium level, and 3.4 to 5 as high level.

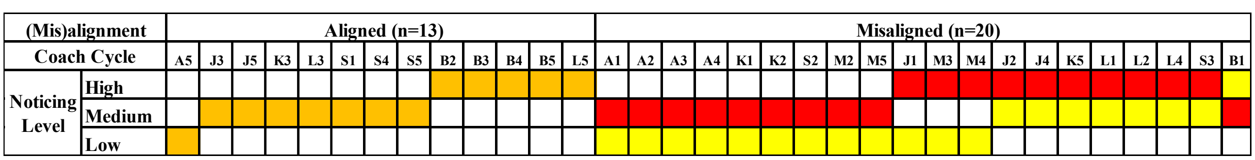
Post-coaching conversations. We examined 33 post-coaching conversations (two teachers were not available) to identify the clips the teachers selected. Then we analyzed the conversation around these videoclips by using Van Es' (2011) noticing framework to determine PIN. We assigned a score of 1 to 4 for (1: low and 4: high) *what* and *how* they noticed for each of the videoclips, and we took the average scores to show their PIN level. We defined the average score between 1 to 1.3 as low level, 1.4 to 2.6 as medium level, and 2.7 to 4 as high level.

To answer the research question, we examined both the IMN and PIN levels per coaching cycle (Figure 1) to determine the alignment patterns. We further grouped the seven teachers into three pattern categories based on the (mis)alignment features.

Findings

Overall (Mis)alignment Pattern

We compared each teacher's IMN level with the corresponding PIN level to determine the nature of alignment between them (Figure 1). The IMN and PIN comparison showed both alignments and misalignments. Specifically, in 13 of total 33 lessons teachers' IMN aligned with their PIN (the orange squares: one L-L; seven M-M; five H-H); in 19 lessons, teachers IMN levels were higher (the red squares are above the yellow squares: seven H-M; nine M-L; three H-L) while only in one lesson, the teacher's PIN level was higher (the yellow square is above red square, B1). Overall, there were more misalignments than alignments and teachers IMN levels were higher than their PIN levels, except for one case, B1. B1 means Bo's first coaching cycle.



RED: IMN level; **YELLOW**: PIN level; **ORANGE**: Alignment between IMN and PIN. Coaching cycle: Teacher's initial and the order of coaching cycle. These norms also apply to Figures 2 and 3.

Figure 1: Alignment Patterns Between IMN and PIN

Three (Mis)alignment Pattern Categories

Cases of mixed alignment. Mixed alignment cases appeared to be more common among all cases. Four teachers' cases (Kai, Sky, Joy, and Liv) belonged to this type (Figure 2). Their IMN and PIN levels did not show a regular pattern of alignment. The teachers' IMN levels varied from medium to high, while PIN levels ranged from low to high. Their alignments clustered at medium level. For all the cases PIN was at an equal or at a lower level to IMN.

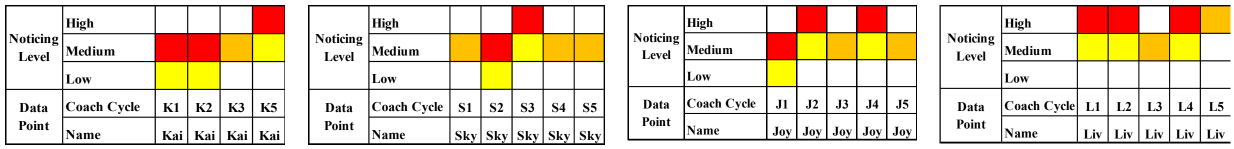


Figure 2: Four Cases of Mixed Alignments

Cases of low reflective noticing. Figure 3 shows two teachers' cases (Avi and Mia) whose PIN levels were consistently low although their IMN levels varied. Avi's IMN was medium across the five coaching cycles, while his PIN levels were consistently low. Mia's IMN levels ranged from medium to high while her PIN levels were also consistently low. These two cases show that for some teachers PIN level are stable regardless of their IMN level. Also, IMN was higher or at the same level as PIN.

Case of H-H alignment. Figure 3 includes a special case where the teacher's (Bo) IMN and PIN levels were aligned at the high level (four over five instances). In the first coach cycle, the PIN is higher than the corresponding IMN.

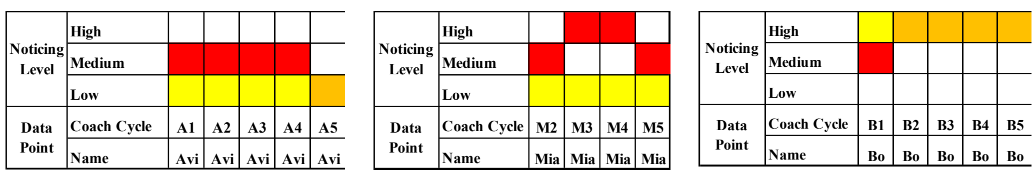

Figure 3: Three Cases of Consistent PIN Level

Discussion and Implication

In this study, we found that the teachers tended to notice in the moment of instruction, but they were not always able to recall or re-notice those moments when they watched their own teaching videos. This situation indicates that as Jacobs et al., (2010) stated, the nature of noticing involving "attending, interpreting, and deciding how to respond – happen in the background, almost simultaneously, as if constituting a single, integrated teaching move" (Jacobs et al., 2010, p. 173), may render IMN "invisible" even for the person who enacted that noticing during their instruction. It may be that in the heighten activity of the classroom, more focused attention is placed on the more salient aspects of teaching. However, when watching the video post instruction, other aspects of the classroom activity become more visible, for example classroom management as in the case of Mia. In this regard, more research is needed to understand the distinctive nature of both types of noticing and how to support teachers in better focusing their attention after instruction. In this study, we found Bo was the only teacher who showed H-H alignment. We observed that Bo had a strong teacher identity that foregrounded students' thinking (Cross Francis et al., 2021). We believe such identity might have contributed to his attentiveness to students' mathematical thinking in both IMN and PIN. We inferred that Bo's identity might have played a key role. Supporting teachers in developing their identity and to change their beliefs about student learning to be in accordance with a student-centered teaching approach would make a difference.

Practically, as Mason (2002) explained, noticing is "an opportunity to act appropriately" (p. 1) and teachers' IMN impacts opportunities for effective instructional decisions in the classroom while PIN influences teachers' opportunity to learn from their own practice for growth. Therefore, as teacher educators we must focus on developing both IMN and PIN among the prospective and in-service teachers. By doing so, teachers would be more consistent in foregrounding students' thinking as a central part of their math teacher identity and instructional practices.

As part of an ongoing study, this paper reports on teachers' use of instructional routines for modelling prior to and during remote teaching. We problematize the use of instructional routines through notions of adaptive and routine expertise and pose questions to explore how routines can be adapted to attend to instructional responsibilities in remote learning environments. This study contributes to modelling instruction literature and extends research on use of instructional routines in innovative teaching.

Keywords: modelling, instructional activities and practices

Mathematical modelling is an opportunity to engage students in real-world, meaningful, mathematical activity (Cirillo, Bartell, & Wager, 2016; Kaiser, 2017; NCTM, 2018). Modelling instruction has the potential to engage students in mathematics relevant to their interests and asks teachers to support students' non-routine solution pathways (Aguirre et al., 2019). This instruction aligns with ambitious mathematics teaching, which centers supporting all students to see themselves as capable of solving authentic mathematics (Jackson & Cobb, 2010). With the move to remote learning, teachers have been pressed to modify instruction with new modes of student interaction, (re)focused mathematics content (e.g., Achieve the Core, 2020), and the need to support students' learning as holistic human beings (Horn & McGugan, 2020). Modelling has the potential to engage students in key mathematics and humanize mathematics such that students see themselves as capable mathematicians.

Classroom mathematical modelling asks students to grapple with authentic and ill-defined problems in a cycle where they make decisions, defend those choices, and revise their thinking as part of a classroom community (Consortium for Mathematics and Its Applications (COMAP) & Society for the Industrial and Applied Mathematics (SIAM), 2016). To support students, teachers may recruit instructional resources, such as modelling routines, to navigate the complex and ill-defined mathematical demands across the modelling cycle (Elliott, Stoddard, & Brunner, 2019; Lucenta & Kelemanik, 2020). Instructional routines are sequences of interaction that, when used regularly, scaffold student learning and teachers' instructional decision-making toward specific goals.

As part of an ongoing research project, this paper investigates teachers' self-reported instructional shifts regarding use of existing modelling routines prior to the pandemic and during remote teaching. We explore the patterns that arose around teachers' self-reported modelling instruction via their responses to a questionnaire and interviews. We discuss our questions for further research based on observed trends. This paper adds to the scholarship on pandemic impacts for ambitious instruction with a focus on modelling instruction and routines.

Framework

Instructional routines allow teachers to flexibly engage with students and content, relying on structures to support risk-taking or adaptation of practice (Lampert & Graziani, 2009). They are *routine* in their regular use and flexible in application to support teaching and learning across contexts. Researchers posit that instructional routines build familiarity for students and teachers and can shift the cognitive work to the mathematical content under study (Lampert & Graziani, 2009). In this paper, we examine the use of teacher designed modelling routines that support specific modelling processes. Two routines, henceforth referred to as Routines 1 and 2, focus on the practices of making mathematical assumptions (Routine 1) and developing processes for revising a model (Routine 2); these elements of the modelling cycle have been documented as challenging for both students and teachers to navigate (Galbraith & Stillman, 2006).

Remote learning calls teachers to develop new instructional practices or adapt existing ones to fit new contexts. As a result, teachers are pressed to apply their knowledge and skills of teaching to flexibly modify instructional tasks and interactions to meet student learning goals. We frame how teachers deploy their expertise in teaching via the interaction of routine and adaptive expertise (Hatano & Inagaki,1986). Routine expertise is the efficient and accurate expertise that emerges in stable contexts. Adaptive expertise is leveraged towards innovation when teachers must effectively attune instruction to shifting situations, such as remote learning. Further, because modelling routines offer *both* predictable sequences of activity *and* tools to responsively and flexibly elicit students' use of modelling practices (Lampert et al., 2013), we were interested in how teachers in the study might draw upon routine and adaptive expertise to enact modelling instruction across their transition to remote learning.

Context and Methodology

The data in this paper are part of a broader study on the use of instructional tools in mathematics classrooms in a mid-sized suburban school district. We coordinate data from a questionnaire on ambitious instruction and modelling, completed by secondary mathematics teachers who had participated in a district-led professional development series on modeling instruction and incorporating instructional routines, and interviews on similar topics with a subset of these teachers who had long term commitments to designing modelling routines.

Here, we draw upon a subset of questions from the Qualtrics (Provo, UT) questionnaire, where teachers recorded an approximate number of times they had used Routines 1 and 2 prior to and during remote learning. Ten teachers from the district completed the questionnaire. While this sample size is limited, it represents the majority of teachers from one mathematics department and from the set of teachers participating in the professional development, therefore providing insight on general department trends. Four teachers completed a semi-structured interview, providing detailed descriptions of their use of Routines 1 & 2 prior to and during remote learning. After reading all data multiple times, the research team identified and discussed themes from teachers' reported use of the routines and coordinated them across data sources and participants. These analyses allowed us to frame a problem space for further inquiry. We present findings from our analysis and identify an area for continued exploration in light of current literature.

Findings and Discussion

We wanted to understand how teachers drew upon their expertise around the modelling routines in their instruction. Teachers were asked to identify if they never used the routine, if they used it 1-2 times an academic year, quarterly, monthly, or at least weekly. *Prior to remote learning*, every teacher responded that they had enacted Routine 1 at least once, and all but one teacher had used Routine 2 at least once (Table 1).

Table 1: Reported use of the instructional routines prior to and during remote teaching.

Routine Use	Routine 1(Pre)	Routine 1 (During)	Routine 2 (Pre)	Routine 2 (During)
Weekly or more	2	0	1	0
Monthly	4	4	2	2
Quarterly	2	2	3	2
1-2 times a year	2	1	1	2
Never	0	3	1	4

Prior to remote learning, all ten teachers stated in their use of the modelling routines helped students make real-world connections with mathematics. A majority of teachers noted the routines fitting into their curriculum (n =8), guiding the flow of their lessons (n=9), and supporting work on future modelling problems (n=9). Additionally, almost all the teachers (n=9) reported that the use of the routines promoted student critique of models and explicit metacognitive reflection on learning. During an interview, one of these teachers reflected on the regularity of Routine 1 use in their classroom, saying, “I would say it is definitely becoming more of a regular routine for me in my teaching…kids really seem to enjoy the experience. They’re just getting used to not being able to all get the same answer in the end, and they’re getting more comfortable with that.” This teacher saw a relationship between routine use and student engagement in mathematical modelling processes that could invite students into doing mathematics, a challenge teachers may experience during remote instruction (Horn & McGugan, 2020). Another teacher, however, reflected on the challenge of feeling routine expertise with the modelling routines, even prior to the shift to remote learning:

> I was reflecting back on when and when and how often I use the routine that we built, and it was sporadic and random. And its always felt like it had to be forced in some way. Like, it wasn’t natural to want to use the routine, because [they were] still in this developmental stage and it never really has landed in a place where it just is automatic.

After the transition to remote learning, we recognized that teachers’ use of both routines had decreased. In particular, four teachers had never used Routine 2, three teachers had never used Routine 1, and no teachers were using either routine weekly. While this is not surprising due to the variety of needs and expectations teachers have had to balance over the last year, we were interested in continuing to learn more about why this particular resource was impacted. Even though these teachers identified benefits of the routines that could attend to needs for innovation and practice in remote learning, the use of the routines still decreased. We saw clues as to why this might be in teachers’ questionnaire responses describing challenges they faced. Half of the teachers noted time as a leading challenge prior to and during remote learning. They also noted limitations of find “good [modelling] tasks” that don’t feel like “field trips” outside of the typical curriculum and uncertainty in how to assess progress on modelling. We found these responses especially interesting in light of teachers’ regularity of use of modelling-routines prior to remote learning. We wondered how the use of modelling routines had supported the majority of teachers’ *routine expertise* prior to remote learning, given the comment that they were still in development. To this end, we are currently exploring how the modelling routine may need to be adapted to be an effective resource for both teachers and students in a virtual environment so that teachers may develop *both* routine and adaptive expertise. Further, is it possible to have a routine for modelling that can attend to mathematical challenges as well as support the ever-evolving needs and responsibilities for teachers and students in a remote learning environment?

Conclusion

This study explores how teachers enacted modelling routines in pursuit of ambitious instruction and considered features of the instructional environment that impacted their use during remote learning. Teachers recognized benefits to using the routine and these benefits aligned with some of the central goals for remote learning. However, teachers' reported use of the routines declined since the shift to remote learning which may indicate a need for more routine and adaptive expertise to support flexible use amongst the group of teachers. We continue to advocate for the use of routines and other resources to support modelling instruction and invite the research community to engage in our shared inquiry: what features of classroom instruction and expertise might support the adaptation of routines to serve different needs and scenarios? How might routines be useful in teachers' development of adaptive expertise?

Keywords: Inservice Teacher, Professional Development, Research Methods, Coaching

In this project, we have designed, implemented, and started to research an innovative fully online video-based professional development model for mathematics coaches in rural contexts. Coaches in rural areas often lack access to professional development available in more populated areas, fueling the need for an online model that bridges geographic barriers (Howley & Howley, 2005; Maher & Prescott, 2017). The intent of the poster will be to share the professional development model and describe the research processes that are currently in progress.

The goal of the project is to support mathematics coaches in rural contexts to improve their ability to (a) facilitate productive planning and debriefing conversations with teachers; (b) notice salient coaching practices and their impact on teachers' thinking; and (c) use evidence of teacher learning to make decisions about their own coaching practices. Focal research questions include: (1) How do the nature and content of coaches' contributions evolve across the multiple components of the model? (2) How are the contributions in one part of the model associated with those from other parts of the model? (3) What resources (e.g., time, logistics, skills) are required to enact the three-part model?

We are currently engaging coaches in a three-part professional development model that includes (a) an online course on content-focused coaching, (b) one-on-one video-based coaching cycles with a Mentor Coach, and (c) an online video club in which practicing coaches reflect on dilemmas of practice and the impact of coaching moves, using evidence from their own coaching. Three cohorts, each comprised of 12 Coach Participants (supporting rural teachers), will engage in a two-year professional development model, each supported by a Mentor Coach (project personnel recruited for their expertise in content-focused coaching). The first cohort is completing Year One. In Year One, participants engage in all three parts of the model, and in Year Two they engage in online video clubs only. The study follows a design-based research model (e.g., Barab & Squire, 2004) with iterative cycles of design and revision of the three-part online model. These cycles are being used to test and revise our theory of action and our conjectures about the affordances and constraints related to online professional development for coaches. We follow Sandoval (2014) in developing and using *conjecture maps* to articulate our model, guide our research, and build theory. There are two types of measures: (1) baseline and outcome data related to the perceptions and practices of the Mentor Coaches and Coach Participants; and (2) measures related to the content and nature of interactions across all three components of the professional development model.

The focus of the poster presentation will be to share the overall project design, including descriptions of the three-part model as well as the data collection process and initial analysis processes, as related to the research questions.

LEVERAGING TEACHERS' COMPLEX PERCEPTIONS OF STUDENTS

Mari Altshuler
Northwestern University
marialtshuler@u.northwestern.edu

Erica N. Mason
University of Illinois, Urbana-Champaign
enmason@illinois.edu

Keywords: Teacher Beliefs, Instructional Activities and Practices

Researchers have reported that mathematics teachers hold unproductive views of students (e.g., Jackson et al., 2017; cf. Lambert, 2015), or adjust their instruction in unproductive ways (Wilhelm, 2014). *Unproductive* views attribute students' struggle to factors characterized as internal to the student such as ability or motivation; *unproductive* instructional adjustments are aimed at decreasing the rigor of learning opportunities. Here, we bring together findings from two studies that, in some ways, reiterate these trends. However, when we further unpacked participating teachers' talk, we found nuance in teachers' perceptions of their students, which led us to ask how we might leverage teachers' ability to understand their students in complex ways and shift their discourse to be more productive.

The first study, *Teachers' Views of Students with Disabilities as Mathematically Capable,* found that mathematics teachers explained students' struggle in unproductive ways and gave unproductive rationales for instructional adjustments (Mason, 2019). Also, there were differences between explanations and rationales for students with and without disabilities. The second study, *Unpacking K–3 Teachers' Stories of their Students as Mathematics Learners*, found that teachers combined their perceptions of students' performance and aptitude in mathematics with other factors including personality, effort, engagement, behavior, and family context (Altshuler, 2019). Also, teachers drew on different sources of evidence when supporting their descriptions of students in relation to their perceptions. Taken together, these studies echo the narrative that some teachers describe students' mathematics learning as outside of their instructional control. This is an important finding, and one that is problematic for students' opportunities for learning. However, data from both studies also revealed that teachers talked about their students in multi-faceted ways, including students' assets. Even when teachers' descriptions of students were ultimately coded as unproductive, we noticed nuggets of productivity, which, upon reflection, complicates these findings and suggests the need to identify ways to support teachers in leveraging these views.

One approach is supporting teachers to reconceptualize the nature of intelligence as malleable rather than fixed (e.g., Boaler, 2013). This may lead to more productive instructional responses because when teachers attribute students' struggle to innate traits, they may be more likely to absolve themselves of instructional responsibility (e.g., Horn, 2007). By reframing intelligence as malleable, teachers can leverage their agency to support learning. Further, as teachers work to shift their discourse about students, we should similarly shift research practices and analyses. We frequently ask teachers to notice, collect, and share data about their students; what would it look like to identify moments of productive talk and use such instances as a springboard for discursive (and instructional) change? Together, shifting teachers' discourse and perspectives to be more productive and aligning analytical tools to do the same may be one step toward creating richer mathematics learning opportunities for all students.

MASTER'S PROGRAM FOR IN-SERVICE TEACHERS WITH A FOCUS ON IMPROVING MATH TEACHING AND LEARNING

Teruni Lamberg
University of Nevada, Reno
terunil@unr.edu

Lynda Wiest
University of Nevada, Reno
wiest@unr.edu

David Kirkland

Keywords: Teacher Knowledge, Teacher Noticing, Teacher Beliefs, Professional Development

In-service teachers need sustained professional development that influences practice to positively impact student achievement (Even, 1999). A master's program for in-service teachers is a good context for providing teachers with sustained professional development. Unfortunately, getting a master's degree does not necessarily translate into shifting teacher practice and student achievement. Therefore, it is important to consider what criteria are needed to develop a high-quality master's program that impacts teacher knowledge, beliefs, and practice. Some key criteria that can impact teacher learning and practice are professional learning communities (Graven 2004; Hill, 2007) and rich pedagogical and content knowledge (Basista & Mathews, 2002; Darling Hammond, 2000; Borko & Putman, 1995; Lamberg et al., 2020; Swackhamer et al., 2009). In this session, we will present the design (Lamberg et al., 2020) and data from our master's program that is currently in its seventh iteration. Twenty-five participants participated in our study. The data collected include teacher reflection on the impact of the program, a survey of teachers' teaching practices framework (Lamberg, 2019) and MAP test student scores. The teachers' written reflections were analyzed using Strauss and Corbin's(1998) constant comparison method to identify themes. Mean pre and post test scores were calculated, with the differences used to assess the growth of individual teachers and to compare with national normed scores.

Findings

The analysis revealed that teachers' teaching practices were positively influenced as indicated in the teachers' self-report survey. Student achievement pre and post scores were positively impacted, and the gain scores were above national norms. The following respondent comments was representative of how teachers were impacted:

- When I began the first math class of our program, I could figure out everything from an algorithm, but that did not get me very far when I had to prove my answers. It was a steep learning curve to not only change my thinking process on what mathematics is, but I had to change everything I had believed for so many years. Along with mathematics concepts, we were learning progressions and digging deeply into the common core standards. Digging into those standards and looking at exactly what students need to know and how we can get them there was "eye-opening".
- What I learned from this program is that teaching does not necessarily equal learning. I was teaching my students procedures that I was familiar with in an environment where nothing was making sense to a lot of kids. The teaching was there and I was going through all the motions. However, the learning was not evident the way it should be. This

program has helped me evolve from being a teaching to being a facilitator of professional discussions.

Conclusion

This master's program design has been effective in supporting shifts in teachers' classroom practice and impacting student achievement. It meets the criteria outlined on teacher quality and student achievement by Darling-Hammond (2000). A master's program's effectiveness is dependent on whether it impacts student practice. The program discussed here considers teachers' mathematical and pedagogical content knowledge and develops a professional learning community of practice as outlined by Hill (2007). The poster presentation will include details on the design of the master's program.

THE STRUGGLE OF COVARIATIONAL REASONING ABOUT EXPONENTIAL GROWTH: EMBRACE IT OR ERASE IT

Exponential functions are an important part of secondary school mathematics (NGACBP & CCSSO, 2010). Yet not much is known about the link between a teachers' knowledge and student learning with respect to exponential functions (O'Bryan, 2018). Covariational reasoning has been identified as one important component important in learning and understanding exponential functions (Ellis et al., 2016; Strom, 2006).

As part of a larger study, we engaged several secondary mathematics teachers in analyzing a task designed to support the development of covariational reasoning. The task had several nonstandard features that supported covariational reasoning such as not asking for an expression or equation, not providing an initial value associated with time $x = 0$, and asking about fractions of a growth period. Here we focus on two teachers' responses that highlight their thinking as they struggled to make sense of a fractional growth period. Kathy and Ben represented a spectrum of views on the Growing Rabbits Task and evidenced different ways the teachers engaged in covariational reasoning concerning non-integer multiples of the growth period.

Both Ben and Kathy completed the task by writing an exponential equation. Ben initially used reasoning about growth periods but quickly abandoned this reasoning in favor of an equation-oriented approach. He recognized the existence of alternative approaches but saw procedurally using an equation as the best approach to the problem. His focus was on producing a solution as opposed to engaging in covariational reasoning of exponential change.

Kathy initially used an equation but then extended her inquiry to make meaning of what that equation was doing. She embraced the relationship between additive and multiplicative change, grappled with the effects of estimation on an exponential function, and used ratios to compare interval lengths of the dependent variable. She struggled to identify how that relationship worked with non-integer multiples of the growth period but did not let her struggle derail her inquiry.

The two teachers shifted between covariational and correspondence perspectives (Ellis et al., 2016) in different ways and each encountered different difficulties extracting a rich interpretation of a fractional exponent or partial growth cycle. Neither teacher demonstrated the full covariational reasoning underlying the fractional growth periods in the task, though Kathy's work demonstrated that she sought rich meaning. Additional research on teachers' covariational reasoning with exponential functions, particularly fractional exponents, can inform teacher training and professional development to prepare teachers to embrace these topics more deeply.

THROUGH THE STUDENTS' EYES: MATHEMATICS TEACHERS' CURRICULAR NOTICING IN A PROBLEM-BASED CURRICULUM

Sunyoung Park
Michigan State University
sunpark@msu.edu

Kristen N. Bieda
Michigan State University
kbieda@msu.edu

Keywords: Curriculum, Middle School Education, Professional Development

Although problem-based mathematics curriculum materials have the potential to provide opportunities for students to develop mathematical understanding (Harris et al., 2001; Reys et al., 2003), teachers who did not learn mathematics through an inquiry approach can find it challenging to implement (Edson et al., 2019). If they do not notice student learning opportunities in the curriculum, teachers are less likely to promote students' mathematical understanding (Amador & Earnest, 2019). This study investigated teachers' curricular noticing when they solved textbook problems from a student's perspective. The following research question was addressed: How does solving problem-based textbook problems in the process of planning lessons engage mathematics teachers in curricular noticing?

Theoretical Framework

This study draws on the Curricular Noticing Framework (Dietiker et al., 2018) and an active learning approach to teacher learning (Darling-Hammond et al., 2017). Focusing on problem-solving experience as leverage for curricular noticing, we utilized the Curricular Noticing Framework, which consists of *Attending, Interpreting, and Responding*, to describe how teachers make sense of a curriculum and how they find opportunities in it for students' understanding.

Data Collection and Data Analysis

Data sources included both audio-visual recordings of interviews and the written responses from two middle school mathematics teachers. Both participants used *Connected Mathematics Project* (*CMP3*) (Lappan et al., 2003) as a school designated curriculum. For each participant, we conducted two interviews and asked for one written response regarding their problem-solving process and curricular attending. Data analysis was guided by a qualitative method (Saldaña, 2016), applying both a structural and a holistic coding approach. The teachers' curricular noticing phases (Attending, Interpreting, Responding) were identified, followed by an analysis of how their problem-solving experience related to their noticing phases.

Findings and Implications

When solving textbook problems from a student's perspective, the teachers spontaneously engaged in curricular noticing from a teacher's perspective as well. Further, as they planned lessons, they attended to resources within the teacher's guide that could support students' various problem-solving strategies; they interpreted guidelines based on their problem-solving experiences and their own solutions; and they responded by creating lesson plans that would ensure their students would be able to develop agency while doing mathematics. For example, one teacher came up with a unique strategy to solve a problem, while the other teacher struggled to generate two equivalent expressions. Based on their problem-solving experiences, both teachers decided to encourage students to create various strategies. These teachers reported that problem-solving from a student perspective did not take them very much time, and further helped them better understand curriculum materials and thus be well-prepared for the lessons.

THE EFFECT OF RESEARCH EXPERIENCES ON TEACHERS' BELIEFS AND INSTRUCTION: PILOT STUDY

Seyedehkhadijeh Azimi Asmaroud
Illinois State University
khaazimi986@gmail.com

David Barker
Illinois State University
dbarker@ilstu.edu

Research suggests many benefits of adopting Discovery Learning (DL) methods for teaching mathematics (Herdiana, Wahyudin, & Sispiyati, 2017). The question then becomes, how do we prepare teachers to use DL in their classrooms? One potential avenue is to provide them opportunities to experience DL themselves. Professional Development (PD) programs are one of the ways that teachers can gain knowledge and skills for teaching by DL methods. In this study, 14 volunteer mathematics teachers participated in a PD program in which they had the opportunity to participate in an eight-week authentic research experience and then taught DL in a one-week Math Camp (MC) for high school students. The theoretical perspective supporting the design of the PD was Professional Learning Communities which is "a group of people sharing and critically interrogating their practice in an ongoing, reflective, collaborative, inclusive, learning-oriented, growth-promoting way" (Stoll et al., 2006). This study explored how this PD and DL practice in the MC changed participants' beliefs and teaching methods? Furthermore, this study provided suggestions to improve the measurement tool for future studies.

This study was a mixed-method. Participants answered an online survey (consisted of 16 items including open-ended and scaled questions about demographic information, teachers' beliefs, teaching methods, and MC effects). After data collection, the authors looked for patterns in responses to open-ended questions for emergent themes, did open coding separately, and then compared the results and agreed on the coding method.

Responses to the scaled questions showed that more than ⅔ of participants believed that this PD caused moderate or significant change in their beliefs (78% mentioned changes in their beliefs about teaching mathematics, and 84% of them mentioned changes in their beliefs about doing mathematics). Furthermore, results showed that after this PD, participants use more exploration methods in their classroom (77 % use exploration at least 1-2 times each week, and 22% of them use exploration three or more times every week). Furthermore, 64% of them found the MC moderately or extremely beneficial.

Responses to the open-ended questions revealed changes in participants' beliefs about their own ability and their students' ability to learn mathematics, and also teachers' expectations from students had changed. Factors mentioned as affecting these changes were MC experience and the DL situation of PD. They mentioned that DL "enhances and deepens students' understanding of mathematics", it "makes mathematics more accessible to students", and "it is a great way to introduce new topics" and "increase student engagement". Also, they mentioned that they more frequently use DL and problem-solving methods after this PD. Learning classroom management skills, designing a week-long lesson and implementing it, and a chance to talk to students one on one and support their conjectures were mentioned as beneficial features of the MC.

This pilot study helped the authors identify some themes about changes in teachers' beliefs and teaching methods that will help in developing questions for interviews. However, it did not show a relation between the effect of change on specific beliefs and their consequent effects on teaching methods. Several modifications were implemented to the research questions (they will be mentioned in the poster presentation) to get more detailed responses to answer this concern.

The purpose of this study is to explicate how a group of Texas Mathematics Teacher Educators (MTEs) used the professional development tool of Lesson Study to examine use of an equity framework, namely the Torres' Rights of the Learning (RoTL; Torres, 2020), into their practice. This lesson study served as a peer-professional development in which each of the authors brought their own ideas to the work as a means of collectively improving our practice. The research will outline aspects of Lesson Study, share the development of a task, and the results from the analysis.

The study used a Design Experiment methodology (Cobb et al., 2003) in whIthe group of MTEs refined and revised the lesson while reflecting on their own practice and needs of the students. Lesson Study process encourages teachers to study, plan, do, reflect, and refine (Lewis & Perry, 2014; Lewis et al., 2006). The researchers focused on how teacher candidates can learn about the Torres' Rights of the Learner which are the right to be confused, to claim a mistake; to speak, listen, and be heard; to write do and represent what makes sense (Torres, 2020) through a groupworthy task (Lotan, 2013) about non-standard units of measurement. The lesson first introduced the Torres' ROTL, then showed Cognitively Guided Instruction (Carpenter et al., 2015) of a video with a child solving a mathematics problem and exercising his Torres' ROTL. The lesson took three iterations that varied slightly (e.g., limiting unnecessary dialogue by the MTE and making transitions in and out of the breakout rooms to the main room more smoother). Data collected through the various iterations along with experiences of the MTEs were analyzed to explore and examine MTEs own practice in incorporating equity framework for teacher candidates. The research results will not only describe the experiences of the lesson and how the teacher candidates experience the Torres' RoTL, but also how the process of Lesson Study and collaboration supported our own practices as MTEs, especially during a challenging time as COVID 19.

Keywords: Teacher Noticing; Teacher Knowledge; High School Education

Researchers have suggested that how teachers understand the connections between teaching practice and student learning can develop over time through their everyday classroom experience (Hiebert et al., 2003; 2007), which could explain why teaching practice improves as teachers gain more experience (Papay & Kraft, 2015). Teachers' explanations of student events have been shown to influence teaching quality in the classroom (Jackson et al., 2017; Wilhelm, 2017). Furthermore, teaching experience has been linked to improved teaching ability (Copur-Gencturk, 2015; Santagata & Yeh, 2016).

This study explores how teachers use causal reasoning (CR) to explain student events. CR is characterized by "identifying explanatory factors (i.e., causes) that lead to particular outcomes (i.e., effects) in the classroom related to students" (Dyer, 2016). We hypothesize (*H1): Teachers with more experience (ten years or more) will be more likely to explain student events with teacher-oriented explanations (productive causal reasoning) than teachers with less experience (less than ten years).* Additionally, we hypothesize (*H2): Teachers will be less likely to use teacher-oriented explanations (productive causal reasoning) to explain negative student events.*

We analyzed the causal reasoning of ten high school math teachers in four interviews (40 total) from point-of-view observations (Sherin et al., 2011), in which the teachers discuss moments they tag in real time during a lesson. We qualitatively coded instances of causal reasoning ($n=587$) for whether the explanatory factor included the teacher (*teacher-related factor*; $K = 1.0$) and the outcome was negative ($K > .90$). Comparisons between teachers with greater than 10 years of experience to those with less were done using multilevel mixed effects logistic regression models to account for clustering in the data by lesson and moment discussed.

Our results indicate that teachers with more than ten years of experience were more likely to use explanatory factors about teacher-related factors ($\alpha = .7143$, $SE = .3107$, $z = 2.299$, $p = .0215$), and overall teachers were less likely to explain negative outcomes with teacher-related explanations ($\alpha = -0.6493$, $SE = 0.2070$, $z = -3.137$, $p = .00171$). Thus, *H1* and *H2* are supported.

MDISC FOR GTAS: A DISCOURSE-ORIENTED TEACHING PROFESSIONAL DEVELOPMENT FOR GRADUATE TEACHING ASSISTANTS

Valentin A. B. Küchle
Michigan State University
kuechlev@msu.edu

Keywords: Classroom Discourse, Doctoral Education, Professional Development

Many mathematics graduate students receive little or no support for their teaching. As the *Progress through Calculus* (PtC) survey (Apkarian & Kirin, 2017) showed, more than half of the 223 responding institutions did not offer a university-wide teaching professional development (T-PD) to their graduate teaching assistants (GTAs) and a third had no department-specific GTA T-PD. When a T-PD is offered to GTAs, it is typically confined to GTAs' first year of teaching: Fewer than 20% of the institutions who responded to the PtC survey (Apkarian & Kirin, 2017) offered GTAs T-PD beyond their first teaching year. The problems presented by this lack of continued T-PD are three-fold: (a) a yearlong course is insufficient for learning how to teach; (b) even if one could cram all there was to learn about teaching into a yearlong course, one's priorities while teaching for the first time may not be in line with topics that go beyond classroom management (e.g., equity and active learning); and (c) when one looks at available data on GTA T-PD activities (Apkarian & Kirin, 2017), it appears as though topics beyond classroom management may indeed be receiving little attention.

To address the lack of support that mathematics GTAs receive, particularly beyond their first year of teaching, I adapted and offered the "Mathematics Discourse in Secondary Classrooms" (MDISC) (Herbel-Eisenmann et al., 2017) T-PD in spring 2021 to three GTAs who were teaching undergraduate mathematics and who were no longer in their first year of teaching. The MDISC T-PD, among other things, introduces participants to the mathematics register (Pimm, 1987), six teacher discourse moves (Cirillo et al., 2014; Herbel-Eisenmann et al., 2013) (i.e., waiting, inviting student participation, revoicing, asking students to revoice, probing a student's thinking, and creating opportunities to engage with another's reasoning), and positioning. The goals of this poster presentation are to share details of the adapted MDISC T-PD's implementation and findings of a research study involving this GTA T-PD. Regarding the latter, I present the discourse-oriented T-PD I offered as an instrumental case study (Stake, 1995).

As Stake (1995) noted, an instrumental case study is driven by issues rather than the case itself, and issues evolve and emerge as the study progresses. Currently, my focal issues can be summarized through the following questions:

1. Which changes in discourse (as described by the usage of teacher discourse moves and dimensions of the EQUIP [Reinholz & Shah, 2018]) and positioning (of mathematics, oneself, and students) occur in the participants' classrooms over the course of the T-PD?
2. Which aspects of the adapted MDISC T-PD—a T-PD originally developed for secondary school teachers—are perceived relevant by the T-PD participants and why?

The data I draw on to answer these questions consist of: (a) video-recordings of thirteen weekly 2-hour T-PD sessions; (b) reflective memos written by me after every T-PD session; (c) three video-recorded semi-structured interviews with each of the three participants before, during, and after the T-PD; and (d) audio-recordings of all classes taught by the participants in spring 2021. Findings from the data analysis will be shared at the conference.

Keywords: Instructional Leadership, Professional Development, Sustainability

Over the last three years, the Responsive Math Teaching Project (2021) has been developing and refining a model for the development of mathematics instructional leadership in a network of 14 urban under-resourced elementary schools. The project is a research-practice partnership with the School District of Philadelphia, where more than 80% of students live below federal poverty levels, in a state with some of the largest gaps in the country between wealthy and poor districts. The goal of the project is to develop a sustainable model for instructional improvement and improve outcomes for students by increasing opportunities for professional learning situated in and around practice (Ball & Forzani, 2009) and fostering a networked community across schools (Coburn et al., 2012; Penuel et al., 2006).

Drawing on research on professional learning, teacher instructional capacity is built through developing new visions of mathematics teaching and learning (Ebby et al., 2020; Munter, 2014; Wilhelm, 2014), practice-based pedagogies of enactment and reflection (Grossman, 2018; Grossman et al., 2009), and mentored engagement in collaborative lesson design and enactment (Hiebert & Morris, 2012). Teacher leaders first learn what high quality math instruction and instructional leadership looks and feels like, then develop the necessary teaching and coaching skills and practices through practice-based professional development (representation, decomposition and approximation) and support for enactment in the classroom through collaborative planning and coaching. Over time, and with ongoing opportunities for practice, teacher leaders take over professional development facilitation and peer-coaching roles in their own schools, and across the network.

In this poster, we will present our current model which has been refined through cycles of development, implementation, and revision. We will also show how we are continually analyzing data and responding to local conditions to improve and refine our model. Through qualitative analysis of interviews, we trace the development of teacher leaders over time along several dimensions of leadership capacity, highlighting three key shifts that take place in their *instructional leadership vision*. We also show shifting from a school-based coaching model to a virtual cross-school model of collaborative lesson design, enactment, and reflection provided more equitable and sustainable opportunities for teacher learning and instructional support across the network, particularly for those schools that face the greatest challenges around resources.

MATHEMATICAL MOTHERS: INVESTIGATING SHIFTS IN PERSPECTIVE AROUND WHAT COUNTS AS MATHEMATICS

Sam Prough
University of Wisconsin-Madison
sprough@wisc.edu

Bridging the gap between mathematical learning at home and school has been an issue for education research for decades (Galindo & Sheldon, 2012). Expectations for mathematics do not often align for teachers and parents (Posey-Maddox & Hayley-Lock, 2016) and a limited view of what counts as mathematics persists. What needs more attention is the meaningful mathematical learning that happens at home but is rarely seen as mathematics. Parents frequently struggle in supporting their children's mathematical learning, but that struggle becomes productive when parents are recognized as mathematically capable. This paper shows how two mothers shift their perspectives of what counts as mathematics and recognize the rich content in their current interactions with young children. Making such connections between mathematics and parent action can strengthen the relationship between at-home and school learning.

Keywords: early childhood education, informal education

Many parents and teachers struggle to connect mathematics learning for children at home and in school. In many cases, parents feel that they do not understand school mathematics and struggle to help (Jackson & Remillard, 2005), while teachers wish that parents would be more involved in their children's learning (Wilder, 2017). Parents and teachers are often talking past each other, with different goals for children in mathematical learning. Previous work has been done to help parents engage with the mathematical activity that happens at school (e.g., Blevins-Knabe, Whiteside-Mansell, & Selig, 2007; Starkey & Klein, 2000). However, attention to connecting parents to mathematics is frequently school-centric (Jackson & Remillard, 2005) and ignores the meaningful mathematical interactions that may already be happening at home. This element is often missed because parents do not often see these interactions as mathematical (Goldman, 2005), further exacerbating tensions in parents about their mathematical ability. As such, supporting at-home mathematics research would benefit from helping families recognize the mathematics that already happens in their everyday lives. I explore this issue of at-home mathematics recognition in a case study analysis of two mothers of young children by responding to the question: How do parents begin to change their perception of interactions with mathematics when made aware of the mathematics they already do? Making home connections to mathematics may not be a re-teaching of school mathematics for parents, but eye-opening to what happens already in the everyday that is mathematical and supports meaningful connections to children's mathematical learning.

Literature Perspective

In addressing the disconnect between school and family mathematics learning and considering perception changes in parents, this paper highlights literature around parental engagement, parents' current perceptions of at-home mathematics through Funds of Knowledge literature, and common activities rich with early mathematical context. Together, this literature perspective shows how helping parents recognize the mathematics they already do can support their intentionality and confidence in such engagement.

Many studies investigating parental engagement indicate a difference in the expectations of student learning for parents and teachers (Quaylan & White-Smith, 2018; Wilder, 2017). Some teachers want parents involved in learning by being physically present at the school, but this is not always possible (Posey-Maddox & Hayley-Lock, 2016). Beyond the disconnect of parents' and teachers' expectations of mathematics is a large body of work around at-home mathematics that shows parents are interacting with mathematics in meaningful ways but are not seeing it as mathematical (Pea & Martin, 2010; Skwarchuk et al., 2014). As Goldman (2005) recommends, "getting parents to recognize their life skills as mathematics is a first and necessary step for building more connections for students with mathematics" (p. 71). Goldman's recommendations, and the continued trends around a lack of recognition of at-home activity as mathematical, frames the intent of this study and its results, that parents of even very young children can be highly engaged with mathematics, and with attention to their interactions as mathematical, they may become more intentional in the mathematical learning for their children.

The literature on at-home mathematics that centers Funds of Knowledge (Moll, Amanti, Neff, & Gonzalez, 1992) is one area that recognizes the value of the mathematical activity that occurs in the everyday lives of families. Funds of Knowledge work has shown the significance in validating parents' mathematical skills by increasing engagement in parents, which in turn can support children's mathematical engagement (Gonzalez, Andrade, Civil, & Moll, 2001; Whyte & Karabon, 2016). The present study acts to enhance the intent of Funds of Knowledge literature on parental engagement in mathematics. The existing literature stresses the impact on children and creating stronger school and family relationships. This study highlights the specific impact on parents' mathematical identity when shifting perspectives of themselves as more mathematical thinkers.

Given this study's focus on parents with young children (i.e. pre-kindergarten age), it is important to identify what kinds of activities are likely to occur in families that are rich in mathematics. Significant literature has explored types of mathematics in authentic activity that can be done (or have been done) by parents for the sake of school readiness (e.g., Anderson & Anderson, 2018; Leyva et al., 2017) and include skills such as numeracy, shapes, spatial reasoning, and measurement. At its core, Cannon and Ginsburg (2008) argue that "mathematics education should be fun, be relevant to young children's lives, and build on their fledgling mathematical understandings" "p. 242). This means activities that parents do with their children that are connected to their interests and building on beginning math understandings are meaningful forms of mathematics education. The activities present across the literature in early childhood mathematics become touch-points for activity in the work of the participants of this study, drawing attention to similar activity that they already do, as mathematical activity.

Theoretical Perspective

Supporting parent recognition of their actions as mathematical is tied to concepts of mathematical identity. Drawing from Bishop (2012) and Martin (2000), I frame mathematics identity to mean that how a community recognizes certain actions as mathematical or not will influence an individual's perspective of their own mathematical identity. Mathematics identity is about beliefs of ability, constraints, opportunity, and positioning of self and others in what it means to do mathematics (Martin, 2000). As Bishop (2012) summarizes, "a mathematics identity is dependent on what it means [to] do mathematics in a given community, classroom, or small group" (p. 39). I understand this perspective to mean that how a community recognizes certain actions as mathematical or not will influence an individual's perspective of their own mathematical identity. It is centered around how people see themselves and others, particularly its limitations, as mathematical thinkers, doing work that is mathematical. Previous literature has already indicated that many parents do not see their interactions with children as mathematical (Goldman, 2005) because those actions have not been given recognition as mathematical within their community, whether that be family, schooling experience, or messages from the media. Because identities are malleable (Bishop, 2012), if people are influenced by perspectives around the self, identities can change and grow. If the actions of an individual are given credence as mathematical, then their perspective of themselves as mathematical can strengthen. Mathematical identity is a combination of positioning and action, such that affirming people's actions as mathematical can enhance their mathematical identity. As such, a parent's acceptance of their mathematical identity through recognition of their actions can support more intentional and positive interactions with their children around mathematics.

Study Details and Methods

The results reported for this paper is a case study of two participants from a larger study on the impact of past experience on current mathematical interactions for mothers. While all participants from the larger study demonstrated transitions in their understanding of what counts as mathematics, this paper focuses on the experiences of two participants, given the limited space. The two focal participants, Kelsey and Elizabeth (pseudonyms), are white middle-class mothers living in the Midwest with challenging past math experiences. These mothers are the focal points of this paper because of the interesting transition of their perspectives of what counts as mathematics over the course of the study. The results of Kelsey and Elizabeth shared here are not meant to act as a generalization of what all parents experience, as there are certainly limitations in the range of their perspectives, but the results show what may be possible in shifting parental identity and ultimately engagement with mathematics for families.

The overall study involved a series of three interviews and two observations with debriefs of mothers' past mathematical experience and their current interactions with their children in mathematical activity. All interviews and debriefs were audio recorded and transcribed. Observations were captured with written field notes. The design of the interviews as well as analysis of the data came from a narrative inquiry perspective (Clandinin & Connelly, 2000; McAdams, 1993). Analysis began with reading and rereading the words of the participants, ultimately focusing on themes of the stories told by participants (McAdams, 1993). Further analysis for capturing the participants' meanings and stories was through strategies of meaningful qualitative analysis suggested by Corbin and Strauss (2012): asking questions of the stories told, making comparisons within and across participants, and looking at the emotions expressed in their stories.

The first interview focused on past experience and drawing on memory of what mathematics was like for the participants growing up, in both in-school and out-of-school experiences. Stories shared about past experiences were attached to particular feelings, locations, and individuals. The second interview focused on current practices with mathematics, both for themselves and in interactions with their children. In order to achieve depth in responses that connect to a story-telling model, I related initial questions within Clandinin and Connelly's (2000) three-dimensional space of inquiry, where "stories have temporal dimensions and address temporal matters; they focus on the personal and the social in a balance appropriate to the inquiry; and they occur in specific places or sequences of places" (p. 50). Questions were directed to consider experiences in mathematics at different times within the lives of the participants, consider the personal emotions attached and the social context of the moment, as well as the location and its context to the moment. The final interview acted as a form of authenticating what participants shared across the study, with review of particular transcript excerpts and making changes to make sure the excerpts best reflected the participant.

The observations were an opportunity for participants to show activity that could be mathematical and the debriefs of the observation were a time to reflect on how it went and what mathematics was actually present. My aim was to draw attention to the positive forms of interaction that were discussed in their interviews and carried out in meaningful interactions, to show that the mathematics at home can be rich and meaningful (Pea & Martin, 2010). The debrief was also a time to expand on what is recognized as mathematical. After participants discussed what they saw as mathematical in the observation, I would point out actions that I noticed they did and how it was connected to mathematics based on early childhood mathematics literature (Anderson & Anderson, 2018). In both participants and at every observation, there was at least one moment that involved mathematics that was not initially mentioned by the participants that was mathematical. Participants were then given an opportunity to reflect on how the newly proposed mathematical connection to an activity happened in other interactions they had. The time in the debrief sessions that drew attention to, validated, and allowed for reflection of previously unrecognized mathematical action allowed the participants space to shift their perspectives of what counted as mathematics and their perceptions of themselves as mathematical.

Results

Kelsey and Elizabeth showed throughout this larger study how they were developing new understandings of the mathematics they did on a daily basis, building their confidence and their intentions to engage with their children. Kelsey was a confident and effervescent mother in her late 20s, with a 15-month-old daughter, Amelia (pseudonym). She lived with her family in a medium-sized village in the Midwest. Kelsey worked from home, teaching violin lessons, but was a speech language pathologist before Amelia was born. Kelsey consistently spoke of how hard math was for her to understand, and the extra effort she had to put in to make the good grades she wanted. Elizabeth was a deeply empathetic mother in her late thirties living in the suburbs of a city in the Midwest. She stayed at home with her two daughters, Talia who was almost two and Luna (pseudonyms) who was seven years old, both adopted as infants. Talia was part Hispanic and Elizabeth was incredibly intentional in the experiences she provided to make sure that Talia was surrounded by people, books, and toys that looked like her. Elizabeth identified a constant lack of confidence in understanding mathematics that made her more hesitant to engage in mathematics with her daughters at the start of this study.

Math Disconnection

Early experiences in mathematics for both Kelsey and Elizabeth were challenging and often confusing. Both participants identified issues with understanding mathematics and believing that math was not for them. Kelsey found math frustrating because she had to work significantly harder to understand it than any other subject. Her frustration translated into a constant desire to avoid the subject because she felt math was not for her. Elizabeth struggled with confidence in doing the work, feeling that to be considered a good math student she needed to figure it out on her own. Elizabeth thus avoided math classes she felt she would not excel in on her own. Mathematics did not come easily and was a subject both participants avoided when possible.

Kelsey and Elizabeth did not first believe that what they did with their children was mathematical, and that mathematics was strongly associated with what happened in school. As Kelsey reflected, when she did not feel she did anything with mathematics, "well it's not a worksheet and not a test so I guess I just don't associate math with it" (Interview 2). Elizabeth made similar remarks that indicated an understanding that mathematics was something that happened at school, and for older children, when she shared "my daughter is in first grade so she started doing math already. Um, I don't remember doing math that young but maybe we did" (Interview 1). Although this study was centered on the interactions of mothers with pre-kindergarten aged children, Elizabeth's connections to mathematics frequently returned to her 7-year-old and her school work, struggling to identify what types of mathematics she might be doing with her youngest child. Kelsey and Elizabeth's statements at the start of the study reflected particular perspectives of what mathematics is (problems on worksheets or tests) and when it happens (in school and at later grades) and paralleled their own early experiences with mathematics.

In addition to their remarks about what mathematics is and where it occurs, Kelsey and Elizabeth pointed out how they did not recognize their actions as involving any kind of mathematics. Kelsey's first response to ways she interacted with her young daughter Amelia and mathematics was to laugh and say she did not think she did anything with math. As my study was focused on the interactions of mothers with their pre-kindergarten aged children, I was most interested in Elizabeth's actions with her youngest, Talia. However, Elizabeth's connections to mathematics were almost always centered around her 7-year-old and her school work, struggling to identify what types of mathematics she might be doing with her youngest child. In the debrief of the first observation, Elizabeth claimed "I think, there's a lot that happens that I don't' I don't realize is math." This claim was the first indicator from Elizabeth that her perspective of what math is and what she thought she did with math was limited. Kelsey and Elizabeth's perceptions of mathematics tied to school activities and later grades paralleled the lack of mathematical activity they saw in the interactions they had with their younger children.

Transition of Perspectives

The asking of pointed questions about mathematical activity and affirming actions seen in observation led to a shift in perspective. Following the debrief meetings that pointed out particular instances of mathematical activity that the participants already did were reflections on how they saw those interactions with new eyes, and how many other practices contained meaningful mathematics. It was the participants' reflections on recognizing current activity as mathematically rich that framed their transition of perspective about what mathematics is and their mathematical identity.

Kelsey, as a speech language pathologist, initially talked about how she did not do math but was intentional to connect to language and reading for her daughter. After the second observation, Kelsey reflected on the change in the math language she thought she used before the study:

> I feel like I've noticed a lot more since doing this [study]. Um, just different words…and initially I didn't really, when you were like 'what experiences with math do you have with Amelia?' and I'm like 'hm, nothing, she's 15 months old' [laughs] but now, having thought about it more and you asking questions I've realized how much those, how often those words

> come up and I feel like they come up in everything. In bath time, in meal time, in playtime, in story time in…like everything. So it's the same kind of vocabulary, but in lots of activities (Debrief 2).

Her recognition of the language modeling she did as mathematical helped her to realize that math learning was possible and already occurring with her young daughter. She used language that supported size comparison, amount, compared shapes, and described quantity, in the activities she did every day. This study prompted Kelsey's attention to her actions and word choice as mathematical and already occurring in her interactions.

Elizabeth showed similar recognition of the mathematics she was already doing with her youngest daughter, when before she did not believe that mathematical learning could really happen for a toddler, starting instead in school. During the observations, Elizabeth showed engagement with her youngest in a number of activities that used mathematics: making patterns out of blocks, comparing the size of towers, fitting toy people in a train, and counting sheep in a farm book. For Elizabeth, this growth was in reflecting on ideas of what mathematics could be possible and also prompting from observations the particular interactions that were viewed as mathematical. In taking more time to think about her involvement in mathematics after the second interview, Elizabeth shared how she went to bed thinking of many more activities that they did as a family that involved mathematics but she had never thought of before. Time for reflection on what math happened brought up many other affirming actions that Elizabeth recognized in herself. Additionally, the debrief of observations for Elizabeth prompted numerous interactions that were pointed out by the researcher as mathematical. For example, in pointing out her use of patterns in a play scheme with Legos, Elizabeth explained "you said 'oh do you see patterns in other activities that you do?' and I was like 'wait patterns? This is about patterns. Oh that would be math.'" (Final Interview). Affirming a small activity involving mathematics helped her see it as a mathematical situation and prompted her to make connections to other ways she did or could in the future use mathematics with her children.

Discussion

How Kelsey and Elizabeth understood what mathematics is shaped their perspectives of themselves as doing (or specifically not doing) math. Their past experiences with mathematics shaped their perspectives of what mathematics must be and how they fit into the narrative of mathematical experience. How they framed themselves and mathematics before the study is not new for parents. Their perceptions of mathematics from their past and schooling experiences is pervasive across the United States, with mathematics viewed as doing algorithms and mental calculations (Stevens, 2013b). However, Kelsey and Elizabeth were doing mathematics with their children, in meaningful and important ways. The perspective of what counts and how Kelsey and Elizabeth saw themselves as supporting mathematical learning was already adapting with the naming and recognition of their activities as mathematics. Their initial experience reflected a continued problem in the disconnect between at-home and at-school mathematics, that the meaningful mathematics learning that was already happening in the home was not recognized as mathematics (Anderson & Minke, 2007). The transition in perspective highlights two key features for understanding parents' mathematical engagement: that what counts as mathematics is much broader than what many people would recognize and that much mathematical learning is already happening outside of school even for very young children.

Kelsey and Elizabeth's past experience in school mathematics and initial understanding of what counts as mathematics reflects a limited view of what counts as math: higher level work, tests, and worksheets. These earlier perspectives are built from what their surrounding culture has taught them that math should be, and for them that was centered on what happened in school. As Stevens (2013a) highlights, "what counts as math or science depends on how the culture represents them, and school is but one setting where math and science are represented" (p. 4). Mathematics that happens at home may not involve worksheets or algorithms but can still build important skills in mathematical thinking. What counts as mathematics includes both formal and informal activity. As Skwarchuk et al. (2014) emphasize, formal and informal mathematical learning is important for early mathematical development, and those informal activities that happen at home are part of that learning. Much of the activities that Kelsey and Elizabeth engaged in paralleled activities in existing literature about early math skills (Leyva et al., 2017).

While what counts as mathematics is much broader than what happens in a school setting, this does not mean parents need to change or incorporate specific activities to engage in real world mathematical activity. The recognition of more activity as mathematical shows how those skills are already being learned at home. There is so much mathematics that can and already is happening at home with families. For Kelsey and Elizabeth, this included describing numbers of objects and comparing them in books, talking about objects fitting into other objects during play, and describing patterns in building blocks. Each of these interactions was related to a foundational mathematical concept that before this study, neither participant would have indicated is mathematical. These sample activities of Kelsey and Elizabeth are also part of a larger list of activities parents have been shown to do with their children, engaging in informal mathematical connections (Anderson & Anderson, 2014; Leyva et al., 2017). Much of the interactions with children parents already have are mathematical, even if they do not initially recognize them as such (Goldman, 2005).

Research using a Funds of Knowledge approach (e.g., Whyte & Karabon, 2016) does center families as mathematical knowers. Similar to what occurred in this study, Funds of Knowledge research draws attention to parents' activity and mathematical skills in the context of their lives. For example, in Gonz lez and colleagues' study (2001) they found "that household knowledge is broad and diverse, and may include information about, for example, ranching, farming, and animal husbandry, which are associated with households' rural origins" (p. 117). These activities have embedded mathematics that is not often highlighted or validated as mathematical in a school setting. The body of work within Funds of Knowledge research highlights the value of parents' skills in mathematics, while the current study pushes further to consider the impact of valuing parents' skills on their changing mathematical identities.

The final link between these themes of mathematics as a broader field than what happens in school and recognition of the mathematics that parents already do with their children is shaping parents' mathematical identities. As framed earlier, mathematical identity is about what it means to do mathematics in different settings (Bishop, 2012). In the case of this study, when the participants were positioned as mathematical through the activities they engaged in with their children, it strengthened their own mathematical identities. Kelsey and Elizabeth's past experience with mathematics shaped a particular perspective of who they were in the subject: bad at mathematics. However, reflections and time in the study helped them recognize other ways to engage with mathematics and build confidence in what they did with their children in the subject. Kelsey and Elizabeth's changing perceptions of themselves and mathematics was similar to what Esmonde and colleagues (2013) found in families engaging with mathematics activities at home, that it is more than just "someone who was good or bad at mathematics" (p. 18). The current analysis of Kelsey and Elizabeth digs deeper into Esmonde and colleague's (2013) results by looking at the evolution of perspective for parents with a history of mathematics aversion. The difference being made for these participants shows that pointing out the mathematics that was already happening in their homes helped them recognize their actions as mathematical and feel more confident to encourage types of play that would incorporate that mathematics later.

Significance and Future Work

The experiences of parents and families interacting with mathematics can be significantly different and more diverse than what happened in the lives of Kelsey and Elizabeth. The point of this paper was not to generalize the experiences families have with mathematics and mathematical identities. Instead, it was meant to show what changes are possible in the parent perspective in mathematics and spark more research that engages exploration of parents' mathematical identities and activities with their children. Creating connections between the everyday activity of parents and that of mathematical thinking has the potential to further support children's mathematical development. As Goldman (2005) argued, "getting parents to recognize their life skills as mathematical is a first and necessary step for building more connections for students with mathematics" (p. 71). Recognition and action in mathematics has ties to Bishop's (2012) perspective of mathematical identity. Mathematics identity is built off of the actions of an individual and how those actions are accepted as mathematical by the community. In the case of this study, Kelsey and Elizabeth were already doing mathematics, but needed the recognition that their actions were mathematical. Funds of Knowledge research grounds families' experiences as legitimate mathematics, but can be pushed further to consider the change in mathematical identity of parents when their activity is validated. This change in mathematics perspective for families can build confidence and create further engagement with mathematics, ultimately supporting children's learning.

Mathematics learning is often studied as school-centric, privileging the knowledge and structure of learning that happens in school (Jackson & Remillard, 2005). However, rich and meaningful mathematical learning can and does happen outside of school (Pea & Martin, 2010). Researchers can create better connections between schools and families in mathematics by recognizing and encouraging the mathematical learning that happens from the parent perspective. Stevens (2013b) proposes this call for the research community to "build a conceptual vocabulary that does not take school mathematics as the exclusive reference frame for understanding mathematical work across society and that can follow mathematical practices in and across time and place, including school" (p. 81). This study focused specifically on parents, to recognize the authentic and contextual mathematical experiences as a bridge to children's mathematical learning. Broader vocabulary, broader understanding of experiences and what counts as mathematics has the potential to validate the mathematical activity that happens at home.

OPPORTUNITIES TO DEVELOP STATISTICAL LITERACY: A COMPARISON OF STATE STANDARDS TO GAISE II

Anita Sundrani
University of Houston
asundrani@uh.edu

Travis Weiland
University of Houston
tweiland@uh.edu

In today's polarizing political climate, there is a need to build citizens' statistical literacy to combat misinformation and support data-based arguments. To that aim, we investigate K-12 standards documents for their alignment with the American Statistical Association's Guidelines for the Assessment and Instruction in Statistics Education (GAISE II). We found that the states that explicitly reference GAISE or had standards that explicitly addressed the statistical investigative process did not offer consistent opportunities for students to engage in each element of the investigative process and at each developmental level. We discuss the implications of the findings and provide recommendations for policy makers and standards writers.

Keywords: Data Analysis and Statistics, Policy, Standards

The current political climate of the United States is polarizing, often fueled by inflammatory rhetoric. Messaging that attempts to use data-based evidence for proposed policies or statistics to explain the spread of a deadly disease is met with disbelief and the cry of "fake news!" Some politicians have pushed the public to mistrust data and have been aided by people leaning on partisan trust instead of statistical literacy. This has created a heightened sense of urgency among data scientists, journalists, and educators to foster statistical literacy in the citizenry across all age groups. In schools, statistics is generally embedded as a content strand within the larger K-12 mathematics curriculum and may be offered as a separate course for students at the high school level (National Governors Association Center for Best Practices [NGA Center] & Council of Chief State School Officers [CCSSO], 2010). However, many states do not include statistics as a formal area of study within their mathematics courses until students reach the middle grade levels. This has been met with some pushback by researchers (Confrey, 2010) and there has been a concerted effort in providing educators and policymakers with resources to improve access to quality statistics-related content. For instance, the American Statistical Association (ASA) developed and released the *Guidelines for Assessment and Instruction in Statistics* (Franklin et al., 2007), which has had some impact on the grades 6-12 content in the Common Core State Standards for Mathematics. To give further guidance to educators and policymakers on statistics literacy, the ASA has recently published an updated report entitled the *Pre-K-12 Guidelines for Assessment and Instruction in Statistics Education II (GAISE II)* (Bargagliotti et al., 2020). In spite of such guidance, the opportunities to learn statistics through state mathematics standards vary from state to state and many are not aligned to the GAISE reports (Dingman et al., 2013; Newton et al., 2011; Weiland & Sundrani, under review).

Objective

With the current reality of statistical literacy in the U.S. and the resources now available to aid in creating opportunities to learn statistics, policymakers have the opportunity to update and improve state mathematics standards with statistics learning goals in mind. To support such efforts, in this study we investigated present efforts at purposefully incorporating the GAISE framework into state standards. Building on previous findings (Weiland & Sundrani, under review), we utilize state standards documents that explicitly reference the GAISE framework to answer the following research question: *To what extent are state K-12 statistics standards aligned to the GAISE II Framework for states that considered the GAISE report in their revision process?* To answer this question, we will investigate states' current efforts at building statistical literacy through incorporating suggestions from the GAISE framework into standards and to provide policymakers and standards writers with recommendations for future standards work based on our findings.

Background

When the Common Core State Standards for Mathematics (CCSSM) were developed in 2010, they were adopted by 48 states. This move signaled a shift towards a national set of standards designed to provide students with equal opportunities to succeed in mathematics. However, some politicians and citizens felt that this was the federal government's attempt at taking control of K-12 education from states (Orrill, 2016), in spite of it not having a role in the writing of the standards. Further, educators and families were unclear on how to enact the new standards, leading to frustration with the implementation and assessment of the standards. As a result of political pressures, a multitude of states have revisited their mathematics standards. Furthermore many states have revised their standards because of policies that require them to pass new standards after a set number of years (Achieve, 2017). The process to rewrite standards differs from state to state and involve a variety of constituents.

In a larger study, Weiland and Sundrani (under review) found that some states have referenced external sources in their standards revision process. Of the states that have mentioned the use of additional documents, five specifically cite the GAISE framework in their K-12 mathematics standards document – Louisiana, Massachusetts, Ohio, Virginia, and Wyoming. Louisiana, Massachusetts, and Wyoming all include the GAISE report in their updated standards document references, but their standards still do not differ from the CCSSM statistics standards in any substantial way. Ohio has made changes to their statistics standards to explicitly include the GAISE report. Virginia is the only state that did not adopt the CCSSM and has therefore incorporated the GAISE report differently from the CCSSM. Additionally, while Kentucky does not reference the GAISE report in their standards document, they do explicitly use the four-step statistical investigative process referenced in the GAISE report in their grade 1-6 standards. This inclusion of the investigative process may come from textbook *Elementary and Middle School Mathematics Teaching Developmentally*, which makes use the GAISE report (Van de Walle et al., 2019), and is used as an external reference document within the Kentucky state standards (Kentucky Department of Education, 2019). The only other state to explicitly name the statistical investigative process in their standards is Ohio, but only in grades 6 and 7.

GAISE II Framework

The GAISE reports were developed by the statistics education community to support the development of statistical literacy at the K-12 level (Bargagliotti et al., 2020; Franklin et al., 2007). The reports emphasize the need for students to understand statistical concepts and reasoning. The reports differ from other policy documents as they do not detail standards to cover at each grade level, rather they provide three levels of development (i.e., level A, B, and C) around the statistical investigative process. The investigative cycle includes four steps: formulate question, collect/consider data, analyze data, and interpret data. Though the three levels seemingly follow a grade band trajectory, the GAISE authors clarify that a student cannot progress to Level B unless they have mastered Level A skills regardless of their age or grade. The second iteration of the report, GAISE II keeps the core of the original report, adds on to the framework, updates the language, and provides more recent examples. We use the GAISE II report in our standards analysis because it has been developed by the statistics education community, provides more detailed guidance than other standards documents, and has been recommended by the National Council of Teachers of Mathematics (2020).

Methods

Data Sources and Collection

The data for this study includes official standards documents from states in the U.S. that reference the GAISE report. The states were identified one of two ways, searching for "GAISE" or "Guidelines for Assessment and Instruction in Statistics Education" within the state's standards documents , or from a larger analysis, where we noticed a close alignment with GAISE framework, though not explicitly stated. The only states that met the criteria of referencing the GAISE framework and differing from the CCSSM were Ohio and Virginia. Louisiana, Massachusetts, and Wyoming referenced the GAISE report, but did not meaningfully alter their standards from the CCSSM, so we considered them together as a case using the CCSSM standards. Kentucky was also identified for this study. Although Kentucky did not mention the GAISE report within their standards document, the standards incorporated the statistical investigative process in a way that was clearly aligned to the GAISE framework.

Identifying Learning Expectancies

Because states use different structures to organize their standards, we decided to analyze what we call learning expectancies (LEs). Learning expectancies represent the lowest unit of standard designation that provide a unique learning objective within the official standards documents analyzed. Virginia's standards only incorporate one level of standards, so these were taken as the LEs in that state. Kentucky and Ohio standards may include two or more sub-standards that elaborate on the top-level statement, so the sub-standards were taken as the LEs, in place of the top-level statement (see Figure 1).

~~*KY.7.SP.2:* Use data from a random sample to draw inferences about a population with an unknown characteristic of interest.~~

> *KY.7.SP.2.*a. Generate multiple samples of categorical data of the same size to gauge the variation in estimates or predictions.
> *KY.7.SP.2.*b. Generate multiple samples (or simulated samples) of numerical data to gauge the variation in estimates or predictions.
> *KY.7.SP.2.*c. Gauge how far off an estimate or prediction might be related to a population character of interest.

Figure 1: Example of Standards from the grade 7 Kentucky Mathematics Standards

At the elementary level, many states do not include a formal statistics strand, but do include a Measurement & Data strand that include statistics-related content. Therefore, we included any standards from the Measurement & Data strand that were statistical in nature. At the middle and high school grade bands, we included standards from the Statistics & Probability strand. However, we did exclude a number of probability LEs that focused on the mathematical aspects of theoretical probability (Bargagliotti et al., 2020).

Analytical Framework

In order for the findings to be useful to policymakers, standards writers, statistics education researchers, and educators, we analyzed the data utilizing the GAISE framework as our lens. We used a binary coding to identify which process element(s) each learning expectancy addressed and also determined what developmental level was appropriate for each LE. It is possible that a single LE could encompass multiple process elements and developmental levels, depending on the language used. We discussed and agreed upon all coding to ensure inter rater reliability.

Results

The number of statistics LEs vary by state and differ substantially by grade level (see Table 1).

Table 1: Number of Statistics LEs by State and Grade Level

	0	**1**	**2**	**3**	**4**	**5**	**6**	**7**	**8**	**A1**	**A2**	**HS**	**Total**
CCSSM	2	1	2	2	1	1	8	7	4			31	59
Kentucky	2	4	4	7	3	1	13	10	3			30	77
Ohio	2	1	2	2	1	1	11	11	4			31	66
Virginia	2	2	3	2	3	7	5	5	6	2	3		40
Total	**8**	**8**	**11**	**13**	**8**	**10**	**37**	**33**	**17**	**2**	**3**	**92**	**242**

Kentucky and Ohio utilize a great deal of the CCSSM language in their LEs, but have added, edited, or deleted some of the verbiage. Additionally, while it seems that Kentucky includes the greatest number of statistics LEs, many of them are smaller, discrete concepts covered in a single LE in the CCSSM. For instance, the CCSSM includes the following standard, "Generate measurement data by measuring lengths using rulers marked with halves and fourths of an inch. Show the data by making a line plot, where the horizontal scale is marked off in appropriate units— whole numbers, halves, or quarters." This LE is broken up into two in Kentucky – "Generate measurement data by measuring lengths using rulers marked with halves and fourths of an inch" and "Show the data by making a dot plot where the horizontal scale is marked off in appropriate units – whole numbers, halves, or quarters." Virginia, being the only state to not adopt the CCSSM in this study, greatly differs in content and number of LEs in each grade level. It is also important to note that Virginia does not combine their high school level standards into one grade band. Instead, their standards are separated by mathematics course. For the purpose of this study, we only included LEs Algebra 1 and Algebra 2, which are required for graduation in the state (see Table 1).

Alignment to GAISE II

The data were coded with respect to the statistical investigative process elements and developmental level. *Formulate question* LEs (5%) lead students to create or verify questions that are statistical in nature. *Collect and consider data* LEs (31%) focus on data collection strategies, bias, and simulations. *Analyze* LEs (74%) ask students to make meaning of a data set's variability and distribution and create visualizations. *Interpret* LEs (45%) concentrate on summarizing, drawing conclusions, and making predictions based on the context in statistical problems. Statistical process elements are not mutually exclusive; one LE may be coded as one element or as many as all four elements. Because of the large overlap in LE language, Kentucky, Ohio, and the CCSSM all include a similar proportion of collect and analyze LEs in their state standards documents (see Figure 2). Ohio and the CCSSM also include similar proportions for the formulate question and interpret LEs. Kentucky deviates slightly – 10% of this state's LEs incorporate the formulate question element compared with 3% and 5% in the CCSSM and Ohio respectively and include 13% less interpret LEs than the CCSSM and Ohio. Virginia's LEs differ significantly, as the state does not include any formulate question LEs and incorporates the analyze element in almost every statistics-related LE.

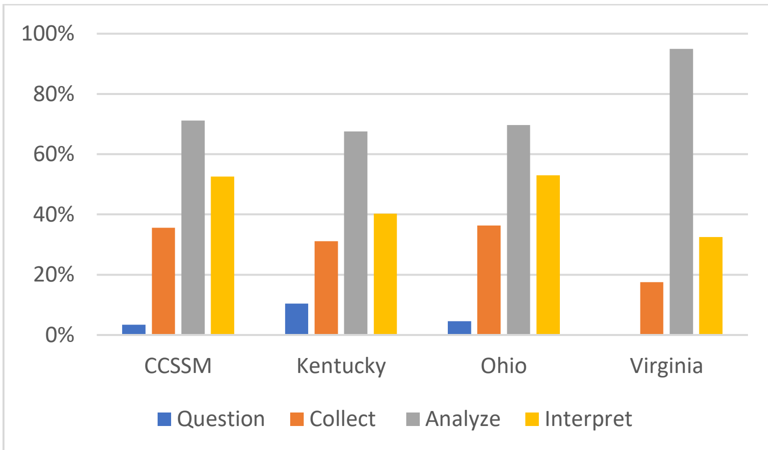

Figure 2: Bar Graph of Proportion of LEs for Each Statistical Investigative Process Element by State

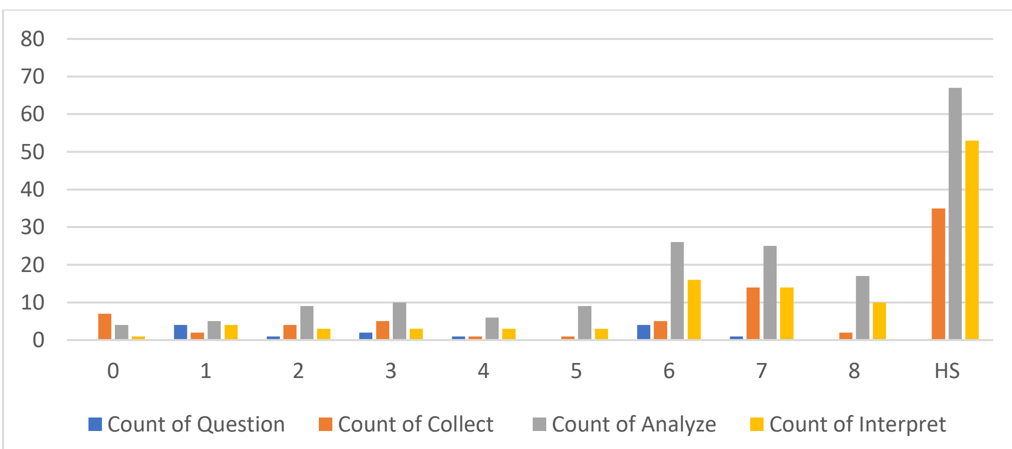

Figure 3: Bar Graph of Total Number of LEs by Statistical Investigative Process Element and Grade Level (N=242)

As the standards documents progress from grade band to grade band, the number of LEs generally increases as well (see Figure 3). In the CCSSM, Kentucky, and Ohio, as the standards progress from elementary to middle school grade levels, students have more access to the collect, analyze, and interpret elements. In the middle grade levels, formulate question LEs stay the same in the CCSSM, decrease in Kentucky, and increase by one in Ohio as compared to elementary grades. Virginia's statistics LEs provide students with more opportunities to analyze data in the middle grade levels, equal opportunities to interpret data in elementary and middle schools, no opportunities to formulate questions in either grade band, and less collect data LEs at the middle grade levels. The transition to high school adds more LEs on the collect, analyze, and interpret elements of the statistical investigative process in the CCSSM, Kentucky, and Ohio. It is important to note that while the number of statistics LEs increased in the high school grade band, this is potentially distributed over four grade levels. Again, Virginia differs and only provides a handful of experiences in the Algebra I and Algebra II courses offered to students. Overall, analyze data LEs make up the majority of students' experiences with data in the K-12 setting in all states, followed by interpret data, and then collect and consider data. Lastly, formulate question LEs are absent at the high school level in all four standards documents, continuing the pattern that as students move to higher grade levels, they have fewer opportunities to engage in the statistical questioning. Therefore, students have almost no experiences with formulating questions in the K-12 setting.

Approximately 26% of all LEs are at developmental level A, 34% are at level B, 41% of LEs are at level C, and 1% of LEs' developmental level is unclear typically due to vague wording. Kentucky, Ohio, and the CCSSM provide similar opportunities at each developmental level, whereas Virginia substantially differs (see Figure 2). Level A LEs are clustered in the elementary grade levels in all four state standards documents, while level B are mostly present in middle grade levels, and level C LEs are clustered in the high school grade levels. Grade six serves as a transition year as students move from level A LEs to level B. Virginia is the only state that does not provide any learning opportunities at level A for grade six students. During the middle grade years, most LEs are at level B, with a few experiences at level C. In high school, students gradually move from level B to level C LEs. Again, Virginia differs from the other three sets of standards, as it only includes level C LEs at the high school level. The CCSSM, Kentucky, and Ohio seem to align their LEs' developmental level with the recommendations from the GAISE II report. Formulate question LEs are only present at levels A and B in the CCSSM, Kentucky, and Ohio and as previously mentioned, formulate equations LEs do not appear in Virginia's standards. Collect LEs appear throughout the grade levels and cover all three developmental levels in all standards documents, except Virginia which does not include any collect LEs at level B. Analyze LEs are also split between levels A through C, with gradually more LEs at each level; again, the only exception is Virginia. This state provides equal opportunities for students to engage in statistical reasoning at levels A and B, but fewer opportunities at level C. Interpret LEs greatly increase as the developmental level increases with LEs almost doubling for as the level progresses in the CCSSM, Kentucky, and Ohio. This may mean that standards developers place increasingly more importance on the interpret element of the statistical investigative process but may not have provided enough opportunities at the earlier levels to support this move.

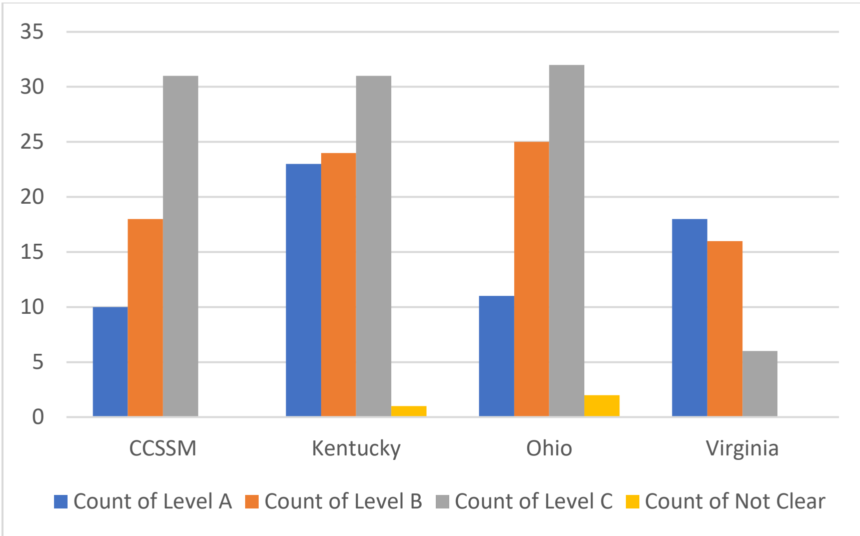

Figure 4: Bar Graph of Statistical Investigative Process Element of Total LEs by Developmental Level and State (N=242)

The GAISE II framework also details the need for students to experience different elements of the statistical investigative process in tandem. Therefore, it is also important to identify how many of the process elements are linked through the LEs in each state. The CCSSM and Ohio provide similar linkages, though Ohio's percentages of overlap between different process elements are slightly more spread out across the grade levels (e.g., the CCSSM provides no linkages in grade five, while about 2% of Ohio's overlap occurs in grade five). Both of these standards documents include some overlap between process components for over 80% of their LEs. The greatest proportion of connected elements is between analyze and interpret, followed by collect and analyze. Kentucky, as discussed above, has made a concerted effort to separate CCSSM language into smaller, discrete LEs. As a result, approximately 62% of Kentucky's LEs have some elemental overlap, compared with the CCSSM's 88% overlap. This has also created no opportunities for students in Kentucky to engage in multiple aspects of the statistical investigative process in grades K, one, and four. However, just like the CCSSM and Ohio, most overlap occurs between the analyze and interpret elements and then collect and analyze. Virginia offers the least proportion of linkages between process components, with only 55% of LEs combining two or more elements. Virginia also follows suit with the other three states in providing the most linkages between analyze and interpret and then collect and analyze.

Discussion and Implications

Overall, the CCSSM, Kentucky, Ohio, and Virginia offer some alignment to the GAISE II framework supporting student's development of statistical literacy to take on the demands of our data rich society. The most developed area is the support for students to move between developmental levels. Also, each standards document incorporates LEs that span the statistical investigative process, but do so in varying ways. Virginia, as the only state in this analysis that did not adopt the CCSSM, significantly veers from the statistical content covered and provides fewer opportunities for students to engage in each process element throughout K-12.

Through our analysis, we found few formulate question LEs. Virginia is the only state that did not include any LEs of this type, and Ohio and the CCSSM only included two and three LEs, respectively. These documents provide one LE at level A and the others at level B. Additionally, the first two opportunities to formulate questions is separated by four grade levels, making it difficult for students to build on prior knowledge. Kentucky was the only state to provide multiple opportunities for students to ask and identify statistical questions in grades one through six but did not incorporate any opportunities at the high school level. This element is crucial in teaching statistical literacy, as it is central to the statistical investigative process. Although all four states utilized the GAISE framework in designing their standards, there is still a need to purposefully include this element within the LEs and to connect it to other process elements across grade levels. Standards writers should consider including formulate questions LEs throughout K-12 and explicitly connect this element to the collect, analyze, and interpret elements to give students opportunities to engage in the entire statistical investigative process.

Another important consideration is the deliberate incorporation of all four elements in each grade level. Students need to have experiences with each process component throughout their K-12 careers to fully understand the purpose of each. Further, through repeated experiences with all four components at different grade levels, students will gain more consistent instruction at each developmental level. Kentucky creates the most consistent experience for students to engage in each component of the statistical process throughout K-12, with Virginia, Ohio, and the CCSSM following close behind. The CCSSM creates opportunities for students to engage in the entire statistical investigative process but does so sporadically. Ohio does not include opportunities for students to collect or consider data in grades one, four, and five. While the state does include more collect LEs overall, students do not receive instruction on collecting and considering data between grades four and five and are then expected to learn content at developmental level B in grade six. In addition, while each process component plays its role in developing statistical reasoning, students need to be exposed to the connections between each. Currently, there is significant overlap between process elements in the CCSSM and Ohio standards documents. Kentucky and Virginia do not include as many links, but do still connect at least two elements across their K-12 statistics LEs. However, most of the linkages offered in each state's LEs exist between the analyze and interpret elements. Without a solid grasp of how analyzing and interpreting data begins with statistical questioning and data collection, students will have difficulty developing statistical literacy. Therefore, we recommend that standards writers consistently incorporate LEs that provide students opportunities to experience each process element in isolation and together throughout K-12. Further, we recommend that researchers explore the impact standards on the instruction students receive at the classroom level.

One type of LE that was included in state standards documents that was missing from the GAISE II report is establishing the difference between correlation and causation. While this is an important statistical concept that every student should have the opportunity to learn, it is all but absent from the GAISE framework. Additionally, there is no formal mention of the normal distribution within the framework, despite the central importance of this concept within the statistics field. Therefore, it is important to note that the GAISE framework is an invaluable document, but should be supplemented by other statistics-related guidance.

While Kentucky, Ohio, and Virginia have used the GAISE report while rewriting their mathematics standards, each state has taken a different route to achieve this goal. Ohio's writing teams explicitly used the GAISE report when updating the mathematics standards and did not reference any other external resource in their standards document (Ohio Department of Education, 2017). Virginia's standards writing committee developed their mathematics standards using a number of impactful resources, such as the National Council of Teachers of

Mathematics's (NCTM) *Principles and Standards for School Mathematics* and the GAISE report (Virginia Board of Education, 2016). Kentucky did not include the GAISE report, but the standards writers in the lower level grades utilized the textbook *Elementary and Middle School Mathematics Teaching Developmentally*, which explicitly makes use the GAISE report in their tenth edition (Kentucky Department of Education, 2019; Van de Walle et al., 2019).

Each of the states analyzed referenced the GAISE framework when developing their standards. Despite this, each varied in their alignment to the statistical investigative process at each developmental level. This is due to a multitude of factors. Of note is the CCSSM, as Ohio and Kentucky have kept much of the language from this set of standards, influencing how much statistics could be incorporated into the standards documents. There also seems to be a disconnect between grade bands, particularly at the high school level. Additionally, statistics LEs are embedded within the larger mathematics LEs, restricting its space to one content thread among many others. Therefore, utilizing the GAISE framework does not seem to provide enough guidance to ensure appropriate alignment with the statistical investigative process. Policymakers and standards writers should aim to include teachers and university faculty with a background in statistics education in the standards writing process at all grade bands.

It is through the deliberate and consistent inclusion of the statistical investigative process throughout K-12 schooling and accompanying statistics concepts that students may develop their statistical literacy to become well-informed citizens, capable of interrogating data and the sources they come from.

In this paper we examine how teachers who are pursuing their Elementary Mathematics Specialist certification—Elementary Mathematics Specialists in Training (EMSTs)—are positioned in their advice and information networks for mathematics. We analyzed the instructional networks of six elementary schools in one Midwestern school district. Our analysis suggests that EMSTs did occupy central positions in their networks. EMSTs were sought out by more individuals compared to other teachers, and when sought out by others, provided advice and information at a greater frequency than formal leaders. We also considered the school's informal and formal structure, finding that EMSTs' positioning was related to the broader school's information seeking behavior and whether there is a math-specific formal leader.

Keywords: leadership; elementary mathematics specialists; social network analysis

Teacher leaders have the potential to play an important role in supporting instructional improvement. While some teacher leaders occupy formal, full-time positions (e.g., as coaches), many continue as full-time classroom teachers. Though they are not afforded dedicated time for leadership, teacher leaders with full-time classroom responsibilities may be more likely to engage with other teachers about classroom instruction and viewed as more credible sources than formal leaders (Spillane & Kim, 2012). Therefore, a potentially productive type of informal leadership that teacher leaders can enact is offering advice and information about mathematics teaching and learning. The extent to which teacher leaders can engage in such leadership, however, depends on the context of their schools. A collegial and collaborative school culture, for example, supports teacher leadership, while hierarchical and formal designations can increase distance between teachers (York-Barr & Duke, 2004). In this paper, we examine how novice elementary mathematics teacher leaders who maintain full-time classroom responsibilities are positioned in the instructional and advice networks for mathematics, and how their positioning might be related to the school's informal and formal leadership structures.

Theoretical Framings & Related Literature

In line with research that takes a distributed perspective (Spillane et al., 2004), we recognize leadership as extending to those with no formally designated position, and as the product of *interactions* between leaders, followers, and their situation. The situation shapes teacher leaders' interactions with others and includes, for example, school norms, structures and routines (e.g., grade-level teams), and formal positions (e.g., presence of an instructional coach) (Diamond & Spillane, 2016). Thus, teacher leaders' social influence interactions—providing advice and information about mathematics teaching and learning—constitute a form of leadership. We focus on advice- and information-giving because such leadership activities improve mathematics teaching through a variety of professional supports, including increasing teachers' knowledge about the learning and teaching of mathematics (Gigante & Firestone, 2008). Social network analysis allows us to examine social influence interactions while simultaneously attending to the school's formal structure and how it constitutes said interactions (Moolenaar & Daly, 2012).

Previous research on advice and information networks in mathematics suggests that, while principals do not figure prominently in their school's networks, formal leaders with subject-specific positions are the most central, with teacher leaders offering advice and information to more people than other teachers (Spillane & Kim, 2012; Spillane & Hopkins, 2013). This research has primarily focused on *centrality*—the extent to which an individual is connected to others—and less so on the nature of those interactions. A notable exception is the study by Coburn and Russell (2008) which investigated how district policy shapes teachers' social networks, including the frequency of interactions (*strength*), the substance of those interactions (*depth*), and the extent to which those interactions span different functional areas (*span*).

Research has identified factors of the situation that support and constrain teacher leadership. In general, the literature suggests that inadequate time for collaboration and traditional top-down structures can inhibit teacher leadership, while cultural norms of openness and trust, positive working relationships, and support from school administration support it (Wenner & Campbell, 2017; York-Barr & Duke, 2004). Because leadership, particularly exercised through social influence interactions, is grounded in authority and legitimacy (Diamond & Spillane, 2016), the positioning of teacher leaders as knowledgeable and expert is crucial. Therefore, our study builds on this literature by investigating how novice teacher leaders are positioned—in terms of centrality, span, strength, and depth—in their networks for mathematics instruction, and how their positioning might be related to their situation. Specifically, the research questions that guided our investigation are: 1) How are novice teacher leaders positioned in their advice and information networks for mathematics, especially compared to teachers and formal leaders? 2) How is their positioning related to school level factors?

Methods

Study Context

The data analyzed for this paper is part of a larger project in which 24 teachers in a Midwestern state received funding to complete Elementary Mathematics Specialists (EMS) certification and serve as informal leaders in their schools. Data was collected in Fall 2019, the first year of teachers' participation in their EMS programs. Because teachers were not formal leaders, nor necessarily identified by school administration or colleagues as experts, we consider them novice teacher leaders, or Elementary Mathematics Specialists in Training (EMSTs). In this paper, we focus on survey data from six elementary schools (Briar, Palm, Reed, Rowan, Thorn, Woods) in one participating district. Thirteen EMSTs worked together in school-based teams, ranging in size from 1-3 EMSTs in each of the six schools. As part of their graduate coursework, each team was asked to distribute a survey to the teachers in their school, analyze the results, and use the results to inform a plan for improving support for mathematics instruction at their school.

Data

The survey included items related to advice- and information-seeking interactions in mathematics, which were based on those developed and validated in other studies (Pitts & Spillane, 2009). In particular, we asked "During this past school year, is there a person in your building or district you have turned to for advice or information about teaching mathematics?" (Middle School Mathematics and the Institutional Setting of Teaching, n.d.). Respondents listed up to three individuals, and for each of those individuals, were also asked "how often do you seek advice or information from this person" and "what type(s) of advice or information do you seek from this person? Please check all options that apply." The options for these questions are described in the analysis section, which we turn to next.

Analysis

For each individual that responded or was named, using the school and district websites, we collected data for the individual's role (e.g., leader, teacher), associated site (e.g., school, central office), and, if applicable, grade level. Using the social network data, we calculated centrality, and span, strength, and depth of relationships (ties) of each individual. *Degree centrality* measures how well connected an actor is in a network (Freeman, 1979), and can be broken into in-degree—the number of people who sought out that actor for advice and information—and out-degree—the number of people that actor sought out. *Betweenness centrality* measures brokering and the extent an actor connects two other actors in the network (Freeman, 1979). Specifically, betweenness measures the number of shortest paths between two other actors that go through a given actor.

In addition to centrality, we also calculated measures to describe ties actors had with others. For each, we considered whether the tie *spanned* outside the actor's grade level (1 = yes, 0 = no). For ties with teachers that taught multiple grade levels, if the two teachers had at least one overlapping grade, we considered this as not spanning grade levels. For *strength*, we considered the frequency of the interactions, with four options: a few times a year (1), once or twice per month (2), once or twice per week (3), and daily or almost daily (4). For *depth*, we based our definitions on those of Coburn and Russell (2008), with three options: low (1), medium (2), and high (3) (see Table 1). Because respondents were able to select multiple options, we calculated an average depth, in addition to whether or not the interaction included at least one high-depth activity (1 = yes, 0 = no). For any relation between two actors, there are two possible ties, one from actor A to actor B, and the other from actor B to actor A. For example, if actor A responded that she asked actor B for advice daily, then the strength of actor A's out-tie with actor B and strength of Actor B's in-tie with actor A would be 4. For individuals that were named but did not respond to the survey (e.g., formal leaders), we only computed measures related for in-ties, including in-degree centrality and associated strength and depth; span was not relevant since respondents (teachers), by definition of role, were outside leaders' functional area.

Table 1: Depth of Interactions

Depth	Types of Advice and Information
Low	• Discussing pacing • Sharing materials or activities • After a lesson, sharing whether students "got it" • Updating one another on a student or students' progress in mathematics
Medium	• Discussing what materials to use for a lesson • Analyzing student work to see if students "got it" • Discussing why some students didn't learn as expected in a lesson in order to plan for future success • Doing mathematics problems together with discussions of different solution strategies
High	• Discussing different ways students are likely to solve tasks • Analyzing examples of student work to understand the different ways that students solve problems • Analyzing examples of student work in order to adjust instruction • Discussing how to make use of student solution strategies in whole class mathematical discussions

To examine the positioning of EMSTs in their networks, for the first research question, we compared the measures previously described (centrality, span, strength, depth) for EMSTs, teachers, and formal leaders and tested differences for significance using analysis of variances with permutation tests. Because social network data are not independent, we used UCINET software (Borgatti et al., 2002) to conduct a random replication procedure with 5000 permutations (Carrington et al., 2005; Spillane & Kim, 2013). Because respondents had ties with those outside their school, including district leaders, we did not limit networks to those of the school.

For the second research question, to examine the relation between EMSTs' positioning and school factors, we limited networks to those of the school. First, we explored to see if there were between-school differences in how EMSTs were positioned. To account for the size of the network, we normalized centrality by expressing it as a percentage of the maximum possible centrality an individual could have had. The school factors that we investigated included the school's formal (e.g., whether there was a mathematics-specific formal leader) and informal (e.g., advice- and information-seeking behavior) structure. Regarding the latter, we calculated network *density* for each school. Network density is the total number of ties divided by the total number of possible ties. In addition, we compared the average span, strength, and depth of ties between schools and tested differences for significance using analysis of variances with 5000 permutations. To illustrate our findings, we share network diagrams of three schools, selected based on contextual variation. Some of this variation included the size of schools, the nature and density of school networks, and whether there was a mathematics-specific formal leader.

Findings

First, we describe the positioning of EMSTs in their advice and information networks for mathematics, especially compared to other teachers and formal leaders. Then, we turn our attention to school networks and how EMSTs' positioning might be related to school factors.

EMSTs' Positioning in District Network

Overall, the EMSTs in our study occupied central positions in their advice and information networks for mathematics (see Table 2). Specifically, EMSTs were sought out by more individuals than other teachers (in-degree, $p < 0.01$), and were more often positioned as brokers for advice or information (betweenness, $p < 0.001$). All of the EMSTs had at least one tie, while 19.35% of teachers had no ties. There were no significant differences in advice-seeking behavior (out-degree), nor differences in span, strength, or depth of ties.

Only three formal leaders were named as individuals whom teachers sought out for advice and information, and none of those included school principals. The three formal leaders named were the district mathematics coordinator, an instructional mentor in the district special education department, and the Title I Math teacher at Woods (Title I is a United States government program in which schools with high levels of low-income students receive federal funding which can be used to hire additional teachers or instructional aides (United States Department of Education, n.d.). While these three formal leaders did have the highest average in-degree, because we did not ask formal leaders to complete the survey, we were not able to compare centralization between formal leaders and EMSTs. We were, however, able to compare the strength and depth of the ties that were reported. When sought out by others, EMSTs provided advice and information at a greater frequency than formal leaders (strength, $p < 0.05$), but the depth—average and whether or not the interaction included at least one high-depth activity—did not differ significantly.

Table 2: Means and Standard Deviations of Centrality and Tie Dimensions by Position

	EMSTs	Teachers	Formal Leaders
N	13	124	3
Betweenness	5.231 (10.892)	0.548 (1.876)	
In:			
Degree	2.077 (1.979)	0.694 (0.785)	7.333 (4.643)
Tie Span	0.193 (0.267)	0.086 (0.273)	
Tie Strength	2.686 (0.682)	2.924 (0.620)	1.389 (0.550)
Tie Depth (Avg)	1.902 (0.215)	1.808 (0.269)	1.675 (0.139)
Tie Depth (High)	0.765 (0.377)	0.737 (0.413)	0.398 (0.308)
Out:			
Degree	1.385 (1.003)	0.944 (1.117)	
Tie Span	0.533 (0.420)	0.290 (0.413)	
Tie Strength	2.518 (1.011)	2.522 (0.913)	
Tie Depth (Avg)	2.008 (0.273)	1.825 (0.368)	
Tie Depth (High)	0.900 (0.200)	0.674 (0.434)	

Note: As a reminder to the reader, tie span refers to whether it extended beyond a teacher's grade level, strength refers to frequency, and depth refers to the substance of an interaction.

EMSTs' Positioning in School Networks and Related Factors

There was great variation in the centrality among our EMSTs. We found that, while the normalized in-degree averaged 0.098, it ranged from 0 (EMST was not named as a provider of advice or information) to 0.333. Similarly, normalized out-degree averaged 0.045 and ranged from 0 to 0.136, and normalized betweenness averaged 0.095 and ranged from 0 to 1.183. Because of this variation, we wondered how differences might be related to school-level factors. In particular, we looked at the school's advice- and information-seeking behavior (see Table 3) and the formal structure—whether there was a formal mathematics leader. Regarding the former, we found significant between-school differences for span ($p < 0.05$) and strength ($p < 0.01$) of in-ties, and span ($p < 0.01$) and strength ($p = 0.08$) of out-ties, suggesting that some schools had more frequent sharing of information, particularly across grade levels. The only school in our sample with a formal mathematics leader was Woods. To illustrate our findings, we focus on and share network diagrams for three schools: Briar, Rowan, Woods (see Figure 1). Individuals were labeled by role and grade, with those teaching multiple grades labeled as "Other."

Briar was one of the larger schools in our sample but had the lowest network density. A significant number of teachers (31%) had no relationships with others, though the ties that were present were quite frequent (second highest strength). The Briar network also had more substantive interactions (an above average depth rating), but they were only within grade levels. We see these school-level patterns repeated in the ties EMSTs had with colleagues at their schools. Only one EMST sought out colleagues for advice and information, with the other two being sought out by others. And, all EMST ties were with peers teaching at the same grade.

By contrast, the network at Rowan was the densest (i.e., had the most total ties relative to possible ties). However, teachers' ties were not as frequent or deep, though this might be because of the higher proportion of interactions that spanned grade levels (often teachers seeking EMSTs for advice). In addition to being sought out, EMSTs at Rowan also went to colleagues for advice and information. Because of this, the EMSTs at Rowan connected and brokered advice and information about mathematics across the first and 3-5 grade levels. Though the kindergarten and

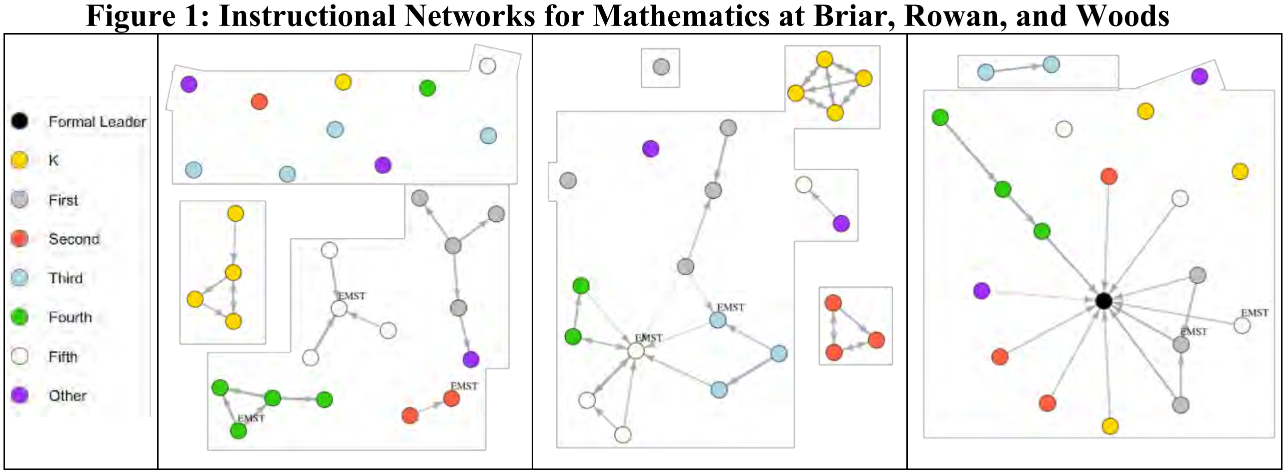
	(0.250)	(0.328)	(0.326)	(0.347)	(0.816)	(0.365)
Depth (High)	0.833	0.857	0.667	0.667	0.750	0.607
	(0.389)	(0.363)	(0.449)	(0.424)	(0.500)	(0.487)

second grade teachers were isolated from those in other grade levels, they had fairly reciprocal relationships as teachers reported ties with one another.

Woods was the only school with a mathematics-specific formal leader. Though the school had an average network density, a large majority of ties were to the formal leader. Ties spanned outside the grade level, though this was, again, only to the formal leader. So, similar to the ties at Briar, teachers were isolated from those outside their grade level, and sometimes, even from those in the same grade. Ties were somewhat frequent but were less substantive (relatively low depth). Both EMSTs only sought the formal leader, and only one had others seeking her for advice and information.

Figure 1: Instructional Networks for Mathematics at Briar, Rowan, and Woods



Discussion

There is little research on the positioning of (novice) teacher leaders with full-time classroom responsibilities, and this research primarily considers centrality. Our findings align with this literature—that EMSTs were more central than teachers, but not as central as formally designated leaders with subject-specific positions—and also adds to it by examining the nature of social influence interactions. We found that, when sought out by others, EMSTs in our study provided advice and information at a greater frequency than formal leaders. This is important because interactions with greater frequency facilitate the learning of complex knowledge (Coburn & Russell, 2008), which teachers need to improve their instruction. For example, researchers have found that interactions with colleagues who have developed more ambitious instructional visions can support improvements in teachers' own visions, particularly in cases where interactions were more frequent (Munter & Wilhelm, 2020).

Findings from our study also add detail regarding how teacher leaders' positioning is related to school structures. First, EMSTs' interactions with their colleagues were similar to the overall school advice- and information-seeking behavior (e.g., density and if interactions spanned grade levels). Second, similar to prior research that identified subject-specific formal leaders as the most central actors in school networks (Spillane & Kim, 2012; Spillane & Hopkins, 2013), at Woods, the majority of interactions, including those of the EMSTs, went to the formal mathematics leader. One interpretation of these findings is that school norms of collaboration and views of expertise shape teachers' advice- and information-seeking behavior, particularly who they turn to (Wenner & Campbell, 2017; York-Barr & Duke, 2004). And the extent teachers at a school interact and communicate regularly, particularly with those outside their grade level, influences whether and how they seek information from teacher leaders. Also significant is whether colleagues perceive teacher leaders as knowledgeable. For schools with a mathematics-specific formal leader, like Woods, EMSTs' expertise might be undervalued by their colleagues.

Implications

One of the implications of our findings is related to the division and coordination of leadership between formal leaders and teachers who exercise leadership through informal means. Because effective professional development typically includes sustained learning opportunities over time and sensitivity to local contexts (Sztajn, Borko, & Smith, 2018), it seems that there are opportunities for formal leaders to enlist novice leaders with mathematical expertise in change efforts. That is, teacher leaders like the EMSTs in our study could serve as brokers for efforts initiated at the district level, as well as sources of information with regard to teachers' perspectives and impressions of these efforts. Formal leaders could explicitly position teacher leaders as resources for ongoing conversations about mathematics teaching and learning, including serving as leaders of professional learning teams, book studies, video clubs, etc.

Our findings also highlight the limited nature of some of the information networks that exist in schools, limitations that could be explicitly attended to by school leadership. For schools with only grade-level connections, like Briar, it might be helpful to leverage teacher leaders as agents for promoting across grade-level collaborations. The presence of a formal mathematics specialist at Woods seemed to promote advice-seeking, but such interactions were dominated by the formal leader. Positioning teacher leaders with expertise and authority could support more collaboration among teachers and teacher leaders. And, for schools with a robust network of within and across grade-level connections like Rowan, teacher leaders can be mobilized to support bottom-up change across a school by, for example, creating additional opportunities for teachers to share their practice, visit classrooms, and talk with colleagues teaching at different grade levels.

MATHEMATICS DOCTORAL STUDENTS' PRIORITIES: WHAT THEY LOOK FOR WHEN CHOOSING A PH.D. PROGRAM

Katrina Piatek-Jimenez
Central Michigan University
k.p.j@cmich.edu

Christine Phelps-Gregory
Central Michigan University
phelp1cm@cmich.edu

Mathematics doctoral programs have high attrition rates, however, the research examining students' experiences in doctoral programs is limited. The work presented in this paper examines the priorities doctoral students describe when transferring to a new Ph.D. program in mathematics. Although our participants provide both climate and programmatic desires for a program, the two most influential reasons for choosing a new program were wanting a good fit mathematically and professionally between the program and their career goals and wanting more opportunities to do research. These results have implications for the design of mathematics doctoral programs.

Keywords: Affect, Emotion, Beliefs, and Attitudes; Doctoral Education

The work presented in this paper looks at mathematics graduate students' priorities when choosing and transferring to a new doctoral program in mathematics. This work has implications for understanding what mathematics graduate students are looking for in a doctoral program and reasons for why they might leave.

Theoretical Lens

When considering the experiences of mathematics doctoral students, we draw on the theory of *communities of practice* (Lave & Wenger, 1991; Wenger, 1998). Mathematicians, as a cultural community, have developed their own common activities, practices, language, thought processes, and beliefs and therefore can be considered a community of practice. New members are able to join such a community through *legitimate peripheral participation*, a process in which *newcomers* are educated and transformed into *full-members* and eventually *old-timers*, who must then draw in more newcomers (Lave & Wenger, 1991). This transformation process comes from being accepted as a legitimate member of the community, like an apprentice, who focuses on participating in small parts of the practice within the community. As the newcomer's experience increases, they are given further tasks that are more central to the practice to learn, also providing a more central perspective from which to observe the practice as a whole. We view the graduate school experience as playing this role.

Literature Review and Purpose of the Study

Although only a small body of research has been conducted on the experiences of mathematics doctoral students, specific themes can be found within the literature. Most notable is the role that faculty-student relationships play in the success and perseverance of graduate students in mathematics (Borum & Walker, 2012; Herzig, 2002, 2004). When supported and encouraged by faculty, mathematics graduate students are more likely to feel a part of the department and overcome programmatic and personal obstacles. However, when graduate students feel ignored by their faculty or lack the mentoring they desire, it leads to high attrition rates (Borum & Walker, 2012; Herzig, 2002, 2004; Sumpter, 2014a). Furthermore, one's choice of advisor and dissertation topic also seem to be influential in graduate students' success and satisfaction with their program. Graduate students describe wanting an advisor who is approachable, shows an interest in them, and encourages them (Earl-Novell, 2006; Herzig, 2004). Similarly, having a manageable dissertation topic, and ownership of the topic, also influences success within the program (Earl-Novell, 2006; Morton & Thornley, 2001).

In addition to support from faculty, experiencing social and scholarly support from peers is crucial to the success of graduate students in mathematics (Borum & Walker, 2012; Morton & Thornley, 2001; Sumpter, 2014a, 2014b). Unfortunately, due to narrow research interests and small programs, graduate students in mathematics often feel isolation from their peers, at least with respect to research interests (Morton & Thornley, 2001).

A lack of resources and financial hardship are also hinderances to the success of graduate students in mathematics. Although many graduate students in mathematics are funded through their programs as graduate teaching assistants, they often experience mixed emotions regarding the need to teach while completing their programs. While they appreciate the opportunity to teach, they also want to be able to do so in small amounts, so that it does not interfere with their studies (Earl-Novell, 2006; Morton & Thornley, 2001).

While some research has been conducted to examine graduate students' experiences in mathematics doctoral programs, more work remains to be done. The work presented here addresses the following research question: What do Ph.D. students in mathematics prioritize when choosing and transferring to a new graduate program?

Method

The work presented here is part of a larger study examining the experiences of graduate students who left a Ph.D. program in mathematics to either transfer to a doctoral program at another university or to leave graduate mathematics altogether. In this paper we will focus on the participants who transferred to an alternate program.

Participants

For this subset, we identified 10 graduate students who transferred from one mathematics Ph.D. program to another and invited them for interviews. Eight (80%) agreed to participate. All eight were male; four were international students. To protect participant identities, the international pseudonyms we use do not necessarily match with the international participants.

Interviews and Data Analysis

To avoid bias, a researcher outside of mathematics administered the interviews. The interviews were conducted electronically and ranged in length from 20 to 45 minutes, with an average of 30 minutes. The interview protocol focused on questions such as why they chose their original graduate program, why they left, why they chose their next graduate program, and what they believed were the strengths and weaknesses of any graduate program they had enrolled in.

After the interviews were transcribed, we coded the data following Campbell and colleagues (2013). We discussed all coding together and reconciled any disagreements. After coding was complete, we examined all data instances for each code, looking for commonalities across participants and identifying themes addressing our research question.

Results

Participants believe several priorities are important when choosing a graduate program and choosing whether to remain in a graduate program. In particular, the following themes were identified as important: a good fit mathematically and professionally, a positive and friendly peer climate, approachable faculty, more academic options, and the opportunity to do research.

Participants also identified practical concerns such as location, funding, and acceptance as reasons for picking or remaining in a graduate program, though only if other priorities were also met. In this paper, we will be focusing only on the two most influential themes mentioned above.

A Good Fit Mathematically and Professionally

All participants in the study said they were looking for a good fit mathematically when choosing a graduate program. Generally, this mathematical fit was described as a fit between them, their mathematical interests, and the faculty who were available to do research within that mathematical sub-field. Ajit described leaving his previous program because he did not believe he had this fit. He said it “didn't feel like I was a good fit… with the few faculty that were in my area.” When Hayden was asked if he would recommend his previous program, he said:

> It depends on which area they are working… suppose somebody wants to work in algebraic geometry and, currently, they don’t have any people in algebraic geometry, I would not recommend them..So, it depends on which area they want to work in.

Participants expressed a similar concern about the shortage of graduate students working in a specific sub-field as well. For example, Hayden said of his previous program that there was a “very limited number of graduate students in a certain area of the mathematics. So… I could not find a big group to work with, work in my area.”

Participants also described the importance of having a good fit between the school and the level of challenge provided by classes. For example, Eric said he left his previous program partially due to the lack of challenge, which he found appropriate at his new school:

> I probably said this before, that [at my previous program] I wasn't being challenged much. My thing is that if I can do better, I really want to push to do better and I could say that. I felt that at some point I was not doing the best I can, and I think that, in retrospect, I think that is true because after coming here [to my new program], I pushed myself and now… I'm functioning on a higher level. Like I have a better understanding of math and things like that.

Participants also wanted a good fit between the program and their other professional goals. For example, Fareed explained that a lack of fit between his professional goals and his previous program was the main reason he chose to switch programs:

> There was a trend that I noticed about graduating PhD students [at my former university]. Not a lot of them were applying for further research, as in, for post docs or anything. A lot of them were going for, like college jobs, which is OK, but like I wasn't’ I'm an international student. I want to go back home, and I want to do a job there. So, I need to have more research experience before I can start the job. That's a requirement. So, I wanted to do a postdoc.

Fareed explained that because other doctoral students in his former program did not pursue postdocs after earning their degrees, he would not know how or where to apply. Instead, he wanted a program that was designed to transition doctoral students into postdocs.

Opportunities to Do Research

Six participants said they wanted or liked having a graduate program that gave them the opportunity to do research, meet outside researchers, or attend outside seminars or conferences on research. Eric described a strength of the program he transferred to as:

> There's a lot of activity going on in the Department in terms of people visiting from outside, there's a place… right next to our University that hosts people from all over the world and we

> get to attend a lot of lectures and talks going on. There is so much more activity in just in terms of seminars and talking to people.

In contrast, about his previous program, Eric said, "I guess, to put it succinctly, would be that I'd probably needed a lot more exposure and interaction with people from other, other universities and things like that." Cameron also described the exposure to outside researchers as a benefit of his new program, "I think also that there, ah, the number of Departmental seminars and talks and all of these things. They're also much more common in my current Department, so we get to interact more with researchers in the field."

Discussion

Similar to the previous literature on this topic, our study found that graduate students provided both programmatic as well as climate reasons for what they deemed as important in a doctoral program in mathematics. Interestingly, although the participants in our study stated that having a positive departmental climate, including approachable faculty and a positive peer environment, was an important characteristic for a graduate program, they prioritized programmatic features. In fact, many of them left a program that they found welcoming and supportive for a program that better fit their programmatic needs. In particular, one participant even suggested that it was a necessary trade-off.

While there were many programmatic criteria that students mentioned as important belonging to a program that was a good fit for them either mathematically or professionally seemed to be the most important criteria. In particular, mathematics graduate students found it crucial that there was a cohort of faculty and graduate students in the department working in their particular sub-field of mathematics. Even when their previous program had one or two faculty members specializing in their area of expertise, they felt that their options were limited and opted to transfer to an institution that provided them with more choices for their future dissertation advisor. This seems to be a common difficulty that many smaller graduate programs in mathematics face (Morton & Thornley, 2001).

Another programmatic feature that graduate students found important was having direct exposure to research and outside members of the mathematics research community. These graduate students wanted the opportunity to work with faculty on original research, even prior to embarking on their own dissertation project. Furthermore, they believed that being able to attend conferences or seminars with external speakers was critical to their success as future research mathematicians. We view this as the mathematics graduate students expressing the desire to become *legitimate peripheral participants* within the community of mathematicians by being exposed to tasks central to the work of an academic mathematician (Lave & Wenger, 1991).

Overall, the results of our study suggest that graduate students in mathematics prioritize programmatic features that they believe will provide them with a research community and research opportunities while they are in their doctoral program. We find these results to be promising, even for smaller doctoral programs that might have a limited number of faculty within their department. For example, to provide their graduate students with such opportunities, departments can redesign their curricula or program requirements to provide research opportunities early on for their graduate students. Furthermore, while department budgets may be tight, smaller departments may find it worth the investment to fund graduate students to attend national conferences or to bring external speakers to the university to present research colloquia. Modest investments such as these may pay off in the retention of doctoral students in the program, as well as provide the students with experiences that will assist them in their transition into *full-members* of the community of mathematicians.

CAREGIVER-CHILD INTERACTIONS: INFORMAL WAYS OF DOING MATHEMATICS DURING ENGINEERING TASKS

Amber Simpson

Caregiver's involvement in their child's engagement of everyday mathematical practices is foundational to children's learning and doing of mathematics in out-school contexts. The purpose of this study is to understand how applications of math concepts and practices unfolded between children and caregivers during making-engineering activities in their home environments. Through the analysis of approximately 5.65 hours of video collected from four families, we observed caregivers and children involved in three mathematical practices – informal measurement, spatial reasoning, and curiosity. In this paper, we present how informal measurement unfolded differently among two child-caregiver dyads within one making-engineering activity – creating a rain gauge. We demonstrate how physical objects and caregiver guidance afforded children a way to externalize their mathematical thinking.

Keywords: Everyday mathematical practices, Caregivers, Making

Purpose of the Study

Regardless of caregivers' own experiences as mathematics students and negative feelings and emotions towards mathematics, they are able to act as mathematical educators and support their children's learning and doing of mathematics at home (e.g., Berkowitz et al., 2015; LeFevre et al., 2010; Sheldon & Epstein, 2005). Some of these opportunities to engage children as mathematical learners are not grounded in what may be considered more formal ways of learning and doing mathematics, but framed within everyday family experiences such as gardening, cooking, budgeting, and sports (e.g., Esmonde et al., 2012; Goldman & Booker, 2009; Jay et al., 2018). Engaging in engineering design processes may also serve as an everyday experience to support children's application of math concepts and practices (e.g., Berland et al., 2014); yet, little is known how this may unfold between children and caregivers in their home environments.

We intend to look for alternative ways to acknowledge caregivers as math educators by addressing the following research question - –ow might caregivers and children engage in everyday mathematical practices through participation in making-engineering kits in their home environments? These kits were developed as part of a larger project aimed at integrating engineering design practices into home environments of families with children in grades 3-6. Hence, these kits were not developed with increasing caregiver-child interactions specific to mathematical concepts and practices. Yet, in this paper, we demonstrate how caregivers and children can engage in making-engineering tasks that provide opportunities to utilize everyday mathematical practices in their home environments. The significance of this study lies within new possibilities for engaging caregivers and children in the doing and thinking of mathematics within their home environments. The development and use of making-engineering kits may provide opportunities to legitimize ways of doing mathematics outside of school contexts (Masingila et al., 2011), opportunities aligned with humanistic and work-based perspective of mathematics (D'Ambrosio & D'Ambrosio, 2013; Masingila, 1993).

Perspective

This study is informed by mathematical practices for making (Simpson & Kastberg, under review). This framework builds upon Civil's (2002) everyday mathematical practices and situated within any learning environment (e.g., kitchen, garage, museum) and activity that includes creating, designing, transforming and/or repurposing materials and objects into a new physical or digital product (Vossoughi & Bevan, 2014). As an example, within this study, pasta noodles, pipe cleaners, rubber bands, and paperclips were used to construct a container of any shape and size. Simpson and Kastberg (under review) characterized mathematical practices for making as (a) mutual opportunities to teach and learn from one others (e.g., caregiver-child) through social interactions (Bevan et al., 2018, Petrich et al., 2013); (b) imaginative play and/or exploration of mathematics within contextualized activities (Featherstone, 2000, Petrich et al., 2013); (c) personalization of the process and/or object through mathematical strategies, tools, and/or risk-taking (Lindsey et al., 2018); and (d) hidden mathematics or mathematics that is not apparent to those involved as it does not resemble mathematics in school settings (Smith III et al., 2011). These four characterizations were utilized to identify opportunities that caregivers and children engaged in everyday mathematical practices in their home environments.

Methods

The context for this study was a community-based program that invited families with at least one child in grade 3-6 to engage in engineering design processes as part of their home environment. The program consisted of two phases and this study utilized data collected from the second phase the program - the incorporation of take-home engineering kits developed by our team. Five engineering kits were distributed; these are Package for Delivery, Rain Gauge, Trendy Tennies, Joystick, and Blooming Flower. Guided by a set of instructional cards, these kits engaged families in different engineering design stages. The kits also included reusable materials that ranged from "no tech" (e.g., straws, felt) to "low tech" (LED lights, battery pack).

Participants

A total of four families that lived in the Midwest region of the United States were included in this study. Together, these family participants included 1 female and 6 male child participants between 6-12 years of age and 4 female and 1 male caregiver participants. The self-identified ethnicity of the child participants included 2 African American, 4 Caucasian, and 1 self-identified as two or more ethnicities. Caregivers' educational backgrounds ranged from a bachelor to a doctoral degree and two caregivers had a career in a STEM field and/or some experience related to STEM.

Data Source

The data source for this study was video recordings of caregiver-child dyads interacting with one another in their home environment. The data was collected through a tablet distributed to families together with the kits. Caregivers were instructed to record their interactions from the beginning to the end of their engagement with each kit. They were also informed that finishing the kit in one sitting is not required. The duration of each video depended on families' progress with the tasks and ranged from 25 min to 96 min with an average of 48 min. A total of 5.65 hours of video data were collected and analyzed.

Data Analysis

The first and third authors watched each video, identifying events that were characteristic of the mathematical practices for making. We each identified 15 events and agreement for these events were 100%. These events were then transcribed and included both verbal and non-verbal acts of communication (Ochs, 1979), as well as descriptive and analytical memos regarding the mathematical concepts that unfolded between caregiver and child as experienced within the context of the engineering kits (Birks et al., 2008). These memos informed the specific mathematical practices for making observed in the videos and were discussed in more detail and depth between the first and second authors.

Results

Across the video data, we observed children involved in three mathematical practices for making while engaging in the various making-engineering kits in their home environment – informal measurement, spatial reasoning, and curiosity. In this paper, we describe and share examples for one mathematical practice for making – informal measurement. Informal measurement in this study was broadly defined as intuitive approaches grounded in cultural experiences and meaningful contexts in out-of-school settings (e.g., Owens & Kaleva, 2007). The goal is to illustrate the ways that two children-caregiver dyads engaged in the doing and thinking of mathematics during the creation of a rain gauge to measure the amount of rain fall over a period of time. They were challenged to create a simple circuit so that LED lights would light up when a certain amount of rainfall had accumulated (e.g., 1 cm=green light, 2 cm = blue light). See https://youtu.be/MRv1VsA7RBM for an example (Maltese, 2020). One of the steps in the kit instruction asked them to use the provided ruler to measure and mark the vertical distance (e.g., cm, mm, or inches) on the outside of a clear cup (i.e., rain gauge). Specific to the following two examples, the children were observed using visual intuition (Cox, 2013; Owens & Kaleva, 2007) to reason through how the shape of the cup (i.e., rain gauge) affected how the amount of rain fall should be measured.

Example 1

The first example is from Sara (child) and Amanda (caregiver). Sara was curious and questioned why they were being asked to measure the vertical distance of a cup and not volume. She reasoned, "Because if it's a cup, the volume will change through it, so it wouldn't really be accurate if you measured it in centimeter." Amanda, Sara's caregiver, supported this curiosity as they further explored different-size measuring spoons to determine an appropriate and visual amount of water to "mark" as a place to insert a LED light. Sara stated, "I'll do 30 [mL]." The transcript below occurred as Sara marked 120 mL on the cup as a line, while Amanda adds another 15 mL of water into the cup. Actions are italicized and first names abbreviated to their first initial.

S: *Looks closely at the cup.* See right now, it's barely going up from 15, and 30 is only going to be a little.
A: Why do you think that is?
S: Because like…It's because it's spacing out a little. *Takes two fingers – thumb and pointer finger – and seemed to place along an upper and a lower line previously marked.* So these two are the same. *Moved two fingers down to next upper and lower lines.* These two are the same. No, those two are…
A: So the cup gets wider as it goes up?
S: Yeah, and so it's going to get smaller and smaller and smaller. *Pinching motion with two fingers.*
A: So you wanted to measure something and have more visual height, what would you want to do for your cup?

S: I would want to make it…like a tube.

In the first line of the transcript, we observed Sara visually noticed that the space between the lines of 120mL and 150 mL is "barely going up." She further described this as the space between any two lines as getting smaller and smaller as the cup gets wider and wider as it goes up. Sara used her fingers as a way to informally compare the difference in vertical distance between the lines and considered this in relation to another measurement, volume. We further acknowledge how engagement in this mathematical practice for making was supported through Amanda's knowledge of Sara and in the questions posed.

Example 2

The second example is from Roberto (child) and Jared (caregiver). This dyad spent time thinking through how to appropriately mark the vertical distance on the cup. Roberto was observed placing the ruler vertically on the inside of the cup, turning the cup on its side and laying the ruler alongside the top, and placing the ruler across the diameter of the bottom of the cup as three examples. The transcript begins as Roberto is adding lines to the cup to represent the vertical distance for the LED lights.

J: Now you do realize that…as we go up, what changes as we go up with this, which would make it slightly less accurate.

R: Because it like curves up. I mean like at the bottom it's the smallest and then it starts getting bigger and bigger and bigger. *Moved hand from bottom to top of the cup.* I have an idea. We can measure the bottom…*Picked up the ruler and laid across the bottom of the cup*...and see how much it is and then take like all the of the way. And then when we know that number…*circled his hand around the top of the cup*…and when we get the answer, we can subtract that much from it.

Similar to Amanda, Jared noted how the shape of the cup would lead to an inaccurate measurement. Using everyday language, Roberto noted how the circumference gets bigger from the bottom to the top of the cup. Roberto understood this inaccuracy of the vertical distance between each line or LED light in relation to the circumference of the cup.

Conclusion

In this paper, we illustrated how caregiver-child dyads engaged in a specialized form of everyday mathematical practices (Civil, 2002) - mathematical practices for making (Simpson & Kastberg, under review) - during a making-engineering kit within their home environments. We provided two examples above in which the shape of the cup and the support of caregivers through questioning afforded the children a way to externalize their mathematical thinking within an authentic and "worldly" problem (Civil, 2016). We further contend that this study highlights new possibilities for mathematics learning and teaching in out-of-school contexts while positioning caregivers in the role of educator based on their own humanistic and work-based perspectives of mathematics (e.g., Bartlo & Sitomer, 2008; Jay et al., 2018). Specifically, the two children intuitively conceptualized the relationships between the vertical distance between lines on the cup and either the volume or the circumference as a quantity (Thompson, 1994). "A person is thinking of a quantity when he or she conceives a quality of an object in such a way that this conceptual entails the quality's measurability" (p. 184). It is an indirect relationship, which may serve as a seed for the children's understanding of inverse proportional relationships.

"FIRST TEACHERS TALK, TALK, NOW THEY LISTEN, LISTEN": GHANAIAN TEACHERS' PROFESSIONAL READINESS FOR MATHEMATICS REFORM

Dionne Cross Francis
University of North Carolina
dicross@unc.edu

Pavneet Kaur Bharaj
University of North Carolina
pkbharaj@unc.edu

Anna Hinden
University of North Carolina
annarh@live.unc.edu

This study examined one Ghanaian teacher's, Eugenia, professional readiness to make significant curricula and pedagogical changes within the context of a nationwide educational reform initiative. Using Scaccia et al.'s (2015) organizational readiness framework, we examined the alignment among Eugenia's professional readiness, what the reforms were asking of her, the supports provided to her to fulfil these demands, and what she was actually doing in her classroom. We found that Eugenia's beliefs, emotions, and efficacy primed her for implementing the reform. We discuss the importance of teachers' knowledge, beliefs, emotions, and efficacy as indicators of professional readiness and how they bode well for successful reform implementation.

Keywords: Curriculum, Instructional Activities and Practices, Policy, Systemic Change, Professional Development

Education reform initiatives often fall short of intended effectiveness due to insufficient capacities or mediocre stakeholder commitment (Elliot & Mihalic, 2004; Gottfredson & Gottfredson, 2002). Theoretical or empirical grounding for an initiative is insufficient to ensure a positive outcome. The availability of relevant intellectual and physical resources coupled with the motivation to implement the initiative is essential (Markle, 2016). For educational reform that foregrounds curricular and pedagogical changes, effective implementation requires teacher capacity and buy-in. In this regard, teachers' professional readiness serves as a good indicator of success potential. In this study, we draw on Scaccia and colleagues' (2015) readiness framework to explore one Ghanaian teacher's professional readiness for nationwide mathematics education reform and the ways in which her interpretations of the reform were translated into her instruction.

Ghana Education Context

In September 2019, Ghana underwent its third national education reform initiative (National Council for Curriculum and Assessment, 2019). With respect to math, the reform involved major shifts in teaching emphasizing the importance of applying inquiry-based approaches (GhanaWeb, 2019). This focus meant a shift in the roles of teachers, moving from lecturer or knowledge bearer to serving as facilitators, prioritizing students' cognitive engagement to support the development of their critical thinking and problem-solving skills. With respect to content and teaching, these articulated changes align very closely with the content of educational standards documents in the U.S. [e.g., Principles and Standards for School Mathematics [2000] *Principles to Action*, (NCTM, 2014)]; however, significant differences exist in the educational landscape across countries. First, Ghana's new curriculum includes a strong focus on cultural identity and global citizenship that is explicitly articulated in the math standards documents (Aboagye & Yawson, 2020). Second, the reform requires a reconceptualization of the roles of teacher and student. However, cultural expectations of Ghanaian elders and youth (i.e., teachers and students in the context of the classroom), tends to elevate the voice of the elder – an expectation that shapes teacher-student interactions.

Teachers' Professional Readiness

We draw on Scaccia et al.'s (2015) organizational readiness framework which posits that readiness is a combination of general capacities, innovation-based capacities, and motivation. We foreground aspects of innovation-specific capacities and motivation. One central component of innovation-specific capacity is stakeholders' knowledge, skill, and abilities that align with the needs of the initiative. Within the context of reform implementation, teachers' knowledge and skill capacity are critical for ensuring effective assimilation of newer ideas into their existing practices. There is a strong correlation between mathematical knowledge for teaching [MKT; see Ball et al., 2008)], which combines pedagogical and content knowledge and skills, and teachers' mathematics quality of instruction (Hill et al., 2008). We consider teachers' professional readiness to implement mathematics reform to be their investment in, and motivation to, implement the reform for which their cognition (math knowledge), psychology (beliefs, efficacy), and affect (emotions) are key indicators. In particular, strong efficacy beliefs enhance teachers' abilities to navigate challenging situations, thus, making them more likely to take professional risks and to persevere and persist (Guskey, 1988; Pintrich & Schunk, 1996; Stein & Wang 1988). Thus, teachers with strong efficacy beliefs are more likely be open and willing to implement reform. Emotions is an important construct in teachers' relationships, instructional decision-making, and overall well-being (Zembylas & Schutz, 2016). Positive high-arousal emotions (e.g., excitement), tend to focus attention on events that are desirable or rewarding (Tamir & Robinson, 2007). Thus, if an event or experience elicits positive emotion, then the teacher will be inclined to increase the frequency of that experience. A plethora of research (Cross, 2009; Cross Francis 2015; Ernest, 1989; Fives & Gill, 2015) suggest that teachers' math-related beliefs influence their instructional practices, teacher-student relations, and how they organize their classrooms. In this regard, there will be greater likelihood of implementation success, if teachers' beliefs are aligned with core reform mandates.

We consider these factors to be very influential in teachers' professional readiness. In this regard, teachers who exhibit reform-supportive beliefs, emotions, and knowledge, to be primed, and highly motivated to implement the reform, thereby increasing the likelihood of positive outcomes. Our study is guided by the following questions*: (i) In what ways were Ghanaian primary teachers primed to implement national mathematics education reform? (ii) How do Ghanaian primary teachers translate reform mandates in their instructional practices?*

Methods

Data were collected during Fall 2019 - seven weeks after reform implementation began. This study is situated within a larger study including eight primary teachers. In this case study, we focus on Eugenia, to develop an in-depth understanding of how her readiness, coupled with reform-based supports, were translated into practice.

Participants. Eugenia was a fourth-grade teacher at a public school. She was identified by one of the district's educational supervisors as one of the best math teachers to assimilate the practices outlined in the reform documents into her instruction. Additionally, intermediate analysis of data showed Eugenia's strong enthusiasm for the reform, exuding confidence and enjoyment related to teaching mathematics. In-depth analysis of her interview and survey data confirmed our observations showing that she was primed for the transition.

Data Sources and Analysis

Interview. Eugenia completed one semi-structured, 30-minute interview. Questions focused on her knowledge, thoughts, and feelings about the reform specific to mathematics. We analyzed her responses by developing a codebook based on Scaccia et al.'s (2015) framework. All three authors coded the same transcript, then discussed any discrepancies in our coding until an agreement was reached, leading to refinement of the descriptions or addition of new codes.

Surveys. The participants completed the *adapted* Self-Efficacy Teaching and Knowledge Instrument for Science Teachers (SETAKIST) survey (Roberts & Henson, 2000), to capture teaching efficacy measuring confidence related to the teaching of mathematics and knowledge efficacy measuring teachers' confidence about their knowledge of math*;* Teacher Emotion Scale (TES: Frenzel et al., 2016), to capture teachers' discrete emotions in relation to their teaching; the NCTM published scale *Principles to action: Ensuring mathematics success for all* (PtA), to capture teachers' mathematics-related beliefs.

MKT Survey. The participants responses on the multiple-choice items from the Learning Mathematics for Teaching Instrument (Hill et al., 2008) were used to get a measure of teachers' content knowledge and knowledge of content and students. As the LMT instrument is designed to be used to determine MKT changes in groups over time, we used the scores as an indicator of MKT relative to other participants and not as an absolute measure of MKT.

Instructional Videos. Each participant taught a 45 – 60 minutes mathematics lesson which was videorecorded. Videos were analyzed using the Mathematical Quality of Instruction (MQI) rubric to determine the quality of instruction (see Hill et al., 2008; https://cepr.harvard.edu/mqi). Acknowledging a different cultural context, we excluded items that we deemed required Ghanaian linguistic and cultural knowledge (e.g., *Imprecise language and notation*).

Findings

Analyses of the survey results showed that Eugenia was primed for reform implementation. With respect to MKT, Eugenia had the highest score (of the 8 teachers) for knowledge of content and students (KCS = 0.65), and the second highest score for mathematical content knowledge (CK = 0.54). She was very confident about her mathematical knowledge (4.25) and had medium level confidence about her ability to teach in ways that supported students' learning (3.38). She experienced high levels of enjoyment (4) and had strong beliefs related to teaching and learning (4). She supports the use of mathematical tools to help students communicate their ideas (4.17). Eugenia expressed she was eager to assimilate the reforms into their instruction because they promoted a pedagogical shift supportive of students' development. Although the reform included changes to mathematics content and what should be taught at each grade, she emphasized that the most significant change was to how they (teachers) were teaching,

> *… the new one is more child centered, yeah. The target is the child, and the child should be allowed to do more activities. The child should be helped to discover things for themselves. So, the teacher is just serving as a guide or a facilitator, helping the child to achieve what he wants to achieve within that period.* (interview)

She noted that the reforms mandated the teachers to engage students in learning so they could explore mathematics. She recognized that teachers should not "tell, tell, tell", rather they should be a guide to support students' meaning making. Eugenia excited and surprisingly positive, about the reform. Eugenia explained that "the children we have today want to explore … so this [curriculum] will help them to have a firsthand context". Eugenia's knowledge, beliefs, emotions, and efficacy indicated that she was highly motivated and primed for reform implementation. Eugenia seemed to be an advocate for the reforms because it facilitated student engagement so students could learn, discover, and find mathematics interesting.

Translating Reforms into Practice

Given Eugenia's high level of professional readiness, we examined the ways the mandates were translated into her instructional practices. The results of the MQI showed that although her instruction was error-free and demonstrated medium levels of mathematical richness, teacher talk was still prominent in her instruction. We noted the contrast between her enthusiasm about, and knowledge of the specifics of the reform, with the instructional practices we observed. Our analyses highlighted three possible barriers including minimal professional support, lack of mathematical tools and resources, and activation of cultural filters.

Lack of professional support

Eugenia stated the training organized by education authorities was short and while helpful in communicating the goals of the initiative and expectations of teachers, there was minimal substantive information to assimilate the reform in their existing practices. She suggested that "once a while they should organize workshops, service training, just to keep us abreast with..new things, yes. Different way of doing it, we'd be happy to learn". Eugenia scored a score of zero for *Errors and Imprecision* on the MQI scale, showing that she had a strong grasp of the content. However, score of one for the dimension *Working with Students and Mathematics* shows that she struggled to respond productively to students' mathematical contributions

Lack of Mathematical Tools and Materials

The challenges of incorporating reforms into her teaching practices were further compounded by the lack of *mathematical tools and materials.* Eugenia reported that they were required to adopt these reforms from the start of the school year onward, but they did not receive any physical resources (e.g., textbooks or manipulatives). She voiced the concern that the teachers cannot devise productive lessons in the absence of instructional materials.

Activation of filters

We observed the interpretation of child-centered pedagogical strategies through existing filters, that may have been cultural. Eugenia foregrounded physical (e.g., singing a song) over cognitive engagement (Cross et al., 2012) in selecting her starter activities. This shows an interesting case of how the meaning underlying suggested reforms can be misinterpreted. Second, interpretations of "more student talk" and "group work" were skewed. Eugenia interpreted "more student talk" as having students respond more verbally and not necessarily on the content of their productions, hence, she asked a lot of direct structured questions. Although she did put students in groups, the groups comprised many students which inhibited productive interaction.

Discussion

Eugenia perceived the reforms as a catalyst to shift the ways roles were assigned to both students and teachers and expressed sheer enthusiasm to accept these changes. This perspective contrasts teachers' typical levels of motivation to implement mathematics reform, which is often lackluster (see Choi, 2017; Ling, 2002). Eugenia was primed for implementation and at seven weeks into implementation was working hard to teach in these new ways. Despite this professional readiness, Eugenia experienced multiple barriers: lack of pedagogical support, lack of mathematical tools and materials, and the activation of filters. Change of any form tends to be challenging and arduous. Thus, teachers, who are the "boots on the ground" for educational reform and tend to carry the brunt of its burden, often pushback or implement changes only under compulsion. Eugenia was willing, even enthusiastic to engage in the productive struggle characteristic of reform implementation despite minimal support. In this regard, we draw attention to the important role of productive math-related beliefs, positive math-related emotions, and strong efficacy in gauging teachers' professional readiness, which bodes well for investment in the reform, thus, increasing the likelihood of sustained change when appropriate supports are provided.

THE SOCIAL COMMUNITY OF A MATHEMATICS SUPPORT PROGRAM

Jenna Tague
Clovis Community College
jenna.tague@cloviscollege.edu

The purpose of this report is to share the facets of a mentoring program set in a mathematics department in a mid-sized western university. To examine the efficacy of the program, I use the social community framework (Mondisa & McComb, 2015) to compare the students in the program to a control group of students. Results indicate that the program is helping the students develop connectedness and a community of practice.

Keywords: Undergraduate Education, Systemic Change, Equity, Inclusion, and Diversity

Increasing the amount of people of color and women in mathematics is imperative (i.e., PCAST, 2012). While most would not argue with that statement, the question of how to help support students in mathematics majors remains open (Karp, 2011). Studies about the leaky pipeline indicate that we lose students from high school to college (Snyder & Dillow, 2011), and also lose them throughout their undergraduate careers, but specifically within their first year of college (Chen 2009; Higher Education Research Institute 2010). Some students leave mathematics majors because they want to pursue a different subject, and for those students, we wish them well. However, research indicates that many students who are capable of achieving in mathematics, leave the major because they have a bad experience or feel unwelcome (Seymour & Hewitt,1997). Both people of color and women are more likely to leave mathematics majors than white or male students (e.g., Anderson & Kim 2006; Hill, Corbett, & Rose, 2010; Griffith, 2010).

With these disparities in mind, I worked with a team of mathematicians to design a support program for mathematics majors at a mid-sized western 4-year university. While our program was open to all students, the majority of the students we recruited were people of color, and more than half were women. The purpose of this presentation is to describe the parts of our support program, and then to share the second year results of studying the students' reactions to the program.

Literature Review

Karp (2011) in conducting a review of non-academic supports that are necessary for students found there were four main categories: building *social relationships*, educating students about *career options*, illuminating the *college structure*, and supporting students through *life issues*. Italics have been added to indicate the shortened names that will denote each of these categories in this paper. *Social relationships* means helping find a sense of belonging within a community at school. Students who built communities at college were more likely to remain in college (Crisp, 2010). Karp (2011) found that educating students about *career options* helped them to see how college was useful to their future goals. Illuminating the *college structure* is necessary because many students do not understand how to register for classes, or apply for financial aid. The last category is *life issues*, which Karp (2011) explains that students experience and leave college without realizing that there are resources they make use of, or alternate ways to make up work. Karp's (2011) metanalysis indicated that while the studies showed the helpfulness of these four categories, many of the studies did not ask students why or how the supports were helpful.

Estrada et al. (2017) noted there is a further need for documentation of what works to help support underrepresented students in STEM.

Mondisa and McComb (2018), in studying a minority mentorship program, described how many other studies of mentorship programs focus on comparisons of students' GPA or attrition rates without examining how mentorship programs affect individual students on a social level. "Evidence is needed identifying what social elements contribute to the positive experiences of program members, how these elements influence an array of participant outcomes (i.e., not simply academic achievement), and what characteristics may explain differences across member experiences (Mondisa & McComb, 2018, p. 94).

The Support Program

The study was conducted at a mid-sized western comprehensive university. The university has a student population including 67% first generation students, and 61% Pell-eligible, indicating a financial need. The overall student population demographics are: 3% African American, 14% Asian (mainly Southeast Asian: Hmong and Cambodian), 49% Hispanic, 6% non-resident students, 3% two or more races, 5% unknown, and 20% white.

Two focus groups of mathematics majors were held to gather information so that we could create a program that was most beneficial for the students. The themes that came out of these focus groups were: (1) students had multiple off-campus jobs and were often care-givers for family members, (2) students were unaware of programs offered by the university that might support them, (3) students struggled to find a community of other students, (4) students did not see faculty members as mentors (i.e., individuals they could go to for help with *life issues*), and (5) students were unaware of career options in mathematics besides teaching.

The results from the focus groups reinforce Karp's (2011) four supports: *social relationships* (1), (3), (4); *career options* (5); *college structure* (2), (4); *life issues* (1), (3). With this grounding, I worked with a team of three mathematicians, who I will call mentors, to create supports to help address these four categories. The program, which began in Fall 2018, consisted of four main supports: scholarships, advising, workshops, and problem solving challenges.

Social relationships were addressed through scholarships, weekly meetings, and required use of office hours or tutoring. The scholarships are in this category because as noted by (1) above, the students' jobs to support their tuition limited the amount of time they were able to be on campus, and thus limited the amount of relationships they were able to build on campus. Additionally, the scholars met with the mentors and each other on Fridays for either problem solving, workshops/speakers, or tutoring. *Career options* were addressed through advising meetings (at least one each semester) and through the guest speakers on Fridays. *College structure* issues were addressed through workshops on Fridays when various campus offices (financial aid, health center, mental health center, etc.) were brought in to talk with the scholars. Lastly *life issues* are difficult to address directly, but the hope was that through their connections to the mentors, the students would communicate when they needed help.

Theoretical Framework and Methods

Mondisa and McComb (2015) define mentoring programs as being comprised by the following elements: "(a) program values, (b) access to faculty and peers, and (c) formal and informal group activities (Ehrich et al., 2004; Gershenfeld, 2014; Hrabowski & Pearson, 1993; Maton et al., 2000; Treisman, 1992)" (p. 3). To measure outcomes from mentoring programs, they proposed using the framework of Social Community (Mondisa & McComb, 2018). In this framework, the researchers measure the connectedness, resiliency, and communities of practice level of each participant. Communities of practice is defined as “collections of like-minded individuals sharing similar experiences and social resources as they interact with and support each other (Eckert, 2006; Wenger, 2000)” (Mondisa & McComb, 2018, p. 98).

Thus, to measure the social community outcomes of our support program, I used this framework to design interview questions for the students. An example of a connectedness question was: Do you feel you have a mentor (peer or faculty member or otherwise)? An example of a resiliency question was: What was an obstacle you faced this year, and how did you overcome it? An example of a communities of practice question was: Do you feel like you belong as part of the math department?

In total, there were 16 scholars in the second year of the program. Of the 16 scholars, 6 were second year students from the first cohort, and 10 were first year students from the second cohort. There were 12 students recruited in the control group: 5 second year students, and 7 first year students. All of the scholars and control group students were mathematics majors, and the control group was chosen to be the same level in the program, and both groups were majority people of color. All of the participants were interviewed for approximately 30 minutes in October-November of 2019. The interviews were audio recorded, transcribed, and were coded according to the three themes of the social community framework: connectedness, resiliency, and community of practice (Mondisa & McComb, 2018).

Results

The results will be divided according to the three themes from the social community framework: connectedness, resiliency, and community of practice.

Connectedness

The Scholars were more likely to identify as feeling connected than the control group. In particular, in answer to the question of if they had a mentor, 12 out of 16 of the scholars versus 3 out of 12 students stated that they felt like they had a faculty member as a mentor at the university. The general feeling from the scholars is captured in this expression: "*For the first year I did. So it’s really easy to talk to [one of the mentors] because he was the first person that I really talked to and kind of felt since I already knew him…But through the course of that year and a little bit of this semester, I can talk to anybody now.*" Many of the scholars also mentioned that they relied on one another for help in courses, or just support in school in general. In contrast, the control group had mentors, but those people were either a family member outside of the university, or one other student in the program. This indicates that the control group were less connected to faculty members, and also to less other students in the department than the Scholar group.

Resiliency

The biggest challenge that all of the students faced (Scholar or control group) was time management. It was less evident in the second year students, but because the schedule change from high school to college can be extreme, it was difficult for the students to try to schedule their days at first. Two women from each of the control group, and from the scholars mentioned their biggest challenge was being “too shy”. All of them said it was difficult for them to make connections with other people in college. The two scholars mentioned that it became easier because they got to know people through the Friday meetings, so even if they were not in the same classes, they saw each other around campus. Out of the two control group women who mentioned shyness, one of them said she was getting past that by using a first generation college student group, and the other one said it was still something she was working on. Both groups also mentioned that the classes were much harder in college than in high school, but that they were working through the challenge: "*When I fail, I have to beat it. That's how I've gone through most of my life*." In summary, all of the students displayed resiliency. Resiliency might also be a topic that comes up more later on in their academic careers when more of the students start reaching the proof courses in the mathematics major.

Communities of Practice

The main interview question that I used to code this aspect of the social community framework was: Do you feel like you belong at (university) in the math department? Out of 16 scholars 15 said they felt like they belonged, and out of 12 of the control group, 10 of them said they felt like they belonged. However, the specificity of the group's answers varied quite a lot. Here is a representative answer from the control group: "*I would say yes. There was a point where I just felt like, a little lost in my math class. Okay, so I felt like I didn't belong, but then I got the ball rolling in.*" Now, in comparison, here is a representative answer from the scholar group: "*I feel like I am home. Like, I have so many professors and advisors and now, like I walk in math department and like, I always encounter someone like hello*." In comparing these two responses, both students stated they belonged, but notice that the control group is basing this belonging on their relationship with mathematics, and not with other people in the mathematics department. In contrast, the scholar group focused on their interpersonal connections with other scholars (through the Friday meetings), with faculty members, and with other students in the mathematics department. Their responses indicated more of a social community and network than the control group students.

Conclusions

The results indicate that while all of the students expressed resiliency, the scholar students had much greater connectedness and communities of practice developed within the mathematics department. This builds off of research shared from the first year of the program. In the first year, themes indicated that the scholars were more likely to feel comfortable seeking out a faculty member for help with academic or life issues (6 out of 7 versus 1 out of 6) (Tague, 2019). That has continued to grow with the first cohort, and has held consistently for the second cohort as well. The control group students seemed to define their belonging and their community of practice as their relationship with mathematics rather than their relationship with people within the mathematics department. That is troubling because as mathematics courses get more difficult, it could lead to a drop in a feeling of belonging to the community of practice. The support program has helped the students in the first two cohorts develop a community of practice amongst one another, and also amongst others in the mathematics department. More research in the following years will indicate if the patterns will continue in this way, however, preliminary it seems this model of mentorship program could benefit mathematics students.

Mathematics Education Researchers (MERs) contribute to the growth of mathematics education when joining interdisciplinary groups. However, little is known about the ways of work within such groups (i.e., practices). We aimed to enhance our definition of practices by exploring practices reported by an MER in her interdisciplinary group. A transcript from a semi-structured interview comprised the data. Our grounded theory analysis resulted in an enhanced definition of practices informed by the participant's descriptions of interdisciplinary work. We argue that practices in interdisciplinary groups involve ways of being, operating, and interacting.

Keywords: Interdisciplinary STEM/STEAM, Research Methods, Sustainability

Williams et al. (2016) defined disciplinarity as a "phenomenon" involving "specialization" of work and discourse (p. 4). Interdisciplinary group members are practitioners of different disciplines who have been socialized and encouraged to exhibit specialized forms of work and discourse, also called practices (Hyland, 2004; Williams et al., 2016). Researchers define practices in various ways (e.g., Cobb & Yackel, 1996; MacIntyre, 1984; Schön, 1983; Wenger, 1998). Most definitions of practices include descriptions of methods for functioning within a group or community. Based on existing definitions and Williams et al.'s (2016) description of disciplinarity, we described practices as "established or emergent ways of *being*, *operating*, and *interacting* [italics added] with others" during collective activity (Suazo-Flores et al., 2021, para. 4). *Being* referred to how an individual conceptualizes thIs part of a group. *Operating* referred to ways of doing within a community. *Interacting* referred to developing and communicating standards for group discourse (Suazo-Flores et al., 2021). In this study, we explored: In what ways can our original definition of practices be enhanced using empirical data from a mathematics education researcher's (MER's) reported experience in an interdisciplinary research group?

Mathematics Education and Interdisciplinary Group Practices

Work in interdisciplinary groups has become common for MERs since integrated expertise is an effective way to solve large-scale problems (Bruce et al., 2017) and enhance education (e.g., National Governors Association, 2007). Given that researchers use disciplinary-based practices, MERs are likely to face challenges when interacting with researchers from other disciplines. Bruce et al. (2017) described the challenge of framing a research idea within an interdisciplinary research team "in ways that permit all potential research collaborators to identify and situate themselves" (p. 158). Goos and Bennison (2018) described physical and institutional challenges during interdisciplinary work like traveling to different disciplinary meeting venues and ensuring that interdisciplinary work contributed to achieving tenure. These examples suggest that MERs need to navigate and negotiate new practices in interdisciplinary groups.

Although interdisciplinary groups can present challenges, they offer opportunities for MERs to address complex problems and develop new knowledge for mathematics education. Four examples from published articles in mathematics education are provided here. Bruce et al. (2017) explored different disciplinary understandings of spatial reasoning to illustrate the discipline-specific educational significance of spatial reasoning. Goos and Bennison (2018) documented collaborations of mathematicians and mathematics educators designing teacher education curricula. The authors described ways group members created curricula integrating mathematics content and pedagogy. Biology education researchers and a MER studied undergraduate biology students' graphing practices to address the complexity of assessing graphing knowledge using auto-scored question formats (Gardner et al., 2021). Krummheuer et al. (2013) used a socio-constructivist approach and psychoanalytic perspective to contribute new understandings of children's creativity in mathematics problem-solving. The researchers used attachment theory to explore a child's activity in mathematical situations.

To better understand interdisciplinary groups that include MERs, Suazo-Flores et al. (2021) identified three examples of interdisciplinary practices reported in published research articles: "working towards research interests," "cultivating trust and open-mindedness," and "understanding of institutional support" (para. 9). "Working towards research interests" referred to researchers establishing shared research interests. "Cultivating trust and open-mindedness" referred to researchers finding ways to express themselves freely and consider the perspectives of others. Finally, "understanding institutional support" referred to researchers operating within existing structural and institutionalized norms. Since the published articles communicate findings from empirical studies rather than describe interdisciplinary group practices, the examples we identified were initial and tentative. To extend this research, we enhanced our definition of practices drawing from the experiences of one MER who participated in an interdisciplinary group.

Methods and Analysis

This study is part of a larger project exploring MERs' lived experiences working in interdisciplinary groups. We conducted semi-structured interviews (Kvale, 1996) with MERs and sought to understand practices reported by participants in such groups. Amelia (pseudonym) was an MER who led an interdisciplinary group. Evidence of practices reported by Amelia in the form of an interview transcript constitutes our data.

We used grounded theory (Charmaz, 2005) to analyze Amelia's descriptions of working in an interdisciplinary group. The analysis involved three phases. First, we used our original definition of practice to identify instances of practices from Amelia's reported experience in interdisciplinary group activity. Each instance was coded as *being*, *operating*, or *interacting* and assigned a short phrase to summarize the practice. Second, we refined our descriptions and definitions of *being*, *operating*, and *interacting* and identified examples of practices for each category from the transcript. The third phase of analysis involved using the revised definitions and collections of practices to review and update the codes for our data corpus, resulting in new enhanced definitions of *being*, *operating*, and *interacting*.

Findings: Ways of Being, Operating, and Interacting

Our findings comprise three parts. First, we developed a more robust definition of practices as they relate to ways of *being*, *operating*, and *interacting*. Second, examples are provided that illustrate the need for the elaborated definition. Third, although each practice was coded as *being*, *operating*, or *interacting*, we found that these categories were not mutually exclusive. We provide an example of the ways the practices are not mutually exclusive.

The initial definition of *being* practices referred to how an individual identifies as part of a group. Based on Amelia's experience, ways of *being* also referred to how other group members were identified. For example, Amelia described members as being "champions" who supported innovation. "When you do something innovative, to get started you need champions. So these, these people were champions." Another refinement to the definition of *being* includes specific roles such as leading and providing disciplinary expertise. For example, Amelia described her role as a leader and the roles of other members, "Yes, I am the leader of this. I do have a lot of experience. I do have things to offer, but I don't know everything and there's various ways of thinking." Amelia describes that other members contribute "various ways of thinking" referring to their disciplinary expertise. Based on the data, ways of *being* are defined as how an individual identifies these others as part of the group, including specific roles such as leader or providing disciplinary expertise.

The initial definition of *operating* practices referred to ways the interdisciplinary group worked. Amelia's experience helped us clarify what working in an interdisciplinary group entailed. For example, Amelia described a practice for the group of making small changes rather than having a grand design that could only be enacted with permissions from outsiders.

> Amelia: So I think our project was not so much about, "Let's have this grand design" [...] it was about thinking about the small changes that we can actually make that are not going to require layer upon layer upon layer of [institutional] approvals which we know is going to take a long time. [...] And it becomes doable and possible because big changes are frightening and threatening to people.

Operating practices are now defined as the group members' understandings of the group's work, organizing ideas that enable the work, and ways of navigating institutional policies to get the work done.

The initial definition of *interacting* practices referred to developing and communicating standards for group discourse. Amelia described experiences that helped us clarify that *interacting* also involved negotiating the meaning of ideas, frameworks, or representations. For example, Amelia described how the mathematicians and scientists who were part of the interdisciplinary group had to develop new ideas and language.

> Amelia: It was much more challenging for my mathematician and scientist colleagues to do this work because the project was located within teacher education. That's my world. So they were the ones who really had to step into this world and learn new ways of thinking and new language.

Amelia's examples further illustrated ways she advocated for the value of the group's work. Instances like this example were identified as *interacting* because the interdisciplinary group had to find ways to communicate findings to people outside of the group.

> Amelia: Talking about getting promoted to me [...] [was one of] the best outcomes out of this project. [...] [Two] cases independently of each other, they asked me if I would be one of the referees for their research portfolio. Their teaching was fine, their service was fine, but research you know the things we're looking at this stuff and saying "What is this? What are these journals? What's this project about? Why are you doing this? What is your

> mathematics research?" So I was able to be a referee for both of them and explained and advocated for this project. Talk about the conferences I go to, the journals like publishing and why it matters. And they both got promoted.

Interacting practices are now defined as ways members of the interdisciplinary group: (1) develop and communicate standards for group discourse, (2) negotiate the meanings of ideas, frameworks, or representations to develop common understandings (i.e. taken-as-shared meanings), and (3) communicate findings to people outside of the group.

Beyond redefining the practices, Amelia's experience highlighted the ways the practices were not mutually exclusive. For example, Amelia explained that how the group pursued goals and learned to work together evolved over the course of the interdisciplinary work.

> Amelia: What did change over time was an evolution in the way that we pursued those goals. And there were other off-shoots and new things that were generated because of the fact that we had twenty-five or so people from six different universities learning how to work together.

Amelia described her understanding of the group pursuing goals, a way of *operating*. She also described that the way the group worked together evolved over time, suggesting that the group negotiated the meanings of ideas and developed new understandings, a way of *interacting*. Amelia's example illustrates how *operating* practices such as an understanding of the group's work and *interacting* practices such as negotiating new ideas are mutually informing.

Discussion and Conclusion

We have enhanced our original definition of practices (Suazo-Flores et al., 2021) and provided examples of ways of *being*, *operating*, and *interacting* from Amelia's interview. *Being* now refers to MERs describing their view of themselves and others in the interdisciplinary group including specific roles taken on by group members. *Operating* has been expanded to mean members' ways of doing in the interdisciplinary group and acknowledging institutional policies and actions in order to complete the work. *Interacting* is now understood as developing communication standards, negotiating the meaning of ideas that allows the group to collaborate, and explaining work to people outside of the group.

Practices in interdisciplinary groups comprise ways of *being*, *operating*, and *interacting* (Suazo-Flores et al., 2021). As members of interdisciplinary groups exhibit different practices based on their disciplinary backgrounds (Hyland, 2004; Williams et al., 2016), MERs can benefit from being conscious of how they see themselves as part of the group in addition to how they see others in the group (i.e., *being*). Amelia recognized that she needed to understand and identify ways to operate within the group and under institutional policies (i.e., *operating*). Also, similar to the researchers in Bruce et al. (2017) who strived to frame a research idea within the interdisciplinary research team while allowing the collaborators to maintain their identities and situate themselves relative to the ideas of others, Amelia understood the group's need to negotiate and reconstruct meanings of ideas (i.e., *interacting*).

Amelia's experiences allowed us to enhance our definitions of ways of *being*, *operating*, and *interacting*. To feel sustained in interdisciplinary interactions, MERs need to be aware of their personal and disciplinary identity, acknowledge the personal and disciplinary identity of other group members, negotiate and develop standards of discourse, and identify ways to collaborate with respect to institutional and group norms. Given the limitations of personal accounts as evidence of practices, research explorations of practices should include observations of group members' interactions to situate practices in the *being*, *operating*, and *interacting* in activity.

A THEORETICAL FRAMEWORK FOR DESCRIBING COMMON MANIFESTATIONS OF MATHEMATICAL ANTHROPOCENTRISM

Thomas E. Ricks
Louisiana State University
tomricks@lsu.edu

Keywords: Equity, Inclusion, and Diversity; Ethnomathematics

This paper uses the constant comparative methodology (Glaser, 1965) to categorize the most common mathematically anthropocentric manifestations of mathematicians and mathematics educators. The literature is replete with statements that mathematics is a “human creation”, “human activity”, “human construct”, “human construction”, “human endeavor”, “human enterprise”, “human invention”, “human potential”, “human social activity”, or their human-only equivalents. I call such anthropocentric mathematical perspectives that place humans as the central element in mathematical development and operation *mathematical anthropocentrism*. In the literature, I distinguish three main types of mathematical anthropocentrism: (1) *absolute*, (2) *strong*, and (3) *weak* mathematically anthropocentric perspectives. In particular, the *absolute* mathematically anthropocentric position maintains that mathematics is exclusively a human domain. An example of an absolutist would be fler (2007), who considers it a “trivial fact mathematics is a human activity.... Under all circumstances mathematics is done and produced by human beings. …Thus, mathematics is deeply and genuinely human” (p. 105). The *strong* mathematically anthropocentric position considers mathematics to be essentially a human domain; Núñez and Marghetis (2014) manifest this perspective by at least acknowledging some rudimentary mathematical ability in animals, although they limit these examples to rare exceptions. The *weak* mathematically anthropocentric position (e.g., Denahue, 1997) gives broader latitude to non-human mathematical ability, but still centers human mathematics as superior. I conclude by challenging mathematical anthropocentrism as anachronistic (in lieu of recent scientific developments in a wide range of scientific fields, such as animal cognition, plant behavior, bacteriology, genetics, etc.; see Howard, 2018 [Fig. 1, p. 12] for a brief introduction to animal mathematics), significantly limiting the interpretation of what counts as legitimate mathematics (and hence, limiting the paradigms of mathematics education). I posit that mathematical anthropocentrism is a culturally reproduced phenomenon that can be troubled through adequate education about non-human Other mathematics. I recommend that mathematicians and mathematics educators consider post-anthropocentric mathematical perspectives legitimizing non-human Other mathematics by elevating this Other mathematics onto an equal plane with the mathematics that humans do.

Fraction proficiency continues to be a challenge for many learners of mathematics. Valid and reliable methods for assessing fraction understanding are critical tools in the pursuit of meeting this challenge. Written assessments have been widely used with K-12 students to assess fraction understanding, including units coordination. However, using these types of assessments with a preservice PreK-8 teacher population has proved difficult and inconclusive. Preservice PreK-8 teachers have a variety of algorithmic techniques at their disposal, which has resulted in the need to reexamine how units coordination is assessed in this population. This paper shares the subsequent reconceptualization of assessing preservice PreK-8 teachers' units coordination.

Keywords: Mathematical Knowledge for Teaching, Rational Numbers, Preservice Teacher Education

For decades, proficiency with fraction concepts and computations has been a bane to many students and teachers alike (e.g., Ball, 1990; Bentley & Bosse, 2018; Borko et al., 1992; Izsák et al., 2010; Menon, 2009; Olanoff et al., 2014; Rathouz, 2010; Rizvi & Lawson, 2007; Schneider & Siegler, 2010; Stafylidou & Vosniadou, 2004; Tirosh, 2000). In a previous study of preservice PreK-8 teachers' (PSTs') fraction knowledge (Busi et al., 2015; Lovin et al., 2018), we found evidence that many PSTs struggled with the more sophisticated reasoning needed for fluency with rational numbers. Subsequently, we investigated ways to improve PSTs' fraction content knowledge through changes in our pedagogy (Stevens et al., 2020).

The framework we have used to guide our work in assessing and making sense of PSTs' conceptions of fractions is based on a trajectory of fraction schemes and operations (Norton & Wilkins, 2012; Steffe & Olive, 2010; Wilkins & Norton, 2011). A key component of moving through this trajectory relies on the number of levels of units the learner can coordinate simultaneously. Specifically, to reach the higher levels of reasoning in the trajectory, the learner must be able to coordinate three levels of units simultaneously (3UC) – meaning they can anticipate the outcome of this coordination before they do it. Having this anticipation is known as interiorizing the ability to coordinate units. If someone is unable to anticipate the outcome of the coordination, they may either not have acquired this coordination or may solely coordinate units in action, in the midst of solving a fraction task.

Throughout our work, we have experienced a productive struggle with confidently assessing PSTs' ability to coordinate three levels of units. Our initial study identified 13 cases in which it appeared PSTs had developed a fraction scheme in the developmental trajectory beyond coordinating three levels of units before they had acquired 3UC. This is contradictory to the validated theory in which each step of the developmental trajectory requires the acquisition of the previous scheme or operation.

One confounding fact is that the written assessment used in this first study was initially developed for use with upper elementary and middle school students (Norton & Wilkins, 2012; 2013; Wilkins & Norton, 2011). When used with PSTs, PSTs' overreliance on procedures to find common denominators or to do fraction computations masked evidence of whether they had interiorized the operation of coordinating three units. Since this first study, we have been exploring alternative tasks and strategies to better assess PSTs' ability to coordinate three levels of units. Our ensuing productive struggle led us from solely written assessment tasks to observations of PSTs completing written tasks to structured interviews and has helped identify issues with our tasks that can be used to create improved assessments. Our goal is to share some observations from this process.

Theoretical Framework

An existing developmental trajectory of fraction schemes and operations serves as our framework. This trajectory was validated for upper elementary and middle school students (Norton & Wilkins, 2012; 2013; Wilkins & Norton, 2011) and later validated for PSTs (Busi et al., 2015; Lovin et al., 2018). These schemes and operations can be grouped into three bands of developmental knowledge of fractions with each subsequent band relying on an increasing number of levels of units the learner can simultaneously coordinate: fractions as solely part-whole concepts (only requires the coordination of one level of unit); fractions as measures (requires the coordination of two levels of units); and fractions as numbers "in their own right" (requires the coordination of three levels of units) (Hackenberg, 2007, p. 27; Hackenberg et al., 2016). Our previous work discovered a majority of PSTs were not proficient in being able to reason about fractions as numbers "in their own right" (Hackenberg, 2007, p. 27). This finding corroborates existing research (e.g., Chinnappan, 2000; Olanoff et al., 2016; Son & Crespo, 2009; Son & Lee, 2016). The catalyst for developing this reasoning is being able to simultaneously coordinate three levels of units (Steffe & Olive, 2010), which is the part of the trajectory we focus on in this paper. (For more information about this developmental trajectory of fraction schemes and operations, please see Norton & Wilkins (2009), Norton & Wilkins (2012), Norton et al. (2018), Steffe (2002), Steffe & Olive (2010), Wilkins & Norton (2011).)

Methods

Participants and Instrument

Participants in the study comprised seven undergraduates enrolled in one of three required mathematics content courses for PSTs at a southeastern university. The first in this sequence of courses focuses on number concepts and operations, with significant time dedicated to developing fraction understanding. Four of the participants were enrolled in the first course and participated in the study prior to fraction instruction. The other three participants were enrolled in one of the subsequent courses.

Because the motivation for the study was to investigate strategies that may impact or mask PSTs' ability to demonstrate the interiorization of 3UC, a written 3UC assessment was developed that paralleled assessments used in previous studies (Busi et al., 2015; Lovin et al., 2018). Previous studies showed some evidence of PSTs' reliance on algorithms such as dividing fractions or finding equivalent fractions as masking evidence of 3UC interiorization. This study sought to further investigate these potentially confounding algorithms by combining clinical interviews of the participants with the written assessment so PSTs' approaches and reasoning could be explored further.

Data Collection

The participants completed a twelve-item assessment designed to determine whether or not they were able to coordinate three levels of units. PSTs who have interiorized the ability to do this have an immediate, productive plan to solve a 3UC fraction task and can anticipate the results irrespective of context, denominator choice, or representation; they do not rely on their written work to discover a productive strategy in action (Hackenberg et al., 2016).

The assessment began with four items with no accompanying representations or context. For example, PSTs were posed the following question: "Envision 2/3 of a whole. Now consider 1/12 of the same whole. How many 1/12s are in the 2/3 you originally envisioned?" The remaining eight items were written within a specific context (e.g., an amount of pizza or the length of a jump rope) and provided a specific representation (e.g., a portion of a circle or a line). The fractions used in both sections were varied in structure; the denominators either allowed for halving strategies (e.g., relating 3/¾nd 1/8) or required strategies other than halving (e.g., relating 3/5 and 1/15).

For each item, the PSTs were asked to provide both a solution and a demonstration of their reasoning. For the first four items, the PSTs provided no written documentation of their thinking; their explanations were verbal. For the remaining eight items, the PSTs were asked to use the provided representation to diagram their thinking, and the researchers asked them clarifying questions about their diagrams. The PSTs were observed and video-recorded while completing the entire assessment. The observations and clinical interviews were an essential portion of the study because they enabled the researchers to watch the participants' approaches in action, rather than solely evaluating written evidence of their strategies after they submitted the assessment.

Data Analysis

All four researchers independently rated the written responses for each item and then compared the documentation to the video recordings of the verbal explanations to evaluate each participant's interiorization of 3UC. The researchers then discussed their ratings and came to a consensus based on the evidence provided by the comparisons.

The video recordings allowed the researchers to look for discrepancies in the written documentation, the participants' observed approaches, and the participants' verbal descriptions of their strategies. Participants may show evidence for 3UC in their written work, but then describe their reasoning in a manner that indicates otherwise. In this case, looking solely at written work would result in a *false positive*. Participants may also show counterevidence for 3UC in their written work, but then describe their reasoning in a manner that indicates otherwise. In this case, looking solely at written work would result in a *false negative*. Based on previous findings, the researchers hypothesized these discrepancies would exist between some participants' written evidence and their verbal descriptions of their approaches.

Results

We will share one illustrative example of a *false positive* assessment of 3UC and one illustrative example of a *false negative* assessment of 3UC.

False Positive Example

The PST was given this written question: "The candy bar shown below (represented by a rectangle) is 5/6 of a whole candy bar. If each person wants 1/24 of a whole candy bar, how many people can share the amount shown below?" In her written work (Figure 1), the PST seemed to create the whole by partitioning the given diagram into five 1/6 pieces and adding on one additional 1/6 piece to the given diagram to create six 1/6 pieces. From there, it seemed like she further partitioned each 1/6 piece into four smaller pieces, essentially cutting each 1/6 piece into fourths. There are now 24 pieces within the whole candy bar. Each group of four 1/24 pieces (contained within each of the original 1/6 pieces) is marked with four symbols to show they make a group. For example, there are four x's above four 1/24 pieces in one 1/6 piece and four +'s above four 1/24 pieces in another 1/6 piece. (Note: the symbols above the four 1/24 pieces in the added-on 1/6 piece are difficult to decipher.) The PST seemed to be coordinating the 1/24 pieces within each of the 1/6 pieces within the whole and showing she has five groups of four 1/24 pieces in the given amount, indicating she was coordinating three levels of units.

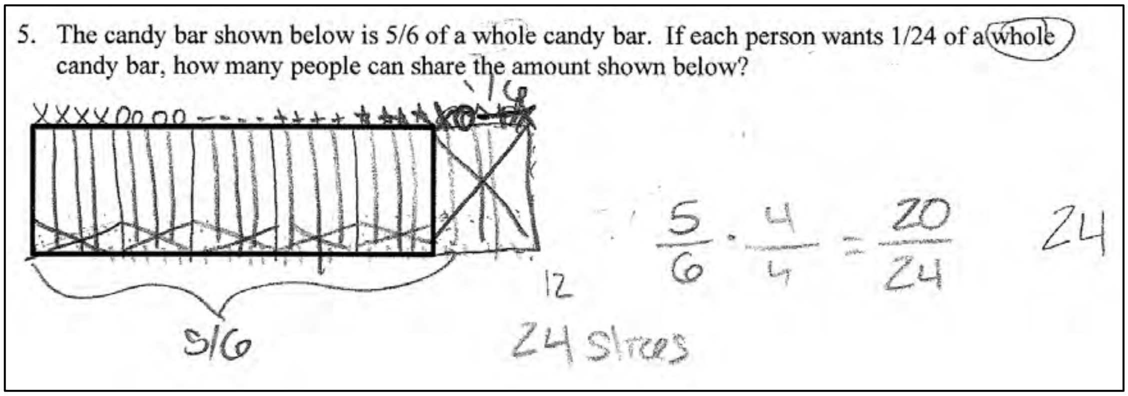

Figure 1: PST Solves Candy Bar Problem

The same PST was given this written question: "The length of rope shown below (represented by a line) is 3/5 of a whole length of jump rope. If each jump rope requires 1/10 of the whole length of rope, how many jump ropes can you make from the length of rope shown below?" In her written work (Figure 2), the PST again seemed to create the whole by partitioning the given diagram into three 1/5 pieces and adding on two additional 1/5 pieces to the given diagram to create five 1/5 pieces. This can be seen with the dotted lines. From there, it seemed like she further partitioned each 1/5 piece into two smaller pieces, essentially cutting each 1/5 piece in half. This can be seen with the solid lines. She then labeled each piece as 1/10 in size and circled the six 1/10 pieces that were in the given diagram. The PST seemed to be coordinating the two 1/10 pieces within each 1/5 piece, five of which make the whole, again indicating she was coordinating three levels of units.

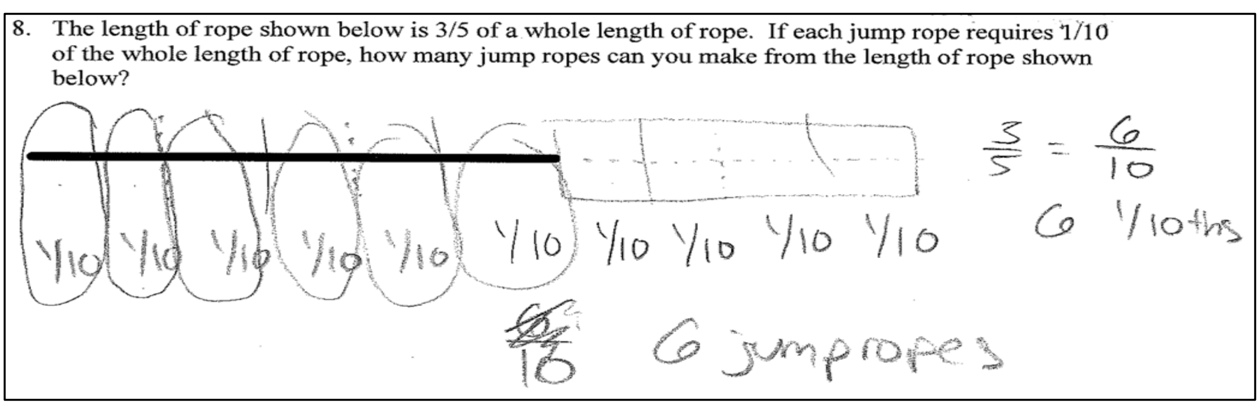

Figure 2: PST Solves Jump Rope Problem

Based solely on her written work, it would seem this PST was coordinating three levels of units. She identified four 1/24 pieces within each 1/6 piece, five of which were given and six of which make the whole. She also identified two 1/10 pieces within each 1/5 piece, three of which were given and five of which make the whole. However, listening to this PST answer the first four questions of the interview protocol, it was clear this PST is not coordinating units and is instead using a generalized procedure to create equivalent fractions.

For example, she was asked: “Suppose you have 3/¾f a whole, can you explain to me how many 1/8 pieces of the whole you have?” She almost immediately answered correctly that she would have six 1/8 pieces of the whole because she “converted [3/4] into eighths.” She described a procedure she named the “giant one” (see Figure 3 for a visual representation of the “giant one”) which tells her she has to multiply the numerator and the denominator by the same factor so she is “not changing the value… just changing the representation of it.” In this example, she explained she multiplied the four by two (in the denominator) so she must multiply the three by two (in the numerator) to get six 1/8s.

In another example, she was asked: “Suppose you have 2/3 of a whole, can you explain to me how many 1/12 pieces of the whole you have?” The PST used the same process of “multiplying by the giant one, or four-fourths” to know there would be two times four or eight 1/12 pieces of the whole. With this strategy, this PST claimed, “I don’t change the value of the original fraction, I’m just changing the way it looks.” When posed with a third, similar question, the PST asked the interviewer, “Is it okay if I use the same explanation?” indicating the “giant one” strategy is what she is most comfortable with and most confident in.

This PST’s strategy for each conceptual problem at the beginning of the interview protocol was to create an equivalent fraction. She could clearly articulate her strategy of multiplying the numerator and the denominator of the given fraction by the same number. She could also clearly articulate that by doing this, she is not changing the value of the fraction, she is just changing “the way it looks” or the “representation” of it. However, this strategy does not give any evidence of coordinating three levels of units; there is no indication she sees two 1/8 pieces in each 1/¼iece or four 1/12 pieces in each 1/3 piece.

When listening to this PST explain her thinking about her written work, there was further evidence she is not actually coordinating three levels of units. The PST was given this written question: “The pizza shown below is 2/3 of a whole pizza (represented by 2/3 of a whole circle). If each person wants 1/9 of a whole pizza, how many people can share the amount shown here?” In her written work (Figure 3), the PST initially performed the “giant one” procedure to get an answer of 6/9, which she correctly interpreted as six people eating pizza. Then she moved to the diagram. She split the given amount (2/3 of a whole pizza) into thirds and then split each of those into three smaller equal pieces, making 1/9-sized pieces relative to the given amount (2/3 of a whole pizza). When she did this, it seemed like she might be coordinating three 1/9-sized pieces within each 1/3 piece, even though she is ignoring the size of the whole pizza, giving some indication of coordinating units. However, when she verbally described her thinking, she explained, “I have three parts of a pizza and if each person wants 1/9, I must split up the thirds…I must multiply by something to get nine and I know three times three is nine. So, I split it up again into three equal pieces…so then it was a total of nine pieces and when I multiplied by the numerator it was six, so I know that six people could eat pizza.” When asked to identify the six 1/9 pieces in the diagram, she could not find them. She went on to say, “I was just thinking about it numerically. I was thinking about whatever I multiply by the denominator, I must multiply by the numerator.” This PST did not seem to be coordinating units and was instead attempting to use the diagram to explain the "giant one" procedure. In reality, conceptualizing equivalent fractions requires one to see there are two groups of three 1/9 pieces within the given amount and three groups of three 1/9 pieces within the whole, which does require the coordination of units.

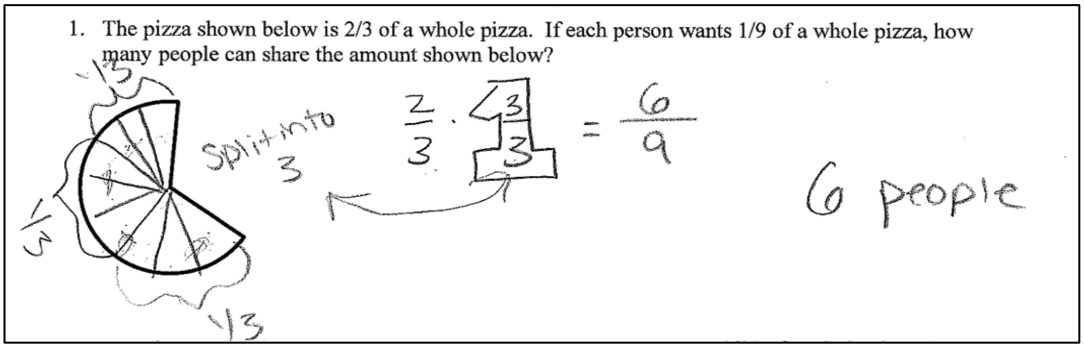

Figure 3: PST Solves Pizza Problem Using a "Giant One"

This situation was thus labeled as a false positive. After the clinical interview, it was determined the PST was in fact completing and trusting the multiplication algorithm to find an equivalent fraction and then translating that number onto the diagram. As static work, it appeared multiple levels of units had been coordinated, but after hearing from the PST, it became clear she was not seeing units within units. Rather, she was retroactively placing the units onto the diagram without any coordination of unit size. It was ultimately concluded this PST has not interiorized the operation of coordinating three levels of units, even though her written work seemed to provide evidence that she had.

False Negative Example

The PST was given this written question: "The pizza shown below is 2/3 of a whole pizza (represented by 2/3 of a whole circle). If each person wants 1/9 of a whole pizza, how many people can share the amount shown here?" In her written work (Figure 4), it seemed as though the PST is trying to figure out how to partition a whole circle into nine relatively equal pieces. She made a few attempts, including a familiar cut-in-half, cut-in-half method, before achieving her goal. But that was where she stopped; she did not provide an answer to the question. There is no evidence of coordinating units in this written work.

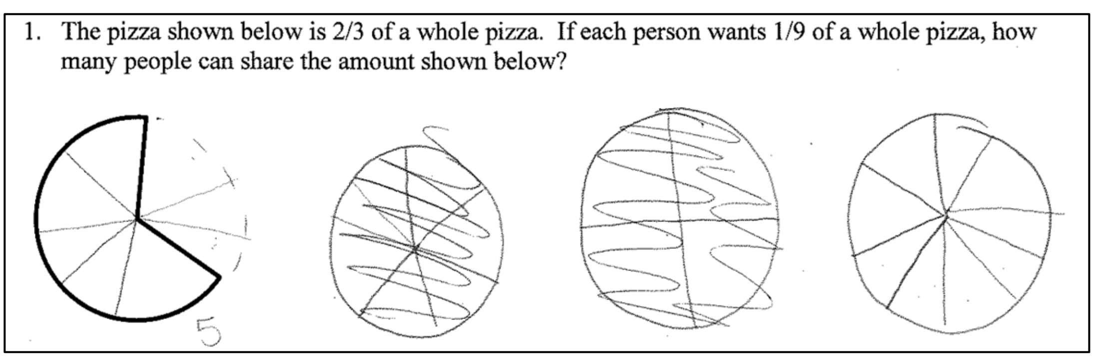

Figure 4: PST Attempts to Partition a Circle into Nine Pieces

The same PST was given this written question: "The length of rope shown below (represented by a line) is 3/5 of a whole length of jump rope. If each jump rope requires 1/10 of the whole length of rope, how many jump ropes can you make from the length of rope shown below?" In her written work (Figure 5), the PST initially labeled the given amount as 3/5, extended the line to represent the whole length of rope, and drew four larger pieces, creating 1/¼ieces, with six smaller pieces within each of the larger pieces, creating 1/24 pieces. She labeled each set of two of the larger pieces as 1/10, making a total of 2/10. The PST abandoned this attempt and started again below it. She drew a second line that has five clear larger pieces, creating 1/5 pieces, with three smaller pieces within each of the larger pieces, creating 1/15 pieces. She labeled three of the larger 1/5 pieces as 3/5. Like the previous question, the PST stopped and did not provide an answer to the question. Considering both attempts on this question, there is no evidence this PST was coordinating multiple levels of units.

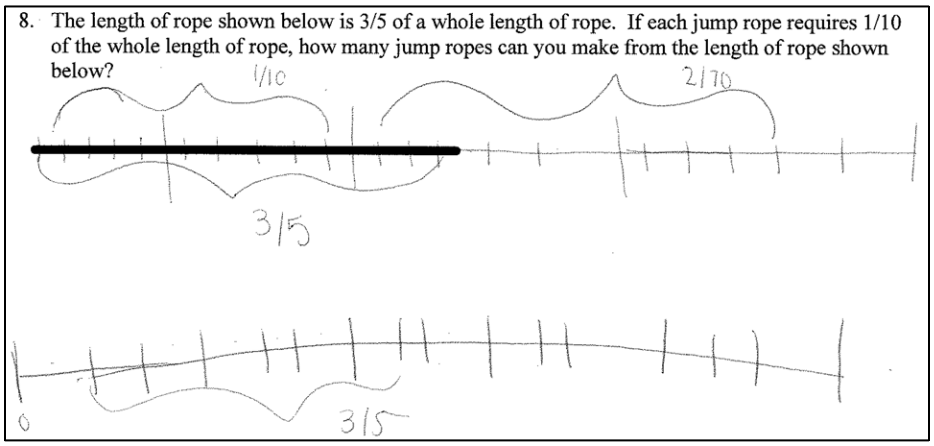

Figure 5: PST Makes Two Attempts at Jump Rope Problem

Based solely on her written work, it would seem this PST was not coordinating three levels of units. She struggled to make connections between the relative sizes of the pieces of the pizza, which was represented with a circular area model, or the pieces of the jump rope, which was represented with a linear model. However, listening to this PST answer the first four conceptual questions of the interview protocol, it did seem like she is able to coordinate units.

She was first asked: "Suppose you have 3/¾f a whole, can you conceptually explain to me how many 1/8 pieces of the whole you have?" She responded with, "If you have a pizza and you cut it into four slices and you shade in three of them, then you can divide all of the fourths into half again and that will give you eighths. So then the section of the three-fourths that isn't shaded, you would have two-eighths not shaded and the rest…you would have six-eighths shaded." The PST was able to confidently describe cutting each 1/¼iece in half to create eight 1/8 pieces within the whole pizza.

Next, she was asked: "Suppose you have 2/3 of a whole, can you conceptually explain how many 1/12 pieces you would have in the whole?" Her answer was, "You would take a pizza and divide it into thirds and then shade two of those thirds. And then you could divide each slice into fourths, each third into four additional sections. And then you would have the section not shaded; there would be four pieces not shaded of the one-twelfths, so four-twelfths not shaded. And then you would have the remaining part of the pizza would be the shaded twelfths…so you would have eight-twelfths shaded." The PST was able to confidently identify the number of 1/12 pieces within each 1/3 piece of the whole.

This PST gave a very similar response to the remaining two questions included in this portion of the interview protocol. In each response, this PST gave a clear articulation of the number of fractional pieces within another. Furthermore, she was able to describe the pieces within the pieces of the shaded part of her diagrams as well as the pieces within the pieces of the unshaded part of her diagrams. For example, she was able to coordinate the number of 1/12s not shaded (four 1/12s) as well as the number of 1/12s shaded (eight 1/12s). This shows a coordination of units within units within the whole (i.e., 3UC).

It is interesting this PST initially asked if she could draw a visual representation to help her solve these four problems. Even though the interviewer asked her to share her thinking without drawing a visual representation, the PST still visualized and described exactly what she would have drawn. This PST clearly favors visualization, but struggled with the visual representations of any type in the written work portion of the interview.

This situation was thus labeled as a false negative. After the clinical interview, it was clear this PST was in fact able to confidently coordinate units even though she struggled to show it in writing. Her static work appeared void of unit coordination. But, when given the opportunity to talk about the problems, it became clear she was very capable of this coordination. It was ultimately concluded this PST has interiorized the operation of coordinating three levels of units.

Discussion

In our previous work with written assessments, many PSTs used computational procedures to solve 3UC tasks, masking evidence of coordinating three levels of units (Busi et al., 2015; Lovin et al., 2018). Through this previous work, it became evident that intentionally designed assessments were necessary to help unpack the masking issue. Originally, the new written assessments aimed to vary contexts, (e.g., candy bars), denominator choices (e.g., allowing for halving strategies) and representations (e.g., rectangular area) to further explore PSTs' true ability to coordinate three levels of units. However, it quickly became apparent PSTs were still exhibiting inconsistencies with how they solved these written problems. We again noticed algorithm use and incomplete diagrams caused us to be inconclusive in our attempts to determine if 3UC was evidenced in the work.

To help guard against the inconclusive nature of the written work, a clinical interview protocol was also created. Striking observations were made in terms of the differences between looking at a PST's static work and hearing a PST talk about her reasoning. As described in the results section above, there were some PSTs whose written work showed evidence of coordinating three levels of units, but when listening to their reasoning during the clinical interview, it became clear that seeing units within units within the whole was not occurring. This indicated they had in fact not interiorized 3UC. On the other hand, there were some PSTs whose written work indicated they could not coordinate three levels of units. But when they described their thinking about the problems during the clinical interviews, they could clearly and confidently talk about units within units within the whole. This showed evidence that they in fact had interiorized 3UC.

The additional interview data is providing evidence that PSTs' written work as a single artifact of evidence is not sufficient to determine the presence of the interiorization of 3UC. This is a significant finding given that many previous studies (e.g., Busi et al., 2015; Caglayan & Olive, 2011; Lovin et al., 2018; Son & Lee, 2016; Ubah & Bansilal, 2018) have relied on written assessments to determine PSTs' ability to coordinate units. This begs the question: how do we best assess 3UC in PSTs? The clinical interviews we conducted seem to be effective. By listening to a PST reason about 3UC problems conceptually and by listening to a PST describe her thinking about a specific problem in context, we felt confident about our assessment of whether or not that PST had interiorized 3UC. Although clinical interviews are time consuming, our findings indicate they must be conducted to develop and validate interventions for developing PSTs' 3UC.

ELICITING DISPOSITIONS FOR TEACHING IN THE CONTEXT OF A VIDEO-BASED INTERVENTION FOR SECONDARY TEACHER CANDIDATES

For years, teacher education programs have focused considerable effort on teacher knowledge and how to develop the types of knowledge that matter in teacher education candidates. Meanwhile, candidate dispositions for teaching have received little attention, particularly in mathematics courses for candidates. As developers and practitioners of a curriculum intervention designed to support candidates' mathematical knowledge, we are beginning to see how much disposition towards teaching mathematics matters in a candidate's ability to attend to students' ideas. In this paper we share results from a pilot study investigating the dispositional characteristics elicited in an online video-based curriculum focused on students' ideas on a figural pattern task. Results indicate that efforts to cultivate secondary candidates' disposition for teaching may have payoffs with respect to both dispositions and knowledge.

Keywords: Affect, Emotion, Beliefs, and Attitudes, Preservice Teacher Education, Teacher Beliefs, Teacher Noticing

Video-based instructional interventions have been used in mathematics teacher education for decades (Lampert & Ball, 1998; Philipp, 2008; Seago et al., 2004) and can have a positive impact on teachers and teacher candidates' (TCs') mathematical knowledge (Jacob et al., 2009), professional noticing skills (van Es & Sherin, 2008), and knowledge of students' conceptions of mathematics (Powell et al., 2003). Influenced by others' success with video-based interventions, two of the authors embarked upon a design-based research (DBR) project, VCAST (video case analysis of student thinking). From the beginning of the VCAST project, we hypothesized that engaging TCs in analysis of video and written evidence of student thinking could serve as a meaningful way to structure candidate engagement with a) key ideas of the secondary mathematics curriculum and b) a range of productive ways students might interact with those same key ideas. And while candidate data do support our initial hypotheses, themes related to candidate dispositions emerged. As a result, we recently turned our attention to how we might cultivate particular dispositions for teaching mathematics in TC in the context of attending to students' mathematical work.

An important part of DBR is the involvement of practitioners--those responsible for implementing the intervention (Amiel & Reeves, 2008). To that end, a team of practitioners (partner instructors) and VCAST curriculum developers (developers) collaborated to investigate the evidence of dispositions for teaching mathematics elicited as secondary mathematics TCs engaged in a curricular module focused on student thinking on figural pattern tasks. Our research question is: *What do partner instructors and developers learn about candidate disposition towards teaching the mathematics of figural pattern tasks?* In this paper we share a summary of the results of our collective analyses, including interpretations from each partner instructor, along with implications for module revision and implementation.

Background

This is the fourth year of VCAST, a four-year DBR project funded by the National Science Foundation (Award #1726543) focused on designing video-based curriculum to improve secondary mathematics TCs' ability to attend to student thinking. In this section we provide an overview of the project and make connections to the literature relevant to the current study.

Mathematical Education of Teachers

The mathematical preparation of teachers has received significant attention over the last couple of decades, with mathematicians and educators collaborating on the educational expectations for beginning teachers at various levels of the school curriculum (CBMS, 2012). A repeated theme is the importance of being able to elicit and interpret students' ideas (NCTM, 2014). For instance, a TC's ability to complete a mathematical task, recognize the potential mathematical complexities for students, make inferences about a particular student's understanding based on the evidence students produce, and then decide on an appropriate response that builds upon, as opposed to simply redirecting or correcting, that student's thinking all rely upon various subdomains of candidate knowledge.

Dispositions for Teaching Mathematics

We think about dispositions for teaching mathematics as a set of interrelated habits of mind that teachers embrace to carry out their practice. Interestingly, professional standards documents for teacher education programs rarely address these habits of mind explicitly. Rather, they are implicit in the sets of knowledge and skills TCs are expected to acquire by the time they enter the teaching profession. However, one can readily see the influence of various fields of study with standards that advocate for 1) the use of culturally relevant pedagogy (Ladson-Billings, 1995), 2) the application of educational ethics and caring (Noddings, 2003), 3) attending to students' mathematical thinking (Author, 2017; Jacobs et al., 2010), and 4) understanding power and privilege in the history of mathematics education (Gutierrez, 2013).

Given the focus of VCAST, this study is centered upon dispositions associated with attending to students' mathematical reasoning. That is, we are concerned with the habits of mind needed to put a candidate in the best position possible for analyzing and interpreting student thinking. We have tentatively identified two such habits of mind: *awareness of differences in reasoning*, and *adaptability in one's own thinking*. Awareness of differences in reasoning is about acknowledging that individuals will necessarily have different ways of reasoning in sensible ways about mathematics. Such awareness involves considering any evidence of student reasoning on its own merits and places great value on individual student perspectives. With awareness, the expectation is that students' ways of reasoning are sensible and it is up to the TC to identify how the student is making sense of the ideas. Adaptability in one's own thinking is about being willing to revise one's knowledge and assumptions when presented with additional evidence that warrants such a change. Adaptability involves recognizing that all knowledge is tentative and the active pursuit of additional information and evidence in an attempt to more fully understand. In the context of attending to student mathematical reasoning, TCs demonstrate adaptability when they recognize that additional information about a student's reasoning may alter their perceptions about what the student understands and is able to do. These habits of mind provide the foundation for our coding framework.

The Intervention

From a design perspective, we focused on featuring nonstandard mathematics tasks, collecting evidence of secondary students working on those tasks, and then selecting artifacts of student evidence that revealed a range of productive approaches and strategies to solving those tasks. The intent was to introduce TCs to new ways of thinking about the featured tasks and to support the development of attentiveness (Carney et al., 2017). Developers also purposely selected artifacts to illustrate how students' productive struggle can lead to important insights.

Design and context. The intervention consists of four modules, each of which features an asynchronous online component, a synchronous in-class component, and an asynchronous exit ticket. TCs engage with the asynchronous components via the project's digital platform and instructor support materials are made available through the project's website. The in-class component can be completed in a variety of synchronous formats and leverages social learning through group activities. The modules are designed for use in the Functions & Modeling course, a mathematics course for secondary mathematics TCs taught at replication sites of the UTeach teacher preparation program. The case studies reported on here involve partner instructors from the third and fourth year of implementation.

The hexagon task module. The Hexagon Task (see Figure 1) is a figural pattern task designed to encourage far generalizations which can be determined using a variety of approaches. For example, a student might choose to focus on how the configuration of hexagons contributes to the perimeter, on how the perimeter increases from one figure to the next, or perhaps a combination of these and other approaches. The range of approaches that can be productively leveraged while completing the Hexagon Task afforded multiple opportunities for TCs to examine a variety of students' mathematical reasoning (Cavey et al., 2018). The task also requires students to attend to three interrelated quantities: the figure number, the perimeter of the figure, and the number of hexagons in the figure.

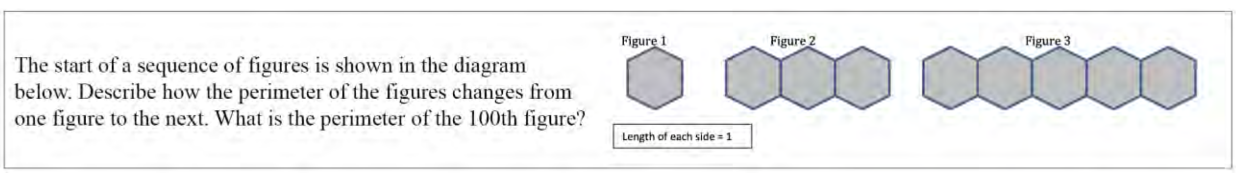

Figure 1: Adapted Hexagon Task; Hendrickson et al. (2012)

The module features video and written evidence produced by three students who approached the task differently and exhibited productive struggle in a range of ways. The pseudonyms and images of each student, along with their final written work included in the module, are provided in Figure 2. Ashley focused on geometrical aspects and developed a function for the perimeter of a figure based on the number of hexagons in the figure. Maria began her work on the task using an approach similar to Ashley's but then switched to an approach that focused on using the increase in perimeter from one figure to the next to determine the relationship between perimeter and figure number. Brandon, like Ashley, remained focused on the relationship between perimeter and the number of hexagons. He made a more explicit assumption that there are 100 hexagons in the 100th figure, recognized his error, and then tried to correct his final answer by using recursive reasoning to determine the number of hexagons in the 100th figure.

The in-class component features written student evidence from an additional six students. This work was selected for candidate group analysis and discussion. Providing this broader range of student thinking affords social construction of candidate knowledge related to the mathematics of figural pattern tasks and how students think about and reason with that mathematics (Franke and Kazemi, 2001). By highlighting areas of secondary student struggle, our intent was to help TCs gain an appreciation for the complexity of figural pattern tasks and to foster empathy for how each individual student navigated that complexity.

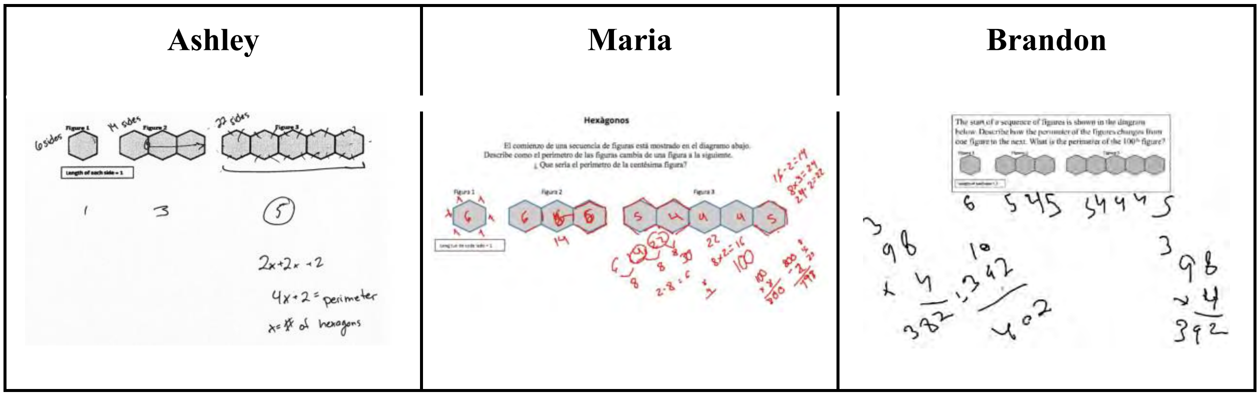

Figure 2: Student evidence featured in the asynchronous components.

Methods

Participants and Settings

Partner instructors for project X were recruited using the UTeach email listservs and during annual conference presentations for Functions & Modeling instructors at the UTeach conference. Both instructors for this study are faculty at mid-size, public university UTeach replication sites located in the United States. Instructor K implemented the year 3 version of the VCAST curriculum materials in fall 2019, whereas Instructor N implemented the year 4 version in fall 2020. As such, Instructor K was in the first group of partner instructors and was able to meet with their students in a standard face-to-face classroom setting for the in-class component. Instructor N was in the second group of partner instructors, who had the benefit of improved materials based on the lessons learned in year 3, but implemented the in-class component remotely due to the ongoing COVID-19 pandemic. Both instructors used the same order of modules during their implementation, with the Hexagon Task as the second. Candidate participants who elected to participate in the study were undergraduate students enrolled in the partner instructors' courses. See Table 1 for summary information about each instructor.

Table 1: Partner Instructors and Their Candidate Participants

	Participation Year	# of TCs	In-Class Format
Instructor K	Year 3 (fall 2019)	8	face-to-face
Instructor N	Year 4 (fall 2020)	13	remote

Data Collection

Data for these case studies were collected using observations, instructor reflection surveys, digital captures of candidate work produced during the in-class component, and the online platform designed specifically for VCAST's delivery of asynchronous module content. Instructor K's in-class session was recorded by a VCAST research team member. Instructor N's class was captured via Zoom, as its synchronous enactment occurred online during the COVID-19 pandemic. Following implementation, each instructor submitted reflection feedback via a Google Form. Each reported their perceptions regarding candidate engagement with the module content and uploaded candidate artifacts produced during the in-class session. Candidate data consisting of responses to asynchronous module prompts were collected digitally via the VCAST digital platform and then downloaded for analysis.

Data Analysis

Candidate data were analyzed using a coding framework derived from the literature on professional noticing (Jacobs et al., 2010; van Es, 2011) and attentiveness (Carney et al., 2017; Carney et al., 2019) that focuses upon the two habits of mind outlined earlier for dispositions associated with attending to student thinking. With respect to awareness, we looked for evidence that the candidate was able to focus explicitly on a student's way of reasoning with the Hexagon Task rather than imposing their own ideas or that the candidate engaged in making sense of student reasoning. With respect to adaptability, we looked for evidence that the candidate was receptive to new information about a student's reasoning and for evidence that the candidate was willing to acknowledge when their own original ideas were proven incorrect.

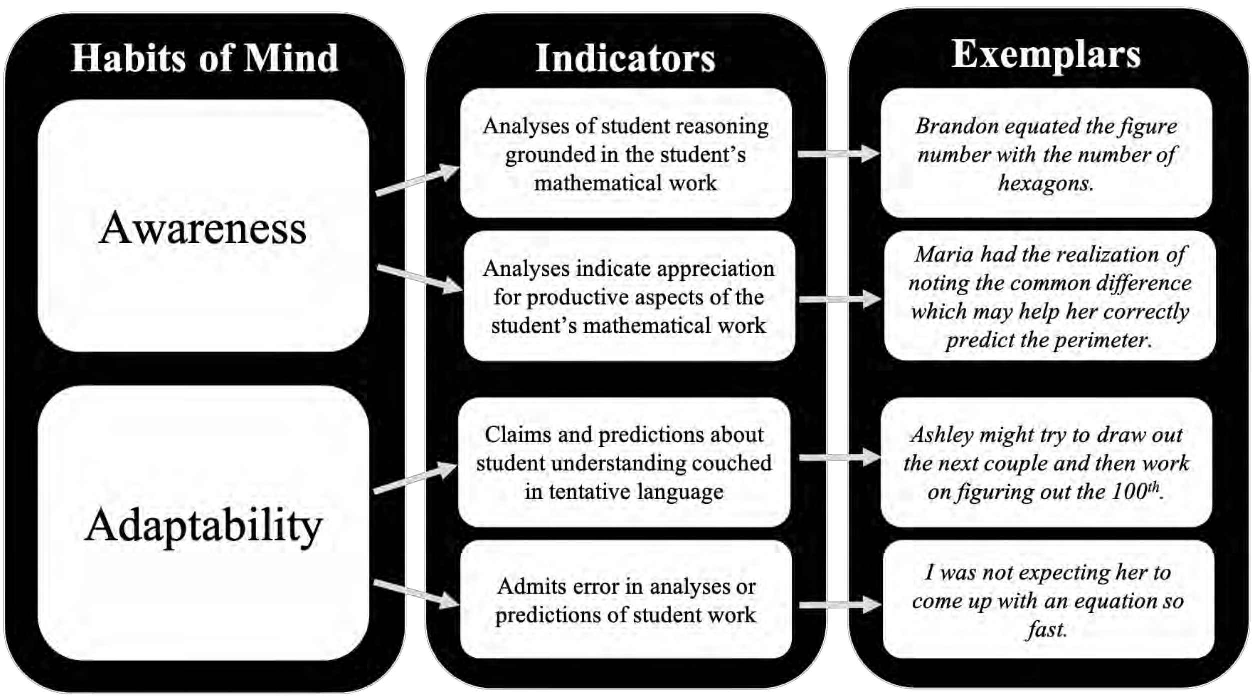

Figure 3: Selected Indicators of the Candidate Dispositional Coding Framework

To start, researchers decided on the unit of analysis to be coded using a methodology similar to that used by van Es and colleagues (van Es et al., 2014). Because we were interested in analyzing evidence of candidate disposition elicited through sequences of student work analysis, we first identified the particular segments of data, or units of analysis, we felt were most likely to provide this evidence. Pairs of researchers then applied the coding framework to a selection of data for each instructor, then met to calibrate codes and reach consensus on the meaning of framework indicators. Following these conversations, all four researchers met to share results of calibration conversations and to collectively refine indicators and interpretation of the framework. The original researcher pairs then coded and calibrated the remaining data for their assigned instructor. Each unit of analysis was independently coded by two researchers and calibrated until consensus was met.

In the following section, partner instructors present emerging findings from their case studies. We deliberately use a first-person narrative so as to enable readers to gain deeper insight into individual perspectives and lenses that instructors used to interpret candidate data.

Instructor K's Results

As a mathematics educator who prepares TCs to teach students with diverse backgrounds and experiences, my goal is to implement strategies that increase their mathematical knowledge, skills, and dispositions for teaching all students. Thus, when approached to participate in VCAST, with its focus on student thinking, I saw it as an opportunity for TCs to develop an awareness of various student approaches and openness towards multiple forms of reasoning. Additionally, I hypothesized that engaging in the cognitively demanding tasks and productive struggle could lead to an increase in TCs' content knowledge and an appreciation of their future students' struggle. My experience as an instructor, coupled with the recent analysis of the Hexagon Task data, indicates growth in the TCs' awareness of student thinking and evidence of their ability to predict student moves and admit when those predictions were incorrect.

Growth in Awareness of Student Thinking

Initially, when TCs reviewed written students' responses to the task associated with the first module, they focused their analyses on whether students' work was correct or incorrect. However, to develop their attentiveness, I prompted my TCs to look beyond correctness by focusing on the students' explanations. By the second module, 4 out of 8 TCs commented on how the module made them aware of the multiple solution paths, and all of the TCs were describing, discussing, and making comparisons between the various students' approaches or comparing their approaches to those of the students. For example, TC4 wrote "In my process, I did not use the number of hexagons to calculate the perimeter. [Ashley] took the number of hexagons times 2 for the bottom perimeter and did the same for the top then added the other sides." TCs were also able to analyze and interpret student thinking based upon evidence. Consider the following statements by TC3 and TC9:

- TC3: Maria wrote 6, 14, 22. Then drew a line in between them to show the increase of 8. This is the increase per figure …, to find out the perimeter per figure.
- TC9: So, by multiplying 4 by 98 and adding the extra sides for the end [h]exagons [Brandon] is assuming there are 100 Hexagons in the 100th figure.

Evidence of Adaptability

When making predictions about students' thinking, TCs demonstrated adaptability in both their tentative language and their willingness to revise their assumptions. Most of their speculations began with the phrases "I think …", "I believe …" or "She may or might..." indicating the TCs' were trying to identify how the student is making sense of figural patterns. The data analysis revealed that 7 out of 8 TCs admitted to incorrectly predicting Ashley's next move, while only 3 out of 8 admitting errors with Maria, possibly because their approach was more similar to hers. When the students' actions did not match the prediction, the TCs would either acknowledge the error or adjust their interpretations. The TCs made comments like "I'm surprised!", "My prediction was completely wrong with what Maria actually did," and "[Ashley] … pulled in the number of hexagons in the figure …, which I did not anticipate."

As the Hexagon Task was only the second of the four modules, the TCs were already showing evidence of important skills necessary for effective mathematics teaching. They were able to shift their focus from the correctness of students' answers to an awareness of diversity in students' mathematical reasoning. They were able to assess, compare, and make predictions about students based on video and written work, and became open and willing to learn and revise their assumptions when presented with new evidence. Even the two TCs who initially incorrectly solved the task themselves exhibited these skills. This suggests that giving TCs opportunities to examine, discuss, and predict student thinking may help them develop effective teaching practices to use in their classrooms.

Instructor N's Results

As a mathematics teacher educator who focuses on equitable teaching and culturally responsive pedagogy, I emphasize the importance of treating all students as capable learners. Thus, I was interested in how the VCAST materials, with their emphasis on the analysis of student evidence of mathematical reasoning, would provide opportunities for me to surface and support the dispositional development of my TCs. Analysis of their data from the Hexagon Task module illuminated several interesting areas of potential insight and growth for my TCs. I discuss two themes in particular that emerged from my TCs' engagement with student work analysis: (1) TCs appeared to grow in their own mathematical understanding and (2) TCs appeared to develop a more empathetic stance toward the students whose work they analyzed.

Growth in Mathematical Understanding

Data analysis indicates that 6 out of 13 students exhibited growth in their own mathematical understanding, either by improving the quality of what they noticed and described in student strategies, articulating that a featured student strategy was something they had not initially thought about, or by solving the adjusted version of the task correctly after submitting an incorrect answer for the Hexagon Task. For example, TC3 responded, "I realized that Maria's way of thinking also works and makes a lot of sense, even though I hadn't initially considered thinking the way she did" and TC13 observed, "Some of the strategies used by different people for this task surprised me because I did not think of the problem in those ways." For TC5 and TC14, both of whom initially solved the Hexagon Task incorrectly, analysis of student thinking not only appeared to reinforce their dispositional traits, but also appeared to enable them to correct their own mathematical errors and solve a related task, presented later in the module, correctly.

Growth in Empathetic Stance

Data analysis indicates that 10 out of 13 students exhibited growth in their ability to empathize with students' struggle with the task. For instance, TC13 acknowledged, "Pattern tasks are really easy to get confused on if you do not know what to look for," while TC10 noticed, "Brandon is focusing on how many hexagons each figure has, and he is struggling to find the pattern to find the number of hexagons in the 100th figure." Developing more empathy towards students' mathematical reasoning also allows for more flexibility in their interpretations and helps TCs recognize that students' mathematical thinking is fluid. As TC13 notes, "Predictions are predictions, they are not factual. Always be ready for any reaction or questions asked by the students."

TCs across the board agreed that 'brief isolated episodes' may not portray a complete picture of students' thinking and that it is necessary to initiate and engage in an ongoing mathematical discourse to gain insight into their thinking. This is evidenced by TC5, who observed, "It helped me make sure that I try to understand each student's thinking and why they did [a] certain mathematical process" and TC6, who realized, "Students need to be given time to show their mathematical process, thinking, and reasoning before making assumptions."

During my implementation of the Hexagon Task module, I noticed my TCs shift from attending to students' ideas for the purpose of evaluating student work to a desire for understanding students' mathematical ideas. The analyses of TCs' responses to the Hexagon Task module not only support my impressions during implementation but also highlight other areas of growth. From an equity standpoint, I am excited about the potential to cultivate TCs' dispositions for teaching mathematics while also supporting TCs' mathematical knowledge.

Discussion and Implications

Instructors and developers, alike, observed shifts in the evidence of TCs' dispositions as TCs engaged with the VCAST materials. Our curiosity about this phenomenon led to a shared interest in investigating the extent to which TCs' dispositions for teaching mathematics were elicited with a single module. Since none of us had previous experience researching dispositions for teaching, one primary aim was to settle on a framework that would allow us to capture the nuances we observed in the language TCs used when analyzing and reflecting on their analyses of student evidence for reasoning. By doing so, we not only have a framework for future analyses, but we also uncovered several potential directions for future research across all partner institutions as well as implications for module revisions.

For one, we did not expect to see marked shifts in evidence of TCs' dispositions within a module. Moreover, we observed shifts in TCs' dispositions in two distinct ways. The data from Instructor N's TCs showed impressive gains in disposition from the beginning to the end of the online component, with all TCs demonstrating evidence of awareness and adaptability by the end. For Instructor K, we observed shifts in evidence of TCs' dispositions in relation to the students featured in the module. Naturally, we wonder, *In what ways does the evidence for TCs' dispositions for teaching mathematics shift when engaging in a video-based intervention focused on student thinking on figural pattern tasks?*

Second, while the focus of this pilot study was on TCs' dispositions, our work has led to a hypothesis about the relationship between disposition and the ability to learn from students' mathematical work. Of the TCs who started the module with an incorrect solution, those who exhibited multiple indicators from both habits of mind were more likely to correct their mathematical errors by the end of the module. As a result, we wonder, *How are TCs' disposition for teaching mathematics related to their ability to learn mathematics from students?*

Lastly, our analyses revealed a gap in module questions about Brandon's reasoning evidence. In particular, the current questions are not structured to elicit evidence with respect to one of the indicators for adaptability. Thus, the developers must now decide whether that type of evidence is desired and how to restructure the questions to elicit that evidence.

In summary, what began as a trend in TCs' module responses about student thinking has evolved into a list of potential lines of inquiry into TCs' disposition for teaching mathematics. And while we have more questions than answers at the end of this study, we hope this work sparks interest from the larger field of professional noticing.

PROSPECTIVE MATHEMATICS TEACHERS' DESIGNED MANIPULATIVES AS ANCHORS FOR THEIR PEDAGOGICAL AND CONCEPTUAL KNOWLEDGE

Denish Akuom

Steven Greenstein, PhD
Montclair State University
greensteins@montclair.edu

Positioning teachers as designers of curricular resources invites opportunities for exploration at the intersection of content, pedagogy, and design. As researchers accepting greater responsibility for preparing teachers to maintain a commitment to their pedagogical vision in practice, this work seeks to cultivate the imagination of humanistic forms of mathematics teaching and learning by supporting these explorations. Toward that end, this paper reports on research that examines connections between the pedagogical/conceptual knowledge that prospective teachers embed in the designs of original manipulatives and how those designs mediate the pedagogical moves they make in teaching situations. The promise of this work is that these connections may reveal a viable means to support bolder connections between teacher preparation and practice. Implications of our findings for teacher preparation are considered.

Keywords: Teacher Knowledge, Technology, Preservice Teacher Education

It is an unfortunately perennial problem that teachers often experience considerable challenges in transferring their theoretical knowledge into practice (Ünver, 2014). While teacher education programs that explicitly link teacher preparation coursework to field experiences tend to be more effective than those that do not (National Academy of Education, 2005), colleges and universities have often been criticized for implementing teacher education programs that do not sufficiently engage their students in actual and ongoing practice situated in authentic education settings. Although future teachers tend to craft their pedagogies as they learn about research-supported instructional methods, teacher educators also stress the importance of developing one's practice in real classrooms with real students (Kazemi, et al., 2009). It is with this critical concern in mind that the field seeks to determine the means by which teachers can transform teacher knowledge from theory into practice through approximations of practice (Grossman, et al., 2009) that simulate the work of teaching.

Our work connects with the body of literature that frames teachers as *designers* (e.g., Brown, 2009; Svihla et al., 2015) of teaching and learning experiences and the material resources that mediate them. We conceive of design broadly to include the "intentional activity of transforming ideas and knowledge" (Carvalho et al., 2019, p. 79) into "tangible, meaningful artifacts" (Koehler & Mishra, 2005, p. 135). Our purpose in doing so is to present a novel Making experience within mathematics teacher preparation that we hypothesized would inform their conceptual and pedagogical thinking. Making in this sense is conceived as the creative production of artifacts via activities that include designing, building, and innovating with tools and materials to solve practical problems (Halverson & Sheridan, 2014). Thus, the experience tasks prospective mathematics teachers (PMTs) with digitally designing (using Tinkercad; Autodesk Inc., 2016), 3D printing, and evaluating original manipulatives that are responsive (Akuom & Greenstein, 2021) to the curricular (Dewey, 1990; Pinar et al., 1995) needs and interests of actual learners.

While there is a considerable body of research on *students'* mathematical Making (e.g., Bower et al., 2020; Valente & Blikstein, 2019), research is only beginning to uncover the benefits that *teachers* experience in Making contexts (Greenstein & Seventko, 2017; Greenstein & Olmanson, 2018; Greenstein et al., 2019). Our prior research (Akuom & Greenstein, 2021) addressed this gap by exploring the conceptual, social, and material resources that mediate (Vygotsky, 1978) the design decisions of prospective teachers' Making of mathematical manipulatives. This paper reports on research that extends that work by discerning whether connections can be made between the pedagogical/conceptual knowledge that prospective teachers construct in teacher preparation and how that knowledge is enacted in their teaching. Specifically, this work seeks to address the question: *As prospective teachers Make new manipulatives for mathematics teaching and learning, can connections be made between pedagogical/conceptual resources for their design decisions and how those designs mediate the pedagogical moves they make in practice?* If connections can be made between the knowledge that prospective teachers construct in teacher preparation, how that knowledge materializes in their designs of physical manipulatives, and how those knowledge-embedded designs mediate their teaching interactions, we propose that these findings can illuminate and subsequently strengthen the relationship between instructional intention and enactment in particular (see Remillard, 2018), and teacher preparation and practice more broadly.

Theoretical Framework

Fundamentally, this research is about the mediating role of conceptual, social, and material resources in design activity. In particular, we seek to extend prior research on the resources and rationales that mediate design decisions when designing a tool by exploring the mediating role of those tools in teaching situations. Accordingly, we take a sociocultural perspective and ground this work in the notion of mediated activity, derived from Vygotsky (1978) and advanced as instrumented activity by Verillon and Rabardel (1995). In terms of instrumented activity, an artifact is a material object that becomes an instrument (e.g., tool, sign) for the subject (e.g., actor, learner, teacher) when the subject has integrated it with their activity. Thus, an instrument is a psychological construct (as opposed to a material one) that "results from the establishment, by the subject, of an instrumental relation with an artifact" (p. 85). What the distinction between artifacts and instruments reveals is the possible range of actions one might take with an artifact and what those actions might implicate about a subject's knowledge. For our purposes, we are specifically interested in PMTs' pedagogical and conceptual knowledge and how their practice is mediated by such knowledge as it is intentionally embedded in their designed artifacts.

In our prior research, we analyzed PMTs' design decisions – and the rationales they gave for those decisions – as they made original manipulatives to teach a mathematical concept. As they designed these manipulatives, it was the PMTs' intention (Malafouris, 2013) to embed their tools with particular affordances (Gibson, 1977) for utilization schemes (Verillon & Rabardel, 1995) that they hypothesized would enable the child to form abstractions, through their sensorimotor engagement (Kamii & Housman, 2000; Piaget, 1970), of the perceptual elements that are the groundings (Nathan, 2014) for target concepts. As this *learning by design* (Koehler & Mishra, 2005; Koehler et al., 2004) process invites occasions for their active inquiry, PMTs made a host of design decisions for a variety of reasons; they drew on a range of conceptual, social, and material resources to mediate them. In order to characterize and organize these resources, we appealed to Sc (1992) design-centered notion of "knowing in action" (p. 2). Sc considers knowledge to be in action as "the designer sees what is 'there'… draws in relation to it, and sees what [they have] drawn, thereby informing further designing” (p. 5). This thought-revealing (Black & Wiliam, 1998) process of seeing-drawing-seeing is what Schön means by the phrase “designing as a reflective conversation with materials” (p. 3).

For this phase of the research in which we analyze PMTs’ usage of tools in practice, we use the term *embedding* to connote an intentional design element that embeds a PMT’s pedagogical and/or conceptual (i.e., mathematical) knowledge. As an example, a PMT named “Moira” designed a fraction tool with a variety of fractional pieces of a whole. She was concerned that if each piece had its own unique color, that might “take away reasoning from children. If a student believes that a yellow ring represents sixths, they will immediately reach for yellow the second that they hear sixths.” By giving the pieces the same color and leaving them “unmarked,” she intended for children to construct their own meanings for each of the [pieces]. Thus, we say that pedagogical/conceptual knowledge mediated this design decision and refer to the corresponding design element as an *embedding* of that knowledge. In addition, when we infer from a PMT’s use of the manipulative in a teaching situation that the tool served as a resource for (e.g., a reminder of) pedagogical and/or conceptual knowledge embedded in the tool, we will refer to that as an *anchoring* phenomenon, as in, “Moira’s fraction tool served as an *anchor* for her attention to the pedagogical practice of implementing tasks that promote mathematical reasoning.”

Methodology

This study is part of a larger project that aims to test and refine the hypothesis that a pedagogically genuine, open-ended, and iterative design experience centered on the Making of a mathematical manipulative would be formative for the development of PMTs’ inquiry-oriented pedagogy. The larger project took place across two semesters of a graduate-level specialized mathematics course for PMTs at a mid-sized university in the northeastern United States. Forty students comprised thirty-four groups. For the study reported here, we took an exploratory case study approach (Yin, 2009) in order to determine what connections could be made between pedagogical and conceptual rationales for PMTs’ design decisions and how those designs mediated the pedagogical moves they made in enactment. We did so by taking as the unit of analysis *instances* in PMTs’ teaching when the use of their manipulative implicated the pedagogical and/or conceptual knowledge underlying their design rationales. The locus of these particular research efforts among the broader research project is depicted as the arrow from “Design Decision” to “Enactment” in Figure 1. In addition to the PMT’s designed manipulative and a video recording of problem-solving interviews with them and their elementary-age focus student, four written project components comprised the data corpus: a “Math Autobiography,” an “Initial Idea Assignment,” a “Project Rationale,” and a “Final Paper/Reflection,” which includes findings from their problem-solving interviews.

We took a grounded theory (Corbin & Strauss, 2008) approach to analyzing the data. We began by collectively analyzing the written and video components of one PMT’s design case to identify instances in their teaching from which we could infer that the PMT leveraged a particular embedding of a design decision in their manipulative to enact a teaching move that was consistent with aspects of their purported pedagogy, which they shared in the written artifacts of their Maker projects. These inferences constitute our conjectures that their designed manipulative served as an anchor for the pedagogical/conceptual knowledge they had been constructing in the course. We generated codes for this design case to characterize connections between embeddings of design decisions and their mediating role in the PMTs’ teaching. Next, we collaborated to identify additional instances of anchoring in other design cases. Analysis involved the constant comparison of data to ensure coherence is maintained across the generated codes and to get a good sense of the variety of ways in which affordances of the designed manipulatives that were either intended (those that PMTs intended to embed in their tool) or unintended (those that PMTs hadn't intended but realized in practice) could be leveraged to support a PMT's pedagogy.

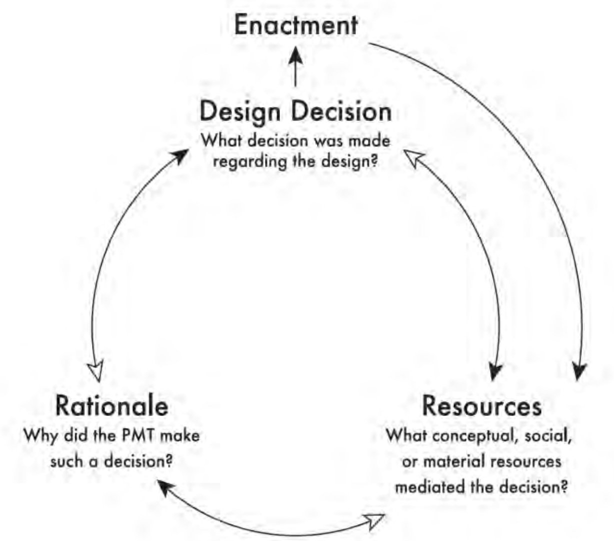

Figure 1: Conceptual resources inform rationales for design decisions and may also be evoked in enactment. Open arrows acknowledge that feedback is reciprocally informing.

Results

Here we present just three excerpts from among the thirty-four task- and tool-based problem-solving interviews that PMTs conducted with the intended user of their manipulative. Findings from our analyses of these excerpts suggests that they are instances in a PMT's teaching when a pedagogical move they made was mediated by the instrumental leveraging of a design affordance whose rationale was explicitly linked by the prospective teacher as designer to their pedagogical and/or conceptual knowledge. In short, these are instances in which a design embedding served as an anchor for a PMT's pedagogical and/or conceptual attention. The manipulatives mentioned in these results are shown in Figure 2.

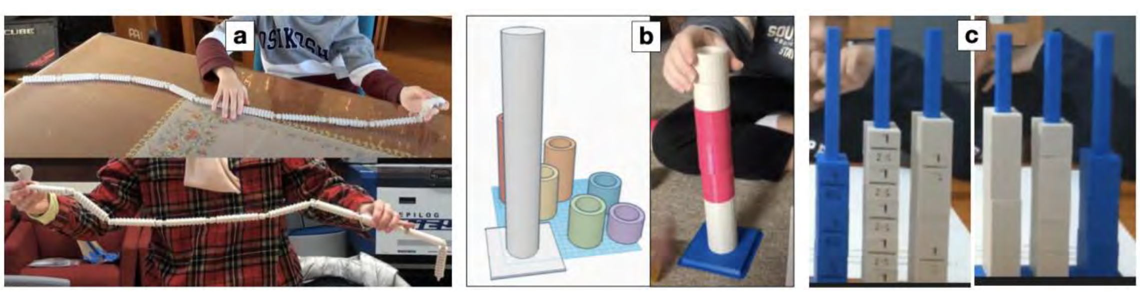

Figure 2: (a) Roda's decimal tool; (b) Kerina's fraction tool; (c) Anyango's fraction tool.

Reasoning about the unit whole

Roda designed a "Decimal Snake" in order to teach a child about decimals and decimal comparison. As shown in Figure 2a, her tool consists of ten connected pieces. Each of these pieces is equally partitioned into ten parts. Thus, the decimal snake can be used to represent tenths of tenths, or hundredths, of a whole, that is, any value between 0.01 and 1 to two decimal places. These design features are Roda's embeddings of the concepts of the whole and its decimal parts.

At one point in the interview, we observe Roda asking the child to compare 5.5 and 5.47. [Note that it would not be possible to represent 5.47 if the entire snake represented 1 or even 10.] The child responds, "5.47 is 5 and 47 hundredths, because it's 3 hundredths away from 5 and 5 tenths." Perhaps because Roda is interested in how her tool can support the child's reasoning, she then asks him to "Use the tool to show me?" Over the next sixty seconds, we witness the child struggling to locate 5.5 and 5.47 on the tool. Finally, he locates 5.5 at (what we would identify as) 0.55 (if the entire snake represented 1), and 5.47 at 0.47. Given that several minutes earlier the child established that entire snake is the "whole" and that each piece of the snake is one tenth of a whole, we infer from his solution – locating 5.5 at 0.55 – that he had unintentionally designated each piece of the snake as 1 (as opposed to 0.01) and each partition of a piece as 0.1 (as opposed to 0.01). In doing so, he changed his designation of the entire snake from the whole (1) to 10, and consequently, each piece of the snake now represented 1. Thus, 5.5 would be presented as the 5th partition of the 5th piece.

Roda's next move aims to help the child identify and resolve this confusion. When she asks him to "Show me one tenth," he points to one of the tenth pieces. When she asks for, "Two tenths," he points to the second piece. Then she asks, "Where is 5 and 5 tenths?" And in doing so, she perturbed his thinking and provoked disequilibrium. Soon thereafter, he resolves it and declares, "Oh, wait! This [entire snake] is one whole! 5 and 5 tenths, you can't even make it out of the snake!" In response to this unanticipated move in the child's activity, Roda leverages an affordance of her tool – namely that each piece of the snake could represent either a tenth of a whole or one of ten wholes – and she exploits it to support new ways of thinking for the child as he resolves his confusion about the representational capacities of the tool.

R(oda): You need how many snakes to make 5.5?

C(hild): You need 5– No, 6 snakes!

R: How can we compare [5.5 and 5.47] using 1 snake? Is that possible?

C: We can pretend that each piece is one snake.

In this instance, Roda leverages the embedding of a conceptually resourced design decision that enabled the snake's user to engage in conversations about the unit whole. Specifically, she leveraged a design decision that allows for flexibility in naming the unit whole in relation to the snake and its pieces. And her rationale for leveraging that affordance was a pedagogical one. Rather than correct the child's interpretation, she sought to help him reason through his interpretations in order resolve the confusion himself. In this respect, the tool's capacity for flexible interpretations of quantities (a conceptually resourced design decision) served as an anchor for pedagogical knowledge about the value of revealing student thinking and posing purposeful questions to advance their mathematical reasoning. Worth noting, Roda did not plan for this conversation about the unit whole, nor had she anticipated it. Regardless, her tool mediated activity that made it possible to do so.

Generating a space of inquiry

The second instance we present is from the problem-solving interview that Kerina conducted using the fraction tool she designed for conversations about the meaning of a fraction's denominator (see Figure 2b). Kerina's tool features "*a variety of rings which each represent different fractions (from 1/½o 1/8) that are scaled in relation to the pedestal [whole] that they go on top of.*" Each set of like fraction pieces is a *"different color, so it's easy to determine which pieces are the same size."* When fraction pieces are stacked on the pedestal, the tool provides feedback to the child that they can use to determine whether that combination is equivalent to a whole.

Kerina's fraction pieces have no identifying attributes other than color, so if a child wanted to determine what fraction of a whole is represented by a pink piece, for example, they would make that determination by seeing how many pink pieces it takes to "fill" one pedestal. If 6 pink pieces fit on a pedestal, then each pink piece would represent ⅙. This finding would give meaning to the 6 in the denominator of fractions of the form $n/6$. As she designed her manipulative, Kerina was mindful that students tend to struggle with symbolic representations of fractions, particularly in the context of adding fractions and "finding least common denominators." As an alternative, she proposed that "students' brains will work in more creative ways than we can anticipate." Accordingly, she wanted to design her tool that would accommodate such diversity and enable students to "visualize" concepts and avoid the "frustration" that purely symbolic approaches to fractions often cause.

With these intentions in mind, Kerina embeds a particularly salient feature of her pedagogy in the design of her tool that is made evident in one task that challenges a child to use the tool to "Find three different ways to make a whole." Operating in tandem with a tool that requires its users to construct their own meanings for each of its pieces, the task generated a space (Stroup et al., 2004) for the child's active, creative, and playful inquiry and insight into fraction meanings and relationships. Indeed, Kerina designed her tool for such an imagined utilization scheme in which the child, at least initially, uses trial and error to stack different pieces onto the pedestal and then "see how much space is left" before adding on more pieces to make the whole. These accomplishments would be seen as groundings (Nathan, 2014) for connections she would subsequently help the child make to symbolic representations of their tool-based activity.

In practice, we observed Kerina's commitment to her design intentions. At one point, when she posed her "Find three ways" task, the child selected pieces of the same size to place on the pedestal in order to form a whole. Kerina notices this strategy and asks the child to "Try to use ones that have different denominators." Note her use of "different denominators" as opposed to "different sizes," even though she's referencing physical objects. In doing so, she is cultivating a connection between physical and symbolic representations of fractions. At the same time, it's also important to note that Kerina had written the symbolic names of each fraction piece on its interior where they could be concealed from the child's view. Thus, she seems to have a trajectory in mind for the meaningful development of fraction proficiency from physical to symbolic representations of collections of different unit fractions. Her tool and tasks are anchoring pedagogical and conceptual knowledge that mediate her response to the child's initial activity at this moment as she supports his construction of procedural fluency on a foundation of conceptual understanding. Specifically, design elements of her tool embed conceptual knowledge relevant to that trajectory (e.g., a "complete" stack of pieces represents a sum of unit fractions equal to 1), and design elements of both the tool and the task embed pedagogical knowledge about the value of enabling multiple solution strategies in order to generate a space for open and productive inquiry.

Noticing in action

Anyango designed a fraction tool “to help the student visualize and deepen their understanding as they explored fraction relationships.” Her tool looks similar to Kerin’s and appears in Figure 2c. In contrast, however, Anyango emphasizes a different purpose for a similar affordance. She explained that her design decision to stack fraction pieces on vertical pegs rather than lining up those pieces horizontally would enable her to use those pieces to represent “height as value and amount.” “What was most important to me,” she wrote, “was having all the fractions mounted on one platform with the 1 (whole) always being visible, so that the student could begin to grasp how all the smaller parts can equate and compare to the whole.” Also in contrast to Kerin’s design, Anyango engraved the name of each piece on one of its lateral faces.

In practice, Anyango posed the following task to an intended user of her tool: *Jack and his two friends each had the same size pizzas for lunch. Jack ate 5/8 of his pizza. Judy ate 2/3 of her pizza. And Sam ate 3/6 of his pizza. Who ate the most pizza? Who ate the least?* In response, the child stacks five one-eighth pieces, two one-third pieces, and three one-sixth pieces, each on their own pedestal with their labels facing him (as shown in the image on the left of Figure 2c) and says nothing further. Following up on the child’s activity, Anyango asks, “So, if we just look at this, who ate the most?” We interpret this pedagogical move by Anyango as one that leverages her design decision to represent fractional values in terms of height by directing the child’s attention to the relative heights of the three fraction pieces. In other words, she’s prompting the child to decide which person ate the most pizza by choosing the fraction piece that is the tallest, and which person ate the least by choosing the piece that is the shortest. Counter to her expectations, the child attended exclusively to the symbolic representations engraved on each piece and not their heights. This led him to decide that, “It’s Jack” (represented by the ⅝ piece) who ate the most. He justifies his answer by saying that “5 out of 8 is the biggest of all of them… 2 out of 3 is smaller and 3 out of 6 is… kind of small.” When Anyango asks, “What makes you think it is small?” he explains that, “The top is two and the bottom is three.” We infer from this response that the child is basing his comparisons on interpretations of fractions not as parts of a whole but as two separate whole numbers. This would explain why, for the child, ⅝ is greater than 3/6, which is greater than ⅔.

We interpret Anyango’s next move as a noticing one (Sherin et al., 2010) that leverages her pedagogical knowledge about the efficacy of attending to, interpreting, and responding to student thinking. Indeed, the design of her tool embeds this knowledge, as a primary rationale for its design was to enable a child to compare fractions without having to rely on the overhead of a symbolic representational infrastructure. In a move that we interpreted as unplanned and that was therefore striking for each of the researchers to observe, Anyango turns her tool around (see Figure 2c, right) in order to hide the symbolic labels on each piece.

A(nyango): If I turn this [*pedestal*] around [*so that the child’s gaze can no longer be restricted to the fraction labels on the pieces*], who has the most?

C(hild): This one [*points to the stack of two one-third pieces, which corresponds to Judy’s share*].

A: Who has the lowest?

C: This one [*points to the stack of three sixth-pieces, which corresponds to Sam’s share*].

What we find remarkable is that while Anyango made the intentional design decision to label each of her pieces, this "flipping" move leveraged an *unintentional* design affordance, that the opposite face of each piece is *not* labeled. In this regard, we suggest that Anyango's tool served as an anchor for a pedagogical *knowing* in action mediated by that affordance. Translating Sc oncept of knowing-in-action as a noticing-in-action, we suggest that in this instance, Anyango sees what is there, makes a move in relation to it, and sees what that move accomplishes, thereby informing her next steps. In those next steps, she returns the tool to its initial, label-facing orientation so that she can connect the physical representation of amount to the symbolic one, and asks the child, "Who ate the most?" "Judy," he says with a smile, and points to her stack of fraction pieces.

Concluding Discussion

This work set out to explore teacher learning at the interface between theory and practice by discerning whether connections can be made between the pedagogical/conceptual knowledge that prospective teachers construct in teacher preparation and how that knowledge is enacted in their teaching. The following question framed the inquiry: "*As prospective teachers Make new manipulatives for mathematics teaching and learning, can connections be made between pedagogical/conceptual resources for their design decisions and how those designs mediate the pedagogical moves they make in practice?*" We pursued this inquiry by analyzing approximations of practice in order to identify instances in PMTs' teaching when their manipulative served as a mediating anchor for pedagogical and/or conceptual knowledge acquired in teacher preparation and subsequently embedded in their designs.

Findings from previous work that explored the conceptual, social, and material resources that inform the rationales for PMTs' design decisions suggest that engagement in an open-ended and iterative design experience centered on the Making of a mathematical manipulative can be formative for their conceptual and pedagogical thinking. Findings from this work extend the value of that experience by considering the use of made manipulatives in practice. Specifically, the identification of instances of anchoring phenomena suggest that the experience can also yield material epistemic scaffolding (in physical manipulative form) that supports teachers and their commitments to the models of knowing and learning they construct in teacher preparation. Relative to theory, these findings suggest the analytic value of our design, rationale, resource, and practice (DRR-P) framework for revealing the promise of such an experience. Relative to practice, they suggest that the experience offers a viable means by which more robust connections between teacher preparation and practice can be nurtured.

Mediated Field Experiences (MFEs) provide teacher candidates (TCs) structured opportunities to unpack and enact core teaching practices, gain mathematics content and pedagogical knowledge, and reflect critically on mathematics teaching and learning. In this paper we present findings from a multi-institutional descriptive pilot study that investigates the impact of MFEs on TC learning. TCs reported that they (1) deepened their understanding of the targeted core teaching practice(s), (2) developed a vision of ambitious mathematics teaching, (3) recognized the importance of cultivating a positive classroom learning community, and (4) increased their confidence when teaching after their completion of a one-term course implementing MFEs.

Keywords: Preservice Teacher Education, Instructional Vision, Teacher Beliefs

Efforts to improve the preparation of teachers are not new, and recent publications have begun to define the knowledge, skills and dispositions of a "well-prepared" beginning teacher of mathematics to provide ambitious mathematics instruction (AMTE, 2017). By definition, ambitious teaching facilitates a learning environment that is accessible to all students because it requires that teachers teach in response to students' thinking and actions (Kazemi et al., 2009; Cawn, 2020). Beginning teachers are increasingly expected to teach ambitiously from day one (Anagnostopoulos et al., 2020), which requires teachers to engage deeply with each student's thinking and adjust their instruction accordingly to promote student learning—actions that are predicated on creating an environment that is accessible, strengths-based, and community oriented (Yeh et al., 2017). Creating such equitable spaces and enacting such practices is challenging. In particular, learning to listen effectively and respond to the variety of factors specific to students' thinking "is surprisingly hard work" (Empson & Jacobs, 2008, p. 257) requiring immense amounts of support during teacher preparation. We, along with others (Ball & Forzani, 2011) argue that attending, interpreting, and responding appropriately to students' mathematical thinking is a specialized pedagogical skill that needs to be explicitly taught within teacher preparation programs.

To meet this challenge, we re-envisioned our own mathematics content and methods courses, modeling our approach on the practice-based "third spaces" (Zeichner, 2010). In each of our respective initial certification programs, we as mathematics teacher educators (MTEs) now accompany our teacher candidates (TCs) into authentic classroom settings to prepare, enact, and reflect on practice in shared classroom spaces. These *mediated field experiences* (MFEs) have provided incredible opportunities for TCs to learn with and from children (Billings et al., 2021; Billings & Swartz, 2019; Campbell, 2012; Campbell & Dunleavy, 2016; Horn & Campbell, 2015; Knapp et al., 2018; Lynch et al., 2019). MFEs are intentionally structured opportunities for beginning teachers to (1) learn about core practices in teacher preparation coursework, (2) implement those practices during a facilitated K-12 classroom experience, and (3) debrief the classroom experiences as a whole group with teacher educators and at times with the partner teachers to build a shared vision of ambitious and accessible mathematics instruction. MFEs address a critical need for supporting TCs to develop ambitious teaching practice through partnerships with local K-12 schools, while embracing the power of appropriate struggle as an opportunity for learning and growth. When MTEs support and engage TCs in productive struggle to make sense of and develop the skills of ambitious teaching through their work with K-12 students, an opportunity for TCs' development occurs that they would not experience in a university classroom setting alone. This paper presents our findings from a descriptive pilot study investigating TCs' perceived learning from our MFE courses that supported TCs in this productive struggle of learning about and enacting ambitious mathematics teaching.

Conceptual Framework

This research team joins a growing body of educational research (e.g., Ball et al., 2014; Ghousseini & Herbst, 2014; Lampert et al., 2010; McDonald, et al., 2014; Santagata & Yeh, 2014) that explores what has been characterized as "the turn to practice-based education" (Zeichner, 2012). The premise of these studies is based on the belief that in order to better support TCs to learn to *do* ambitious teaching we, as MTEs, need to teach them both the interactive skills required to engage students in meaningful mathematics work, and flexibility to use this knowledge in particular moments of practice. Like others, we argue preparing TCs for doing the complex work of ambitious mathematics teaching requires we implement *different* pedagogies of teacher education in *deliberate* ways that make the practice of teaching a central focus.

Practice-based learning describes types of field experiences that situate TCs' learning in K-12 classrooms coupled with coursework focusing explicitly on the work of teaching (Forzani, 2014). Grossman et al. (2009) describe how a core-practice approach in teacher education necessitates organizing coursework and fieldwork around core practices of the teaching profession while simultaneously providing TCs ample opportunities to "practice" enacting these teaching practices in structured and supported ways. Other research within the teacher education community has identified "core" or "high-leverage" teaching practices that effective teachers use while teaching (i.e., Ball & Forzani, 2009; McDonald et al., 2013; NCTM, 2014) and we draw on these in this paper. By purposefully designing teacher preparation coursework to include the pedagogies of enactment that have MTEs side-by-side with TCs in a K-12 school setting, we are working to develop TCs' understanding of such core teaching practices and know how to enact them skillfully.

An important factor in redesigning our teacher preparation courses, we drew on McDonald et al.'s (2013) learning cycle (Figure 1) to illustrate how core practices are embedded into the MFE design and developed across the four phases. The four phases of the learning cycle provide structured supports to develop TCs' understanding and enactment of such teaching practices by: (1) learning about the instructional activity (including envisioning the practice), (2) preparing for enacting the activity (including rehearsing), (3) having opportunities to enact that practice via the activity in authentic classroom settings and (4) analyzing those enactments as a way to connect the educational theory to the classroom practice. The learning cycle puts core practices into conversation with a vision of professional learning (McDonald et al., 2013) and gives a structure for MTEs to support TCs learning to understand and skillfully enact core practices.

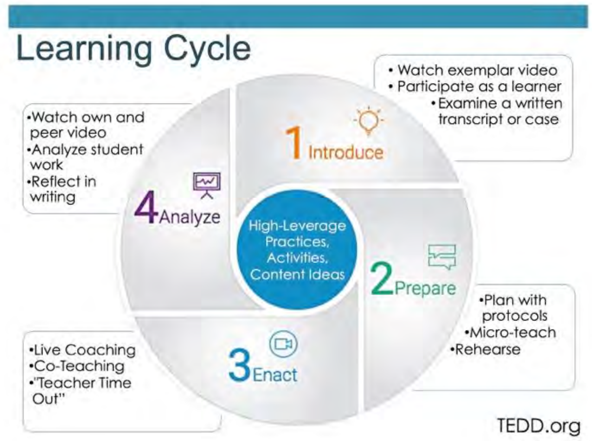

Figure 1. Cycle for learning "core" or "high leverage" teaching practices

To support TCs' understanding of ambitious teaching in each of our courses, we focused on at least one of the National Council of Teachers of Mathematics (NCTM, 2014) eight research-informed effective (core) teaching practices. These practices represent "a core set of high-leverage practices and essential teaching skills necessary to promote deep learning of mathematics" (NCTM, 2014, p. 9), examples include: facilitating meaningful discourse, supporting productive struggle, and eliciting and using evidence of student thinking.

Methods

In this paper we present the findings from a multi-institutional descriptive pilot study investigating the impact of MFEs on TCs' learning. This work is a collaboration between five different colleges and universities where MTEs teach either integrated content-pedagogy or methods courses implementing MFEs. To document the shared learning outcomes of the TCs enrolled in our courses implementing MFEs, we analyzed TCs' written reflections. The research question guiding this study was: What do TCs report in their end-of-course reflections, where MFEs were enacted, as most impactful for their learning to teach mathematics?

Context and Participants

Data collected included TCs' written reflections of the MFE experience. Each institution had a different context for the course and grade level focus for the MFE. Two institutions situated MFEs in elementary methods courses, while one university incorporated the MFEs in an integrated content and pedagogy course for elementary teachers. The other two universities placed MFEs in middle-grades methods courses. Additionally, the MFE at each institution focused on a different subset of core practices. This data collectively represents 97 TCs and their responses to culminating course assignments related to MFEs.

Data Collection and Analysis

The data collection spanned one to three terms of the courses across the five institutions, comprising a collective repository of written artifacts from each course. These end-of-term written assignments asked TCs across all institutions to share the most impactful aspects for their learning during the term and what aspects of this learning they plan to bring to their future classrooms. We aggregated all TC responses across institutions to have a reasonable sample size (97 TCs) and to look for themes across the MFE and independent of the institution/instructor.

We utilized the six phases of thematic analysis (Nowell et al., 2017) to create and apply codes to the entire data set. For the first phase of thematic coding, familiarizing ourselves with the data, we met weekly to discuss theoretical perspectives of the data set and brainstorm potential themes and codes by looking at the common reflection prompts in course assignments as well as elements of the NCTM effective teaching practices. After examining our own data sets and drafting initial themes of each individual data set, we used peer debriefing to generate initial codes (phase two) and utilized our theoretical framework to organize our codes into logical clusters. Using elements of analytic induction (Erikson, 1985), we used confirming and disconfirming evidence to verify the existence of each emerging theme. In phase three, we searched for themes, documenting any excerpts from the data that seemed problematic for the next phase of peer debriefing. At this point the group entered phase four and five, reviewing themes and defining and naming themes. In this process, we cross examined data sets both collectively and individually, discussing examples from all data sets to determine working definitions to accurately depict the data and align with our theoretical framework. We then divided the data by codes and individually re-examined individual code applications. The group continued to reconvene for peer debriefing addressing any anomalies in the data and reconciling codes as needed. In this iterative process, code application was triangulated by individual researchers taking on different codes in each analysis. Finally, in phase six of thematic analysis we present our final analysis. For the purposes of this paper we are using a subset of our codes utilizing findings related to TCs' reporting related to ambitious teaching and the number of TCs referring to these practices within our data set. The coding scheme was further expanded as other themes and elements emerged from the data (e.g., TCs' attribution to distinct phases in the learning cycle).

Findings

In this descriptive pilot study, we sought to identify any common learning outcomes identified by the TCs in our courses due to the common implementation of MFEs. TCs reported that they deepened their understanding of the targeted core teaching practice(s), developed a vision of ambitious mathematics teaching that aligns with NCTM's vision, recognized the importance of cultivating a positive classroom environment, and identified the importance of knowing students and building on students' knowledge when planning and/or teaching along with an increase in confidence when teaching. The common learning outcomes identified by a threshold of at least one-quarter of all TCs in the study are presented in Table 1.

Table 1: TC's Self-Reported Most Impactful Aspects of Learning in Courses with MFEs

TCs' Learning as Reported in Open-Ended Reflection Question	**# of TCs**	**%**	**Representative Quote**
Core teaching practice that was a focus of MFE	82	85%	*This class has taught me the importance of asking purposeful questions to students to elicit deeper thinking and to help connect the math.*
Teaching mathematics in ways that align with NCTM's vision	56	58%	*Another one of the eight practices that really change[d] my mind about math was facilitating meaning for mathematical discourse. Instruction that is focus[ed] on mathematical discourse engages students as active participants and making sense [of] mathematical ideas and raising of a mathematical relationship.*

Importance of creating positive classroom environment	55	57%	*..I will be important to create a community among my students, sharing the idea that it's okay to not understand, and we can support each other in the process of learning through respectful discussion, and sometimes debate.*
Importance of knowing students as people/learners	34	35%	*I learned that in order to understand your students, you must get to know them. I had the opportunity to get to know my math buddy well, along with several other students we worked with when co-teaching some of the math lessons. Getting to know these students gave me insight to how they each learned and what I could anticipate from them in order to prepare in a way that would support their learning.*
Importance of building on students' knowledge in planning or teaching a lesson	34	35%	Planning: *I feel as though my lesson planning has improved. Anticipating student strategies and misconceptions has helped me figure out in advance the kinds of questions I might ask, what student work might look or not look like, and what group conversations might sound like.* Teaching: *Another important aspect of math that I have learned throughout this semester is allowing students to work through their thoughts before jumping in and correcting/helping them. I have a tendency to interrupt students as soon as they start to make a mistake, but this course has taught me that these mistakes are crucial to student thinking.*
Confidence in teaching or teaching mathematics	27	28%	*Reading the textbook and putting the concepts into action at* [site of MFE] *has raised my own confidence about teaching math as I have watched my math buddy overcome his own hurdles and enjoy problem solving.*

Core Teaching Practices and Additional Learning

Across each of our courses, all five MTEs focused on a subset of NCTM's (2014) eight effective teaching practices as our "core practice." Given the variety of the courses and MTE's learning goals for each of their respective courses, no particular core practice emerged as key. However, it is notable that 83% of the TCs highlighted the importance of at least one core practice for students' learning or self-reported they improved in their enactment of the practice: the specific core practices named corresponded to those that were a focus of the iterative MFE cycle in their respective course. For instance, in a methods course that focused on the connections across all eight ETPs, a TC wrote:

> Often, you can utilize multiple teaching practices by doing one thing. Using mathematical representations helps elicit thinking, which they then use to engage in discourse. While this is all being done, they might be engaging in productive struggle. Seeing how everything ties in together makes it far less intimidating.

Whereas in a course that emphasized a subset of NCTM's core practices, and one core practice was the focus of multiple iterations of the MFE so TC could have multiple ongoing opportunities to hone and enact this core practice, TCs reflected about learning specific to that core practice. For example, where posing questions was the targeted core practice, this representative quote highlights TCs' self-reported learning:

> My observation of [our partner classroom teacher], along with my new found knowledge of the power of questioning, has encouraged me to implement questioning into my own practice. I have put an emphasis on using questions as a tool to uncover student understanding, much like [partner classroom teacher]. This small change has dramatically changed my interactions with students. Instead of telling students how to fix their mistakes, I ask students to take me through their thought process.

In addition to reporting on their deepened understanding of the targeted core teaching practices of the course, TCs wrote that they learned about the importance of the classroom environment, knowing their students, and incorporating their students' thinking into their lessons. They also envisioned a supportive and productive mathematics classroom that included positively framing students as capable mathematicians, providing access for all students to learn mathematics including choice, and incorporating a growth mindset where mistakes are viewed as essential aspects of learning. Almost 60% of the TCs across all five institutions described their vision for teaching mathematics in ways that align with NCTM's vision (when they chose to describe that vision; not all TCs described their vision in this open-ended question). In these end-of-the-term reflections, many TCs described what a positive mathematics classroom environment looks like, sounds like, and feels like for every student and reflected on how important these aspects are for ambitious mathematics lessons. Lastly, almost 30% of the TCs mentioned an increase in their confidence in teaching after just one term of a course implementing MFEs.

Impact of the MFE Structure

85% of the TCs specifically named at least one aspect of the learning cycle structure as impactful for their learning, and roughly one-quarter explicitly pointed to the specific feedback received, including peer, partner classroom teacher, and MTE feedback, as reported in Table 2. Collectively, TCs specifically named each phase of the learning cycle as important for their learning. For approximately one-fifth of the TCs, the impact of experiencing the lesson themselves, before enacting with students during the *Introduce Phase*, was highlighted. Approximately one-third of the TCs pointed to the *Prepare Phas*e, and co-planning with peers and/or receiving feedback from the MTE in preparation for teaching, or *Analyze Phase*, where TCs reflected about their experiences and debriefed about their experiences working with students both through discussion and individual writing assignments facilitated by the MTE, as essential. The phase identified the most often as impactful was the *Enact Phas*e of the learning cycle. TCs attributed their experiences of teaching and working directly with students as key for connecting theoretical (course) learning with the practice of teaching.

Table 2: TC's Self-Identified Impact of the MFE Structure on their Learning

TCs' Attribution of Learning to MFE Structure	# of TCs	%	Representative Quote
TCs attribute learning to at least one aspect of the learning cycle	82	85%	*Having the opportunity to put my teaching into practice within [partner classroom teacher's]class has helped me to grow and adapt to become a better teacher in the future. Three areas that I have grown throughout this semester are planning and organizing lessons, creating*

			and implementing student-centered learning experiences and creating a positive learning environment.
Introduce Phase	18	19%	*I found it useful putting ourselves in the student position first in doing the lesson we were about to teach to the students, it helped us become flexible, intuitive, and help to predict student reactions and areas of struggle.*
Prepare Phase	29	30%	*During our own planning of the Three Reads Lessons, my team was able to determine what materials to provide students that would be the most helpful. For example, one of our problems had numbers that were too big to use cubes like we had done the week before. If we had not planned out the lesson, then we might have given students manipulatives that made the problem harder for them instead of helping them make sense of the problem. In short, a solid plan makes a solid lesson.*
Enact Phase	53	55%	*I think the aspect of being able to apply what we learned every week by physically teaching it to our students had a heavy impact on my learning.*
Analyze Phase	30	31%	Live: *We were able to debrief after every lesson … and that really helped bring everything we did and learned together.* Written: *As much as I didn't honestly enjoy doing math reflections every week, they were actually very helpful. They helped me not only analyze what students were understanding and how they came about the answers that they had gotten, but it also helped me know what things I should add to the next lesson in order to ensure better understanding and more successful instruction. It helped me to see what parts of my instruction were successful, unsuccessful, or what I needed to include in my next lesson to better reach the students.*

In addition to attributing their learning to the specific phases of the learning cycle, 27% of the TCs identified feedback during at least one aspect of the learning cycle as impactful. Most notable, TCs highlighted feedback during the *Enact Phase*, when a teacher time-out was called and the TC conferred with either their TC partner, the MTE, or the classroom teacher to solicit support and confer about what to do next, in that moment. Others pointed to the specific feedback received during the *Analyze Phase*, either (1) during the debrief as they shared instructional moves and received verbal feedback from their partners/peers or the MTE or (2) written feedback on assignments given at the conclusion of the cycle for TCs to continue reflecting and analyzing their learning. Because MFEs provide that *shared* and authentic teaching experience, TCs are able to receive feedback across all phases of the learning cycle (e.g., on their planning, teaching, *and* reflecting) from the MTE, the partner classroom teacher, and their peers, to which many credit their deepened understanding and improved enactment of these core teaching practices and other important aspects of the course (e.g., positive classroom community).

Discussion and Implications

Working in authentic classroom environments within the MFE structure, where TCs' productive struggle was supported through the iterative structure of the MFE and feedback across all phases of the learning cycle, provided TCs with a working vision of ambitious mathematics instruction. In addition to identifying how their understanding of core teaching practices and their impact are essential for teaching and learning, they reported this approach impacted their appreciation and aspiration of a productive mathematics classroom environment where students are central, viewed as capable learners and where the teacher actively plans and teaches lessons to build upon their students' ideas.

The MFE structure offers unique means of supporting the development of beginning teachers' practice and awareness of ambitious mathematics teaching (Campbell, 2012; Campbell & Dunleavy, 2016; Horn & Campbell, 2015). The TCs' self-reported understanding or growth in enacting targeted core teaching practices and cited how various phases of this iterative learning cycle supported their understanding and enactment of these practices. This suggests the MFE structure is effective for developing TC's knowledge and awareness of the importance of these core practices for teaching mathematics. Further study is needed to ascertain how effective this instructional approach is for their proficiency in enacting these teaching practices.

The MFE provides a promising pedagogical approach for preparing beginning teachers. TCs, through this structured learning experience, identified at the end of the course, without explicitly being prompted, specific core teaching practices and characteristics of a classroom that provide access, support and challenge for their students, an essential standard in the preparation of math teachers (AMTE, 2017, p. 13-Indicator C.2.1). In addition, the learning cycle and structure of the MFE provided iterative opportunities for TCs to: "plan for effective instruction" (p. 14, Indicator C.2.2), "use a core set of pedagogical practices that are effective for developing students' meaningful learning of mathematics" (p. 15, Indicator C.2.3) and "analyze teaching practice" (p. 16, Indicator C.2.4) as the MTE provided feedback and support to TCs at all phases of the learning cycle. The MTE served to mediate tensions arising as TCs were asked to apply and integrate their theoretical learning about mathematics and ambitious teaching through the practice of teaching (Billings et al., 2021). What we are asking TCs to do is a challenging way of teaching: it is notable that more than one-quarter of TCs self-report they developed confidence to teach this way. We attribute this in part to the highly supportive MFE environment.

A limitation of this study is that TCs self-identified aspects of their learning, and thus areas of learning may not have been reported. The open-ended nature of the questions did not guide the TCs to reflect on specific course learning objectives. Consequently, TCs may have acknowledged growth in an area, such as confidence, if directly asked, but may not have reported a growth in this area due to the nature of the questions posed. Revision of the data collection tools, explicitly asking TCs to report about specific areas of learning, are needed for future study about the impact MFEs have on TCs' learning. Looking forward, we hope to document TCs' perceptions of the impact MFEs have on their learning during their preparation and follow TCs into the field to investigate their enactment of the ambitious teaching practices into their own classrooms.

To support productive struggle, prospective secondary mathematics teachers (PTs) need to elicit and respond to students' mathematical ideas in ways that focus on those ideas and that position students to build on those ideas. Using the Teacher Response Coding framework (Van Zoest et al., 2021) we analyzed PTs' responses in three rehearsals of instruction. We identified significant differences in the natures of responses in one rehearsal compared to the other two. Using a Levels of Constraint framework based on findings of Kavanagh et al. (2020) we compared structures of the rehearsals and developed hypotheses regarding which aspects of structure might account for differences in PTs' responses.

Keywords: Classroom Discourse; Instructional Activities and Practices; Preservice Teacher Education

Over multiple decades, mathematics education researchers have identified mathematics teaching practices that aim to use and build on student thinking. Particularly, practices that invite students to share and elaborate their thinking (Franke et al., 2009) and that build on student thinking by asking students to connect their thinking to others' ideas (Smith & Stein, 2018) have been shown to support student learning (Webb et al., 2014). One goal of teacher education is to support prospective teachers (PTs) in developing such practices. Yet there is often dissonance between what prospective teachers learn about teaching in their professional coursework and the teaching that they have opportunities to enact and witness in field placements (Grossman et al., 2009). In response, MTEs have developed approximations of practice (Grossman et al., 2009) in which PTs to interact with simulated or authentic students (e.g., Arbaugh et al., 2019; Lampert et al., 2013). Our use of *approximations of practice,* in this context, is meant to describe events that occur in a context that is similar to authentic classroom teaching but less complex, less authentic, and more controlled. In theory, such opportunities provide contexts for PTs to engage in teaching practices, such as eliciting and responding to student thinking, in settings that are less complex than those in which teaching typically occurs. However, approximations of practice differ with regard to multiple features, including how students are embodied and by whom, and the duration of the experience. The purpose of this study is to examine how differences in the structure of approximations of practice relate to differences in how PTs engaged in teaching within those approximations of practice.

We report our empirical investigation into the following research questions:

1. How do the ways that PTs respond to student thinking within approximations compare across approximations of practice that differ in structure?

2. What aspects of structure of approximations of practice might account for differences in the ways that PTs respond to student thinking?

Theoretical Perspectives

Our study is situated at the intersection of research and scholarship on how teachers respond to instances of student mathematical thinking and research and scholarship related to the use of approximations of practice in mathematics teacher education. In the next two sections we share the perspectives informing this study.

Perspective on Teacher Responses

In a thorough review of literature on researchers' ways of examining teacher responses, Van Zoest et al. (2021) identified three core aspects that describe productive teacher responses: the "who, what, and how" of a response. In other words, *who* in the classroom is asked to publicly interact with a student's mathematical contribution (SMC)? *What* actions do classroom member(s) get to take with respect to the SMC? And *how* does the teacher's response relate to the substance of the SMC? For students to engage with each others' SMCs, it is important for teachers to attend to SMCs in their responses and for teachers to position students to take action on the mathematical idea contained in the SMC (Bishop et al. 2020; Robertson et al. 2016).

Perspective on Approximations of Practice

Grossman et al. (2009) described the nature of professional learning in human improvement professions, including teaching, in terms of three constructs: Representations of practice, decompositions of practice, and approximations of practice. We define an approximation of practice as an activity that is similar to, but not identical to, typical activities of a professional teacher, such as participating in a simulation of an interaction with students around mathematics content. Engaging in approximations of practice provides PTs with opportunities to act as teachers in a context designed to resemble an instructional interaction. Approximations of practice aim to support PTs to learn in and from practice (Lampert, 2010). Based on the positions taken by others who have worked in this area, we argue that the use of approximations of practice in mathematics methods courses is guided by three principles. First, PTs need repeated opportunities to engage in practices that are challenging for novices (Grossman et al., 2009), such as responding to student thinking. Second, rehearsals must increase in complexity across consecutive rehearsals by involving more authentic classroom interactions, broader components of instruction, and less intervention from the teacher educator (Boerst et al., 2011; Grossman, 2009). The third principle is that a teacher educator (TE) must mediate PTs' experiences in an approximation. This includes representing teaching in terms of significant practices (e.g., Grossman et al., 2009) to support the PTs' "development of situationally appropriate knowledge and skill" (Lampert et al., 2013). Mediation is significant because it can shape what teachers attend to within an approximation and how they respond (Kavanagh et al., 2020).

Methods

Context of The Study

We report the results of an analysis of prospective teachers' responses to SMCs within three approximations of practice conducted across a single semester in a secondary mathematics methods course at a large public university in the mid-Atlantic region of the United States. Each approximation occurred within a learning cycle (Lampert et al., 2013) in which PTs engaged in a mathematical activity, examined representations of teaching the activity, planned to teach an activity, enacted that teaching within the methods course, and reflected on their experiences (see Arbaugh et al., 2019). These activities were all focused on a set of communication moves (Freeburn & Arbaugh, 2017) that served as a decomposition of eliciting and responding to student thinking. We focus our study on the planning and enactment within each cycle in which PTs focused on developing those communication moves. We refer to a *rehearsal* as an approximation of practice in which PTs, in the role of teacher, interact with one or more individuals in the roles of students, whom we call Enacted Student(s) (ES). We designed each rehearsal to align with the three guiding principles described in the theoretical perspectives. Figure 1 provides a summary of the intended variations in structure across the rehearsals.

Element	**Rehearsal 1**	**Rehearsal 2**	**Rehearsal 3**
Ratio Teachers: Students	2:1	1:2	1:7
Intended Duration	6 minutes	3 minutes	15 minutes
Enacted Student(s)	Elif or Lewis	Elif and Lewis	Small Group of Peers
Student Behavior	The ES is partially finished with the task at the start of the rehearsal	The ESs believe they are finished with the task at the start of the rehearsal	ESs begin the task at the start of the rehearsal
Student Work	Student work constructed prior to and during the rehearsal	Student work constructed prior to and during the rehearsal	Student work constructed during the rehearsal
Mathematical Task	Textbook task focused on linear functional relationships	Construct an argument for a given number theoretic claim	Textbook task focused on exponential functional relationships or statistics

Figure 1: Intended Variations Across Rehearsals

Prior to each rehearsal PTs received a copy of the task that would frame their conversation with one or more ESs. PTs did the task and then planned in small groups to enact the task in their rehearsals. In RH2, PTs received copies of partially-complete student work before the rehearsal. We did not provide partially-complete work prior to RH1 or RH3. In Rehearsal 1 (RH1) and Rehearsal 2 (RH2), PTs interacted with Elif or Lewis, who were graduate students portraying ESs based on protocols that we designed to guide the representations and student misconceptions that the graduate students would enact during the rehearsal. In Rehearsal 3 (RH3), peers were the ESs that were engaging with the mathematical task for the first time.

Data Collection and Analysis

We analyzed transcripts of video-recorded rehearsals for three pairs of PTs. Each pair participated in RH1 together, and then in RH2 and RH3 as individuals, which resulted in a total of 5 rehearsals per pair and 15 rehearsal videos as data for the study. We also analyzed artifacts of class sessions (e.g., boardwork, handouts, and other such artifacts) as well as statements made verbally or in writing by the research team during their planning sessions.

We analyzed data in three phases. In Phase 1 we analyzed recordings of our planning sessions, video-recordings and artifacts from the class meetings preceding each rehearsal, and video records of rehearsals using a framework based on the findings from Kavanagh et al. (2020) which delineated four elements of rehearsals that can vary in degrees of scaffolding:

- *disciplinary content* (e.g., task, learning objective)*,*
- rehearsing teacher's *instructional routine,*
- *texts/tasks* used in the rehearsal*,*
- and TE *facilitation moves.*

Kavanagh et al. further delineated each element along a dimension of constraint ranging from *loosely constrained* to *tightly constrained,* depending on the extent to which decisions related to that element are made by the TE or left open for the PT to decide. We analyzed the design and enactment of each rehearsal to characterize levels of constraint with respect to each of the elements from Kavanagh et al. (2020). Our analysis led us to extend to two additional elements, which we describe in the findings.

In Phase 2 we applied a subset of the Teacher Response Coding Scheme (TRC; Van Zoest et al., 2021) to video transcripts to analyze PTs' responses to each ES mathematical contribution. The subset of the TRC is composed of three categories of codes that align with the *who*, *what,* and *how* facets of teacher responses described in our perspectives section. We coded a total of 304 PT responses across the three rehearsals and compiled contingency tables that reported the frequency of each code in each category of the TRC across rehearsals.

Category Description	**Code Descriptions**
Actor (Who?): The person publicly given the opportunity to consider the instance of SMC.	**teacher, same student(s), other student(s), whole class**
Action (What?): What the actor is doing or being asked to do with respect to the instance of SMC.	**check-in** (elicits self-assessment or understanding of a SMC), **clarify** (asks an actor to make an SMC more precise), **collect** (asks an actor to contribute a new or alternate SMC), **connect** (asks an actor to connect an SMC to a previously introduced idea), **develop** (asks an actor to build on an SMC)
Student Ideas (How?): The extent to which the student who contributed the instance of SMC is likely to recognize their contribution in the teacher response.	**core** (the response explicitly references the SMC), **peripheral** (the SMC is implicit but recognizable in the response), **other** (the SMC is not recognizable in the response), **not applicable** (SMC can not be inferred or the teacher response is too vague)

Figure 2: Subset of TRC Categories and Codes

In Phase 3 we compared differences in proportions of codes in the three categories of Actor, Student Idea, and Actions pairwise between the rehearsals. Because our goal was to examine the development of practices that engage students in sharing ideas and in building on their own and others' ideas, we grouped codes for Actor into student-centered codes (e.g., student, other student(s), and whole group) and teacher codes, and grouped codes for Student Idea into two groups: Core/Peripheral versus Other/Not Applicable. We used Chi-Square Tests of Independence (p=0.05) to test for significance of differences related to Student Idea and Actor. Because there are 15 distinct codes for Actions in the TRC, the Chi-Square test becomes inappropriate (28 degrees of freedom with many small expected values. Therefore, we identified those Actions that accounted for 10% or more of the codes in each Rehearsal and compared the results across Rehearsals.

Results

Finding 1: RH2 Was Constrained Differently From RH1 and RH3

Our analysis revealed that RH2 was constrained at a different level from RH1 and RH3 in five elements: *Disciplinary Content, Text/Tasks, Student Work, Instructional Routine,* and *Pedagogical Learning Objectives*. We found the *Facilitation Moves* element had the same level of constraint across all three approximations. We elaborate in the next few paragraphs.

Disciplinary Content: Learning Objectives. In RH1 and RH3, PTs constructed the mathematical goals for student learning based on mathematical content and practices that the PTs identified while working through their respective mathematical tasks. In contrast, for RH2 the TE identified and communicated the mathematical learning goal to the PTs during the planning class session prior to the rehearsal.

Texts/Tasks: Mathematics of the Tasks. The TE scaffolded PTs' engagement with the mathematics of the tasks differently in RH2 than in RH1 or RH3. In preparing for RH1 and RH3 the TE did not constrain PTs' activities to focus on the mathematical content or practices involved in the task. Mathematical ideas in the tasks surfaced when PTs asked questions during their planning. For example, one group shared the difficulty they were having with creating questions in preparation for RH1 because they were uncertain of student approaches. The TE responded, "So, one way you may approach those is to think about what the mathematical goal is. Then, go back to your assessing questions and examine how well these questions help me to understand where the student is with respect to that goal." However, in preparing for RH2, the TE pushed PTs to stipulate criteria for acceptable student responses and to explicate multiple ways that students might engage in the task. The TE also engaged PTs in constructing arguments and critiquing arguments.

In addition, there was a difference in the nature of the mathematical tasks for the rehearsals. The mathematical tasks in RH1 and RH3 were both selected from units in the *Connected Mathematics Project* (Lappan et al., 2002) that presented questions about a realistic scenario in order to develop the mathematical content, such as linear versus exponential growth or measures of center in data sets (see Figure 1a for one example). While mathematical content was certainly involved in the RH2 argumentation tasks (Figure 1b), the nature of the task was oriented more towards mathematical practices than content.

a.cerpt from *Moving Straight Ahead Task* (Lappan et al., 2002b, pp. 24–25) from RH1.

1.

Cycling time (hours)	Distance (miles)		
	José	Mario	Melanie
0	0	0	0
1	5	7	9
2	10	14	18
3	15	21	27

b.) **Perfect Squares Task from RH2.**

Write an argument for the claim, "the product of perfect squares is a perfect square".

1. a.) How fast did each person travel for the first 3 hours? b.) Assume that each person continued at this rate. Find the distance each person traveled in 7 hours.	

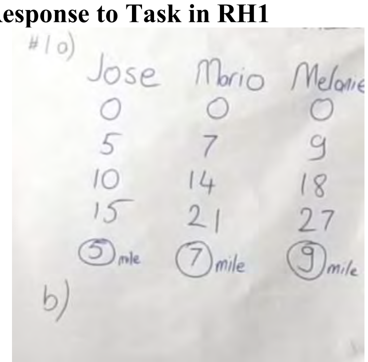
Figure 3: RH1 and RH2 Tasks

Instructional Routine: Discussion Structure. In RH1 and RH3 the TE did not stipulate a prescribed discussion structure for PTs' interactions with ESs. TE instructed PTs to ask questions to elicit ESs' thinking and to support their progress towards the mathematical goals of the activity, but otherwise left it to PTs to decide the structure of their interactions with ESs. However, in the planning session for RH2, the TE directed PTs specifically to facilitate a conversation between two ESs to support their progress in constructing a valid argument. The TE directed,

> You are to work with these two students to get them to talk to each other in a way that takes the arguments they've crafted and help them make progress . . . in writing a valid argument by connecting the representations together. . . . Questions you are asking are not just for you to get information . . . but also to get them to give information to each other . . . . The arguments don't have to be the same [by the end of the rehearsal] but they need to be coordinated.

Student Work: Availability and Amount. RH2 was more constrained than RH1 or RH3 with respect to 1) how PTs accessed student work and 2) the extent to which student work represented a "finished" product. In RH2 the TE provided PTs with ESs' arguments the day before the rehearsal as a resource for their planning (see Figure 2a). The work was presented as each ESs' "finished"''rgument for a given claim. In RH1 and RH3, however, PTs' first encounters with ESs' work was during the rehearsals, and the presented work was that of a student(s) still in the process of completing the task (see Figure 2b).

a.**if's Partial Response to Task in RH1**



2.

b.) **Lewis's Argument in RH2**

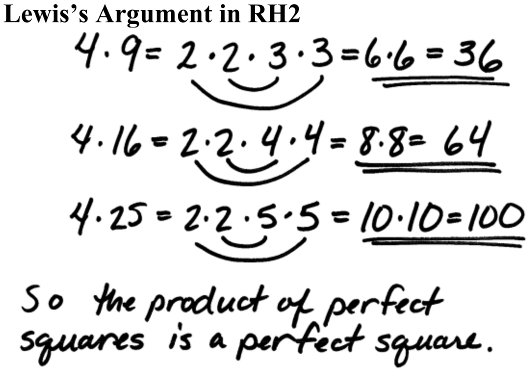


Figure 4: Samples of Student Work from RH1 and RH2

Finding 2: PTs Positioned Actors Differently in RH2 than in RH1 or RH3

The contingency table shown in Table 2 presents the number of PT responses that we coded from each rehearsal in the Student Idea category and in the Actor category. The extent to which responses explicitly incorporated student ideas does not appear to depend on whether the responses occurred in RH1, RH2, or RH3 (X^2 (2, N = 304) = 2.42, p = .30). However, the proportion of PTs' responses that positioned students as actors was significantly different across rehearsals (X^2 (2, N = 304) = 25.9, p <0.05). Closer examination revealed that the proportion was significantly different in RH2 than in either RH1 (X^2 (1, N = 111) = 12.15, p < 0.05) or RH3 (X^2 (1, N = 247) = 29.44, p <0.05), but not between RH1 and RH3 (X^2 (1, N = 250) = 4.365, p = 0.113). We interpret this as evidence that some aspects of RH2 must have supported a different kind of response pattern, not with respect to student ideas, but in terms of the extent to which students were invited to consider and to build on their own and others' ideas.

Table 1: Contingency Tables of Codes in Student Ideas and Actor Across Rehearsals

Coding of Response for Student Ideas	RH1 (n=57)	RH2 (n=54)	RH3 (n=193)
Student Idea: Core or Peripheral	44	37	128
Student Idea: Not applicable or other	13	17	65
Coding of Responses for Actor			
Teacher	26	10	111
Student(s)	31	44	82

Finding 3: Responses Involve A Broader Set of Actions In RH2 than in RH1 or RH3.

As shown in Table 3, PTs' responses in RH2 had the greatest variety of *actions* with relative frequencies of 10% or above. We found this somewhat surprising, given that PTs had the least amount of time (three minutes) to interact with Elif and Lewis in RH2 than with students in RH1 or RH3 (6 minutes and 15 minutes respectively). The *develop* action was the most frequent action across all three rehearsals. These actions were ones in which the PT expanded or requested ES(s) to expand on an ES's contribution.

Table 2: Most Frequent Actions Across Rehearsals

	Check-in	Clarify	Collect	Connect	Develop
RH1 (n=57)	**	8 (14.04%)	**	**	26 (45.61%)
RH2 (n=54)	6 (11.11%)	7 (12.96%)	9 (16.67%)	9 (16.67%)	12 (22.22%)
RH3 (n=193)	**	**	25 (12.95%)	**	55 (28.50%)

Discussion

If we characterize PTs' capacity to build on student thinking in terms of their observed patterns of response via the TRC scheme, our findings suggest that progressive increase in complexity and authenticity across approximations is insufficient to account for differences in the patterns of their responses within the approximations --in fact, variations in constraints across other elements of the approximations seem to better explain those differences. We found that

PTs' responses in RH2 were directed more at students and involved a greater repertoire of actions than in either of RH1 or RH3. When we examine the structures of approximations through the lens of levels of constraints with respect to some elements (Kavanagh et al., 2020), we find ways that RH2 was more constrained than RH1 and RH3--namely, in terms of *disciplinary content, texts/tasks, instructional routine,* and *student work*. Our findings further support the findings of Kavanagh et al. (2020) which suggested that more tightly constrained rehearsals might explain differences in how PTs engage in those rehearsals.

Grossman et al. (2009) used the metaphor of "learning how to kayak in calm waters" (p. 2076) to describe the notion of learning to engage in complex practices in environments of decreased complexity. Kavanagh et al. (2020) used this metaphor to describe how various constraints serve to calm the waters for novices by constraining the complexity of the context in which they engage in approximation of practice. We also find this metaphor helpful for thinking about how some of the constraints may be related to differences in the PTs' responses.

Truly learning to kayak involves learning to navigate toward a destination while considering and choosing among multiple possible routes. The constraints in *disciplinary content, texts/tasks, and student work* that we identified in RH2 may have served to support the PTs by making explicit the destination (the learning goals and the criteria for evaluating students' arguments) and anticipated routes (potential ways that students might approach the task, and the specific discursive structure to use in the rehearsal) that they might experience within the rehearsal. For *disciplinary content*, the MTE established a well-defined and common mathematical destination for the PTs to focus their students towards in RH2. Additionally, they had more scaffolded experiences working with mathematics related to the *texts/tasks* and *student work* of RH2 than in RH1 and RH3. In preparing for RH2, PTs were able to become more familiar with the mathematics of the rehearsal tasks and the ways students might approach the task. Having a greater understanding of the mathematical goal and of the multiple routes students may take may have freed PTs to invoke a broader repertoire of actions to help copilot students in ways that positioned the students as the ones to consider each other's thinking.

The constraints in *instructional routine* related to the PTs' discussion structure in the RH2 may also have contributed to calming the waters in the rehearsal. In preparation for RH2, the MTE and PTs discussed how a teacher may support students in connecting their thinking and analyzed the way a teacher in a narrative case positioned the students to consider each other's thinking. Understanding how a teacher is able to enact this discussion structure seems to have supported the PTs with the repertoire of *actions* in our findings that one would use to get students to notice and respond to each other's contributions during a classroom discussion. Additionally, the discussion structure itself in RH2 naturally oriented the PTs to position the students (*actor* category) as the ones who needed to make sense of each other's work.

Preparing PTs involves supporting them to develop knowledge about teaching alongside their emergent skills as teachers. Lampert et al. (2013) and others suggest that the exchanges that TEs have with PTs during rehearsals affect the opportunities for PTs to develop knowledge of concepts and ideas related to teaching. Our study extends that understanding by illustrating how differences in rehearsal design, along with TEs' pre-rehearsal actions, also may shape PTs' opportunities to engage in core practices within rehearsals. Our study reinforces the findings of Kavanagh et al. (2020) on teacher responses to student thinking in rehearsals and extends that work by characterizing responsiveness in ways that allow for clear examination of differences across rehearsals.

Although our study contributes to understanding how differences in structure may relate to PTs' enactment of core practices within approximations of practice, our rehearsals share important features with each other (e.g., use of semi-scripted ESs in a live interaction) that are not necessarily characteristic of all approximations of practice. Further research will be needed to explore other aspects of design and enactment of approximations of practice and their relationships to the ways that PTs engage in core practices within those approximations.

ELEMENTARY PRESERVICE TEACHERS' VIEWS AND ENACTMENTS ON FOSTERING PERSEVERANCE

Christina Koehne
SUNY New Paltz
koehnec@newpaltz.edu

The purpose of this study is to investigate three elementary preservice teachers' (PSTs') conceptions of and reflections on the role of perseverance in mathematics. This study presents findings regarding the PSTs' perseverance conceptions, student interactions, and the PSTs reflections from a two-week summer math camp in which they assisted in teaching elementary student campers. Additionally, this study used an analytic framework based on a corpus of literature to capture how the preservice teachers' conceptions, interactions, and reflections aligned with each other and with current and relevant research recommendations.

Keywords: Preservice Teacher Education; Affect, Emotion, Beliefs, and Attitudes

Research has connected student perseverance to many constructs, including productive struggle, self-efficacy, motivation, mindset, locus of control, and grit (Bettinger, Ludvigsen, Rege, Solli, & Yeager, 2018; Dweck, 2006; Pajares & Miller, 1994; Warshauer, 2015), all of these aid in students learning mathematics. How then can teachers help support students in their perseverance? How are practices of perseverance conceived, viewed, and developed for future teachers? More specifically, as elementary teachers "develop the foundation of mathematical understanding, beliefs, and attitudes among young learners that start children on their mathematical journeys" (Association of Mathematics Teacher Educators [AMTE], 2017, p. 48), how do they conceive, viewed, and develop the practice of perseverance?

Literature Background

Conceptions

Elementary preservice teachers (PSTs) often enter teaching programs with preconceived conceptions based on their own experiences as learners (Stohlmann et al., 2014). Thus, it is critical to understand PSTs' conceptions about teaching mathematics early in their educational program. These conceptions have been known to change through content courses that use artifacts of children's' mathematical thinking (Thanheiser et al., 2013) and are taught in ways that align with content standards for doing mathematics (Conference Board of Mathematical Sciences [CBMS], 2012). Thus, by changing PSTs conceptions to align with teaching standards, there is reason to believe that these newly-formed conceptions may influence teacher practice (Ambrose, Clement, Philipp, & Chauvot, 2004; Stohlmann et al., 2014; Thompson, 1984, 1992).

In order to better focus PSTs on the content, Philipp (2008) suggested centering the content around children's thinking. However, certain positive conceptions regarding teaching and mathematics should be maintained to optimize the benefits of this focus, as conceptions "play a significant role in shaping the teachers' characteristic patterns of instructional behavior." (Thompson, 1992) Therefore, mathematics teacher educators must understand what PSTs conceptions are, how they and other experiences influence their teachings, and how we as a mathematics community can help the PSTs develop.

Perseverance

In this study, I follow Dweck's (2006) notion that perseverance is related to having a growth mindset. Students with a growth mindset pursue goals to attain a deeper understanding (Sun, 2018), see success as expanding their capabilities, thrive on challenges, and don't give up easily (Dweck, 2006). Bettinger and colleagues (2018), in agreement with many other researchers, note that "growth mindset interventions shape students' beliefs in their ability to learn and cause lasting improvements in school outcomes" (p. 2). Dweck (2006) maintained that confidence is not always needed to persevere in a task. In other words, confidence and perseverance do not automatically hold a bidirectional relationship, in that perseverance instills confidence but confidence is not necessarily needed for perseverance. In order for teachers to impart a growth mindset to their students, the teachers must take care that their praises are of the child's learning process and not ability, that mistakes are not met with anxiety or concern for the child's ability but should not be glossed over either, and teaching should be focused on understanding and not memorization of facts, rules, or procedures (Dweck, 2006). In addition, teachers should supplement textbook material with curricular tasks that incorporate opportunities for collaboration and sensitivities toward student autonomy (DiNapoli, 2016). Thus, "the aspects of classroom culture that seem to support student willingness to engage with challenging tasks are those related to the ways that the lessons are conducted and the expectations set for the students not only in terms of the mathematics but also the ways of learning it" (Sullivan, Aulert, Lehmann, Hislop, Shepherd, & Stubbs, 2013, p. 621).

Encompassed within the idea of a growth mindset, Russo, Downton, Hughes, Livy, McCormick, Sullivan, and Bobis (2020) note that further study on the topic has informed and altered Australian teachers views and beliefs about struggle. Moreover, "[i]n the United States…creating opportunities for students to persist in problem solving is a tenet of effective teaching that is often described as creating the condition for productive struggle." (Sengupta-Irving & Agarwal, 2017, pp. 115-116)

Productive struggle ensues when "students expend effort in order to make sense of mathematics, to figure out something that is not immediately apparent" (Hiebert and Grouws, 2007, p. 387). Warshauer, Starkey, Herrera, and Smith (2019) found that preservice teachers (PTs) in a mathematics content course, were unfamiliar with the ideas of productive struggle and generally saw struggle as something negative. Additionally, "PTs placed the responsibility of productive struggle on the student, not the teacher, when learning mathematics…and had not considered it as a teacher-driven educational tool for learning mathematics (Hiebert and Wearne,2003)" (Warshauer et al., 2019, p. 26). Although the semester was not long enough to fully develop "robust mathematical interpretations" of productive struggle, most PTs were able to indicate at least one teaching strategy notated from Warshauer (2015):

> (1k questions to help students focus on their thinking and identify the source of their struggle, (2) encourage students to reflect on their work, (3) give time and support for students to manage their struggles, and (4) acknowledge that struggle is an important part to learning and doing mathematics (Warshauer, 2015; Warshauer et al., 2019, p. 25).

3. Furthermore, there is evidence that shows mixed results regarding teachers' comfort with pedagogies that lead to students engaging with struggle, especially low-performing students (Russo et al., 2020). Although beliefs often differ from what is incorporated into practice, Russo and colleagues (2020) found that most teachers in their study (n=93) held positive beliefs about the value of struggle, citing "benefits of struggle were the

opportunities it provided students to persist through challenge, take risks, build autonomy, build confidence, foster self-efficacy, learn through mistakes, and acquire a growth mindset" (Russo et al., 2020, p. 6), and only nine of the 93 teachers in this study held descriptive beliefs that contained neutral or negative ideas.

In an effort to illuminate teaching moves that could be made in the daily-classroom that help foster perseverance, Lewis and Özgün-Koca (2016) shared five categories of teacher moves to foster student perseverance in problems solving:

1) Selecting Mathematical tasks that require and support perseverance,
2) Talking about strategies for problem solving,
3) Demarcating phases in problem-solving process,
4) Naming feelings attendant to problem solving, and
5) Narrating internal processes.

Thus, research on these teacher moves is relatively new, and has not yet made its way into the teacher preparation work. Therefore, similar to other research about mathematical practices, Warshauer and colleagues recommend that teacher educators "introduce opportunities to connect PTs mathematical content knowledge to practices like understanding productive struggle in mathematics early in their teaching continuum" (Warshauer et al., 2019, p. 26).

Theoretical Orientation

This study operationalized a social constructivist perspective of collaborative learning (Vygotsky, 1978). In using this approach, the study conformed with the Vygotskian ideals of learning, meaning that people learn as they work to form understandings and create meaning through their shared experiences in any given situation. Therefore, the researcher acknowledges that the participants in this study were learning due to a multitude of factors from the social environment, such as their experiences from this study's interviews and the daily camp classroom and accompanying professional development. Thus, the study draws on these factors whilst operationalizing and tracking the categories from the study's perseverance framework.

Methods

Settings & Participants

This study, which is part of a larger project, follows three typical PSTs majoring in interdisciplinary studies, who had completed both content courses but had not yet completed elementary observations, and were participating as Fellows (teaching assistants) in a two-week research-based summer math camp program for elementary and middle school students and professional development. Specifically, the PSTs assisted in the classrooms focused on Integers & Algebraic Modelling (Grades 3-4). At the time of selection, one of the PSTs had two years of prior experience as a Fellow, two had one year experience, and one had none. The PSTs were chosen based on their applications, camp administrator recommendations, and selected degree plan. The PSTs are referred to typical PSTs in the sense that they could not explain why the basic algorithms of addition and subtraction of integers worked before learning the models used in this setting or from their content course. The PSTs mentioned that they were excited to work with students and hoped to learn how to teach math in helpful and engaging ways for their future students.

Data collected consisted of pre-surveys, PST-student (individual/group) interaction recordings, stimulated-recall interviews, post-survey reflections, and clinical interviews. During the camp, whole class discussions were led by an experienced middle school teacher, but group and individual work were frequently facilitated by the PSTs. The PSTs helped answer questions, provided feedback, and assisted with other classroom needs and management. These PST-student interactions were recorded, with a select number used for the stimulated-recall interviews. Clinical interviews and post-survey reflections were conducted on the last day of the two-week camp.

Analytic Framework

The unit of analysis for the stimulated-recall interviews consisted of a daily interview. The interviews could not be separated into clear distinct segments since PSTs would often refer back to previously watched interaction recordings from the daily interview and blend their reflections regarding the different interactions together. Thus, this study looked at each interview holistically. However, the clinical interviews, which were task-based, were analyzed per task. Therefore, the framework was applied to the recorded interactions used in the stimulated-recall interviews and the clinical interviews. Moreover, the pre- and post-surveys supplied additional information, along with the clinical interviews as to the conceptions the PSTs held regarding perseverance. This allowed for a triangulation between what was observed by the researcher and how the PST reported and reflected upon their supports of perseverance.

In each of the selected interactions and reflections, instances of PST moves, or lack of moves, to support the students' mathematical perseverance were noted. These fell into one of three categories: (1) praise for unsuccessful efforts to answer a question (2) praise for the process, or (3) fosters perseverance. The first two categories stemmed from Dweck's (2006) growth mindset ideas, while the third category was based on Lewis and Özgün-Koca's (2016) ways of fostering perseverance. Based on Dweck's approach, the PST could have chosen two routes: (1) the route which can produce a fixed mindset and decreased perseverance by praising the student's unsuccessful effort or answer, or (2) they could have chosen the direction of a growth mindset and praised a productive process that yielded understanding. Adapting some of the teaching moves from Lewis and Özgün-Koca's whole class orchestration to a small group or individual conversations surrounding pre-determined problems, five moves similar to their five themes were established: (1) attending to students' emotional needs, (2) focusing the discussion on the strategy or different strategies, (3) changing the participation format of the conversation, (4) creating opportunities for students to reflect on their work, stuck points, or the language of the problem, and (5) creating an opportunity for the students to extend their knowledge beyond the problem.

After assigning the categories, I conducted individual member checks with two of the three participants about their conceptions and views to verify the accuracy of the coding and interpretations. Additionally, an external reliability check was made for a random 25% of the stimulated-recall interviews and 40% of the clinical interviews were checked. Resolution discussions were had and adjusted the framework, which was then reapplied to all remaining data.

Results

This section focuses on describing how the PSTs conceptualized, used, and reflected on supporting young students' mathematical perseverance. The PSTs will be known henceforth as Amy, Becky, and Linda. The conceptualizations were primarily based on the pre- and post-surveys, but also included information from the clinical interviews. Since the camp structure focused on using the word persistence, the surveys asked the participants to describe and define the teaching practice of fostering persistence, and to address what they thought to be valuable in the practice.

Amy

Amy was the most experienced PST in the study and had been a Fellow for the previous two summers. In conceptualizing perseverance, Amy was asked to think about persistence as this was the term used by the camp. She wrote the following:

> Allowing students to have enough wait time. Asking guiding questions instead of giving direct answers. The value is creating a growth mindset which gives students endurance to work on hard problems longer.

Amy's definition aligned with the ideas of *fostering perseverance* because it focused on providing time for the students to work on the problem, while focusing the student on the process and strategies through questioning during the problem-solving process. Additionally, Amy attributed the value of perseverance to the amount of time spent working on a problem and establishing a growth mindset. At the end of camp, when asked to reflect on what she had written about perseverance, Amy said, "I think like if I would add something, something that we talked about in seminar was asking purposeful questions and so I think that's more important than just like guiding questions, … purposeful questions would be like asking questions for understanding". This addition, although clarifying what type of questions Amy would use to foster perseverance, still did not add or alter Amy's conception of perseverance.

Throughout the camp, Amy was observed not only supporting the students both by *fostering perseverance*, and by *praising the process*. When reflecting on her interactions during the stimulated-recall interviews, Amy was able to point out some instances of both of these supports, noting her remarks about emotional states, focusing on the wording of the problem, changing the participation format, reflecting on the problem, extending the problem, and praising a productive process. Most of her reflective efforts regarding perseverance were spent toward ideas of *fostering perseverance*, with only one observed instance from the stimulated-recall interviews reflecting *praising the process*. The reflection seemed almost an oversight to Amy, who recalled more of her excitement for the student's discovery than her actual turn of praise by saying, "I got excited when she came to the conclusion that you had to do 7 minus 5 in the other problem. So I was like, "yeah you do, dang"…" In fact, Amy did not acknowledge her own efforts in the students' perseverance. Amy recognized when students persisted but did not attribute any of her own supports to students' persistence even if it meet her definition. She noted how the students persevered in the problem by responding to Amy's prompt to reflect and explain their process and answer.

> I really liked their responses, that they didn't give up. … And both [students], too, didn't go straight to thinking that they were wrong. So I liked that. That wasn't necessarily anything I put in them, but whoever they had in the past, teachers and stuff, they've given them that sense of confidence.

From this statement, it is clear that Amy attributes parts of perseverance and "endurance" to levels of confidence.

Linda

Linda had been a Fellow for the camp the previous summer and was about a semester behind Amy in their educational program coursework. When conceptualizing perseverance, she wrote the following:

> I would see this as an environment where students feel comfortable not getting the right answer on the first attempt. Instead its viewing problems as a journey that takes multiple attempts and you don't give up. These [sic] is extremely valuable when learning topics to truly understand the material.

Linda's definition aligned with the ideas of fostering perseverance because it focused on providing time for the students to work on the problem while focusing them on the process and strategies instead of the answer during the problem-solving process. Additionally, one can see that Linda attributed the value of perseverance to learning and understanding mathematical concepts. During the clinical interview, Linda noted that follow-up questions served to foster perseverance in that it made the student continue to think about a problem.

Like Amy, Linda although conceptualizing perseverance in terms of *fostering perseverance*, also supported and reflected on both *fostering perseverance* and *praising the processes*. During her stimulated-recall interviews, Linda reflected on her supports for perseverance by noting instances when she changed participation formats, praised students' processes, extended the problems, had students reflect on the problem, and prompted students to try different strategies. However, there was no observed instances of emotional supports for fostering perseverance, and Linda primarily worked in a one-on-one environment except on a rare occasion. Although her interactions were not typically group interactions, Linda frequently thought about wanting to have included other students in her conversations, noting that she thought this would have been beneficial. Linda also pondered the idea of using different strategies for the same problem. However, Linda reflected on the students using a model or strategy they were unsure of after they were already confident in their answer. Lastly, Linda made several moves to *praise processes* but did not always reflect on them. Linda would frequently and explicitly praise students during and after a productive conversation by saying things like, "Nice. Okay, so let's go look at our paper again", "Right. Awesome", or "Cool". Additionally, Linda would also show praise implicitly by becoming more excited and animated when a student began a productive argument using vocabulary and descriptive words. This was also evident in her reflection on the interaction when she noted, "I think it shows they're understanding when they start using that in their vocabulary… that's why I got excited when she said operator". This also highlights that Linda viewed student understanding as being tied to the student's processing and use of vocabulary words to describe their processes.

Becky

Becky was new to the camp program but was at a similar rank in her educational program to Linda. Although Becky's reflections and descriptions were often very detailed, they would sometimes double-back and re-examine things in a different way. Thus, her conceptions were constantly assimilating to her current experiences and she would often bring these ideas up during her reflections. When asked at the beginning to conceptualize perseverance, Becky wrote her definition from the prospective of the teacher by saying the following:

> Persistence to me is defined as the continuing to push through something with determination. So I believe fostering persistence would be able to grow/develop the ability to push through

negative behavior, confusion, and other obstacles that teachers may face in the classroom and turn it into positivity so the student can overall learn.

Becky's definition discussed how teachers persist in the classroom to help their students learn, but also spoke about helping the students persist. Becky added that you shouldn't just give up on students and that it is important for the students to persevere; however, she also stated that she wasn't sure how to "make them be persistent…if they don't want to". Thus, Becky spoke about pushing through negative behavior and confusion to foster perseverance.

In the clinical interview, Becky noted that the interviewers were persistent in asking the student questions, which encouraged the student to persevere in problem-solving. Becky said that by asking questions, the interviewers encouraged the student to keep thinking about the problem. Therefore, although unclear in her definition, Becky alluded to the importance of questioning related to fostering perseverance in students.

Becky's conceptualization of perseverance, in terms of *fostering perseverance*, was unclear as to how exactly she would support students, but when she reflected on her interactions, she noted supports for both *fostering perseverance* and *praising processes*. Becky attended to changing participation formats, emotional needs when students became frustrated, wanting to bring in multiple strategies, praising processes and productive efforts, problem extensions, and having students reflect on completed problems. Although a few of these interactions did successfully include a change in participation format and multiple strategies, these were two supports of fostering perseverance that Becky continually echoed wanting to include more. In fact, Becky noted that exploring ideas students are uncertain of after being confident in their answer would result in a more answer-driven process, whilst the opposite ordering, although less confident, would instill a sense of growth. Additionally, when trying to support students, especially those who were becoming frustrated, Becky would rely on praising their productive efforts. Becky notated this by saying, "I felt like I needed to give her some validation and that she was doing something right, she was in the right direction, she just kind of got confused on something or tripped up, … to help her not get so discouraged and still want to participate because she had turned her body away and gave her pencil away." Moreover, Becky was observed praising another student every step of the way by saying "good" or "good job", but didn't reflect on the praise she gave but reflected more on the questions she was using to have the student explain and reflect on their process.

Cross-Case Analysis

The conceptualization of perseverance seemed to be viewed uniquely across the PSTs, but all thought of it as a way to overcome struggles and confusion. Amy viewed perseverance as being synonymous with a growth mindset, which is similar to Linda's definition of "viewing the problems as a journey" and not being afraid of getting the wrong answer. Becky's definition was slightly different from Amy and Linda's, but this may be because Amy and Linda's perception of perseverance had been affected by the camp since persistence is a key component of the camp structure. Becky's ideas revolved around turning a negative situation into a positive one, and not giving up on the problem.

In addition, all of the PSTs have a conceptualization related to fostering perseverance, they all enacted moves to support this categorization and praising the students' processes. However, Linda was the only PST to not be observed supporting students' emotional needs for fostering perseverance but was more likely to praise the students' productive processes in a more purposeful way. In contrast, Becky used praise as a form of student support when the student's emotional needs came to the forefront.

Discussion and Future Research

The PSTs mostly conceptualized perseverance in terms of productive struggle and a growth mindset but also included remarks that aligned with the five ways of fostering perseverance in the analytic framework that was adapted from Lewis and Özgün-Koca (2016). The PSTs intentions to define perseverance in terms of growth mindset (Dweck, 2006) and productive struggle (Hiebert & Grouws, 2007; Warshauer, 2015) was not surprising, given that their content courses and the camp were structured around these ideas. Moreover, this suggests that introduction to and involvement in such work altered the PSTs beliefs to include components of perseverance. This finding agrees with that of Russo and associates, who found that recent emphasis on growth mindset helped shift "teachers' willingness to embrace struggle and view it as a necessary aspect of learning mathematics" (Russo et al., 2020, p. 8). The PSTs views on perseverance fit mostly into Russo and colleagues (2020) ideas of conditionally positive responses, in that they held positive beliefs, but mentioned teacher involvement in the struggle. Linda's conception was the only one that fell into the perspective of a positive belief; however, in her reflections, she would often structure struggle with questions.

A possible explanation for why the PSTs viewed supporting perseverance in terms of fostering perseverance instead of both fostering perseverance and praising productive process could be influenced by how the PSTs perceived their role in students' perseverance. Evidence suggests that the PSTs saw perseverance as something that the students were responsible for, and the PSTs often had difficulty noticing their supports of perseverance as related to the practice. This was especially evident for Amy, who described students' confidence and willingness to explain ideas from previous problems as attributed to past teachers. This finding agreed with what Warshauer and colleagues (2019) found in their preservice teachers' understandings of productive struggle. Furthermore, the PSTs viewed perseverance as connected to confidence, however, it is unclear as to the direction of this relationship the PSTs imparted between the two ideas when research suggests a clear directional connection. Dweck (2000) noted that students with a growth mindset associated with their mathematical ability are more likely to have greater confidence that they will succeed; however, Amy noted that confidence allowed the student to persevere. This conceptualized connection to confidence and perseverance merits further study, to see if it aligns with current literature or if it disagrees, and if so, how.

Additionally, the PSTs noted that having students reflect on their work served the purpose of having students become confident in justifying answers. The thought of this as a move to foster perseverance seemed to be an afterthought or an accompanying outcome. Overall, the PSTs did not view perseverance as something supported by the teacher, but rather as something internal to the student. Although the PSTs' moves aligned with research, these moves were not all recognized as noteworthy, or for the purpose of supporting perseverance. Thus, consistent with the literature recommendations mentioned here (Lewis & Özgün-Koca, 2016; Warshauer et al., 2019), university coursework should include an awareness of perseverance and ways of fostering it. The PSTs in this study were already supporting perseverance to some extent, and when made more aware of perseverance and ways of fostering it, these existing supports could potentially be used more purposefully and provide better support for students' learning. Thus, future studies would benefit from providing PSTs with techniques to better support student perseverance and observing how these supports are taken up and could potentially alter the supports they use with students. Implications from this study suggest a particular need for university coursework to emphasis ways of promoting student-to-student talk as a way to foster a productive and persevering learning environment. Similarly, reflective or metacognitive questions would be a beneficial addition to not only model but include as a topic for discussion in university coursework, as these skills not only foster perseverance but are valuable mathematical reasoning habits (NCTM, 2009).

In recent decades, scholars of teacher education have suggested that teacher educators (TEs) should integrate the development of prospective teachers' (PTs') knowledge with their skills for enacting teaching, characterized in the literature as pedagogies of practice. One way to operationalize pedagogies of practice is through engaging PTs in cycles of enactment and investigation (CEIs). Using an opportunity to learn (OTL) lens, this study investigated one CEI enacted in a secondary mathematics methods course. Analyzing course artifacts and final interviews, we found that the PTs had OTL in all six nodes of the CEI, that OTL differed across the nodes, and that OTL in later nodes depended on knowledge built in previous nodes. Implications include the importance of PTs engaging in all nodes of a CEI to maximize OTL about mathematics teaching practices, mathematics, students, and learning.

Keywords: Preservice Teacher Education, Teacher Knowledge

In recent decades, scholars of teacher education have suggested that teacher educators (TEs) should integrate the development of prospective teachers' (PTs') knowledge with their skills for enacting teaching, which Lampert et al. (2010) described as using a *pedagogies of practice* perspective. TEs who design learning opportunities from a pedagogies of practice perspective focus on specific *decompositions of practice* (Grossman, Compton et al., 2009), which "[break] down practice into its constituent parts for the purposes of teaching and learning" (p. 2058). PSTs interact with *representations of practice* (e.g., narrative cases or video-recorded teaching episodes) and engage in *approximations of practice*, which are "opportunities for novices to engage in practices that are . . . proximal to the practices of a profession" (p. 2058). Theoretically, novices can learn complex practices by engaging in learning opportunities designed from a pedagogies of practice perspective (Grossman, Compton, et al., 2009; Grossman, Hammerness et al., 2009; Kazemi, et al., 2016; Lampert et al., 2010). Some mathematics teacher educators in the United States have taken up this perspective to design learning activities for pre-service teachers that include some form of engagement in approximation of practice (e.g., Lampert et al., 2013; Campbell & Elliot, 2015). Much of the early research regarding these designs has been descriptive in nature; now the field needs research to examine how such pedagogies relate to PTs' understandings and skills.

Theoretical Perspective

Opportunity to Learn (OTL) emerged in the 1960s as a construct for characterizing instructional environments by input variables that might predict student learning as an output (Elliott & Bartlett, 2016). Early works used variables such as instructional time spent on specific content, content coverage, and instructional quality indicators as proxies for OTL (Elliott &

Bartlett, 2016). Gee (2008) explained that from what he called the mental representations perspective,

> learners have had the same OTL if they have been exposed to the same [content] . . . . If they have been exposed to the same content, then, according to this view, they have each had the opportunity . . . to "learn it." (Gee, 2008, p. 77)

As an alternative to the mental representations perspective on OTL, Gee argues that we should conceptualize OTL from a sociocultural perspective by conceptualizing learning as learning how to act in specific kinds of situations in ways that are aligned with the normative practices of some community. From this conceptualization, acting in some particular situation involves identifying objects in one's environment that one could use or act upon to achieve a desired result. The actor identifies *affordances,* which are defined as the possible actions that the individual can envision carrying out on, with, or in response to those objects. The actor then selects and operationalizes one of those affordances. To do so, the action must fit within the actor's understanding of which possible actions would be consistent with the accepted practices of some community that they identify with, which Cobb et al. (2009) describe as a *normative identity* that the actor has co-constructed with other members of that community. Further, the actor must have *effectivity* with respect to the selected affordance, defined as the capacity to operationalize a possible action (Gee, 2008).

Methods

The context for this study was a semester long methods course for secondary mathematics PSTs at a Mid-Atlantic university. Two mathematics teacher educators (MTEs) taught the course, which met two times a week for fifteen weeks. Seventeen of the 18 PTs in the course participated in this research. The MTEs designed the course from a pedagogy of practice perspective. Specifically, the course involved three cycles of enactment and investigation (CEI) (Lampert et al., 2013; Arbaugh et al., 2020) as described in Figure 1. The focal decomposition of practice in all three CEIs was a set of communication moves: Asking assessing and advancing questions, and using judicious telling (Freeburn & Arbaugh, 2017).

Figure 1: The CEI

In general, PTs begin a CEI in Node 1 by doing and discussing a mathematical task. In Nodes 2 and 3, PTs analyze and discuss a representation practice (e.g., narrative case) through the lens of a focal decomposition of practice. In Node 4, PTs use the focal practice and mathematics discussed in previous nodes to frame their planning for enacting teaching in Node 5, where they rehearse a teaching episode with simulated students. In Node 6, PTs analyze their rehearsal videos through the lens of the focal practice. This study focused on one of the three CEIs, which occurred mid-way through the course. In Figure 2, we give a brief description of the events that took place in this specific CEI.

through the focal practice.	Analysis included writing rationales for coding choices as well as an assessment for if the focal practice "worked" or not based on student response.	they learned from engaging in rehearsal and analyses.

Figure 2: Goals for PT learning and descriptions of PT activities in each node of the CEI

Data Collection

Data analyzed for this study include data collected during the multi-day enactment of the CEI. Audio-recordings were collected of whole-class discussions during Nodes 1, 3, 4, and 5 and small-group discussions in Nodes 1, 3, 4, 5, and 6. PTs' rehearsals in Node 5 were video-recorded. Students' written artifacts - notebooks, assignments, reflections that occurred during the CEI were collected. In addition, post-course interviews were captured by audio-recordings; the interview data analyzed for this study focused on responses to questions that asked PTs to reflect on how the CEI activities supported their learning.

Data Analysis

Our unit of analysis was a segment of communication, which we define as a series of turns of talk with a common focus (Bishop et al., 2016) and with a consistent form of participation (whole-class, paired work, individual work, or group work). We analyzed data sources in three phases. In phase one, we randomly chose three participants' data corpus and used the four dimensions of Ghoussieni and Herbst's (2016) Framework for Learning to Teach (FLT) as a priori codes: *Knowledge of Students and Content*; *Repertoire of Practices and Tools*; *Dispositions for Teaching and Learning*; and *Professional Vision* (see Table 1, Column 1 for definitions). At the same time, we began to develop subdimension codes using constant comparative analysis (Miles, Huberman, & Saldaña, 2013) and inductive analysis, and wrote analytic memos that detailed commonalities across the data. Once satisfied with the secondary coding scheme with the limited set of data, we began coding additional participants' data, refining the secondary codes (e.g., renaming, collapsing similar codes) until all coding was complete. Table 1 contains the resulting subdimensions (Column 2). In phase two, we coded segments for appropriate CEI node (1-6). In phase three, we organized our coded segments (*n*=414) and related analytic memos into a data table that allowed us to sort the instances by CEI node, dimension, or Subdimension. We used the sorted table to identify themes (Miles, Huberman, & Sa , 2013) in the data that allow us to describe the PTs' opportunities to learn during each CEI node and in each dimension across the nodes. We constructed frequency counts of the coding in each dimension across the CEI's nodes. Within each dimension, we created frequency counts of the subdimensions identified during phase 2. We then examined the frequency counts and made profiles of the OTL in each node. We then examined OTL across the nodes to arrive at the claims we present next in the findings section.

Dimensions & Descriptions (Descriptions are excerpted from Ghousseini & Herbst, 2016)	**Subdimensions Identified through Data Analysis**
Knowledge of Students* & Content: Understandings of the subject matter, of students as learners, and of ways to support their engagement with this subject matter . . . Teachers not only need to know the content but also understand the kind of reasoning that is entailed in doing mathematics. They should be able to interpret student work in light of what students already know and the tools at their disposal. (p. 82–83)	**Criteria for Valid Arguments -** PTs articulate criteria for a valid argument or criteria for why an argument is not valid.
	Type & Components of Arguments - PTs describe a type of an argument (e.g., proof by induction) or components of proof and reasoning (e.g., identifying a pattern).
	Representations in Arguments - PTs recognize a type of representation and address how the representation is incorporated into an argument.
	Mathematical Ideas and Practices - PTs describe a particular mathematical concept(s) or practice(s).
	***Student difficulties -** PTs identify students' errors in arguments or suggest ways a student could improve an argument.
	***Students think differently about the same task.** PTs explain similarities or nuances among student arguments as well as attributes among student arguments.
	***Validity of Arguments vary depending on grade level -** PTs share ideas about validity or appropriateness of student arguments as a consequence of grade level.
	***Student mathematical understanding -** PTs address student's understanding of mathematical content or capabilities to engage in mathematical practices.
Repertoire of Practices and Tools: Support teachers' beginning enactment of important aspects of instruction. Tools . . . can help teachers translate abstract conceptual tasks into more concrete steps and objectives (p. 83).	**Recognizing practices and tools -** PTs recognize a teaching move or routine in a segment of classroom instruction.
	Attributes of practices and tools - PTs articulate features, definitions, purpose, or characteristics of a teaching move or routine.
	Engaging in Practices - PTs engage in or reflect on their engaging in a teaching move or routine.

Dispositions for Teaching and Learning: Teachers' dispositions to see students as sense makers and learn the intellectual and professional stance of inquiry are important aspects of teachers' learning in and from their practice (p. 83).	**Honoring Student Thinking -** PTs communicate their stance that mathematics instruction should recognize, incorporate, or build on student thinking.
	Learning mathematics for understanding - PTs communicates their stance towards learning mathematics for sensemaking or understanding.
Professional Vision: The ability to notice and interpret features of practice in ways that are valued by a particular professional group. . . . A vision of practice may also delineate what is possible and desirable in teaching . . . it gives teachers a sense of direction (p. 82)	**Visions of instructional practice -** PTs notice and interpret a component of instruction as desirable based on the PTs' interpretation of a community's considerations for teaching and learning.

Figure 1: The A Priori Dimensions and Emergent Subdimensions of the FLT

Findings

One adaptation of the Gousseini and Herbst (2014) framework that resulted from our analyses is a need to separate *Knowledge of Students and Content* into two distinct dimensions: *knowledge of students* and *knowledge of mathematical content*, which more closely reflects a pedagogical content knowledge (Grossman, 1990) perspective. Subdimensions for *knowledge of students* are indicated by asterisks in Figure 1. We present three claims in this paper (see Table 1), and then, due to limited space, we expand only upon Claim 3 to show how the OTL in later nodes depended upon knowledge developed in previous nodes.

Table 1: Three Claims

Doing the mathematics (Node 1) and planning for teaching (Node 4) created opportunities to develop knowledge of content.
Analyzing the narrative case (Nodes 2&3), engaging in the rehearsal (Node 5), and reflecting on the rehearsal (Node 6) created opportunities to develop a repertoire of practices and tools.
Doing the mathematics (Node 1), planning for teaching (Node 4), and reflecting on rehearsals created opportunities to develop knowledge of students.

Doing the Mathematics, Planning for Teaching, and Reflecting on Rehearsals Created Opportunities for PTs to Develop Knowledge of Students

Evidence of opportunities to develop knowledge of students was much more prevalent in Nodes 1, 4, and 6 than in Nodes 2, 3, or 5. Further, the number of PTs providing that evidence is higher in Nodes 1 (n = 12), 4 (n = 11), and 6 (n = 7) than in Nodes 2 (n = 3) or 5 (n = 2). For those reasons, we conclude that OTL in the *knowledge of students* dimension are primarily accounted for in Nodes 1, 4, and 6 and we next describe the progression of the OTL across these nodes in two subdimensions: *student difficulties, errors, and areas for improvement* and *differences* and *students have different ways to think about the same task.*

Student difficulties, errors, and areas for improvement. The discussion of the student work samples in Node 1 provided OTL for PTs to develop their knowledge of the kinds of errors that students might make when attempting to engage in argumentation. For example, as PT10 read the Student Work Sample A, she noticed a similarity between the argument from Student A and the argument that PT10 had constructed, namely that both Student A and PT10 had used one variable (n) to represent two different odd integers. The instance is evidence of OTL for identifying an error that might occur as a student engages in constructing an argument. Similarly, as PT10 and PT13 examined Student F's argument, PT10 stated, "I don't know how you would judge what they know from this." T13 stated, "Well, they have some errors." The PTs agreed that the algebra of the argument is wrong, and that the argument lacked coherence. As PT13 said, "[“he] statements are not connected to the ones before it." In Node 4, as PTs responded to the elements of the TTLP, they discussed possible errors that students might make or misconceptions that they might have when attempting to argue for the given claim. These errors fell into two broad categories: Errors that were general to argumentation, and errors that were specific to possible approaches to arguing for a particular claim. For example, PT7, PT8, and PT9 suggested that a student might not understand definitions of *even* and *odd*, that a student might consider examples sufficient justification for a general claim or might not use enough evidence to justify the claim. These potential areas of difficulty are more general across claims. However, they also examined errors for each of five different possible approaches to proving the specific claim that they were assigned.

In addition to opportunities to consider both difficulties at the general level and at the specific level, PTs’ statements again gave evidence that their OTL was mediated by their experiences in previous nodes. Specifically, in Node 4, while discussing potential errors related to how students might argue for their claim, PT3 anticipated that students might use a table of values to present examples in support of the claim that the product of two squares is a square. PT3 connected that anticipated response to their experience in Nodes 2&3: "Kind of like the students in [the case narrative]. Using examples to prove, but we need to get them to do a general case. Not just use examples."

Students have different ways to think about the same task. In Node 1, PTs had the OTL to see that students (themselves, their peers, and the students represented in the student work samples) had different approaches for writing an argument that the sum of two odd numbers is always even. In Node 1, PT12 and PT15 briefly discussed their arguments for the task - –T15 explained that his argument involved stating that odd numbers are even numbers plus 1 and that the sum of the two odd numbers then will be an even number plus 2. PT12 replied that she had argued for the claim using the same approach. Each of the groups noted strong similarities between the arguments from Student B and Student C and interpreted the differences as a distinction between a valid argument (Student B) and a not valid argument (Student C). The activity also included opportunities to recognize similarities between the arguments in Student Work Samples and their own attempts at proving the claim--for instance, while reviewing Student D's argument, PT10 stated that the argument was valid because it was similar to an argument that she and PT13 had previously identified as valid (though she did not clearly indicate which Student Work Sample she was referencing) as well as to the argument that PT10 had made in her own attempt to prove the claim.

The main areas of OTL within the Node 1 activities were in the dimensions of Knowledge of Content and Knowledge of Students. Given that the activities were explicitly intended to engage PTs in conversations about criteria for valid arguments, it is unsurprising that the plurality of instances coded in Knowledge of Content dimension were related to the domain of Criteria. However, in the context of those conversations about criteria there was also OTL about types of arguments, the components of arguments, and to compare and contrast students' arguments toward a claim as well as the errors or areas for improvement in students' arguments. These domains of knowledge are important for establishing learning goals for students' argumentation, for anticipating the kinds of arguments that one might encounter in a secondary learning environment, and for framing how one determines, of the affordances he or she recognizes as possible actions to take in response to student argumentation, which affordance to attempt to transform into action.

In Node 4, the OTL about students' mathematical understanding was primarily a consequence of PTs anticipating students' solutions in response to an element of the TTLP. Drawing on the PTs' arguments in Node 1 as well as the Node 1 student work, PTs discussed arguments students may make for their assigned number theory task. PTs also raised questions about what knowledge students might be expected to already have, and whether that would change which parts of the argument would need to be supported rather than assumed. For example, PT8 and PT9 wondered whether students could be expected to know that N^2 is even if and only if N is even, and if so whether that would mean that students could draw on that fact without justifying it. Evidence in Node 4 indicates that PTs drew upon their experiences in Node 1 as a resource to support their anticipation of student thinking. For example, PTs referred back to the student work samples from Node 1 for ways to represent even numbers and odd numbers.

Connecting to the theoretical perspective. Viewed through the sociocultural perspective, the PTs had OTL in Nodes 1 and 4 about how to act as a teacher who knows how students think mathematically in ways that are aligned with what it means to prove, which is a normative practice of the mathematics community. In doing the mathematical task and analyzing student work in Node 1and then anticipating student responses in Node 4, the PTs had the opportunities to build the kinds of knowledge that will allow them to preplan possible actions they can choose from in Node 5 (rehearsal).

Discussion and Conclusion

This study contributes to the field's understandings of what PTs and the opportunity to learn from engaging in pedagogies of practice, extending the work of Arbaugh et al. (2019; 2020), Ghousseini and Herbst (2016), Tyminski et al. (2015), and Baldinger et al. (2016) and adding to current evidence of the impact of CEIs on PTs' building of knowledge about teaching mathematics. What makes this research unique is that we studied OTL through the content of what PTs took up and discussed in small groups, large groups, and in reflective interviews. Much OTL work has been done from a researcher-down perspective – what we, as researchers, intend for PTs to learn. Considering OTL through a PT lens provides powerful indicators of the possible impacts of engaging in CEIs. One implication from this research is that it is important to engage PTs in a whole CEI – not just choose to do parts of it (e.g., planning and then enacting practice in rehearsals). Our findings indicate that opportunities to learn occurred in all CEI nodes and, perhaps more importantly, OTL in latter nodes depended upon knowledge built in previous nodes. We have also come to understand the power of having PTs analyze student work samples in Node 1. Simply doing the mathematical task itself would not have offered the same kind of OTL about student thinking that doing the task and analyzing the work samples did.

This study joins very few others who are examining (possible) outcomes for PTs who learn to teach through engagement in pedagogies of practice and learning cycles. Much work is to be done before the field has a solid understanding of this kind of pedagogy in ways that are convincing about its effectiveness.

EXPLORING CONNECTIONS BETWEEN PROSPECTIVE TEACHERS' VIEWS OF AUTHORITY AND EXPERIENCES IN JUSTIFICATION

The purpose of this project was to understand how implicit views of authority support or limit prospective elementary teachers' (PTs) mathematical activity of justifying and to understand how the experience of justifying might support a development of an internal source of authority. In this case study of 18 PTs, we coordinate an analysis of 1) their responses to two justification tasks and 2) interview transcripts in which they discuss their experiences in learning to justify. Preliminary results indicate ways in which their views of authority limited their reasoning about mathematics by not recognizing their own sense-making and supported a sense-making exploration of mathematics that was freeing and empowering. These results provide mathematics teacher educators with insight to help them identify and address limiting views of authority and leverage productive views of authority.

Keywords: Preservice Teacher Education, Reasoning and Proof, Teacher Beliefs

Purpose of the Study

Attending to this year's theme of "persevering through challenges", we address a familiar challenge encountered in mathematics teacher education. When prospective elementary teachers (PTs) enter content courses, they typically hold limiting views of mathematics as memorizing procedures. They often are not aware that mathematics makes sense and that procedures can be justified (Ball, 1990; Feiman-Nemser, 2001; Ma, 1999; Spitzer et al., 2010; Thanheiser, 2009), nor do they generally view themselves as a source of authority for reasoning about mathematics as mathematical sense-makers (Cady et al., 2006; Perry, 1970; Povey, 1997). As mathematics teacher educators (MTEs), we want our students to take ownership of their mathematical sense-making. Explaining and justifying one's thinking are activities that support the vision of sense-making and argumentation described in national documents: "By developing ideas… justifying results, and using mathematical conjectures… at all grade levels, students should see and expect that mathematics makes sense" (NCTM, 2000, p. 56).

When student generated mathematical contributions are validated through collaborative reasoning, students are supported in developing the skills of explaining and justifying their thinking along with assessing the validity of that thinking (Gresalfi & Cobb, 2006; Reinholz, 2012). Such support is necessary for students to develop an internalized authority that is based on sense-making through their own reasoning, rather than relying on an external source of authority represented by experts such as the teacher or textbook (Boaler & Selling, 2017; Engle & Conant, 2002; Lampert, 2003; Reinholz, 2012; Schoenfeld, 1994). To better understand how to support students in taking ownership of their sense-making, we use the context of a justification-feedback-revision cycle to explore the connections between PTs' justifications, their process of justification, and their views of authority and sense-making in the mathematics classroom.

Understanding how PTs view authority to reason about mathematics in the classroom provides valuable insight into how MTEs can uncover these views, support PTs in interrogating their views, and then help PTs learn how to use their authority to contribute ideas and evaluate the reasonableness of contributed ideas. In this proposal we share how one class of 18 PTs engaged in a justification-revision cycle and argue that attending to PTs' views of authority provides insight into (1) potential barriers to learning to justify and (2) productive views of authority that support learning to justify.

To support this argument, we seek to answer the following questions:

1. How do PTs' descriptions of their justification process provide insight into their views of authority?
2. How do PTs' views of authority support or limit their justification?

Perspective/Theoretical Framework

As justification and authority are central to our study, we unpack these two constructs and explain how the relationship between them frame our work (see Figure 1).

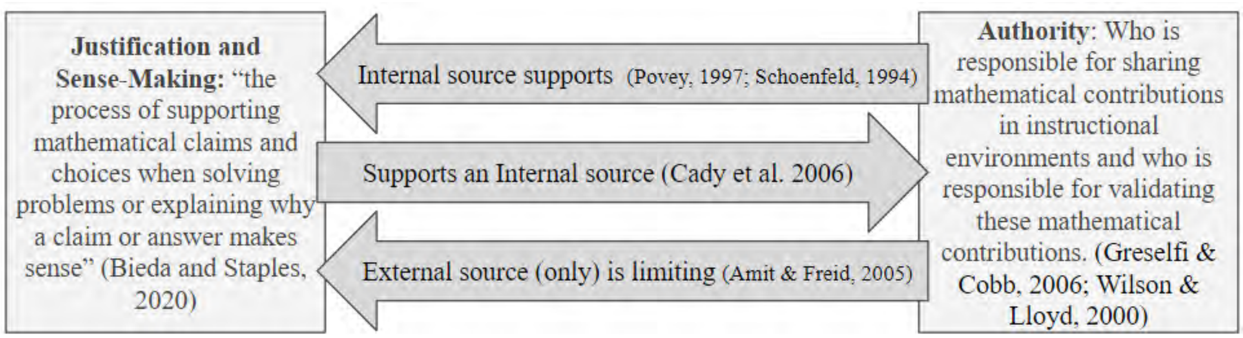

Figure 1: Framework that connects authority and justification

Authority

We define authority as who (or what) is responsible for sharing mathematical contributions in instructional environments and who (or what) is responsible for validating these mathematical contributions (Gresalfi & Cobb, 2006; Wilson & Lloyd, 2000). In instructional environments, students engage with a web of authority that includes instructors, their peers, themselves, textbooks, and other authorities in their life (Amit & Fried, 2005). The development of an internalized source of mathematics authority in which students view themselves as an authority is associated with the development of mathematical sense-making abilities (Povey, 1997; Schoenfeld, 1994). This view of the self as an authority supports sense-making because it carries the expectation that the students take on responsibility for reasoning about what makes sense – first through sharing their own ideas, and then through providing an explanation that justifies their thinking and solution to their peers and instructor. This view is in contrast to the expectation that the teacher or other external sources is responsible for telling them what makes sense and what is correct, a view that limits students' sense-making.

Viewing mathematics authority as residing in the teacher negatively impacts students' conceptual mathematical thinking "by turning always from one figure to another, and never to themselves, the students …fail to develop their own mathematical thinking," (Amit & Fried, 2005, p. 165). In addition, they position "themselves as outsiders with respect to mathematical discourse" (ibid). Undergraduate students develop an internal source of authority as they learn to think critically and develop persuasive arguments (Povey, 1997). A shift in authority from external to internal becomes apparent when students "support their opinions with reason and logic" (Cady et al., 2006, p. 296), in other words, when they justify.

Justification

Students are sense makers (Ernest, 2000) and justification is essential to sense-making (Bieda & Staples, 2020). We adopt Bieda and Staples' (2020) definition of justification as "the process of supporting mathematical claims and choices when solving problems or explaining why a claim or answer makes sense," (p. 103). (See left box in Figure 1). We think of justification as a way of communicating understanding (Jaffe, 1997), and as distinct from mathematical proof, which is a final product, in that a justification does not have to be logically complete (Melhuish et al., 2020). A justification should seek to convey structure and generality if applicable. For example, for their first justification task, PTs were asked to determine if the sum of two odd numbers is always odd, always even, or sometimes odd and sometimes even, and then justify their thinking. While we did not expect them to use a number theoretic approach to the justification, they were encouraged to attend to the structure of an odd number as a collection of groups of two and one left over, or as two groups of the same size with one left over and use one of these definitions of odd to argue a general case (see Table 1 in the next section for examples).

PTs experience challenges in learning to justify and in supporting children in learning to justify. (G. J. Stylianides et al., 2013). PTs often conflate justification with providing/checking multiple examples rather than viewing justification as a general argument based on mathematical properties and definitions of terms (Harel & Sowder, 2007). Teachers (including PTs) need to develop a common language and understanding of justification so they can understand what justification and proving look like in an elementary classroom and can support their students in this activity (Harel & Sowder, 2007; Staples & Lesseig, 2020; A. J. Stylianides, 2007). We add to the literature by building on our understanding of PTs' justifications. We coordinate this understanding with their views of authority through examining the limiting/supporting relationship between views of authority and justification (see Figure 1).

Methods

Participants

The 18 PTs participating in this study were enrolled in their first mathematics content course for prospective elementary teachers. The study was conducted at an urban public university in the Pacific Northwest of the United States. PTs at this university were required to complete a sequence of 3 mathematics content courses to enter their teacher education program. This course was taught by one of the authors.

Context

This first course in the sequence was inquiry-based with the goal to develop students' mathematical knowledge for teaching (Ball et al., 2008; Hill et al., 2008) and the expectation that students share their reasoning as a learning community. The main topics of the course were number and operation with an emphasis on sense-making through justifying, representing ideas in multiple ways, and making connections between these multiple representations.

For the present study, the course was taught asynchronously online via an online learning platform and shared Google slides. Emphasis was placed on the value of reviewing and reflecting on previous work and providing feedback to their classmates with the intention of positioning PTs as sense-makers and as sharing responsibility for theirs and their classmates' learning as a part of a community. To support PTs in sense-making and justification, they were asked to complete multiple cycles of (a) sharing a rough draft (Jansen, 2020) of a justification, (b) reviewing and providing feedback on other PTs' justifications, and (c) revising their initial draft based on the feedback they received from classmates and the instructor. In this study, we focused on their first two justification tasks, in which they completed the following statements and then justified why the statements were true:

- The sum of any two odd numbers is [always odd, always even, sometimes odd/even].
- The sum of three consecutive numbers is [always, sometimes, never] divisible by three.

Data Collection

Data includes (a) PTS' written rough draft and revised justifications provided via Google slides, and (b) transcripts of an hour-long interview with PTs conducted via Zoom. Interviews were conducted by the lead author during week six of a ten-week term after PTs had completed both justification-revision cycles. The semi-structured interviews included questions asking PTs to describe the process they went through when creating their justification, how confident they were that their response was a valid justification, and how (and to what extent) they utilized classmates' 'ork and the instructor's and classmates' feedback.

Data Analysis

To analyze our data, we used an inductive approach (Thomas, 2006). We started with reading through the PTs' responses to the justification tasks (provided in our shared Google slides) and their interview transcripts and recording observations about (1) how PTS justified, (2) key moments in the interviews in which PTs described their experience in justifying, and (3) statements from the transcripts that provided insight into their views of authority. After an initial pass through our data, we then developed categories as described below.

Justification Data. We analyzed PTs' draft (D) and revised (RIesponses to the two justification prompts (see above). Since the PTs were introduced to the construct of convincing yourself, convincing a friend, and convincing a skeptic to characterize PTs' levels of justifications in the class (Mason et al., 1982), we leveraged these categories in our analysis to code their justifications (see Table 1). Note that the code *Misinterpreted* was used to code PTs' justifications that misinterpreted the prompt. Two of the authors coded each of the justifications individually and met to resolve disagreements through debate.

Table 1: Coding Scheme for Justifications

	Description	Example for: The sum of three consecutive numbers is [always, sometimes, never] divisible by three.
Self	PTs relied solely on specific examples	Example: 4+5+6 = 15 Justification: 15/3 = 5
Friend	PTs described general structure and didn't yet use this description of structure to argue for the general case,	If you add any 3 same groups of #s together, that large sum can always be separated again back into 3 equal parts. Because consecutive numbers are 3 of the same number plus an additional 3, that additional 3 that is added into the numbers to make them consecutive, can therefore be separated into 3 equal parts. (PT 1)

	or their argument was unclear	
Friend/Skeptic	PTs written justification is a general argument based on structure and the visual representation uses specific examples	Skeptic	PTs written justification and visual representation that build a general argument based on structure.	The sum of three consecutive numbers is ***ALWAYS*** divisible by 3 because when you add 3 consecutive numbers, it is equal to adding the first number in the sequence times 3 plus 3. 3 consecutive numbers added together can be grouped into 3 equal groups. 
Interview Data

To create an initial analysis of the interview data, the first author wrote brief descriptions of each interview summarizing each PTs' general approach to justification and how their discussion of their justification process provided insight into their view of authority. To further this analysis, we reviewed the interview transcripts and identified moments the PTs talked about sources of authority they looked to while writing their justifications (self, peers, instructor, previous experience, etc.) and how they determined that their justification was valid. For example, in describing their experience with justification, PT 1 said she did not understand "what you guys wanted" and that she didn't "know what you need." This indicated to us that the student was seeking verification from an external source of authority. In contrast, PT 2 shared, "For some reason, especially math, when I learned something that I can connect something on my own. I feel so much more accomplished!" This indicated that this student was starting to view this responsible for their own sense-making, indicating an internal source of authority. After all PTs' responses were read with such moments indicated, we categorized the PTs as having a primarily external source of authority, internal source of authority, or mixed. The mixed source of authority emerged when a student alternated between describing internal and external sources of authority. It is important to note that these interviews are snapshots of one moment during a 10-week term. Thus, their discussions of justification give us insight into their views of authority at the moment of their interview, but do not yet provide a comprehensive description of their overall orientation toward authority.

Results

Justification

Results from our analysis of the PTs' justifications are shown in Table 2. In general, the PTs did attend to the mathematical structure of the concepts they were justifying, as shown by the prevalence of Friend and Friend/Skeptic justifications. However, their justifications demonstrated mixed success with developing logic to link the structure to the concept. For example, for the first justification, 9/18 students' justifications were Friend level with missing or unclear logic preventing the justification from being coded Friend/Skeptic. Including a generalized visual representation of their justification proved to be the challenge that limited many of the justifications to Friend/Skeptic rather than reaching the level of Skeptic. While students demonstrated some success with written generalizations of their justifications, with few exceptions, visuals were limited to "dot drawings" of one or two examples.

Table 2: Results of Justification Coding

Justification	Misunderstood	Self	Friend	Friend/Skeptic	Skeptic
Sum of 2 Odds (D)	2	3	9	4	0
Sum of 2 Odds (R)	0	2	9	7	0
3 Consecutive #s (D)	5	5	3	5	0
3 Consecutive #s (R)	1	3	4	8	2

Authority

In characterizing PTs' views of authority (as seen during their week 6 interview) we found that of the 18 PTs, 8 provided evidence of viewing themselves as an authority (internal), 6 PTs primarily looked to an external source of authority, and 4 provided evidence of a mixed view of authority. From the analysis of interview transcripts, we selected two PTs that represent contrasting examples of views of authority. The two examples are contrasting because one PT's descriptions indicated more external views of authority, whereas the other was more internal. We used the following figure (Figure 2) to represent the distribution of how we categorized PTs' views of authority and how each of 18 PTs' justifications were coded in our analysis. We then trace PT 1's and PT 2's level of justification.

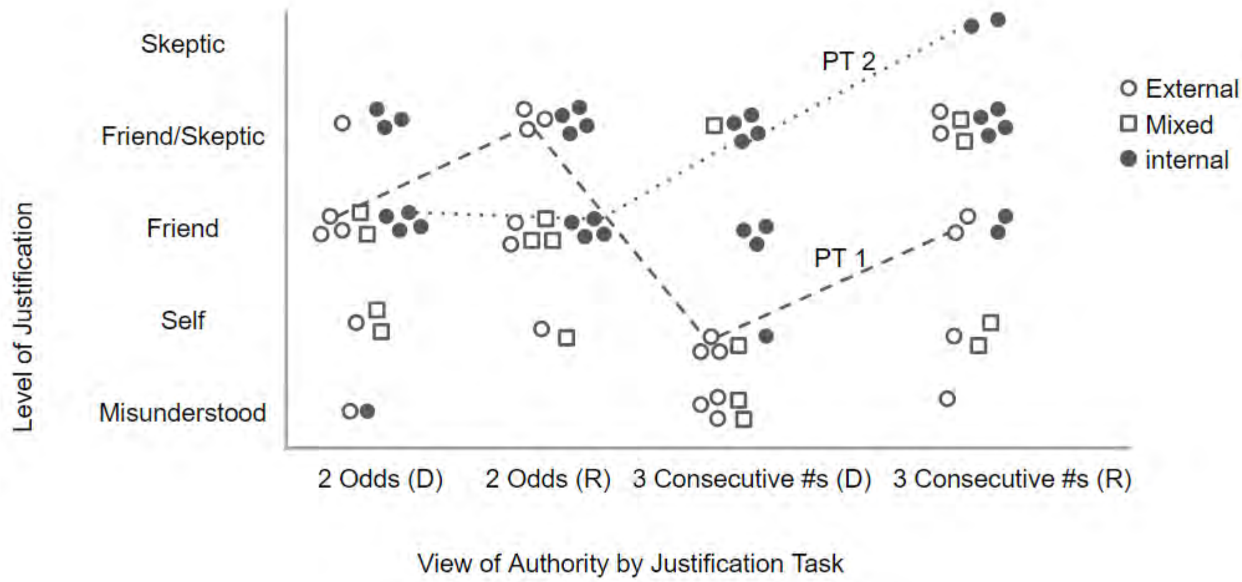

Figure 2: PTs Views of Authority and Level of Justification

PT 1. We categorized PT 1 as primarily looking to external sources of authority. Overall, in terms of justifying, PT 1 struggled with providing a clear argument. For example, for the first justification PT 1 revised her justification from the level of Friend to a Friend/Skeptic, but in the second justification, her justification started at Self and improved to the level of Friend after revision. In her interview she shared a desire to explain the math behind a concept while also wanting to know what "we," as the instructors, wanted for a solution. She explained that she did not understand "what you guys wanted" and that she did not "know what you need." She also shared that she found this difficult because the instructor did not provide an outline of an expected solution. At times, PT 1 did say that her explanation made sense to her: "I'm just like, I think this works. I hope it works. I don't know if it works, but it makes sense to me." This suggests that PT 1 is experiencing tension between viewing herself as responsible for determining what consists of a valid justification and wanting to meet the external standards of what the instructor wants for a justification to be considered valid.

PT 2. In contrast, we categorized PT 2 as having an internal source of authority. PT 2 clearly articulated coming to understand mathematics through her own sense-making. Throughout the interview, she mentioned first wanting to remember "math I was taught" but then recognizing that she could create her justification based on her own understanding, saying "for some reason, especially math, when I learned something… or like I can connect something on my own… I feel so much more accomplished!" In addition to viewing herself as an authority, she also mentioned looking to the instructor as a source of authority in sharing her uncertainty about "what [the instructor] was looking for" and looking to her classmates' slides as a source of authority for contributing mathematical ideas. She stated that she used her classmates' slides to help her know what to do on the first justification. While PT 2 viewed herself as a primary source of authority, she also recognized there is value in seeking help from the instructor, and her classmates. This illustrates how PTs with an internal source of authority incorporate, but do not replace, other external sources of authority with their own internal source of authority.

Discussion

PTs in this study struggled to provide justifications that were general both verbally and/or visually and the prevalence of the Friend and Friend/Skeptic codes indicate that PTs struggled with providing generic examples through a visual representation. This is consistent with current literature in our field (Lo et al., 2008; Martin & Harel, 1989; Rø & Arnesen, 2020). This analysis gives us context as we examine PTs' views of authority. The interview analysis indicated that nearly half (8 of the 18) of the PTs viewed themselves as primary sources of authority, while the others (10 of the 18) looked primarily to external authorities or had mixed views of authority. The purpose of this study is to explore potential limiting and supportive views of authority as evidenced through their discussion of their justification process. We turn now to a comparison of their justifications and their views of authority.

To address our first research question, "How do PTs descriptions of their justification process provide insight into their views of authority?" we analyzed PTs' interview transcripts as described in the results section above, finding that 7 of 18 PTs' first justifications were at the level of friend/skeptic and 10 of 18 PTs' second justification were at or above the level of friend/skeptic. We use this analysis to now address our second research question, "How do PTs' views of authority support or limit their justification?" and look back to PT 1 and PT 2 as illustrative examples, comparing their justifications with our findings about their views of authority.

PT 1

During the interview, PT 1 explained that she primarily looked to external sources of authority for validation. If we look at PT 1's justifications, we see that she did not develop a robust understanding of justification with her second justification remaining at the level of friend (see Table 1). However, several times in her interview she explained that "it makes sense to me, I don't know why." This is a productive place to start – recognizing the need for mathematics to make sense – to develop a robust understanding of justification. However, the need to "do what the instructor wants" appeared to limit her reasoning about each justification task. Instead of reasoning about the examples she had tried out, she expressed that she felt lost because she did not have an outline to follow, saying "Like there's no outline so I'm like, I don't know what you need." PT 1's description of this tension in determining whether or not she had a valid justification indicates that her need for external validation limited her efforts to produce a valid justification by way of making sense.

PT 2

In her interview, PT 2 described a process of discovery as she reflected on her experience in learning to justify. Her growing awareness that she can make sense of mathematics and does not need to rely on rules that she was taught, supported her exploration and reasoning. Several times in her interview she expressed that "When I figured it out, I was so glad!" and "It was like, just a cool connection to make!". PT 2 developed an understanding of justification that aligns with the course goals, i.e., she describes justification as a process of making sense, and we see the result of this in the improvements that were observed across justifications 1 and 2. Her work for her initial justification 1 and revision were coded at the same level of Friend/Skeptic and her justification 2 was coded as Skeptic (see Table 1). PT 2's view of herself as someone who could make sense of mathematics supported her experience in learning to justify.

Conclusion

In this study we observed PTs developing sense-making and mathematical reasoning skills through justification. We saw how students whose ideas about learning mathematics were focused on remembering what they had learned or trying to "do what the instructor wanted" limited their exploration of these tasks and contributed to their sense of frustration. PT 1's story illustrates this experience. In contrast, we saw students excited about their growing awareness that they can reason about mathematics for themselves, that they could contribute ideas in the instructional space through our shared Google slides, and could learn from their classmates' work. PT 2's experience illustrates this freedom in exploring mathematical ideas. Our PTs' descriptions of their experiences in learning to justify provides insight into views of authority PTs hold and provide evidence that what we see in their justifications do not tell the entire story. On the surface, reviewing their justifications does not explain the reasons for their incomplete justifications. Understanding how their views of authority set up barriers to reasoning about mathematics informs our work as mathematics teacher educators (MTEs). For example, noticing when PTs may view justification as writing "what the teacher wants" helps us identify this barrier and then address it through dialogue about a) the value of sharing one's initial understanding of a task and b) how to build on this understanding to reason about mathematics and "justify *your thinking"*. Furthermore, identifying moments when PTs use their authority to reason about mathematics helps us to support and leverage these moments and to alleviate uncertainty PTs may experience about sharing their reasoning. It is when we identify these barriers and address them, and when we identify productive views of authority and encourage these views, that MTEs will be better able to support PTs in justifying their reasoning and make sense of mathematics. Future studies can build upon this understanding and examine the impact of different teaching practices and tasks that are designed to support PTs in developing their internal source of authority.

mnathan@wisc.edu

In this study, we devised research design that provides pre-service teachers to effectively experience embodied geometric thinking with the goal that it will impact teachers' instruction to students in their classrooms. Using a motion-capture video game and design tool, we offered opportunities for pre-service teachers to experience of performing mathematically related movements as well as creating their own directed actions for given conjectures. We hypothesize that these gameplay and co-design activity will reinforce not only teachers' understanding of the embodied nature of geometric thinking, but also their abilities to transfer their understanding to classrooms and the activities and assessments they design for their students. The results showed that after experiencing the interventions including embodied gameplay and co-design activity, teachers' awareness of students' 'sage of gestures was changed and they had better ability to understand and interpret students' gestures as a means of teachers' formative assessment practices.

Keywords: Geometric thinking, embodied learning, gestures, pre-service teacher education

Geometry knowledge is a core component of mathematics curriculum in secondary education. Unfortunately, the formalisms and current pedagogical approaches for instruction in math classrooms are dominated by abstract and a-modal curricula that are often barriers for many students as well as their teachers. It is crucial that geometry instruction connects with students in ways that are intuitive and easier to understand and leverage the inherent, embodied ability of individuals to reason about space and shape.

In order to address such a challenge, our research team created a motion-capture video game, *The Hidden Village* (THV), to both direct and elicit learners' mathematically related movements and enhance geometric understanding. In effect, THV facilitates players' actions (i.e., *directed actions,* ref. Nathan, 2014) that are emblematic of geometric representations and transformations while also providing prompts that elicit gesture production during the process of geometric conjecture reasoning. The current study addresses a practical problem that many teachers often have naïve views of the role of the body in geometric thinking (Walkington, 2019) and fail to understand the cognitive connections that embodiment reinforces in geometric thinking. There is a recognized need for providing empirical guidance for when and how teachers can implement body-based learning activities in curriculum, and evidence-based principles for understanding the usage of gestures in embodied math activities.

Researchers had devised an in-person research program that brings pre-service teachers together to effectively teach embodied geometric thinking with the goal that it will impact teachers' instruction to students in their classrooms. Unfortunately, COVID-19 impacted *in situ* research such that it must be done remotely. The interactions between teachers, the actions they perform, the rationales they provide, the gestures they express, and the designs they co-create must occur virtually. Thus, providing teachers with embodied perspectives on geometry instruction in consideration of how to integrate these practices into their formative instruction and assessment. In the current study, teachers play THV to understand how the embodied curriculum connects to geometric thinking, after which they engage in reflective group discussion and co-design new conjectures with directed actions to help learners conceptualize geometric transformations.

Theoretical Background

Embodied mathematics specifically integrates multi-sensory experiences into conceptual understandings. Embodiment grounds (Barsalou, 2008) multi-sensory perceptions of mathematical structures and patterns that may not be accessible from symbolic representations (Gerofsky, 2007; Sinclair, 2005). With math knowledge grounded in body-based and spatial metaphors (Lakoff & Núñez, 2000; Roth, 2011) and action-oriented language (Nathan et al., 2014), learners often express their conceptual understandings in the form of gestures (Alibali & Nathan, 2012; Edwards, 2009; Ng & Sinclair, 2015a, b). In prior work, students' mathematical intuitions and judgments of conjecture veracity (i.e., *always true* or *false*) were reliably predicted by their dynamic gestures (Nathan et al., 2018).

Creating body-based systems for geometric thinking that employ directed actions offers opportunities for learners to physically mimic the spatial dimensions, relationships, and transformations of geometric conjectures (Nathan & Walkington, 2017). In turn, teachers can translate these experiences into effective embodied instruction (Alibali & Nathan, 2007; Roth, 2001) to connect concepts for students. For the current study, the intersubjectivity (Matusov, 2001) of teachers' collective embodied reasoning is distributed (Walkington, Chelule, Woods, & Nathan, 2019) during our collaborative design intervention.

We hypothesize that this co-design activity will reinforce not only teachers' understanding of the embodied nature of geometric thinking, but also their abilities to transfer their understanding to classrooms and the activities and assessments they design for their students. Thus, our main research questions are: (RQ1) How does embodied video gameplay and co-design activity eliciting teachers' gesture production enhance teachers' awareness of students' use of gestures? (RQ2) How do these interventions improve teachers' ability to interpret students' gestures and develop formative instruction and assessment practices?

Methods

Participants

Participants were K-12 pre-service teachers (N=16) enrolled in math courses at a midwestern research university. Participants received a $150 e-gift card for their participation. COVID-19 health precautions instituted by the chancellor of the university forced this *in situ* research on embodied group collaboration to take place entirely online, using Zoom, a securely private platform approved by the university's IRB. Fortunately, Zoom enables participants to interact and collaborate with each other in a virtual group setting while recording audio and video of each participant.

Materials

We observed teachers' cognitive processes during THV gameplay. This included their performances of directed actions to embody geometric conjectures as well as their reasoning and explanations. Given the constraints of conducting remote research in the time of COVID-19, both direct and indirect scaffolds for each step of the intervention were developed to ensure adherence to research protocols and preserve fidelity of data collection.

The Hidden Village (THV). THV delivers interactive math geometry curriculum in the form of online motion-capture video game in which each player mimics movements of in-game characters and then reads a geometry conjecture to determine its veracity. Levels of the game are each comprised of 6 parts (*see* Figure 1): (A) Meeting members of the hidden village, (B) the village people implore players to mimic movements (e.g., mathematically relevant directed actions), (C) players receive a math conjecture, (D) players indicate if the conjecture is *always true* or *false* and provide explanation, (EIultiple choice, and (F) players receive rewards and progress game achievement.

Prior to gameplay, participants were provided an introductory tutorial containing instructions for setting up for research participation, a practice trial to familiarize participants with THV gameplay. For gameplay, students were paired into dyads with one person performing the directed actions (i.e., the actor) from the game while the other player observes (i.e., the observer). Midway through the game, players switch roles.

After gameplay, participant dyads rejoined their group to discuss any connections between the directed actions and the conjectures they were proofing. Discussion was guided by three prompts: (1) how in-game directed actions affected teachers' understanding of geometry, (2) how directed actions can be applied in the classroom to support geometry learning, and (3) how teachers can interpret students' spontaneous gestures as a formative assessment of students' understanding to improve their instruction.

Figure 1: The overall structure of THV gameplay

The Hidden Village Conjecture Editor. THV conjecture editor is a tool for participants to create new content for THV. This includes the creation of directed actions for each conjecture in the co-design activity. Since the co-design activity was conducted virtually, a researcher served as a proxy to manipulate the conjecture editor at the participants' behest. The teachers were given a tutorial outlining the features of THV conjecture editor and explaining the mechanics for manipulating the in-game avatar to create directed actions for a given conjecture (see Figure 2). The entire co-design activity was video recorded including participants' gestures and discussions.

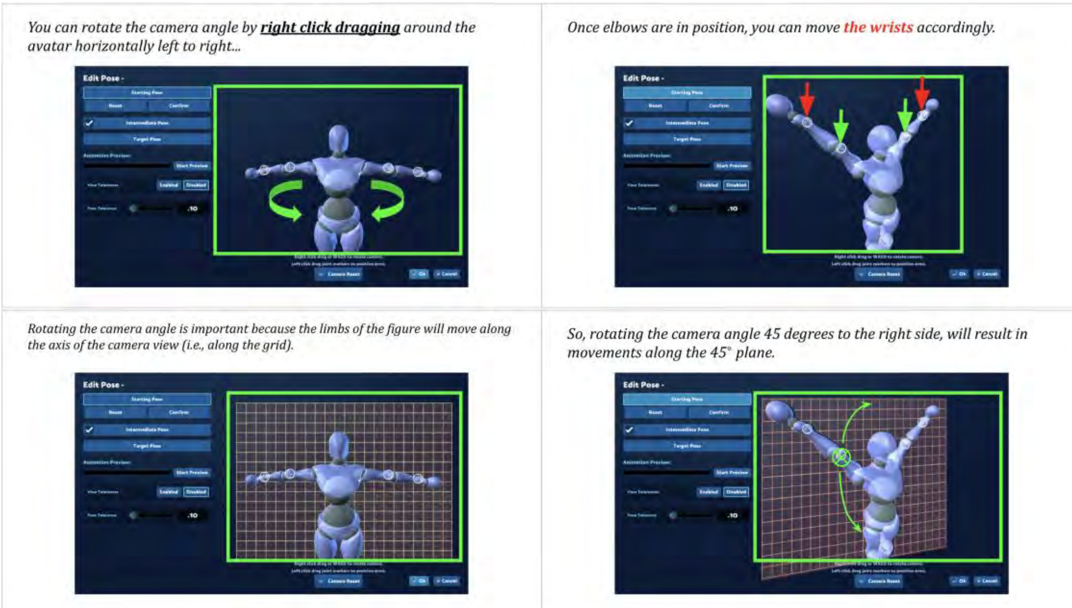

Figure 2: The slides of the design tutorial to inform how to use THV conjecture editor. (e.g., The avatar is posable using computer mouse. The figure can be rotated using a right-click drag or reset back to its origin.)

Online videos

In the beginning and the end of the intervention, teachers watched short 1-minute-long videos in which a student reasoned why a certain geometric conjecture statement is either always true or false. The scenes in the videos depicted high school students reasoning geometric conjectures (re-enacted for confidentiality reasons). In a semi-structured interview, teachers were prompted to comment on the videos and asked to explain (1) how they interpreted or assessed the student's understanding of the mathematical concept, (2) what evidence they observed, and (3) what practices they could employ in their classroom.

Online surveys

One week prior to the intervention, participants received online links to provide consent and complete surveys. These survey measures included: (1) the *Diagnostic Geometry Assessment* (DGA; items clustered in three areas: properties of shape (14 items, $\alpha \geq 0.86$), transformations (10 items, $\alpha \geq 0.795$), and measurement (11 items, $\alpha \geq 0.81$)); (2) a truncated version of the *Spatial Reasoning Instrument* (SRI, 15 items clustered around three constructs of mental rotation, spatial visualization, and spatial orientation, $\alpha \geq 0.88$); and (3) a survey of *Teachers' Attitudes about Gestures for Learning and Instruction* (TAGLI; 40 items, Cohen's $\alpha > .70$).

Procedure

This study is a mixed-methods, repeated-measures, within-subject design. The day of the intervention, participants took part in a number of activities over the course of 3.5 hours. First, participant groups were banded together by grade levels (i.e., grades K-5 and 6-12), after which they began a series of activities, including: (1) each teacher previewing and commenting on a 1-minute video of a student considering whether a geometric conjecture is either always true or false (30 minutes), (2) paired gameplay of four conjectures in THV in which players are encouraged to perform the directed actions by mimicking an in-game avatar's movements (30 minutes), (3) a whole-group discussion and co-design activity in which four pre-service teachers co-create directed actions for given conjectures using THV conjecture editor (90 minutes), and (4) watching and commenting (i.e., interpreting the relationships (if any) between students' gestures and geometric thinking) on two new 1-minute videos of a student considering whether a geometric conjecture is either always true or false as well as retaking the TAGLI survey (30 minutes).

Data analysis

The activities and measures provided researchers with data to assess changes in teachers' awareness and interpretation of students' understandings. The design of the study included pre- and post-intervention measures, teachers' gameplay and co-design activity. As an ongoing study, all videos of gameplay and co-design will be transcribed, segmented, and coded for teachers' speech and gesture usage articulating their intuition, insight, and proof production.

Results

Our major predictions were that gameplay and co-design activity that promote teachers' use of gesture will affect (1) teachers' awareness of students' 'sage of gestures and (2) teachers' ability to understand and interpret students' gestures as a means of teachers' formative assessment practices. In order to find out how the interventions we designed affect teacher's ability to interpret students' gestures, we compared the pre-intervention interviews and post-intervention interviews. The interviews were conducted individually.

Below are the examples of teachers' gameplay (see Figure 3) and co-design activity (see Figure 4) that teachers experienced. After the gameplay, teachers had a debrief of their experiences, discussing how in-game directed actions affected teachers' understanding of geometry. Half of the teachers said that they did make the connection between the conjectures they played and the movements they made during gameplay whereas the rest of half said they honestly did not notice the linkage. In common, the teachers who realized the connection during gameplay mentioned that they were able to get the ideas about the veracity of the geometric conjectures by performing the directed actions and they used that information in their reasoning processes.

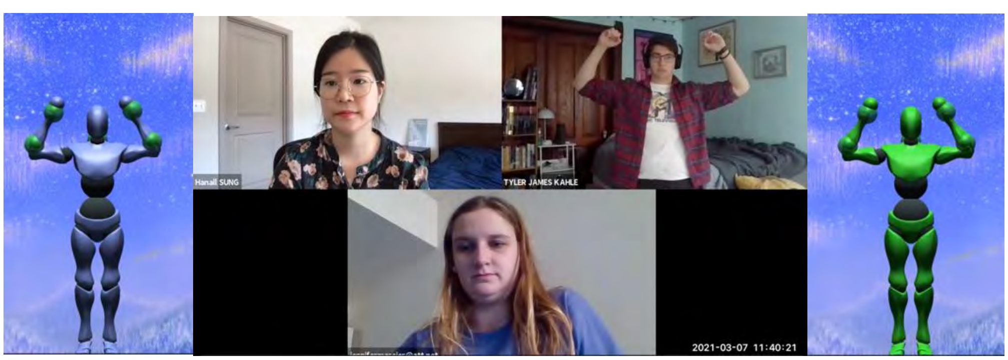

Figure 3: A screenshot of performing a directed action for a conjecture during THV game play

For the co-design activity (see Figure 4), participants were prompted to discuss geometric conjectures and consider how creating body-based directed actions enactive of geometric transformation could foster student learning.

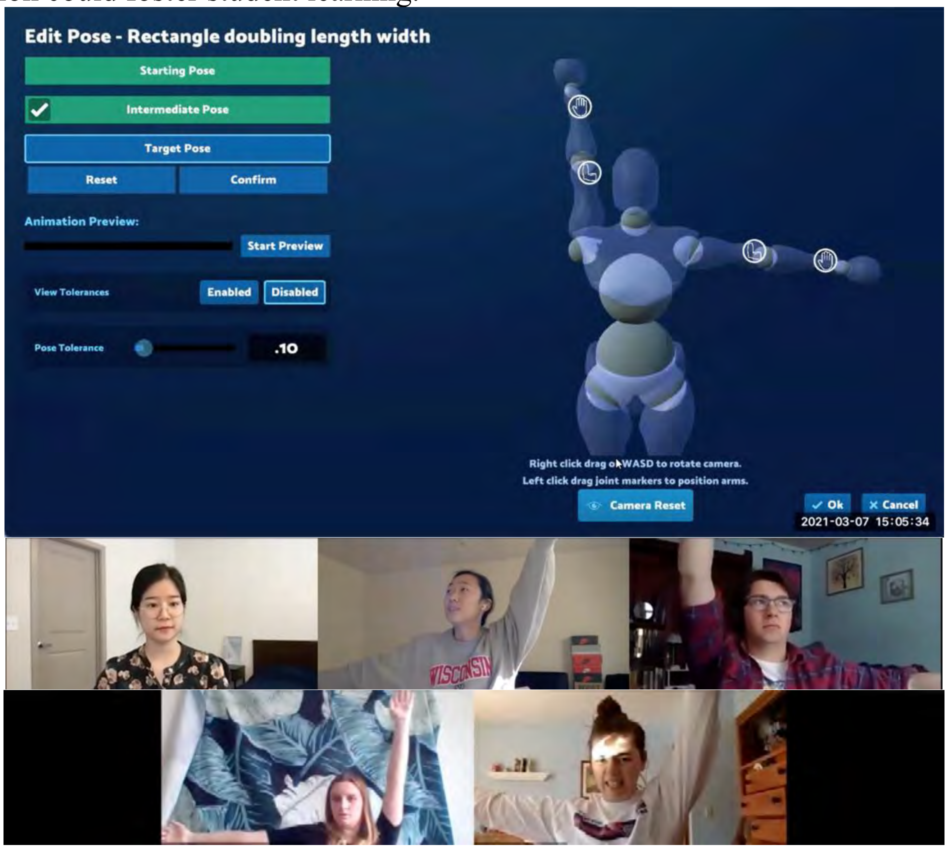

Figure 4: A screenshot of teachers' discussion to create new directed actions for conjectures during co-design activity

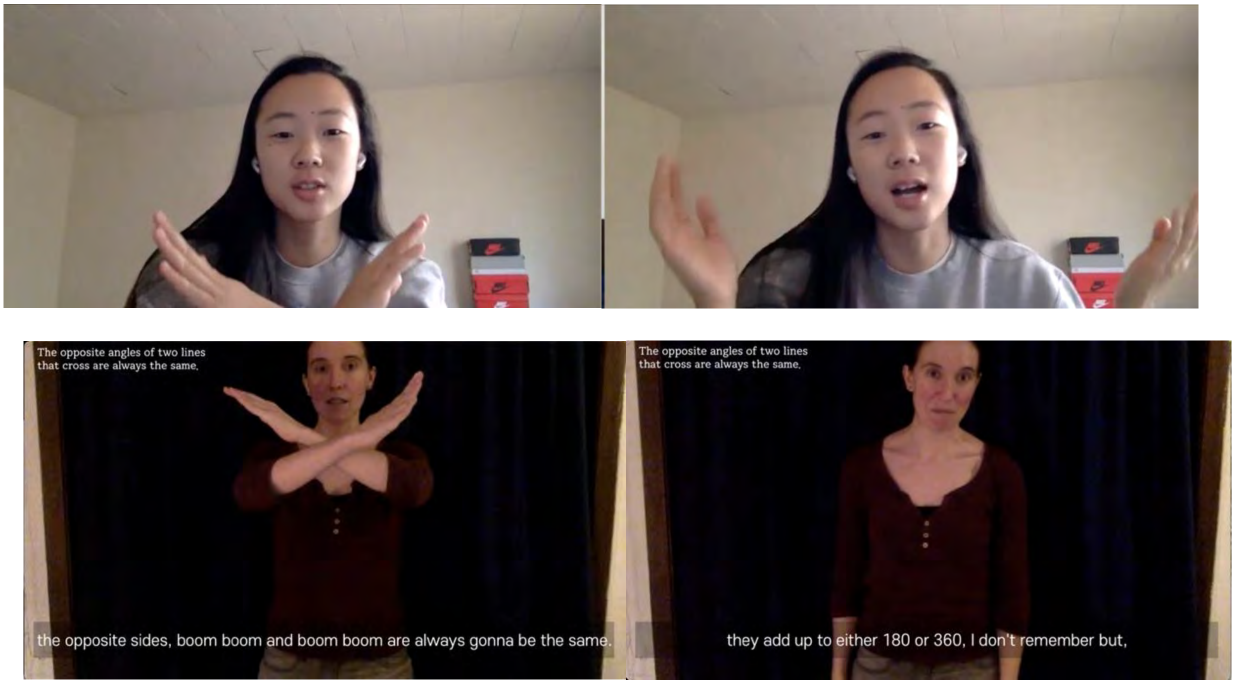
In the pre-intervention interviews with teachers, we found that teachers provided both gestures and verbal utterances of the student in the video as their evidence to assess the student's mathematical understanding of a certain conjecture (i.e., *The opposite angles of two lines across are always the same*). However, teachers' interpretation was limited—they were only able to share their superficial impressions of whether the student has the correct idea of the geometric conjecture, speculating from the student's tone, attitude, and vocabularies.

Presented here is a representative example of the pre-interviews with teachers (see Figure 5). Included is a photo transcript of Teacher 1's gestures and speech while explaining their interpretation of the student's mathematical understanding.

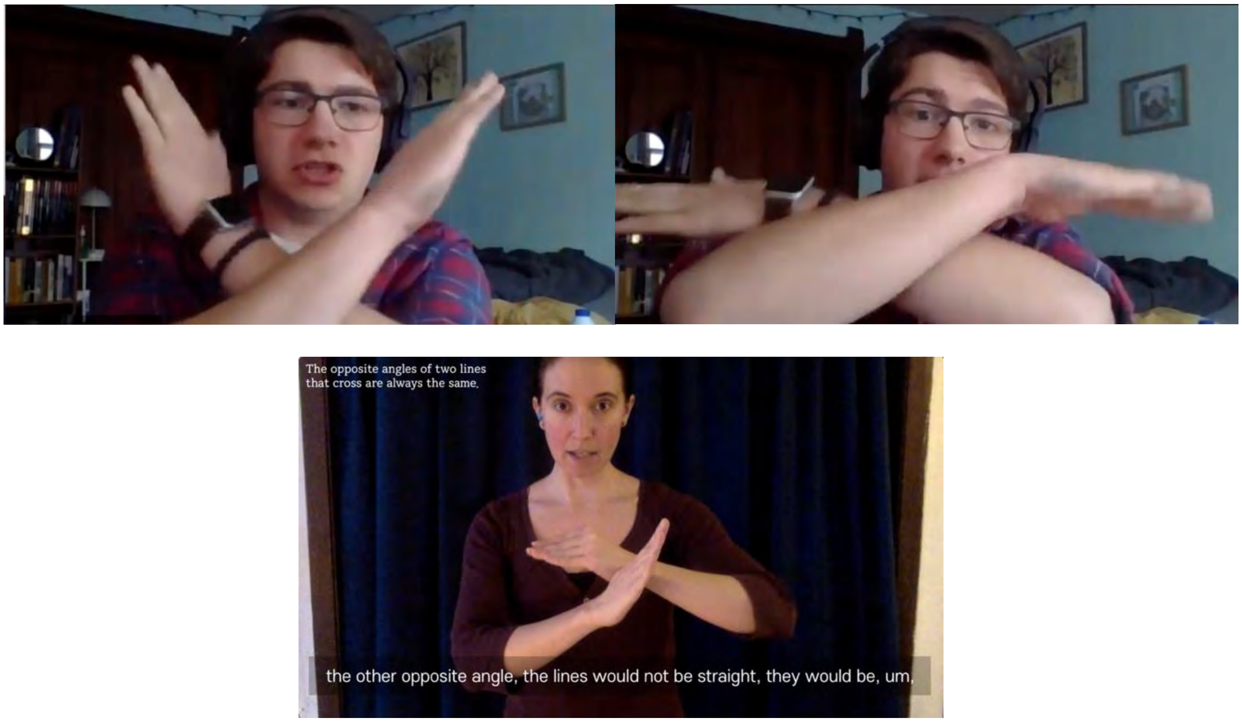


Teacher 1: She understood the opposite rule [mimicking the student’s X pose], but when she said “it either adds up to 180 or 360” and then was like I don't know really [making a pose to portrait ‘I don’t know’] at the end that just tells me that she doesn't fully understand the role, because if you understood the rule that would be like the two side by side angles would equal 180, so she doesn't have like the full understanding, but she has like the very basic core understanding of what the rule should be.

Figure 5: An example of pre-interviews
(top row: Teacher 1, bottom row: the pre interview video clip)

By mimicking student’s particular gesture representing vertical angles (Figure 5, top row), Teacher 1 showed that they perceived the student’s basic understanding of the geometric conjecture, but their focus quickly moved to the utterance and interpreted the student’s level of understanding based on how the student verbally described the utterances (“It either adds up to 180 or 360”).

On the contrary, we found that teachers in the post-interviews were more focused on the connection between the student’s gesture and their reasoning processes. For example, Teacher 2 interpreted that the level of the student’s mathematical understanding of the conjecture is poor and provided several rationales. First, by integrating the information from student’s gesture and speech (Figure 6, bottom row), Teacher 2 noticed that the student in the video was trying to provide reasoning with proof by contradiction (Transcript in Figure 6, “The logic she was trying to use was almost like a contradiction, like a proof by contradiction I felt like”). Next, Teacher 2 pointed out that the ineffectiveness of the student’s gesture in their reasoning process by saying “the gesture, she kept using, which is this [mimicking the student’s poses], but like she didn't’really do anything with it” (Figure 6, top row). That is, Teacher 2 paid attention to not only the meaning of the student’s gestures but also the function of the gestures in their geometric understanding.



Teacher 2: I thought she did a kind of poor job on that one. You very much could see the problems. The logic she was trying to use was almost like a contradiction, like a proof by contradiction I felt like. She was trying to say “okay, well, if the lines aren't straight than the angles won’t work”. And the gesture, she kept using which is this [mimicking the student’s sequence of poses], but like she didn't really do anything with it.

Figure 6: An example of post interviews (top row: Teacher 2, bottom row: the post interview video clip)

Discussions

The qualitative results of this study demonstrated that the interventions that include gameplay and co-design activity facilitated teachers’ use of gesture had impact on changes in teachers’ awareness of students' ’sage of gestures. Although teachers mimicked the student’s gestures that they observed in the videos in both pre- and post-intervention interviews, the level of information that teachers were able to extract from the gestures were different—they were more likely to focus on how and why students used gestures in their proofings in the post-interviews. Moreover, the results showed that the embodied interventions affected teachers’ ability to understand and interpret students’ gestures as a means of formative assessment practices. After experiencing the interventions, teachers were more likely to assess students’ geometric thinking better by focusing on the function of gestures in their reasoning.

This study has several limitations. First, as an ongoing study, we do not provide any quantitative results yet. Second, the recordings of gameplay and co-design have not been fully analyzed, so we were not able to articulate teachers’ learning processes during the interventions. Third, the sample size is pretty small because it was conducted as pilot study. We plan to deal with these limitations in our future work.

Despite these limitations, the preliminary results of the study suggest that the embodied intervention has reasonable potentials to change teachers’ belief and attitudes toward gestures.

Considering an average 14.2-year career of teachers, we expect the potential changes in these 16 teachers could influence over 15,000 students. In a broader consideration, the findings of this research are for the benefit of pre-service and in-service teachers who provide instructional practices at the forefront as well as professors of mathematics education and can be extended to professional development.

TASK DEVELOPMENT TO ADDRESS ERROR PATTERNS IN PROSPECTIVE ELEMENTARY TEACHERS' POSING OF MULTI-STEP WORD PROBLEMS

Ali Foran	Rachael M. Welder	Ashley Williams

aliforan@tamu.edu	welder@tamu.edu	amcraft91@tamu.edu

National and state standards in the US have emphasized the importance of solving and posing word problems in students' mathematics learning for decades. Therefore, it is essential for prospective teachers (PTs) to have the mathematical knowledge necessary to teach these skills to their future students. Unfortunately, little research has investigated how PTs develop problem-posing skills. By employing thematic qualitative text analysis, the researchers identified nine distinct patterns in errors identified in K-8 PTs' posing of two-step addition and subtraction word problems, in the context of a collegiate teacher education course. These results were used to inform the initial design of an interventional task to bring awareness of common errors to PTs.

Introduction

The Standards for Preparing Teachers of Mathematics put forth by the Association of Mathematics Teacher Educators (AMTE; 2017) recognize that well-prepared beginning teachers of mathematics "regard doing mathematics as a sense-making activity that promotes perseverance, problem posing, and problem solving. In short, they exemplify the mathematical thinking that will be expected of their students," (p. 9). Research focuses heavily on teaching prospective elementary teachers (PTs) to persevere and problem solve (Alibali, et al., 2014; Bruun, 2013; Crespo, 2003; Green & Emerson, 2010; Jitendra et al., 2013; Polya, 1945) but, until recent years, has put little emphasis on the problem-posing skills PTs are expected to develop.

The Common Core State Standards (CCSS) Initiative in the United States (NGA & CCSSO, 2010, Table 1; NGA & CCSSO, 2010, Table 2) has presented taxonomies of common addition and subtraction and common multiplication and division situations that can be used to introduce PTs to the intricacies of the operations. These taxonomies can function as a steppingstone for helping PTs develop single-step problem-posing skills. However, the CCSS for Mathematics suggest that children "solve one- and two-step word problems involving situations of adding to, taking from, putting together, taking apart, and comparing, with unknowns in all positions" (NGA & CCSSO, 2010, p. 19) already starting in the second grade. Thus, we argue that once an introductory understanding of problem posing has been developed in teacher education coursework, attention should be drawn to developing PTs' skills for posing multi-step word problems.

When it comes to solving multi-step word problems, Heffernan and Koedinger (1997) found that solvers may experience what they called a "composition effect," meaning that "a two operator problem is harder than both of the parts that make it up put together" (p. 310). Alibali et al. (2014) extended this idea to posing, noticing that middle school students who were able to pose single-step problems also showed increased difficulty in posing two-step problems. As such, the researchers investigated two research questions:

1. What patterns emerge in the errors that arise when PTs write two-step addition and subtraction word problems?
2. What instructional interventions may help PTs to notice and potentially avoid making common errors when posing multi-step problems?

The researchers evaluated a corpus of 282 two-step addition and subtraction word problems posed by PTs enrolled in a problem-solving course for undergraduate education majors to identify common error patterns. With the results of this analysis, the researchers then created an error-analysis task for K-8 PTs to help draw attention to common two-step problem-posing errors with the hope that it might help them prevent making such errors in their own problem-posing experiences. This paper reports on the results of the thematic qualitative text analysis completed to answer the first research question and shows how these findings were used to develop an interventional task. The task was implemented in this course the semester following the word problem analysis. We will share our preliminary findings from this first implementation and discuss how they informed modifications. A second version of the task is currently being implemented and data is being collected to analyze the effectiveness of this task.

Literature Review

While problem posing research has been growing in popularity over the past several decades (Cai, Hwang, Jiang, & Silber, 2015; Einstein & Infeld, 1938; English, 1998; Kilpatrick, 1987; Silver, 1994; Silver & Cai, 1996; Singer et al., 2013), only over the past 15 years have researchers turned their attention to the preparation of PTs as problem posers (Cai et al., 2020; Crespo & Harper, 2020; Crespo & Sinclair, 2008; Ellerton 2013; Lavy & Shriki, 2007; Leikin & Elgrably, 2020). U.S. national and state standards have been encouraging teachers to implement problem-posing activities in their K-12 classrooms for over three decades (NCTM, 1989, 1991, 2000; NGA & CCSSO, 2010; TEA, 2012), but in order for those problem-posing tasks to be implemented well, PTs must be well-prepared to "manage the complexities of such contexts" (Singer et al., 2013). The Standards for Preparing Teachers of Mathematics put forth by AMTE (2017) indicate that effective mathematics education programs "develop positive dispositions toward mathematics, including persistence and a desire to engage in posing and solving problems," (p. 70). Our attention as mathematics educators then turns toward how we can efficiently prepare PTs to pose a variety of word problems and how the skills they learn can be applied in their future classrooms. For the sake of this study, the researchers will be referring to free problem posing, which occurs before problem solving, where problems are generated using a "contrived or naturalistic situation" (Stoyanova & Ellerton, 1996, p. 519).

Problem posing has shown to illuminate areas of conceptual misunderstanding in students (Alibali, 2014; Sharp & Welder, 2014), so it is important that introductory problem-posing activities involve mathematical content with which PTs are familiar. The CCSS Initiative has broken down addition and subtraction scenarios into 15 clearly distinguished categorical structures (NGA & CCSSO, 2010, Table 1). It is important that children are exposed to all 15 types of addition/subtraction problems or they may develop limited conceptions of the meanings of the operations (Van de Walle et al., 2019) or limited solution strategies (Carpenter et al., 2015). Therefore, PTs must not only be aware of the 15 different structure types of additive word problems, they must also be skilled in solving and posing every type. Once familiar with the various one-step scenarios, teacher educators can discuss how to connect multiple scenarios together to form multi-step problems. At this point, PTs can be engaged in developing their skills in posing two-step problems by connecting a variety of problem types.

In mathematics, the literature has recommended the use of error analysis as a means for gaining a deeper understanding of student knowledge (Fleishchner & Manheimer, 1997; Luneta & Makonye, 2010; Raghubar et al., 2009; Seng, 2010). By analyzing the types of errors made by PTs when posing two-step problems, we can design intentional instruction to support PTs in recognizing common errors and understanding why such errors occur. We utilized the skill of error analysis to form the basis of our task design, which asks PTs to analyze a set of flawed, or negative, problems. Research shows that the use of negative examples, in addition to positive examples, can be helpful in teaching good writing habits (Grow, 1987). Instructional psychologists also recommend using negative examples to "prevent certain classification behavior errors" (Ali, 1981). As such, the researchers of this study used the results of our analysis of PTs error to create an interventional task containing a set of negative examples for PTs to analyze, prior to posing their own multi-step problems.

Methods

A team of researchers at a tier one research institution in the southern United States worked over several years to create and incorporate a variety of instructional activities that could effectively support PTs in developing problem posing skills. This work was in the context of an undergraduate mathematics problem-solving course with the purpose of helping PTs understand how to teach mathematics through problem solving (Alwarsh, 2018; Bostic et al., 2016; Chapman, 2017; Fi & Denger, 2012), which puts word problems at the forefront of the lesson and introduces new content through the problems themselves (Alwarsh, 2018). Therefore, problem-posing activities were integrated into this course to support PTs in developing the skills they will need for posing problems for their students – specifically single- and multi-step. The writing and analysis of these word problems creates a productive dialogue between the PTs and the course instructors that allows PTs to develop a deeper understanding of the meanings for the mathematical operations and prepares them for posing problems for their future students to solve.

In this course, PTs are originally introduced to the previously mentioned taxonomy of common addition and subtraction structures as identified by the CCSS (NGA & CCSSO, 2010) as a basis for discussing structural differences between addition and subtraction word problems. The PTs then work on posing one-step word problems to match each of 14 possible problem structures (the fifteenth structure, part-part-whole – both parts unknown, involves multiple unknowns and, for the sake of one-step solvability, is left out of posing instruction). Class activities then turn to focus on categorizing and solving two-step addition and subtraction word problems. PTs are then given a series of assignments in which they practice posing a variety of two-step word problems . Increasingly more complex pairs of structures are assigned to guide PTs' posing to push them beyond using the same or easiest structure types (e.g., PTs tended towards posing change – add to – result unknown and part-part-whole – whole unknown problems, two structures introduced in Kindergarten (NGA & CCSSO, 2010)). Table 1 shows the culminating task for this set of lessons, in which PTs are assigned to pose four two-step addition/subtraction problems to match the four provided pairs of structures.

The data included in this report was collected from a single instructor's course across two semesters (including 74 total PTs). All PTs were enrolled in teacher certification programs in the areas of EC-6 (Generalist) or grades 4-8 mathematics and science or English and history. The assignment in Table 1 resulted in 282 PT-posed, two-step word problems that were analyzed in this study.

Table 1: Two-Step Addition and Subtraction Word Problem Prompts

Prompt	Assigned Pairs of Structures
1	change – subtract from – change unknown; compare – fewer – bigger unknown
2	change – add to – start unknown; compare – more – bigger unknown
3	part-part-whole – addend unknown; compare – more – difference unknown
4	change – subtract from – start unknown; part-part-whole – addend unknown

The researchers used thematic qualitative text analysis to analyze the submitted word problems resulting in 124 correct problems that matched the assigned structures and 158 problems that showed at least one error. As each error was identified, a temporary category was created based on the number of steps required to solve each incorrect problem and whether the structures used matched the assigned prompt. Two researchers independently coded the corpus of 282 word problems and discussed any disagreements until 100% of the analyzed word problems had been assigned an agreed upon code.

Results

Phase 1: Error Analysis

As previously mentioned, 124 of the submitted word problems correctly posed a question that required a two-step calculation utilizing two scenarios that both matched the assigned structures. The remaining 158 PT-submitted problems were coded as having one or more errors. The analysis of these errors led to the identification of nine distinct categories of error patterns (see Table 2), dependent upon the number of steps required to solve the problem, the appropriateness of the question(s) asked, and the use of the assigned structures. Below we will introduce each category of error pattern by providing examples of PTs' work and highlighting where the error occurred.

Two-step – Incorrect structure(s). Fifty-six of the problems correctly posed a question that required two connected steps that required addition or subtraction and were only deemed to be flawed because they did not entirely match the assigned prompts. For example, one such problem submitted in response to the first prompt read:

> Lauren has five apples on the table and Henry has two apples on the table. Lauren gives some of her apples to Henry. Lauren now has three apples. If Lauren now has less apples than Henry, how many apples does Henry have now?

Although the first step correctly matches the first assigned structure (change – subtract from – change unknown), the second step is a change – add to – result unknown scenario (instead of compare – fewer – bigger unknown). The question requires the solver to take the two apples that Lauren lost and add them to Henry's original two apples. There is no comparative structure included in this problem.

Table 2: Frequency of Error Type Exhibited by PTs

Category	Sub-Category	Frequency
Two-step	Incorrect structure(s)	56
One-step	One question: Two correct structures	31
	One question: Incorrect structure(s)	32
	Two questions	5
More than two steps	Including two correct structures	8
	Incorrect structures	4
Zero-step		3
Algebra-style		4
Unanswerable		15
	Total	158

One-step problems. With 43% of the total errors, the most common error group resulted from PTs who could build up two addition/subtraction structural situations but could not properly combine the unknown values from each scenario into a question that required a two-step calculation. These problems can be separated into three subgroups: problems that used scenarios matching both of the assigned prompts , problems that used at least one incorrect scenario, and problems that asked two independent questions.

About 50% of the 63 one-step, one-question problems built contextual scenarios that correctly matched both of the requested problem structures. The remaining 50% of the one-step one-question problems were flawed in the sense that at least one scenario did not fully match the requested structures. However, due to a lack of connection between the two scenarios, in both of these groups, the question posed only required one calculation to be solved. This tended to result from a known from the first scenario being used in the second calculation. One example of such a problem was submitted to Prompt 2. The PT wrote:

> Sarah had some pieces of candy. Four more pieces were given to her, so she had ten pieces of candy total. Amanda had five more pieces of candy than the amount of candy Sarah was given. How many pieces of candy does Amanda have? (Problem 1)

In order to answer the question that was posed, the solver would use the four pieces of candy that Sarah was given and add the comparative difference of five to reach Amanda's total of nine. This only requires one calculation, i.e. step. The PT did correctly set up the structures from the prompt but did not connect the unknown from the first scenario to the second.

A second example of a one-step problem was submitted to the first prompt. It read, "Some balloons were blown up. Two of them were popped. Only three remained. Two of them were red and the rest were blue. How many were blue?" (Problem 2). Both scenarios match the prompts, but notice that with the three remaining balloons, "two of them were red and the rest were blue," only requires one calculation to solve (3-2=1). This PT developed a scenario where the two unknowns could have been connected by referring back to the original set of balloons, but instead posed a question that didn't require the solver to utilize the unknown information from the first step (the original number of balloons) in the second step. The use of a known from one scenario to set up the structure of a second scenario was not specified as an error in the table but was by far the most common issue in one-step problems. PTs could create scenarios matching the given prompt structures independently but experienced the "composition effect" (Heffernan & Koedinger, 1997) of not being able to merge two unknowns into a single question.

In the remaining five of these 68 problems, the poser wrote two separate questions, each only requiring a single step to solve. Four of these problems included the correct assigned structures, one did not. The PTs who wrote these problems knew that two steps were necessary to satisfy the given task but showed difficulty in connecting their unknowns into a single question. One such example is, "Tommy had seven envelopes, then he lost some of them. Now he has four envelopes. Tommy has five fewer envelopes than his friend Milton. How many envelopes did Tommy lose? How many envelopes does Milton have?" (Problem 3). The two, single-step questions here are clear, but a well-developed, two-step problem must require the solver to complete two connected calculations by only asking one question.

More than two steps. Twelve of the remaining problems successfully posed a valid multi-step addition/subtraction problem but asked a question that required three or more steps to answer. Eight of these problems correctly included both of the assigned structures, but the PTs were unable to formulate a question that only used the information found in those two steps. An example of this that was submitted to Prompt 1:

> Lucy has 3 fewer cookies than Julie. Lucy has two cookies. If Lucy and Julie both put their cookies in a jar but someone takes some cookies and leaves only 3 cookies in the jar, how many cookies were taken? (Problem 4)

The first step in solving this problem is a compare-fewer-bigger unknown (which matches the second assigned structure) where the solver calculates Julie's amount. The second step is a part-part-whole where Lucy and Julie merge their cookies together. Once the solver finds the joint number of cookies, some of those cookies are taken out. A third step then asks the solver to find how many cookies were removed, a change – subtract from – change unknown scenario (which matches the first assigned structure).

Zero-step problems. Three problems posed by PTs provided the answer to the posed question within the problem statement. These were labeled at zero-step problems since no computation was necessary to answer the posed question. In one example of a zero-step problem, the PT wrote, "I had some cookies. I got seven more cookies. Now I have 13 cookies. Courtney has some cookies. I now have seven less cookies than Courtney. How many cookies do I have?" (Problem 5). There are no steps required to solve this problem as the answer lies in the statement ("now I have 13 cookies"). This was the least frequent of the error patterns.

Algebra-style problems. A similarly small group of four problems offered scenarios for two unknowns that were not able to be solved by simply computing two sequential one-step arithmetic calculations. Instead, these problems provided information that connected the two unknowns in two different ways making the question posed answerable but requiring the solver to apply more complex algebraic thinking. For example, the following problem was submitted to the Prompt 2:

> Sally had some pencils. Then her mom gave her three more pencils to take to school. When she got to school Ruby had 3 more pencils than Sally. Altogether they had 13 pencils. How many pencils did Sally have when she got to school?

The given information could be represented with two numerical equations, but, in each equation, both quantities are unknown (i.e., $S + 3 = R$ and $S + R = 13$).

Unsolvable problems. The remaining 15 problems posed were deemed unsolvable as there was no clear way to actually answer the question that was asked. However, this error occurred due to multiple reasons three examples are given below. The first problem was unsolvable because no question was asked. This scenario was submitted for the second prompt, "Santa wrapped some presents. His wife helped him wrap 6 more, now there are 10 presents. Santa's elf helped too, he wrapped 2 more presents than Santa did initially" (Problem 6). The context was set up perfectly for the prompt, a question just needed to be asked.

The second example of an unsolvable problem was submitted for Prompt 4. The PT wrote, "Some oranges were on the plate, 3 were big and the rest were small. I ate 3 oranges. Then there were 2 oranges left on the plate. How many small oranges are left?" (Problem 7). This problem is missing contextual clarification. The poser chose to distinguish small oranges from big oranges, but then went back to discussing "oranges" in general. In order to solve the problem, the reader would need to know what size of oranges were eaten and what size of oranges remained at the end.

The final unsolvable problem example was submitted to Prompt 2. The PT wrote, "Nine bananas were on the table. Five were green and the rest were yellow. Then my mom came and took 2 of the yellow bananas. How many more bananas do I have than my mom?" (Problem 8). In order to confidently solve this problem, the solver needs more information about who each set of bananas belongs to. It is not clear whether all nine of the beginning bananas belong to the problem poser or the family in general.

Phase 2: Task Design

The results of the error analysis provided the researchers with valuable information regarding the challenges faced by PTs when posing two-step addition and subtraction problems. The researchers utilized this information to develop an interventional task for use with future PTs. The task was designed to bring awareness of common errors made when posing two-step problems to PTs prior to having them pose their own two-step problems. The task offered a set of flawed, or negative, problems that PTs would be asked to analyze. To create authenticity, we used example problems from our error analysis instead of constructing our own. The PTs were presented with a set of word problems and the following instructions:

> Imagine that you asked your students to write a 2-step addition/subtraction word problem and below are some of the word problems they wrote. For each word problem, explain to the student why their problem is incorrect or incomplete and briefly discuss how it could be fixed.

To create authenticity, we used the results from our Phase 1 analysis to identify key examples of PT-written word problems exhibiting the identified errors and used these on the task instead of constructing our own flawed problems. In developing this task, the researchers chose to focus their attention on PTs' ability to create well-written, two-step problems rather than on their ability to match a specified set of structures. For this reason, none of the 56 PT-submitted questions that correctly required two steps to solve (but were deemed flawed because the structures were not entirely matched) were included in this error analysis task. Additionally, in this initial version of the task, the researchers chose to focus only on problems that were written arithmetically. At that time, algebra-style problems were not being covered in the course, so those types of errors were excluded from the error analysis task as well. The task included eight questions previously coded as having a structural error (labeled as Problems 1-8 above).

Discussion

Implementation of Task

The error-analysis task created as a result of this analysis was implemented in the following semester. The task was strategically placed between two lessons that ensured PTs had already been exposed to analyzing two-step addition and subtraction word problems but had not yet attempted posing their own two-step word problems. Leading up to the error-analysis task, PTs had spent time learning about the 15 categories of addition and subtraction word problem types, practiced posing one-step addition and subtraction word problems, and categorized and written number sentences to solve two-step addition and subtraction word problems. The error-analysis task was assigned for PTs to complete individually outside of class time. Each problem on this task and PTs' responses to this task were discussed in the following class meeting. After this work, PTs began posing their own two-step addition and subtraction problems. As they practiced posing two-step word problems, first with addition/subtraction and later with multiplication/division and mixed operations, the errors described in this task continued to be identified and discussed.

Preliminary Task Results

Initial analysis of the task's first implementation showed promising results in terms of PTs being able to accurately identify most of the intended errors on the task and to identify common errors later when reflected in their own and others' posed problems. However, the researchers found that four of the problems were not demonstrating the errors strongly enough. During a preliminary qualitative analysis of the results, researchers aimed to identify the cause for PTs' difficulties in identifying the intended errors in the word problems on the error-analysis task. The researchers observed that Problem 2 was missing contextual information which distracted PTs from the intended error of it being a one-step problem. On Problem 4, a three-step problem, PTs focused on the tense of the verbs in the word problem and the order of which the numbers appeared; for example, some thought the result would be a negative amount of cookies. Similarly, on Problem 1, PTs seemed confused by the verb tense used throughout the problem and this took focus away from the intended issue that it was only a one-step problem. Finally, Problem 3, an example with two individual questions, also has the error of one of the knowns from the first step being used in the second step, making it a one-step problem. Although it was useful for PTs to point out all of these issues, these four problems were not adequately focusing PTs' attention on the type of error we intended the problem to highlight. Therefore, all four of the problems were traded for other PT-submitted problems that were coded under the same error category during the original data analysis. The instructions were also adjusted to reflect the fact that PTs' responses tended to offer fixed versions of the problems instead of identifying the error. The PTs were more explicitly asked to identify the error made, without fixing it, and to provide an explanation that would help a peer understand why the problem is not a two-step arithmetic addition and subtraction problem.

Future Research

The modified version of this task is being implemented in current sections of the course. Data is being collected and the researchers will analyze results from the implementation of the updated error-analysis task for future use and improvement. Additionally, researchers will perform a comparative analysis of PTs' posed word problems from the semesters in which the interventional task was implemented to previous semesters to investigate the possible implications the task may have had towards supporting PTs' problem-posing abilities through raising their awareness of common error patterns.

FORMS OF NASCENT POLITICAL CONOCIMIENTO LEVERAGED IN A CONTENT COURSE FOR PRESERVICE ELEMENTARY TEACHERS

Alexa W.C. Lee-Hassan
Learning Sciences Research Institute, University of Illinois Chicago
aleeha2@uic.edu

This study examines the nascent forms of political conocimiento demonstrated by elementary preservice teachers before and after a series of activities designed to engage them in thinking critically and quantitatively about the impacts of different grading systems. In reflections about their learning, the preservice teachers most frequently raised considerations related to knowledge with students and communities, followed by political knowledge. Many of the preservice teachers anticipated using their new knowledge in the near future to understand the implications of their professors' grading systems and in the more distant future to design grading scales in their own classrooms. A few reflections showed awareness of the tensions involved in grading systems, potentially a sign of developing Nepantla, while others evidenced more binary thinking.

Keywords: Social Justice, Preservice Teacher Education, Affect, Emotion, Beliefs, and Attitudes

Introduction

Teachers, especially those working in urban environments, need political *conocimiento* for teaching—a nuanced, situated form of political knowledge-in-practice—to effectively advocate for their students and themselves in the multi-layered, complex political environments of schools (Gutiérrez, 2013). From renewed controversy around standardized testing (Barnum, 2021) to conflicts over school reopening plans (Ludlow, 2021) to debates about student needs and claims of learning loss (Gabriel, 2021), the effects of and societal response to the novel coronavirus in 2020 have made teachers' need for political *conocimiento* even more apparent and more urgent than before the pandemic. Teacher preparation programs must do everything possible to help preservice teachers (PSTs) develop political *conocimiento*. While many researchers and teacher educators whose work focuses on helping PSTs develop political and cultural understanding have distinct but interrelated goals including social justice, equity, culturally relevant/sustaining pedagogy, and political *conocimiento*, there is broad agreement that to effectively prepare PSTs, teacher preparation programs must integrate these goals as broadly as possible throughout multiple courses and program components (e.g. Garii & Appova, 2013; Gutiérrez, 2013; McDonald & Zeichner, 2009; Nieto, 2000; Wiedeman, 2002; Xenofontos et al., 2020).

Math content courses are a perhaps unexpected but potentially powerful category of courses into which political *conocimiento* could be integrated. Math content courses are often among the first courses that elementary PSTs take, and they rarely focus on social justice topics (Felton-Koestler, 2020), so using a math content course to foster political *conocimiento* can create new opportunities for PSTs to start to develop and integrate mathematical and political understanding early in their programs. PSTs can then build on that understanding in future courses such as math methods courses in which they must connect mathematical and social justice goals, with the additional complexity of creating lesson plans (Meyers, 2019). Exploring topics related to political *conocimiento* in content courses could also potentially increase PST investment in content courses which are sometimes perceived as "relearning" elementary mathematics (Zazkis, 2011) by linking them more closely with PSTs' other courses.

The current study explores PST learning in one such content course. It attempts to make two main contributions to the existing research. First, the course design—discussed further below—focuses specifically on integrating political *conocimiento* in a math content course rather than drawing on a more general understanding of social justice as previous work has done (e.g. Bateiha & Reeder, 2014; Felton-Koestler et al., 2016; Martinez & I, 2019). In particular, the unit that is the focus of this study explored the quantitative and political implications of using different possible grading systems in a class. Second, while the framework of political *conocimiento* is based on extensive field research with practicing teachers (Gutiérrez, 2012, 2013, 2017) there is no empirical work describing its early stages of development in elementary PSTs or in the context of a math content course. Therefore, this research report uses PST reflections before, during, and after a unit on grading systems in an elementary math content course to examine the following research questions:

- What forms of political *conocimiento* underlie PSTs' reflections about their own learning, questions that they have, and what teachers need to consider?
- What roles does mathematical reasoning play in PSTs' reflections?

Theoretical Framework

Both this study and the design of the course from which the data are drawn are rooted in the intersection of two theoretical frameworks: Gutstein's (2006; 2016) framework for Reading and Writing the World with Mathematics (RWWM) and Gutiérrez's (2012; 2013; 2017) framework of political *conocimiento* for teaching mathematics. Gutiérrez's framework was used to conceptualize the goals for the course, while Gutstein's framework was used to inform the design of mathematical activities intended to facilitate those goals. Both frameworks were used to inform this study's data analysis, with Gutiérrez's framework structuring the response to the first research question and Gutstein's framework structuring the response to the second.

Gutiérrez (2012; 2013) describes political *conocimiento* as the situated knowledge-in-action that successful teachers of Black, Latinx, and low-income students use to successfully advocate for their students in the multi-layered, political environments of schools situated within the larger neo-liberal education system. The word *conocimiento* indicates a form of knowledge that is developed through subjective personal experience and grounded in solidarity and praxis. The use of "political" in political *conocimiento* refers to the political implications of actions and systems at multiple levels of society, from the micro to the macro, and the ways in which power and identity operate across and between those levels. For example, the choices that individual teachers make about how to set up grading in their classrooms are shaped and constrained by the requirements and expectations of their fellow teachers, school and district administrators, families of students, and schools that students may attend in the future. In turn, teachers' grading choices may significantly affect students' academic and extracurricular opportunities and mental health, and these effects may have complex predictors based on characteristics including students' racial and socio-economic backgrounds, family structure, disability status, and physical and mental health.

Gutiérrez's (2017) framework of political *conocimiento* for teaching mathematics builds on Shulman's (1986) framework of teacher knowledge. Like Shulman, Gutiérrez acknowledges the importance of developing content knowledge and pedagogical knowledge. She emphasizes the importance of developing knowledge related to students and their communities through interdependent relationships rather than abstract study, and therefore describes it as "knowledge with students/communities." To these three categories she adds the form of political knowledge described above and emphasizes that these four forms of knowledge are all interconnected. She grounds the forms of knowledge in the context of what she calls "community en el mundo zurdo," evoking the necessity of communal action and solidarity with those who have been disenfranchised. Gutiérrez situates developing political *conocimiento* in "histories in society" emphasizing the situated, non-generalizable nature of *conocimiento* and the ways in which it influences and is influenced by the histories of a particular context. Finally, Gutiérrez (2012) highlights the role of *Nepantla*—a liminal "third space" that entails constant tensions and an awareness of multiple, potentially contradictory realities and possibilities for the future—as a necessary state for opening the possibility of the development of new *conocimiento*. In the case of grading described above, *Nepantla* could entail a teacher's awareness that adjusting particular category or assignment weights could help some students and hurt others, a tension that could lead to a desire to fundamentally change the underlying system. The teacher would then need to integrate their various forms of knowledge to work to enact change: they might explore different alternatives with students and communities, consider the pedagogical implications of their options, and use their understanding of the political pressures inside and outside their school to join with others in solidarity and figure out the most effective ways to make change happen.

As referenced above, I used Gutstein's (2006; 2016) framework to make sense of how to integrate these goals for preservice teachers into a math content course. Gutstein describes his pedagogy as teaching students to read and write the world with mathematics (RWWWM). When he teachers RWWWM he builds on a Freirean framework, working to use students' experiential community knowledge as a foundation on which they can develop classical knowledge and critical knowledge. In my context, the PSTs' community knowledge was based on their own experiences with grading systems as students and their common goal of becoming teachers who would use grading systems in their future classrooms. The classical knowledge that PSTs needed to develop was their math content knowledge related to ratios, percentages, and weighted averages, and the critical knowledge was the political *conocimiento*—the integration of content, pedagogical, and political knowledge with knowledge with students and communities to consider the constraints and implications of different grading systems. Gutstein further divides critical knowledge into reading the world with mathematics (using mathematics to understand the world) and writing the world with mathematics (leveraging mathematics to change the world). In the context of this study, PSTs could read the world with mathematics by using what they learned to better understand the grading systems that their instructors used and act accordingly, and they could anticipate writing the world by advocating for instructors to change their systems or by planning to make considered choices about grading when they themselves become teachers.

Methods

Positionality Statement and Context

An important piece of context to provide for any math education research, and especially for research situated at the intersection of math, politics, and education, is my positionality as a researcher and an educator (D'Ambrosio et al., 2013). I grew up white, middle-class, and female identified, identities that I share with the majority of in-service and preservice teachers in the United States. I began to develop a more critical political consciousness during my own teacher training in a program focused on preparing teachers to work in urban environments, and my political *conocimiento* developed further through over seven years working in multiple roles in two public schools. I spent the last four of those years working as a school's data coordinator, a role in which I often collaborated with teachers and administrators to analyze and address problems related to different data systems, including intervention data, grades, standardized tests, and school rating results. Since moving from an elementary setting to a university setting I have had the opportunity to explore more theoretical critical perspectives that have helped me connect my personal experiences to an understanding of the larger, neo-liberal education system.

I currently work at a public research university in a large city in the Midwest. The university's undergraduate teacher preparation program focuses on preparing students to teach in urban settings, and many of the faculty specialize in critical theories, including some of the faculty who frequently instruct the undergraduate math methods courses. PSTs are required to take multiple courses related to the politics of education, including an introductory course on urban education and a course on race, ethnicity, and education during their first year in the program. Before the current study, the elementary math content courses focused on broadening PSTs' understanding of mathematics, developing their problem solving skills, deepening their conceptual understanding of elementary mathematics, and fostering the mathematical knowledge for teaching; there was not a focus on political understanding. Until the coronavirus pandemic, all courses were taught in-person; the data for the current study were collected during a semester in which the content course was taught entirely online.

Course and Activity Description

The data for this study are drawn from a series of activities around grading systems that took place during two class periods of an introductory math content course for elementary PSTs. The course met remotely twice a week for 110 minutes. The original intention was to include multiple activities connected to political *conocimiento* throughout the semester. Unfortunately, the course moved much more slowly than anticipated, so there was only time to do two mini-units, and the second mini-unit (which explored the local school district's school rating policy) occurred in an abbreviated form in the final class period and was not followed by student reflections. The course centered collaboration and problem-solving, though both were more challenging in the virtual context. The course was also designed to help students develop a supportive community, giving PSTs a variety of ways to share their experiences and emotions. One key form of communication was brief reflections that PSTs completed after every class session, for a total of 26 reflections. These reflections had a consistent format: upload a picture of your work from class, explain what you learned or figured out in today's class, and ask the instructor a question. The intention was to normalize regular communication and the value of asking questions—questions could be about anything, including creating an extension question based on a problem from class.

The grading system activities were designed to help familiarize PSTs with different ways of weighting assignments and grades. The activities alternated between PSTs collaboratively reflecting on the potential implications of and problems with different forms of grading and solving quantitative vignettes based on problems that I had seen arise during my work in schools when there was a mismatch between the design of a grading system and how teachers were using it. The goal was to support PSTs in taking the perspectives of others with different experiences, and connecting the implications of those differences with the quantitative choices made within the grading systems.

Participants

The participants in this study were drawn from PSTs enrolled in two sections of the relevant content course. I was the instructor for one of the sections of the course, and I co-planned with the instructor of the other section. There were 70 students enrolled in the two sections, and 29 consented to have their coursework analyzed for the purposes of this study. I suspect that the low rate of consent was related to the stress of the pandemic and the sense of surveillance that PSTs expressed as part of remote instruction. The majority of PSTs were freshmen or transfer students. Three participants did not provide demographic information. Of those who did, 3 were male, and 23 female. One identified as Middle Eastern, 2 as Asian, 5 as white, and 17 as Latina/o.

Data Sources and Analyses

The data for this study are drawn from four reflections that PSTs completed as class assignments before, during, and after the unit on grading systems. Before the activity PSTs reflected on their personal experiences with grading ("Have you ever had an experience as a student in which you felt like the grading for a class was unfair? What was unfair about it?") and their initial beliefs about teacher obligations ("What do you think teachers need to consider when they plan the grading system for their class?"). After each of the class sessions focused on grading systems, PSTs completed reflections describing what they learned and what questions they currently had. At the end of the unit they answered the prompt about teacher obligations again and commented on whether they felt that their answer had changed.

The reflections were first analyzed with respect to the first research question, looking for examples in which PSTs' reflections implicitly valued or applied any of the components of political *conocimiento*: content knowledge, pedagogical knowledge, knowledge with students/communities, political knowledge, community en el mundo zurdo, histories in society or *Nepantla*. Some reflections valued or applied multiple components, while others did not clearly reference any, so some reflections were given multiple codes and others received none. For the second research question, PSTs' reflections were analyzed to find instances in which PSTs referenced explicitly mathematical activities, and then those examples of referencing mathematics were coded for the roles for which they used mathematics: classical content knowledge, reading the world with mathematics, or writing the world with mathematics. Classical content knowledge was used to code reflections in which PSTs focused on calculations specifically as a course assignment or intellectual puzzle. Reading the world with mathematics was used to code reflections in which they described or anticipated making sense of an instructors' grading system or finding what score they needed on an exam to get an A in a course. Writing the world with mathematics was used to code reflections in which PSTs discussed quantitative reasoning that was important for either teachers in general or that they anticipated using when they became teachers.

Findings

Nascent Political *Conocimiento*

A total of 66 codes related to political *conocimiento* were assigned. Every code was used at least once except for histories in society. Examples and descriptions of the characteristics of each code follow:

Knowledge with students/communities. With 25 examples, this was the most common form of political *conocimiento* that PSTs referenced and valued. It emerged across the different reflections both before and after the activities. Some PSTs showed increased specificity and a shift away from their individual perspective in their reflections from after the activity. For example, "I used to think teachers should be more flexible with grades in case students don't have enough time to do homework, or don't have help at home, but now I think there are many other factors such as an unstable living situation, health concerns, and many others."

Political knowledge. This was the second most frequent form of political *conocimiento* referenced, with 13 examples. Many of the relevant reflections indicated a concern for fairness and for the implication of different grading systems (responses to the prompts that specifically asked about fairness were not included under these criteria). Some reflections also indicated an awareness of the complexity of roles and pressures that teachers need to navigate with grading: "My question is are all teachers required to grade a certain way depending on their school or do they each get to decide. I know for high school, teachers usually get to decide, but I wonder if it's'the same for elementary school teachers," and "Do you see there being a big change to standard based grading in the near future that we might have to implement with our own students?"

Community en el mundo zurdo. PSTs did not explicitly describe themselves as oriented in solidarity with social change, but there were 9 examples in which the positioned themselves as part of a community and emphasized how important the group collaboration was to them, both in the mathematical problem solving and the critical discussions. For example, "I also enjoyed being able to share out our different ideas on grading," and, "When answering and doing the grading problems I remembered how we talked them through in class and it really helped me to solve them."

Content knowledge and pedagogical knowledge. These codes were the least frequently used, with 3 and 7 examples respectively. Identifying cases of valuing content knowledge had many of the same challenges described below for identifying classical mathematical knowledge—there were relatively few examples where the PSTs were clearly valuing the mathematics for its own sake rather than for its potential use in RWWWM. One exception was, "We decided that the best way to show the grades equally weighed was to see what the fraction would look like if the final project was worth the same amount of points as the classwork assignments." A concern for pedagogical knowledge in this context was generally reflected as concerns that hypothetical students understand a class's grading system and considerations about how to make that happen—"I think whatever grading system they choose, they need to make sure to explain it to their students well to make sure they know what to expect if they miss a class or do poorly on an assignment."

Nepantla. Some PST reflections (7) demonstrated awareness of *Nepantla* when they described the inherent tensions in designing grading scales, where often the same choice can improve one student's grades and hurt another's. For example

> When teacher plan the grading system for their class teachers need to consider what will benefit students and what seems fair. This, however, I realized it can be very difficult to achieve because no matter what, not all students will benefit. In the excel page, I was playing around with how much each category should be weighted, but even when 2 students' 'cores would increase, the third student's score would stay the same or decrease so that student was not benefitting from the changes. (Kaila)

Importantly, for these PSTs the tension was something to be grappled with but not necessarily resolve. In contrast, there were 5 examples of reflections in which PSTs moved away from *Nepantla* and tried to identify clear-cut binaries in which one form of grading was always superior to another as in the claim "Teachers should also be grading things equally rather than proportionally because proportionally, in my opinion, only affects the student more."

Reading and Writing the World with Mathematics

In the reflections, there were a total of 49 codes for the different forms of using mathematics. The most common was reading the world with mathematics—it was used to code 24 responses. Five of those responses were based on student reflections about their personal experiences that referenced quantitative reasoning such as

> [W]e only have writing assignment every two weeks. Although that sounded fun at the beginning not having quizzes or tests, these writing assignments are worth 10 percent and can affect our grade if we do not get a good grade. (Julie)

The majority of the rest were descriptions of how useful it was to be able to do calculations about grades such as:

> This was a moment that made me realize how useful it is to know math. I always wished I knew how to calculate my grade or knew how and why a single score affected my grade so much. It was an Aha! moment both as a student and as a future teacher. (Imani)

Seventeen responses focused on mathematics specifically in the context of class assignments or in the abstract, and 8 referenced writing the world from a teacher perspective when designing grading systems.

Implications

This work provides some initial examples of what forms nascent political *conocimiento* can take for elementary PSTs in the context of a content course, and how PSTs may integrate mathematical content knowledge as part of their *conocimiento*. It found that for this particular set of activities and prompts, PSTs tended to value knowledge with students and communities and reading the world with mathematics. It indicated some potential for even relatively sparse PST reflections to show preliminary evidence for the acceptance or rejection of *Nepantla*. One somewhat surprising aspect of the findings was the relatively small number of references to pedagogical knowledge—surprising because questions related to “How would you teach this?” were one of the most common types of reflection questions during the rest of the course. It is possible that this finding is related to Myers’s (2019) description of the struggles that PSTs experienced when planning units that integrated mathematical and social justice standards. The cognitive complexity of balancing the mathematical and critical thinking may make it more challenging for PSTs to also consider pedagogy, at least this early in their teacher preparation programs. Another aspect of the findings is the lack of reflections that connected to history in society. This may be due to the design of the activities, which were specific in terms of individuals’ situations, but were not situated in a specific historical or geographical contexts. This is a weakness that was addressed in the abbreviated activity around school rating systems, and is something that I plan to address more thoroughly in future work.

There are a number of other ways in which I hope to be able to build on this work in the future. One is to more explicitly address race and various forms of racism in future activities—the individual focus of this set of activities afforded an unfortunately race-evasive discussion in which students discussed characteristics of students and communities such as income and linguistic background but did not explicitly talk about race. This has been identified in previous research as a common problem with integrating mathematics and social justice (Harper, 2019; Larnell et al., 2016), and I plan to address concerns of race and racism more directly and intentionally in the future. Follow-up research in which I am currently engaged will also integrate data from local schools and political lenses more thoroughly throughout a content course and will collect more robust forms of data to hopefully enable a richer description of PSTs' development of political *conocimiento*.

We describe an investigation on the use of mathematical tasks in mathematics methods courses in teacher preparation programs in two contexts: the United States and Colombia. Specifically, we elucidate how mathematical tasks influence teacher training. This research supports a larger project studying how identities as a teacher and global citizen intertwine with the contribution of mathematics as a science to the development of nations. Preliminary results indicate that mathematical tasks strengthen a positive attitude towards the teaching of mathematics in both contexts. Likewise, we find differences between the contexts that align with characterizations of individualistic and collectivist societies described by different researchers.

Keywords: Preservice Teacher Education, Teacher Educators, Problem-Based Learning, Affect, Emotion, Beliefs, and Attitudes

Our article describes research developed in collaboration with two higher education institutions, one in the United States and the other in Colombia. In this article we document the planning, development, and initial implementation of a mathematics teaching methods course in the two contexts. This documentation forms only the initial phase of a research project that seeks to understand, from a critical point of view, what it means to be a teacher and global citizen, a discussion frequently absent from the school curriculum and sometimes from teacher education programs (Subedi, 2013). The research question guiding our study is: *what do pre-service teachers report having learned in their mathematics methods courses after engaging in mathematical tasks specifically designed to impart instructional practices for teaching mathematics in elementary school?*

Background and Theoretical Framework

We focused on preparation for teaching mathematics in elementary school for two main reasons. First, this provides the context most familiar to us and the focus of our work as teacher educators. Second, a global perspective underlying current teacher preparation is that both the mathematical content and the pedagogies of mathematics teaching inform the teaching practice that will prepare future teachers to be active citizens with knowledge and skills specialized for competing in the global economy (National Board for Professional Teaching Standards, 2016). This perspective is inclined to promote consumption; locate, distribute, and use resources; in addition to offering services for production and marketing throughout the world (Spring, 1998). To develop these capacities, according to Spring's (1998) explanation, it is essential for developing certain types of specialized knowledge, skills, and values. Mathematics lies at the center of this knowledge (Mochón & Morales, 2010). In contrast to this capitalist perspective, another critical perspective encourages teachers to be public intellectuals with a moral vision and analytical tools to form future citizens who participate in a critical democracy (Bates, 2008). We also see mathematics at the center of discussions of equity in society and therefore in the classroom. Either way, these three positions place mathematics in a place of importance.

Local Contexts

United States. This context focuses on the use of students' mathematical thinking as a way to inform instructional practices for teaching mathematics (Carpenter et al., 2014). In this context, the mathematics methods class focuses on providing opportunities for the pre-service teachers to share, justify, connect, and extend mathematical ideas. In this class, pre-service teachers learn to design, select, and implement instructional activities with a high degree of mathematical content.

Colombia. In the Colombian context, the class, Didactics of Mathematics, targets those preparing to become teachers at the preschool level. In this context the class places particular importance on the development of logical thinking, and problem solving (Pachón Alonso et al., 2016).

Global Context

Having identified the theoretical bases that guide the design and implementation of each local context, we proceed to identify how to study both contexts simultaneously. Based on studies previously carried out by the first author, we decided to implement the Mathematical Autobiographies as an initial instrument to be used in common in the two classes (Krause & Maldonado, 2019). The first author has used this task throughout her years preparing teachers and has found that pre-service teachers are not infrequently “afraid” of mathematics or feel that at some point during school they stopped understanding it (Krause & Maldonado, 2019). Naturally we wondered whether in the Colombian context we would find the same commonality. When analyzing the responses of the pre-service teachers, we found that a most of the students in the Colombian contexts described having little understanding of mathematics (Avila et al., In preparation). Through this process, we were able to identify “fear” of or “dislike” of mathematics as a problem we shared in our practice as teacher educators. We point it out as a problem because, by identifying mathematics as an area that they do not like, future teachers can pass the same impressions on to their students (Lee, 2005).

Once this common problem of practice was established, we proceeded to the next step: the design of activities that might improve these feelings about mathematics. We call such activities *math tasks*. For its design, we used as a basis the idea of equilibrium and disequilibrium (Van de Walle et al., 2013) and the concept of productive struggle (Franke et al., 2001). The fundamental idea was based on designing mathematical tasks that (1) were at the academic level of the pre-service teachers, that is, whose mathematical content accorded with what they should learn within the curriculum established for them, (2) had a certain level of difficulty so that they could experience productive struggle, and (3) whose solution could be found through different processes or strategies. These three components of what we call mathematical tasks are based on the three components that Hiebert et al. (1997) have described as components of a problem. In accordance with these theoretical foundations, we define four essential components that a mathematical task must include: (1) the mathematics that students already know, (2) the mathematics that students must learn, (3) different ways of reaching the solution, and (4) generation of a change in the way pre-service teachers perceive how they understand or how they feel about their ability to engage with mathematics.

Methods

Data

The mathematical tasks were implemented at the beginning of each class during the Fall semester of 2020. In the context of Colombia there were a total of 14 tasks, in the context of the United States 11. In addition, to recognize the impact of the tasks in component (4) mentioned above, at the end of each class the pre-service teachers documented their in-class experience in writing. Each of us designed and adapted the tasks according to the class topic of the day. As an example, we describe two of them below. The first we used in the class in the United States and the second in the Colombian class.

Example 1

Which is bigger, the height or the circumference? The activity begins with the teacher holding a jar of tennis balls. At the same time the teacher asks: which is greater, the circumference or the height? Almost immediately, students responded that the height is greater, because it is “obvious” just by looking at it. Once the question is asked, pre-service teachers were given a few minutes to write an explanation of their reasoning. Then we measured individually the height and circumference of the can with a separate pieces of string. In this case we used different colored strings to facilitate comparison of the lengths. The circumference of the can naturally turns out to be larger. Finally, the pre-service teachers are asked to find a way to explain why this is the case.

Example 2

Which is the impostor? The activity begins with the instructor showing the numbers 7, 9, 16, and 25 organized as shown in Figure 1. The pre-service teachers were told to look at the numbers and identify which one was the "impostor".”The pre-service teachers had 3 minutes to make their decision. Then, as a class, we took a survey on who had selected 7, 9, 16, or 25. At first only their choice was indicated, without an explanation. Then, as a class, we discussed why they had selected a particular number as the impostor. The second part of the task consisted of an adaptation of the first part. Here the pre-service teachers had to identify the impostor figure (Figure 2).

7	9
16	25

Figure 1: Impostor Number

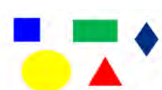

Figure 2: Impostor Figure

Results

After analyzing the responses of the pre-service teachers, we found 4 aspects in common in the two contexts: (1) the pre-service teachers tried different solutions. For example, in the tennis ball challenge, some made a list of formulas that they remembered (the formula for the circumference and even the formula for the area of a triangle), even though they weren't sure if they were going to use them. Others imagined cutting the can of tennis balls open completely, yielding a rectangle. In the impostor number task, the students presented their arguments for their answers by touching on concepts such as odd and even numbers, prime numbers, perfect squares, and addition and subtraction operations allowing them to identify relationships between the numbers. (2) Pre-service teachers reflected on understanding mathematics beyond a rote application of formulas and memorization. For example, in the case of the United States the pre-service teachers shared that “today I learned that memorizing formulas is not so useful if I do not understand how I should apply them. At the same time, I was able to reflect that the processes and making connections with ideas and concepts that we have already learned are fundamental to understand the solution of a problem." (3) The pre-service teachers expressed how they realized that they understood more about mathematics than they thought. In Colombia a student shared that "many of us found it somewhat complex even though the problem was not difficult, when we went to share our solutions, it was easier because of collaboration." "4) Pre-service teachers shared their love and motivation for our classes. However, we did not find any specific reference to how their mathematical knowledge has improved. In this data set we also found two emerging ideas that were not shared in the two contexts. In the Colombian context, for example, the pre-service teachers reported surprise when they saw the diversity of thoughts among their own classmates and how, thanks to the group work in class, it was easier to understand each challenge. In addition, they shared that they "really liked" discussing all the ideas. In the context of the United States, on the other hand, we found that students reflected on the importance of allowing time to think, analyze, and make connections when students are asked to find solutions to mathematical problems.

Discussion and Conclusions

In our first attempt to understand our local contexts to then understand the global context, we encountered a common problem in our practice: pre-service teachers, in both of our contexts, tend not to feel confident in their mathematical knowledge nor do they have a passion for this area. Although our decision regarding how to tackle this common problem did not produce a significant change, it nevertheless did produce a series of results that informs our practice both locally and globally. In particular, we found that pre-service teachers felt more comfortable facing solutions to mathematics problems given in each context after engaging in the mathematical task. We conjecture that this might have an impact on their comfort level teaching mathematics in the future. We make this conjecture based on the preliminary results of this study; our next step is to see if this is actually what happens.

On the other hand, we were able to identify some aspects unique to the local context. For example, in Colombia the pre-service teachers referred to the mathematical thoughts and ideas of their classmates and how they learn with others. Whereas in the context of the United States, the students did not refer to anyone other than themselves in their reflections. This result aligns with studies described by Triandis (2001), who describes individualistic and collectivist societies. According to Triandis (2001) the US is listed as one of the most individualistic societies, whereas Colombia is listed in 4^{th} place on the list of collectivistic ones. Finally, pre-service teachers in the United States made reference to the importance of giving more time to think about solutions, while in Colombia this aspect was not specifically mentioned. Time or the lack thereof in educational contexts is a widely discussed topic in educational research in the United States. Our conjecture in this regard is that pre-service teachers can identify this stress while working with their cooperating teachers in their practicum placements.

The use of mathematical tasks and the respective reflection around them has allowed us to identify common problems of practice in both contexts. We plan to further study these problems of practice as we continue to learn about how to best inform our instructional practices in a global setting.

Describimos una investigación sobre el empleo de retos matemáticos en cursos de métodos de enseñanza de las matemáticas en la formación de maestros de preescolar y primaria en dos contextos: Estados Unidos y Colombia. Nuestro enfoque principal es describir cómo los retos matemáticos influyen en la formación de maestros. Resultados preliminares indican que estos inciden en el fortalecimiento de una actitud positiva hacia la enseñanza de las matemáticas en los dos contextos. Así mismo encontramos diferencias en cada contexto alineadas con caracterizaciones de sociedades individualistas y colectivistas descritas por diferentes investigadores.

Palabras clave: Preservice Teacher Education, Teacher Educators, Problem-Based Learning, Affect, Emotion, Beliefs, and Attitudes

Nuestro artículo describe un trabajo de investigación desarrollado en colaboración con dos instituciones de educación superior, una en Estados Unidos y la otra en Colombia. En este artículo documentamos la planeación, desarrollo e implementación inicial de un curso de métodos de enseñanza de las matemáticas en los dos contextos. Esta documentación es sólo el proceso inicial en un proyecto de investigación que busca entender, desde un punto de vista crítico, lo que significa ser un maestro y ciudadano global, discusión que está frecuentemente ausente en el currículo escolar y algunas veces, en el currículo de formación de maestros (Subedi, 2013). Nuestro estudio tuvo como pregunta orientadora *¿qué reportan los maestros en formación haber aprendido en las clases de métodos de la enseñanza de las matemáticas después de abordar retos matemáticos específicamente diseñados para cada clase?*

Antecedentes y Marco Teórico

Nos enfocamos en la formación de maestros en matemáticas; primero, porque este es el contexto que más conocemos y el enfoque de nuestro trabajo como formadores de maestros. Segundo, porque una perspectiva global subyacente a la formación actual de docentes es que, tanto el contenido matemático como las pedagogías de enseñanza de las matemáticas, dan forma a la práctica docente que va a preparar a los futuros maestros como ciudadanos activos con conocimientos y habilidades especializados para competir en la economía global (National Board for Professional Teaching Standards, 2016). Esta perspectiva se inclina en fomentar la capacidad para desarrollar el consumo; localizar, distribuir y usar recursos; además de ofrecer servicios para la producción y comercialización en todo el mundo (Spring, 1998). Para poder competir y desarrollar estas capacidades, según lo que explica Spring (1998), es fundamental desarrollar ciertos tipos de conocimientos, habilidades y valores especializados. Las matemáticas se encuentran justo en el centro de estos conocimientos (Mochón & Morales, 2010). En contraste a esta perspectiva capitalista, existe una perspectiva crítica que promueve que los maestros se preparen para ser intelectuales públicos con una visión moral y herramientas analíticas para formar futuros ciudadanos partícipes de una democracia crítica (Bates, 2008). Esta perspectiva pareciera no contemplar las matemáticas, sin embargo, como Moses and Cobb (2002) lo han expresado en el mundo de hoy la ciudadanía depende fundamentalmente de sus conocimientos en matemáticas para el acceso a beneficios económicos. Para Moses and Cobb (2002), este conocimiento de las matemáticas en las comunidades urbanas y rurales (en los Estados Unidos) es un tema urgente. El caso colombiano no es diferente, según lo resalta la Misión Internacional de Sabios (2019). Nosotros también vemos las matemáticas en el centro de las discusiones de equidad en la sociedad y por ende en el salón de clase. De cualquier manera, independientemente de nuestra perspectiva, estas dos posiciones ubican a las matemáticas en un lugar de importancia.

Contextos Locales

Estados Unidos. Este contexto se centra en el uso del pensamiento matemático de los estudiantes como centro del aprendizaje (Carpenter et al., 2014). En este contexto la clase de métodos se enfoca en proveer oportunidades a los estudiantes para compartir, justificar, conectar y extender ideas matemáticas. En esta clase los maestros en formación aprenden a diseñar, seleccionar e implementar actividades de instrucción con un alto contenido matemático.

Colombia. En el contexto colombiano, la clase, Didáctica de las Matemáticas, está orientada a quienes se están formando para ser maestros del nivel preescolar. Este enfoque da especial importancia al desarrollo del pensamiento lógico matemático, la resolución de problemas, y el planteamiento de nuevas situaciones en diversos contextos (Pachón Alonso et al., 2016).

Contexto Global

Identificadas las bases teóricas que guían el diseño e implementación de cada contexto local, pasamos a identificar de qué manera estudiar los dos simultáneamente. Basados en estudios realizados anteriormente por el primer autor, decidimos implementar las Autobiografías Matemáticas como instrumento inicial para usar en común en las dos clases (Krause & Maldonado, 2019). El primer autor ha usado esta tarea a través de sus años preparando maestros y ha encontrado un factor que parece emerger en los datos, los maestros en formac e "temen" a las matemáticas o sienten que en algún momento en sus años de estudio dejaron de entenderlas o de apreciar su belleza (Krause & Maldonado, 2019). Este factor común nos llevó a preguntarnos si en el contexto colombiano llegaríamos a encontrar lo mismo. Al analizar las respuestas de los maestros en formación encontramos que un número alto se describió como poco entendedor de las matemáticas (Avila et al., en preparación). A través de este proceso pudimos identificar "el temer" o "no sentir gusto por las ma ticas" como un problema común en nuestra práctica como formadores de docentes. Lo señalamos como problema porque al identificar las matemáticas como un área que no les gusta, los futuros maestros pueden transmitir tal idea a sus estudiantes (Lee, 2005).

Una vez establecido este problema de práctica común, seguimos con el siguiente paso: el diseño de actividades que puedan cambiar esta identidad matemática. Llamamos a estas actividades retos matemáticos. Para su diseño usamos como base la idea de equilibrio y desequilibrio (Van de Walle et al., 2013) y el concepto detrás del conflicto productivo (*productive struggle*) (Franke et al., 2001). La idea fundamental se basó en diseñar actividades que (1) estuvieran al nivel académico de los maestros en formación, es decir que el contenido matemático estuviera de acuerdo con lo que deben aprender según el currículo establecido para ellos, (2) que tuvieran cierto nivel de dificultad para que pudieran experimentar un conflicto productivo (*productive struggle*), y (3) que la solución pudiera encontrarse a través de diferentes procesos o estrategias. Estos tres componentes de lo que llamamos retos matemáticos están basados en los tres componentes que (Hiebert et al., 1997) ha descrito como componentes de un problema. De acuerdo con estos fundamentos teóricos nosotros definimos cuatro componentes esenciales que un reto matemático debe incluir: (1) la matemática que ya saben los estudiantes, (2) la matemática que los estudiantes deben aprender, (3) diferentes formas de llegar a la solución, y (4) generar un cambio en la forma como el maestro en formación percibe cómo entiende o cómo se siente con respecto a su capacidad de entender las matemáticas.

Métodos

Datos

Los retos matemáticos fueron implementados al inicio de cada clase durante el semestre del otoño de 2020. En el contexto de Colombia fueron en total 14 retos y en el contexto de Estados Unidos fueron 11. Además, con el fin de reconocer el impacto de los retos en el componente (4) antes señalado, al finalizar cada clase, los maestros en formación documentaban de manera escrita su experiencia en la clase. Cada uno de nosotros diseñó y adaptó los retos de acuerdo con el tema de clase. Como ejemplo, a continuación, describimos dos de ellos. El primero lo usamos en la clase de Estados Unidos y el segundo en la clase de Colombia.

Ejemplo 1

¿Qué es más grande, la altura o la circunferencia? La actividad comienza con el profesor sosteniendo un tarro de pelotas de tenis. Al mismo tiempo el profesor pregunta: ¿cuál es más grande, la circunferencia o la altura? Casi de inmediato, los estudiantes responden que la altura es mayor porque es "obvio" con solo mirarla. Una vez hecha la pregunta, el profesor da unos minutos a los estudiantes para que escriban una explicación de por qué creen que la altura es mayor. Luego el profesor mide la altura de la lata con una cinta de lana. En este caso usamos cintas de diferentes colores para poder comparar las longitudes. La circunferencia de la lata resulta ser mayor. Finalmente, el profesor pide a los maestros en formación que encuentren una manera de explicar por qué eso es cierto.

Ejemplo 2

¿Cuál es el intruso? La actividad inicia con el profesor mostrando los números 7, 9, 16 y 25 organizados como los muestra la Figura 1. La indicación para los maestros en formación era ob944anderbios números e identificar c l era el "intruso". Los maestros en formac enían 3 minutos para tomar su de944anderbi Luego, como clase hacíamos un sondeo sobre quiénes habían seleccionado el 7, el 9, el 16 ó el 25. En este primer momento só944ande indicaba su elección, no se explicaba el por qué. Después, como clase, discutíamos sobre el por qué la elección del número intruso que fue seleccionado por la mayoría. La segunda parte del reto consiste en una adaptación de la primera parte. Acá los maestros en formación tenían que identificar la figura intrusa dentro de 5 posibles (Figura 2).

7	9
16	25

Figura 1: Número Intruso

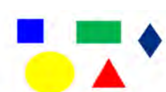

Figura 2: Figura intrusa

Resultados

Después de analizar las respuestas de los maestros en formación encontramos 4 aspectos en común en los dos contextos: (1) los maestros en formación intentaron diferentes soluciones. Por ejemplo, en el reto de las pelotas de tenis algunos hicieron una lista de fórmulas que recordaban (la fórmula de la circunferencia e incluso la fórmula del área de un triángulo) aunque no estaban seguros si las iban a usar. Otros hicieron una representación imaginando que cortarían el tarro de pelotas para abrirlo completamente y así tendrían un rectángulo. En el reto del número intruso los estudiantes expusieron sus argumentos respecto a sus respuestas tocando conceptos como números pares e impares, primos, cuadrados perfectos y realizando operaciones de suma y resta que les permitieran ubicar relaciones entre los números. (2) Los maestros en formación reflexionaron sobre entender las matemáticas más allá de un proceso que sigue fórmulas y memorización. Por ejemplo, en el caso de los Estados Unidos los maestros en formación compartieron que "hoy aprendí que memorizar f rmulas no es tan útil sino entiendo c aplicarlas. Al mismo tiempo pude reflexionar que los procesos y el hacer conexiones con ideas y conceptos que ya hemos aprendido son fundamentales para entender la solución de un problema". (3) Los maestros en formac esaron que se dieron cuenta que entiende e mate s de lo que en realidad pensaban. En Colombia un estudiante expre "a muchos de nosotros nos pareció algo complejo a pesar de que el problema no estaba difícil, cuando fuimos a compartir nuestras soluciones fue cil por la colaborac (4) Los maestros en formación compartieron su gusto y motivación por nuestras clases, sin embargo, no encontramos ninguna referencia específica a cómo ha mejorado su conocimiento matemático. En este set de datos también encontramos dos ideas emergentes que no fueron compartidas en los dos contextos. En el contexto colombiano, por ejemplo, los maestros en formación reportaron sorpresa al ver la diversidad de pensamientos entre sus propios compañeros y cómo gracias a los momentos de socialización era más fácil comprender cada reto. En sus respuestas, durante las reflexiones, incluso dieron crédito con nombre propio a estas ideas. Además, compartieron que “ ucho” discutir todas las ideas. En el contexto de los Estados Unidos, por el otro lado, encontramos que los estudiantes reflexionaron sobre la importancia de dar tiempo para pensar, analizar, y hacer conexiones cuando se les pide a los estudiantes que encuentren soluciones a problemas matemáticos.

Discusión y Conclusiones

En el primer intento de entender nuestros contextos locales para así poder extenderlos en un contexto global, encontramos un problema común en nuestra práctica: los maestros en formación tienden a no sentirse seguros de su conocimiento matemático ni tener gusto por esta ciencia. Aunque nuestra decisión sobre cómo afrontar este problema común no arrojó un cambio significativo, en el primer punto, sí produjo una serie de resultados que informan sobre nuestra práctica tanto local como global. Particularmente encontramos que los maestros en formación se sienten más seguros en la manera de afrontar soluciones a problemas de matemáticas dado el contexto en el que son presentados, lo cual, muestra su proyección como docentes de matemáticas. Esto es sólo una conjetura que hacemos basados en los resultados preliminares de este estudio, nuestro paso siguiente es tratar de comprobar si en realidad esto es lo que pasa.

Por otra parte, pudimos identificar aspectos característicos únicos al contexto local. Por ejemplo, en Colombia los maestros en formación hicieron referencia a los pensamientos e ideas matemáticas de sus compañeros y cómo se aprende con otros. Mientras que en el contexto de los Estados Unidos los estudiantes no hicieron referencia a nadie diferente a ellos mismos en sus reflexiones. Este resultado se alinea con estudios descritos por Triandis (2001) quien describe sociedades individualistas y colectivistas. Por último, los maestros en formación en los Estados Unidos hicieron referencia a dar más tiempo para pensar en las soluciones, mientras que en Colombia este aspecto no se mencionó específicamente. El tiempo o la falta de tiempo es un tema bastante discutido en investigaciones educativas en los Estados Unidos. Nuestra conjetura al respecto es que de alguna manera los mismos maestros en formación ven en sus prácticas este estrés por la falta de tiempo. En nuestra práctica formando maestros con una perspectiva global, que también incluya lo local, el empleo de los retos matemáticos y la respectiva reflexión en torno a ellos nos ha permitido identificar problemas de práctica comunes en los dos contextos.

This study investigates preservice mathematics teachers' instructional approaches to teach multiplication to students with mathematical learning disabilities (MLD). 17 preservice teachers' lesson design were qualitatively analyzed. Findings revealed that the PTs modified mathematical strategies by providing a variety of multiplicative concepts and various types of representations. PTs set their expectations based on individual needs, manage lesson structure, and adjust cognitive demand level of lesson tasks. Results suggest that PTs need opportunities to consider deeper responsive teaching so their modification and accommodation for students with MLD enable quality learning opportunities.

Keywords: differentiated instruction, students with disabilities, preservice teacher education

Teaching mathematics for *all* students means that teaching should support each student's access to high quality learning opportunities. While previous research has proven that there are unequal distributions of high-quality learning opportunities within mathematics classrooms (Jackson & Wilson, 2012), how instructional strategies should be modified to maximize the quality of learning opportunities for each student has been an urgent need (NCTM, 2014; Urick et al., 2018). Modifying and accommodating mathematics instruction for all students can achieve this. Modification means a change that is being taught to or what students are expected to learn, and accommodation means a change that helps a student overcome or work around the disability. Our study aimed to let preservice teachers prepare to teach mathematics while including students with mathematical learning disabilities (MLD). PTs in our study were asked to develop lesson ideas on multiplication with single digit multipliers for an average performing student and a student with MLD. We investigated the PTs' lesson approaches for providing access and opportunity for those learners.

Literature Review

Teaching Students with MLD

While Mathematical Learning Disabilities (MLD) has multiple aspects, we consider students with MLD to be those that create unique patterns or different kinds of errors from typical or low achieving peers (Lewis, 2010). Following this perspective, our study centers on the idea that some students have special needs and teachers should modify and accommodate instructional strategies to respond to their special needs. Successful teaching approaches for students with MLD include explicit teaching (Fuchs & Vaughn, 2012; Kroesberfen & Van Luit, 2003; Leach, 2016; Stein, Carnine, & Dixon, 1998), Antecedent-Behavioral Response-Consequence (ABC) teaching sequences (Leach, 2016), **scaffolding (**van Garderen, Scheuermann, & Jackson, 2012), and Concrete-Representational-Abstract (CRA) (Fyfe & Nathan, 2019; Gibs, Hinton, & Flores, 2018).

Teaching Multiplication

Multiplication in elementary school is one of the fundamental operations across grades in school mathematics, and it is the basis for early algebra (Anghileri & Johnson, 1992; Otto et al., 2011). Greer (1992) classified four situations that can be modeled by multiplication, which include (1) equal groups, (2) multiplicative comparison, (3) rectangular area and rectangular array, (4) the Cartesian product. Models are external representations of those multiplicative concepts, and we identified four multiplicative models: grouping model, number-line model, array model, and combination model (Table 1).

Table 1: Multiplicative Strategies

External Representations of Multiplications		Multiplicative Situations and Structure			
		Equal groups	Multiplicative comparison	Rectangular array/area	Cartesian product
Grouping Model	A model of grouping of objects having the same number in each group.	Can be represented[1]	Can be represented		
Number-line Model	A number line model equally divided by constant intervals and drawing regular arcs of each interval.	Can be represented	Can be represented		
Array Model	A model that uniformly arranges several objects in a rectangular shape of rows and columns.	Can be represented	Can be represented	Can be represented	Can be represented
Combinations	A model that identifies possible ordered pairs made between two or more sets.				Can be represented

Research Questions

In our study, mathematical approaches including multiplicative concepts and its representation were used as *mathematics strategies*; non-mathematical approaches including lesson goals, structure, flow, and task were used as *instructional strategies*. Research questions that guided our study were:

1. How do preservice teachers modify and accommodate *mathematics strategies* to teach multiplication to students with different backgrounds and needs?
2. What *instructional strategies* do preservice teachers use for teaching multiplication in their lesson design for students with different backgrounds and needs?

Methods

Participants

Participants (N = 17) were undergraduate PTs enrolled in the early childhood licensure program (ECE, grades PreK-3) at a university in the Midwest United States. They had learned general educational theories and practices and special educational theories in their junior years. In their senior year, PTs continued to learn theories and applied their learning in practice through methods courses and fieldwork. Data for our study were collected from a mathematics methods course in their senior year.

Data Collection

Artifacts from lesson design activity were analyzed. The lesson design activity consisted of two phases: (1) PTs brainstormed and developed a plan to teach a mathematics concept to typically performing 3rd graders, including *Jose* and then (2) they were asked to modify their lessons to address the needs of a student with MLD, called *Liam*. Artifacts collected were mainly documents that described in detail their lesson plans and how they would modify and accommodate the lesson plans.

Data Analysis

Using open coding (Strauss, 1987; Strauss & Corbin, 1994), we categorized the meaningful strategies for responsive teaching revealed in PTs' lesson design documents as following: (1) mathematical strategies, involving concepts of multiplication in teachers' instruction and/or support of students' better understanding of the multiplicative concept; and (2) lesson design elements, including general pedagogical supports, task selection, lesson structure and process of instruction.

Table 2. Data Analysis Categories and Codes

Categories	Properties	Codes
Mathematical Strategies	Multiplicative concept	Situation modeled; External representation
	Ways of representing the multiplicative concept	Visual aid; Physical experience; Symbolic objectification; Verbal expression; Contextual transition
Lesson Design Elements	Articulation of expectations	Mentioned the standard; Stated learning objectives
	Instructional activity	Task selection and development; Instructional structures; Instructional Progress
	Formative assessment	Gathering/sharing; Attending/interpreting; Supporting/feedback

Results

Modification and Accommodation in Math Strategies

The PTs' approach to introducing the multiplication concept to both learners (*Jose* & *Liam*) was grounded in the same modeled situation, the equal group situation. For the average performing student, all PTs modeled multiplication based on equal group situations and used external representations. To represent the multiplicative concept, PTs used the grouping model most frequently followed by the array model. It was noted that the modification in the instruction of the multiplication concept occurred most often for Liam. This decision stemmed from the assumption that students with MLD generally have difficulty in skip counting and must derive the product of multiplication through one-by-one counting. Some used the number-line to prevent the omission of numbers or double counting in counting with manipulatives, which is a responsive teaching strategy for students with MLD by enabling them to visualize repeated addition of discrete quantities with directionality.

Most PTs provided physical experiences with visual aids and manipulatives for Jose, and physical experience was the most frequently used for Liam. PTs judged that students who have difficulty in understanding abstract concepts need a physical experience such as counting familiar objects or manipulatives. Discrepancies in the type of representation used for different learners were most clear in the use of symbolic objectification. Eleven out of 17 PTs provided a multiplication formula ($a \times b = c$) to Jose, which is an objectified symbol of multiplication learned by visual and physical reification, whereas no PT provided such objectified symbols to Liam. These results show that the PTs make instruction more responsive by encouraging Liam with physical experiences expressed by manipulating concrete materials.

Modification and Accommodation in Instructional Strategies

PTs discussed their plan for how they would execute their lesson in three areas: task/activity selection and development, instructional structure (how they would manage students' actions), and instructional progress (beginning and flow of the instruction). Only four PTs mentioned distinct mathematics tasks according to student profiles. PTs used the exact same number standards in their mathematics task for both Liam and Jose without any modification. PTs provided tasks with the same or a similar level of cognitive demand for Jose, while they provided tasks with a lower level of cognitive demand for Liam indicating such modification was necessary to reduce Liam's math anxiety and provide emotional support.

Most PTs implemented a combination of whole group, small group, and/or independent activities for Jose. In their modification for Liam, more than half of PTs addressed Liam's need for additional instructional time with tutoring during or after the lesson. However, there was no discussion of how Liam could join small group activities or contribute to the whole group discussions. Almost all PTs started their lesson with the teacher-direct instruction approach, such as modeling, demonstrating, or explaining to teach typically performing students. The lesson plan had progressed with a combination of concrete examples and representations, concreteness fading, and abstract representation. All PTs used concrete examples and objects at some point in their lesson plan, but the progression of the lesson varied.

Regarding assessment, approximately half of the PTs used formative assessment geared toward gathering and sharing; 35% of PTs gathered information on students' mathematical thinking and used the information to attend to their learning; and 15% of PTs gathered information, attended to the information, and supported and provided feedback. There was very limited discussion on assessments in PTs' plans (only two) for Liam.

Discussion and Implication

The results in this study highlight the need to reconsider responsive teaching with regard to preparing teachers who can maximize quality opportunities for *all* students. PTs indicated more emphasis on deficits than the strengths of the individual student. With Liam there was only discussion of teacher support, while peer support may have lessened his anxiety. Another point worth noting is that unlike Jose, there was no PT who provided symbolic objectification support to Liam. And too many of the PTs did not seek to challenge Liam with high level thinking requirements. It means that differentiated assistance provided to students with special needs could have the possibility to limit the chances of approaching the abstract mathematical concepts. For students with special needs, PTs did not seek ways to "ensure shared power" through inviting them to engage in whole-class or small group discussion and by encouraging them to share their ideas or respond to one another's ideas (Van de Walle et al., 2019).

Taking a deep dive into what PTs did allowed us to identify gaps in the skills needed for applying research-based responsive teaching. The PTs need more instruction in peer tutoring and explicit teaching for MLDs. They all need more understanding of what it means to aim for high levels of cognitive demand for *all* students. As PTs should learn to modify and accommodate instruction for diverse learners with explicit instructional strategies, teacher educators need to support PTs to construct and provide high-quality learning opportunities for improving their knowledge and practice. Another implication of this study is that the analytical tools for responsive teaching in elementary level multiplication can be useful in capturing equitable learning opportunities. By merging the two different perspectives of mathematics and special education, we enhanced the analytical tool to cover both mathematics and instructional strategies. We believe that this analytical tool contributed not only to the methodological lens of responsive teaching for *all* students but also to the theoretical lens. It allows both the mathematics and special education fields to make real progress in persistent challenges in the teaching and learning of mathematics.

Mathematical modeling is an important process, concept, and practice in solving real-life problems but a source of concern for the preparation of preservice teachers (PSTs). To investigate this concern, we examined 31 PK–8 PSTs' conceptualization of mathematical modeling. We collected data using both qualitative and quantitative methods. Results indicated that most PSTs had minimal understanding of mathematical modeling. Most of our PSTs had misconceptions of mathematical modeling, and perceived mathematical modeling as an exclusive action reserved for only teachers. Based on our study results, we believe that infusing or integrating modeling courses or modules into existing methods or content courses can be an effective way to elevate PSTs from unfamiliarity with mathematical modeling practices and standards as emphasized by the Common Core State Standards for Mathematics.

Keywords: preservice teachers, mathematical modeling, conception, modeling, standards

The attention on mathematical modeling in teacher preparation programs is relatively low in the United States of America (U.S.), and this suggests that most teachers have not experienced mathematical modeling processes, standards, and practices (Asempapa & Sturgill, 2019), and learned it efficiently and consistently (Phillips, 2016). Looking back, Blum (2002), explained the rare use of modeling standards and process in mathematics education courses in teacher preparation programs. Moreover, Hamson (2003) further clarified as to why this occurred by arguing that "including more modeling in mathematics education has been a slow process" (p. 222). Before teachers implement modeling-based practices, they must not only have the required content knowledge but also the experiences with mathematical modeling standards. The luck of mathematical modeling practices in teacher preparation programs possess a problem for developing students' problem-solving skills (Borromeo Ferri, 2018; Kaiser et al., 2010; Paolucci & Wessels, 2017). Therefore, the purpose of this study was to exploratorily increase our understanding and describe PSTs' conception of mathematical modeling.

Few teacher preparation programs address mathematical modeling, its standards, and practices at the PK–8 level (Borromeo Ferri, 2018; Matthews & Reed, 2007; Zbiek, 2016). Additionally, the majority of teachers who are now expected to teach mathematical modeling have neither encountered modeling themselves nor studied it systematically (Borromeo Ferri, 2018; Phillips, 2016). According to Baumert et al. (2010), "the repertoire of teaching strategies and the pool of alternative mathematical representations and explanations available to teachers in the classroom are largely dependent on the breadth and depth of their conceptual understanding of the subject'' (p. 138). Furthermore, many teacher preparation programs rarely explore issues surrounding mathematical modeling practices, and these issues are often considered after teachers are on the job during professional development programs (Borromeo Ferri, 2018; Paolucci &Wessels, 2017). Thus, teacher preparation programs must develop modeling proficiencies and competencies in PSTs. Such goals are needed so they can experience the Common Core Mathematical Practice–*model with mathematics*–during their teaching.

The research question that guided this study was: What are preservice teachers (PSTs) conceptions of mathematical modeling?

Background and Relevant Literature

Mathematical Modeling

Historically, mathematical modeling has meant the use of mathematics to solve problems arising in everyday life (Blum & Boromeo Ferri, 2009; Lesh & Doerr, 2003). Mathematical modeling cuts across all levels of education, even teacher education. There is no question that teachers play an important role in motivating students to study mathematical modeling and the application of mathematics through engaging in mathematical modeling practices. Tremendous efforts have been made by the mathematics education community in studying mathematical modeling (Blum & Borromeo Ferri, 2009; Borromeo Ferri, 2018; Galbraith, 2012). Additionally, mathematical modeling, its applications, and the learning of it in schools have become prominent topics in mathematics education which have been discussed and advocated intensely in teacher preparation programs (Borromeo Ferri, 2018; Cai et al., 2014; Zbiek, 2016). Nevertheless, there exists a lack of attention to mathematical modeling in some U.S. mathematics teacher preparation programs (Borromeo Ferri, 2018; Newton et al., 2014).

Mathematical modeling “is the art or process of constructing a mathematical representation of reality that captures, simulates, or represents selected features or behaviors of that aspect of reality being modeled” (Cai et al., 2014, p. 150). Additionally, modeling involves an iterative process of interpreting a situation, constructing representational descriptions, and developing through revision cycles (Jung & Newton, 2018; Lesh & Doerr, 2003). Moreover, modeling requires a well-connected set of mathematical concepts and skills that, used flexibly, enables individuals to solve problems and better understand the real world, which goes beyond mere computational proficiency. On the contrary, learners’ success with routines or traditional tasks do not imply competencies or proficiencies with mathematical modeling because the process of moving from the givens (assumptions) to the goals (outcomes) may not be obvious (Lesh & Doerr, 2003; Lesh & Lehrer, 2003).

Preservice Teacher Education and Modeling

There is broad consensus that teachers need to have strong and sound knowledge of the subject content, as these influences both what they teach and how they teach it (Ball et al., 2008; National Council of Teachers of Mathematics [NCTM], 2014; Ponte & Chapman, 2016). Both elementary and secondary PSTs’ content knowledge of teaching mathematics have received attention in most recent studies in mathematics education (Borromeo Ferri, 2018; Ponte & Chapman, 2016). Studies on PSTs’ mathematical knowledge, including mathematical modeling practices, indicate serious issues that teacher preparation programs ought to address (Borromeo Ferri, 2018; Ponte & Chapman, 2016). Issues include misconceptions and deficient competencies for different topics of modeling standards, such as modeling process, modeling competencies, and modeling tasks. Therefore, it is no surprise that PSTs’ mathematical modeling content knowledge continues to be a central research theme for preservice mathematics teacher education.

Knowledge and experiences do impact individuals’ actions as well as form the foundation from which PSTs build upon to become high-quality, impactful teachers. To better prepare future teachers for the current classroom, they need to be engaged in mathematical modeling to support student learning and help students develop related competencies (Borromeo Ferri, 2018; Philips, 2016). Research has found that PSTs’ understanding of mathematical modeling varies and is impacted by the engagement in this modeling as well as through the investigation of modeling resources (Jung & Newton, 2018; Zbiek, 2016). Most research on the intersection of teachers and mathematical modeling focuses on inservice teachers or secondary preservice teachers. Yet, these populations are not the only ones who need to fully understand this modeling and integrate into their practice. To better prepare all mathematics teachers, more research is needed to understand elementary PSTs' knowledge of and experiences in mathematical modeling.

Methodology

Study Setting and Participants

The study participants were 31 PK–8 PSTs enrolled in mathematics methods courses. They were recruited from two, four-year universities located in the northeastern and midwestern U.S. Most participants were sophomores and juniors who enrolled in teacher preparation programs to gain licensure to teach elementary or middle grades. All PSTs were enrolled in mathematics methods courses whose objectives included the development of pedagogical knowledge and practice regarding mathematical modeling. The PSTs in this study have not taken any course in mathematical modeling.

Data Collection and Analysis

We used both qualitative and quantitative methods to examine how PSTs grapple with the concept of mathematical modeling. Data consist of participants' responses from a questionnaire that drew upon their conception of mathematical modeling. Their written responses were collected and converted into PDFs. We developed codes inductively and deductively to analyze the data. The process for coding transitioned from initial coding to focused coding (Saldaña, 2013). During initial coding, we collectively read participants' responses discussing potential themes and making memos. Initial codes were adapted and combined so distinctions among them were recognizable and applicable. These actions flowed into a focused coding of the data in which HyperResearch© was used to record and organize our results.

Validity was maintained due to the cyclic nature of coding, memo writing, collective agreement, and attributes of our expertise in mathematical modeling, representations, and qualitative and quantitative analysis. Data analysis began with creating and refining a rubric used to support the thematic analysis of participant's conception of mathematical modeling. Due to the nature of the data, Intraclass Correlation Coefficient (ICC) was chosen to measure our rating consistency of the rubric we created. The single measures ICC was used in this study because it is the appropriate coefficient (LeBreton & Senter, 2008; Liljequist et al., 2019) and has the ability to determine that the judgment of one rater is the same as that of the others. The ICC measures were acceptable and all above 0.89 (Liljequist et al., 2019).

Results and Discussion

All but 1 of 31 participants responded to the question: "What is mathematical modeling?" Twenty-six (87%) PSTs had a poor or fair understanding of mathematical modeling, while only four (13%) had a good understanding. Quotes from the respondents depicting fair and poor definition was "*using manipulatives to represent math/thinking*" and "*I believe it will be like the graphic organizers we made for the article review*" respectively. For instance, one PST described modeling as "showing examples to students of similar problems and then to solving the[se] problems" (Participant 6). Nonetheless, there were 4 PSTs whose conception or understanding of mathematical modeling were rated as good. For example, participant 29 stated, "mathematical modeling is taking concepts, formulas, etc. … and applying them to the real work." Table 1 below summarizes the categorized responses of the participants to the definition of mathematical modeling based on the rubric.

Table 1: Rated Definitions of Mathematical Modeling

Category	# of Count	%
Excellent	0	0
Good	4	13
Fair	15	50
Poor	11	37

n = 30

Given the nature of participants responses, we next summarize the common themes that emerged. The common themes include (a) *who uses mathematical modeling*—most of participating PSTs placed the act of modeling on the teacher; (b) *how and why use mathematical modeling*—majority of the PSTs explained that teachers use mathematical modeling during instruction to solve examples, show strategies, or both; and (c) *representations of mathematical modeling*—most participants described the act of mathematical modeling as either a visual element (n =10) or as a symbolic representation (n = 6). Per anecdotal evidence, we were not surprised that no participating PST had an excellent understanding of mathematical modeling.

The results indicate that almost all the participants in the study had minimal understanding of what mathematical modeling entails. Additionally, most PSTs perceived mathematical modeling as an exclusive action reserved for only teachers. This perception is contrary to what the Common Core modeling standards expect of teachers: "mathematically proficient students can apply the mathematics they know to solve problems arising in everyday life, society, and the workplace" (National Governors Association Center for Best Practices [NGA Center] & Council of Chief State School Officers [CCSSO], 2010, p. 7, 2010). Moreover, PSTs described the act of mathematical modeling to include a visual element or symbolic representation. Again, this notion carried by our participants about mathematical modeling shows their inadequate understanding of what mathematical modeling is about—the translation between mathematics and the real world—as described and discussed in standards and modeling education literature (Association of Mathematics Teacher Educators [AMTE], 2017; Borromeo Ferri, 2018, COMAP & SIAM, 2016; Hirsch & Roth McDuffie, 2016; NGA Center & CCSSO, 2010).

Conclusion and Implications

The purpose of this study was to examine how elementary PSTs grapple with the concept of mathematical modeling standards and practices. Because modeling standards are relatively new in the U.S. Common Core mathematics curriculum, but an important concept in mathematics education, it was necessary and essential in undertaking this research study with PSTs. The results from this study show that elementary PSTs' conceptions of mathematical modeling standards were minimal. Notwithstanding the suggestions by researchers that students should engage in mathematical modeling early in their mathematics education, PSTs need more training and support in meeting this challenge. It is worthwhile for teacher preparation programs to reexamine their curricula and consider mathematical modeling so PSTs conceptual models could be revised and extended. We believe that infusing or integrating modeling courses or modules into existing methods or content courses can be an effective way to elevate PSTs from unfamiliarity with mathematical modeling practices and standards.

Writing in mathematics is critical to students' learning, yet few teachers assess students' mathematical writing (MW) or incorporate MW into their instruction. In an effort to increase preservice teachers (PSTs) attention to MW, we examined PSTs' experiences with MW and the impact of a content module focused on MW embedded in mathematics methods courses at four institutions. Findings indicate PSTs had limited experiences with MW in K-16, yet saw it as valuable to students' learning. After completing the module, the PSTs' self-efficacy related to MW grew, indicating a greater likeliness of incorporating MW into their future practice.

Keywords: Preservice Teacher Education, Curriculum, Communication

Since the National Council of Teachers of Mathematics (NCTM) published their *Principles and Standards for School Mathematics* (2000) over 20 years ago, communicating mathematical ideas clearly, coherently, and effectively to teachers, peers, and others, has been a distinct goal of mathematics instruction. One way students are expected to communicate their mathematical ideas is through writing. Writing plays a critical role in advancing students' mathematical learning by promoting reflection and clarification of ideas through explanations, descriptions, definitions, and critiques (Freeman et al., 2016; Marks & Mousley, 1990; NCTM, 2000). In addition, mathematical writing (MW) can support students' 'evelopment of productive mathematical identities (Boaler, 2002; Cobb & Hodge, 2002; Ivanič, 1998; Murphy & Hall, 2008). Yet, writing in mathematics classrooms is often overlooked even though it plays an important role in developing mathematical thinking.

Elementary teachers in the U.S. are typically responsible for teaching every content area to the same group of students, thus they are well positioned to foster students' MW and draw on students' competencies in mathematics and English Language Arts. Yet, many teachers report they do not provide instruction on MW nor provide many opportunities for students to write in mathematics (Banilower et al., 2018; Powell et al., 2017). Thus, in an effort to draw increased attention to MW and support preservice teachers (PSTs) in their ability to assess and craft instruction that facilitates students' MW, we created a module focused on MW that was embedded within mathematics methods courses across four institutions. In this paper, we report on early findings from this study. Specifically, we sought to answer the questions: *What are preservice teachers prior experiences with MW? In what ways, if any, does completing a module focused on MW impact preservice teachers' self-efficacy and their perception of the uses and benefits of MW to students' learning?*

Mathematical Writing

Mathematical writing is "a writing activity in which students write about mathematics concepts or procedures" (Powell et al., 2021, p. 418) that can vary based on purpose, level of formality, audience, structure, and required language (Chval et al., 2021). Although there are multiple MW genres (e.g., explanatory, argumentative; Casa et al., 2016), explanatory writing is the primary focus of teachers (Gillespie et al., 2014; Swinson, 1992), curriculum (Casa et al., 2019), state assessments (Powell et al., 2020), and research (Powell et al., 2017).

Although teachers recognize the value and importance of MW to students' learning (Powell et al., 2021), few teachers ask their students to write in mathematics and, even less, incorporate instruction on how to write in mathematics (e.g., model; Powell et al., 2017). Importantly, whether teachers incorporate activities and/or instruction related to MW is tied to their self-efficacy for MW, regardless of grade level (Powell et al., 2021). Consequently, if teachers have higher levels of self-efficacy, they are more likely to incorporate MW into their instruction.

Assessing students' MW is critical to craft instruction that is responsive to student learning. Yet, teachers who incorporate MW may not assess students' writing or encourage students to self-assess (Powell et al., 2021), which raises the question of how to effectively support future teachers in assessing students' MW.

Methodology

This study is part of a larger project examining the impact of a MW module on PSTs' MW and their ability to assess elementary students' MW. Data for this project was collected at four universities and involved 116 PSTs.

Participants

All participants in this study were junior or senior undergraduate PSTs enrolled in a mathematics methods course at one of four universities in the U.S. Each methods course was designed to prepare elementary PSTs seeking initial licensure in elementary education, special education, or elementary and special education.

Mathematics Writing Module

All participants completed a week-long asynchronous MW module as a part of their mathematics methods course. The module was composed of (1) a pre-survey, (2) MW content, and (3) a post-survey. The pre- and post-survey collected similar information and included PSTs' demographic data (e.g., age, race/ethnicity); self-efficacy related to MW instruction and assessment; prior experiences with and beliefs about MW; and asked PSTs to provide written responses to two mathematics tasks. The MW content included: an explanation of what MW is and why it is important to students' learning, a description of how to use a rubric to assess students' writing, and asked PSTs to score two student's MW using a rubric.

Data Analysis

To answer the research questions for this study, we drew from PSTs' pre- and post-surveys. This data included PSTs responses to items measuring self-efficacy in MW (see Table 1) and open responses. PST's indicated strongly disagree (-2), disagree (-1), neutral (0), agree (1), or strongly agree (2) to each Likert scale item. To analyze the quantitative data, we used descriptive statistics and Cohen's d for individual questions as well as t-tests with Cohen's d for general self-efficacy in MW (overall mean of the four Likert scale questions). To analyze PSTs open responses, we used a constant comparative method (Patton, 2015). We began with open coding and then moved to axial coding after themes had been identified. All qualitative data was coded by two of the authors who met to resolve disagreements and reach consensus.

Findings

General findings indicated that PSTs saw benefits to MW despite limited MW experiences prior to the module, but demonstrated improved self-efficacy in MW and expanded conceptualizations of how MW could be used in instruction after engaging with the module.

PSTs' Experiences Related to Mathematical Writing

The PSTs in the study had limited prior experiences related to MW. When describing their K-12 experiences, a third (31%) of PSTs stated they were never asked to write in their mathematics classes and just over a half (52%) were asked only once to several times a semester. Across their K-12 experiences, the majority (77%) of PSTs received no formal instruction on how to craft a written response to a mathematics task. Of those PSTs who did receive instruction, this was commonly described as a need to provide their answer in a complete sentence or to explain their problem-solving procedures. As one PST stated,

> In math when we were taught to write our answers out, we were simply taught to explain how we got it. For example, our sentences would look something like this, "I got the answer ______, I found this answer by _____."

The majority (83%) of PSTs also received minimal education or instruction in their teacher preparation program related to writing in mathematics, even though the PSTs had completed at least one elementary mathematics content course prior to their methods course.

PSTs' Self-Efficacy about Mathematical Writing

PSTs' mean responses across the four self-efficacy questions in MW were neutral on average prior to the module but moved in a positive direction toward an average of agree after the module, with medium to large effect sizes. Means and standard deviations are reported for each of the self-efficacy questions at pre- and post-survey as well as the effect sizes (see Table 1). The largest growth was seen for the self-efficacy questions with the "I know how to" stem as opposed to the "I feel confident" and "I can" stems, which suggests PSTs felt they improved the most in their pedagogical knowledge as opposed to their confidence in their ability to employ pedagogical skills once they learned them. The highest self-efficacy score at the post-survey was in relation to MW assessment, which aligns with the focus of the MW module. A paired sample t-test was used to evaluate growth in general self-efficacy. General self-efficacy in math writing increased from pre- to post-survey, which was a significant increase of 0.82, $t(112) = 14.34$, $p < .001$, for a large effect size of $d = 1.35$. Therefore, the MW module had a significant and large positive impact upon PSTs' general self-efficacy in MW instruction and assessment.

Table 1: Preservice Teachers' Self-Efficacy

Question	Pre M (SD)	Post M(SD)	Effect Size Cohen's *d*
I feel confident in my ability to teach math writing to the grade I currently teach.	0.26 (.86)	0.84 (.71)	0.69
I can effectively teach math writing.	0.21 (.60)	0.77 (.64)	0.84
I know how to teach math writing.	-0.31(.90)	0.69 (.73)	1.08
I know how to assess a student's math writing.	-0.12 (.94)	1.03 (.57)	1.23
General self-efficacy in mathematical writing	0.01 (.68)	0.83 (.57)	1.35

PSTs' Perceptions about the Uses and Benefits of Mathematical Writing

Although the PSTs expressed limited prior experiences related to MW, nearly all the PSTs reported that writing in mathematics is beneficial to students' learning. The PSTs also expressed they would ask their students to write in mathematics on a monthly, weekly, or daily basis. The differences between pre- and post-survey responses to this question were minimal, indicating the PSTs had already intended to incorporate this as a part of their practice. However, the PSTs conceptualization of what MW is appeared to have been rather limited at pre-test (e.g., writing out answers to word problems in complete sentences) and to have expanded at post-test (e.g., writing about multiple strategies or critiquing the ideas of other students).

When asked to identify MW activities for fourth-grade students, the PSTs consistently identified explaining a problem-solving procedure before and after completing the module. For instance, a PST stated students would be asked to write "A step by step explanation on how to do certain problems, mainly word problems and multiple step problems." The PSTs also identified other types of writing activities, but the focus of these shifted after the module. Before the module, the PSTs identified asking students to identify connections or applications of mathematics to their daily lives or write a story problem to a small degree. After the module, the PSTs identified asking students to write about their reasoning, justifications, or critique the reasoning of others to the same degree as writing explanations. The PSTs described such activities like, "I might have my students write about how they might approach a problem in contrast to another student" or "I would ask them to explain their answers, create problems, and explain how students in example problems may have made a mistake." Although the module focused on assessing students' 'W, it seemed to also expand PSTs' views of how MW could be used in instruction (i.e., beyond procedural descriptions).

At the completion of the module, the PSTs reflected on the evolution of their thinking about MW. To support this reflection, we offered the optional stem, "I used to think ____, but now I think ______" that PSTs could use in their responses. Nearly all the PSTs noted their thinking had changed and had a greater understanding of the importance and benefits of MW to students' learning. Although some PSTs spoke in broad terms, like "I used to not know much about mathematical writing, but now I think mathematical writing is a crucial aspect of math instruction", others spoke in specifics. For instance, one stated,

> I used to think that math writing was just the process of using words to relate math to the real world, but now I know there are many different types of math writing and levels. I think now that this process allows students to think deeply about course material and it's a good alternative to quizzing for understanding.

Whereas another PST said, "I used to think writing and math combined was silly and just extra work on students, but now I think it can benefit students in many ways including their understanding of mathematical concepts." In summary, while PSTs perceived value of MW was generally high even prior to the module, their perceptions of what MW is and its potential uses expanded.

Discussion and Conclusion

Like other studies have found (Gillespie et al., 2014; Powell et al., 2021; Swinson, 1992), the PSTs in this study experienced few opportunities to write in mathematics as a K-12 student and, when they did, it was often explanatory writing (e.g., write an explanation of procedure). Moreover, the PSTs had received minimal instruction in their teacher preparation program related to MW; yet they expressed intent to regularly incorporate MW into their future mathematics instruction and saw MW as critical to students' learning. However, PSTs grew in their self-efficacy in MW and expanded their conceptualizations of what MW entails in response to the module. Although these findings show promise, additional research is required to refine the module and examine its impact on actual classroom practices and student performance.

In our study, we used video analysis to examine how preservice elementary teachers (PSTs) noticed and described the equitable teaching practices that leverage students' multiple mathematical knowledge bases (MMKB) including prior mathematics knowledge, cultural, community, family, and linguistic knowledge and experiences; student interests; and peers, to support productive struggle. The PSTs (n=40) in their final mathematics content course analyzed a video episode of a classroom with a teacher and students engaged in productive struggle about a task. Frameworks of teacher noticing and productive struggle were incorporated in their assignment to guide the PSTs in their analysis. We report on the levels of connections PSTs made of the MMKB to the support and resolution of productive struggle.

Keywords: Pre-Service Teacher Education; Equity and Diversity; Teacher Noticing; Mathematical Knowledge for Teaching

Introduction

In this study, we focused prospective elementary and middle school teachers' (PSTs') attention to particular resources teachers use to support students in productive struggle. "Student resources included: prior mathematics knowledge; cultural, community, family, and linguistic knowledge and experiences; student interests; and peers as supports for learning," (Roth McDuffie et al., 2014, pp. 246-247), which is also referred to as students' multiple mathematical knowledge bases (MMKB). We used video clips showing classroom interactions between teachers and students to introduce the PSTs to how teachers draw upon and leverage resources and knowledge bases that students bring to the classroom and that support and empower students' mathematical understanding and productive struggle in inclusive settings (Lynch, Hunt, & Lewis, 2018; Santagata and Guarino, 2011). We are also informed by the Five equity-based practices to support mathematics learning as articulated in *Taking Actions* (NCTM, 2017), and focused the PSTs on their noticing of two practices in particular: 1) Leverage multiple mathematical competencies and 2) Draw on multiple resources of knowledge.

Theoretical Perspective and Related Literature

Studies suggest introducing frameworks to PSTs in aspects of teaching such as teacher noticing and productive struggle provide support and structure more effectively when discussing and analyzing important teaching practices (Warshauer, et al., 2019; Roth McDuffie et al., 2014; Santagata and Angelici, 2010; Stockero et al., 2017; Walkoe, 2015). The PSTs were introduced to the skills of noticing including the components of attending to, interpreting, and deciding on actions based on student thinking (Jacobs, Lamb, & Philipp, 2010). By learning to notice children's mathematical thinking and their cultural funds of knowledge, teachers can leverage these resources to better support students equitably and inclusively in their classrooms (Turner & Drake, 2016). The *Productive Struggle Framework* (Warshauer, 2015) provides a way of examining elements of a productive struggle episode from the initiation of a student struggle when students engaged in a task to the interaction between the teacher and student(s) with an action or response to support the students' struggle. In addition, we focused PSTs on ways that the resources were implemented by teachers in support of students' struggle and understanding. Studies on teacher noticing of equity suggest that teachers who notice equitably perceive mathematical and interpersonal activity as inextricably linked and notice individual student participation (van Es et al., 2017; Hand, 2012; Turner et al., 2012, Wager, 2014). Thus, including the use of resources and its connection to student struggles and teacher actions can inform how teaching can support student struggles productively or not.

Our research questions for this study are:

3. How do PSTs notice and describe the equitable teaching practice of leveraging students' MMKB (resources), to support student struggles and teacher actions during a video episode of students engaging in productive struggle?
4. How do PSTs interpret the role resources play in equitably supporting the productive level of students' mathematical struggle, as viewed in a video episode of a class discussion?

Methodology

This study was part of a larger study conducted in 2017 at a public, four-year, Hispanic Serving Institution in a rural area in the Western United States over a 14-week period. The original study consisted of 40 PSTs enrolled in one of two sections of their final mathematics content course for elementary teachers, taught by the same instructor. The PSTs completed three productive struggle writing assignments (WA), in which they reflected on a video episode of productive struggle with the use of resources. The PSTs were asked to connect the mathematical content of the video to the components above and decide how productive the struggle was for the student(s). The writing assignments provided opportunities for the PSTs to apply and develop their understanding of the mathematics and student's mathematical thinking from the content course. These assignments also served as approximations of practice to initiate PSTs learning key practices for engaging with children's multiple mathematical knowledge bases (Turner et al., 2011).

We coded all 40 WAs using qualitative content analysis (Hsieh & Shannon, 2005). The four researchers agreed on expert codes and the WAs were coded inductively to compare and identify themes in the PSTs' responses based on the MMKB. A sample of the WAs were analyzed by all researchers to ensure inter-rater agreement. This study focused on WA3. The video used for WA3, which we refer to as the *Equality* video, includes a dynamic class discussion about the concept of equality. In the video, the students demonstrate a misconception with regard to the equal sign. The sequence of events builds on multiple students' perspectives, actions, knowledge bases and misconceptions, as well as, the interpretations of the teacher's actions and practices she implemented to support student learning. Based on open coding, we developed our coding scheme and analyzed at levels 1, 2, and 3 of noticing of resources. At level 1, the PST only identified the resource, at level 2, the PST noticed how the resource to support learning in general, and at level 3, the PST noticed how the teacher leveraged a resource to support students engaging in productive struggle. Level 3 students particularly identified a student struggle, student interaction, teacher action, or mathematical interpretation of the struggle. The four researchers inductively coded all WAs focusing on the PSTs' noticing and description of the resources leveraged to support student struggles and teacher actions.

Findings

The PSTs noticed that the teacher drew upon students' mathematical knowledge, linguistic knowledge, and peers to support students' math understanding to solve the equation $8 + 4 = \_ + 5$. In addition to noticing how the teacher leveraged the students' mathematical thinking and funds of knowledge, PSTs identified visual aids and manipulatives as resources the teacher utilized to support students learning. One PST identified non-verbal communication (gestures) being used as a resource.

Table 1: Resources noticed by PSTs

	Mathematical Knowledge	Translanguaging	Peers	Visual Aids	Non-verbal Communication
Number of PSTs	27	25	28	8	1

Mathematical Knowledge Resource

Of the 27 PSTs who noticed the teacher leveraging the students' prior mathematical knowledge, two PSTs only identified without elaboration the teacher's use of this knowledge base. Ten PSTs discussed scaffolding problems that build upon prior concepts as a general, good teacher practice that supports students in understanding new ideas. Their analysis was generalizable to a general learning situation, whereas, 15 PSTs identified the specific mathematical concepts the teacher tapped into, such as prior knowledge of addition, equations and what an equal sign means. Additionally, the PSTs linked how specific problems were intended to address students' misconceptions, thus connecting the teacher action, prior mathematical knowledge and the mathematical struggle, as seen in this PST's observation:

> She uses what they already know about equations to push their thinking into how they could solve the problems on the board. The teacher writes $5 = 5$ to set a foundation for the fact that a number equal to itself is true. This helps the teacher to demonstrate that $5 = 4 + 1$. The students are able to use their newly gained knowledge to solve all the more complicated problems written on the board. (PST1240, Level 3)

Linguistic Knowledge Base

Twenty-five PSTs noticed the teacher drawing upon students' linguistic knowledge bases by translanguaging between Spanish and English. Four PSTs with a level 3 analysis connected the teacher's action of translanguaging to a particular mathematical struggle. These PSTs described how translanguaging engaged more students in the mathematical struggle, helped build a community of learners, familiarized students with math terms in English, and was an indication of the teacher's knowledge of each of her students and their needs. One PST discussed how peers (another resource) translanguaged amongst themselves to make sense of the equation. Nineteen PSTs with level 2 analysis discussed translanguaging as a general teacher action to support learning but did not connect translanguaging to any particular student struggle or student thinking. Three of these PSTs connected linguistic and peer resources and one PST with a level 2 analysis gave a negative evaluation of the teacher translanguaging in the video.

Peers as a Support for Learning

Of the 28 PSTs who noticed the teacher using peers as a resource, five did so with a level 3 analysis and 23 with a level 2. The PSTs with a level 3 analysis connected the use of peers to the teacher actions and the mathematical struggle of the students. The PSTs described the use of peers as a way for students to discuss their understanding of the problem and to learn from each other. The 22 PSTs with level 2 analysis connected peers as a resource to teacher actions as a general classroom learning tool. One PST discussed classroom community and another discussed zone of proximal development, which we categorized as a peers resource. These PSTs did not connect peers to the mathematical struggle or student thinking.

Findings Related to Resolution of Productive Struggle

Our second research question examined how PSTs interpreted the role student resources played in the productive level of students' mathematical struggle, as viewed in a video episode of a class discussion. Our analysis showed that 33 of the 40 PSTs agreed that the student struggles observed in the video episode resolved productively. Eight of the PSTs described individual students' struggles as being productive at a low level (6) or not productive (2). Two of these PSTs had also indicated a class resolution at a productive level. One PST did not state a resolution. Of the 37 PSTs who viewed the episode as productive or productive at a low level, 22 mentioned specific resource(s) that were leveraged in support of productive struggle while 15 made no mention of any resources tied to the resolution. Resources most often mentioned were students' mathematical knowledge (11) and peers (14). While mentioned by only six PSTs, PST1250 connected the translanguaging resource used to support the productive struggle of student S who, "showed a high level of productive struggle because even though she stumbled to say the answer to one of the problems, she did give the correct answer in Spanish." PST1221 noticed that both translanguaging and peers as a teacher action were being used to support the students' struggle, "The teacher was constantly asking questions [direct and probing guidance], responding and translating in Spanish to help students better understand the content. I thought it was great that when she saw the students begin to struggle she allowed them to speak in small groups …". PST1156 attributed three resources and the teacher's knowledge of their students that appeared to support productive struggle, "The students were able to struggle with a math problem and the teacher was able to scaffold their understanding using their previous knowledge, speak their language, and draw upon peer discussion to help the students understand equality."

Conclusion and Implications

Our analysis suggests PSTs are able to notice equitable teaching practices and resources and use their observations to inform their determinations of the productiveness of students' struggles, but do not concretely develop *how* equitable practices are implemented to support productive struggle. The PSTs overall made deeper connections about students' prior mathematical knowledge than peer and linguistic knowledge, with 15 PSTs connecting specific examples used to leverage students' previous mathematical knowledge. This discrepancy may stem from this video analysis occurring in a mathematical content course that places an emphasis on developing PSTs' understanding of students' mathematical thinking. Perhaps providing more context about the students in the video, i.e. if they are English Learners and if their proficiency level is emerging, expanding or bridging, would encourage PSTs to interpret more non-mathematically-based resources such as linguistic or peers. Providing them with authentic student information, student work and interactions may be key to help PSTs connect equity-based practices to effective practices.

DISCIPLINARY CONTENT KNOWLEDGE ABOUT SOLVING PROBLEMS WHERE THE FRACTION ACTS AS OPERATOR

carlos.b.gomez@uv.es

This research tries to investigate the disciplinary knowledge of recently qualified teachers of Primary Education (PE), in its different mentions, about the fraction when it acts as an operator. For this purpose, a test was carried out in which two problems had to be solved, both arithmetically and graphically. The common characteristic of the problems is the fraction as an operator, on a natural number, and on a fractional number. The results reflect higher levels of success when the fraction operated on a natural number, and, in general terms, the graphical solution was more complex than the arithmetic one. As for the different mentions, the best results were obtained by mathematics teachers.

Keywords: Problem Solving, Fraction, Disciplinary Content Knowledge, Teacher Education

Introduction

However, at present, the training of mathematics teachers is still considered a topic of latent importance within mathematics education. This fact is determined by: a) unfavorable results in the development of cognitive abilities of students in national and international exams, and b) dissatisfaction of teachers in carrying out their work, together with the different curricular reforms that require a certain renewal of teachers (Godino, Batanero and Flores, 1999).

The question is that, faced with this panorama, the idea persists as to whether it is possible to do something more in initial teacher training in order to develop specific professional knowledge (of mathematics, in this case). The fact is that, as Lappan and Theule-Lubienski (1992, cited in Godino et al. 1999) state, an exclusively mathematical or psycho-pedagogical teacher training, of a generalist nature, does not seem to be sufficient given the cognitive and didactic complexity of specific mathematical concepts and methods.

Within this framework, this paper seeks to investigate the knowledge that recently qualified primary school teachers have about a specific mathematical concept, the fraction as an operator, in a problem-solving context.

Many authors highlight the importance of teaching fractions through problem solving (Llinares, 2003), however, a large part of the studies in this area show that the concept of the fraction as an operator, as well as its application, is not fully understood or mastered. In their day, authors such as Kieren (1976) and Freudenthal (1983) alluded to this idea, which is still present in works such as that of Egodawatte (2011), where they detect that students make mistakes about the whole on which the fraction acts, or even in teachers, as in Livas (2004), who studied the mathematical conceptions of eight PE teachers in relation to the fraction as an operator, with the result that their knowledge of the fraction is incomplete and, therefore, the teaching they can give about it will be deficient.

Purpose of the work (Objectives)

In the present study, the aim was to investigate the skills and disciplinary knowledge of PE teachers (with different mentions) about fractions as an operator in problem solving. In this way, the conjectures that are raised are:

1. The majority of PE teachers do not have enough level of knowledge of fractions, with Science and Mathematics (SM) teachers standing out as having a higher level of knowledge of the content.
2. The greatest success will be obtained when the operator acts on a natural number because it involves a simpler mathematical content, with SM teachers obtaining the best results.

Method

Sample

Forty teachers (16 men and 24 women) recently graduated from a primary school teaching degree at a Spanish Public University participated. Respondents ranged in age from 22 to 26 years, with a typical age of 22 years. The sample was a non-probabilistic sample of convenience and included participants from different mentions, with 13/40 being teachers of Science and Mathematics.

Instrument

In order to address the two objectives outlined in this paper, one battery of questions is required. It is a pencil and paper questionnaire on solving two problems; one where the fraction acts on a natural number (P1) and the other where the fraction acts on a fractional number (P2).

> *P1. A well with 20 liters of water was emptied three-fifths (3/5) parts to water the plants. How many liters have been emptied?*
>
> *P2. Half (1/2) of a well is full of water. If we empty one third (1/3) for consumption, how much of the initial amount of water has been emptied?*

The teachers' answers are coded in terms of the study variables according to the value of 0 (incorrect answer) or 1 (correct answer) and through the distribution of the answers in different variables established as follows: arithmetic and graphic resolution of a natural number (P1A and P1G, respectively), arithmetic and graphic resolution of a fractional number (P2A and P2G, respectively) or the mastery of both resolution methods in each of the cases. The aim of this tool is to explore possible difficulties of teachers with this disciplinary content, considering the two methods of resolution (arithmetic or graphical) and the two types of context depending on the problem (natural or fractional).

The analysis of the results will be a) descriptive, where the frequency of each of the coding values for each of the variables will be observed, and b) inferential, where the relationship between the different pairs of these variables will be studied according to the proposed objective. For this purpose, Fisher's test (TF), Cramer's V (VC) and Proportions Test (TP) will be used.

Results

Problem Solving Questionnaire

For P1, where the fraction acts on a natural number, all teachers answer (or try to) both ways. More successful results were recorded for arithmetic resolution (38/40) than for graphical resolution (28/40). Of the 28 who do well in graphical solving, none do poorly in arithmetic solving. This indicates that, out of 40 respondents, only 28 have solved P1 correctly. See Figure 1 for more detail.

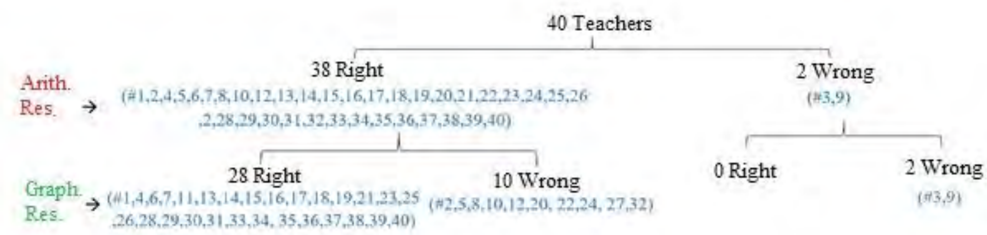

Figure 1: Analysis of results of Q1 of questionnaire 1

For the mentions, in P1 we obtain that all SM teachers have good arithmetic resolution, but 5 have bad graphic resolution. On the other hand, in the rest of the mentions, 2/27 and 7/27 have bad arithmetic resolution and graphic resolution, respectively.

Figure 2 shows the results obtained with P2. It can be seen that all teachers respond to both resolution, with more successful results in arithmetic resolution (29/40) than in graphic resolution (11/40). Of the 11 who do well in graphical resolution, none do poorly in arithmetic resolution. This indicates that, out of 40 respondents, only 11 have correctly solved P2.

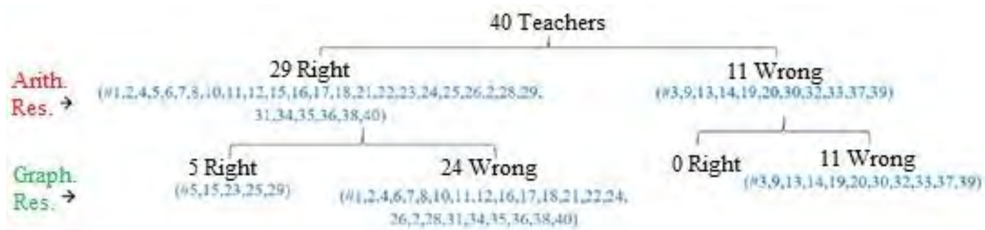

Figure 2: Analysis of results of P2 of questionnaire 1

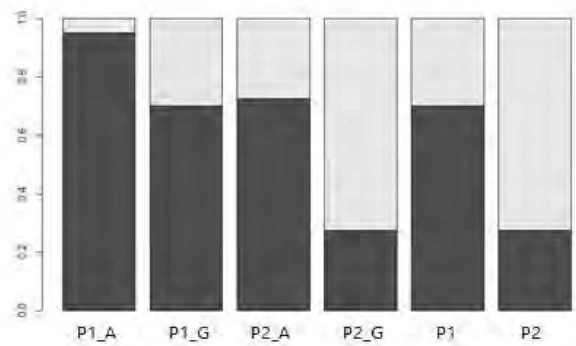
On analyzing this P2 by mentions, we find that 2 of 13 SM teachers have poor arithmetic resolution and 7 have poor graphic resolution. On the other hand, of the 27 teachers of the other mentions, a) 9 have poor arithmetic resolution, and b)13 have poor graphic resolution.

The comparative analysis between the success rates is shown in Figure 3a). The numerical results (Figure 3b) reflect a median association (VC<=0.45) and differences between the successes in solving the problems (p-value<=0.015).



a)

	TF (p-value)	VC	TP (p-value)
P1_A vs P1_G	8.658(0.006)	0.329	7.013(0.008)
P2_A vs P2_G	16.797(<0.001)	0.45	4.45(<0.001)
P1_A vs P2_A	7.440(0.013)	0.305	5.878(0.015)
P1_G vs P2_G	14.459(<0.001)	0.425	12.808(<0.001)
P1 vs P2	14.459(<0.001)	0.425	12.808(<0.001)

b)

Figure 3: (a) Success rates by problem and type of resolution; (b) association and difference in rates

If we consider the different mentions, there are no statistically significant differences. However, there are significant differences within the mention itself, depending on cases: a) for SM teachers, P1 in the type resolution, arithmetic or graphic (TF=4.452, p=0.040; VC=0.488 > 0.3; TP= 3.962, p=0. 046); b) for non-SM, in P1 differences in the type of arithmetic or graphical resolution, (TF=8.761, p<0.001; VC=0.487 > 0.3; TP= 10.906, p<0.001); and c) for non-SM, in the resolution of P1 and P2, (TF=9.463, p<0.001; VC=0.557> 0.5; TP= 14.599, p<0.001).

Discussion and conclusion

If we recapitulate the different contributions of our research, we can see that with respect to the experimental PAEVs, there are two main elements that generate relevant differences in the final consideration of the results. By this we refer, on the one hand, to the quantity or whole on which the fraction acts as an operator, depending on whether it is a natural (discrete) or rational (continuous) number and, on the other hand, to the method of resolution requested, depending on whether it is arithmetic or graphical.

The results of this research point to a record of better grades when the fraction operates on a natural number, and not on another fraction. This fact may be obvious because it can be justified by the fact that natural numbers are a simpler content and introduced in school education earlier. On the other hand, Ríos (2007) points out that, in the teaching of fractions, the most dominant context is the discrete one, since the part-whole interpretation usually taught through graphical representations of discrete objects or quantities tends to predominate. Moreover, a recent study (Sanz et al., 2020) on the relationship between complexity -measured through the reading comprehension of the statement itself- and success in solving problems with the same characteristics as those present in this study, shows that they are related, with those whose whole is a fraction being more complex.

Considering each resolution method, the majority of participants obtain by far a higher level of success in arithmetic resolution than in graphical resolution. One of the important references is the role played by the curricular materials based on the provisions of Royal Decree 126/2014 of 28 February, since, given that in this document graphical representation is included as one of the key contents in relation to fractions up to 3rd year of Primary School, subsequently, this type of representation takes second place, being replaced by the prioritization of the arithmetical treatment of operations with fractions.

PROSPECTIVE MATHEMATICS TEACHERS' GEOMETRIC DEFINITIONS AND CONCEPTIONS ABOUT PROPERTIES OF TWO-DIMENSIONAL SHAPES

Suzanne R. Harper
Miami University
Suzanne.Harper@MiamiOH.edu

Shannon O.S. Driskell
University of Dayton
sdriskell1@udayton.edu

This qualitative study sought to investigate the understanding of middle grades prospective mathematics teachers' (PMTs) geometric definitions and conceptions about properties of two-dimensional shapes. Hierarchical classification systems for two-dimensional shapes created by 18 small groups of PMTs (n=52) were analyzed. Preliminary findings document inconsistencies for the definitions of kite and trapezoid. Implications concern *the role participants' concept images and their experiences using dynamic geometry*.

Keywords: Geometry and Spatial Reasoning; Instructional Activities and Practices; Preservice Teacher Education

Purpose of the Study

Although children typically learn about shapes prior to attending kindergarten, teachers play a significant role helping them form definitions of and relationships between two-dimensional shapes (Türnüklü et al., 2013). It has been documented that students experience difficulties with identifying quadrilaterals (Currie & Pegg, 1998; de Villers, 1998; Pratt & Davison, 2003; Vinner, 1991; Zaslavsky & Shir, 2005) and their hierarchical classification (Erez & Yerushalmy, 2006; Fujita, 2012; Fujita & Jones, 2007; Monaghan, 2000; Okazaki & Fujita, 2007; Pickreign, 2007). Researchers report that prospective mathematics teachers (PMTs) also have difficulty identifying types of shapes based on properties, rather than visual recognition (Burger & Shaughnessy, 1986; Türnüklü et al., 2013), and struggle to perceive properties of figures, notice relationships among figures, or understand class inclusion (McCammon, 2018; Ozdemir Erdogan & Dur, 2014). These limited understandings about shapes were likely later embedded in their own teaching, possibly causing their students to construct limited conceptions about geometric properties of shapes. Therefore, it is critical that teachers have clear understandings about properties of shapes in order to assist their students in constructing these understandings. Using proactive dragging (Hollebrands, 2007) and examining non-prototypical shape examples with dynamic geometry software (DGS), PMTs have the opportunity to deepen their concept definitions and form relationships between classes of shape. The purpose of this qualitative research study was twofold: (1) to investigate the understanding of middle grades PMTs' geometric definitions and conceptions about properties of two-dimensional shapes; and (2) to analyze the geometric language and reasoning PMTs employ after participating in dynamic geometry activities to explore definitions of and relationships between classes of shape.

Theoretical Frameworks

Two theoretical constructs guided this study. The first was Tall and Vinner's (1981) concept definition and concept image. The concept definition is "a form of words used to specify that concept" (Tall & Vinner, 1981, p. 152). The concept image is "the total cognitive structure that is associated with the concept, which includes all the mental pictures and associated properties and processes … built up over the years through experiences of all kinds, changing as the individual meets new stimuli and matures" (Tall & Vinner, 1981, p. 152). Cunningham and Roberts (2010) documented that PMTs demonstrate inconsistencies between their geometry concept images and concept definitions.

The second theoretical framework was the van Hiele levels of geometric thinking (van Hiele, 1985). The van Hiele levels are commonly used to describe students' development of geometric reasoning. In general, level 0 students rely on visual prototypes to identify polygons, level 1 students use properties to describe shapes, and level 2 students use properties to describe relationships between classes of shapes. Therefore, students at level 0 use visual strategies to describe individual shapes, students at level 1 use attribute strategies to describe a class of shapes, and students at level 2 use property strategies to describe inclusive relationships between classes of shapes. These levels were used to characterize the language PMTs employed during a Hierarchical Classification Diagram Activity (see Figure 1), and provided information about each PMT's geometric reasoning about definitions and conceptions of shapes and their properties. This framework guided the data collection and analysis. Together, these frameworks provided a lens to examine the understanding of middle grades PMTs' geometric definitions and conceptions about properties of two-dimensional shapes.

Activity: Using the provided paper and pen, organize the following geometric shapes in a hierarchical classification diagram.

Circles, equilateral triangles, hexagons, isosceles trapezoids, isosceles triangles, kites, octagons, parallelogram, pentagons, polygons, quadrilaterals, rectangles, rhombi, scalene triangles, squares, trapezoids, triangles

Figure 1: Hierarchical Classification Diagram Activity (adapted Sowder et al., 2017, p. 410)

Methods

This study investigated the understanding of middle grades PMTs' geometric definitions and conceptions about properties of two-dimensional shapes. This study was enacted in two sections of a Geometry for Teachers mathematics content course with 52 PMTs seeking licensure to teach mathematics in grades 4-9 at two Midwestern universities. While the sections were taught by two different professors/researchers, the study was enacted similarly for both sections. The data collected at the beginning of the course (and part of a larger study) included: a van Hiele Geometry pre-assessment (Usiskin, 1982); a researcher-developed quadrilateral pre-assessment with adapted research tasks from Burger and Shaughnessy (1986) and Razel and Eylon (1991); and a Geometry Beliefs Survey (Utley, 2007).

Over a period of 4.5 weeks, topics from chapters 16 & 17 in *Reconceptualizing Mathematics for Elementary School Teachers* (Sowder et al., 2017) were discussed. During this time, the researchers shared the same class activities and homework problems to ensure both sections were introduced to the same mathematical concepts and topics. After completing in-class activities using DGS, the PMTs were asked to organize shapes (e.g., circles, various types of triangles and quadrilaterals, pentagons, hexagons) in a hierarchical classification diagram, in groups of 2-3 students (see Figure 1). The small-group activity was recorded using a Livescribe™ smartpen, recording both the PMTs' written work and their audio discussion. The PMTs individually completed a researcher-constructed quadrilateral post-assessment and the Geometry Beliefs Survey (Utley, 2007) seven weeks after the hierarchy group assessment task.

The van Hiele (1985) levels of geometric reasoning were used as a framework to assess each PMT's mathematical responses to the hierarchical classification diagram small-group activity. Using these levels to analyze responses provided information about each PMT's geometric reasoning about definitions and conceptions of shapes and their properties and helped document any changes that occurred in each PMT's understanding of shape properties.

Results

More results and implications will be shared during our presentation. Here, we present an overview of available findings to the first research question, what are PMTs' definitions and conceptions about geometric properties of shapes?

The 52 PMTs were placed into groups of 2-3 students to create hierarchical classification diagrams, resulting in 18 total diagrams (see Figure 2). Of the 18, there were 14 unique hierarchical classification diagrams for the set of quadrilaterals. It was common for PMTs to begin with the set of quadrilaterals at the top of the diagram. Many groups made single branches from quadrilaterals to kites (n = 16), trapezoids (n = 13), and parallelograms (n = 14), but only nine included all three single branches. Although one group placed trapezoids as a branch under polygons and did not connect trapezoids to any other set of quadrilaterals (i.e., parallelograms, rhombuses, etc.), all 18 groups included isosceles trapezoids as a subset of trapezoids. Only two groups permitted rectangles to be a subset of isosceles trapezoids. These two groups also identified squares as rectangles; therefore, for them, squares were also isosceles trapezoids. One other group identified squares as isosceles trapezoids.

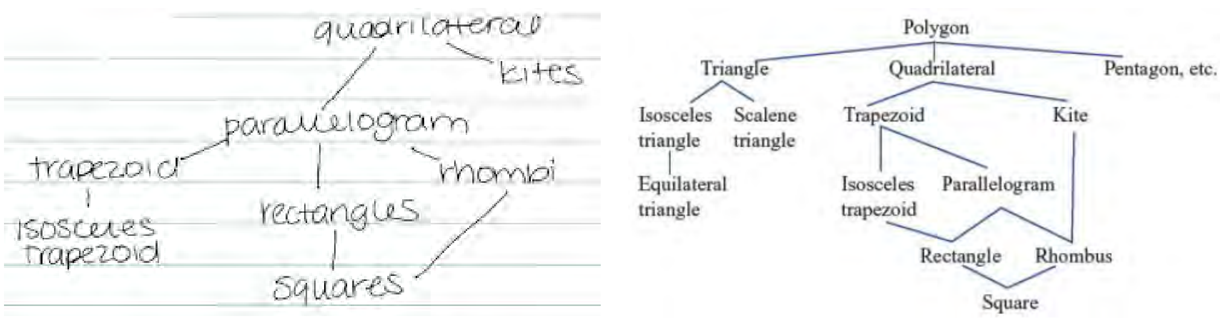

Figure 2: Sample Hierarchy (left) and Inclusive Hierarchical Classification Diagram (Sowder et al., 2017, p. 410) (right)

Zero groups placed parallelograms below trapezoids in the hierarchical classification diagrams, yet four groups did the reverse and placed trapezoids below parallelograms (e.g., see Figure 2 - –eft). Two groups correctly placed rhombuses underneath trapezoids, but they did not connect rhombuses to parallelograms. Four other groups drew a branch from trapezoids down to squares, parallelograms down to rectangles, and rectangles down to squares. Twelve groups drew two different branches from parallelograms down to rectangles and rhombuses; they also drew one branch each from rectangles and rhombuses down to squares. Four other groups drew a branch from rectangles to squares; therefore, 16 of 18 groups correctly identified squares as a subset of rectangles.

As for the hierarchical classification diagram of kites, seven groups drew a branch from quadrilaterals to kites and did not connect kites to any other shapes (e.g., see Figure 2 - left). Four groups drew a branch from kites down to rhombuses and then a branch from rhombuses to squares. These groups also drew a separate branch from kites down to squares even though they had connected rhombuses to squares. Four different groups placed squares underneath kites and separately placed squares underneath rhombuses; therefore, they did not link rhombuses to kites. One group placed rhombuses beneath kites but did not connect rhombuses to squares. Two groups correctly identified rhombuses as kites and squares as rhombuses.

Discussion

No groups correctly completed the hierarchical classification diagram, which is evidence that no group was working together completely at the van Hiele level 2. For all PMTs, kite was a new shape, and the results indicate that some students constructed the inclusive definition of kite which includes both rhombuses and squares as kites. This is evidence of van Hiele level 2 geometric thinking since they were using properties to analyze classes of shapes. Some groups demonstrated that they were still working with developing the relationship between kites, rhombuses, and squares or between classes of shapes. These groups connected kites to rhombuses and rhombuses to squares, yet also connected kites directly to squares; or the group connected kites to rhombuses but not rhombuses to squares. Many groups, however, were not thinking about the interrelationships among kites, rhombuses, and squares when creating their hierarchies.

Creager and Zeybek (2018) recommend that students have opportunities to evaluate alternate definitions of shapes to “help students make connections between terms they see as distinct, and to see distinctions between terms that are similar” (p. 258). Zaslavsky and Shir (2005) found that asking students to consider a variety of definitions is a powerful learning environment wherein personal concept definitions could be gradually refined along with conceptions of definition in general. The results of this study suggest that this refinement is definitely gradual since zero groups identified parallelograms as a subset of trapezoids. PMTs’ concept image (Tall & Vinner, 1981) of a trapezoid was the exclusive definition of a trapezoid with exactly one set of parallel sides, and the results indicate that they did not transition to the inclusive definition of a trapezoid with at least one set of parallel sides. There was some evidence that PMTs were making this gradual transition since four groups placed trapezoids below parallelograms in the hierarchical classification diagram and two groups placed rhombuses underneath trapezoids. Furthermore, four groups drew a branch directly from trapezoids to squares, although bypassing parallelograms and rectangles. These students were demonstrating both van Hiele level 1 geometric level of thinking, as they used properties of shapes to describe their location in the diagram and van Hiele level 2 geometric thinking as they used properties to describe relationships between classes of shapes. Since all 18 groups included isosceles trapezoids as a subset of trapezoids, it is evident that they had a correct definition of what it means for a set to be a subset. This is further evidence that not allowing parallelograms to be a subset of trapezoids directly relates to their difficulty with transitioning to a new definition for trapezoids. These results align with Bharaj and Francis’s (2020) results who found that preservice elementary teachers’ “reasonings seemed to be fixed towards certain images rather than mental manipulation of the attributes and concept definitions” (p. 727). In addition, these results align with implications from Miller (2019) who suggests that “the relationship between the complex collection of attributes which are true about a particular shape family and the concise concept definition which names that shape family is not always obvious to learners” (p. 429). Examining alternative definitions (e.g., the inclusive definition of trapezoid, a quadrilateral with *at least* one pair of parallel sides) provides students “with an opportunity to work in an authentic mathematical environment, and see that some, but not all, properties meet necessary and sufficient conditions" (Creager & Zeybek, 2018, p. 258). This suggests that it is extremely important for students to experience activities that include the inclusive definition of trapezoids during their PK-12 experiences.

THE DEVELOPMENT OF PRESERVICE TEACHERS' THINKING ABOUT ENGAGING CHILDREN IN MATHEMATICAL ARGUMENT

Kate Kline
Western Michigan University
Kate.kline@wmich.edu

Gina Kling
Western Michigan University
Gina.garza-kling@wmich.edu

This study examined the development of 41 preservice elementary teachers' understanding of what it takes to engage children in mathematical argument. Findings indicate that when preservice teachers are provided opportunities to struggle with generating and justifying claims themselves, they more effectively recognize the value in having children discuss the same ideas. In addition, their characterization of argumentation becomes more honed when they are provided multiple opportunities to analyze teaching (their own and others') to discern when children's productive struggle is being undermined or utilized to enhance understanding.

Keywords: Pre-Service Teacher Education, Elementary School Education

Many studies have established that argumentation is an important component of developing mathematically proficient students simply because it requires higher levels of reasoning (e.g., Forman et al., 1998) and encourages productive struggle with valuable outcomes (Jager, 2017). Mathematics educators have contended that encouraging children to engage in argumentation helps them develop the willingness to try out ideas without prejudice and to share work that might be wrong (Russell et al., 2017). Therefore, many policy documents encourage teachers to create opportunities where children construct and critique mathematical argument (NGA and CCSSO, 2010; NCTM, 2014, 2020).

The call for increased student participation in argumentation provides a particular challenge for mathematics teacher educators working with preservice teachers (PTs). It is likely that most PTs have had little experience constructing arguments in mathematics class themselves, or if they have, are not aware of how to engage children in this work. Therefore, we designed a series of activities for our elementary mathematics methods course to engage PTs in considering how to encourage mathematical argument with children. The purpose was to determine 1) how preservice teachers characterize children's full engagement in argumentation; and 2) to what extent do deliberately-designed activities in a methods course help develop and strengthen that characterization.

Theoretical Framework

Researchers have found that PTs do not have a robust understanding of what is entailed in mathematical argumentation nor a vision of how to enact argumentation in (e.g., Kosko et al., 2014; Wagner et al., 2014). They have identified the following challenges for PTs: recognizing the value of extensive work on articulation of claims, distinguishing between specific and general claims, and recognizing valid justifications for those claims.

In their study with secondary preservice teachers, Wagner et al. (2014) describe an instructional sequence used in their methods course to develop PTs' understanding of argumentation. They began by engaging the PTs in geometry tasks to develop their characterizations of argumentation as involving claims (what is being argued for), referents, and a narrative link that describes how the referents support the claim. They followed this with observations and discussions of field experiences where they had to identify and reflect upon one episode of argumentation. Wagner et al. found that the PTs' characterizations of argumentation became more robust as a result of the sequence of activities they experienced.

Russell et al. (2017) provide a framework to engage students in argumentation that is focused on the elementary school level. They suggest that teachers should provide children opportunities to (1) notice patterns or regularities in problems; (2) articulate claims about the regularities they discover; (3) use representations to justify why the regularity must be true for specific cases; and (4) generalize for any case. The teachers they worked with found this sequence helped to elevate classroom discussions beyond typical sharing of strategies; children deeply considered the generalizability of strategies. Furthermore, productive struggle came from encouraging children to wrestle with wording in the articulation and justification phases as it takes time to develop solid arguments that are convincing to classmates.

As a result of these studies, we designed activities for the methods course that would move the PTs through a three-part instructional sequence beginning with doing mathematical work themselves, including making claims based on generalizations and justifying those claims in order to convince their classmates they were true. Next, we asked them to analyze videos of classroom discourse and discuss what they noticed using the argumentation framework by Russell et al. (2017). Finally, they taught lessons to small groups of children where they focused on encouraging argumentation using that same argumentation framework.

Methodology

Forty-one preservice elementary teachers from a large Midwestern university participated in this study. Students were either in their third or fourth year of college and were enrolled in a methods course that addressed the teaching of elementary school mathematics. In the beginning of the semester, the PTs analyzed a video of an elementary school classroom where children were engaged in argument in order to provide baseline data on their thinking. Then throughout the rest of the semester, PTs often worked on problems, creating and discussing claims and justifications, followed with analysis of videos of children working on similar problems.

This paper focuses on one three-part sequence about subtraction equivalence. This idea was taken from Russell et al. (2017) where they used subtraction equivalence to effectively engage second graders in argument. For their own work, the PTs were asked to generate three subtraction expressions that all had the same answer, produce a claim based on what they noticed about the patterns, and provide a representation-based justification for why they thought this was happening with subtraction. These ideas were discussed and the class collectively revised their claims and justifications. This was followed by an analysis of a video clip where second-grade students worked on the same idea using a story context. The PTs completed a writing reflection examining the children's claims related to the specific story context along with their attempts at generalizing their claims. The last step in the sequence involved a field experience where PTs worked with small groups of children on the same subtraction equivalence idea and encouraged the children to engage in argument. The PTs summarized with a written analysis of the children's claims and justifications as well as their own reflection on their teaching.

The aforementioned challenges identified from research (articulation of claims, specific and general claims, and valid justifications) informed the first level of data coding and analysis across all three parts of the instructional sequence. The PTs' own generated subtraction expressions and claims were sorted into categories according to the nature of their claims and the extent to which they were able to generalize their claims. The written reflections on the elementary classroom video and the field experience were analyzed for identification of specific and general claims and assessment of thoroughness and clarity of articulation of those claims.

Results

PTs' Initial Characterization of Argument

Early in the semester, the PTs discussed the meaning of CCSSM Standard of Mathematical Practice 3 (which focuses on argument) and were asked to use this practice to analyze a video of elementary children discussing a story problem that had more than one solution. As the children discussed possible solutions, they began to provide brief claims about what counts as a solution. However, they were not encouraged to justify their claims and the teacher intervened to resolve the issue herself. On their written reflections, the PTs were asked to use Mathematical Practice 3 as a lens to discuss the extent to which the teacher encouraged children to engage in argument about the solutions. Despite the teacher's intervention that circumvented the children's opportunity to justify their claims, about two-thirds of the PTs stated that they believed the students were fully engaged in argument. This confirmed the findings of Wagner et al. (2014) that a deliberate sequence of activities with the PTs would be needed to develop their understanding of effectively engaging children in argument.

First Activity in Sequence: PTs' Own Work on Argument

To begin our work on subtraction equivalence, the PTs were asked to generate three equivalent expressions for subtraction, (e.g., 22 – 8, 20 – 6, and 24 – 10). They were then asked to list what they noticed about their three expressions and write a claim about subtraction equivalence. While we did not expect an algebraic expression such as (a + x) – (b + x) = a - – or (a – x) – (b – x) = a - –, we considered an articulation of this relationship to be something like the following: "If you increase or decrease the minuend and subtrahend by the same amount you will get the same answer." Results from the PTs' work are shown in Table 1.

Table 1
PTs Claim Statements About Subtraction Equivalence (n=41)

Category of Claim	% Student Response
Correct Generalized Claim (Both Increasing/Decreasing)	37%
Generalized Claim (Only Increasing or Decreasing)	17%
Partially Generalized Claim using Specific Examples	15%
Other Correct Claims Not Addressing Equivalence	24%
Incorrect Claims/No Response	7%

As expected, this articulation was challenging for the PTs. It was interesting that 17% were close to a generalization, but only referenced either increasing or decreasing seemingly depending on the examples they generated. The partially generalized claims were also interesting as they highlighted the challenge PTs had in navigating between specific examples and generalizations. These PTs tended to use "number" to represent any starting number but used specific amounts for increases or decreases. For example, one PT said, "As you increase one number by 2, you have to increase the other number by 2." While promising, these findings showed that doing the mathematical work themselves was not sufficient for helping PTs fully appreciate distinctions between specific and generalized claims.

Second Activity in Sequence: PTs' Analysis of Classroom Video

After these ideas were discussed as a class so that students could come to an understanding of the fully generalized claim, they analyzed a video from Russell et al. (2017) of second-graders working on subtraction equivalence. The second graders worked on the following problem in pairs: *Alyssa had 15 cookies but she needs only 12, so Kussita ate 3. If Alyssa gets more cookies, how many cookies could Kussita eat?*, created representations, and the teacher facilitated a whole-class discussion of their findings. They discussed 16 cookies/4 eaten, 17 cookies/5 eaten, and 18 cookies/6 eaten. Then the teacher asked, "Okay, so what happens if we add any amount of cookies? What do we have to do so that Alyssa still will only have 12?"

Two children responded to this prompt with specific claims while the third student had a partially generalized claim using specific examples but then finally saying "As the numbers go up, the second number is going up too." The PTs were asked to analyze the three student contributions and consider the extent to which they were answering the teacher's question about what would happen if any amount of cookies were added. Almost all of the PTs were able to recognize that none of the students had articulated a satisfactory generalization of equivalence. However, only two-thirds were able to identify the student who provided the partially-generalized claim as being closest to articulating an accurate generalization.

In addition, the PTs reflections on what might be needed for the students to develop an accurate generalization highlighted two themes. One common misconception was that the PTs believed the students needed more work with specific examples in order to articulate the generalized claim. Another common misconception was that providing a context like Kussita's cookies would hinder students' ability to generalize, a direct contrast to the argument by Russell et al. (2017) of the importance of children using representation and context as a vehicle for proof.

Third Activity in Sequence: PTs Field Experience

While it was clear that the PTs were inching towards a more robust understanding of argument, we believed that working with children themselves would provide new opportunities to address expectations around both articulation and justification. Thus, we designed a field component where PTs worked with children to develop arguments for both addition and subtraction equivalence. Due to space constraints, we are not able provide detailed findings from the field experience. In general, on their written reflections the PTs did show a more fervent appreciation of the effort needed to articulate claims. They also demonstrated a deeper understanding of the distinctions between specific and generalized claims and the appropriateness of different representation-based justifications.

Discussion and Conclusions

This analysis has provided a beginning picture of the knowledge PTs bring to and the issues they have with understanding the important components of mathematical argumentation. Our intervention using the three-part sequence (PTs create and discuss mathematical claims, watch classroom video of children discussing claims, and then work with small groups of children on claims) encouraged more nuanced understandings, but also illuminated further challenges PTs have with understanding how to encourage children to use representation and context as a vehicle for articulating generalization.

In concurrence with other research (e.g., Borko et al., 2011) using video of actual elementary school classrooms proved beneficial. It allowed PTs to think more deliberately about how argument might play out with children and how valuable this is for developing understanding. One finding from that part of the sequence that was particularly enlightening was the PTs' inclination to work in a space between specific and generalized claims. While we expected a proclivity towards using specific cases to support claims given prior research (e.g., Adams et al., 2016/2017), the inability of some PTs to identify children's claims as close to a generalization suggests this is an important area to study further. In the end, working with children themselves to help PTs productively navigate through their struggles to articulate generalized claims is likely the mitigating factor to bridge the space between specific and general claims.

RACIAL RECKONING IN TEACHER EDUCATION: USING CASES TO GET PRESERVICE TEACHERS TALKING ABOUT RACE

Alesia Mickle Moldavan
Fordham University
amoldavan@fordham.edu

Monica Lyn Gonzalez
East Carolina University
gonzalezmo18@ecu.edu

Preservice teachers must have opportunities in teacher education to critically reflect on race and racism in mathematics education. Engaging preservice teachers in such conversations during methods courses can be challenging. This study uses a case specifically designed in a digital context to encourage preservice teachers to talk about race, including their understanding of race and racism in an authentic mathematics classroom situation and how a teacher might respond to the situation. Findings show that preservice teachers talk about race in terms of differing perspectives of discrimination (social versus racial exclusion) and how a teacher might respond (reactive and proactive initiatives). Recommendations and future research considerations are shared to address ways mathematics teacher education can shape preservice teachers' racial reckoning and critical consciousness.

Keywords: Preservice Teacher Education, Instructional Activities and Practices, Equity, Inclusion, and Diversity

With the teaching profession characteristically White, female, and middle-class and a growing public-school population composed of children with diverse cultural and racial backgrounds (National Center for Education Statistics, 2020a, 2020b), preservice teachers (PTs) must have opportunities to talk about race and racism within the context of teaching. The mere mention of these topics can often be difficult to discuss; however, research suggests that PTs who engage in such conversations can begin to critically reflect on race, including their racial identities and ideologies in mathematics education, and use racial noticings to examine lived experiences of students of color (Martin et al., 2017; Shah & Coles, 2020). Additionally, PTs can use conversations of race and other educational inequities to challenge spaces of marginality and create equitable learning environments in the mathematics classroom (Association of Mathematics Teacher Educators, 2017; National Council of Teachers of Mathematics, 2020).

One way for mathematics teacher educators (MTEs) to foster spaces for PTs to explore race and racism is by using case-based instruction during methods courses to promote prompt-based discussions (Gonzalez & Moldavan, in press; Gorski & Pothini, 2018; Kavanagh, 2020; Moldavan & Gonzalez, 2020). With COVID-19 forcing MTEs to rethink their instructional strategies in the context of a digital space, these discussions have also had to adapt with the aid of digital tools (e.g., asynchronous modules, discussion boards) to facilitate reflections about the discriminatory culture of mathematics education and how to disrupt racial inequities facing students of color. This study uses a case specifically designed to encourage PTs to identify race and racism in an authentic mathematics classroom situation and reflect on how a teacher might respond. Through the context of critical race theory, we examine the research question: *How do PTs leverage a case in a digital context to recognize race and racism in the mathematics classroom and a teacher's response to such situations?*

Theoretical Framework

To guide this inquiry, we referenced the work of critical race theory (CRT), which aids in examining issues of race in educational research (Ladson-Billings & Tate, 1995). CRT offers a theoretically grounded approach to explore aspects of race and racism, including the experienced discrimination and inequities from people of color and the counter-stories that undermine deficit narratives (Creswell & Poth, 2018). In the context of mathematics education, CRT can be used to examine how race and racism are embedded in school structures and practices and how racism has negatively impacted minorities and vulnerable communities, specifically their access to high-quality mathematics instruction (Davis & Jett, 2019). According to Berry and colleagues (2014), Black learners are "routinely given the least access to advanced mathematics content, the fewest opportunities to learn through methods other than memorizing facts and mimicking teacher-modeled procedures, and the least well-prepared teachers" (p. 541). Deficit discourse around mathematics learning for students of color perpetuates ideologies that problems exist with students' abilities to learn rather than with the responsibility of teachers to recognize how social and cultural experiences in school are shaped by racism and inequities (Gutiérrez, 2009). We engage PTs in case-based experiences, through a lens of CRT, to educate PTs in understanding the race-related experiences of students of color and how teachers can respond to such situations for purposes of advancing equity-oriented pedagogy.

Research Methods

We conducted a collaborative action research-based study across three online mathematics methods courses at two different universities. One university is situated in an urban northeastern city, while the other university is situated in a rural southern town. Both universities had instructors who used case-based instruction to incorporate cases depicting authentic mathematics classroom situations in their respective methods courses. The cases were used to engage PTs in conversations around equity and justice in mathematics teaching. One of those cases was designed to specifically elicit discussion related to race and racism and how it may present in mathematics classrooms. That case, reported here, depicts a Black student that was rejected from her peers based on her physical appearance and the deficit notions that her racial background could potentially cause disruption within a collaborative group activity. This case leveraged the national attention of racially motivated media rhetoric that unjustly depicts Blacks for disruptive behavior in local communities (e.g., riots), which students may have associated with as they organized their groups. The case provided the opportunity to examine the impact discrimination in the classroom can have on students of color, as well as the role of the teacher in responding to the situation to create an inclusive learning environment for all students.

The case was assigned to the PTs at the beginning of the Fall 2020 semester as an online discussion forum. The digital aspect of the instructional activity required the instructors to be methodical in their facilitation, given that the PTs would use the forum to host a "digital conversation." The PTs were asked to read the case and use the forum to respond to the prompts that elicited reflections on the racial injustices observed and how a teacher might respond to the situation. Their peers then reflected on the initial posts and provided feedback and suggestions. The forum posts were coded using in vivo and descriptive coding techniques (Saldaña, 2016). We then interpreted those codes using Kvale's (1996) meaning-making methods to capture the PTs' shared perspectives. Analytic memo writing was performed to specifically look for aspects of CRT that then moved our codes to themes (Grbich, 2013).

Findings

Two themes emerged from the data through the lens of CRT. The first theme addressed the PTs' awareness of race and racism in the mathematics classroom, particularly in the context of exclusion and how it stems from a perspective of racial discrimination. In the second theme, the PTs acknowledged teachers' roles in taking action with observed racism in the mathematics classroom. A close look at how teachers assume reactive and/or proactive initiatives provides insights into how students of color experience mathematics teaching and learning. It is notable that both themes depict PTs' recognition, and strong reactions at that, to developing critical consciousness of injustices in mathematics education and how reflection on racial dispositions and biases can prompt change in one's professional practice.

Recognizing Race and Racism in the Mathematics Classroom

In the PTs' responses to the case's prompts, the PTs were quick to write about how a group of students alienated a peer from participating in an assigned task. This observed exclusion presented itself in two ways: social exclusion versus racial exclusion. In the former, we define social exclusion as an observed injustice of a student being prohibited from working in a group without an explicit mention of race. While race may be a factor in the act of exclusion, the mention of race fails to be explicitly identified in the response. A handful of PTs who reflected in this way refrained from calling out the racial make-up of the students and justified potential blame for a student's actions on others (e.g., media, parents). For instance, a PT posted: "In our world today, there have been a lot of problems with diversity." The PT then went on to discuss how the media can influence one's action, which influenced why a student was targeted for exclusion. Another PT shared, "She [the White student Susan who made the comment to the Black student Dominique] may have misunderstood the context… She isn't trying to intentionally create harm. She is doing it because that's what she learned and doesn't know any better." This PT recognized that an injustice occurred but seemed to assume that being uneducated about one's racial disposition and biases could excuse one's actions. Likewise, another PT said, "Because I know that it is not Susan's fault for thinking this, I would contact her parents and explain to them that Susan's comments are hurting others in the class." The PT deflects blame away from the student, which is similarly noted by another PT who posted: "Susan may say this because Dominique looks different than her and she may not live in a diverse community or be around different races and ethnicities often." In several of the PTs' responses, the conversation of exclusion is sustained at a surface level response about race rather than digging deeper into the rhetoric of racism in school.

In the latter observed exclusion, we define racial exclusion as the observed discrimination based on the color of a student's skin. In this case, there is recognition of race-based privilege from a dominant group and how power can be used to marginalize or "other" a person who does not fit the color of the majority race. This notion of racial exclusion is noted by the majority of PTs and can be exemplified by the following shared responses from the PTs. For instance, a PT posted: "Susan obviously made a prejudice statement about Dominique based off of the color of her skin." Likewise, another PT said, "Susan, a White student in the class, may have said Dominique is dangerous due to her implicit (and quite obviously explicit) bias against African Americans. It is clear that Susan referred to Dominique's skin when she made that comment." This comment was followed by similar responses from PTs that said, "Susan has pushed false and negative stereotypes toward people of color, hurting Dominique in the process." Another PT posted: "Susan could not comprehend due to a lack of understanding of her White privilege," while a peer responded saying, "White students have plenty of time and space where they do not think about race. Black students do not have that privilege." These PTs consider the racial dynamics of the students and explicitly note the students' skin color and privilege when examining the situation. Some PTs also considered the intersectionality of other oppressions (e.g., gender, sexual orientation, language) to recognize the complex dynamics of exclusion and how discrimination impacts the participation and success of students of color in similar settings. One PT posted: "Maybe since Black women are portrayed as being aggressive, Susan thought it was okay to place that judgement on a student." The PTs used the case to leverage conversations about skin color and how racism is composed of racial prejudice, power, and privilege.

Teachers' Roles in Taking Action

The power and responsibility of the teacher in advocating for her marginalized student is demonstrated through these words from one PT: "The teacher has the authority to help Susan develop more truthful and less destructive beliefs about people of other races and to help Dominique feel safe in the classroom." This "authority" and responsibility was echoed in many of the PTs' responses and led to the second theme that addressed the role of the teacher in taking action to stop racism in the mathematics classroom. The PTs' responses considered reactive and proactive initiatives that could be made by the teacher. We define reactive initiatives as those that a teacher could do in the moment to intervene, while proactive initiatives refer to those that a teacher could do outside of the current situation to create an inclusive classroom environment.

The reactive initiatives the PTs described were either public or private in nature. Some PTs described how the teacher would need to "address the class as they were a witness to this event." These public discussions ranged from "shutting down what Susan said" to "discussing how the behavior is not acceptable." However, most of the PTs posted about how the teacher should have private conversations with Susan and Dominique. Although these private conversations could assist in helping those involved in the situation recognize the ramifications of their actions, private conversations could potentially restrict open dialogue about race and may not use the teachable moment to model how to be advocates for peers in similar situations.

The PTs also described proactive initiatives that focused on the various ways a teacher could create an inclusive classroom environment to prevent situations like that described in the case. The proactive initiatives targeted both racial representation directed at the classroom environment as well as at the student level. The PTs who targeted racial representation directed at the classroom environment wrote about "hanging diversity posters on the wall" or "having diverse children's books" in the classroom to honor narratives about people of color and challenge deficit notions. Other PTs placed more emphasis on the direct cultural and racial assets of the students in the classroom and provided opportunities for them to "get to know each other" as a way to "create mutual respect." Many PTs also mentioned having the teacher involve students in conversations related to "stereotypes" and "diversity" and then develop classroom norms for how to interact with one another. These proactive initiatives suggest the need to create space for marginalized students to be included so their stories counter deficit viewpoints.

Conclusion

Efforts to prepare PTs to identify and address race is crucial to examining the racial dynamics of mathematics classrooms. This study used a case specifically designed in a digital context to encourage PTs to discuss race and racism in mathematics classrooms. The PTs noted differing perspectives of discrimination (social versus racial exclusion) and how a teacher might respond (reactive and proactive initiatives) when racism arises in classroom situations. The responses provide insight into how instructional activities, such as case-based instruction, can be used to shape PTs' racial reckoning and critical consciousness (Freire, 1970). Further, the lens of CRT can be used to examine the ideologies of race to understand how race impacts the lived experiences of students in mathematics education (Berry et al., 2014). Teacher education must assist PTs in developing their awareness of race and the power they hold in advocating for students of color so such students are recognized as contributors in the mathematics classroom.

MIDDLE GRADES PRE-SERVICE TEACHERS' STRUGGLE TO CREATE PRODUCTIVE STRUGGLE

Monica Anthony
Georgia Gwinnett College
monicareneeanthony@gmail.com

Task selection is a critical element of mathematics teaching because mathematical tasks differ in the learning opportunities made available to students. This study examines the tasks selected by pre-service teachers (PSTs) in a field based middle grades mathematics methods course. In this brief research report, I examine how PSTs' understanding of productive struggle informs their selection and implementation of tasks. Overall, PSTs sought to avoid unproductive struggle but were unsure how to create and sustain productive struggle. Implications for teacher education include supporting PSTs in developing a robust understanding of productive struggle and the types of tasks and instruction to support it.

Keywords: Preservice Teacher Education; Teacher Beliefs; Teacher Knowledge

Mathematical tasks are a critical component of mathematics instruction and continue to be an object of research interest (Tekkumru-Kisa et al., 2020). Research over the past 30 years demonstrates that the types of mathematical tasks students engage with heavily influences their learning opportunities (Stein et al., 2000; Tekkumru-Kisa et al., 2020). Thus, it is critical to continue to examine what tasks teachers select and why they select those tasks (Pimm, 2009). In this brief research report, I explore one influence on pre-service teachers' (PSTs) task selection and implementation by asking, *How do PSTs understand the relationship between productive struggle and mathematical tasks?*

Relevant Literature

Hiebert and Grouws (2007) identify engaging students in productive struggle as one of the key elements of mathematics teaching that promotes conceptual understanding. Productive struggle occurs when students are engaged in problem-solving, grappling with mathematical concepts that are within reach (Hieber and Grouws, 2007). In these instances, students are challenged to apply their mathematical knowledge in new ways. The notion of productive struggle is encompassed by the first Standard for Mathematical Practice in the Common Core State Standards: Make sense of problems and persevere in solving them (CCSS; 2012).

One way teachers can engage students in productive struggle is through the use of high cognitive demand tasks (e.g., Smith & Stein, 1998; Stein et al., 2000). The two higher levels of cognitive demand, *procedures with connections* and *doing math*, require students to link procedures with mathematical concepts as they engage in tasks that are open-ended. Tasks classified at the level of *doing math* engage students in problem-solving and complex thinking, ideally resulting in productive struggle. When students are engaged in a higher cognitive demand task, teachers can further support productive struggle by asking purposeful questions and encouraging students to explore multiple solution paths (Lynch et al., 2018).

PSTs often struggle with selecting and implementing high cognitive demand tasks that foster productive struggle. When beginning to design lesson plans, PSTs often select mathematical tasks that are procedurally focused, and rely heavily on memorization and reproduction (Anhalt et al., 2006; Nicol & Crespo, 2006). Even when provided with rich math tasks, PSTs modified the language of the tasks to prevent student struggle, not considering how their modifications altered students' opportunities to engage in mathematical discourse and productive struggle (de Araujo et al., 2021). When monitoring PSTs' problem-posing to elementary students during a methods course, Crespo (2003) found that initially PSTs tended to create or select tasks that were uncomplicated, unambiguous, and easy to solve. PSTs posed leading questions and strove to avoid student confusion. Over time, PSTs became more adventurous in their problem-posing, inviting students to solve open-ended tasks, which promoted productive struggle. Crespo attributes these changes in problem-posing to both PSTs' sustained interactions with elementary students and PSTs' reflections on those interactions. In this study, I highlight how PSTs' understanding of productive struggle informs their problem-posing, or task selection.

Methods

This brief research report presents findings from a larger study that investigates middle grade mathematics and sciences PSTs' task selection during a middle grades mathematics methods course (Anthony, 2021).

Middle grades mathematics methods course

The participants in this study are 10 middle grades mathematics and science undergraduate PSTs who completed a mediated field experience mathematics methods course, instructed by the author (Fall 2018). The field experience component of the course was an after-school enrichment program, which took place at a local middle school. Bumblebee Middle School (all names are pseudonyms) is a large Title 1 school with a student population that is majority Latinx (86%) and Black (10%). Each week PSTs prepared 90 minute lessons for their assigned small group of two to five middle grades students. PSTs had autonomy over the content of their lesson plans.

The concept of productive struggle permeated the mathematics methods course. Given the importance for teachers to regularly select and implement tasks that provide students with opportunities to actively partake in reasoning, sense-making, and problem solving (NCTM, 2014), the assigned readings and class discussions regularly addressed engaging students in productive struggle. In particular, PSTs read Lynch, Hunt, and Lewis' (2018) article about strategies for sustaining productive struggle through differentiated instruction.

Data sources

The data sources include PSTs' discussion board posts, final course papers, and individual interviews. Each week PSTs responded to discussion board prompts that asked them to reflect on their lessons at Bumblebee Middle and to connect course readings to their field experiences. The final course paper asked PSTs to reflect on what they learned in the methods course and how the course supported their growth as a learner and doer of mathematics. Given the open nature of the prompt, if PSTs wrote about productive struggle, it was voluntary.

PSTs participated in two semi-structured one-on-one interviews, which were audio recorded. The first interview was conducted the semester following the methods course (Spring 2019). PSTs were asked to reflect on their process for selecting tasks and preparing lesson plans for the after-school enrichment program. The second interview was conducted a year after the methods course (Fall 2019). PSTs were asked about their teaching internship and their perspectives on the essential roles and responsibilities of teachers.

Analysis

I used NVivo to code data sources for the phrases "struggle" and "productive struggle." With each instance, I examined the context of the phrase to look for patterns in how PSTs were describing productive and unproductive struggle or how they were attending to productive struggle in their lessons.

Findings

In their final course papers, six of the ten participants wrote about productive struggle as a necessary and beneficial aspect of learning mathematics. For example, Vincent wrote, “While seemingly counter-intuitive initially, it is this productive struggle that challenges students to ask questions, think critically, and solidify their understanding. As a teacher, it is my job to support this productive struggle.”

PSTs identified productive struggle as something to cultivate and unproductive struggle as something to avoid. According to PSTs, unproductive struggle can be avoided by selecting tasks that leverage students’ prior knowledge or by lowering the cognitive demand of the task. There was a shared concern among some PSTs (Briley, Carson, Grace) that when the cognitive demand of the task is “too high” students will descend into unproductive struggle. For example, Carson stated, “keeping the demand high but also not too high. Like, if it's too high then they won't get it at all. So, making sure it's productive struggle rather than non-productive struggle” (Interview 2). Thus, while Carson identifies maintaining high cognitive demand as important, this should not supersede the goal of students “getting it” through productive struggle.

PSTs identified supporting students in accessing and applying their prior knowledge to the task as a way to maintain the cognitive demand. Briley concluded that her students’ lack of prior knowledge led to unproductive struggle with tasks: “This lesson plan had a high cognitive demand, but it did not go as planned because the students were struggling past a productive level; they didn’t have the background knowledge necessary to complete the task” (Final Paper). In their reflection posts, several PSTs wrote about being surprised that students did not have the prior knowledge that they expected them to have, like Claire, who wrote, “I was in panic mode when they said that they had no experience working with percents since the entire lesson was literally on percents” (Discussion board post, Oct 25). When students lacked the prior knowledge necessary to engage with the planned task, PSTs often resorted to direct instruction, which lowered the cognitive demand of the tasks. In some cases, the PST’s subsequent lesson was of lower cognitive demand.

In their reflective writings, PSTs wrote about the benefits of productive struggle. For example, Carson wrote, “The students are willing to struggle through concepts instead of just giving up right away. This allows for more questioning and learning which is really cool” (Discussion Board, Oct 25). However, PSTs did not articulate how to create or sustain productive struggle. A few PSTs were able to identify when students did engage in productive struggle (Carson, Claire, Jessica, Grace). For example, Grace showcased a moment when her students demonstrated productive struggle:

> I could see that the students were struggling with reaching an answer, but they were not stuck, they were constantly coming up with new methods and ideas on how to solve this problem. After a while they got the answer of how much each item cost and they both were so proud of themselves. Then after I had a conversation with one of the boys who said that this had been the hardest lesson yet, but it was his favorite! He said that he really liked being challenged in math and it made him think more and that it was a lot of fun to figure out the prices. (Final Paper)

Undergirding PSTs' statements about struggle is the belief that productive struggle will lead to students successfully solving the task, while unproductive struggle results in students giving up, or otherwise being unable to complete the selected task. Interestingly, although PSTs write about the importance of supporting students in productive struggle, they still seem to value the successful completion of the task (arriving at a solution) over what they can learn about student thinking while working on the task (regardless of completeness).

Discussion

In both their reflective writings and interviews, PSTs communicated that they valued productive struggle as an important part of mathematics teaching and learning. However, PSTs had difficulty cultivating productive struggle through task selection. Regardless of the cognitive demand of the selected task, PSTs' interpreted students' unproductive struggle as a misalignment between students and the cognitive demand of the task. As shown in previous studies, PSTs sought solutions to alleviate struggle, such as direct instruction or choosing tasks of lower cognitive demand.

One explanation for the presence of unproductive struggle could be a failed launching of the task. How a teacher introduces the task to students is a crucial element in sustaining high cognitive demand tasks (Cobb et al., 2018). In a successful launch, the teacher supports students' development of a common language around the task features and cues students to key mathematical concepts without suggesting a solution method (Cobb et al., 2018; Jackson et al., 2012). When Grace's students showed signs of unproductive struggle, she found it helpful to "take a break and be like, 'Okay, so maybe, what do you guys remember about this? What are some aspects that you do know?'" (Interview 2). Grace's questions to students mirror the questions modeled in the methods course when learning how to effectively launch a task (Jackson et al., 2012). Her suggestion is to revisit those launch questions when students start to devolve into unproductive struggle while working on the task. Grace's solution to students' struggle implies that perhaps the initial launch was not successful at activating prior knowledge and creating a common language. Thus, revisiting the elements of a successful task launch throughout the methods course may be beneficial to PSTs.

Teacher educators can support PSTs' understanding for how to cultivate productive struggle through increased opportunities to observe students engaged in productive struggle. These observations will equip PSTs to not only identify productive struggle, but hopefully identify teaching practices and types of mathematical tasks that sustain productive struggle.

Attending to students' actions and mathematical thinking is an important aspect of professional teacher noticing. In this paper, we used 360 videos as a medium to examine the relationship between preservice teachers'(PSTs) observed attending behaviors and their written noticing. Findings suggest that PSTs focusing on students, instead of the teacher, during class discussions provide more specified descriptions of children's mathematical thinking.

Keywords: Teacher Noticing; Technology; Preservice Teacher Education

Professional teacher noticing involves "honing in on a key aspect of or instance that occurs during a lesson and engaging in reasoning to make sense of it" (Stockero & Rupnow, 2017). Experienced and knowledgeable teachers generally make sense of such instances by unpacking the mathematics that students engage in detail (Jacobs et al., 2010; Mason, 2017). By contrast, more novice teachers, such as many preservice teachers (PSTs), initially focus on the teacher's actions or on students' non-content related behaviors (Barnhart & van Es, 2015; Huang & Li, 2012). The differences in content-specificity of teachers' noticing corresponds with how and where teachers look when viewing a classroom scenario (Cortina et al., 2015; Dessus et al., 2016; Kosko et al., 2021). Scholars using eye-tracking have found that teachers with more specific descriptions of content focus on fewer students in a recorded classroom, whereas teachers with less specific descriptions of their noticings attempt to focus on multiple students (Dessus et al., 2016). Examining PSTs' teacher noticing while viewing a 360 video with a VR headset, Kosko et al. (2020) found that where and how PSTs turned their head and focused corresponded with how they described events within the recorded scenario. Such findings provide useful evidence of how teachers' physical actions of attending correspond with their verbal and written descriptions of what is noticed.

In this paper, we use the 360 video medium to study PSTs' tacit choices of where and what to attend with a focus on how such choice informs their articulated professional noticing. Contrasting standard video recorded from camcorders and Swivel cameras, 360 video records omnidirectionally so that the viewer can choose where to look within the classroom. This facilitates a sense of being in the classroom, as it more closely approximates standing in the classroom (Ferdig & Kosko, 2020; Walshe & Driver, 2019). Recording PSTs' 360 video viewing sessions provides useful data to examine their tacit choices of what, where, and when to attend (Gold & Windscheid, 2020; Kosko et al., 2020). We used such data to examine the nature of PSTs' attending in relation to the specificity of students' mathematics described in their noticing.

Classrooms where such student-centered actions can be observed are sometimes perceived as chaotic. Often, students are engaged in different content-specific actions that are happening simultaneously. Teachers must be able to make sense of what they notice in the moment and respond accordingly (Luna, 2018; Sherin, 2011). Less sophisticated noticing is evidenced by attending to superficial aspects of the classroom environment such as class management rather than focusing on student learning (Mitchell, 2015). More nuanced professional noticing is evidenced by attending to more specific student actions (Huang & Li, 2012; Jacobs et al., 2010).

Sherin (2007) describes two interrelated subprocesses of professional noticing: selective attention and knowledge-based reasoning. Selective attention, what we have referred to as attending, is when the teacher "selects certain stimuli of a perceived scene for detailed analysis" (Scheiner, 2016, p. 231), where knowledge-based reasoning, or interpreting, is the act of using one's professional knowledge and prior experience to unpack what was attended (Sherin & van Es, 2009). Studying the interrelationship between these subprocesses is complex, and video has traditionally been used in examining this phenomenon (Rosaen et al., 2008; van Es, 2002).

The use of video can help PSTs to refine their descriptions of students' actions to be more content-specific reflections that shift from more general, to procedural, and then to conceptual descriptions of children's actions (Barnhart & van Es, 2015). Early evidence suggests that 360 videos provides a more immersive viewing experience to study teacher noticing (Kosko et al., 2021; Walshe & Driver, 2019). Particularly, different scholars have begun to record where PSTs attend in a 360 video and relate those attending behaviors to their pedagogical decisions and reasonings (Huang et al., 2021; Ferdig et al., 2020; Gold & Windscheid, 2020). Examining where and how PSTs look *at* a scenario, such as with eye-tracking data with standard video (Dessus et al., 2016), is useful. However, examining where and how they look *within* a scenario provides an added dimension of data regarding what Sherin (2007) describes as PSTs' selective attention. In this paper, we present a preliminary analysis of PSTs' attending behaviors (via recorded 360 video sessions) in relation to their interpreting acts of the recorded scenario.

Therefore, the purpose of this paper is to examine the relationship between where PSTs chose to attend in a 360 video and the specificity of their descriptions of children's mathematics.

Method

Sample and procedure

Participants included 21 preservice teachers enrolled at a Midwestern U.S. teacher education institute in Spring 2020. Most participants identified as white (91.7%), and female (76.1%). After completing consent and basic demographic questions, participants engaged in a brief tutorial describing how to watch 360 videos on a laptop and how to screen record their 360 video viewing sessions. Analysis of participants' screen recordings enabled us to identify their field of view (FOV) (Huang et al., 2021), where FOV includes the *location* and *time* a viewer looked at a specific point. After the tutorial, PSTs watched a 360 video (5 minutes and 49 seconds) of fourth grade students explored equivalent fractions using fraction strips. Within the video, students were asked to use their fraction strips to find an equivalent fraction to 5/6. Midway through the video, the teacher engages students in a brief class discussion where two students describe not being able to reduce the fraction because 5 is a prime. Students are then asked to find an equivalent fraction to 3/8. The video ends after a brief discussion of how students needed to use an algorithmic approach, instead of fraction strips, to find an equivalent fraction. After viewing the 360 video, PSTs were asked to describe all pivotal moments they had noticed in their viewing (i.e., any moment you (PSTs) believe is important for the teaching and/or learning of mathematics). Then, PSTs selected one of these moments as the "most informative for them for teaching and/or learning of mathematics" and describe it in further detail.

Analysis and findings

In order to analyze participants' written noticing, Systemic Functional Linguistics (SFL) was used (Halliday & Matthiessen, 2014; Eggins, 2004). SFL is an approach to linguistics that examines how grammar functions to convey meaning. This method allows "the detailed and systematic description of language patterns" (Egging, 2004, p.21).

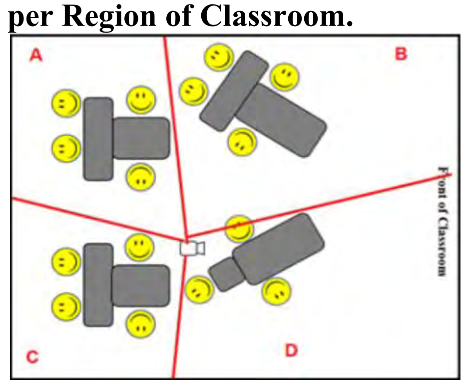
PST's math-specific written noticing	PST's generic written noticing
The teacher **challenged** her students **to use** the fraction strips for the second fraction (3/8). I noticed// the students closest to the 360 camera quickly **realized** that // the second problem (3/8) *could not be* **demonstrated** using the fraction strips.	When the students **shared** what answers they got // and [students] **worked** together, [students] **talking** through the problem. *Sometimes* it is helpful for students **to discuss** their thought process // and [students] **work** with their peers to come to a conclusion.

Figure 1: Examples of a specific (left) and nonspecific (right) written noticing.

In the current study, we examined the grammatical resource of reference. *Reference* refers to "how participants are introduced and 'managed' 's the text unfolds" (Mehler and Clarke, 2002, p. 160). The repeated patterns of referencing builds reference chains, which can also convey how a particular referent is operationalized by an individual. Figure 1 illustrates two participants' excerpts with coded reference chains. The PST on the left introduces the referent "fraction strips" which is then connected to "the second fraction (3/8)." As the text continues, these two referents are conveyed as not being the same, since "(3/8) could not be demonstrated using fraction strips." By contrast, the student on the right references "answers" and builds a reference chain that identifies students conveying their answers along with their "thought process" to come to a "conclusion." Although this PST incorporates discourse in how the referents are conveyed, the reference chain clearly ends with a focus on a final answer (i.e. "conclusion"). After examining PSTs' written noticing using reference chains, reliability of whether the theme was observed or not was examined by the first and second author (0=fractions not referenced; 1=referenced fractions). The Kappa coefficient (.857) indicated near perfect agreement, with 52.3 % of PSTs attending to fractions in their written noticing and 47.7% not doing so.

Table 1: Contingency Table for Seconds Focusing per Region of Classroom.

	A	B	C	D	n/a*	Total
Not Attend	**166** **219.9**	**1157** **1092.3**	**460** **440.7**	**1622** **1655.3**	**47** **43.8**	**3452**
Attend	**296** **242.1**	**1138** **1202.7**	**466** **485.3**	**1856** **1822.7**	**45** **48.2**	**3801**
Total	**462**	**2295**	**926**	**3478**	**92**	**7253**



**Indicates a region could not be identified (i.e., scanning or moving back-and-forth).*

To examine variations in PSTs' specificity of noticing equivalent fractions across four regions of classroom we analyzed their recording videos second-by-second. A total of 7253 seconds across 21 participants were examined for which region of the classroom PSTs' FOV included at any given second (see Table 1). We estimated a chi-square statistic to determine whether where PSTs focused during the video was independent from whether they attended to fractions in their written noticing. Results indicated a statically significant chi-square statistic (χ^2 (df=4)=35.85, p<.001), suggesting PSTs' written noticings and where they attended in the video were not independent from chance. To better understand this finding, we conducted a post hoc chi-square analysis using z-scores to compare observed and expected counts within cells of Table 1. In particular, PSTs who attended differently in mathematical noticing, spent different amount of time in region A and B. Next, we created graphical representations of each individual PSTs' viewing patterns across the length of the 360 video (see Figure 1 for a cumulative example). Based on the chi-square analysis, we focused our attention on variations between participants' attending for regions A and B. Notably, a specific time frame [2:28-2:44], indicated in Figure 2 by a yellow rectangle, illustrates considerable traffic in the fraction-specific group (blue) for region A. This prompted a review of PSTs' screen recordings to better understand what was happening in this 16 second interval. Essentially, PSTs who attended to students' fractions in their written noticing were looking back-and-forth between one student in region A describing their math and the teacher in Region B writing on the board. By contrast, PSTs who did not attend to fractions in their written noticing focused almost exclusively on the teacher during this timeframe (only one PST looked at the student, and did so for 1 second).

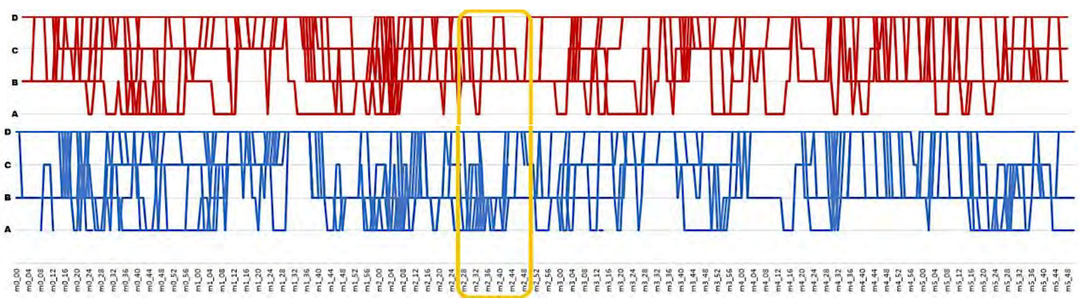


Figure 2: Region PSTs focused by second for not specific (top) & specific (bottom) noticing.

Discussion

The study described the relationship between PSTs' attending within their FOV and the specificity of their written noticing. PSTs selective attending as well as their reflection on what they attend are considered as key elements of professional noticing (Sherin, 2007). Using 360 videos allowed us to understand how PSTs' content-specific descriptions of students' thinking related to their FOV being, literally, student-centered. Thus, PSTs with student-centered attending behaviors provide more specific descriptions of students' mathematical thinking. This corresponds with prior research on teacher noticing (Jacobs et al., 2010). Future study is needed to confirm trends observed in this paper, as well as applied to different contexts to provide additional empirical evidence of how PSTs' develop their professional noticing.

CONFRONTING COLORBLINDNESS: THE IMPACT OF CRITICAL MATH MODULES ON PRESERVICE TEACHERS' 'ONCEPTION OF RACE AND RACISM

Luke Carman
North Carolina State University
LBCarman@ncsu.edu

Robin Anderson
North Carolina State University
Randers6@ncsu.edu

How do undergraduate preservice teachers (PSTs) incorporate their conceptions of race and racism into their understanding of math methods and their teaching philosophies? We report on an intervention conducted in an introductory math methods course. PSTs experienced course content that was explicitly reframed around issues of critical mathematics, social justice, and systemic racism. Data from final assignments was analyzed to determine students' conceptions of race. While the majority of conceptions remained colorblind, students more critically analyzed race and racism when course topics explicitly presented and supported their importance.

Keywords: Preservice Teacher Education, Social Justice, Teacher Beliefs

Purpose of Study

Sociopolitical issues of equity, race, and social justice have been central in challenging the paradigm of math education over the past two decades (Gutierrez 2013; Gutstein, et. al, 2005; Martin, 2009 are just a few of these extensive works). The call to build explicitly antiracist, socio-politically conscious, equitable and critical mathematics teacher education programs has reverberated throughout the math education world (Wilkerson & Berry, 2020; PMENA, 2020; TODOS, 2020). It is necessary for teachers to understand how race and racism affect teaching as part of their preparation to become effective educators**.**

Responding to this call, we, two mathematics teacher educators (MTEs), redesigned the first math methods course for undergraduate preservice teachers (PSTs) at a large public university in the southeastern United States by adding topics with an antiracist, critical lens on mathematics teaching and learning. In doing so, we sought to understand the impact of these changes on PSTs' experience in the course, their beliefs and their future teaching practice.

To understand how our shift impacted students, we sought to answer the question: Which resources and tasks presented to new pre-service mathematics educators were most impactful in shaping their identity and philosophy towards antiracist teaching?

Theoretical Perspectives

Critical Race Theory (CRT) has become essential in helping education scholars explore the centrality of race in classrooms (Tate, 1995; Ladson-Billings, 1995, 1998). CRT proceeds from the understanding that racism is normative in U.S. society, and that these normative structures reinforce a dominant Whiteness throughout society and education. Employing this CRT lens has shown math education to be a White-institutional space in both visible and invisible, central and peripheral ways (Battey & Leyva, 2016; Larnell, et. al, 2016; Martin 2013). In order to address this reality, MTEs must develop students' explicit awareness of race in the mathematics classroom, "to counteract the mechanisms and institutional ways in which White supremacy in mathematics education reproduces subordination and advantage" (Battey & Leyva, 2016, p. 51). Mathematics education is situated in the larger, overwhelmingly White field of teacher education (Sleeter 2001, 2017; Matias & Lackey, 2016), which points to a need for greater understanding of how PSTs are learning to enact antiracist and critical pedagogies.

If teachers are to deconstruct the otherwise invisible White "frame" of math education, they must escape from a "colorblind" or "race-neutral" perspective that dismisses the racism embedded within these systems (Ladson-Billings, 1998; Milner, 2006) and supports the racial ideological status quo (Battey & Leyva, 2016). Milner (2006) proposes that PSTs' conceptions of race change when they: 1) move past pervasive colorblindness and to become racially and culturally aware, 2) engage in critical reflection about their own positioning and 3) explore both theory and practice to help them make sense of their awareness and positionality. Gutstein (2016) notes that this antiracist approach can support critical mathematics pedagogies.

Particular resources and pedagogical moves can be utilized to change pre-service teacher beliefs around race (Matias & Lackey, 2016). However, the study of teachers' beliefs and practices is replete with evidence that change is difficult (Pajares, 1992), particularly shifts towards antiracist practices (Haaviland, 2008; Lawrence & Tatum, 1997). Given this added challenge, continued research is critical to better understand how PST beliefs and practices can begin to shift, at the time when PSTs are developing knowledge from course experiences and incorporating their learning into their beliefs and future practices.

Methods

Participants + Context

The course was adapted from a previous introductory methods course, which had a focus on lesson planning, mathematical tasks, and adopting mathematical mindsets. The authors made the decision to adapt the course: maintaining a focus on these methods while infusing each week with an antiracist and critical lens on math education. (Following Gutstein (2016), we used the terms critical mathematics and social justice math interchangeably.)

Including these lenses explicitly throughout the course, was an attempt to overcome the apprenticeship of observation (Lortie, 1975) through the principle of overcorrection—a pedagogical move where pre-service teachers experience ideal learning situations (Grossman, 1991). To that end, the instructors made certain to include issues of critical mathematics explicitly each week, including within topics previously covered without this lens. For example, classroom activities around assessment explored the racist and inequitable effects of standardized testing (see Table 1 for a full list of topics covered).

The class was taught synchronously online. Students and instructors met once weekly as a group to do math together and discuss course material for 75 minutes. Three to five further hours were budgeted per week for asynchronous work. The authors adopted the stance of "texts, texts and more texts" (Matias & Mackey, 2016) to allow students to engage with these critical and antiracist philosophies and practices not only through research articles but podcasts, videos, newspaper articles, lesson plans, and mathematical tasks.

Participants were new secondary mathematics education undergraduate majors. This was their first course in mathematics education. 19 of the 27 students in the course consented to the research. Based on self-reported information, the students were majority White women, with a small group of students of color across genders, and a few of White men. Exact numbers are not reported to retain anonymity of participants. Both authors were instructors. The first author is a White, male PhD student, teaching the course for the first time. The second author is a White, female assistant professor of math education, teaching the course for a fifth time.

Data Collection and Analysis

The data analyzed for this qualitative study was the two-part final assignment. The first part of this assignment was an annotation of the course syllabus. Students selected nine of the 15 course topics and explained how those topics influenced their vision of math teaching. The second part of the assignment was a teaching philosophy, written as a personal statement highlighting important learnings from the semester. A priori codes were applied at the paragraph level based on module topics (Table 1) and race-discussion-type (Table 2). Codes for race-discussion-type were generated from Milner's (2006) discussion of 1) colorblindness ("colorblind"), 2) racial/culture awareness ("race-aware," acknowledging race, often in a list of ways students are diverse) or 3) critical reflection on race and its societal importance ("race-critical") (see Table 2). Assignment paragraph was chosen as the unit of analysis because students usually discussed one course topic, and their understanding of race in relation to it, per paragraph. During the initial coding process, we observed that students engaged in more than one race-discussion-type at different points in the assignment. Data analysis focused on the co-occurrence of critical racial reflections with course topics.

Table 1: Course Modules Taught

Topics kept from previous iteration of course		**Critical / sociopolitical / antiracist topics added**	
Norm Setting	Assessment	Carceral Pedagogies	Caring Classrooms
Mathematical Mindsets and Valuing Mistakes	Heterogeneous Math Groupings	Learning Pods and Inequity	Antiracist Teaching Through Mathematics
An Introduction to Mathematical Tasks	Math Tasks & Classroom Environment	Teaching Math in Diverse Classrooms	The Math Teacher Community
Technology	Launching Tasks	Creativity, Beauty in Math & Number Talks	

Table 2: Race-Discussion-Type Codes & Examples

"color-blind"	This week's topic really encouraged me to rethink the purpose of a math classroom. Traditionally, math has been thought of as a class with a narrow scope that should avoid all controversial issues. However, … math is among the most powerful tools we have as humans to understand and change the world; thus, teaching math in a vacuum to students is essentially denying them the preparation they need …
"race-aware"	I learned about the inclusion of mathematics in a process called culturally responsive-sustaining education. Focusing on diversity in a math classroom with CR-SE, I learned that students use their own identity to get education. They learn using aspects of their race, social class, gender, language, sexual orientation, nationality, religion, or ability.
"race-critical"	I would like to learn more about anti-racist teaching practices … I have learned, after the events of the past year, that you cannot simply proclaim to be *non-racist*, but must actively declare *anti-racism.* As America's political landscape has started to shift after George Floyd's death, my students' perceptions about race in society will have shifted and I would like to know how to better react.

Results

Across all paragraphs in both annotated syllabi and philosophies (n=286), 84% were colorblind, 8% were race-aware and 12.5% were race-critical. Of the 28 total race-critical comments, 54% (n=15) were discussed in the context of the Antiracist Teaching module of the course. Eight more were spread across four other "critical" topics (Teaching Math in Diverse Classrooms, Carceral Pedagogies, Caring Classroom, Inequity/ Learning Pods), while only five were in relation to modules taught in the previous iteration of the course (Tasks, Classroom Environment, Mathematical Mindsets). As one student noted about learning pods: "I had never realized or understood the racial segregation that created and the increase in the opportunity gap between my classmates and me."

Antiracist teaching was one of three topics most frequently cited as significant. However, of the 15 teachers who cited antiracist teaching as impactful, eight discussed the module in a colorblind way. For example, PSTs avoided the term "race" or "racism" by using "social issues," "culturally relevant issues," "diversity," or by shifting the discussion to class or ability level. Teachers who discussed antiracist teaching practices in aware or critical ways were frequently concerned with how they would implement those practices consistently. As one noted:

> Equity is definitely something that should be discussed in schools, though it is hard for math teachers. I think that introducing racism in regular conversation in class when talking about how to apply mathematics would be beneficial. Getting to know each of my students and building a relationship with them…will help me to introduce active conversations about race and where math applies in each of their lives.

Four students indicated explicitly that discussions of antiracist teaching and culturally responsive and sustaining education were new ideas to them, and that these discussions had revealed the importance of incorporating these pedagogical stances moving forward. For example, one student named her own growth from the course:

> I have now adopted anti-racist teaching, specifically social justice learning, as one of the main pillars of my teaching philosophy. I had never seen social justice be incorporated into a math lesson before in my entire academic career, so I was very excited to create my own lesson! ..It made me feel hopeful that I will be able to teach my students about the world around them and math at the same time, which I hadn't felt confident about before.

Discussion

We are excited that this intervention impacted student understanding and beliefs, and it is clear there is more work to be done. First, we believe that the shift in course content partially opened critical reflection space for teachers. In answering the research question of which topics were most impactful, we find particularly suggestive the connection between explicitly race-conscious modules and PSTs' critical reflections, particularly for the antiracist teaching module. When assigned an explicitly race-aware context, students were more able to reflect critically.

This intervention also made visible the White institutional frame in documenting how most conceptions of math teaching remained colorblind, even as course modules stated the importance of racism. This is not unique to our course. In courses specifically oriented towards social justice in White-majority PST classes, there is still an extreme reticence to talk about race explicitly (Lolkus, 2021). We also hope more research follows Shah & Coles (2020) on racial noticing, to provide insight into how to create critical reflective space for PSTs.

We recognize the limitations of our own planning for this course in the Fall of 2020. Efforts to live and create an antiracist, humanized, critical and rigorous course for students understandably will require edits and updates in future iterations. Our lack of a pre- and post-survey around concepts of race in math classrooms prevented us from measuring more directly the impact the course itself had on teachers' understanding of their knowledge and beliefs. In this study, racial and gender demographics were understood based solely on how students described themselves and their experiences in class discussions and assignments. Moving forward we must collect this demographic data explicitly: there can be no question that PSTs' racialized lived experiences will impact conceptions of race in any coursework.

Some of our students ended the course less hesitant to openly discuss issues of race and its impact on math classrooms than the start. However, discussions of race, power, oppression, and systemic injustice, even when intentionally and thoroughly centered in a methods course, will not take hold for more students without these ideas being reinforced systemically throughout

PSTs' coursework and fieldwork (Sleeter, 2017). Seeds planted within this first methods course may take years to flower.

Researchers increasingly take a design-based research approach to iteratively design, implement, and revise interventions. In this paper, we describe how our iterative design led to improvements in design principles aimed at supporting secondary mathematics teachers' attentiveness development. We describe issues we encountered and insights for developing video-based interventions to improve attentiveness.

Keywords: Design Experiments, Mathematical Knowledge for Teaching, Preservice Teacher Education, Teacher Noticing

Video-based interventions can lead to growth in teachers' and teacher candidates' (TCs') knowledge of mathematics (Jacob et al., 2009), professional noticing skills (van Es & Sherin, 2008), and knowledge of students' mathematical ideas (Powell et al., 2003). Lacking in the literature, however, are detailed accounts of how iterative curriculum design processes are used to improve video-based interventions (Cavey et al., 2020). We are in the fourth year of a design-based research (DBR) project (VCAST) focused on developing video-based modules to improve secondary mathematics TCs' ability to attend to student thinking (Carney et al., 2017). Data analysis revealed limitations in TC responses to prompts about student thinking. In this paper, we describe how the iterative design process led to improvements in our ability to elicit better evidence of TCs' mathematical knowledge associated with figural pattern tasks.

Background

For decades educators have leveraged online instructional materials to maximize in-person class time (Graham, 2006). We began this project interested in developing an intervention with online videos and supporting materials for mathematics courses, similar to earlier work (Goldman & Barron, 1990; Lampert & Ball, 1998). Instructional interventions are rarely iteratively designed, implemented in authentic environments, and improved over time (Amiel & Reeves, 2008). DBR focuses on solving educational problems by connecting research, theory, and practice through iterative theory-driven development focused on making an intervention effective in authentic settings (Anderson & Shattuck, 2012). We took a DBR approach when developing our intervention.

Attentiveness is the ability to analyze and respond to a student's mathematical ideas in ways that build upon student understanding towards formal mathematics and its conventions (Carney et al., 2017) and is grounded in professional noticing (Jacobs et al., 2010), mathematical knowledge for teaching (Ball et al., 2008), and progressive formalization (Freudenthal, 1973). It narrows the focus of professional noticing to an individual student and provides a lens through which to theorize how a teacher's mathematical knowledge and pedagogical stance are elicited in the analyses of student work. Two key aspects of this lens are the ability to recognize, articulate, and connect (1) a student's productive reasoning along with ideas that may be in need of refinement, and (2) the key ideas associated with a mathematical task.

The Intervention & Design Principles

Each VCAST module centers on a mathematical task and features video clips and written artifacts produced by secondary students during their engagement with the task. Each module has an online, in-class, and exit ticket component. In each module, TCs complete the online component, then take part in class discussions on the task and artifacts, and then complete the exit ticket. Each module is typically implemented over a week. Design principles guided our iterative development.

Design Principle 1 (DP1): Solve non-routine mathematical tasks. The use of non-routine tasks creates opportunities to exhibit mathematical reasoning and can be more accessible to students with a range of background knowledge (Schoen, 2003). Each module begins with TCs solving the same task as the secondary students. The Hexagon Task (Figure 1) elicits a range of approaches and is ideal for analysis of student reasoning (Cavey et al., 2020).

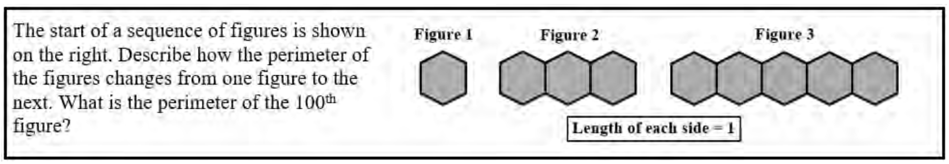

Figure 1: Adapted Hexagon Task; Hendrickson et al. (2012)

Design Principle 2 (DP2): Analyze a range of student evidence. Directed analysis of student evidence can help TCs improve their ability to notice students' mathematical reasoning (Sherin & van Es, 2009; Star & Strickland, 2008). To target DP2, we selected three students who used a range of different strategies and approaches to solving the Hexagon Task (Figure 2).

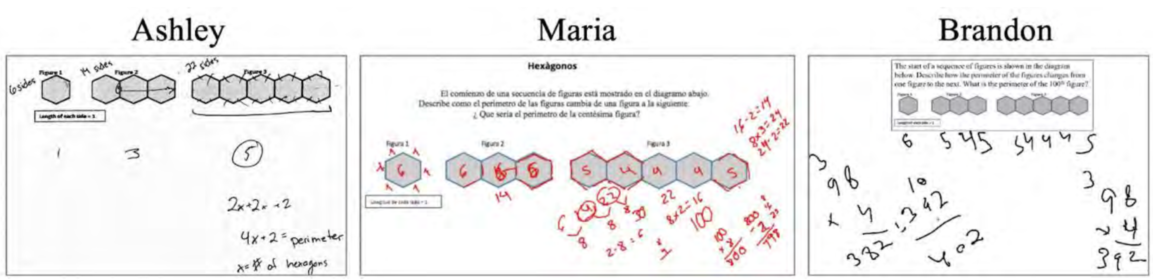

Figure 2: Student evidence featured in The Hexagon Task module

Design Principle (DP3): Engage in Cycles of Inference and Prediction. Effective teachers do more than analyze and interpret student strategies; the inferences they make about students' understanding and their predictions about students' next steps help inform their responses to students (Hill et al., 2005; Jacobs et al., 2010; Lesseig & Hine, 2019). We target DP3 by sequencing video clips from the three featured students throughout the module.

Design Principle (DP4): Describe the Mathematical Challenges for Students. Teachers who understand the specific mathematical challenges students may encounter with a non-routine task are better positioned to respond to students in ways that support students' productive struggle (Stein et al., 1996). We target DP4 by including multiple opportunities for TCs to recognize the challenges students face when focusing on how the configuration of hexagons in each figure contributes to the perimeter.

Methods

We report on this design-based research project following its third revision cycle and after implementation at six public US university Uteach replication sites (Uteach, n.d.). Participants (n=73) were undergraduate students enrolled in the study's partner instructors' mathematics courses. Six partner instructors either taught at the host university or were recruited through the Uteach listservs and annual conferences.

Data were collected via the project's digital platform. TCs submitted responses to open-ended, single- or multiple-selected response, ranking, and upload prompts. Prior to analyzing module responses, three researchers from the design team discussed the expected range of responses. Though we anticipated a range of quality across responses with respect to descriptions and inferences about student work (Jacobs et al., 2010; van Es, 2011), we assumed TCs would have sufficient mathematical knowledge to make sense of the task and the students' work. With each design cycle, the research team applied a variation of magnitude coding (Saldaña, 2016) to review the quality of alignment between expected response and the actual response data. Three researchers independently reviewed all TC responses for each module prompt and compared them to what the prompt had been intended to elicit. Then, researchers reviewed the sets of individual TCs' responses to each sequence of prompts focused on a featured secondary student in the module. Researchers met weekly to discuss emergent areas of concern and to reach consensus on module content warranting revision. The areas of concern connected to TCs' own mathematical knowledge which emerged from these cycles of analysis and discussion are the focus of this paper's results and inform our conclusion and its implications for future research.

Results

Due to limited space, we focus on DPs 3 and 4. An area of concern related to DP3 arose when we were unable to determine whether TCs' superficial predictions stemmed from weaknesses in mathematical knowledge. For example, in Maria's first clip, she narrates how the two outer hexagons in the third figure contribute five units each, while the interior three hexagons contribute four units each, to yield a perimeter of 22. When predicting Maria's next steps, some TCs predicted that Maria will try to solve the task. In the next video segment, Maria creates a sequence of the first three figures' perimeters and computes the common difference of 8 between them. When asked how Maria's next steps compared to TCs' predictions, some TCs made a judgment about her progress with the task, seemingly ignoring the shift in her problem-solving process. In the third video clip, Maria successfully solves the task. Interestingly, some TCs appeared to either not value or not notice some aspects of Maria's productive work. Sample TC evidence elicited from this cycle illustrates the challenge we encountered (Figure 6).

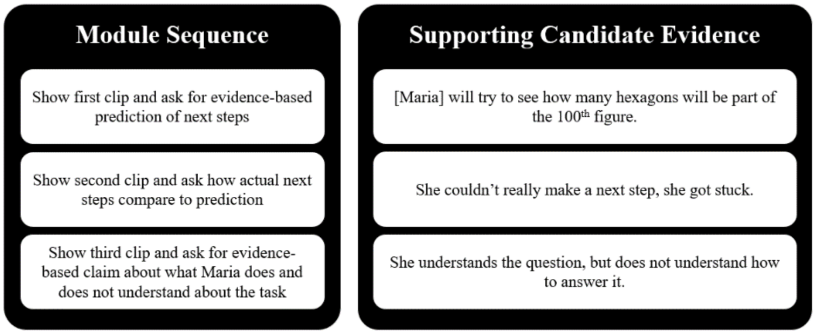

Figure 6: Sample TC Evidence Elicited During a Prediction Cycle

To address this concern, we followed the cycles of prediction in the online component with an adjusted version of the task, the Octagon Task, and provided selected-response prompts which asked TCs to apply each featured students' approach to the new task. This revision accomplishes two goals: (1) it provides scaffolded support to TCs who struggle with the task and (2) it allows us to differentiate between TCs who simply struggle to articulate the mathematical approach they might notice from those who struggle to make sense of the approach itself.

The DP4 area of concern is related to TCs' persistent inability to articulate the mathematical challenges for students. Many of these TCs also appeared to struggle with the same mathematical challenge themselves. To address this concern, we added an official Exit Ticket to the module where we explicitly direct TCs' attention to the challenge that arises when students focus first on the relationship between the number of hexagons and the perimeter and then try to connect their reasoning to the figure number. By Year 4, the Exit Ticket featured video of our third student, Brandon, who made an initial misstep by assuming there were 100 hexagons in the 100th figure. After he noticed his original perimeter of 402 was incorrect, he observed:

> It's going to be more. That's plus two, plus two. I guess it's going to be plus two again. Okay. Five, seven, nine. Okay, [the perimeter's] going to be more than 402. Because there's more than 100 hexagons in the 100th figure. [...] But I need to find how many hexagons the 100th figure has. Um, so it increases by two every time. One plus two equals three. Three plus two equals five. Seven, nine ..Ihat would take too long.

We follow this with two prompts: "Describe the challenge that Brandon encountered in this clip. Use evidence from the clip to support your answer" and "Describe how Brandon's approach to the Hexagon Task is contributing to the difficulty he is experiencing."

Conclusion

Given the importance of conceptual understanding in mathematics education (Ball, 1990), we feature non-traditional tasks that require conceptual understanding to solve in the VCAST modules. With each of our design principles, we work to position TCs in ways that support their ability to analyze, interpret, and make inferences about the range of student reasoning they might encounter in their future classrooms. Our intent is to support TCs' development of the knowledge and skills they will need to enact responsive teaching practices in the classroom.

Yet with each round of our iterative design process, we have discovered areas of ambiguity in the TC response data. We found that we cannot make assumptions about the reasons behind TCs' struggles to make sense of student reasoning evidence while engaged in those same tasks. Engaging in this revision process improves our ability to discern whether TCs' mathematical knowledge might be posing barriers to their attentiveness development and also improves our understanding of the attentiveness construct itself. By sharing some of the challenges encountered in refining the operationalization of design principles through iterative cycles of implementation data collection and analysis and illuminating implicit researcher assumptions which impact design decisions, we hope to support others in similar work.

Research has not yet examined the linguistic patterns of additive problem types nor explored how linguistic analysis might be applied to support preservice elementary teachers in making sense of the semantic and structural differences amongst them. Using a corpus of 150 word problems, the authors conducted an ideation analysis, drawing from systemic functional linguistics theory. The findings resulted in a distillation of language features key to the mathematical processes in the three types of additive problems (i.e. change, part-part-whole, and compare). Preservice elementary teachers (n=97) were introduced to metalanguage as a tool for analyzing structural differences in additive word problems. Analysis of their work demonstrated their ability to employ the functional metalanguage to identify challenges and describe specific linguistic characteristics associated with each type of additive problem.

Introduction & Background

Encompassing mathematical operations within contextual word problems is an important pedagogical strategy for supporting children in developing meaning for operations and connecting computational knowledge with an understanding of how such calculations are applicable in everyday life (e.g., Briars & Larkin, 1984; Carpenter & Moser, 1982; Nesher et al., 1982). The Common Core State Standards in Mathematics (CCSS-M; NGA Center & CCSSO, 2010), adopted by the majority of the United States, identify the need for children to be able to apply the four basic operations to all possible types of contextual situations in which they naturally occur. If students' exposure to different types of situational word problems is limited, it may cause them to develop misconceptions about the meanings for the operations (Van de Walle et al., 2019) and/or limited solution strategies (Carpenter et al., 2015).

However, research shows that the language of word problems can pose greater obstacles than the mathematical concepts involved in solving for solutions (Kintsch, 1987; Lager, 2006; Wyndham & Säljö, 1997). One strategy for overcoming such challenges encourages learners to identify "keywords" (such as "altogether") to determine operations, but this practice has been shown to be highly problematic (Huang & Normandia, 2008). Taking a different approach, the authors of this work aimed to help preservice elementary teachers (PTs) develop disciplinary linguistic knowledge (Turkan et al., 2014) that could enable them to unpack the language of different types of word problems. Systemic Functional Linguistics (SFL) is a social semiotic language theory that offers such a meaning-based metalanguage: a language for helping students and teachers talk about the functions of language and how it shapes meaning in the subject areas (Fang & Schleppegrell, 2010; Halliday, 1975; Halliday & Matthiessen, 2013). Our goals were to describe the salient linguistic features of the multiple types of additive word problems, as well as explore PTs' uptake and application of the linguistic metalanguage.

Van de Walle et al. (2019) categorize addition and subtraction problems into four disjoint situations: Change-Join, Change-Separate, Part-part-whole, and Compare. For the purposes of this paper, we use the singular term "change" to refer to problems involving an action that causes a set to undergo an additive increase (Join) or decrease (Separate) collectively. Part-part-whole (PPW) problems involve the relationship amount a set and its two disjoint subsets, whereas Compare problems involve the additive comparison of two sets.

Research to date has not yet examined the linguistic patterns of these particular problem types, nor explored how linguistic analysis might be applied to support PTs in making sense of the semantic and structural differences amongst them. Therefore, our research questions were: 1) What linguistic patterns exist in one-step additive word problems? 2) How can PTs use SFL metalanguage to identify the semantic and structural features of additive word problems?

Methods

The sample for this study included undergraduate PTs in a College of Education at a southern public university in the United States. All PTs were enrolled in a mathematics problem-solving course designed for education majors (n=97). The intervention developed through this research project was implemented by two instructors across three sections of this course. Data collection and analysis were conducted in two phases: 1) analysis of word problems to develop an intervention and 2) implementation of intervention and analysis of resulting student work.

Development of Intervention

Word problem analysis. First, using a corpus of 150 one-step additive word problems, our research team conducted an ideation analysis, examining taxonomic relations of participants, process types, and connectors (Martin & Rose, 2003). *Participants* refer to the nouns or noun phrases in the word problem. To distinguish between significant and contextual participants, we used the term *referents* to denote the specific participants that are quantified and tracked through the word problem. The term *processes* refers to the verbs and verb phrases, and *connectors* comprise of conjunctions and words or phrases that convey relationships between clauses. These initial analyses resulted in a distillation of language features that are key to the mathematical processes of the three types of additive word problems: *time markers* and *active processes* in change problems; *taxonomic relations* among participants in PPW problems; and *connectors of comparison* in compare problems.

Linguistic patterns in one-step additive word problems. Findings from the word problem analysis indicated distinct linguistic patterns across the three types of additive word problems. Change problems involve one referent being tracked as it is acted upon over time, in which there occurs either an additive increase or decrease in the quantity of the referent. In change problems, the process moves from stasis into action and back to stasis as the referent is being acted upon. Furthermore, because actions happen over time, change problems utilize internal conjunctions of time (i.e. *time markers*) that often serve to differentiate distinct stages in the problem with indicating language such as "then/now, before/after, yesterday/today," etc.

Compare problems are characterized by situations where two referents are being compared at one point in time. Therefore, is it highly unlikely for time markers to appear in compare problems. Instead, these problems include the quantification of two unique referents and the assessment of how these two quantities compare additively. Thus, these types of problems include *comparative connectors*, such as "more than/less than, greater than/fewer than." Also, since the quantities of the referents are only being compared, there tends not to be any significant active process occurring as a key feature, thus processes are typically static in nature.

PPW problems include three referents that are situated in a specific hierarchical fashion. Two of the referents are subsets of the third overarching referent. These "sub-referents" illustrate one way in which the items in the overarching referent can be broken into two inclusive and disjoint subsets according to some differentiating characteristic, at one point in time. Thus, time markers are typically not used and the processes in these problems also tend to be static.

The results of this analysis informed our design for an instructional intervention. Instructors implemented a series of lessons that introduced the metalanguage of *participants, referents, processes*, and *time markers* during PTs' initial exploration of additive word problem types. Our goal was to support PTs in developing the taxonomic categories of additive word problems through inductive reasoning instead of providing them with a taxonomy upfront.

Implementation of Intervention

The intervention occurred after PTs completed an introductory task in which they analyzed and sorted 22 one-step additive word problems into categories based on what they initially noticed about the problems' similarities and differences. Approximately 70% of the PTs sorted the 22 problems into two categories: addition and subtraction, only considering the operation required to solve the problem.

Following this initial sorting activity, instructors introduced the metalanguage of *participants*, *referents*, and *processes* and as a way for PTs to analyze the word problems based on the meaning of the language used in them. After these terms were introduced to the PTs, they were asked to consider three word problems (one change, one PPW, and one compare). The purpose was to highlight the fact that each of these problems can be solved using addition, yet the operation is used in different ways to address a variety of situations (though no categorical language was explicitly revealed to PTs at this time). After working together in class to identify the *participants, referents,* and *processes* of these problems, the PTs were then asked to apply this SFL metalanguage to find new ways of sorting the original set of 22 word problems, again.

During discussions around iterative cycles of this work, the idea of *time markers* was introduced to help distinguish between situations that are happening at one point in time (i.e., PPW and compare problems) and those involving changes occurring over time (i.e., change problems). By the end of the intervention, PTs had *inductively* arrived at the distinguishing characteristics underlying the three taxonomic categories of additive word problems based on their attention to the linguistic patterns, at which time the instructors introduced the associated vocabulary related to each category (i.e., change, PPW, and compare).

Analysis of Student Work

We collected PTs' reflections on their challenges in classifying word problems, as well as their articulations of the linguistic differences they found among the problems. The first source of data came from a reflection question where PTs were asked to identify the word problems they found most challenging to classify. The initial, iterative analysis (Strauss & Corbin, 1997) of PTs' responses identified the types of word problems PTs struggled with, as well as their use of SFL metalanguage. Five weeks after the intervention, PTs completed a midterm video reflection in which they were asked to explain the difference between additive words problems that have a change structure and those that have a PPW structure. Transcripts from these video reflections (n=40) were analyzed for metalanguage articulated by the PTs.

Findings

Analysis of PTs' work demonstrated an ability to employ the functional metalanguage to describe specific linguistic characteristics associated with different types of additive word problem types. PTs were able to use metalanguage to: 1) Distinguish between contextual participants and referents; 2) Identify the number of referents and use this knowledge to distinguish amongst change, compare, and PPW problems; 3) Identify active versus static processes and apply this knowledge to distinguish between change and PPW problems; and 4) Identify time markers in change problems. In what follows, we showcase PTs' responses to illustrate how they used the SFL metalanguage to identify challenges, and in turn key features, of the additive word problems.

PTs initially found it challenging to identify the referent(s) amongst several participants in a given word problem. However, the metalanguage of referent versus participant eventually helped PTs identify patterns in the word problems based on the number and characteristics of the *participants* and *referents*. This led to an inductive categorization scheme separating the problems with one referent (i.e., change) from those with two referents (i.e., compare) and three referents where two sub-referents are encapsulated in one major referent (i.e., PPW). In turn, the identification of the number (and structure) of referents became a key feature PTs analyzed when categorizing additive problems.

PTs initially articulated challenges in identifying processes as being static or active, but this also developed into a tool they later used to help distinguish between problem types. During the sorting activity, the metalanguage of static versus active helped PTs identify patterns in the word problems based on their *processes*, inductively categorizing the problems with active processes (i.e., change) separately from those with static processes (i.e., compare and PPW). Later in midterm reflections, they showed a deeper understanding of the role of active and static processes, particularly their role in change problems, articulating several key features of the *processes* within change problems: 1) change problems indicate a change in a referent's quantity, 2) a relationship exists between time markers and the type of process, i.e., that time markers indicate a change over time in which the *process* moves from stasis to active and back to stasis, and 3) the active process denotes either an additive increase or decrease in the resulting referent. Last, attending to the metalanguage of time markers helped PTs identify change problems. Most PTs were able to initially identify time markers, but some struggled to determine the timing of events in a word problem. By the midterm reflection, however, most PTs did note that time markers were a significant key feature in change problems.

Discussion

The language of mathematical word problems can greatly influence how students make sense of situations posed and identify appropriate solution strategies, which vary according to the type of word problem they are being asked to solve (Carpenter & Moser, 1982; Carpenter et al., 1988; Sarama & Clements, 2009; Verschaffel et al., 2006). PTs need tools for unpacking the language in word problems so that they (and their future students) can access their mathematical meanings. The findings presented here demonstrate how a targeted application of SFL metalanguage can succinctly describe the linguistic features that articulate the key mathematical functions in additive word problems. This work likewise demonstrates that such a targeted approach can support PTs' abilities to apply this metalanguage in accurate and purposeful ways. The functional metalanguage enabled PTs to pay attention to the key *functions* in additive word problems, rather than identifying "keywords" to identify operations, a strategy researchers are encouraging teachers to remove from work with students (e.g., Van de Walle & Lovin, 2006).

In this study, we explored how elementary preservice teachers (PTs) demonstrate supporting productive struggle in a peer teaching activity, after they were engaged in supporting productive struggle practice through a series of activities in a math methods course. While PTs demonstrated strategies that support productive struggle in giving time, asking questions, task, and discussion/feedback in several different ways; the results indicated that they were not able to support productive struggle in use of tools, scaffolding, praising, and mistakes categories. Implications for teacher educators are discussed through connections between and among the strategies.

Keywords: Productive Struggle, Pre-service Elementary Teachers, Mathematics Method Course, Peer Teaching, Effective Mathematics Teaching Practices

Supporting productive struggle in learning math is identified as one of the eight effective math teaching practices by the National Council of Teachers of Mathematics' ’NCTM, 2014) *Principles to Actions (PtA)*. Math methods courses that focus on how productive struggle fosters learning math with understanding may help pre-service teachers (PTs) use supporting productive struggle practice in their future teaching, as methods courses affect PTs’ use of effective instructional practices (Clift & Brady, 2005). There is, however, little evidence in the literature that indicates the introduction and study of supporting productive struggle teaching practice at the teacher preparation programs (Warshauer et al., 2019). In this study, we explored how elementary PTs demonstrate supporting productive struggle in a peer teaching activity, after they were taught a variety of strategies to support productive struggle, and engaged in supporting productive struggle practice through a series of activities in a math methods course. To this end, the research questions guiding the study were: (1) How and in what ways do PTs demonstrate supporting productive struggle in learning math in a peer teaching activity in the math methods course? (2) How and in what ways do PTs not demonstrate supporting productive struggle in learning math in a peer teaching activity in the math methods course?

Theoretical Framework

Struggle is often attributed to something negative as opposed to an opportunity for learning in math education (Borasi, 1996; Hiebert & Wearne, 2003). In the U.S., learning is considered as an activity that is supposed to be fun; however, students do not learn deeply if learning is only fun, without any struggle (Stigler, 2016). Although, struggling is considered a critical component of learning math deeply (Hiebert & Grouws, 2007), due to the adverse effects associated with struggle, such as frustration and overwhelm, teachers often look for ways to remove the cause of students' struggle (Adams & Hamm, 2008; Borasi, 1996). Therefore, teachers, particularly in the U.S., tend not to use high cognitive demanding tasks in their lessons, or they often transform the tasks into procedural exercises during instruction (Stigler & Hiebert, 2004), perhaps because they do not know how to support struggle productively.

Hiebert and Grouws (2007) described productive struggle as "students expend effort in order to make sense of math, to figure out something that is not immediately apparent" ”p.387). Warshauer (2015a) elaborated on Hiebert and Grouws's’notion of struggle in three parts: the purpose of struggle to make sense of math; the characteristics of math tasks and their connection to students' struggle; and teacher's role in supporting the productive struggle. Teaching practices that maintain productive struggle with high cognitive level tasks promote a high degree of engagement and persistence throughout the task, deepen students' understanding (Dweck, 1986; Santagata, 2005; Stein et al., 1996; Sun, 2018), and hence help students make sense of the math concepts. Introducing productive struggle to PTs in their math methods courses may not only expand their understanding of math concepts for teaching, but also equip them with strategies to support struggle productively. This could potentially help PTs embrace struggle as a learning opportunity instead of avoiding it, and use high cognitive demanding tasks in their teaching.

Research on supporting productive struggle is still in its infancy, and little is known in the context of PT education. Prior research on productive struggle focused on students' struggle (Warshauer, 2011; 2014a), effective math teaching practices to support productive struggle with inservice teachers (Smith et al., 2017), and PTs' understanding of productive struggle with professional teacher noticing of student thinking (Warshauer et al., 2019). PTs’ development and implementation of strategies to support productive struggle remains undiscovered.

Methods

This study presented preliminary results that were part of an extensive study and was exploratory in nature. The participants were 25 PTs in an elementary/middle education program at a Mid-Western university in the U.S. They were enrolled in a math methods course, which they typically take in the semester before their student teaching experience. The PTs studied and practiced supporting productive struggle throughout the methods course through a variety of readings, discussions, and activities within eight effective math teaching practices stipulated in PtA, as well as in relation to differentiation, inclusion, and equitable pedagogies. The data analyzed in this study consisted of video-recorded instances of peer teaching as well as lesson supplements or relevant materials that were used to assist the research team's analysis of the videos. While the videos were focused mainly on the PT as the teacher, it also included recordings of the peer PTs communicating with the presenting teacher. To analyze the videos and strategize a consistent coding criterion, we developed a rubric that helped us identify and describe the supporting productive struggle practice across a variety of criteria and sub-criteria. The criteria were derived from the literature, as well as from the content of the math methods course. An expert validation and a coding agreement were established through discussion and consensus among five researchers. The coding rubric consisted of eight main criteria including task, tools, giving time to struggle, asking questions, scaffolding for access to productive struggle, mistakes and confusions, praising and encouraging students, and discussion/feedback. Beneath eight criteria, there were a total of 37 sub-criteria that describe specific strategies. For instance, mistakes and confusions included five sub-criteria: (1) helping students realize that confusion and errors are a natural part of learning by facilitating discussions on mistakes, misconceptions, and struggles; (2) calling on students who may not have the correct answer, and then guiding students in the process of questioning their thinking; (3) acknowledging student contributions whether it is a misstep, misconception, or inappropriate approach; (4) publicly valuing mistakes; and (5) creating disequilibrium. Praising and encouraging students comprised of two sub-criteria: (1) praising for their efforts and struggle in making sense of mathematical ideas and perseverance in reasoning through problems; not for being smart and/or fast; and (2) for generating multiple representations and methods even if these do not lead to a successful solution. It is worth noting that during the video analyses, the research team was cautious in providing credit to the type of praise that explicitly values students' efforts and struggles, as well as varied strategies and representations, not their intelligence, success, speed, or correct answers. After the rubric preparation, the entire research team received training and gained experience in how to code the video clips using the newly developed coding rubric. To ensure inter-rater reliability, the research team individually coded the same video footage collaboratively, discussed coding differences and similarities among people, and finally reached a consensus. Later on, 25 videos, 30-35 minutes each, were coded by the research team independently using qualitative thematic coding.

Results

A total of 482 codes were generated for the instances that PTs demonstrated supporting productive struggle strategies across 25 videos. Percentage frequencies were computed for each criterion and sub-criterion, for three phases of the lesson. The PTs' ’se of supporting productive struggle strategies were similarly distributed among the three parts of the lesson; launch (29.6%), explore (37.6%), and reflect (32.8%). As shown in Figure 1, the PTs, most frequently, demonstrated supporting productive struggle in the discussion/feedback, task, giving time, and asking questions categories. In the discussion and feedback category, PTs most frequently (10.4%) encouraged students to make their ideas public; (6.0%) engaged students in purposeful sharing of mathematical ideas and reasoning; and or (2.7%) honored and built on student thinking. In the task category, PTs supported productive struggle by implementing tasks that allow for/encourage multiple solutions, strategies, and representation (4.4%); have real life context (7.1%); or require written explanations for reasoning (4.1%). The PTs often provided time for struggle by working in pairs and groups and engaging in whole group discussion. PTs supported productive struggle by asking assessing (8.7%) and advancing (4.1%) questions more than any other questioning strategies in the same category such as questions that help students identify the source of their struggle and or surface an error (0.2%).

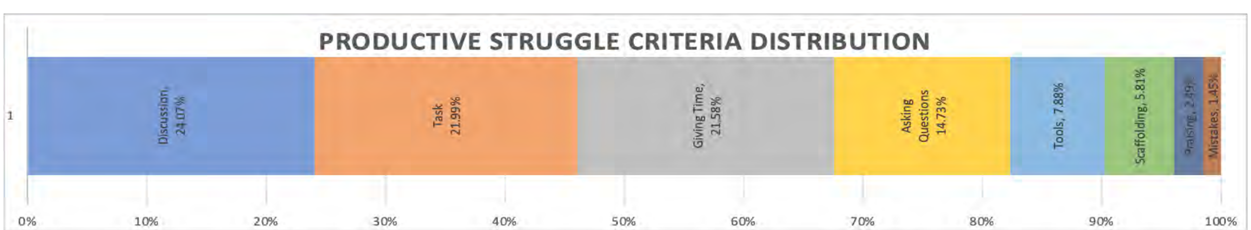

Figure 1: Distribution of Supporting Productive Struggle Strategies

On the other hand, the PTs rarely demonstrated supporting productive struggle strategies in tools, scaffolding, praising, and mistakes/confusions categories. As displayed in Figure 1, the

PTs low frequently gave access and or required using a variety of tools, strategies, and representations in order to support thinking processes. Scaffolding for access to productive struggle was observed only when PTs elicited prior knowledge by purposefully planned questions or activities that illuminated key mathematical ideas that would likely be useful when students faced the subsequent task (3.7%). Praising, in the context of productive struggle, was defined as praising for effort and struggle, and or for generating multiple representations and methods. The PTs seldom praised for struggle and effort (0.8%) and multiple representations (1.7%). Although, mistakes and errors were emphasized as an essential component of supporting productive struggle, the PTs rarely (0.3%) helped students realize that mistakes and errors were a natural part of learning, or (0.4%) publicly valued mistakes; and they never created a disequilibrium.

Implications and Conclusions

While PTs demonstrated strategies that support productive struggle in giving time, asking questions, task, and discussion/feedback in several different ways; the results indicated that they were not able to support productive struggle in tools, scaffolding, praising, and mistakes categories. Giving access and requiring students to use tools and representations supports students' thinking processes (NCTM, 2014), and enforces the idea that it is not about how fast you work, it is about knowing a lot of strategies and tools that can help you (Huinker & Bill, 2018), and hence fosters productive struggle (Warshauer, 2011). Requiring use of multiple tools, representations, and strategies is often linked to implementing high-cognitive demand tasks (NCTM, 2014). Therefore, PTs' infrequent use of the strategy could be attributed to their infrequent use of high-cognitive demand tasks. Providing scaffolding without removing the demands or doing the thinking for students has been often discussed in relation to productive struggle (Huinker & Bill, 2018; Kapur, 2014), and possible techniques have been suggested in Barlow et al. (2018) and Lynch et al. (2018). Although PTs engaged in a variety of such techniques during the methods course, they were unable to utilize them in peer teaching, except for eliciting prior knowledge scaffolding technique (Barlow et al., 2018). This can be explained by PTs' infrequent use of high cognitive demand tasks, as scaffolding for access to productive struggle is applicable when the tasks require complex and non-algorithmic thinking, and considerable cognitive effort. The results revealed that the PTs did not utilize praising, as defined in the context of productive struggle. Praising students for their efforts in making sense of mathematical ideas and perseverance in reasoning through problems, rather than for correct answers, is also linked to productive struggle (Baker et al., 2020; Bray, 2018; NCTM, 2014). PTs' infrequent use of the praising strategies possibly arose from their failure to require a variety of tools, representations, and strategies. Although, publicly valuing mistakes, creating disequilibrium (Boaler, 2016), and viewing mistakes and struggle as inevitable parts of learning (Bray, 2014; Kapur, 2014; NCTM, 2014; Warshauer, 2015) are considered essential components of supporting productive struggle, the PTs were not able to utilize mistakes and errors as a portal for supporting productive struggle. The PTs', as well as teachers', difficulty in helping students question or leverage an incorrect idea toward a more productive strategy, and in treating student mistakes and flawed approaches as objects of inquiry was noted in the literature (Hallman-Thrasher, 2017), and asking questions that encourage reflection and justification was suggested as an avenue to help PTs facilitate learning around mistakes and struggle (Morissey et al., 2019). The PTs' difficulty with using mistakes as learning opportunities can be linked to their low-none frequency of asking questions that help students identify the source of their struggle and or surface an error. Our goal is to take the positive findings of this study and further extend them with a focus on the strategies that PTs had difficulty with, so that future K-12 students will have teachers who provide them opportunity to productively struggle through the important mathematical concepts and relationships.

As integrated STEM/STEAM education gains prominence in PreK-5 classrooms, prospective elementary teachers face new challenges in learning to focus on children's mathematical thinking and community funds of knowledge (i.e., multiple mathematical knowledge bases) in instruction. We explored prospective teachers' attention to multiple mathematical knowledge bases in integrated STEAM lesson plans, co-planned and co-facilitated at an informal STEM event for preschool children and families. Analyzing three lesson plans, we asked how prospective elementary teachers connected children's mathematical thinking, funds of knowledge, and STEAM. We found transitional connections – explicit attempts that were underdeveloped in one or two areas – in two lesson plans and meaningful connections in one. We discuss implications for elementary teacher learning and integrated STEAM practice.

Keywords: Integrated STEM/STEAM; Learning Trajectories and Progressions; Preservice Teacher Education; Equity, Inclusion, and Diversity

Increasingly, educational initiatives are pushing for the development of teachers' capacity for STEM integration in K-12 classrooms (e.g., Division of College Career & Technical Education, 2018). However, learning to teach integrated STEM education presents new challenges for prospective teachers and teacher educators (e.g., Ryu et al., 2019; Shernoff et al., 2017; Stohlmann et al., 2012). Among these challenges lies the concern that situating mathematics within integrated STEM will negatively impact the quality of mathematics curriculum and instruction (Weinstein et al., 2016). In other words, efforts to center children's mathematical thinking (e.g., Carpenter et al., 1996) and funds of knowledge – the cultural, community, linguistic, and cognitive resources from home and community settings (e.g., González et al., 2001) – in mathematics may fall to the side as science and engineering take center stage.

We share preliminary findings from efforts to extend the work of the Teachers Empowered to Advance CHange in Mathematics (TEACH Math) group, which explored how prospective elementary teachers learn to incorporate multiple mathematical knowledge bases (MMKB), namely children's mathematical thinking and funds of knowledge, into mathematics instruction (e.g., Turner et al., 2012). We asked: *In what ways do prospective elementary teachers connect children's MMKB and STEAM in integrated lessons they design?*

Theoretical Framework

We build on the learning trajectory proposed by the TEACH Math group (Aguirre et al., 2012; Turner et al., 2012) for prospective teacher learning of critical practices for incorporating MMKB into instruction (Figure 1). Accordingly, we share the perspective that teacher learning along this trajectory is "dynamic and assume that [prospective teachers'] understanding and practices will reflect different points on the trajectory at different times" (Aguirre et al., 2012, p. 180). We also assume that teacher learning requires multiple entry points and collaboration.

Initially, teachers engage in three interrelated practices: (1) attention – what teachers notice; (2) awareness – how teachers interpret what they notice; and (3) eliciting – how teachers interact with children and families to elicit MMKB (Turner et al., 2012). The second phase reflects teachers' initial attempts to make connections to children's MMKB, and the third phase involves ongoing and purposeful incorporation of MMKB in instruction (Aguirre et al., 2012). We sought to extend this framework by considering prospective teachers' efforts to leverage children's MMKB with and through connections to other academic disciplines incorporated within integrated STEAM (Figure 1). By integrated STEAM, we mean that mathematics learning occurs alongside and/or through science, computer science, engineering, and/or arts learning. We take a broad stance on what counts as "art" and include fine arts, music, and humanities (e.g., literacy, history). Our study focused on the second phase within the learning trajectory, making connections. We explored the extent to which integrated STEAM provided additional access points for prospective teachers leveraging MMKB.

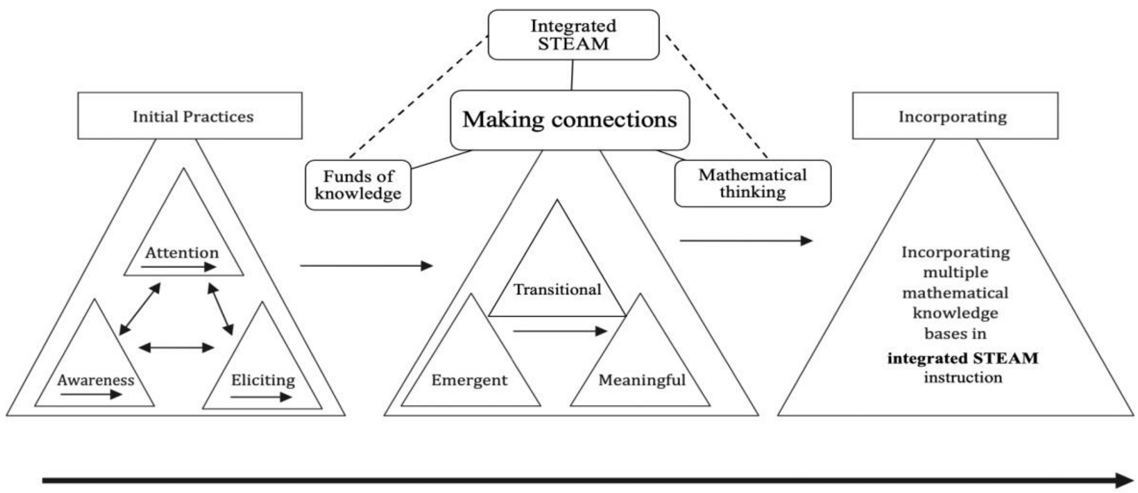

Figure 1: Prospective teacher learning trajectory of key practices for engaging with children's multiple mathematical knowledge bases in transdisciplinary instruction

Methods

Data sources for this analysis came from 124 prospective elementary teachers collaboratively producing 44 lesson plans across three years. Data was generated from 2018-2020. Harper taught all sections of the courses and used a modified version of the TEACH Math Community Engagement Module (Turner et al., 2015) to support prospective teachers' collaborative lesson planning and facilitation. Enrolled prospective teachers designed, planned for, and facilitated integrated STEAM lessons using MMKB at informal STEM events. These lessons and events were hosted by a nearby public title I preschool in a predominately Black community, and children and their families attended. In this brief report, we share findings from our preliminary analysis of three lesson plans. The following groups of prospective teachers from the PreK-3 licensure program co-planned and co-facilitated the lessons: (1) *Vet Clinic* by Georgia, Khloe, and Helen in 2018 (All names are pseudonyms); (2) *Sink or Float?* by Devon, Zara, and Chelsea in 2019; (3) *Codename: Mouse* by Dallas and Hope in 2019.

We coded the lessons by section as our unit of analysis; this allowed for the greatest consistency across all coders and lesson plans. Lesson plans included four sections: (1) the task; (2) learning intentions; (3) plan for enactment (i.e., anticipated student strategies; teacher responses); and (4) wrap up. We began analysis with iterative rounds of inductive coding (Sa , 2013) of the "Vet Clinic" and "Sink or Float?" lessons, meeting to reach consensus and develop a codebook. Our emergent codes were compared to the codebook from previous analyses (Harper et al., 2021) and pre-existing codes were adopted as appropriate. Parent codes included: Science; Technology; Engineering; Art; Literacy; Social Studies; Mathematics; and Funds of Knowledge. We elaborate on subcodes, as themes within these broader domains, in the findings section. Harper deductively applied codes to the "Codename: Mouse" lesson and then categorized (i.e., theoretical coding; Saldaña, 2013) the connections among mathematical thinking, funds of knowledge (i.e., MMKB), and STEAM in all three lessons as *emergent* (superficial attempts to make connections), *transitional* (explicit attempts to make connections, but connections remain underdeveloped), or *meaningful* (connections support rich, problem-solving) (Aguirre et al., 2012). Finally, Harper generated data displays (e.g., code co-occurrence) in Dedoose (8.3.45) to identify the themes described in the next section.

Findings

We found that prospective teachers made meaningful connections in the "Codename: Mouse" lesson. Prospective teachers made transitional connections among children's MMKB and STEAM in the "Vet Clinic" and "Sink or Float?" lessons. The transitional connections included explicit attempts to connect MMKB and integrated STEAM, but attention to funds of knowledge and STEAM integration were both underdeveloped in the "Vet Clinic" lesson. The focus on children's mathematical thinking was underdeveloped, and explicit attempts to connect MMKB and integrated STEAM were consistent but problematic in the "Sink or Float?" lesson.

Meaningful Connections

Prospective teachers Dallas and Hope visited the preschool community and, with attention, identified several important community sites nearby to include in their lesson (e.g., local businesses, parks). In "Codename: Mouse," Dallas and Hope planned for students to choose two familiar sites (pre-identified ones or ones named by students), students placed markers on a grid and navigated a robot mouse from one site to another (for more details, see Harper et al., 2021). The lesson was authentic to community mathematics in that it elicited children to draw on their experiences navigating between familiar places and encouraged children and family members to become experts by "engage in conversations with their children about directions and distances between places in their daily lives." We categorized these MMKB connections as meaningful from the attention Dallas and Hope paid to the local community sites and their awareness that families and students are the "experts" of the site locations. Navigating the robot mouse was consistently connected to children's mathematical thinking about counting principles (e.g., one-to-one correspondence) related to the concept of unit measurements of distance and computational thinking, namely putting steps in a sequence to perform actions. We categorized these STEAM integrations as meaningful because the mathematics engagement supported the development of computational thinking and vice versa.

Transitional Connections

Georgia, Khloe, and Helen visited an animal hospital near the preschool and learned about the authentic ways in which a veterinarian calculates dosages for pet medication. In their "Vet Clinic" lesson, students chose a "sick" animal and determined the correct medication dosage based on the animal's weight (half a pill per five pounds). To support the necessary proportional reasoning, prospective teachers consistently elicited children's mathematical thinking across various strategies, such as direct modeling with fraction bars, drawings, and paper "pills" and counting strategies (e.g., skip counting). Funds of knowledge remained underdeveloped, focusing on children and families understanding "the intricacy of a veterinarian's job." Here we found the prospective teachers had an awareness of funds of knowledge but ultimately missed the opportunity to leverage children and families' knowledge of taking medicine or giving it to pets. Further, although the task was set within the context of veterinary/medical science, with the goal of children "understanding a specific weight coincides with a specific dosage," the specific science concepts remained vague and underdeveloped.

Devon, Zara, and Chelsea visited local businesses near the preschool but decided to use a commercially available "sink or float" STEM set as the main inspiration for planning. In their lesson, students chose two objects, judged their weight and shape, predicted whether they would sink or float, and then tested the hypothesis. Attention to funds of knowledge was consistent throughout the lesson with encouragement for children to "think back to experiences they have already encountered (swimming pool, bathtub) and connect or compare those items they have observed to the new items introduced during the lesson." Further, prospective teachers asked children to weigh objects using an informal, home-based method of holding one object in each hand to judge which was heavier. Attention to children's mathematical thinking about comparisons of weight and properties of shapes (e.g., size) were consistent but remained vague. Although the scientific method and physical science concepts, namely density, were integrated throughout the lesson, prospective teachers never made explicit the inversely proportional relationship between mass and volume; therefore, we categorized the STEAM integration as transitional. Some parts of the lesson seemed to reinforce a misconception that heavy objects sink while light objects float (i.e., weight alone determines density), which may be problematic.

Discussion and Conclusion

Elementary teachers are not new to the daunting task of instructing across disciplines, and exemplars exist that show the potential for integrated STEAM to foster deep mathematics learning in K-5 classrooms (e.g., Bush & Cook, 2019). We found that integrating computer science education into mathematics lessons fostered productive struggle for our prospective elementary teachers, which facilitated meaningful connections to both children's mathematical thinking and funds of knowledge (this analysis; Harper et al., 2021). Sense of place, or place attachment and identity that is contextually dependent, offers one such entry point for integrating MMKB and computer science (Harper et al., 2021; Leonard et al., 2016; Rubel et al., 2017). This analysis suggests that integrating science into mathematics lessons can provide different entry points for prospective teachers to make connections among children's MMKB. In the "Sink or Float?" lesson, attention to children's scientific thinking and funds of knowledge were more developed than the focus on mathematical thinking. Nevertheless, the focus on the science and mathematics practices observed in everyday activities (e.g., bath) provided an additional entry point for leveraging MMKB and highlighting weight, shape, and comparison during the scientific processes of predicting and observing, which also engaged children in practices authentic to STEM communities and professions (Civil, 2016). Leveraging funds of knowledge, in addition to children's mathematical thinking, in integrated STEAM lessons is necessary within broader efforts to diversify STEM. Such attention to funds of knowledge can disrupt the expectation that those from marginalized groups will disregard their unique lived experiences and perspectives and conform to (white, masculine, middle class) professional norms upon entering STEM fields (Verdin et al., 2016).

PRE-SERVICE MATHEMATICS TEACHERS IDENTIFY CRITICAL EVENTS: WHAT CHANGES IN THEIR ATTENTION?

This study explores the changes in pre-service mathematics teachers' 'ttention to critical events within the context of a year-long teachers' 'reparation program in which noticing critical events was a key preparation tool. We asked 20 pre-service teachers to identify and describe critical events they witnessed during school observations/teaching. We then used an empirical and theoretical-based model developed to explore the ways in which pre-service teachers changed their attention to these critical events. Our findings reveal that the pre-service teachers' 'oci of attention were broadened; they were attentive to more details, especially to students' 'ffect. We demonstrate these findings using the case of Nasim.

Keywords: Preservice Teacher Education, Teacher Noticing, Critical Events, Professional development

Introduction and Theoretical Background

Critical events have been defined in many ways. Here, we consider critical events to be classroom situations in which students' mathematical thinking is apparent and can serve as an opportunity to delve into the mathematics that was presented (Leatham et al., 2015). We use critical events as a tool to prepare pre-service teachers (PSTs) to teach high-level secondary school mathematics, in the context of a larger research project. In particular, we use critical events to teach PSTs to notice instances where the teacher can develop students' mathematical thinking. Noticing students' thinking is considered a core teaching practice (Grossman et al., 2009), leading researchers to study ways to support PSTs' learning of these skills (Jacobs et al., 2010; Simpson & Haltiwanger, 2017; Sun & van Es, 2015).

We conceptualize noticing according to Jacobs et al.'s (2010) framework of *teachers' professional noticing of students' thinking*, which consists of three components: (1) attending to critical events that involve student thinking that the teacher could build on, (2) interpretation of a student's thinking, and (3) offering alternative teaching responses. Some scholars argue that current conceptualizations do not fully reflect the complexity inherent in noticing (Jacobs, 2017; Scheiner, 2016). The complexity of noticing is connected to the complexity of classroom situations, which stems from the different dimensions of learning and teaching mathematics – cognitive, affective, and social (Op't Eynde, et al., 2006; Skott, 2019). Being attentive to multiple dimensions embedded in a critical event means being attentive to its details. This is important as it allows a more appropriate interpretation of students' thinking, which, in turn, may lead to informed and effective responses (Barnhart & van Es, 2015; Mason, 2011).

In this paper, we focus on investigating the changes in PSTs' attention to critical events within the context of a year-long teachers' preparation program in which noticing critical events was a key preparation tool. To explore changes in PSTs' attention to details over the year, we defined the term of *degree of foci of attention*, which is the number of combinations of the different dimensions (cognitive, affective, and social) embedded in the PSTs' descriptions of the events. We ask: *What is the change in the PSTs' foci of attention when identifying critical events, they have witnessed while observing/teaching mathematics classrooms?*

Theoretical Framework

To characterize the different foci of PSTs' attention, we draw on two theoretical perspectives, which together with our previous empirical work (Rotem & Ayalon, in preparation) constitute a three-axis model: (1) *the participants of the event*, (2) *the content of the event*, and (3) *the dimensions of learning and teaching mathematics* (see Figure 1). To characterize the participants and the content of critical events, we build on van Es and Sherin's (2008) *Content and Stance framework*, drawing on two components: the *actor* in the excerpt that the teachers commented on (student, teacher, or other) and the *topic* of teachers' noticing, i.e., the mathematical thinking and/or the pedagogy (e.g., teaching strategies, classroom climate and management). To characterize the dimensions in learning and teaching mathematics, we draw on Op't Eynde et al.'s (2006) perspective, which addresses the interplay between different participants in different dimensions – cognitive, affective, and social. All in all, the three-axis model consists of 27 possible triples that we refer to as combinations of attention.

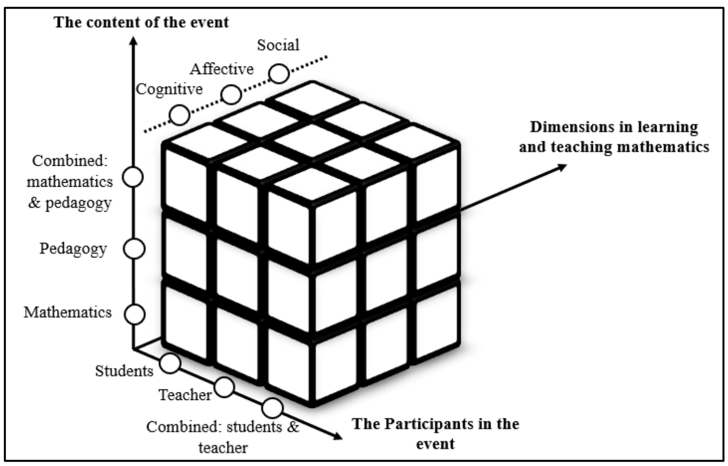

Figure 1. The three-axis model for characterizing critical events

Methodology

Data Collection

This study is framed within a larger research project, ACLIM-5. The project aims to examine the longitudinal change PSTs undergo as they identify, interpret, and respond to critical events in mathematics classrooms. The participants here were 20 PSTs who participated in the program in 2017-2019. They were asked to identify critical events while observing and teaching lessons as part of the program's practical experience. Additionally, they were required to submit 4-5 written reports in which they described and interpreted these events. The reports were built on Jacobs et al. (2010) conceptualization of noticing (see above). Overall, the 20 PSTs submitted 80 reports. To explore the change in foci of attention, we consider the first and last reports, 40 in total.

Data Analysis

We consider each report a unit of analysis and distinguish between the PSTs' first reports (20 units) and last reports (20 units). In the data analysis process, we first used our model (Figure 1) to code each of the analysis units. We identified 11 combinations (out of a possible 27). For example, the combination *student-mathematics-cognitive* [SMC] is the combination of the component 'students' from the *x* axis: the participant of the event, the component 'mathematics' from the *y* axis: the content of the event, and the component 'cognitive' from the *z* axis:

Olanoff, D., Johnson, K., & Spitzer, S. (2021). *Proceedings of the forty-third annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Philadelphia, PA.

dimensions of teaching and learning mathematics. Due to the lack of space, we will not share all 11 combinations here, but rather use them according to our needs; we will describe and demonstrate all the categories in our presentation.

We coded each unit of analysis with a specific combination if that combination was present within the analysis unit at least once. For example, when a critical event was coded as SMC, it means that this code appeared at least once. Then, to reveal a change in the PSTs' degree of foci of attention, we counted the number of combinations for each PST's first and last critical event. We then compared the degree of foci between the first and last critical event.

Preliminary Findings

The analysis reveals that for most PSTs, the degree of foci of attention was broader in the last critical event; 12 PSTs were attentive to more combinations in the last critical event. For four PSTs, the degree of foci was unchanged, and four PSTs attended to fewer combinations in the last critical event. Here we focus on the 12 PSTs whose degree of foci of attention was broadened. We illustrate these preliminary findings using Nasim's case as an example. Below is Nasim's first critical event, followed by our analysis (Table 1). Nasim's first critical event occurred during a lesson on trigonometric function analysis; he did not give details regarding the lesson, however, in Israel this would normally be taught in a high-level 11th-grade class.

> A student was asked to find the extreme point of the function. The derivative obtained was: $\cos\left(2x+\frac{\pi}{3}\right)=0$. He suggested solving by making $2x+\frac{\pi}{3}=0$ and [then] finding the x. The teacher turned to the class [CPS]: "remember what is $\cos(0)$?" and everyone answered: "1" [SMC]. Then the teacher said: "but we obtained that $\cos\left(2x+\frac{\pi}{3}\right)=0$ and not $\cos\left(2x+\frac{\pi}{3}\right)=1$. [Also,] what about the unit circle?" [TCC].

Table 1: Analysis of Nasim's first critical event using the model

Combination [Acronym]: Name	Definition	Brief analysis of Nasim's event
[SMC]: Students-Math-Cognitive	The students suggested various mathematical ideas, concepts, representations, solution strategies, or considerations for solution strategies.	In the event, the students raised two solution-related considerations: the student's suggestion that the cosine's argument equals to zero, and the students' mathematical statement that $\cos(0)$ is 1.
[TCC]: Teacher-Combined math & pedagogy-Cognitive	The teacher used various mathematical ideas, concepts, representations, or solution strategies in their teaching.	The teacher used various mathematical ideas and concepts. He simplified the students' statement by asking them about $\cos(0)$ instead of asking them about the original expression. Additionally, he also mentioned the unit circle.
[CPS]: Combined Teacher & Students-Pedagogy-Social	The teacher used strategies that make students' statements public to prompt the students' participation.	The teacher made the student's statements public. The teacher turned to the class and asked questions to prompt their participation.

Nasim's last critical event occurred in a 10th-grade high-level mathematics lesson, focusing on the circle theorems (for analysis see Table 2):

> In the past, they studied the theorem that, in front of equal arcs, there are equal chords. [In this lesson], the teacher taught the theorem that if two angles are inscribed on the same arc, they are equal. Then, coming to the question where there were two angles - each from the other side of the chord - one student said the two angles are equal because they rest on the

same chord. Some students said that it did not look right because the first angle seemed larger than the second angle. Other students started shouting [SMA] and saying that the two angles are not on the same side [SMC]. The teacher pointed toward the direction of the students' statement that the two angles were not from the same side until the students were convinced that the side of the chord is important [CCS]. [He] reminded them that before they were talking about arches and not chords. [he] draw them a drawing on the board [TCC].

Table 2: Nasim's last critical event's analysis using the model

Combination [Acronym]: Name	Definition	Brief analysis of Nasim's event
[SMC]: Students-Math-Cognitive	The students suggested various mathematical ideas, concepts, representations, solution strategies, or considerations for solution strategies.	The students offered some considerations for refuting the claim that the two angles are equal; some judged the claim by the angle's appearance while others used the theorem that the angles should be on the same side of the chord.
[TCC]: Teacher-Combined math & pedagogy-Cognitive	The teacher used various mathematical ideas, concepts, representations, or solution strategies in their teaching.	The teacher used two representations in his teaching: he went back to the exact words of the theorem and then used a drawing to illustrate why the theorem does not hold in this case.
[SMA]: Students-Math- Affective	The students indicated feelings, emotions, beliefs, attitudes, motivation, values, and moods towards mathematics.	Nasim articulates the students' behavior to indicate their motivation and interest toward the mathematics that was taught. The students were "shouting"; it seems that they were engaged in the debate in a way that got them involved emotionally.
[CCS]: Combined Teacher & Students-Combined math & pedagogy-Social	The teacher prompted and connected the students' ideas in the discussion, so one idea is built on another idea.	The teacher built on the students' statements and connected their ideas in the discussion.

In Nasim's case, the degree of foci of attention changed from 3 in the first critical event to 4 in the last. The broadening of his attention was reflected not only in his attention to the cognitive aspect of the students' mathematics, but also in attention to affective and social dimensions.

Discussion and Implications

In this paper, we started to explore PSTs' change in attention to critical events within the context of a preparation program in which critical events were a key preparation tool. We found that for most PSTs, the foci of attention were broadened from the first to the last critical event. These findings add to the existing research by indicating that learning to notice includes broadening the degree of foci of attention, expressed in attention to the details of different dimensions of teaching and learning. In particular, our findings demonstrate that within the moment in which noticing occurs, the different dimensions – cognitive, social and affective – play a part. A possible explanation for the change is the PSTs' experience within classrooms, both observing and teaching, an experience which has been demonstrated to be productive for learning to notice students' thinking (Simpson & Haltiwanger, 2017).

Currently we are examining if and how this change is reflected in the PSTs' interpretations of critical events. We investigate Jacobs's (2017; p. 278) question: "when teachers do not report noticing something of interest, did they fail to notice it or simply fail to report noticing it?" We believe that examining PSTs' interpretations of critical events will shed light on the change (or lack thereof) that could not be captured solely by analyzing the descriptions of the critical events.

Additionally, we propose that noticing could be seen more broadly, and suggest the three-axes model as a starting point for further conceptualization of noticing of critical events. Had we analyzed our data using existing tools, usually comprised of rubrics for levels of quality of attention (Scheiner, 2016), the changes we found here would have been overlooked.

The present study focuses on examining transitions in elementary pre-service teachers (PSTs)' understanding of, and skills in, leading argumentation-focused discussions in mathematics during participation in a sequence of three different practice-based activities, collectively referred to as the Online Practice Suite (OPS). We will examine 14 PSTs' responses to post-activity surveys targeting their understanding of argumentation-focused discussions and emotional experiences, over the course of a single semester. From this initial coding, we will select three to four cases that represent a range of understandings and emotional experiences and conduct in-depth analyses on the patterns of engagement in the OPS, drawing on records of practice from their experiences in the OPS. We discuss ways that teacher educators can scaffold PSTs' experiences as they develop the skills to facilitate argumentation-focused discussions.

Keywords: Instructional Activities and Practices, Preservice Teacher Education, Classroom Discourse, Technology, Approximations of Practice, Simulation

Purpose of the Study

This study is situated within a larger project focused on examining how participation in a sequence of three practice-based activities, collectively called the *Online Practice Suite* (OPS), supports PSTs in facilitating argumentation-focused discussions in elementary mathematics. The larger project aims to address two challenges simultaneously, one acute and the other longer-term. The first challenge is COVID's impact on teacher preparation, which has pushed methods courses online and limited preservice teachers' (PSTs) access to field work (e.g., Reich et al., 2020; Saenz-Armstrong, 2020). The second is the endemic challenge of providing PSTs authentic and appropriately scaffolded opportunities to engage in the work of teaching—ideally across different contexts and diverse student populations (Grossman, 2018; Lampert et al., 2013; Sleeter, 2001; Whitaker & Valtierra, 2018). The OPS is designed to allow PSTs to experience a carefully scaffolded set of approximations of practice (Grossman, Compton, et al., 2009), all via an online environment that is resilient to COVID-induced constraints and provides teacher educators with an alternative resource to access field placements for PSTs. It is also designed to be appropriate as a future tool for teacher development across multiple contexts, including to complement field placement, and with a goal of supporting PST learning in ways that are easily adaptable to what teacher preparation comes to be in a post-pandemic world.

In the larger project, we will study teacher educators' use and adaptation of the suite across elementary and secondary mathematics and science teacher preparation and measure PST learning via a pre/post design. The study described here draws on pilot data from implementation of the elementary mathematics OPS to explore the research question: *how do PSTs'* *understandings of, and skills in, leading argumentation-focused discussions emerge over the course of an OPS engagement semester*?

Perspective(s)

The Importance of Argumentation-Focused Discussion

Communication is fundamental to mathematics teaching and learning. In mathematics education, there is a tradition of focusing on classroom discussions as a space to examine the teacher's role in facilitating communication among students (National Council of Teachers of Mathematics [NCTM], 2014; Stein & Smith, 2011). This line of research considers whose mathematical contributions the teacher takes up, how students are encouraged to talk about their ideas with one another and how the teacher moves the class toward collective meaning-making. With recent education standards, argumentation has taken the spotlight as a preferred discursive practice for students to learn and take up (National Governors Association & Council of Chief State School Officers [NGA & CCSO], 2010). Argumentation in mathematics involves students comparing, analyzing and critiquing one another's approaches to solving mathematics problems (NCTM, 2014; Smith et al., 2008). Facilitating these kinds of interactions among students in such a way that the outcome is, in fact, productive for students' sense making is difficult (Ball, 1993; Lampert, 2001). The combination of a focus on argumentation as a goal for students and the difficulty teachers have facilitating it has drawn recent attention to how pre-service and in-service teachers learn this practice (Gosek et al., 2018; Hallman-Thrasher, 2017).

Approximations of Practice as A Site for Teacher Learning

During the last decade, there have been increased calls for a focus on practice-based teacher education to address the widespread challenge of providing opportunities for PSTs to rehearse components of complex practice, like facilitating argumentation (Ball & Forzani, 2009; Francis et al., 2018; Grossman, Hammerness, et al., 2009; Lampert, 2010). Research has shown that teacher candidates are more effective when their preparation is directly linked to practice (Association of Mathematics Teacher Educators, 2017; Goodson et al., 2019). Approximations of practice entail immersing novices in the activities in which they routinely engage during instruction (Grossman, Compton, et al., 2009). More recently, technological advances have enabled the development of digital practice spaces and virtual classrooms (such as those used in this work) to engage teachers in rehearsals. These digital practice and classroom spaces, while simplified, contain core elements and behaviors typical of real classrooms (Brown, 1999; Dieker et al., 2014), thereby providing sheltered environments for PSTs to engage in repeated practice, (Badiee & Kauffman, 2015; Garland et al., 2016; Grossman, 2010; Straub et al., 2014), and can be customized to meet a teacher educator's instructional purposes (Herbst & Kosko, 2014).

Emotions are closely connected to cognition and action, and are considered influential on how teachers make, and enact, instructional decisions (Hargreaves, 2000; Oatley, 1991). Research around teachers' emotions has increased significantly over the last decade, with studies focused on understanding the relationship among emotions and other constructs more emergent, and very little focus on how these relationships unfold in virtual learning environment. Recent work (Cross Francis et al., 2020) has shown that elementary mathematics teachers experience a complex array of emotions that vary in fluctuation patterns as teaching unfolds. These patterns served to stimulate productive teaching practices (e.g., professional noticing; Cross et al., 2017) for some teachers, while for others, they exacerbated adverse physiological and cognitive responses non-conducive to effective teaching. Virtual classroom spaces afford opportunities to systematically investigate the relationships between teachers' emotions and instructional practices and provide a supportive space for PSTs to hone their emotional regulatory skills.

Methods

Study Context: The Online Practice Suite

The practice-based activities that make up the OPS include: (1) Focused-Practice Spaces (FPS): interactive, online digital games that create targeted practice spaces to engage PSTs in considering and responding to students' content-focused ideas; (2) Avatar-Based Simulations (ABS): performance tasks that provide opportunities for PSTs to practice facilitating discussions with a group of five upper elementary avatars; and (3) Virtual Teaching Simulator (VTS): a virtual reality environment that allows for verbal, textual, and non-verbal interactions between a teacher avatar (played by the PST) and 24 student avatars in an immersive whole classroom.

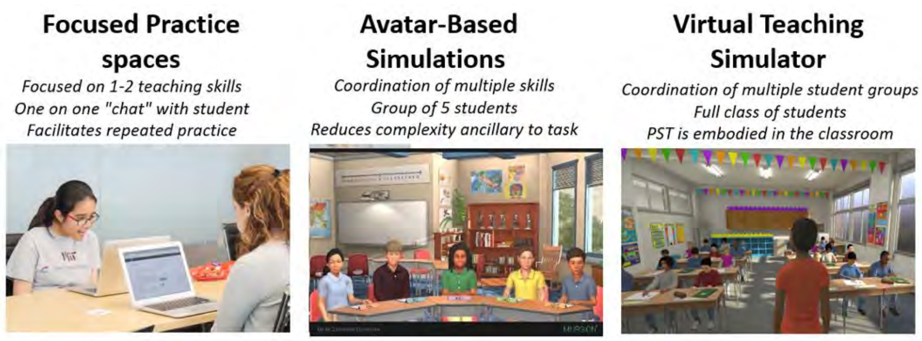

Figure 1: Activities that make up the Online Practice Suite

Participants

For the purpose of this paper, we focus on data from a pilot study involving PSTs enrolled in elementary mathematics methods courses at two different university sites in the Northeastern United States. All enrolled PSTs (24) engaged in three practice-based activities sequentially over the course of a single semester. A subset (14) consented to have their records of practice retained for research purposes; among those eight completed all required research activities.

Data Sources

Selected responses to post-activity surveys. Each PST completed a post-task survey after each activity (three time points), including a combination of Likert and open-ended responses. We analyzed items focused on PSTs' perceptions of discussions and argumentation (e.g., how they define discussion and argumentation) and items focused on PST's emotional experiences during engagement (e.g., what emotions they report feeling).

Records of practice. Each activity generates records of the PST's practice. For FPS this includes transcripts of PSTs' responses that are typed or spoken into the system; for ABS and VTS, the records are video-recordings of the PSTs facilitating small and whole-group discussions with student avatars.

Analyses

There are two phases of analyses, the first of which is complete as of the submission of this brief report. In phase one, PSTs' responses to the post-activity surveys across the three time points were coded to capture their ideas about argumentation-focused discussion and their

Olanoff, D., Johnson, K., & Spitzer, S. (2021). *Proceedings of the forty-third annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Philadelphia, PA.

emotions as they engaged in the activities. We looked across these responses for patterns present in the data set to select two cases for further investigation in phase two.

During phase two, we examined the records of practice for the selected PSTs, attending in particular the degree to which their stated understandings of what teachers should to do support argumentation-focused discussion are observable in the actual teaching moves they make during the simulations, and the degree to which we can observe evidence of their reported emotional state hindering or supporting their engagement.

Results

Phase 1 Results

A total of eight PSTs consented to participate in research and completed all three surveys. PSTs described high quality discussions and argumentation as centered around “student-to-student interaction”, and involved “critical thinking around math ideas” with a “focus on understanding”. With respect to argumentation, PSTs additionally emphasized debate grounded in defense of claims, reasoning and justification of ideas. We observed different trends in emotional experiences across the activities. Half of the PSTs (four) experienced a consistent emotion across the three activities, with two experiencing anxiety (negative) and two excitement (positive). The other four PSTs experienced a mix of positive and negative emotions.

We selected two PSTs for deeper analysis, whose responses with respect to argumentation-focused discussion and what teachers should do to support it were both robust and similar, but whose emotional experiences were quite different. Their descriptions of the teaching moves that support argumentation-focused discussion included “asking effective questions”, “promoting respectful student interaction”, “guide discussion”, “creating opportunities to hear and learn from other ideas”. One PST consistently experienced excitement, making statements such as, “I was excited to take part of an innovative experiences like this one!” whereas the other expressed anxiety in comments such as “It was new and scary. I don't know who I am talking to”.

Phase 2 Anticipated Results

We anticipate, based on initial observations of the OPS implementation, that understanding argumentation-focused discussion may be a necessary but not sufficient condition for success in leading such discussions, and that the case study PSTs may or may not consistently make the teaching moves they describe as important, although we expect to see more such moves across the time points. The role of emotion in PST learning is complex, and we hope, from this analysis, to develop provisional hypotheses about whether and how the nature of the observed emotional pattern may hinder or support learning that can then be tested in later analysis of the broader set of PST data.

Discussion

As the world recovers from COVID-19, teacher education will inevitably re-normalize, but will likely never be completely the same. It is critical that we capitalize as a field on the innovation sparked by necessity, incorporating the best inventions borne out of crisis into our future work. Technology-based interventions, such as the OPS, designed to focus on complex, content-intensive teaching practices, not only afford us a bridge to the end of the pandemic, but also a way of thinking about deliberately scaffolding PST learning around the very practices that are most difficult to learn to do well, and that PSTs are least likely to encounter by chance in field experiences. Understanding how PSTs learn from such experiences and how that learning intersects with emotion is critical in informing the design of such experiences and in helping teacher educators to make sense of and use such innovative tools effectively.

MIDDLE SCHOOL MATH PRE- SERVICE TEACHERS AND ABILITY-BASED COURSE ASSIGNMENT: EXPERIENCES, BELIEFS, AND DISPOSITIONS

Kateri A. Sternberg
University of Delaware
ksternbe@udel.edu

This study aims to understand the beliefs that middle school math PSTs hold about tracking practices in the middle grades and potential influential experiences that have lead to the development of these beliefs. Through a survey and semi-structured interviews, I examine what experiences middle school math PSTs have had with ability-based course assignment as well as what affordances and constraints they perceive for teaching and learning within tracked math classrooms. I find a lack of awareness in how course placements were determined in middle school. The lack of mobility in more highly tracked systems was seen as an important constraint for PSTs. Most PSTs did not explicitly attend to the equity aspects of detracking when presented with the idea. I propose some potential implications for math teacher educators.

Keywords: Preservice Teacher Education, Teacher Beliefs, Equity, Inclusion, and Diversity, Middle School Education

Although tracking in middle school mathematics is widespread in the United States, NCTM (2019, 2020) has called for an end to tracking due to the inequities the practice perpetuates, particularly for students of color or from families living in poverty. One potential reason that tracking persists despite these inequities is that teachers feel underprepared to teach in more diverse classrooms (Jackson et al., 2017; Loveless, 2013). To support new teachers in this effort, pre-service teachers need to be adequately prepared to teach in and promote these heterogeneous classroom environments. Since entering beliefs and dispositions often interfere with efforts to pre-service teachers to promote more diverse classrooms (Major & Brock, 2003), an initial step in this effort is to better understand the beliefs and dispositions these pre-service teachers hold as well as the experiences that have contributed to their development.

In this study, I focus on understanding middle school mathematics pre-service teachers' (PSTs) experiences with ability-based course assignment, beliefs about how course assignment should be structured, their dispositions toward more diverse classrooms, and how these three components relate to each other during teacher preparation. I build upon Garmon's (2004, 2005) framework for promoting positive change in PST's beliefs in regard to cultural diversity. This framework, posits that three types of experiences (intercultural, educational, and support group) along with three dispositions (self-awareness/reflectiveness, openness, and commitment to social justice) are key factors associated with changing PST's attitudes toward and beliefs about diversity. To address this, I ask: In what ways have middle school math PSTs experienced ability-based course assignment? What beliefs about and dispositions toward teaching and learning within tracked and non-tracked learning environments do middle school math PSTs hold? What experiences do these PSTs credit as influential in the development of these beliefs?

Background

Many teachers and administrators, even those who espouse ideals of equity and diversity, support tracking in practice (Linchevski & Kutscher, 1998). Some believe that tracking allows teachers to better match content and pedagogy to students' ability level (Garmon, 2004; Jackson et al., 2017; LeTendre et al., 2003). Some find it challenging to adequately support the full range of students in mixed-ability classes (Loveless, 2013). Despite these beliefs, heterogeneous classrooms have consistently shown more equitable outcomes than homogenous ones (Boaler & Staples, 2008; Cohen & Lotan, 1997; Linchevski & Kutscher, 1998). Although tracking may be intended as a way to meet the needs of all students, in practice students of color and from families living in poverty are more likely to be placed in lower-level courses (Battey, 2013; Morton & Riegle-Crumb, 2019). Furthermore, there is a lack of transparency in how course placement decisions are made and how early placements may restrict future course options (Akos et al., 2007; Kilgore, 1991; Rice, 1997). Historically marginalized families often do not share in the cultural capital needed to navigate this inconsistent system in ways that would advantage their children (Antony-Newman, 2019; Kilgore, 1991; McDonough, 1997).

Teachers have an important role to play in potentially disrupting the status quo of tracking, starting in middle school where most formal tracking begins. However, if teachers are to do so, they must develop equity-oriented beliefs about how middle school classrooms should be organized. One way to address this is by focusing on teacher preparation, supporting PSTs to understand the issues associated with tracking and preparing PSTs to teach in more heterogeneous settings. Teachers often enter the workforce underprepared to teach mathematics effectively in more diverse classrooms (Howard, 1999; Kitchen, 2005; Sleeter, 2001; Wiggins & Follo, 1999) and to advocate for more equitable instruction, especially when it involves disrupting the status quo (Herbel-Eisenmann et al., 2013). PSTs enter into this tracked system and must navigate the cognitive dissonance between what they may have been taught about equity in their education programs and what practices they perceive as successful in classrooms (Neumayer-Depiper, 2013; Webel & Dwiggins, 2019).

To support PSTs in developing an equity-focused stance toward tracking, we must first understand what beliefs they hold and how they developed. Causey et al. (2000) called for more research on how students' prior experiences and dispositions may influence their responses to more diverse classrooms. Major and Brock (2003) highlight that the interference of PSTs entering beliefs and dispositions create persistent problems in fostering positive dispositions toward diversity. PSTs are more likely to embrace information consistent with their existing beliefs and prior experiences and so, it is important for teacher educators to learn about these beliefs, experiences, and dispositions in order to incorporate educational experiences that will effectively challenge them (Garmon, 2005). If we wish to increase teacher advocacy for more heterogeneous classrooms for the sake of equity, PSTs must believe that more diverse classrooms are more equitable, feel confident in their ability to teach in heterogeneous classrooms, and be able to navigate the cognitive dissonance they may face between their beliefs and the practices in their schools. To achieve this, we need to better understand the beliefs PSTs hold about tracking and how these beliefs have developed through their preparation and transition from student to teacher.

Methods

To address these research questions, I first surveyed a sample of PSTs from a mid-Atlantic university who are majoring in elementary education and have chosen a second certification in middle school math. I do this to provide a broader overview of the types of experiences that PSTs in this concentration have had with tracked math environments. I received responses from 20 PSTs. From this group, I selected a sub-sample of 9 students (1 freshman, 3 sophomores, 5 juniors) to participate in semi-structured interviews. Interview participants were chosen due to varied experiences with course assignment (as indicated on the survey) and to reflect different points within their undergraduate course of study. This sample consisted of eight females and one male. Seven participants identified as White (two of whom also identified as Hispanic), one participant identified as Asian, and one participant identified as both White and Asian. All interview participants attended public middle schools in the Mid-Atlantic or Northeast regions.

The interview consisted of three components. First, the PSTs were asked to elaborate on their survey responses about their course placements in middle and high school and to reflect on how their course placements were determined. They were also asked about their own feelings toward their course placements and their level of preparedness for future math classes. Finally, they were asked about how, if at all, their university coursework has addressed components of ability-grouping or ability-based course assignment. Next, the PSTs were provided two descriptions of fictional middle school math teaching positions, one school more highly tracked than the other. They were asked to indicate in which school they would prefer to teach and to explain the affordances and constraints of each option. Finally, the PSTs were presented with an excerpt from a recent article about one district's detracking efforts (Yoder, 2020), asked to annotate the article, share their reactions, and reflect on if and how their own experiences relate to their responses.

I analyzed surveys for common themes in mathematics placement (all on-level, all advanced, mixed levels), grade of first ability-based division, and the level of awareness students had of how placement decisions were made. The interview analysis was guided by the framework of Garmon (2004, 2005) and Mills and Ballantyne (2010). I coded interview transcripts for dispositions and types of influential experiences (as student, classmate, or PST), also using open coding for beliefs related to ability-based course assignment and PST's feelings toward their own course placement.

Results

All 20 PSTs experienced ability-based course assignment, beginning between late elementary school and ninth grade. The majority of PSTs were placed in an advanced class for all or most of their math placements. None of the participants were ever enrolled in a remedial math class. Almost all respondents were aware of how (n=19) and by whom (n=18) course assignment decisions were made in high school. In contrast, about half the PSTs were aware of how (n=12) or by whom (n=8) course placement decisions were made in middle school. In interviews, students described or hypothesized what factors determined their math course placements in high school and middle school. For high school, PSTs cited that student input and grades were key factors (see Table 1 for the hypothesized factors in middle school). Furthermore, eight of the nine indicated that they felt their course placement was appropriate at least some of the time.

Table 1: Middle School Course Placement Factors by Placement Trajectory

	All Advanced	Mostly Advanced	Mostly On-Level	All On-Level	Total
Grades	3	-	2	2	7
Teacher	3	1	1	1	6
Student input	1	-	-	2	3
Test Scores	1	1	-	1	3
Guidance Counselor	1	-	-	1	2

When asked to choose where they would prefer to teach, PSTs were given two options: a more highly tracked school (Jupiter) that divided math classes beginning in 6th grade based on standardized test scores and a less highly tracked school (Zeus) that divided math beginning in 8th grade based on student choice. Four PSTs chose Jupiter and five PSTs chose Zeus. See Table 2 for the affordances and constraints cited for each school.

Table 2: Affordances & Constraints for Each School Choice

	Jupiter		Zeus	
	Affordance	Constraint	Affordance	Constraint
Match student ability	7	2	-	3
Standardized testing	3	4	2	-
Student choice	-	2	4	1
Difficulty of mixed-ability	1	-	-	5
Mobility	-	4	2	-
Student emotional wellbeing	1	1	3	-
Mixed ability classroom	-	-	3	1
Dividing on ability	2	-	-	-

Finally, when asked to respond to the article about detracking (Yoder, 2020), most PSTs were open to the idea of detracking at least somewhat, but they varied widely in their reasoning. Some interviewees focused only on the academic statistics prompting the change. Only four PSTs mentioned the equity aspects of detracking highlighted in the article and it was only the focus of the response for one PST.

Discussion and Conclusion

This study focused on examining the beliefs, experiences, and dispositions middle school math PSTs hold in regard to tracking in the middle grades. Results indicate that, while PSTs were aware of how course assignment decisions were made in high school, they experienced a lack of transparency in how their middle school course decisions were made. Lack of mobility between tracks and the use of standardized test scores were important factors that PSTs in this study considered a constraint of a more highly tracked system. The beliefs PSTs hold about course mobility and standardized testing could be potential entry points for developing equity-oriented beliefs around detracking. Notably, none of the PSTs included the practice of dividing students into classes based on ability as a constraint within a tracked system. Only two PSTs mentioned it as a benefit of the tracked school. When reflecting on the article, a number of PSTs indicated this was the first time they had heard of middle schools without this division despite being several semesters into their education program. One possible implication for math teacher educators is that they need to introduce their PSTs to such possibilities if they wish to see the PSTs become advocates for detracking. PSTs cannot question the status quo of tracking if they are unaware of alternatives.

HOW MATH ANXIETY AFFECTED MY TEACHING PHILOSOPHY: PERSPECTIVES FROM PRE-SERVICE SECONDARY MATHEMATICS TEACHERS

J. P. Mannix
North Carolina State University
jpmannix@ncsu.edu

Brianna Bentley
North Carolina State University
blbentle@ncsu.edu

Teachers with math anxiety can pass their anxiety on to students and even affect student achievement. In this project, we attempt to analyze pre-service secondary mathematics teachers' (PSMTs) feelings about how their math anxiety affects the way they view teaching as a profession. Preliminary findings indicate that math anxiety could affect multiple areas of a teacher's outlook on teaching, including preparing for class, engaging with students, and their overall philosophy about teaching. This case study can serve as a launching point for further research into how math anxiety affects both pre-service and in-service secondary mathematics teachers.

Keywords: Affect, Emotion, Beliefs, and Attitudes; Teacher Beliefs; Preservice Teacher Education

Math anxiety, defined as "an adverse emotional reaction to math or the prospect of doing math" (Maloney & Beilock, 2012), is a condition that is estimated to affect 50% of students (Beilock & Willingham, 2014) and has been shown to affect elementary education majors to a large degree (e.g., Hembree, 1990; Sloan, 2010). Unfortunately, the literature is lacking when it comes to exploring math anxiety in secondary mathematics teachers. In the research that does exist, any discussion of math anxiety in teachers is often included as a subset of discussions of identity or teacher beliefs (e.g., Ertekin, 2010; Ren & Smith, 2018; Unlu et al., 2017) A meta-analysis showed that only 28% of research articles focusing on math identity were focused on teachers, and only 17% of similar articles focused on pre-service teachers (Darragh, 2016). As such, we felt it was pertinent to dedicate this study to mathematics anxiety in pre-service secondary mathematics teachers (PSMTs).

Background

Research has shown that teacher math anxiety negatively affects student performance, particularly for female elementary teachers of female elementary students (Beilock et al., 2010). Another study demonstrated that 9th-grade students' math achievement was negatively affected by teacher math anxiety (Ramirez et al., 2018). This effect of math anxiety seems to be largely due to negative emotions expressed by teachers as they address mathematical content in the classroom, which leads to the students adopting similar attitudes that may encourage the development of math anxiety (Ramirez et al., 2018; Rozgonjuk et al., 2020; Szczygiel, 2020). This relationship presents a myriad of possible research topics, such as the prevalence of math anxiety in secondary math teachers, common experiences among secondary math teachers with math anxiety, and why someone with math anxiety would decide to become a secondary math teacher. For this paper, we decided to investigate the following research question: What areas of teaching do those with math anxiety identify as connected to their anxiety?

Methodology

Data were gathered from four PSMTs (Caroline, Rachelle, Shelby, and Willow) at a large, research-focused university in the southeastern United States. The participants initially responded to an online survey that was developed by the research team and distributed to all PSMTs at the university. After answering questions about their feelings towards math and self-reporting whether or not they had math anxiety, the potential participants either agreed or disagreed to be contacted for further research. If they agreed, they were sent a link to another survey, where they could schedule a time for a one-on-one interview with the first author.

The semi-structured interviews were conducted via online conferencing tools and lasted anywhere from 20 minutes to one hour and were composed of several questions about the participant's mathematical background and feelings about math in general. Interviews were recorded for the purpose of transcribing. The interview transcripts were analyzed individually by both authors for large themes and commonalities between participants. The interviews were coded using descriptive coding, defined as coding that "summarizes in a word or short phrase…the basic topic of a passage" and in vivo coding, which is described as "a word or short phrase from the actual language found in the qualitative data record" (Salda , 2013). These codes emerged as the transcripts were reviewed. After each author had reviewed the transcripts, we met to discuss our codes and worked together to develop our final codebook and coding scheme.

Findings

The four PSMTs included in this study shared stories about how they came to identify as mathematically anxious, and to situate the findings, we outline some of the key points from each of their narratives in Table 1.

Table 1: Math Anxiety Narratives by Participant

Participant	Math Anxiety Narrative
Caroline	Math anxiety tends to manifest in avoidance of mathematical tasks, especially homework. Grew up being told she was gifted in math, which is why she believes she was good at math; her success was not correlated to effort.
Rachelle	Remembers answering an order-of-operations question incorrectly in class, and the class laughed at her. Considered mathematically gifted growing up and felt pressure to perform perfectly.
Shelby	Intimidated by the formal language of mathematics. Might fall behind and then worries that she will stay behind and never fully understand that material.
Willow	Has had many unsupportive and disparaging math teachers. Does not believe herself to be a quick mathematician. Tends to be anxious in other STEM classes, as well.

Each of the participants in this study shared connections between their math anxiety and teaching practices. Several commonalities existed between participants, including ways in which math anxiety affected their lesson planning, experiences with students and as a student, and their overall teaching philosophies.

Lesson Planning

Each of the participants discussed how math anxiety had affected their lesson planning process in some capacity. Three of the PSMTs, Caroline, Shelby, and Rachelle, explicitly stated that their lesson planning processes were hindered by their math anxiety. These hindrances manifested in the several ways, including that participants:

- Believed they spent longer planning lessons than they should.
- Felt the need to overprepare for class or tutoring.
- Became distracted by tangential topics in their planning.
- Found themselves including too many topics in their lesson, leaving little time for practice or questions in class.
- Doubted whether they had thought of enough possible student responses, methods, or questions to be adequately prepared for class.

These PSMTs worried that they would not be effective teachers due to their anxieties about the content. Specifically they worried that they would spend too much time preparing to understand the content that they would have to sacrifice time planning how best to explore the topics with their students. Even so, Caroline looked at these hindrances through an optimistic lens, stating, “I think [math anxiety] hinders my side of the planning, but I’d like to think that it benefits the end result. The end of it is justified by the means.”

Experiences with Students

Several of the participants described how their math anxiety manifested in physical symptoms while working with students. Willow described visibly shaking and playing with her nails; Caroline also recalled times when she was so nervous to be in front of students that she would shake, stutter, and notice her palms were sweaty. Shelby noted that she would often play with her hair or twiddle her fingers, and she described her experiences with students in the following way: “When I'm actually up at the front, I am, start to finish, kind of nervous, like ‘stomach in knots’ kind of thing.” Fortunately, Shelby was able to identify events that lessened her anxiety, primarily when students would ask questions that she was able to answer confidently.

Shelby also noted that she was more at ease with the students when she did not have to be up at the front of the room. If she could meander through the desks and work with students on a more individualized basis, she noticed that her anxiety was lower than when she was standing at the board. Willow also attributed her ease in the classroom to primarily having had experiences working one-on-one with students. These interactions led her to get to know her students better, which also lessened her anxiety in the classrooms. As such, these PSMTs came to realize the importance of developing meaningful relationships with their students.

Caroline described her experiences leading class as “diving off the diving board into the deep end of the pool.” At the beginning of a lesson, she might be nervous, but as she received positive feedback from her students that they were understanding the material, her anxiety went away. She also noted that if she received negative feedback from the students, her anxiety increased and caused her to doubt her knowledge of the content and abilities as an instructor. Similarly, Rachelle remembered a time when she was tutoring a 4th-grade student and felt helpless upon encountering a method for multiplying two-digit numbers that she had not seen before. “I felt clueless and incompetent. I thought ‘Am I smarter than a 4th grader? No.’ I was there to help her, and I couldn’t do anything about it. That was stressful.” Rachelle used this opportunity to revise her thinking by researching the method that the student wanted to use. In the end, she found that she really enjoyed the method, so much so that she "used it on the SAT." Because of their experiences, these participants developed an appreciation for the feedback they received from students and the effect this feedback could have on their anxiety in the math classroom.

Teaching Philosophies

In accord with the lessons learned through their experiences with students, each of the PSMTs' teaching philosophies centered on the relationship between the teacher and the student. Each of our participants expressed a unique point of view when it came to their philosophy, but when taken together, they created a cohesive picture of a thoughtful classroom.

Willow set the scene by envisioning a classroom where students feel welcome and open to "contribute without being shamed or [made to] feel like they can't ask questions." She believes that math is a broad subject to be explored by all students, not just a select few. Caroline echoed this sentiment in her musings, stating that "every student is great and has potential, and every student can do what they put their mind to." She believes that no student is unable to succeed in math or any other academic subject, for that matter.

Shelby seemed to agree with Caroline, but she issued a word of warning in her philosophy. She cautioned against "hyping someone up too much," citing this as something that happened to her in school and saying that it was detrimental to her in the long run. She encouraged teachers to meet students where they are, academically and developmentally, without making the students feel like they are better or worse than they really are. Her final thoughts hearkened back to Willow's sentiments about "creating a very hospitable environment where students can speak up about concerns."

While Rachelle shared many of the sentiments expressed by her peers, particularly about creating wholesome, safe environments for students, she shared that she was leaving the College of Education at the end of the semester because of her math anxiety. She came to realize that she "was probably drawn to teaching more for connecting with people than the actual teaching itself." Rachelle had struggled to complete her Calculus sequence, and she developed the mindset that she might not have the content skills necessary to be a truly excellent math teacher. For her, being good wasn't good enough, and for the sake of her future students, she decided to leave the profession before her career even started.

Discussion and Implications

The four PSMTs in this study each developed math anxiety in unique ways, but they shared many similarities in their teaching philosophies. Each of the participants recognized that their anxiety might cause them to spend additional time preparing for class when compared with their non-mathematically anxious peers. They also believe that a positive teacher-student relationship is a critical component of any successful math classroom.

The findings presented in this paper indicate that there is a viable research agenda in the realm of math anxiety in secondary mathematics teachers. Future research might address any of a litany of questions, including:

- How prevalent is math anxiety in secondary math teachers?
- Are there common experiences among secondary math teachers with math anxiety?
- What other facets of a secondary math teacher's career are affected by math anxiety, and how so?
- What causes people with math anxiety to decide to become secondary math teachers?

The answers to these questions, and many more, will help us to better serve our students in math classes across the country and around the world. By determining the causes and effects of math anxiety in secondary math teachers, we can work toward reducing the prevalence of math anxiety, thereby opening the doors to untold mathematical endeavors for students, and teachers, everywhere.

'MY HOST TEACHER'S MATH TIME': POWER DYNAMICS DURING ENACTMENTS OF STUDENT-CENTERED ROUTINES IN FIELD PLACEMENT

Brendan Dames
University of Missouri
btdppf@mail.missouri.edu

Corey Webel
University of Missouri
WebelCM@missouri.edu

In this paper we share data regarding preservice teachers' (PSTs') experiences enacting a number talk routine within a clinical experience, focusing on the ways that the PSTs' described their mentor teachers' influence on the routine. In particular, we describe the case of Ms. Brooks, a PST who lamented several instructional decisions made by her mentor teacher, including interrupting the routine with questions and comments that countered the goals of the number talk routine. The case of Ms. Brooks' challenges can help teacher educators consider the ways they might support PSTs' learning in situations where routines like number talks might come into conflict with status quo practices and instructional norms within clinical experiences.

Keywords: Instructional activities and practices, Preservice teacher education

Effective teacher preparation features coordination between methods courses and hosting schools where preservice teachers (PSTs) have opportunities to observe and practice teaching prior to certification (Darling-Hammond & Bransford, 2005). At the same time, mathematics teacher educators are developing programs, courses, and assignments to explicitly "help beginning teachers challenge deficit views about learning by questioning the status quo at a systemic level" (Association of Mathematics Teacher Educators, 2017, p. 35; see also White, Crespo, & Civil, 2016). This includes interrogating instruction that privileges only certain kinds of mathematical competence or certain kinds of students. Importantly, this type of instruction is likely occurring at sites where PSTs are engaged in clinical experiences.

Within most traditional models, clinical experiences are usually wide-reaching, obligatory activities where preservice teachers are socialized into a teaching space and develop a teaching identity (Bolton, 1997). The novice-to-expert frame generates an inherent power imbalance between the positioned novice and expert, which can lead to professional conflict, novice complicity in reinforcing the status quo, and/or missed opportunities for shared learning (Graham, 1993; Graham, 1997; Valencia et al., 2010). Further research is needed in the development of positive, productive student teaching placements which supports productive interaction between preservice teacher and mentor teacher (Darling-Hammond, 2006; Tang, 2003; Graham, 1999) and also enables novices to develop visions of equitable instruction.

Within this paper, we explore tensions inherent in clinical experiences during PSTs' enactment of a student-centered, number talk routine. Number talks feature class discussions focused on building students' number sense through exploring multiple strategies, shared student-teacher authority, and opportunities for public praise of student ideas (Parrish, 2010). In particular, we ask, "In what ways do host teachers' impact the enactment of the instructional routine, as noted by PSTs in their reflections on the enactment?"

Methods

Context. This study took place within a traditional undergraduate teacher education program at a large state university in the Midwestern United States, during the year prior to student teaching. As part of the program, PSTs were required to spend 60 hours over the course of the semester in an elementary classroom that was assigned by the university. Several of their methods course assignments required them to engage in and/or reflect on their experiences in their field placement classes. In their elementary mathematics methods course, taught by the second author and assisted by the first, PSTs were asked to create and rehearse number talk routines before enacting one with students in their respective host classrooms.

Data Collection. PSTs captured audio recordings of their enactment, which were later reviewed by a classmate and a course instructor. All three parties utilized a video annotation tool (VoiceThread) to provide time-stamped comments on their enactment.

Data Analysis: In reading PSTs' annotations on their recorded number talk routines, the authorship team noticed several PSTs mentioning their host teacher's influence on the enactment. We categorized these in terms of whether the influence was supportive (e.g., aligned with the goals of a number talk) or detractive (opposed to the goals of a number talk), and then attended to the ways that PSTs characterized the host teachers' influence. In particular, we focused on tensions that PSTs sought to navigate between the expectations embedded in the number talk assignment, the expectations of their host teachers, and their own ideas about mathematics teaching and learning. In this paper, we feature an episode involving a PST, Ms. Brooks, and her mentor teacher, Ms. Smith, in order to exemplify some of these tensions.

Results

Patterns in PSTs' mentions of mentor teacher's influence. Of the 17 PSTs in the elementary methods course, seven (including Ms. Brooks) added video annotations that mentioned actions or expectations of the host teacher in their implementation of the number talk routine. Two of these seven PSTs described ways in which host teachers supported the routine, such as one PST who shared they were "glad Ms. Donaldson (pseudonym) caught me & told me to change the [marker] color," a consideration when representing student thinking to provide easier access to various students' strategies.

Five of the seven PSTs, including Ms. Brooks, made comments about ways their host teachers detracted from their ideal enactment of the number talk routine. Three of these 5 PSTs only shared ways in which teachers influenced the enactment in non-math specific ways, such as being pressed for time, as illustrated in the following anecdote:

> "My teacher basically only allotted 10 minutes just because they had a really busy math schedule and the time was running out. So after the turn and talk she kind of signaled to me to wrap it up, and that kind of made me a little flustered, so I wish that I had had them discuss what they had just talked to her neighbors about."

The case of Ms. Brooks. Ms. Brooks' discussion of Ms. Smith's influence on her number talk enactment was particularly revealing. In the recording, Ms. Smith introduced Ms. Brooks' number talk routine with the following message:

> Alright, Ms. Brooks is gonna kind of do a little warmup with some number stuff. So your attention needs to be on her and I expect you to have all the same rules with her as you do with me. You sit on your bottom, you have learner look, you face forward, you raise your hand if you have something to say. Ok? They're all yours.

After providing students with the procedures of a number talk, Ms. Brooks asked her 3rd grade students to mentally solve 33+ 58. Later, when addressing the allocated time, Ms. Brooks shared her desire for more time, but also sought to comply with Ms. Smith's expectations.

In my own classroom, I may have waited a little longer, but I wanted to make sure we could get through plenty of strategies without taking up too much of my host teacher's math time.

In the episode, Ms. Brooks collected student answers and then asked individual students to share their ideas, representing their strategies in various colored markers on the whiteboard. The first two students shared solutions based on number decomposition, which featured a “turn and talk” opportunity, verbal questioning and praise from Ms. Brooks, and no engagement from Ms. Smith. A third student, Josie, then shared that she “did the numbers up and down.” As Ms. Brooks asked Josie to clarify her words by asking “Up and down?”, Ms. Smith interjected by saying “So you’re doing the algorithm?” Josie agreed, proceeding to explain the required steps of the multi-digit addition algorithm (see Figure 1). Ms. Smith praised Josie for her explanation, stating “Very good. We haven’t had anybody explain that yet. That was excellent. Very good.”

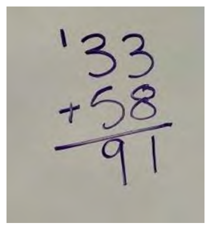

Figure 1: Ms. Brooks’ representation of Josie’s solution

Next, Ms. Brooks praised the clarity of Josie’s explanation, and then called upon Milly to share her solution strategy. While sharing, Ms. Brooks asked Milly “Can I pause you for one second? So you said five plus three…,” to which Milly responded, “equals 11.” While Ms. Brooks prepared to continue questioning, Ms. Smith interjected and had the following exchange with Milly:

Ms. Smith: Five plus three got you 11?
Milly: Wait, no nine.
Ms. Smith: I think, I think you were right on the first one where you said 3 plus 5 is 8 but it really should be 9 because what do you want to do with your answer?

The dialogue continued, concluding with Ms. Smith asking Milly, “so you want to change it, right? OK.”

After a final student shared his strategy, Ms. Brooks concluded the routine by praising the students’ mathematical thinking and identifying them as “good math thinkers,” before asking them to give themselves a round of applause. Ms. Smith agreed, and concluded the experience with the following words of her own:

> “And I also liked to see you work with another teacher because it shows what you’ve learned from the beginning of the year until now. Because I would say most of you probably couldn’t have explained all of this at the beginning of the year and now you can. And we’re talking about open number lines, tens and ones, the algorithm, you know, regrouping, all those really good things.”

Tensions revealed in the episode and Ms. Brooks’ reflections. In this episode, while Ms. Smith and Ms. Brooks were both heard praising and questioning students throughout the recording, the ways in which they did so differed. Ms. Brooks provided verbal praise to each student who shared a strategy, projecting equal value for each strategy. Ms. Smith, on the other hand, interjected to praise Josie's algorithmic solution, and then again did so for Milly's use of the standard algorithm. These interjections, in our view, signaled a high value placed on procedural competence, undermining the number talk's emphasis on multiple strategies and the employment of place value reasoning.

When questioning students, Ms. Brooks primarily asked students to re-voice, further explain and/or interact with other students' ideas, or utilized strategies such as having turn to a partner and talk about a specific idea that had been raised. Ms. Smith's questions primarily required recall and led students to a desired response, as seen in her exchange with Milly. Ms. Brooks noted these differences in her annotations, stating:

> I wish my host teacher hadn't broken in here. I would have liked to have gotten through the rest of the thinking and asked her a few more questions about it to see if [Milly] would have come to this conclusion and changed her mind on her own… I would have continued letting her talk through the strategy, then I may have asked the other students if anyone had any questions for her…or had them turn and talk about how two people got two different answers.

Ms. Brooks' peer reviewer, a classmate, agreed, noting:

> Yes! I wish she wouldn't have said anything. Allowing the student to continue to talk through it would have been a great teaching experience for you & the students. A turn & talk would have been great here as well.

Ms. Brooks also noted that she had wanted to close the number talk with an emphasis on the importance of "being able to change our minds [as] a great way to be smart at math," and suggested that "it probably would have helped if [Milly] had come to the conclusion on her own instead of with the teacher's help." Instead, the routine closed with Ms. Smith's emphasis on demonstrating the various ways in which they had "learned" new ways of doing mathematics throughout the school year, including the algorithm and re-grouping. Despite the challenges in its enactment, Ms. Brooks expressed a desire to use number talks in her future classroom:

> I am really looking forward to incorporating number talks into my future classroom. I think they are a really powerful way to build the big ideas behind math concepts, keep older content fresh in our minds, teach students how to respectfully engage with others' ideas, and build students' confidence and comfort with math.

Conclusion

Though Ms. Brooks was able to acknowledge and reflect upon the conflicting pedagogical goals apparent throughout this enactment, we are struck by Ms. Smith's use of her position and power to reinforce traditional emphases on computation in the midst of a PST's efforts to enact a student-centered talk routine. We also acknowledge that Ms. Smith has been placed into a difficult position with the number talk assignment. Ostensibly, the practices being used by Ms. Brooks were uncommon in her classroom, and there are many reasons why their use could cause discomfort, including concerns for students about the use of unfamiliar routines and possible even perceived implications about her own instructional approaches. Thinking about this episode from the perspective of both Ms. Brooks and Ms. Smith raises questions about the use of such assignments in methods classes and the need for further consideration of potential conflicts with status quo practices and instructional norms in host classrooms. In particular, we are interested in considering, on the one hand, how to better support host teachers to learn about and develop comfort with such routines in their classrooms, and, on the other hand, how we might be more intentional about the assignment of PSTs to host classrooms.

Further research could investigate each of these possibilities, to better understand how the power invested in experienced teachers might be utilized to challenge rather than reinforce the status quo, and to explore the implications this might have for novice teachers' future classroom practices.

FEAR OF FAILURE OR LACK OF MOTIVATION? UNDERSTANDING THE MATHEMATICS ANXIETY OF ELEMENTARY PRESERVICE TEACHERS

Amy M. Olson
Duquesne University
olsona@duq.edu

Kathleen Jablon Stoehr
Santa Clara University
kstoehr@scu.edu

Mathematics educators agree that elementary teachers should possess confidence and competence in teaching mathematics. Yet many preservice elementary teachers pursue careers in elementary teaching despite repeated experiences of mathematics anxiety. Previous studies have defined and documented a range of different experiences of mathematics anxiety related both to learning mathematical content and to pedagogical skill to teach mathematics. This study analyzes the reported experiences of forty-eight preservice elementary teachers in relation to the range of different experiences documented in the literature.

Keywords: Pre-Service Teacher Education; Affect, Emotion, Beliefs, and Attitudes; Teacher Beliefs

Purpose of the Study

High proportions of elementary preservice teachers (PSTs) have been shown to struggle with mathematics anxiety, both as students (Beilock et al., 2010; Olson & Stoehr, 2019; Stoehr & Olson, 2017) and as developing teachers (Brady & Bowd, 2005; Brown et al., 2011; Bursal & Paznokas, 2006; Gresham, 2007; Marbán et al., 2020; McGlynn-Stewart, 2010; Peker, 2009; Sloan et al., 2002). The negative impact of generalized mathematics anxiety on the education and development of elementary mathematics teachers has been well studied (Ball, 1988; Bursal & Paznokas, 2006; Ma, 1999; Mizala et al., 2015; Roberts & Maiorca, 2020; Sanders et al., 2019). However, in order for teacher educators to support the development of confident and competent mathematics teachers, they must first understand the specific experiences PSTs have with mathematics anxiety (Beilock et al., 2010; Bursal & Paznokas, 2006; Johnson & vanderSandt, 2011; Mizala et al., 2015; Sloan et al., 2002; Stoehr & Olson, 2017; Swars et al., 2006).

The Role of Elementary Methods in Supporting PSTS to Cope with Mathematics Anxiety

Mathematics methods courses offer an appropriate space for teacher educators to help support PSTs to process and begin to cope with mathematics anxiety (Ganley et al., 2019). A number of studies have focused on how to construct appropriate learning opportunities in methods courses where PSTs can acknowledge and cope with mathematics anxiety while they are supported to (re)learn elementary mathematics content and pedagogy (Gresham, 2007; Harper & Daane, 1998; McGlynn-Stewart, 2010; Sloan et al., 2002). For example, Harper and Daane (1998) demonstrated that more than 80% of PSTs in their course experienced reduction in mathematics anxiety when the instructors incorporated a student-centered discussion style rather than lecture-based teaching. Gresham (2007), McGlynn-Stewart (2010), and Sloan (2010) added to the understanding of student-centered possibilities using a variety of teaching strategies, heavy use of manipulatives, problem-solving opportunities, and cooperative learning experiences. In all these studies, the kinds of mathematics classrooms we hope to see at the elementary level were modeled for PSTs, with the result of improving PST confidence and competence with the content and pedagogy.

Theoretical Framework: Mathematics Anxiety

The literature demonstrates five major ways mathematics anxiety is defined and studied. First, some researchers frame mathematics anxiety in affective or emotional ways. From these perspectives, mathematics anxiety is a "state of discomfort" triggered by mathematical stimuli (Trujillo & Hadfield, 1999, p. 173). For some people, this discomfort may be mild, but anxious populations often report more intense emotional experiences including fear, panic, shame, and hatred (Jensen et al., 2020; Tobias, 1978; Swars et al., 2006).

Another way researchers study mathematics anxiety is through a physiological rather than emotional lens. For example, Luo et al. (2009) describe mathematics anxiety as a type of fight or flight response, complete with physical reactions such as increased heart rate, sweaty palms, and shortness of breath. Researchers taking this perspective examine how the body engages in a hormonal stress response to a threat assessment triggered by mathematical stimuli.

Some researchers define mathematics anxiety as a type of performance anxiety. This perspective argues that anxious feelings are elicited by the possibility of failure (Trujillo & Hadfield, 1999). A number of researchers taking this approach have looked at the associations between test anxiety and mathematics anxiety (e.g., Brady & Bowd, 2005; Bursal & Paznokas, 2006; Olson & Stoehr, 2019), particularly as it relates to fear of failure. However, individuals may experience mathematics anxiety even when contemplating mathematics, with no plans to engage in a mathematical performance (Hembree, 1990).

The fourth approach examines the relationship between mathematics anxiety and self-beliefs, such as self-esteem, self-efficacy for mathematics, and identity as a "math person" (Lee, 2009; McGlynn-Stewart, 2010; Stoehr & Olson, 2015, 2017). As a way to explore and potentially treat mathematics anxiety from this approach, researchers have used retrospective and autobiographical approaches to explore the potential causes of mathematics anxiety (Hadfield & McNeil, 1994; Usimaki & Nason, 2004). Such studies have demonstrated that humiliating experiences in K-12 mathematics lessons are associated with later experiences of mathematics anxiety (Brady & Bowd, 2005; Dowker et al., 2016, Stoehr & Olson, 2017; Usimaki & Nason, 2004). However, it is also clear from this body of work that the third and fourth approach are not discrete: whether poor performance causes negative self-beliefs about mathematics or whether negative self-beliefs cause poor performance remains unclear.

The last approach examines motivational effects. Correlational work demonstrates that the experience of mathematics anxiety results in decreased motivation and interest engaging in mathematical contexts (Hembree, 1990; Luo et al, 2009). Mathematically anxious individuals are also more likely to opt out of optional and advanced mathematics courses (Beilock et al., 2010; Brady & Bowd, 2005), which is believed to contribute to the negative relationship between mathematics anxiety and mathematics achievement (Hembree, 1990; Ma, 1999).

The study of mathematics anxiety is not new, but the varied affective, physical, performance-oriented, self-oriented, and motivational constructions and approaches may make it more challenging for teacher educators to predict what sorts of experiences of mathematical anxiety PSTs bring to their classroom. In an attempt to begin to explore this issue, the research question that guided this study was: What attributes do elementary PSTs use to describe their experiences of mathematics anxiety?

Methods

Participants and Context

The participants included 48 PSTs (n = 45 identified as women, n = 3 identified as men) enrolled in a 20-week elementary methods course as part of their Master's level initial certification program at a small, private university, located in the western United States. The participants included twenty-four White women, eight Latinas, nine Asian women, two African American women, one Indian woman, and one Persian woman. There were also two men who identified as Latino and one man who identified as Asian. The PSTs were primarily in their early to mid-twenties.

Data Sources

Each PST wrote a mathematics autobiography as part of the methods course. Additionally, the PSTs were asked to reflect on individual experiences that occurred when they were students of mathematics and how their experiences impacted their attitude towards understanding mathematics. They were also asked to think about how their own mathematics experiences might impact their role as teachers. These narrative sources provided a view of their experiences with mathematics and mathematics anxiety.

Data Analysis

We began our analysis by separately reading through each of the 48 PSTs' written prompts. We engaged in an iterative analysis (Bogdan & Biklen, 2006) by demarcating sections that pertained to the ways in which the PSTs experienced episodes of anxiety in learning and teaching mathematics. We identified key words in these sections and then compared the demarcated words and phrases to the five attributes of mathematics anxiety described in the literature (affect, physical, performance, self-beliefs, and motivation). Individually, we coded each word or phrase and then met to compare our coding. We then reconciled our differences in coding and added and/or redefined any codes until we reached a 100% inter-rater reliability.

Findings

Table 1 shows the keywords and phrases each PST associated with mathematics anxiety. The table is sorted from most prevalent to least prevalent. In total, 87 unique words and phrases were coded. Of these, 33 were coded as performance, 27 were coded as affect/emotion, 14 were coded as self-beliefs, 7 were coded as physical, and 6 were coded as motivation.

Table 1: Key Words PSTs Used to Describe Experiences of Mathematics Anxiety

Attribute	Key Words and Phrases
Performance	Completely lost, Difficult, Struggled with understanding concepts, Did not make sense to me, Just plain hard, Struggling so much, Dreaded math class, Slow learner, Struggled, Trying to live up to others' perceptions of me, Extremely afraid to make mistakes, Tedious chore, Cloud of failure looming over me, Repeated 4th grade because of low scores, Abandoned and forgotten by teachers, Not important to teachers, Merely surviving, Hours of work to try and keep up, Placed in remedial math classes, My grades lowered, Left behind, Experienced real struggles with math, Hard for me to keep up, Hard to search for help, Too confusing, Too many steps, Missing key concepts, Falling behind, Felt rushed, Always a few steps behind, Punished for being slow, Failed miserably, Could not "get" math

Affect/Emotion	Nervous & scared, Devastating, Defeated, Despised math, Fear, Despair, Sadness, Embarrassed, Discouraged, Intimidated, Feeling hopeless, Frustrated, Burn out, Stopped enjoying math, A scary shadowy figure, Afraid to take risks, Pressure, Negative attitude, No sense of enjoyment, Isolated, Confused, Stressed me out, Painful & torturous, Shamed, Insulted, Helpless, Humiliated
Self-Beliefs	Lacked confidence, Felt stupid, Not smart enough to do math, Not quick enough, Might not be good at math, Not able to ever understand, Never be good enough, Unsure, Extremely dumb, Confidence in math plummeted, Hurt my self-esteem, Felt inferior, math is not my thing, math is not my strong suit
Physical	Felt sick to my stomach, Tears, Heart racing a million times a minute, Panic attack, Made my stomach turn, Want to cringe and hide, Negative gut reaction
Motivation	Closed the door on math, Gave up, Journey with math ended, Avoid math altogether, Turned off from math, Felt apathetic towards math

Discussion

Previous research has clearly documented that many elementary PSTs have experienced mathematics anxiety while learning mathematics and learning to teach mathematics (Beilock et al, 2010; Brady & Bowd, 2005; Brown et al., 2011; Bursal & Paznokas, 2006; Gresham, 2007; McGlynn-Stewart, 2010; Olson & Stoehr, 2019; Peker, 2009; Sloan et al., 2002; Stoehr & Olson, 2017). Our study confirms that PSTs continue to experience mathematics anxiety while learning mathematics content and learning to teach mathematics and supports previous research that has established that mathematics anxiety cannot be approached from a one size fits all perspective (Bursal & Paznokas, 2006; Hembree, 1990; Luo et al., 2009; McGlynn-Stewart, 2010; Trujillo & Hadfield, 1999). However, our study adds to the literature by presenting the different ways that anxiety manifests in this population. As Table 1 demonstrates, the most common reflections include PSTs recalling performance deficits and emotional responses to mathematical contexts. Research with this same group of PSTs is currently ongoing with an examination of how their intended coping strategies align with their individual experiences of mathematics anxiety. Future research is also needed to confirm these findings across different populations of elementary PSTs and to relate their autobiographical and retrospective findings to the professional experiences of mathematics anxiety teachers may have once they enter the classroom.

Current events have underscored the need for mathematics teachers to facilitate and engage in critical conversations of social justice in their secondary classrooms. After completing a social justice mathematics course, three prospective mathematics teachers (PMTs) and one prospective teacher educator engaged in a critical participatory action research study to explore: (a) how to support PMTs as they engage in social justice mathematics; and (b) how PMTs engage secondary students with social justice mathematics. This study informs ongoing efforts to support PMTs' development of critical mathematics literacy. Furthermore, this study provides an example of the possibilities of engaging PMTs in collaborative research that serves to (a) reemphasize and amplify teachers' voices; (b) support PMTs to engage their students in social justice mathematics; and (c) encourage PMTs to connect education research into practice.

Keywords: Equity, Inclusion, and Diversity, Social Justice, Preservice Teacher Education

Current events, including the climate crisis, racial capitalism, white supremacy, and the global coronavirus pandemic of 2019, have underscored the need for teachers, including those of mathematics, to facilitate and engage in conversations of social justice with their students (Gutstein, 2020). As such, prospective mathematics teachers (PMTs) can benefit from an introduction to critical mathematics (Frankenstein, 1983; Skovsmose, 1994), or social justice mathematics (Gutstein, 2007; Kokka, 2015), which similarly utilize mathematics to understand current social realities (i.e., *read the world*) in order to change (i.e., *write*) the world (Gutstein, 2006, 2020). Learning to read and write the world with mathematics promotes the use of mathematics to model and shape a more socially just world (Gutstein & Peterson, 2013). Social justice mathematical tasks have shown promise for highlighting the voices and experiences of students of color (Harper, 2019) and supporting students' development of socio-political understandings (Rubel, 2017). Recently, Berry et al., 2020 summarized the benefits of engaging secondary students in social justice mathematics tasks: (a) "build an informed society; (b) connect mathematics with students' cultural and community histories; (c) empower students to confront and solve real-world challenges they face; and (d) help students learn to value mathematics as a tool for social change" (p. 23). Our study supports PMTs' development of social justice mathematics pedagogies after completing *Knowing the World Through Mathematics (KWM;* Lolkus & Newton, 2020), a social justice mathematics course Lolkus designed and taught in Fall 2020.

Lolkus continued collaborating with three of the 11 PMTs post-*KWM*. The three PMTs (i.e., Grimes, Adkison, & Miller) and Lolkus (hereafter "the research team", or "we") engaged in a critical participatory action research (CPAR; Kemmis et al., 2014) study in which we explored how to support PMTs' as they developed and interrogated social justice and mathematics pedagogies and engage secondary students with social justice mathematics. In this study, each member of the research team was positioned a as co-researcher; a process that allowed Lolkus to engage in research *with*, not *on*, PMTs (Vithal, 2004) as they developed social justice mathematics practices in secondary classrooms. Engaging in this CPAR provided opportunities for the PMTs to reflect on their social justice mathematics instruction while also further developing their expertise and professional status in the field as full participants in the research and teaching communities (Wenger, 1998). In this CPAR study, we investigated two research questions: (a) how do PMTs engage with social justice mathematics? and (b) how do PMTs engage their students with social justice mathematics?

Relevant Literature & Theoretical Perspectives

We designed our study based on the findings of social justice mathematics education research, a social theory of learning, and the qualities of critical research. Gutstein and Peterson (2013) encouraged teachers and teacher educators to connect liberatory education to the lived experiences of students and to trends in society beyond the classroom through engagement with "critical mathematics literacy" (Frankenstein, 1983, 1990; Skovsmose, 1994). Drawing on Freire's (1970/2018) theory of liberatory education, scholars have defined critical mathematics literacy as the specific understandings about how mathematics can be used to determine whose knowledge is valued (Frankenstein, 1983, 1990; Skovsmose, 1994). Mathematics teacher educators, like Lolkus, have a responsibility to ensure that PMTs are prepared to support their secondary students in learning to *read* and *write* the world with mathematics (Gutstein, 2006). Our research builds on these perspectives to prepare teachers to facilitate and engage in critical conversations about social justice issues in their secondary mathematics classrooms.

Our research is informed by Wenger's (1988) social theory of learning in that our processes of learning and knowing were characterized by participation in our situated and social communities of practice. From this perspective, the research team collaboratively constructed (e.g., Cobb et al., 1990; Vygotsky, 1978) our understandings of social justice mathematics in *KWM,* this CPAR study, and in secondary classrooms, or our shared communities of practice (Lave & Wenger, 1991; Wenger, 1998). Throughout our collaboration, we integrated all three of Wenger's modes of belonging (i.e., *engagement*, *imagination*, *alignment*) as we negotiated our participation and developed common discourse, aims, and practices.

We draw on Skovsmose and Borba's (2004) qualities of critical research (i.e., *current situation, imagined situation, arranged situation*). Analysis of the *current situation* refers to our development of an understanding and recognition of the historical and social contexts that limit our engagement with liberatory and social justice-oriented instruction. As we develop ideas for things that could be (i.e., *imagined situation*), we work toward implementation of the *imagined situation* with consideration of the structural and practical limitations of our contexts (i.e., *arranged situation*). Whereas CPAR is similar to other research methods (e.g., reflective teaching [Schön, 1983; Zeichner & Liston, 2014]), it also incorporates the imagination of, and action toward, a better future (Avci, 2020). Thus, we engaged in CPAR, not through the focus on *what is*, but the focus on *what could be* (Skovsmose & Borba, 2004). Through our research design centered around these concepts, we investigated alternative constructions (Lincoln, 2002) of mathematics pedagogies through social justice mathematics in secondary classrooms.

Methods

Drawing from the CPAR process: (a) planning, (b) acting and observing, (c) reflecting, (d) revisiting the plan, (eIcting and observing, and (f) reflecting (Kemmis et al., 2014), we worked to extend participatory action research by adding a critical approach and utilizing a dialectical perspective on practice (Kemmis, 2011). Beginning in Spring 2021, the research team conducted analyses and reflected on the connections between our ideas for teaching realities that promote social justice mathematics (i.e., *imagined situation*), and our work toward that implementation with consideration of the structural and practical limitations of our contexts (i.e., *arranged situation*; Skovsmose & Borba, 2004). Our CPAR design "invites [PMTs] to engage in education as a double process of helping students to live well, and helping to form a world worth living" (Kemmis, et al., 2014, p. 70). This approach is aligned with Gutstein's (2006) notion of promoting critical mathematics literacy development for students to *read* and *write* the world with mathematics.

Participants and Setting

Three of the 11 PMTs (i.e., Grimes, Adkison, & Miller) in *KWM* volunteered to participate in the CPAR study. All three PMTs identified as white women, a relatively homogenous population that is also representative of the teaching force (Marx & Moss, 2011). Adkison and Miller engaged their secondary students in social justice mathematics during their student teaching field placements in two suburban midwestern cities. In the same city as Adkison, Grimes collaborated with her students in the semester prior to student teaching. The research team became familiar with each other through interactions in class (i.e., *Methods II*, *KWM*), as well as weekly CPAR meetings. While Grimes, Adkison, & Miller knew each other from other classes and contexts, our ongoing meetings allowed Lolkus and the PMTs to get to know one another better, which is necessary for establishing partnerships amongst the research team (Pitts & Miller-Day, 2007) and decentering traditional researcher-participant power relations (Råheim et al., 2016).

Sources of Evidence

As we engaged in the CPAR process, we heeded Kemmis' (2011) recommendations to engage in critical self-reflections of our prejudices and perspectives own understandings of how students learn and why we adhered to those beliefs. From our insider-outsider perspectives (i.e., participant, PMT, researcher), our reflections related to the *arranged situation* provided us with opportunities to modify the research process (i.e., reflexivity). The research team collected multiple sources of evidence and documentation, including written reflections from the PMTs and secondary students, as well as written documentation of social justice mathematics implementation (e.g., lesson plans, mathematical tasks, class handouts).

Nature of Analysis and Interpretation

Essential for CPAR methods (Kemmis et al., 2014; Vithal, 2004), PMTs negotiated their continued participation in the project after completion of *KWM* through (a) active engagement in the coding and writing processes, (b) member checking and revising written drafts of all deliverables, and (c) delivering professional presentations. The research team engaged in thematic analysis (Braun & Clarke, 2012) of all documentation (i.e., written reflections, field notes, enacted mathematics tasks). As an investigation and organization of common themes across evidence sources, Braun and Clarke suggest that thematic analysis is beneficial for novice researchers because it teaches the mechanics of analyzing evidence while encouraging connections to broader theoretical and conceptual ideas.

We attended to the trustworthiness of our evidence through an 18-month-long collaboration and development of shared discourse to ensure our findings were credible, dependable, and transferable (Lincoln & Guba, 1985). Each source of evidence was evaluated by at least two members of the research team to support the triangulation of our findings (Flick, 2018) through open coding. To further ensure ensure we established trustworthy results, we maintained detailed documentation of the coding and debriefing processes, engaged in peer debriefing, and kept reflexive journals throughout each phases of our thematic analysis process (Nowell et al., 2017).

Results

We identified three preliminary themes in the three PMTs' weekly unstructured teaching reflections, weekly CPAR meeting semi-structured reflections, secondary student questionnaires and exit tickets, and curricular documents.

Classroom Environment

In order to effectively engage in social justice mathematics, all three PMTs shared an affinity for first developing a safe and supportive classroom environment that would encourage their secondary students to fully engage in what could be challenging conversations about issues of social justice. Each of the PMTs prioritized developing relationships and subsequently, trust, with students while also working to keep students at the center of activities with group-worthy tasks. Over the course of the semester, each of the three PMTs engaged their secondary students in at least one social justice mathematics activity, covering topics pertaining to climate change and gender inequities in STEM disciplines.

Rigorous Mathematics

The PMTs named that ensuring their students had access to rigorous mathematics was, in and of itself a social justice issue. As such, the PMTs prioritized engaging their students in rigorous mathematical tasks throughout their teaching experiences. While the PMTs worked to simultaneously promote rigorous mathematics and social justice issues, they reflected that developing their own social justice-focused mathematical tasks was challenging. Despite having pre-existing resources available (e.g., Berry et al., 2020), the PMTs either modified or developed their own lessons to promote social justice issues relevant to them and their students (e.g., climate change, women in science).

Discomfort

Beginning in *KWM*, the PMTs shared an underlying discomfort with engaging in social justice conversations they were not experts on, nor having experienced many of the social justice issues first-hand. This perceived tension between the PMTs' identities as white women and their racially diverse students resulted in a mantra from *KWM,* that as white teachers, we need to be comfortable with being uncomfortable. Meaning, as we engage in conversations about race, or racialized policies (e.g., housing, policing, schooling), we need to recognize the discomfort we feel as people who have benefited, implicitly or explicitly, from the systems that have marginalized many of our students. As the PMTs continue on their journeys to better understand issues of social justice, like racialized policies and practices, they seek to draw upon their students' experiences and understandings of current and historical social justice issues.

Discussion

Our study provides insight into PMTs' critical mathematics experiences through a field placement under the co-development and co-direction of the PMTs. As these PMTs began their journeys toward teaching mathematics for social justice, they benefited from unpacking their own understandings of social injustices and developing relationships with their secondary students prior to engaging in social justice mathematics tasks. Our work can inform ongoing efforts to support PMTs' development of critical mathematics literacy and their implementation of social justice mathematics in secondary classrooms. Furthermore, our research showcases the potential for engaging in CPAR with PMTs while also for providing leadership and intellectual opportunities for PMTs through active participation in the research community.

Scripting tasks are a commonly used pedagogy in which teacher candidates (TCs) are presented with a scenario and asked to write a dialogue continuing the discussion. Little attention has been paid to the students that TCs imagine as part of the script. We describe our initial efforts to attend to the characters constructed in scripts in which we observed multiple character traits and ways such traits can coalesce into recognizable characters. This work suggests the importance of intentionally considering various aspects of the scripts as part of efforts to reveal TCs' perceptions of students and the resources they bring to the work of teaching.

Keywords: Preservice Teacher Education; Instructional Activities and Practices

Scripting tasks are a commonly used pedagogy in which teacher candidates (TCs) are asked to write a dialogue that shows how they might continue a class discussion (Crespo et al., 2011; Zazkis, 2017). The scripts TCs write, along with TCs' reasons for writing the scripts as they did, have been used to make visible how TCs' engage in aspects of the work of teaching and their emerging resources, such as mathematical knowledge and instructional practice (Campbell et al., 2019; Zazkis & Herbst, 2018). Little attention has been paid to the students that are "imagined" by TCs in such scripts (Zazkis, 2018). Through viewing scripts as a form of storytelling, we describe our initial efforts to attend to the characters in scripts written by TCs, as part of broader work considering what can be revealed about TCs' resources through scripting tasks.

Background and Theoretical Lens

Representations of practice serve as one category of teacher education pedagogy that structures TCs' investigations into and enactments of the work of teaching (Grossman et al., 2009). Scripts of classroom interactions are commonly used representations of practice in mathematics teacher education (Zazkis & Herbst, 2018) and have been found to support teachers' learning of mathematical content (e.g., Koichu & Zazkis, 2018) as well as pedagogical practices (e.g., González, 2018). While scripts are often developed by teacher educators or researchers, opportunities for TCs to engage in script writing as an approximation of practice (Grossman et al., 2009) have been increasingly used to support and assess TCs' mathematical and pedagogical learning (e.g., Buchbinder & Cook, 2018; Campbell et al., 2019; Crespo, 2018).

Across the literature focused on the use of scripting tasks in mathematics teacher education, there has been little focus on the students that are "imagined" as part of the writing of a script (Zazkis, 2018). Research on scripts tends to focus on the teacher (e.g., Rougée & Herbst, 2018) or acknowledges TCs' potential difficulties in producing student responses (e.g., Lim et al., 2018). Furthermore, the imagining of students in scripts involves not just the nature of the students' turns of talk, but the construction of characters who interact with others in the script and, together, enable the script to tell a story. This is consistent with Herbst's (2018) framing of script writing as "storytelling," as well as Zazkis's (2018) recognition that scripts reveal characters that are created for particular mathematical or pedagogical purposes. Investigation around these representation of students in scripts have the potential to reveal novel aspects of how TCs envision students and classroom interactions. We highlight our initial investigation of student characters in scripts written by TCs by pursuing the following research questions: (1) What character traits are evident in the students created by TCs when writing scripts in response to provided scenarios? (2) In what ways do sets of traits coalesce into characters in these scripts?

Methods

Our work occurs in the context of a multi-year collaboration situated in secondary mathematics methods courses at two large, public research universities, centered on the design and use of practice-based pedagogies, including coached rehearsals and scripting tasks (Baldinger et al., 2020; Baldinger & Campbell, 2019; Campbell et al., 2020, 2019). We consider the scripts TCs across sites (n = 27) wrote during the 2019-2020 school year in response to four different scenarios, each centered on a different classroom activity (Graph Interpretation Task, Number Talk, Sorting Task, and Representation Talk). Each scenario included contextual information (including the mathematical task and goal) and a few lines of script that included a student error to open the discussion. TCs were prompted: "Imagine that you are the teacher. Write the next 5-8 lines of script continuing this discussion." TCs completed the four distinct scripting tasks using Qualtrics. The graphing scripting task was administered multiple times as part of the course design, resulting in a set of 162 scripts for analysis—six from each TC.

The initial analyses we report on here included the writing of analytic memos for each script focusing on the question of what character traits were included among the "students" in the script, defined by how the students were represented as participating and their apparent role in the script. Multiple researchers read each script individually, and then compared observations about the characters and traits being observed. This report reflects our findings from this initial round of open analysis, with a focus on four salient character traits present in the scripts written by TCs, as well as two examples of how those traits formed more complete characters.

Findings

Student Character Traits Emerging from Scripts

One emergent trait was students' ability to readily provide contributions of their own reasoning with little to no prompting. For example, in one TC's script, the teacher asked the class for another description of a provided graph, first commented on by the student in the provided scenario. A new student, Trina, introduced in the script responded,

> Tom walks at a consistent rate of 2 meters/sec for the first 100 meters from school. Then he had to walk back towards home for 20 seconds. Finally he turns back and continues to the bus stop at 4 meters/sec until he reaches the bus stop.

This contribution was mathematically correct and precise and came without any additional prompting from the teacher. At times, these contributions were used to move the story forward in ways that made the student seem almost telepathic. In these cases, this character trait was similar to teacher telling, though with mathematical ideas presented in the voice of a student.

Another character trait was students' ability to readily restate or reason about other students' ideas when prompted by the teacher. For example, in one script, the teacher asked, "Does anyone want to add onto Priya or Amir's claims?" A new student, Joyce, responded, "I agree with Priya that the function is not linear but I think it is because the change in x is 3, 5, 7, and 9." Joyce was positioned as understanding Priya's idea sufficiently to agree with it and extend it. In other cases, this trait took the form of disagreement. In a different script, the teacher asked, "How do you feel about what Priya is saying, Amir?" The TC had Amir respond, "I don't agree. When a linear function has a negative slope the x can increase while the y will decrease so that doesn't mean it isn't still linear?" The TC positioned Amir as able to defend his own thinking and willing to publicly disagree with another student's contribution. This trait allowed for additional students to be added to the conversation in the script and as another way to insert mathematical ideas.

A third trait that emerged was students' explicit willingness to be unsure or to change their thinking. For example, in a script where a student, Jessie, was sharing thoughts on a shape's classification as a polygon, she asked, "It's still a square though right, it just has a line added?" This trait demonstrated the TC's acknowledgement that a student could be unsure about something and also be willing to express that uncertainty. Students in some scripts were also characterized as being willing to change their minds. This took the form of explicit statements that they made an error and now would like to change their thoughts. In one script, in response to another student's reasoning, Foster stated, "Oh that makes sense. So mine was wrong." Often, a student's change in thinking was used to move the discussion towards a resolution.

A final trait we highlight was students' demonstration of actions consistent with actively not listening to the discussion. While most TCs wrote scripts where all represented students were listening in a way that enabled them to directly respond to other students and the teacher, some created students who stood in stark contrast to this. For example, one TC had the teacher ask, "Can anyone restate what Eli just said?" In response to this open call, a newly introduced student, Amira, responded, "Nope, I wasn't paying attention." Amira was represented as not paying attention and brazen in her admittance of not doing so. The creation of Amira through this trait does not necessarily seem to move the story along in the same way as the other traits we observed. Instead, it suggests an attempt to construct "authentic" students, perhaps for the TC to show the teacher educator that they recognize students will not always pay attention.

Compilations of Traits into Characters

As we saw traits emerging from student talk, we also found that they could coalesce into identifiable characters. This notion of character entails considering the role the student plays in service of the overall script—whether mathematically or pedagogically.

The "savior" character. A recurring character across scripts was one we called "the savior." Given that all four scripting task scenarios included the contribution of a student error, what was to be "saved" was both the need for a more correct or complete answer as well as the ability for the discussion to move past the error. The savior student readily provided an alternative (correct) answer to what had been presented and was able to communicate that idea completely and precisely. Key to defining the savior character was not just the contribution from the student, but that the response from the teacher or other students leveraged the contribution from the savior student as something that could resolve and move on from the error. The following script shows an example of a savior character.

Teacher: Who sees things differently?
Trina: I see that Tom starts walking to school, comes back towards home, and then turns around and continues to the bus stop.
Teacher: Trina, can you explain why you think that?

Trina: I noticed that the y-axis of the graph is distance from home so Tom is walking further from home at first.
Teacher: Who agrees with Trina? Does anyone else see it differently?
Foster: I would like to change my answer. I didn't see what was on the y-axis at first but now I see that it is distance. I now agree with Trina.
Teacher: Does everyone now agree with Trina?
Students: Yes.

Trina stepped in to provide a very detailed description of the graph that contrasted Foster's. Her contributions convinced Foster to change his answer, and the teacher took the opportunity to move on with Trina's idea, in part because of apparent agreement among all students.

The "easily convinced" character. A second character we saw across scripts was one who would change their response with little to no prompting—they were "easily convinced," relative to the information provided to them, that their initial idea was incorrect. These characters were willing to change their thinking, and they often were able to readily and robustly restate what another student said. Most importantly, such characters typically functioned to bring the discussion of the error to a close. The following script shows an example of this character in action. The student, Foster, had misinterpreted a graph.

Teacher: Okay Foster, why do you think that?
Foster: Well the graph goes up first and then it goes down and then up again like he is walking up and down a hill.
Teacher: Okay thank you. (to class) What does it mean when the graph goes up?
Stacy: It is increasing.
Teacher: Yes, so the values are increasing over time. What value is increasing?
Foster: Oh the distance from home. I think I thought that that was the height.
Teacher: So now we can see that when the graph goes up, the distance from home increases. So what happens when the graph goes down?

Foster changed his opinion following a very small amount of information from Stacy and a question from the teacher. Moreover, he clearly connected his new thinking to the previous error. This effectively closed the conversation about Foster's initial interpretation and the discussion progressed with the teacher confirming Foster's new opinion and adding in new information.

Discussion and Conclusion

In recognizing the range of character traits and characters in scripts, we noticed that the students made possible certain kinds of teacher moves, which are typically the focus of analyses of scripts. As a result, the practice TCs are approximating through scripting is contingent on the student characters they create, making these student characters vital to understanding scripts and what they make visible about the TCs who write them. This preliminary work highlights the potential in responding to the call from Zazkis (2018) to consider this feature of scripts.

As we continue to pursue the intentional consideration of students that are imagined in scripts, we also recognize a number of open questions. For instance, what do TCs see themselves representing and what is informing that representation? These scripts are telling a story, intended to be consumed by the teacher educator. Are TCs representing actual or idealized classrooms in their storytelling? What is the motivation of the storytelling? TCs might be motivated to "impress" teacher educators with their pedagogical skill, or they might be motivated to develop characters who help them learn to navigate complex classroom situations. TCs might interpret that the script needs to depict closure or resolution, which would influence what they represent. Continued efforts to understand what TCs' scripts reveal about the resources they bring to the work of teaching would necessitate consideration of these types of questions.

EXPLORING RELATIONSHIPS BETWEEN PROSPECTIVE TEACHERS' DECIMAL MODELS AND THEIR PROCEDURAL AND CONCEPTUAL DECIMAL KNOWLEDGE

Rachel Starks
Boston University
RNStarks@bu.edu

Robust knowledge of the mathematics that one teaches plays an essential role in quality teaching and is therefore important for prospective teachers (PTs). For elementary PTs, this must include both conceptual and procedural decimal knowledge. Research reveals that mastery in this domain is elusive for children and adults. However, limited rich descriptions of PTs' knowledge of decimals exist. Even less research explores the role of models, though modeling is an integral part of doing mathematics. In this study, I examine 225 elementary PTs' responses, when asked to create a model for comparing 0.4 and 0.32 and explain the mathematical ideas addressed. Comparing responses by PTs who created area versus linear models reveals that procedural fluency is similar, but more users of area models demonstrate conceptual understanding.

Keywords: Preservice Teacher Education, Rational Numbers, Modeling, Mathematical Knowledge for Teaching

There is growing consensus that mathematical knowledge for teaching (Ball et al., 2008) is an essential component of quality mathematics instruction and student learning (Charalambous, 2010; Hill et al., 2005, 2008; Wilhelm, 2014). This includes deep understanding of the mathematical topics to be taught, such as decimals, a prominent topic in elementary school (NGACBP, 2010). Research shows that decimals can be difficult for students (Graeber et al., 1989; Mehmetlioğlu, 2014; Moody, 2010; Sackur-Grisvard & Léonard, 1985; Steinle & Stacey, 1998) and prospective elementary teachers (PTs) (Burroughs & Yopp, 2010; Depaepe et al., 2015; Muir & Livy, 2012; Putt, 1995; Stacey et al., 2001). Further, PTs' knowledge of decimals is under-researched compared to other content areas (Kastberg & Morton, 2014). There is also little scholarship on PTs' decimal modeling, which is problematic since modeling is an essential component of learners' mathematical activity (Fosnot & Dolk, 2002).

This study begins to address this gap by exploring relationships between PTs' choice of model and their procedural and conceptual decimal knowledge. Improved understanding of these relationships and of PTs' decimal knowledge and abilities generally may better equip mathematics teacher educators to prepare PTs for the classroom. In this study, I pose the following research question: when comparing decimals, what relationships exist between PTs' choice of models and the way they describe decimal place value concepts and procedures?

Background and Theory

Here, I present some of the literature surrounding learners' understanding of and skill with decimals. I then characterize *model* as well as *procedural fluency* and *conceptual understanding*.

Learning of Elementary Decimal Concepts

The base ten place value system is a system of different-sized units, added together, each related to adjacent places by a factor of ten (Kastberg & D'Ambrosio, 2011). Decimal place value concepts are prominent in upper elementary school, where students represent quantities as decimals, plot decimals on number lines, compare decimals, and operate on decimals (*Meeting Standards with EM - everyday Mathematics*, n.d.; *The Curriculum*, n.d.; NGACBP, 2010).

Despite the prominence of decimals in school mathematics, research has shown that mastery can be challenging. Elementary students may apply false rules when comparing decimals, such as assuming the number of digits impacts decimal magnitude (e.g., Mehmetlioğlu, 2014; Sackur-Grisvard & Léonard, 1985; Steinle & Stacey, 1998). Some students believe longer decimals are greater in magnitude (like for whole numbers), others, that shorter decimals are greater (at times due to a misapplication of the fact that further left decimal places represent larger "pieces").

Studies which attend to PTs' knowledge of decimal magnitude and ability to compare have found that *longer-is-larger* thinking is less prominent, while other incomplete understandings persist from childhood to adulthood (Burroughs & Yopp, 2010; Depaepe et al., 2015; Graeber et al., 1989; Muir & Livy, 2012; Stacey et al., 2001). A small number of studies of PTs' decimal knowledge have also attended to modeling, generally finding that PTs may not be able to effectively use models for making sense of decimals (D'Ambrosio & Kastberg, 2012; Starks & Feldman, 2020; Thipkong & Davis, 1991). That decimal mastery remains elusive for many learners suggests that we must learn more about teaching and learning this content.

Models

Models are "mental maps of relationships that can be used as tools when solving problems" (Fosnot & Dolk, 2002, p. 90). Decimal squares, one common model, are squares systematically divided into ten, one hundred, or one thousand sections, with some shaded in to represent a specific quantity. Number lines are also common, and often include sections split further into groups of ten, to represent tenths, hundredths, or thousandths, using a dot plotted at the appropriate location to represent a quantity. Modeling decimals can support processes (e.g., comparing) as well as concept development (such as sensemaking around decimal place values).

Procedural and Conceptual Knowledge

The National Research Council (NRC, 2001) includes *procedural fluency* and *conceptual understanding* as two of five main strands of mathematical proficiency (alongside *strategic competence*, *adaptive reasoning*, and *productive disposition*). *Procedural fluency* is the ability to apply algorithms and solution methods flexibly and effectively. This knowledge of mathematical processes may also be grouped with knowledge of mathematical symbols, vocabulary, and conventions (Hiebert & Lefevre, 1986). *Conceptual understanding* is demonstrated when a learner has a robust internal web of interconnected knowledge of new and previously understood mathematical ideas, as opposed to knowing only isolated mathematical facts (NRC, 2001).

While learners may develop procedural fluency more quickly than conceptual understanding (perhaps due overemphasis on procedures by curricula and instructors), it is flawed to view these strands as hierarchical levels. Rather, scholars have identified both conceptual understanding and procedural fluency as essential components of proficiency, neither more important than the other (NRC, 2001). In the current study, differentiating between demonstrations of procedural and conceptual knowledge allows me to characterize the content of PTs' writing about decimals.

Methods

Data for this study were collected in the context of the NSF-funded Elementary Mathematics Project (EMP), which has developed curriculum for use in mathematics content courses for elementary PTs (Chapin et al., 2021; Gibbons et al., 2018). Decimal topics within *Number Concepts*, one of the EMP units, include places, naming, magnitude, comparing, and modeling. In the 2017-2018 academic year, EMP collected *Number Concepts* posttest data from 302 PTs, taught by 11 instructors at nine institutions of diverse sizes and selectivity, both public and private, in eight U.S. states. Following engagement with the unit, participants completed a five-item open-ended test, including this two-part item.

> As a future teacher, you may encounter a student who is having difficulty determining which of two decimal values is greater. For example, 0.4 and 0.32. (a) Provide a model that would help a student to think about the sizes of 0.4 and 0.32. (b) Explain how your model would help a student compare these quantities and which important mathematical ideas it addresses.

The current analytic sample includes PTs who provided decimal squares or a number line (not both) in response to this prompt; 225 participants met these criteria. The other 77 participants' work will be analyzed in a later phase of this study. I used qualitative content analysis (Hsieh & Shannon, 2005) to make claims about PTs' understanding and hypothesize about relationships with models. I used open coding in a pilot study (Starks & Feldman, 2020), creating a codebook describing the type and features of the PTs' models, and capturing the content of PTs' writing. More recently, I refined the coding scheme, in part by differentiating between knowledge of decimal concepts (11 codes) such as *decimals are parts of wholes*, *tenths are greater than hundredths,* or *decimals may be decomposed additively by place value*, and decimal comparison procedures, conventions, and vocabulary (11 codes) such as "*the tenths place", 0s may be annexed to the end of a decimal,* or *comparing by place value.* My adopted definitions of *conceptual* and *procedural* allowed to do this differentiation; codes were classified as *conceptual* generally if they had to do with mathematical connections, and *procedural* if they had to do with processes or language. My coding was completed using NVivo 12 software. I continued my analysis by exploring to what extent users of each model addressed place value (concepts *and* procedures), as well as exploring the extent to which indicators of procedural fluency and conceptual understanding were present among users of each model.

Preliminary Findings

Of the 225 participants, 72% correctly stated that 0.4 is larger, less than 2% selected 0.32, and the remaining participants did not make an explicit statement. A notable difference was not observed between users of decimal squares (n = 132) and users of number lines (n = 93) in terms of correct identification of the larger decimal.

The concepts and conventions of the base ten place value system are *the* key mathematical ideas which underly models of decimal magnitude and strategies for comparison. When prompted to identify important mathematical ideas addressed in their models and strategies, nearly nine out of ten decimal square users (DSUs) addressed place value, while only two thirds of number line users (NLUs) did so. Some participants accomplished this superficially, simply using the words *place value* (e.g. NLU 0699: "My model would help a student … see which number is longer than the other one. This helps students to see the different place values and how they compare to one another.") Others addressed place value in more robust ways. For instance, over half of DSUs wrote about "tenths" and "hundredths" as mathematical or concrete objects (as opposed to labels for positions), and described their role in modeling and comparing quantities (e.g. DSU 0704: "This would help show students better that there are ten smaller hundredths inside of a tenth so the 0.02 after the .3 doesn't have as much value as the 3 or 4 in the tenths places. This mathematical idea is the idea of place value and that when using decimals the further right you go the smaller the number gets.") This sort of response was far less common among NLUs, only roughly one in nine spoke about tenths or hundredths as pieces of the whole.

Participants demonstrated reasonable procedural knowledge, without substantial differences between DSUs and NLUs. Beyond successfully identifying the larger value, over 90% of both groups received at least one code pertaining to place value procedures, vocabulary, and conventions. In both groups, most described how to interpret their model to compare the quantities, nearly half used the term *place value*, over one quarter described that a zero may be annexed to facilitate comparison, and roughly one in five described comparing by place value.

Conversely, conceptual understanding appeared to be very different between groups. While responses from a large majority of DSUs (eight out of ten) addressed at least one relevant concept, responses from fewer than three out of ten NLUs did so. For instance, most DSUs addressed the basic concept that a decimal quantity represents a part of a whole (e.g., DSU 0746: "The model helps explain this by showing the whole number *one* broken down into 100 smaller parts …"; DSU 0581: "… think of 0.4 as 40/100 and 0.32 as 32/100; DSU 2292: "… [students] can count which has more squares filled … 1 filled column = 1 tenth, 1 box = 1 hundredth …"). However, less than one in six NLUs included similar explanations. Other relevant concepts present in some responses (across users of both models) included the equivalence of 0.4 or four tenths and 0.40 or forty hundredths, the decomposition of 0.32 into 0.3 + 0.02, and the fact that tenths are greater than hundredths. While well under half the responses in each group addressed these concepts, and while statistical significance has not been verified, these ideas consistently seemed to surface more often among the sample of DSUs than they did among NLUs.

Discussion

Since procedural fluency is an essential component of mathematical proficiency (NRC, 2001), it is encouraging that PTs successfully identified the larger decimal and showed facility with decimal place value conventions, vocabulary, and processes. However, it is concerning that not all PTs displayed conceptual understanding, and interesting that it seemed less developed among NLUs than DSUs. We cannot conclude that use of decimal squares necessarily supports development of richer conceptual understanding, but we may conjecture as to why this association emerged. Perhaps certain features of decimal squares support PTs' reasoning about decimal quantities; for instance, they intrinsically capture the relationship between 0 (empty square) and 1 (full square) in a way that number lines may not, if truncated. Alternatively, as decimal squares are introduced before number lines and other linear models in the EMP curriculum, perhaps they are overemphasized, leading to tighter mental connections between them and important concepts in this sample. Or, perhaps learners in general are more comfortable with area models – consistent with a finding by Thipkong and Davis (1991) – and therefore develop or demonstrate deeper understanding when using them versus linear models.

The findings reported here are preliminary findings of a larger study which is currently in process. Next steps in this study are to explore associations between features of the models and the same procedural and conceptual indicators. Further, I intend to re-examine PTs' writing, focusing specifically on when and how they explicitly connect concepts and procedures back to their models. Additional future research in this area is needed to explore potential causation; are there ways in which use of certain models or pedagogies around modeling can or do improve understanding of particular decimal concepts? Additional scholarship in this area will continue to support mathematics teacher educators in providing essential, quality instruction to future elementary school teachers.

Acknowledgments

ESTABLISHING COMMON GROUND THROUGH GESTURAL SCAFFOLDING: A FIRST-GRADE PRESERVICE TEACHER'S USE OF PROBES

Lizhen Chen
Purdue University
lizchen@purdue.edu

Many studies have focused on students' gesture use and learning; however, little attention has been paid to preservice teachers' gesture use in their instruction. Therefore, this study aims to expand existing research by investigating a preservice teacher's gestural scaffolding in her mathematics probes. Sources of data included a video of the preservice teacher's teaching, her identification of probes in a stimulated recall interview, and researchers' identification of probes. Results showed that the preservice teacher packaged spatio-motoric information in her iconic and metaphoric gestures to establish common ground with her students. The research findings provide further implications about how teacher educators teach probing practices in preservice teacher education.

Keywords: Preservice Teacher Education, Classroom Discourse, Elementary School Education, Embodied Cognition, Gesture Use

Many studies (e.g., Alibali et al., 2019; Nathan et al., 2017) have focused on students' gesture use and learning; however, little attention has been paid to preservice teachers (PSTs), who are still learning to teach mathematics and manage their own expressions and displays of meaning. Prior studies on the use of probes have been dominated by the powered lenses of researchers, leaving little space for the teachers' voices of their own probing experiences. Therefore, this study aims to 1) address how gesture scaffolds communicative meaning-making through establishing common ground between teachers and students, and 2) delve into similarities and differences between PSTs' and researchers' identification of probes.

Theoretical Framework

Gesture accompanies speech and contributes to meaning-making by conveying similar or additional information (McNeil, 2017). Gesture in action (e.g., deictic gesture) interacts with concrete materials in context; gesture in verbal communication (e.g., representational gesture) functions as an imitation of action and thus takes on certain selective features of movements so that listeners can make sense of what is being represented (Clark & Gerrig, 1990; Gerwing & Bavelas, 2004). An example of selective movements is the gesture of counting by ones (i.e., pointing to imaginary dots one by one in the air). Its sequenced points and regular stops between two adjacent imaginary points are symbolic of counting concrete objects one by one, therefore signaling the messages speakers intend to convey.

McNeill (1992) categorized gestures into four types: deictic gestures, iconic gestures, metaphoric gestures, and beat gestures. *Deictic gestures,* often called pointing gestures, refer to pointing movements toward concrete objects such as PSTs pointing at numbers when talking about them in a problem. *Iconic gestures* refer to the gestures that directly describe the motion included in the semantic content of speech. Consider a teacher who moves her hands in a circular motion while talking about circles in geometry; the circular hand movement is an iconic gesture. The pace of the movement, which does not exist in speech, sometimes expresses additional information. For example, slow finger movement could imply that the teacher has noticed her students struggling and is slowing down her instruction as a form of scaffolding. *Metaphoric gestures*, which are similar to iconic gestures in terms of referring to imagery representation, describe abstract concepts expressed in speech. An example is a grasping gesture: A student says he wants to understand place value with accompanying gestures, i.e., opening a hand and closing it into a fist. The place value concept is compared to something that the student can grasp. Therefore, this gesture acts as a metaphorical base to hold the concept of knowledge or ideas (McNeill, 1992). *Beat gestures*, which do not usually bear semantic content, are rhythmic movements that reside in the speaker's comfortable or habitual movements, like quick flicks of fingers or rapid pats on the lap.

Gestures, when grounded in physical contexts such as objects and actions, facilitate students' access to the meaning embedded in speech (Alibali & Nathan, 2007). *Common ground* refers to the shared information between speakers and listeners (Alibali et al., 2013; Gerwing & Bavelas, 2004; Holler, 2009). In classroom instruction, when common ground between teachers and students is lost, students become confused. In response, teachers tend to slow down their instruction and apply more verbal and non-verbal signs to assist students in learning. Prior research has confirmed that teachers are likely to increase their use of grounding gestures in trouble spots (Alibali & Nathan, 2007) and in the introduction of new information (Gerwing & Bavelas, 2004). Deictic gestures are a frequently used means of establishing common ground in mathematics classrooms when teachers connect speech with visual representations (e.g., drawings, diagrams). Speakers also change their gesture use based on the common ground that they share with their listeners. Gerwing and Bavelas (2004) asked participants to describe their actions while playing with the toys to those who had played with the toys and those who had not. They found that when describing the action to those with playing experience, participants used less informative and less complex gestures; by contrast, participants' descriptions tended to include more informative and complex gestures in interactions with those with little playing experience. In other words, the more knowledgeable other used more precise and informative gestures to facilitate the learner's comprehension. Meanwhile, the learner developed a better understanding thanks to the more knowledgeable other's use of gestures.

Methods

Participants and Data Collection

This study examines a PST's— Clara— use of probes in a first-grade classroom. Clara was taking an elementary mathematics course as required by the teacher certification program at a Midwest university. After doing lesson planning in the methods course, Clara implemented her lesson plan about two-digit number comparison at an urban elementary school. Her 39-minute lesson targeted the facilitation of meaningful discussions and was videorecorded. Afterwards, a stimulated recall interview was conducted with Clara to record her understanding of her own probe use. The interviewer (the author) asked only pre-planned facilitating questions to minimize influence on the PST. Finally, two researchers (the author and a colleague) independently coded Clara's teaching video and discussed their codes of probes until 100% agreement was achieved.

Analysis

To investigate the issue of gestural scaffolding, I built on existing literature on probing and following-up questions (e.g., Boaler & Humphreys, 2005) and categorized the PST's probes into four types: concept probe, strategy probe, reasoning probe, and clarification probe (see Table 1). Using these codes, my second coder and I coded the PST's teaching video, identified speech and gesture use when the PST probed students' mathematical thinking, and finally formed a list of researcher-identified probes. I provided descriptive explanations for how the PST used speech and gestures to establish common ground with students and particularly captured the scaffolding role that gesture played in the expressions of probes. To explore to what extent the PST-identified probes aligned with the researcher-identified probes, I elaborated on the commonalities and differences between the researchers' and the PST's identification of probes.

Table 1: Categorizations of Mathematics Probes

Probe Type	Description	Example
Concept probe	Points to underlying mathematical relationships and meanings between mathematical ideas (Boaler & Humphreys, 2005)	What does 91 have more of?
Strategy probe	Wants to get students' descriptions of their strategies (Chen et al., 2020)	How do you get 12?
Reasoning probe	Wants students to justify their problem-solving strategies (Franke et al., 2009)	How do you know they were equal?
Clarification probe	Asks students to clarify their explanations; repeat students' responses to resolve uncertainty about what students said (Chen et al., 2020; Franke et al., 2009)	What do you mean? Just two?

Findings and Discussion

Overall, Clara's variation of probes grounded in gesture helped students practice using the mathematical language, helped them dig into their perception of place value, and provided them with opportunities to sharpening their adaptive reasoning. A case in point is when Clara probed a student's conceptual understanding of place value after the student said 59 is bigger than 58. She first probed, "What's bigger?" with a deictic gesture (pointing to the problem on the worksheet) and found out that the student understood her probe as "Which is bigger, 58 or 59?" Then she revised her concept probe as a combination of the question "What does it have more of?" with the same deictic gesture. The student incorrectly answered that "It has more of ten." Going a step further, Clara probed by asking "What does it have more of? Is it ten or one?" and a metaphoric gesture (putting her right hand up vertically, then her left hand up vertically, see Figure 1A), thus making her probe objectively accessible to the student by restricting her probe to two choices. The metaphoric gesture with two hands up vertically abstractly represents ten and one, with the right hand standing for a side for ten and the left hand for the other side for one. Clara confined her probes by means of asking the student to choose a side to stand by; she grounded these two choices in her two hands and made them accessible to the student. One the one hand, the metaphoric gesture bears a deictic aspect, referring to ten and one [gesture is image-based (McNeill & Duncan, 2000)]; on the other hand, the metaphoric gesture represents two choices, i.e., 59 has more of tens or more of ones than 58 (place value). Despite the student's failure to answer what 59 has more of, Clara herself constantly refined her speech and increasingly used grounding gestures to better probe student thinking.

A B

Figure 1: Concept Probe and Clarification Probe

Clara's clarification probes functioned with the purpose of prompting or pressing students to say more (Chapin et al., 2009; Ghousseini, 2015). She either repeated previous talk moves or directly asked students to clarify their thoughts. There were also times when Clara repeated her own questions as clarification probes. For instance, Clara initiated a talk turn with a student by asking "Which one is bigger?" (problem: 60 vs. 88) without using any gesture; the student's response was 100. Realizing that this student might not have understood her initial question, Clara intentionally enriched her probes by using multiple gestures and revised speech. First, Clara probed by asking, "Which one, 60 or 88? Which one is bigger?" accompanied by her hands moving up and down (Figure 1B-a: lifting her right hand up while her left hand was ready to go up; Figure 1B-b: leveling up the palm of her right hand, which was ready to go down while her left hand was going up; Figure 1B-c: both palms leveled up and almost at the same level but in an opposite tendency of movement). Clara moved both her hands up and down three times. She used the up-and-down gesture to denote her conception of a big number and a small number, which may originate from her learning experience of a balance scale or a vertical number line. Thus, Clara packaged the spatio-motoric information in her up-and-down gesture (Kita et al., 2017). She transferred her probe from a conceptual domain (which is bigger?) to a physical space (which is higher or heavier?). Further, she did not reveal the answer by raising a hand along with the verbalization of 88. Instead, she encoded the signal of her waiting for an answer in the motion of moving her hands up and down three times. The series of gesture and speech grounded the teacher's probe tightly in the physical context. Clara, however, did not stop her clarification probe after using the metaphoric gesture. She continued by alternating her way of probing: "Which one is the alligator"— (making an alligator mouth with hands, see Figure 1B-d)— "going to eat?" Connecting with the alligator mouth, which the student was already familiar with, Clara clarified her probe further with an iconic gesture (two hands forming an acute angle, a metaphoric shape of an alligator mouth).

Unsurprisingly, the researchers identified more probes than the PST did, but both identified that concept probes and reasoning probes were used most often. There was a high rate of consistency in speech use between the researcher-identified probes and the PST-identified probes. The PST did not identify gesture use in her strategy probes except the instance of using only gesture in a strategy probe. She tended not to identify the probes followed by students' brief input or silence whereas the researchers did. Clara sometimes did not notice a research-identified probe if the probe followed tightly behind another probe or if she thought she was checklisting students' responses.

Conclusions

To sum up, Clara varied her gestures when she noticed students struggling to understand her questions. The scaffolding role that Clara's gestures played helped establish common ground with students. Varied gestures and questioning imparted flexibility and richness in meaning-making to her probes. With respect to the alignment between the PST-identified probes and the researcher-identified probes, much alignment was found on the speech level rather than the gesture level. These findings highlight needed changes in how the field interprets and investigates probing and further suggest the inclusion of gestures in the probing practices in preservice teacher education.

Acknowledgements

I want to extend my sincere thanks to Laura Bofferding (Purdue University) for her advice in synthesizing my data and Sezai Kocabas (Purdue University) for being my second coder.

PRESERVICE TEACHERS' LANGUAGE USE FOR FRACTION PROBLEMS IN CONTEXT

Susie Morrissey

University of Wisconsin - Whitewater
kartalo@uww.edu

Authors asked preservice elementary teachers to write word problems for fraction equations, then use manipulatives and draw diagrams to model the solutions to the word problems. Through analysis of problems and a follow-up group interview, authors discovered that a focus on contexts using partitive division, as well as the lack of precise mathematical language, impeded further understanding of fraction concepts.

Keywords: Preservice Teacher Education, Rational Numbers

Research on fraction understanding and effective teaching methods is extensive. Teaching fraction concepts using real-world contexts has been seen as a way to improve understanding (Roesslein & Codding, 2019). According to an analysis of fraction problems in three textbooks undertaken by Cady et al. (2015), the most common contexts for word problems with fractions were cooking, money, sharing, and shopping. While fraction multiplication is straight-forward, fraction division problems can be solved by the use of either partitioning or measurement (Lo & Luo, 2012). Typically, researchers seek to determine preservice teachers' (PTs) understanding of fraction multiplication and division in context by providing PTs word problems with real life contexts to solve, asking them to write word problems for equations or expressions, or asking them to analyze given solutions for word problems (e.g., Adu-Gyamfi et al., 2019; Ball, 1990; Jansen & Hohensee, 2016; Mack, 2001; Nillas, 2003; Stohlmann et al., 2020).

For this study, we sought to determine PTs' understandings of fraction multiplication and division by asking them to write word problems for given equations. We provided solved equations so that PTs would focus on the meaning of the equation rather than the solution. PTs wrote word problems, then used manipulatives and drew diagrams to model the solutions to the word problems. To investigate PTs understandings, we asked the questions: 1. Which contexts do PTs relate fractions to? 2. How does the context of a word problem facilitate or impede the understanding of fraction multiplication and division?

Review of the Literature

Fraction multiplication and division have been shown to be difficult concepts to understand, with most PTs, teachers and students resorting to algorithms without knowing the underlying reasoning (Ball, 1990; Unlu & Ertekin, 2012; Zembat, 2004). Language use can be misleading, as seen in the problem provided by Adu-Gyamfi et al. (2019) which was worded as "There is 3/¾f a pie left. Christina and Candace want to divide what is left in half so they each get an equal part. How much does each of them get?" (p. 516). This resulted in half (18) of the PTs rating as correct solutions that showed an answer of 1 1/½which would result from (3/4) ÷ (1/2). This problem was intended to be an example of partition division, where a quantity is partitioned into smaller pieces, with the expression (3/4) ÷ 2 used to generate a unit rate. The wording of the problem is problematic, in that it implies (3/4) ÷ (1/2). Therefore, the misunderstanding could be expected, although it was surprising that 18 of 24 PTs who initially solved the problem correctly accepted an incorrect answer. Based on the wording of the above problem, we can see why many PTs wrote story problems involving division by two in Ball's (1990) study of 19 PTs who struggled to write a story problem for (1 3/¾÷ (1/2). Nillas (2003) also commented that PTs often interpret division by 1/½s division by 2, as was seen in her study of four elementary PTs who were asked to write a story problem for (5/7) ÷ (1/2).

The problem described above from Adu-Gyamfi et al. (2019) could also be solved by taking 1/½f the 3/¾f pie, which is a multiplication problem of (3/4) x (1/2). This method of finding a unit rate was described by Mack (2001) in a study of six fifth graders who built on their informal knowledge of partitioning to solve problems using fraction multiplication. Mack used problems in context such as "Find 2/3 of 3/¾f one whole pizza" (p. 279). Mack's use of partitioning to build up to multiplication skills was recommended by Lamon (1996), who studied students' partitioning skills in grades four through eight. Lamon found partitioning to be foundational for multiplicative reasoning and recommended its continued use beyond third grade.

Jansen and Hohensee (2016) also tasked 17 elementary PTs with looking at partitioning, in this case with the use of fraction division. They found that PTs were mostly successful at writing a correct word problem and discussing their solution in terms of unit rate for the problem "24 DVDs ÷ 4 Hours = ?" (p. 508). However, most wrote a word problem that was represented by multiplication of 24 by 1/¼hen given the problem "24 oz of water ÷1/4 hours = ?" (p. 508) and did not interpret the solution in terms of unit rate. Failure to attend to referent units is a common issue, and largely ignored by most PTs, teachers, and students (Lee, 2017; Stohlmann et al., 2020). Looking at fractions from a measurement perspective, as was the focus for Stohlmann, et al. (2020), presents a model that aligns with the definition of division, in that problems look at how many of one quantity are present in another quantity. Stohlmann, et al. focused on teachers' ability to write a word problem for and solve (2 1/½÷ (3/4) after receiving professional development. Teachers showed significant improvement in their ability to create both a correct word problem and diagram. However, about 17% of teachers struggled with referent units, in that they were unclear on whether the remainder referred to 1/3 of a whole or to 1/3 of 3/¾Similarly, Lee (2017) asked PTs to use a measurement perspective when solving the question, "How many 1/20 sticks can you make from the 3/5 stick" (p. 335). Fifty-two of 111 PTs solved the problem correctly, but only 13 of those showed an understanding of referent units.

Language use and referent units are just some of the issues that make the study of fraction multiplication and division in context difficult. Wording can suggest an improper procedure, whereas failure to attend to referent units leaves PTs unclear on the meaning of the result.

Methodology

To investigate how context facilitated or impeded fraction multiplication and division, we implemented an assignment, followed by a group interview, in math methods courses. The sample was composed of PTs from two universities taught by two of the researchers. Ninety-three elementary/middle school PTs came from a Mid-Western university in the U.S. They were enrolled in a math methods course, which they typically take in the semester before their student teaching experience. Ten elementary PTs came from a South-Eastern university in the U.S., who were in a math methods course in the second semester of their junior year. All PTs completed an assignment that asked them to create word problems for the given fraction equations involving operations of fractions (multiplication and division). The problems instructed students to, (1) Create a real word problem for the given equation; (2) Solve the problem you have created, without using the standard algorithm/rule, using drawings and manipulatives; and explain your solution; (3) Solve the problem you have created using the standard algorithm/rule; and (4) Explain how the standard algorithm is connected to your drawing and your moves with the manipulatives. A variety of equations were given, e.g., $3 \div (1/2) = 6$, $(2/3) \div (1/10) = 6\ 2/3$. The problems used were adapted from Principles to Actions (NCTM, 2014) and the Praxis study guide (Educational Testing Service, 2018, p. 13). Using open coding (Strauss & Corbin, 1990), one researcher analyzed 297 word problems to determine the frequent contexts that PTs relate fractions with. Individually each of the other two authors reviewed the categories and agreed 100%. Next, the researcher, who was not the instructor, conducted a group interview with nine of the PTs from the South-Eastern university. The aim was to gain a better understanding of the PTs' reasoning while solving the given problems. The PTs were first asked to explain how their drawing represented the corresponding equation as well as how it related to the standard algorithm. The transcript of the group interview was analyzed using open coding to identify how a context supports or interferes with understanding of fraction multiplication and division.

Results

First, seven categories were identified in 297 fraction word problems: (1) pizza/cookie/cake/ pie (47%); (2) recipe (13%); (3) distance/height/length (14%); (4) time (5%); (5) weight/volume (8%); (6) population (5%); and (7) other (8%). The PTs most frequently related fractions to the pizza/cookie/cake/pie context. Then, the group interview focused on PTs' reasoning in their non-algorithmic representational solution for the pizza/cookie/cake/pie problems that they created, and connections between their representation and the standard algorithm (e.g., how keep-change-flip rule is connected to the representation). The quotes from the interview, which took an hour and 15 minutes, were coded for the instances where pizza/cookie/cake/pie context was a basis for their reasoning and explanation. Five categories emerged from the interview (see Table 1).

Table 1: Description of the Categories

Categories (frequency)	Description
Split 1 (20)	The word "split" emerged from the context (pizza/cookie/cake/pie) and resulted in a misleading conversation as in "split in half" which indicates dividing by 2 instead of dividing by 1/½
Whole and Parts (9)	Both whole (pizza/cookie/cake/pie) and parts (slices) are referred to as pizzas, cookies, cakes, or pies.
Split 2 (4)	The action of splitting (pizza/cookie/cake/pie) resulted in a misconception that once you divide (i.e., split) then there are no wholes anymore.
Pieces (10)	The word "pieces" emerged from the context and used as in "piece of pizza/cake/cookie/pie)" with ambiguity in size as in daily life language.
How Many (7)	"how many" is used, referring to the number of slices, instead of "how much" "what fraction" which lead to an understanding of a fraction as two separate numbers at the top and bottom instead of "fraction as a number"

In the majority of the instances, the PTs used the word "split" in relation to splitting the pizza or cake, which led to an imprecise and inaccurate interpretation of fraction division (see Split 1 category in Table 1). For example, for the equation 3 ÷ (1/2), one PT explained, “when you split [cake] in half, you are gonna end up in smaller number,” and another PT said, “You have three cakes and then you split those in half, so now you have six cakes.” Both quotes show that splitting the cake in halves idea created confusion. On one hand, the language used, “split in half” suggested that they interpreted the equation as “division by 2.” Their solution, on the other hand, was consistent with the equation, “divide by 1/½ and hence there was a mismatch between the equation, language, and the reasoning. PTs often referred to both whole and parts with the same word, or used “piece(s)” with ambiguity, which impeded an accurate understanding of parts of a whole and unit whole concepts. For example, “..Ike the fact that you end up with six pieces [of cake] versus three” shows how PTs referred to both whole cakes and half cakes as pieces of cakes with no distinction. Another way that PTs were misled with the pizza and cake context was the misconception that once you divide then there are no wholes left. This misconception also arose from the daily life meaning of splitting as evidenced in, “..It now you have six halves [cake] like you don't have any wholes left anymore.” Lastly, PTs often used “how many” referring to the number of slices of a pizza or a cake, which led to an incorrect understanding of a fraction as two separate numbers (top and bottom), instead of a fraction as a single number representing a single quantity. For example, for (2/3) ÷ (1/10), one PT explained, “I did if Katie has two thirds of a pizza that had 10 slices originally how many slices does she have left.” The quote shows how the pizza context led the PT to focus on the number of slices per se, and hence deviated from the fractional content. In summary, the results showed that PTs most frequently interpreted fractions in the context of pizza/cake/pie/cookie; and these contexts impeded their understanding of fractions, instead of facilitating, in many different ways.

Conclusions and Implications

Problems with real-world contexts are commonly used in teaching fractions because such an approach has been seen to support student understanding of fractions. Our study, however, suggests that this might not always be the case. The majority of the word problems PTs created for given fraction multiplication and division equations used pizza, cookie, cake, or pie context. However, their explanations about how their visual representations related to the context of the problem and to the standard algorithm revealed that the context might have affected their understanding of fractions. The use of pizza, cookie, cake or pie context led to an understanding of partitive division but impeded their understanding of measurement division. Similar to past research, they used “split in half,” dividing by 2, to interpret the equation that involves division by 1/½Additionally, PTs also used the word “split” to describe an action of “splitting a pizza/ cookie/cake/pie,” which led them to the conclusion that there were no wholes anymore. The PTs used the terms “piece(s)” or “slice(s)” to refer to both the whole unit and part of the whole, with ambiguity in size, as used in everyday life. Consequently, this may interfere with an appropriate understanding of the part of a whole and unit whole relationship. Finally, PTs focused on “how many” parts were left out of the whole, suggesting their understanding of fractions as two numbers separated by a fraction bar rather than understanding fractions as numbers.

Results of our study suggest that using the context of pizza/cookie/cake/pie might impede an appropriate understanding of fractions. It is essential to pay close attention to the language used by consistently requiring PTs to use mathematical terms when explaining their solutions and reasoning. PTs’ use of words such as slice or piece to refer to both a whole and a part of the whole should be explicitly addressed by asking them to clearly define the whole and the part of the whole in the context of the problem using mathematical terms. The use of words such as slice and piece also seem to present obstacles to understanding fractions as numbers. All word problems with a pizza, cookie, cake, or pie context participating PTs created were partitioning problems that required answers to the question, "how many parts are left out of a whole." Such questions further support an understanding of a fraction as two numbers separated by a fraction bar. In contrast, by requiring PTs to use mathematical terms, the question "how much of an amount is contained in another amount" may be introduced logically, thus beginning to develop an understanding of a fraction as a number.

USING A CRITICAL FRAMEWORK TO MAKE TEACHER RESOURCES VISIBLE

Joshua H. Karr
West Virginia University
Jkarr1@mail.wvu.edu

While practice-based teacher education (PBTE) commonly draws upon multidimensional frameworks for teacher learning, I argue for the expansion of currently utilized frameworks to include dimensions related to justice. I discuss how this expanded framework was developed and draw upon examples from a larger project, focusing on the design and use of practice-based pedagogies centered on discretionary spaces, to illustrate the need for and benefits of this framework. I offer implications for future use of the framework and practice-based pedagogies.

Keywords: Preservice Teacher Education, Teacher Educators

The current wave of PBTE has resulted in the reconceptualization of *what* is taught in teacher education and *how* those things are taught. Alongside these changes has been the formulation of frameworks of teacher learning (Hammerness et al., 2005) that align with, and attempt to understand, the multiple dimensions of learning to teach that support the aims of PBTE. Despite this progress, some have argued the focus of "practice-based" has marginalized justice (Philip et al., 2019). I look to contribute to this body PBTE of scholarship by articulating an expanded framework for teacher learning that sits at the nexus of practice and justice-based teacher education – and then illustrate its benefits for making teacher candidate (TC) learning visible. I use the data from two TCs' engagement with a representation of practice (Grossman et al., 2009) centered in a discretionary space (Ball, 2018) to illustrate the necessity of this framework – showing how "practice-based" can become more contextualized and justice-based. My findings suggest implications for future use of the framework and practice-based pedagogies.

Background and Theoretical Framework

PBTE scholars have sought to build research, pedagogy, and curriculum around teaching practice. This has resulted in a multidimensional approach to teacher education which encompasses necessary knowledge and understandings, the development of tools and practices, and the cultivation of productive dispositions and vision for education. Despite the strides made by PBTE scholars, some critique that by breaking teaching into its constituent parts PBTE fails to maintain the complex, and situational nature of teaching (Horn & Kane, 2019) and situates justice as peripheral to the 'core' (Philip et al., 2019; Dutro & Cartun, 2016).

In response to these critiques, some PBTE researchers have drawn on the "Framework of Teacher Learning" (FLT; Hammerness et al., 2005) – attempting to robustly capture multiple dimensions of learning to teach. The FTL is multifaceted - –t works to capture not only different areas of teacher development, but also seeks relationships between teacher development and the surrounding context. While the FTL has been used by PBTE researchers to demonstrate how the current movement of "practice-based" is not just focused on the technical skills of teaching (e.g., Ghousseini & Herbst, 2016), much of its use has only used the initial definitions set forth, with researchers focusing analysis on a specific core-practice (e.g., orchestrating a whole class discussion). While this has helped some practice-based scholars to contextualize teacher learning, there exists a gap in understanding how TCs learn about teaching for justice through practice-based means. Thus, I argue here for an expanded framework of teacher learning that aims the foci of learning to teach within PBTE onto the enactments of justice-based resources.

This expanded framework entails using the FTL dimensions – dispositions, understandings, practices/tools, and vision – to capture dimensions of teacher learning as has been done previously (e.g., Baldinger et al., 2020) – but then adding four accompanying dimensions – *noticing*, *naming*, *confronting*, and *transforming* – connecting the existing framework to notions of teaching for justice, thus arriving at a Critical Framework for Teacher Learning (CFTL).

To accompany the dimension of dispositions I propose the addition of noticing. While noticing relates to the habits of thinking and action described by Hammerness and colleagues (2009), here the development of critical consciousness (Bell, 2016; Freire, 1998; Schiera, 2019) grounds these habits in the broader sociopolitical sphere. Thus, it is not enough for TCs to develop dispositions related to a belief that 'all students can learn,' but they must additionally notice when broad structures and inequities infringe upon a student's opportunity to learn.

Complimenting the conceptualization of understandings is the dimension of naming. Extending from learning to notice oppressive features in education, TCs need to have understandings that will allow them to name the features of oppression (Bell, 2016) happening at multiple levels (Adams & Zúñiga, 2016). Additionally, teacher learning in this dimension includes naming oppressive features and functions of content and/or pedagogy as well as those working within the intersecting social identities of students – further demonstrating robust understandings in relation to content, pedagogies, students, and social contexts.

Extending the conceptualization of practices/tools is the area of confronting. Much like the way Hammerness and colleagues (2005) outline how the development of practices and tools can help TCs understand complex conceptual tasks and translate them into approaches and rationales, the dimension of confronting is aimed at capturing the complex work that goes into a teacher addressing inequities within practice. Some scholars have already begun to articulate examples of some skills that might exist within this dimension. Examples include posing alternatives, empowering students (Kavanagh, 2017), as well as practices/tools that can be (re)envisioned as justice-based such as, asking clarifying questions (Adams & Zúñiga, 2016), offering feedback, and orchestrating whole class discussions (Hammerness et al., 2005).

To expand Hammerness and colleagues' (2009) dimension of vision, I propose a dimension of transforming. Opportunities must be provided for TCs to not only think about how education stands to be transformed, but to actually begin to enact that work. Directly building from the previous dimensions, transforming encompasses the need to develop a not only a curricular vision (Hammerness et al., 2005), but one that has justice centralized. Additionally, notions of 'good' practice, what is possible, as well as desirable in teaching are shaped by what can transform education and move toward justice. Particularly in mathematics, images of practice are clouded by intersecting layers of oppression. Thus, what is seemingly possible is limited.

Methods

This illustration of two TCs' work is a portion of a larger design-based research project working to design and facilitate cycles of pedagogies of practice (Grossman et al., 2009) centered in discretionary spaces (Ball, 2018) related to authority in secondary mathematics classroom discussions. In this paper, the focus is specifically on how Tacy and Evan's engagement with a single representation of practice (Grossman et al., 2009) illustrates the utility and need for the CFTL in practice-based scholarship.

Data was collected from TCs enrolled in a seminar course that accompanied their student teaching experience (Spring 2021). The set of data included their annotations on a written case of classroom activity. This written case was created to highlight authority relationships that may exist within secondary mathematics classroom (Langer-Osuna, 2017) and how the struggle for authority intersects with social identities such as gender. Within the class session of interest, despite the teacher's use of discourse moves often positioned as productive during a whole group discussion, there exists many discretionary spaces where voices of (white) men are elevated, while those of women are stifled. TCs were given a scenario and asked to annotate the document for things they find interesting, questions they had, as well as anything they noticed or wondered.

A priori codes based on the eight dimensions of CFLT (dispositions, understandings, practices/tools, vision, noticing, naming, confronting, and transforming) were used to conduct an initial round of coding on the annotations. This round sought to identify the dimensions that were made possible by the representation of practice. Following this identification, a round of open, pattern of coding (Saldaña, 2016) was conducted to add contextualization for *how* each dimension of teacher learning was made visible. At this stage, the data from Tacy and Evan was chosen because of their illustration of the use of the CFTL.

Illustrative Examples

Upon reading the written case, Tacy made 14 annotations. During the first round of a priori coding, these 14 annotations translated to 18 instances of Tacy demonstrating a dimension of the CFTL. The complete breakdown of these instances can be found in Table 1.

Table 1: A Priori Coding – Tacy and Evan

	Tacy	Evan
Dispositions	1	1
Understandings	3	3
Practices/Tools	5	2
Vision	1	0
Noticing	4	1
Naming	3	1
Confronting	1	0
Transforming	0	0

Throughout her annotations, Tacy focused on analyzing student thinking (Understandings) as well as identifying teaching moves and lesson planning routines that support students in having a whole class discussion (Practices/Tools). For example, Tacy made the following annotation:

> I like that she consistently goes to the board with the students' thoughts. She highlights, underlines, draws those ideas on the board, which can help students see where their peers' thoughts are coming from. Also, I like that she kept control of how ideas are presented on the board.

This annotation serves as evidence of Tacy making connections of the teacher's gestures, writing on the board, and the organization of that writing to the ways she sees this supporting students who are "visual learners" to engage in the whole class discussion.

Tacy was also able to notice (four occurrences) and name (three occurrences) inequities throughout the written case. Often in Tacy's annotations the coding for "noticing" or "naming" was accompanied by another dimension such as "Understandings" or "Practices/Tools". Within the written case, the teacher gives credence to the ideas of white boys, even when those ideas are very similar to another idea already shared, or less mathematically complete than others. In one of her annotations, Tacy was able to recognize the similarity of two mathematical ideas shared (one by a white boy, Jaron, and another by a white girl, Clara), demonstrating an understanding related to analyzing student thinking. In that same annotation, she went on to say,

> To spend the rest of the lesson discussing "Jaron's idea" when the idea belongs to not only Jaron but Clara and Jess and anyone in their groups who came up with a similar method. Again, it establishes a white boy as the owner and director of the ideas in the classroom when in reality there are multiple students who deserve empowerment in this situation.

Here, Tacy recognizes, despite a very similar idea already being presented by a group of girls, how the teacher named the idea as belonging to Jaron (Noticing). Additionally, she names the implications of these actions (Naming) as positioning white boys as the "owner and director of the ideas in the classroom." This annotation also served as evidence of Tacy contextualizing the teaching moment and seeing it holistically. Attaching a student's name to their idea is a "move" typically noted as being valuable when orchestrating a whole group discussion. But as Tacy notes, within context, this move is harmful particularly for non-white, non-female students.

As seen in Table 1, Evan had demonstrated dimensions of the CFTL eight times across his six annotations. Like Tacy, Evan drew on various aspects of the mathematics and orchestrating a whole class discussion. In one instance, Evan wrote, "I like how she [teacher] restates Clara's comment, but adds more precise language so the class can fully understand what Clara is sharing". Here, Evan has identified where he believes the discussion needs to go mathematically (Understandings). Thus, he identifies this move of "teacher restating" as an appropriate insertion of mathematical language (Practices/Tools) because it allows for students to work on the content.

Similar to Tacy, Evan worked on multiple dimensions simultaneously. At the end of the discussion, Evan felt that the teacher "took over". He recognized an unproductive insertion of ideas by the teacher because it took the mathematical work from the students (Dispositions), suggests a different course of action based on tools of classroom talk (Practices/Tools), and illustrates his ability to analyze student thinking (Understandings) by saying, "students were slowly making connections toward making an equation to model the figures."

Despite his success in demonstrating the four previously established dimensions of the CFTL, Evan was only able to demonstrate his ability to notice and name inequities once through his annotations. Evan wrote, "This is the 2nd time she ignored Jess. The teacher was trying to use different talk moves, but Jess could easily see this as bias against her, especially given her race in a predominantly white setting." Here, Evan noticed Jess, a Black girl, being ignored on two occasions. Attempting to name this moment, Evan assigned the name "bias" and the outcome as being ignored in math class, but simultaneously projected this onto Jess, rather than the teacher. This is representative of Evan's annotations in that he failed to contextualize the written case, and the actions of the teacher, on multiple levels. Other examples of this come from the two instances previously mentioned. Evan failed to notice the teacher's insertion of "more precise" mathematical language into Clara's idea as a possible act of undermining her. Additionally, when Evan felt the teacher "took over," he was focused on the students who were "slowly making connections" – which were all white boys. He did not recognize the mathematically sound, and advanced, contributions of the group of girls represented in the written scenario.

Discussion and Conclusions

Through these two illustrative examples using the CFTL, teacher resources across practice and justice-oriented dimensions were able to be illuminated – an important takeaway for both practice-based teacher educator/researchers and for TCs. By utilizing the CFTL to make teacher resources visible, dimensions needing to be worked on can be identified and opportunities that attend to these dimensions of teacher learning can now be designed, facilitated, and reflected upon to support TCs in learning to teach for justice through practice-based pedagogies.

ELEMENTARY TEACHER CANDIDATES' CONNECTIONS BETWEEN MATHEMATICS AND LITERACY TEACHING

Lisa A. Hawley
Michigan State University
hawleyL2@msu.edu

One persistent challenge in elementary teacher education is supporting teachers in developing confidence in teaching mathematics in ways that develop children's conceptual understanding. This challenge is intensified by the math anxiety that many elementary teachers experience. I argue that elementary teachers' position as subject area generalists could allow them to draw on their strengths in teaching other subject areas. This paper explores the connections that elementary teacher candidates (TCs) make between mathematics and literacy teaching. TCs noted similarities in content and in instructional practices. Creating spaces for TCs to reflect on similarities and differences between subject areas could support them in drawing on strengths in other subject areas to increase their confidence in mathematics teaching.

Keywords: elementary school education, preservice teacher education, instructional activities and practices, teacher knowledge

Elementary teachers tend to be less confident in teaching mathematics in ways that support children's conceptual understanding than they are in teaching other subject areas (Buss, 2010; Wilkins, 2010). Much of this discomfort can be attributed to elementary teachers' feelings of anxiety towards mathematics (Hadley & Dorward, 2011; Wood, 1988). In contrast, elementary teachers report reading and language arts as the subjects they feel most confident teaching (Wilkins, 2010), which makes teaching literacy an area of strength for many elementary teachers.

Researchers have frequently taken a deficit view of elementary teachers' subject-area generalist status, arguing that it limits the depth of content knowledge (e.g., Ding, Li, & Capraro, 2013; Kajander, 2010; Lovin, Stevens, Siegfried, Wilkins, & Norton, 2016; Ma, 1999). I argue that being a subject-area generalist can be a strength for elementary teachers. Their familiarity with pedagogy in multiple subjects gives them a unique opportunity to reflect on teaching practices across subject areas. However, the way that teacher education is structured is unlikely to promote connections across subject areas. Most learning opportunities for teachers are divided by subject areas, including university courses, professional development programs, and journals for teachers, with little communication across those subject area divides. What connections might elementary teacher candidates (TCs), make if they were encouraged to consider the similarities and differences in teaching mathematics and teaching literacy?

Literature Review

One way of connecting mathematics and literacy is content-area literacy. In mathematics, this work tends to be about ways to use reading comprehension skills to help students read mathematics textbooks or to understand word problems (e.g., Adams, Pegg, & Case, 2015; Armstrong, Ming, & Helf, 2018; Beaudine, 2018; Caputo, 2015; Halladay & Neumann, 2012) or strategies for learning new vocabulary words (Altieri, 2009). Writing is also used as a way for students to make sense of mathematics and to explain their thinking. This includes strategies such as keeping mathematics journals to record their thoughts (Armstrong et al., 2018) and bringing writing composition skills into mathematics writing (Carter, 2009).

Much of the research that has been done on connections between mathematics and literacy have focused on connections chosen by the researchers or teacher educators (e.g., Gilles et al., 2016; Lemley, Hart, & King, 2019; Phillips, Bardsley, Bach, & Gibb-Brown, 2009). Although the teachers were doing the inquiry in these studies, the focus on literacy practices in their discipline was chosen by the researchers. In contrast, Matthews and Rainer (2001) specified the subject areas to connect, but left the types of connections to the teachers as they created learning frameworks for mathematics and literacy. As the teachers created separate lists of mathematics and literacy skills, they began to notice more abstract connections between the two subject areas, such as concern with both conceptual understanding and skills, and constructing understanding of texts and mathematical concepts. The study described in this article adds to our current understanding of how teachers and prospective teachers make connections between subject areas, by focusing on the kinds of connections that teacher candidates (TCs) make, rather than those suggested by the researchers.

Methods

This study draws on sociocultural understandings of language and knowledge (Lave, 1996; Rogoff, 2008; Vygotsky, 1978; Wenger, 1998) In groups with peers and experts, we use language to make sense of what we were learning and build a shared understanding of what is "true" (Gee & Handford, 2012).

The data for this paper is drawn from focus group interviews that are part of a larger case study of elementary TCs learning to teach multiple subject areas. Focus groups use group interaction as part of the interview (e.g., adding to others' ideas, responding to others' experiences, etc.; Kitzinger, 1995), allowing an in-depth exploration of the TCs ideas about teaching literacy and mathematics. Eight TCs, who were taking concurrent mathematics and literacy methods courses participated in the focus groups. All participants, including myself, self-identified as White women.

I used an open-coding approach to identify themes in the video transcript of each focus group (Charmaz, 2014). For each group, I collected the TCs' statements about teaching mathematics, organized them by the themes identified in the coding phases, and arranged them into a *collective portrait* (Anderson, 2005), a narrative that expressed their shared understanding of teaching mathematics. I repeated this process with the TCs' comments about teaching literacy, and the connections they noticed across the two subjects. In the findings, I will share excerpts from these narratives that illuminate the themes from data analysis and the connections TCs made.

Findings

Content Connections

The first connections that occurred to the TCs were reading comprehension of word problems and mathematics vocabulary. "Students need to know how to read and distinguish what the problem's asking." They also emphasized the importance of the specialized meaning of words in mathematics. "When you're reading a math text, this is what [this word] means and when you're reading a story about friends, this is what it means." Learning mathematics vocabulary is important to students' understanding of mathematics, and those terms which exist in everyday language (e.g., difference), but with a different meaning may be the most difficult for children to learn (Schleppegrell, 2007).

Another content connection the TCs made is that background knowledge is important in both mathematics and literacy, but it takes on different aspects in the two subject areas. In both subject areas, background knowledge included skills and ideas learned in previous lessons, but only literacy was concerned with contextual background knowledge.

> [In literacy] you teach more explicitly, like "This is what - – don't know baseball terms - –his is whatever this means," so that they can understand it a little better. Whereas, with math, I just don't think there's that same context. Math can be a little more, I guess, straightforward, because you know you're working with numbers, and you already understand that.

Although it is true that a good deal of mathematics in school is without context, mathematics in the real world is often embedded in a context that must be understood to make sense of the mathematics.

Pedagogical Connections

As our conversations turned to the similarities and differences in teaching mathematics and literacy, one group noted that you can use "manipulatives for understanding things in math or blocks for making letters and sounds go together for literacy instruction," as well as using visuals such as diagrams or graphic organizers in both subjects. This focus group tended to take an early elementary perspective (i.e., letters, sounds, early mathematics concepts), which may be why they thought about using manipulatives in literacy.

Another similarity the TCs noticed was using small groups for differentiation and learning from peers. The TCs saw small group instruction as a possible way to meet a large range of learning needs but had some hesitations about managing small groups, as well as about grouping students by "ability."

> And definitely allow kids to work at their ability levels, but also have them work with students who aren't necessarily at their levels, too, so if one's really strong in this area, and this student's not, let them be able to share their strengths, because I do think students learn from each other.

This sort of ambivalence towards small group instruction – that it could help meet students' learning needs and allow them to share strengths, but that it could also reinforce hierarchies of who is perceived as "smart" or "dumb" - –as a big concern for two of the TCs, based on their own experiences with instruction, particularly in mathematics.

A third similarity was the need for assessments to "know where students are at" and to "change up your strategy of how you're teaching this to the student." Although they agreed that the purpose of assessment was the same, they described assessments in the two subjects in very different ways. In literacy, they referred several times to a variety of reading assessments they had learned in a previous course. In contrast, they mentioned very few mathematics assessments, and typically in a negative light.

> I really don't like timed tests. They gave me, as a student, a ton of anxiety. I could probably look at [my students' thinking] with worksheets they do. I know eventually you're going to have to have a math test, to see where the kid is at, and see if they've learned.

Their perception of mathematics assessment was limited to timed tests, worksheets, and written math tests, which were likely the kinds of assessments they had experienced as students, and they may not have been able to imagine mathematics assessments that were different from what they experienced.

A final similarity that was noted by the TCs was the role of process in both subjects, and the way that rough draft thinking could be beneficial in mathematics teaching and learning.

> I think the idea of writing being a recursive process should be transferred over to math as well. We do so many rough drafts and we do outlines and so many steps before you get to the final version of what you're producing, and the growth that happens in between all those revisions. If you sort of approach math in that way, that can help make it seem more like a process where it's okay to trip up and go back and edit it and learn from that.

Discussion

The TCs made many connections between mathematics and literacy when given the opportunity to reflect on their ideas about how to teach the two subject areas. The immediate connections they made were similar to those in the content-area literacy research - reading comprehension of mathematics problems and mathematics vocabulary (e.g., Adams, Pegg, & Case, 2015; Armstrong, Ming, & Helf, 2018; Beaudine, 2018). Noticing these connections would allow these TCs to draw on this literature to support their students in learning mathematics. Continued reflection and discussion led these TCs to make further connections, including pedagogical similarities. This may allow them to draw on their strengths in one area to teach another. For example, the TCs were familiar with a variety of literacy assessments, including both assessments of specific skills (e.g., letter-sound correspondence) and reading comprehension assessments. The mathematics assessments they mentioned (e.g., timed tests, worksheets, math tests) are mainly skills-based, rather than conceptual. Perhaps, by reflecting on how reading comprehension assessments surface students' understanding of text, they could consider mathematics assessments that elicit students' mathematical thinking. A connection these TCs made that I believe holds potential for supporting more conceptually based teaching is that of mathematics as a process similar to writing. By thinking of initial work in class as "rough draft" mathematics, the focus becomes more about revising mathematical understanding rather than getting the correct answer quickly the first time.

Unfortunately, teacher preparation programs, with subject areas siloed in their own courses, with few or no connections between them, are not set up to promote this type of cross-curricular thinking. The focus groups, as a space set aside for reflecting on the similarities and differences in teaching mathematics and literacy, allowed TCs to make connections that did not happen in their separate methods courses. This raises several questions and challenges for elementary teacher education. How might elementary teacher preparation programs reimagine their structure in a way that more closely reflects the day-to-day realities of an elementary school, where a single teacher works with the same group of children in multiple subject areas? In the absence of program-wide structural changes, how can mathematics teacher educators take advantage of knowledge in other subject areas? Collaboration with teacher educators in other subject areas has been explored as one possibility (e.g., Draper & Siebert, 2004; Wohlhuter & Quintero, 2003). Other teacher educators have examined the challenges and benefits of integrated coursework (e.g., DeLuca, Ogden, & Pero, 2015). Other researchers documented the challenges in teaching an integrated course (e.g., Kalchman & Kozoll, 2012), or collaborating with peers in other disciplines in institutions set up to separate disciplines (e.g., Miller & Stayton, 2006).

Despite these challenges, reimagining elementary education in ways that celebrate the strengths of knowing multiple subject areas can result in increased confidence in teaching various subject areas. Researchers in science education have found that integrating science and literacy methods increases elementary TCs' confidence in teaching science (e.g., Akerson & Flanigan, 2000; Brand & Triplett, 2012; Ledoux & McHenry, 2004). In mathematics education, perhaps we can draw on these examples to help TCs develop confidence in teaching mathematics by leveraging their strengths from other subject areas.

PRE-SERVICE TEACHERS' INTERPRETATIONS OF REAL-LIFE EXAMPLES RELATED TO PERCENT

Ji-Eun lee
Oakland University
lee2345@oakland.edu

Keywords: Pre-service teacher education, Number concepts and operations

Theoretical Perspectives and Research Question

Although the understanding and use of percent is vital in mathematics and our daily life, studies report that it is often misinterpreted (Lo & Ko, 2013; Parker & Leinhardt, 1995; Watson & English, 2013). This difficulty exists among students as well as among in-service and pre-service teachers (White & Mitchelmore, 2005). Studies point out that instruction often relies too much on teaching the formalized algorithms rather than exploring various contexts and intuitive strategies, which causes more difficulties (Freudenthal, 1983; Parker & Leinhardt, 1995). This study investigates the following research question: What types of understanding do pre-service teachers (PSTs) demonstrate while engaging in the tasks of interpreting real-life examples related to percent?

Data Collection and Analysis

Forty-six PSTs who enrolled in a mathematics methods course in a Midwestern University in the U.S participated in the study. Individual PSTs were asked to select one real-life example that uses percent (e.g., commercials, news reports, etc.). Each PST was asked to facilitate an online discussion forum on the example of his/her choice for four weeks using various questions/prompts and to report the conclusive interpretation of the initial problem upon completion. The entire discussion forum entries were analyzed by following the inductive content analysis approach (Grbich, 2013).

Summary of Findings and Implications

This presentation will report the detailed progress of the discussion and results of the study. A few aspects noted include the following: (a) Many PSTs focused on applying typical computation procedures they knew, but those efforts were often unsuccessful when using real-life examples where essential information was provided in a vague form compared to the typical textbook problems. (b) One significant difficulty was identifying referent units to interpret relative sizes, which led to incorrect fractional relationships. This study shows that PSTs were familiar with computations procedures for typical percent-related problems but lacked flexibility in applying their knowledge to real-life examples. Designing tasks that promote PSTs' flexible knowledge application in various mathematical content domains is necessary.

PRESERVICE TEACHERS AS RESEARCHERS: A MENTORSHIP MODEL

Kimberly Corum
Towson University
kcorum@towson.edu

Melike Kara
Towson University
mkara@towson.edu

Keywords: Preservice Teacher Education, Research Methods

Participating in research activities can enhance undergraduate students' learning experience during their college education and provide them with opportunities for professional growth (Jahan & Aly, 2018; Madan & Teitge, 2013). For pre-service teachers (PSTs), these research experiences support their professional development as both action researchers and effective classroom teachers. By engaging in undergraduate research focusing on model eliciting activities (MEAs), PSTs can better understand mathematical concepts related to mathematical modeling, practice teaching mathematics with real-world contexts (COMAP & SIAM, 2016), and better conceptualize the research designs in the mathematics education field.

Our goals for the PSTs engaged in undergraduate research are: 1) advance their mathematical content knowledge by designing and developing the modeling activities, 2) improve their pedagogical content knowledge by teaching mathematics in informal settings, and 3) strengthen their understanding and analysis of student thinking and learning (Ball, Thames, & Phelps, 2008). To attend to these goals, we designed a six-phase mentorship model for developing and implementing MEAs.

Table 1: Mentorship Model Phases

Phase	Description
Development	Research and develop the modeling task
Rehearsing	Consider how the task would be implemented in a classroom setting
Implementation	Implement task with intended audience (e.g., local summer camp, classroom setting) and collect data of students' thinking and learning
Reflecting	Reflect on what went well and how could the task be improved post-implementation
Analysis	Analyze student data collected during task implementation
Dissemination	Prepare conference proposals and presentations to share research findings

Thus far, we have mentored or co-mentored six PSTs (two PSTs completed the mentoring cycle and the other four are still in progress). The PSTs' written reflections during the mentorship cycle were collected to assess the effectiveness of the program and to report PSTs' professional growth. These written reflections were often related to PSTs' beliefs about MEAs (e.g., "By including real-life situations, current events, and scenarios relevant to each individual's lives, I will facilitate a learning environment that builds on how the world truly works"), teaching mathematics (e.g., "These implementations really helped me grow as a teacher…I can see my questioning start to get stronger every time I get into the 'classroom'"), and conducting research (e.g., "Students' varying thought processes can create the window of opportunity for many ideas and theories to be explored, discussed, questioned, and potentially solved").

This experience not only provides rich teaching and learning experiences for the PSTs, but it also benefits the faculty mentors. This mentorship model provides faculty mentors the opportunity to work with PSTs in a non-graded setting. This experience also helps faculty mentors to integrate their teaching and their research expectations.

LEARNING TO ASK QUESTIONS ABOUT INSTRUCTION FROM VIDEO

Sarah Larison
Northwestern University
slarison@u.northwestern.edu

Jen Munson
Northwestern University
jmunson@northwestern.edu

Practicum placements, where preservice teachers (PSTs) observe in a classroom over an extended period of time, are a typical feature of teacher education programs. PSTs' opportunities to learn from observations are influenced by discussions with their cooperating teachers (CTs), as discussions can reveal CTs' reasoning about instructional decision-making and student thinking. How can PSTs learn to elicit such discussions? We propose that learning to ask meaningful questions after an observation is a skill that can be learned using video. Video allows teachers the opportunity to reflect on the richness of real classroom interactions while providing needed time for examination (Sherin, 2003, 2007). In turn, video-based opportunities to learn support teachers in nurturing an inquiry stance (Sherin, 2003; van Es et al., 2014), or the ability to consider teaching and learning in new ways (Putnam & Borko, 2000). In this exploratory study, we examine whether using video in a mathematics methods course to practice question-posing influenced the kinds of questions PSTs reported having posed or imagined posing to their CTs following observations of mathematics instruction.

Participants were PSTs in an elementary mathematics methods course (n= 12) at a university in the Midwest. Data were collected from participants at three timepoints: Surveys 1 and 2, given at the start and end of the course, respectively, and a class discussion about video mid-course. Here, we focus on PSTs' responses to one prompt given across these sources, "What questions have you asked your CT (or could you have asked, in the case of the video activity) to learn from what you observed?" Using a combination of top-down and bottom-up coding (Miles et al., 2018) we examined three salient dimensions of PSTs' questions: topic, specificity (e.g., van Es & Sherin, 2008), and function. We ask: How did the topic, specificity, and function of PSTs' observation questions change from Survey 1 to the video-based class discussion, and from Survey 1 to Survey 2? The topic of PSTs' questions were: curriculum, pedagogy, student thinking or needs, or assessment. Questions either referred to a *specific* moment, decision, student, or question or something *general.* Function refers to what the questioner was trying to understand: the observed lesson, the CT's pedagogical approach or belief(s), or logistics. We then created memos detailing changes from Survey 1 to the classroom discussion, and Survey 1 to Survey 2, and compared memos to derive three preliminary findings.

Topic: Between Survey 1 and the class discussion, PSTs shifted from primarily focusing on pedagogy to considering students' thinking and needs; by Survey 2, PSTs' questions focused on students' thinking and needs the majority of the time. *Specificity:* Between Survey 1 and the class discussion, PSTs' shifted from asking nearly all general questions to asking a majority specific questions; by Survey 2, PSTs' questions were nearly all specific. *Function:* Between Survey 1 and the class discussion, PSTs' questions shifted from focusing primarily on logistics to rooting nearly all questions in moments from the video; this held true in their Survey 2 responses. These findings suggest that PSTs can learn to pose substantive questions about classroom observations through video in their methods courses, and point toward the need for larger studies to explore the efficacy of using video to practice posing questions to enrich PSTs' practicum placement experiences.

LEADING GROUP DISCUSSIONS ENACTMENTS IN A METHODS COURSE

Melike Kara
Towson University
mkara@towson.edu

Keywords: Pre-service teacher education, Online and Distance Education

The teacher education field has shifted from emphasizing knowledge for teaching into core teaching practices (McDonald, Kazemi, & Kavanagh, 2013). Focusing on core teaching practices helps teacher educators deconstruct teaching into learnable parts and helps pre-service teachers (PSTs) manage the complexity and uncertainty of teaching (Forzani, 2014). Programs focusing deliberately on core practices have the potential to narrow the gap between university courses and clinical experiences.

Leading group discussions (LGD) is a fundamental practice in teaching mathematics. PSTs are often not sure how to orchestrate a discussion when there are multiple different solutions, when they want to draw other students into the conversation, or when they want to facilitate the conversation towards a particular goal. This practice is still complex but can be deconstructed into learnable components such as using discussion enabling prompts (TeachingWorks, 2019).

Following the rationale described above, I systematically integrated LGD core practice in a methods course and investigated PSTs' reflections on their own implementations. The participants of the study consisted of 11 senior undergraduate students enrolled in a mathematics methods course offered to middle school majors during the Fall 2019 semester (five PSTs, in-person instruction) and the Fall 2020 semester (six PSTs, virtual, synchronous).

During the first half of the course, the PSTs were introduced to the components of the LGD framework (TeachingWorks, 2019), student thinking monitoring tools (Smith & Stein, 2018) and assessing and advancing questioning techniques (National Council of Teachers of Mathematics, 2014). PSTs solved mathematical tasks, anticipated possible solutions, created questions to assess and advance student thinking in the solutions, and analyzed classroom videos. During the second half of the course, the PSTs created their own tasks, prepared a monitoring tool with possible student strategies as well as assessing and advancing questions for each strategy. Next, they decided on follow-up questions for orchestrating the discussion which would unpack 1) key mathematical points, 2) underlying logical necessities of those points, 3) questions to push student thinking further and advance the learning by making connections, and 4) connections between different strategies. Each PST implemented their LGD task during the class sessions in a "peer-teaching" format by utilizing the LGD framework. Additionally, the Fall 2020 group conducted their second implementations with middle school avatar students in a simulated classroom environment (Mursion, 2020). Finally, PSTs wrote reflections on their implementations. These reflections were analyzed using comparative analysis (Merriam, 1998).

Overall, all 11 PSTs indicated that this instructional effort provided them with various learning opportunities related to orchestrating group discussions, eliciting and orienting student thinking, and/or responding with appropriate questions. Almost all PSTs stated that they need to improve their questioning techniques. For example, one PST stated, "*I learned to target my questions so that they aren't yes or no answers but ones that require students to think deeper.*" Another PST stated, *"'Does that make sense?' is not a very productive question because most students are just going to say yes… A better way … is to ask them to explain in their own words* *what you said/what their peer said."* The sophistication of reflections varied based on the cognitive demand of the LGD tasks as well as each PST's mathematical content knowledge.

EXAMINING PRESERVICE TEACHERS' RESPONSES TO AREA CONSERVATION AND VOLUME TASKS

Dae S. Hong
University of Iowa
dae-hong@uiowa.edu

Cristina Runnalls
Cal Poly, Pomona
ccrunnalls@cpp.edu

Keywords: Area, Volume, Preservice teachers

Building procedural fluency from conceptual understanding is one of the effective teaching practices recommended by the National Council of Teachers of Mathematics (National Council of Teachers of Mathematics [NCTM], 2014). Among many topics in mathematics, with a significant number of formulas, area and volume measurements have a high likelihood of students relying on procedural understanding to solve problems (Vasilyeva et al., 2013). As we worked with our PSTs, we were interested in exploring their existing knowledge about area conservation and volume measurement. Our results showed that PSTs in the present study experienced difficulty determining the bases and heights of multiple figures (especially non-prototypical ones), relied on visual comparison of shapes as opposed to geometric and referring to irrelevant information such as the length of the sides or the largest number. Some of the conceptual limitations found in the present work may lead future teachers to lean more on procedurally-focused area and volume measurement lessons, resulting in continued students' learning challenges. In addition to limitations in curriculum materials, PSTs' limited knowledge in area and volume measurements showed an alarming pattern in the teaching and learning of area and volume measurement, and suggest that area and volume measurement may continue to be treated as a primarily formulaic, procedure-drive topic (Hong, Choi, Runnalls, & Hwang, 2018, 2019; Runnalls & Hong, 2019). With a small number of participating PSTs, we can't generalize from our results; however, we suggest that being exposed to the activities specifically address PSTs' challenges to be included in mathematics content classes and/or their teacher education programs. In turn, PSTs can have the potential to develop lessons that can reflect conceptual ideas of area measurement.

NAVIGATING THE IMPLEMENTATION OF BEST PRACTICES IN MATH INSTRUCTION WHILE STUDENT TEACHING DURING COVID-19

Ashley Whitehead
Appalachian State University
whiteheadan@appstate.edu

Christina Tschida
Appalachian State University
tschidacm@appstate.edu

Keywords: Preservice Teacher Education; Instructional Activities and Practices; Elementary School Education

With the shift to hybrid and online learning in the spring of 2020, due to COVID-19, preservice teachers' internships in classrooms were drastically changed. While research has shown the importance of field experiences (e.g., Darling-Hammond et al., 2002; Philipp et al., 2007; Zeichner, 2010), little is known about the impact of virtual field experiences and how COVID-19 has impacted preservice teachers' preparedness to teach. While Kennedy & Archambault (2012) argue *for* the use of virtual field experiences for preservice teachers, they acknowledge that online learning does not take the place of traditional classrooms.

Understanding the impact of the restrictions and policies placed on preservice teachers due to COVID-19 is important as they move into their student teaching placements and into their first years of teaching. Specifically, understanding how COVID-19 is impacting preservice teachers' implementation of best practices in their mathematics classrooms is crucial for teacher education programs. The two main questions guiding this portion of the research study were:

1. How is learning to teach impacted by restrictions and policies due to COVID-19?
2. What does mathematics teaching look like during COVID-19?

Participants and Data Collection

Twenty-four preservice elementary teachers volunteered to participate in a study exploring what student teaching looked like during the COVID-19 pandemic. Of those, ten agreed to take part in more in-depth sharing of their experiences during student teaching. Participants were asked to engage in three interviews and complete three journal entries over the course of the semester. Interviews for this larger study included questions specific to their knowledge of best practices in teaching mathematics and ways that implementation of those practices was enhanced or limited during their student teaching experience due to restrictions from COVID-19 policies.

Results and Implications

This study is relevant and timely as it helps teacher educators understand the implications of learning to teach during COVID-19. Preliminary results of this study show the impact of moving field experiences online during the 2020 school year. Teacher candidates adjusted to this transition to online teaching during their field experiences in the fall and many gained confidence in implementing best practices in that virtual environment. However, when they entered the classroom in a face-to-face setting during their student teaching, many of them struggled with planning for instruction that incorporated the best practices they studied in their mathematics methods courses. Teacher candidates commented on how they struggled to incorporate shared manipulatives, group discussions, and high-level tasks, while meeting the limitations placed on instruction due to COVID-19 policies. While this study is ongoing, the initial findings show the struggle these teacher candidates experienced and how they are persevering through the challenges of learning to teach in the midst of a pandemic.

PROSPECTIVE TEACHERS' QUESTIONING PATTERNS IN A SIMULATED STUDENT INTERVIEW

Sandy Spitzer
Towson University
sspitzer@towson.edu

Christine Phelps
Central Michigan University
phelp1cm@cmich.edu

Keywords: Preservice Teacher Education; Teacher Noticing; Technology; Instructional Activities and Practices

Mathematics teacher questioning is an important and complex instructional practice which is critical to enacting student-centered teaching (Franke et al., 2009). Questioning is essential to successful teaching, adaptable to a variety of teaching contexts and circumstances, and is a manageable and discrete skill which can be developed during pre-service teacher education; it is thus considered a "high-leverage practice" (Grossman, Hammerness & McDonald, 2009). Conducting structured interviews with students can improve prospective teachers' (PTs') questioning skills (Jenkins, 2010; Moyer & Millewicz, 2002), but logistical considerations of field placements often limit these opportunities.

Research Question, Design, and Analysis

This poster presents preliminary results from a study in which PTs interacted with a *simulated student* (programmed using an AI chatbot and the authentic responses of 5 children) to conduct a diagnostic interview about geometric thinking. This work adds to existing research about simulated interviews (Shaughnessy, Boerst, & Ball, 2015) by introducing and investigating a novel technological tool. Participants (20 PTs enrolled in a geometry course) conducted a simulated interview with the chatbot, which we dubbed "Matilda." Each PT independently "interviewed" Matilda, using a given set of example shapes to frame their questions, with the goal of revealing and diagnosing her understanding of geometry. We analyzed the interview transcripts to classify the questioning types and patterns that PTs used. Future work will examine associations between PTs' questioning patterns and their resulting diagnoses of student thinking.

Findings and Implications

Results suggest that PTs asked a variety of question types during their simulated interview. The most common type of question asked was Specific Classification questions (e.g., "Is Shape 5 a rectangle?"), asked 178 times by 16 different PTs (89% of participants), followed by General Classification questions (e.g., "What kind of shape is Shape 7?"), which asked 118 times by 17 different PTs (94% of participants). Nearly all PTs (94%) asked at least one follow-up question to probe Matilda's response to a previous question, with the majority of these follow-up questions (a total of 100 questions) asking *why* Matilda had given a particular response. This suggests that PTs were attending to the simulated student's answers and attempting to probe more deeply. However, the simulated student had been programmed with a variety of children's invented vocabulary for describing the shapes (e.g., "it's too spinny" for a square oriented with no horizontal sides), and only 6 PTs (33%) asked a follow-up question about such vocabulary. This suggests that their questioning patterns could be more specifically targeted to gain richer understanding. Overall, these results, and other data we will share in the poster, suggest that PTs may need specific interventions to improve their ability to ask rich and meaningful questions to uncover student thinking in order to guide their instruction.

EXAMINING THE INSTRUCTIONAL READINESS OF PRE-SERVICE TEACHERS VIA THEIR EPISTEMIC AND MATHEMATICS INSTRUCTION BELIEFS

Guillermo Farfan
Florida State University
gjf14@my.fsu.edu

Keywords: Preservice teacher education, teacher beliefs, professional development

Following *teaching-in-context theory* (Schoenfeld, 1998, 2011), this study investigated pre-service teachers' instructional readiness in mathematics by answering the following questions: (1) How familiar are pre-service teachers with reform-based standards for mathematical practice? (2) What type of epistemic and mathematics instruction beliefs do pre-service teachers have? and (3) What role do these beliefs, prior experience, and program of study play in pre-service teachers' instructional readiness?

Method

Design

This poster presents results from a mixed-methods study that combined online survey responses with follow-up, in-person interviews (QUANT → Qual; Creswell, 2009).

Participants. The sample ($N = 104$) included pre-service elementary teachers, pre-service secondary math teachers, and students minoring in education enrolled at a preeminent research university in the southern United States during the 2017-18 academic year. All participants declared they planned to teach after graduation. A subset of participants ($n = 6$) who were towards the end of their teacher training was also interviewed.

Instruments. In addition to general information, two instruments were used to collect data on participants' beliefs: Mathematics Instruction Beliefs Survey (MIBS), which was designed to assess alignment with reform-based standards for mathematical practice, and Hofer's (2000) Discipline-focused Epistemological Beliefs Questionnaire (DEBQ), which assessed participants' mathematics epistemic beliefs. In-person interviews included questions about participants' prior school experiences, specific questions regarding the MIBS and DEBQ scales, and questions about their program of study and future teaching practice, including using vignettes that aligned with one or more standards for mathematical practice to unpack instructional readiness.

Results

Overall, less than 15% of pre-service teachers in the sample were familiar with reform-based standards for mathematical practice. Participants' epistemic and mathematics instruction beliefs seemed positively correlated; a categorical regression showed participants' MIBS overall scores and program of study as the strongest predictors of their DEBQ scores, $F(4, 102) = 10.187$, $p < .001$. Follow-up interviews showed subtle differences between pre-service elementary teachers and education minors, who leaned more toward traditional mathematical practices and believed mathematics to be about correct answers, and pre-service secondary teachers, who favored reform-based mathematical practices and believed mathematics entails a process of discovery.

Conclusion and Implications

Meaningful mathematics reform requires teachers to be familiar with the principles behind reform-based mathematical practices (Opfer et al., 2017; Schoenfeld, 2020). More needs to be done to ensure students entering the teaching profession are not only familiar with reform-based standards for mathematical practice but aware of their role in implementing them as intended.

A PRELIMINARY INVESTIGATION INTO PROSPECTIVE TEACHERS' PRODUCTIVE STRUGGLES FOR MAKING SENSE OF MATHEMATICAL PRACTICES

Nitchada Kamlue
Western Michigan University
nitchada.kamlue@wmich.edu

Lauren Van Zoest
Western Michigan University
laura.vanzoest@wmich.edu

Keywords: Instructional Activities and Practices, Preservice Teacher Education

For prospective teachers to become teachers who can bring the mathematical practices (NGACBP & CCSSO, 2010) into their classrooms, first, they need to experience those practices themselves. We used the frog problem (see Dixon & Watkinson, 1998; Andrews, 2000 for details) as the first activity of a middle school methods course to provide a chance for the 13 prospective teachers enrolled to *make sense of problems and persevere in solving them* (MP1; NGACBP & CCSSO, 2010). After engaging in making sense of the problem across multiple class sessions, the prospective teachers completed an activity where they analyzed their experiences in relation to the mathematical practices (MPs).

Since productive struggle is an opportunity for students to make sense of mathematics within their *zone of proximal development* (Vygotsky, 1978) and deepen their mathematical ideas and the relationship among those ideas (NCTM 2014; Warshauer, 2015; Zeybek, 2016; Peterson & Viramontes, 2017), productive struggle related to the MPs may also support prospective teachers in making sense of MPs. Our observations of the prospective teachers' struggles during the frog activity led us to the following research question: *What struggles of prospective teachers when engaging with the frog problem support them in making sense of mathematical practices?*

Data collection included videos of all classroom sessions and electronic copies of all prospective teacher work completed in connection with the frog activity. We used Warshauer's (2015) kinds of student struggles for identifying instances of struggle. Then, we applied Kelemanik et al. 's'(2016) diagram of three avenues (*Quantities and Relationship*, *Structure*, and *Repetition*) leading to MP1 as a framework for identifying which avenues or specific MPs the prospective teachers struggled with. After that, we used *expectations for students* from Smith (2000, as cited in NCTM, 2014) as formative indicators to help us decide whether the identified struggles were productive. We used the prospective teachers' MP analysis document as a final indicator of whether the struggles identified as productive supported the prospective teachers in making sense of MPs.

The initial results show that the prospective teachers struggled with looking for a pattern to generate a rule that works for all cases (e.g., "I have a pattern but I don't know how to put it in the equation.") and with providing a meaning behind their expressions or equations in relation to the frogs' movements (e.g., "Even if we know the answer, we don't know why we need to move like that."). Both types of struggles generated opportunities for the prospective teachers to make sense of MPs, especially, MP2, MP4, MP7, and MP8. Those struggles seemed productive as they provided the prospective teachers with an object lesson in the meaning and purpose of the MPs. For instance, most of them mentioned the same key statement from CCSS about MP1 that related to their experience of engaging with the frog problem— "[Mathematically proficient students] consider analogous problems, and try special cases and simpler forms of the original problem in order to gain insight into its solution" (NGACBP & CCSSO, 2010, p. 6).

LEARNING FROM PEDAGOGICAL MISTAKES IN TEACHER EDUCATION

Rob Wieman
Rowan University
gomathman@yahoo.com

Jill Ann Perry
Rowan University
perry@rowan.edu

Keywords: Preservice Teacher Education; Learning Theory

Learning from mistakes has a strong and deep foundation in theory and research. Although there have been recent calls to foreground the roles of mistakes in learning how to teach (Wieman & Hiebert, 2018), little has been written about what this might look like in teacher education. In this poster, we share what we are learning in response to this call.

The questions guiding our research are: (1) *What happens when mathematics teacher educators (MTEs) treat pedagogical mistakes as valuable sites for learning?* (2) *To what extent do pre-service teachers (PSTs) self-report pedagogical mistakes as sites for learning?* and (3) *In what ways do PSTs discuss pedagogical mistakes as sites for learning?* We explore these questions in the context of a two-semester secondary mathematics methods course sequence. As part of this course, PSTs attended a weekly practicum with a partner in a local secondary math classroom and engaged in at least one iterative cycle of collaborative planning, rehearsal, revision, enactment, and reflection loosely modeled on structures and protocols from Lesson Study (e.g., Lewis, 2016, Lampert, et al., 2013, Wieman, 2019). Rehearsals were purposefully designed to position pedagogical mistakes as normal, invaluable opportunities for professional learning and growth, rather than as evidence of professional inadequacy.

Our data set comprised 2 cohorts of PSTs' (C1, N=22; C2, N=12) end-of semester responses to these questions: (1) *What is the most significant way in which you have contributed to your own learning this semester?* (2) *What is the most significant way in which you have contributed to your classmates' learning this semester?* (3) *What is the most significant way that you have changed as a result of this class?* Taking an inductive content analysis approach (Schreier, 2012), we worked within the *Dedoose* data analysis platform. We engaged in initial open coding of C1's data to create our codebook, and then coded data independently. We discussed and came to agreement for every instance when text was coded differently. Using iterative cycles, we continued to code and analyze data from C2.

Our emergent findings indicate that these PSTs experienced learning from mistakes as powerful, valuable, and normal. They saw pedagogical mistakes as opportunities to learn about the effectiveness of specific moves, to make improvements to lesson plans, and to develop pedagogical knowledge and skill. PSTs also saw mistakes as an important part of their own developing identity as teachers. Pedagogical mistakes helped them see themselves and their peers as valuable resources in a professional community dedicated to learning and improvement, and PSTs also described mistakes as connected to their own developing confidence. We hope that this preliminary work will help the field become more thoughtful and purposeful in positioning pedagogical mistakes as normal and valuable opportunities to learn.

"EDUCATION FISH IN A WORLD FULL OF SHARKS": PRESERVICE TEACHERS' EXPERIENCES IN MATHEMATICS CONTENT COURSES

Limin Jao
McGill University
limin.jao@mcgill.ca

Gurpreet Sahmbi
OISE, University of Toronto
gurpreet.sahmbi@utoronto.ca

Keywords: Preservice Teacher Education; Undergraduate Education

University-level mathematics content courses often serve as the primary context in which secondary mathematics preservice teachers (PSTs) develop mathematical content knowledge which is crucial for effective instruction in mathematics (Ball et al., 2008). These courses allow PSTs to explore and make connections across a breadth of mathematics domains, and foster self-confidence in their own mathematical abilities (Hodges et al., 2010). Mathematics content courses are typically taught by mathematicians who do not have a formal background in education (Oleson & Hora, 2014), and are often markedly different in their delivery compared to traditional teacher education courses taught in faculties of education (Leikin et al., 2018). Given the limited research investigating the experiences of PSTs engaging in these courses during their teacher education programs, this study explored the question: What are the experiences of secondary mathematics PSTs taking university-level mathematics content courses?

The data for this study were collected from a series of semi-structured interviews with one cohort of secondary mathematics PSTs' (*n*=7) enrolled in a four-year undergraduate teacher education program at a Canadian university. Interviews were transcribed verbatim and coded for emerging themes using the constant comparative method (Maykut & Morehouse, 2002).

Findings suggest that secondary mathematics PSTs experienced a range of challenges, including difficulties connecting with and understanding course content, and being ignored and dismissed by mathematics professors. Importantly, challenges with mathematical learning did not simply result in roadblocks to completing a course, but also became significant barriers for PSTs trying to complete their teacher education program altogether. When PSTs spoke about specific experiences with mathematics professors, most of their recollections were negative. PSTs shared that when mathematics professors knew they were education students, they were viewed and treated differently. Specifically, PSTs indicated that the mathematics professors spoke down to them and did not think that they were capable of doing advanced mathematics. PSTs also critiqued the pedagogical choices of their mathematics professors.

Yet, the secondary mathematics PSTs leveraged their negative experiences into opportunities to be reflective practitioners. First, after seeing what they felt was evidence of poor teaching, PSTs reflected that they learned what they "don't want to do…as a teacher" and considered the ways that they would be different as future teachers (Zazkis & Leikin, 2010). Additionally, the PSTs' first-time encounters with conceptual difficulties in mathematics (Goulding et al., 2003) helped them develop empathy for the way that some of their future students might feel in secondary mathematics. The PSTs also developed a community by leaning on each other for both mathematical and emotional support throughout their time in the content courses. This *de facto* community helped them successfully complete their mathematics content courses while alleviating feelings of isolation (Grossman, et al., 2001). While the PSTs in this study were able to find some positive features of largely negative experiences, it is worth considering what adjustments need to be made to provide all PSTs with the positive learning environment that we hope they will provide to their own students in the future.

SECONDARY STEM PRESERVICE TEACHERS' CONTINUOUS IMPROVEMENT: FOCUSING ON STUDENT ENGAGEMENT DURING A PANDEMIC

Jenifer Hummer
West Chester University of Pennsylvania
jhummer@wcupa.edu

Keywords: Preservice Teacher Education, Integrated STEM, Instructional Practices

Supporting preservice teachers (PSTs) to practice, in the field, what they have learned in their teacher preparation courses is an ongoing challenge for STEM education (e.g., Roehrig & Luft, 2006; Tatto & Senk, 2011). Some of these challenges are influenced by the structure of teacher preparation programs. Thus, education policy has suggested that programs adopt "holistic practice-based" methods to support PSTs (Hollins, 2011). One such promising method is the use of continuous improvement. Preservice teachers who completed elementary mathematics content courses developed through continuous improvement applied what they learned, when planning lessons, during their first years in the field (Morris & Hiebert, 2017). Thus, applying similar improvement science methods within a teaching and learning course may support PSTs to learn from teaching (see Hiebert & Morris, 2012).

To support this type of learning, continuous improvement methods can be implemented within teaching methods courses (e.g., Bryk et al. 2015; Lewis, 2015). Continuous improvement cycles involve selecting a goal, planning and implementing a strategy to achieve that goal, and improving the strategy through reflection. The cycle is repeated as needed. When seeking to improve practice, small changes over time can influence greater outcomes than one-time attempts to overhaul a system or process. However, few studies discuss improvement science in the context of teacher preparation. Hence, this study focused on how to support PSTs to utilize improvement science through lab assignments implemented in field placements concurrent with methods coursework. The results from this study answer: In what ways do lab assignments support teacher candidates to engage in continuous improvement during their field experiences?

The participants in this study were ten PSTs enrolled in a secondary STEM teaching methods course while completing their teaching field experience. In alignment with continuous improvement cycles, the students planned an activity, implemented the activity, and reflected on their practice. The data consisted of completed lab assignments. This study focused specifically on an assignment where the PSTs worked to improve student engagement in their virtual classes while teaching during a pandemic. The data were analyzed using constant comparative analysis (see Strauss, 1987) to discover themes and trends within the completed lab assignments.

Results showed that through the completion of the student engagement lab assignment, the PSTs reflected on their teaching and learned how to improve the design and implementation of instructional tools. For example, the teachers saw an improvement in student engagement by using online tools such as collaborative presentations slides. They also acknowledged that classroom environment influenced student participation. Lastly, the PSTs reflected on how to improve their implementation of these tools. These results are important as they show that the use of lab assignments can support PSTs to learn from their teaching and show continuous improvement in their instruction.

Acknowledgments

I thank my students who survived the pandemic with me. Excellent work on your assignments!

FENDING FOR THEMSELVES: SECONDARY MATHEMATICS PRE-SERVICE TEACHERS' EXPERIENCES AS OUTSIDERS IN THEIR PROGRAM

Gurpreet Sahmbi
OISE, University of Toronto
gurpreet.sahmbi@utoronto.ca

Limin Jao
McGill University
limin.jao@mcgill.ca

Keywords: Preservice Teacher Education, Undergraduate Education

For preservice teachers (PSTs), the majority of their teacher education (TE) program is comprised of university-based coursework. In our context, secondary mathematics PSTs engage in general education courses centred on subject-non-specific topics (e.g., assessment, technology, etc.), mathematics content courses to support their mathematics content knowledge (Ball et al., 2008), and mathematics methods courses for teaching secondary mathematics (Albayrak & Unal, 2011). While the content of these courses is important, a successful teacher education program is not only reliant on PSTs' academic prowess, but it is also dependent on PSTs' subjective experiences. Indeed, post-secondary students' experiences in their programs of study impact their academic success (Crisp et al., 2015; van Rhijn et al., 2016), feelings of self-efficacy, and development of future goals (Carpi et al., 2017; Pearlman-Avnion & Aloni, 2016). With this in mind, the overarching research question guiding this paper is: What are the experiences of secondary mathematics PSTs in the university-based coursework of their TE program?

The study took place within the context of a four-year, undergraduate-level TE program at a large Canadian university. Participants in this study were the secondary mathematics PSTs in one graduating class of the TE program (*n*=7). General education and mathematics methods courses were offered by the Faculty of Education, and mathematics content courses were offered by the Department of Mathematics and Statistics. Participants were interviewed throughout their program and all interviews were transcribed verbatim and coded for emerging themes using the constant comparative method (Maykut & Morehouse, 2002).

Findings suggest that secondary mathematics PSTs broadly felt like outsiders in their TE program. In general education courses, they were outside of the typical PST experience as *mathematics* PSTs, and in mathematics content courses, they were outside of the typical mathematics- or STEM-major experience as mathematics *education* students. Consequently, PSTs banded together and developed a community of secondary mathematics PSTs. This community was formalized in the secondary mathematics methods courses where the PSTs finally felt like insiders. We argue that this PST-developed community is akin to a cohort, because it was "a group of students who beg[an] and complete[d] a program of studies together, engaging in a common set of courses, activities, and/or learning experiences" (Barnett & Muse, 1993, p.401). In this cohort, the secondary mathematics PSTs supported one another in many ways (Bullough et al., 2001), developed a strong sense of community, and increased professional growth (Beck & Kosnik, 2001; Govender & Dhunpath, 2011; Mandzuk et al, 2005). Because of this self-developed cohort, the PSTs were empowered where they once felt like outsiders in their program.

We hope that these insights propel TE programs to think critically about the ways that they do and do not support all of their students. We encourage teacher educators to consider ways of making courses more inclusive and TE programs, more broadly, to facilitate the formal creation of spaces earlier in programs for students who are not well-represented in the program.

AUTHENTICITY IN ELEMENTARY PRESERVICE TEACHERS' MATHEMATICAL TASK DESIGN

Yi-Jung Lee
University of Arkansas
yl049@uark.edu

This poster session described the results of 30 elementary preservice teachers' (PSTs) task design in a mathematics methods course. The context and task authenticity of the mathematical task were examined. When the task could be set up in a decontextualized, simulation, or real-life setting, more than half of the participants used a simulation (54%) inspired by the contextual features of a storybook in their task design. In terms of task authenticity, PSTs were inclined to include pure computation problems (47%) and modeling/manipulative activities (40%) in their task design. The results contribute to the literature on the quality of task and teaching designs in mathematics education (Watson & Ohtani, 2015).

The conceptual framework involved context authenticity, including an academic setting (e.g., classroom or laboratory), a simulation setting (e.g., a learning environment that either resembles real-world complexity or is established on a virtual platform), and a real-life setting (e.g., field experience or workplace). Another dimension is task authenticity, which consisted of computational, modeling, and realistic categories (Herrington et al., 2009; Strobel et al., 2013) while describing the type of tasks.

The research questions that guided this study include:

1. How do the mathematical tasks designed by elementary PSTs demonstrate context and task authenticity?
2. What are the characteristics and relationship between the context and task authenticity of the designed mathematical tasks?

In this study, PSTs were exposed to children's mathematical literature in the mathematics methods course and then required to design a task that could be employed to facilitate particular mathematical concepts. The collected 30 mathematical tasks were analyzed using a constant comparative method based on the framework addressing context and task authenticities. Axial coding was applied to describe the similarities and differences among the tasks, as well as to relate the identified concepts across various categories (Corbin & Strauss, 2008).

The results showed that 40% of PSTs' tasks focused on memorization and procedure, highlighting the popularity of computation problems when they were not likely to be set in a real-life setting. Simulations also seemed favored as a task setting after PSTs were exposed to various story contexts. Among the tasks set in a simulation and real-life setting, half of the tasks required students to demonstrate their conceptual understanding of the procedure. It is encouraging to observe that relatively more tasks required students to express their understanding through multiple mathematical representations and were situated in a simulation/real-life context. This research sheds light on the correlation between context and task authenticity in mathematical task design, which has pedagogical implications for the coordination of the task type and the assignment of its scenario, as well as how these components interact when designing mathematical tasks at the elementary level.

Keywords: Preservice teacher education, instructional activities and practices

Participants of this study were 80 preservice teachers (PTs) enrolled in an elementary and middle grades math methods course at a Mid-Western university teacher education program in the U.S. The PTs engaged in a series of activities regarding the value and importance of productive struggle in learning and learned and practiced various strategies that support the productive struggle. The strategies included selecting tasks that are conducive to productive struggle and anticipating student thinking (Smith et al., 2018); utilizing multiple tools, representations, and strategies (NCTM, 2014); giving time to struggle (Warshauer, 2015); asking questions (Freeburn & Arbaugh, 2017); scaffolding for access to productive struggle (Barlow et al, 2018; Huinker & Bill, 2018); using mistakes, errors, and confusion as learning portals (Boaler, 2015; Carter, 2008; Catmull, 2014); and mindfully facilitating discussions around activities and giving feedback (Boston et al., 2017; Huinker & Bill, 2017). At the end of the course, they produced a fully documented lesson plan that employs eight effective teaching practices, including productive struggle. Through a literature search, we developed a coding rubric composed of a comprehensive collection of strategies that indicates supporting the productive struggle. Using thematic coding (Gibbs, 2007) and the rubric, we analyzed PTs' lesson plans to determine how and to what extent they supported productive struggle in their lesson plans.

Our results indicated that both scaffolding and high cognitive demand tasks were paid little attention by the PTs. The low frequency of use of scaffolding techniques can be explained by the low frequency of planning for high cognitive demand tasks. NCTM (2014) draws attention to the importance of anticipating solutions in lesson plans to support productive struggle. However, the PTs rarely anticipated solutions in their plans which echoes Kartal et al. (2020)'s findings regarding the deficiencies of PTs in anticipating student thinking. PTs did not plan to emphasize that making mistakes is a natural part of learning (NCTM, 2014), even though publicly valuing mistakes (Boaler, 2015), and facilitating discussions on mistakes, misconceptions, and errors have been considered as important components of productive struggle. Anticipating mistakes and incorrect solutions to mathematical tasks is emphasized as a focal planning practice in the context of effective math teaching and in relation to facilitating discussions (Huinker & Bill, 2017; NCTM, 2014). Therefore, absence of discussion plans for mistakes and struggles can be explained by absence of anticipated solutions and difficulties from the lesson plans.

Gentet.florence@courrier.uqam.ca

Keywords: Reasoning and Proof, Prospective teacher education, High school education, Mathematical Knowledge for Teaching

Mathematical reasoning [MR] has been at the core of school mathematics in several countries for more than 30 years. However, the concept of MR remains vague both in research and in practice. It is associated with a plethora of terms such as thought, deduction, generalization, justification, and proof (Jeannotte, 2015). Very little is known about the different ways in which teachers use this concept. Moreover, within their daily practices, teachers have to create, choose, or even discriminate means of developing and evaluating MR of their students. Davidson et al. (2019) point to the complexity underlying the professional judgment teachers place on student MR. In addition, the discourse of teachers about MR contingents several pedagogical choices they make (Hill et al., 2005; Stylianides and Ball, 2008). This poster aims at exploring how prospective mathematics teachers [PMT] conceptualize MR.

This project is based on a commognitive perspective which is cultural and discursive. From this perspective, cognition and communication are two aspects of the same ontology, i.e., discourse. Discourses are constituted of keywords, visual mediators, rules of discourse, routines, and generally endorsed utterances (Sfard, 2008). They are specific to a particular community. Thereby, PMTs are viewed as a particular community that shares a certain discourse. Three PMTs each participated in one 60 minutes individual interview and one 120 minutes collective interview. All interviews were video recorded. They were finishing their last semester of a four-year Bachelor's degree in mathematics education for secondary teachers. During those four years, they did four teaching internships and some substitute teaching.

By analyzing their discourse, we were able to highlight what MR is for them. First, the participants generally talked strongly about what MR is not. For them, it is clear that MR is not applying techniques per se, rather it is applying in a controlled manner. They endorsed that MR is knowing what concepts or techniques to apply, when it is relevant to apply them, how they are applied, and why it is valid to apply them. This vision of MR can be linked to the concept of control developed by Saboya (2010). Second, exemplifying, as a particular MR, serves a particular purpose and is very close to, but contrasted with trial and error: *She thought, there must be something, I'm going to try some cases… It's not even trial and error. It's more like giving yourself examples.* Compared to primary school teachers' discourse (Jeannotte, Dufour, & Sampson, 2020), PMTs refer less to the aspect of being able to explain (to someone) what, how, and why. The difference, between explaining (primary school teachers) and knowing (PMTs), might reside in the different experiences of those two communities. Indeed, explaining can be related to the traces needed to evaluate students' MR. And, evaluation occupies a major place in teachers' everyday practice but it is an aspect that PMTs have not yet fully experienced.

Acknowledgments

This research would not have been possible without the support of the FRQSC [197178] and the participation of our three PMTs.

IDENTITY JOURNEY MAPS: A GEOSPATIAL ROAD TRIP OF MATH CONTENT IDENTITY

Dennis DeBay
University of Colorado Denver
dennis.debay@ucdenver.edu

Keywords: Teacher Educators, Preservice Teacher Education, Technology

Introduction

The goal of the Identity Journey Map project (IJM) is to explore the impact of student teachers creating IJMs is to allow for the opportunity to reflect and set the stage for all the (possibly different) ways student teachers will experience their mathematics content identity in the classroom. Through geospatial story-telling software (StoryMaps - https://storymaps.arcgis.com/en/), students will communicate their journey and experiences to this point that have brought them to be connected math educators in the hopes of exploring ways to connect their student's content identities in math.

As a teacher educator, many math classrooms I observe maintain to incorporate a one-size-fits-all approach to supporting students through their learning. There is no wonder why many students are turned off by math and begin to believe, "I'm just not a math person." They lack an identity or connection to the content that many of our teachers possess - – love for mathematics. We are referring to this as their *mathematical content identity*. This lack of identity can affect performance in classrooms and lead to a sinking feeling that they do not belong in that math class (Huvard, H., et al., 2020). A growing body of research has revealed the diversity of student strengths and challenges and a wide variety of pathways there are to effective learning (Vincent-Ruz, P., & Schunn, C. D., 2018). How can educators transform their approach and teach math in a way that effectively addresses learner variability? Productive struggle focuses on the math journey instead of simply the destination. It recognizes that there are multiple ways to tackle a problem and views mistakes as opportunities for learning rather than failures. It is this journey that is the focus of this proposal. We are proposing to explore Identity Journey Maps (IJMs). In this project we have students build web-maps using the geospatial technology StoryMaps to explore their own mathematical identities and consider ways to use these journals as entry points to engage students in believing they too have an identity as a mathematician.

Identities are developed and shaped by different experiences influencing how we perceive and relate to the world around us. Identity theory states that our identities are filled with meaning based on how we perceive our roles as an individual and within the larger cultural groups we are part of within society (Burke & Stets, 2009). People hold multiple identities, and each identity is attributed a specific set of meanings. This paper extends this line of inquiry to investigate how participation in the creation of these geospatial stories impacts student teacher's mathematical identities and in turn their perceptions of their student's identities as mathematicians.

In the Summer of 2019 we started to use IJMs in an introductory Planning for Learning in STEM Education course (for Math and Science student teachers) as a way to explore the contexts of the student teacher's that led them to their path as a math educator. They created a narrative using StoryMaps that explained both their connections to content, important opportunities, people and places that led them to their appreciation of mathematics as well as how they believed that this could bring their student's lived experiences to math as well. This become even more important throughout the following 2 years as we explored how content identity connected to student's connections to math.

The aim of this study is to explore how the IJMs impacted their perceptions of their content identity and how this connects to their student's identities in math. Using case study methodology, we will study graduate-level courses at our institution to provide an in-depth examination of students' sense of content identity. We use identity theory to explore the nature of content identity development in preservice teachers who engaged in creating identity journey maps at a university in the western USA. Constructs of content identity development are seen as critical outcomes of experiential math inreach and outreach programs.

CONNECTING PROSPECTIVE TEACHERS' MATHEMATICS UNDERSTANDING

Dr. Marc Husband
St. Francis Xavier University
mhusband@stfx.ca

Theoretical Perspective

This study is framed by the Pirie-Kieren (P-K) theory for the Dynamical Growth of Mathematical Understanding (Pirie & Kieren, 1994). P-K theory characterizes learning by non-linear movements through eight *embedded* layers of understanding. *Embedding* layers of understanding means formal layers of understanding (e.g., formulas/rules) are connected to informal layers of understanding (e.g., pictorial images). *Disjointed* understanding is used to describe how understanding can be fragmented (e.g., algorithm is separated from concept).

Research Question and Design

This case study investigates how prospective teachers (PTs) used their existing understanding to connect elementary mathematical concepts. The setting for the study was a ten-day professional development course and 15 PTs agreed to participate. The course was designed for PTs to elicit their existing understanding by working on elementary mathematics tasks, generating multiple solution strategies and making connections between the solution strategies. This poster will share Deb's (pseudonym) work on the subtraction question: 91 -70.

Data Collection and Analysis

Video recordings and participants' journals provided both real-time and daily-summary data for the study. I used this data to identify and analyze PTs existing images, disjointed understandings, and how they noticed properties and made connections.

Summary of Findings and Implications

To make subtraction easier, Deb used a friendly number strategy she knew worked in addition. Deb recorded: 91 – 79 = 90 – 80 (see Figure 1a). Prompted to use a number line, Deb constructed an image (see Figure 1b) and noticed the difference of 10 between 80 and 90, the +1 on each end, and the total difference of 12. In her journal (see Figure 1c), Deb drew another number line using different numbers, 21 - –4 = 20 – 13 and said how shifting maintained "the difference between the two numbers," whereas her original image "had changed the difference." She referred to this as an "aha moment" that "explained the idea of constant difference."

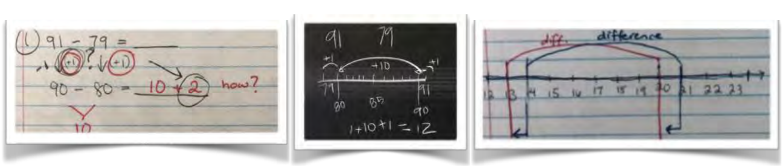

Figure 1a: 91-79=90 - –0, Figure 1b: Number line, Figure 1c: Constant difference

Prior to working with her friendlier number strategy, Deb's formal understanding was disjointed from an image of difference for subtraction. By translating her use of the number line into a new equation and seeing the numerical relationships, Deb's Formalising layer of understanding for subtraction now embeds an image of constant difference. Deb's work suggests a process for how prospective teachers can make connections within their existing understanding of elementary mathematics.

PROSPECTIVE ELEMENTARY TEACHERS' EVALUATIONS OF STUDENT SOLUTIONS TO DIVISION STORY PROBLEMS

Julien Corven
University of Delaware
jcorven@udel.edu

Keywords: Preservice Teacher Education, Teacher Beliefs, Teacher Noticing

The AMTE (2017) *Standards for Preparing Teachers of Mathematics* state, "Well-prepared beginning teachers of mathematics analyze both written and oral mathematical productions related to key mathematical ideas and look for and identify sensible mathematical reasoning, even when that reasoning may be atypical or different from their own" (p. 10). Understanding and evaluating students' written solutions (e.g., on formative assessments to determine what students understand (Joyner & Muri, 2011)) is a critical, everyday skill for the job of teaching.

Various factors can affect teachers' evaluations of student work. For example, teachers tend to rate solutions that match their own preferred methods for solving a problem as better than other correct solutions (Van Dooren et al., 2002). Bartell et al. (2013) noted that prospective teachers' (PTs') evaluations of student understanding were swayed positively by features that superficially seemed to be conceptual (e.g., pictorial representations), even when the solution did not reflect clear evidence of conceptual understanding. Shaughnessy and Boerst (2018) suggest that beginning PTs will often dismiss student work and reasoning when the numerical answer is incorrect. Conversely, Jansen and Spitzer (2009) found that PTs often base their assessments of student understanding solely on whether the answers students obtained were correct. Teacher education must help PTs develop more appropriate bases upon which to evaluate student work.

The data I report came from a pilot test of an interview protocol for a study in progress. Participants were 24 prospective elementary teachers enrolled in their first mathematics content course. Each participant was shown one of four division story problems involving decimals (n=6 for each problem). After seeing the problem, participants were shown seven (simulated) student solutions to the problem, one at a time. Participants were prompted by the interviewer to first reconstruct each student's solution (Philipp, 2018), priming them to attend to the mathematical details in the solution and potentially interpret what the student understood (Jacobs et al., 2010) rather than make evaluative snap judgements. After seeing and reconstructing all seven solutions, participants were asked to rank the solutions in any way they wanted and to select which solutions they would want to see their future students produce. I analyzed and coded the responses qualitatively to answer the research question: *What criteria do prospective elementary teachers say they use when evaluating student solutions to a division story problem?*

When asked which solutions PTs would want to see their future students produce, some PTs cited factors mentioned above (e.g., obtained the correct answer, used a method the PT would have taught) as criteria. However, several PTs preferred solutions in which the student's process was clearly communicated, even if it was incorrect. A similar criterion cited was whether the PT felt the solution served as a productive base from which to build student understanding. These two criteria align with a belief that mathematics instruction should center student thinking (NCTM, 2014). On the ranking task, PTs often used multiple criteria and considered factors on a spectrum. Some PTs employed more objective criteria (e.g., validity of the solution strategy, use of pictures) whereas others cited subjectively relative criteria (e.g., how easily the PT understood the solution). Future research will examine how these criteria evolve during teacher preparation.

Keywords: Equity and Justice, Pre-Service Teacher Education

Mathematics teacher education is in a time of necessary focus on issues of equity and access. This goal is urgent, in part because while populations in the U.S. have grown more diverse, the demographics of teachers have remained mostly the same, with the vast majority being White, monolingual in English, middle-class, and culturally different from many of their students (Marx & Moss, 2011). Thus, teachers' responses toward cultural difference must be a focus of mathematics teacher preparation to meet the needs of the nation's diverse student population.

The Developmental Model of Intercultural Sensitivity (DMIS; Bennett, 1986) is a framework that establishes a continuum of ways to respond to cultural difference ranging from monocultural to intercultural. Monocultural is "the experience of one's own culture as 'central to reality'" (Bennet, 2004, p. 62). In contrast, intercultural is "the experience of one's own beliefs and behaviors as just one organization of reality among many viable possibilities" (Bennett, 2004, p. 62). The framework includes two categories related to monocultural (Denial and Polarization), two categories within intercultural (Acceptance and Adaptation), and a category (Minimization) which is thought of as a transition between monocultural and intercultural. The Intercultural Development Inventory (IDI; Hammer & Bennett, 1998) is a validated instrument that places respondents along the DMIS continuum.

During the spring 2021 semester, a university in the Midwestern United States began offering a program that embedded preservice teachers (PTs) methods classes at a local elementary school. PTs in this program spent every morning throughout the spring semester at this school, participating in their university classes and engaging with students in classrooms. This allowed the opportunity for PTs to immerse themselves in a school where about 80% of the students in this school identify as Black or Hispanic and 68% are eligible for free and reduced lunch (Public School Review, 2018). These are different demographics from PTs participating in this program, many of which identify as white, middle-class, and from small, rural towns in the Midwest.

Twenty-three PTs participated in this program during the spring 2021 semester. Throughout the semester, we explored how participation in this program influenced PTs' sense of cultural awareness and their ability to work across cultures. Data collection included pre- and post-IDI results and journal reflections. At the beginning of the program, 9 students fell in monocultural categories of the DMIS, 2 fell in intercultural categories, and 12 fell in the transitional category of minimization. Throughout the semester, PTs participated in discussions and activities related to culture (e.g. culturally relevant math pedagogy). By the end of the program, many had advanced along the DMIS continuum, becoming more aware of culture and the importance of including their students' cultures in their classrooms and curriculum. One student wrote: "*While my culture (norms, beliefs, practices) is important and makes me who I am, I need to dig deeper into cultures around me, especially my future students*." We argue that this program allowed PTs to develop their sense of cultural awareness while building the skills to work with a diverse group of students. The implications of this study will support other teacher educators in developing their PTs' cultural awareness in embedded methods courses.

LEARNING TO CODE FOR MATHEMATICS TEACHING: THE CASE OF MARIA

Robyn Ruttenberg-Rozen
Ontario Tech University

Nkechi Ibeh
Ontario Tech University

Ami Mamolo
Ontario Tech University

Many schooling jurisdictions have begun to include coding and computational thinking in K-12 curricula. Our own school jurisdiction of Ontario, Canada has just revised our mathematics curriculum for grades 1 through 8 (2020) to include coding expectations connected to algebraic reasoning in every grade. Notably, much of our elementary teaching workforce are women. Yet, since the 1990's in most countries women have been dissociating from actively engaging in many forms of ICT including computational reasoning (Patitsas et al., 2014; West et al., 2019). This poses a new problem for our K-12 system especially, like in Ontario, when computational reasoning curricular expectations are intertwined with mathematics expectations. We need to understand how to support K-12 educators, and especially women, with learning to code for teaching mathematics.

While there is scant research on the support of women learning to code in order to teach coding, we do know from studies in ICT and women that fostering a sense of belonging (e.g., Esquinca et al., 2021) and establishing an identity (e.g., Ulriksen et al., 2010) as a person who codes are important to the persistence of women in coding. Numerous studies have shown that feeling a sense of community (e.g., Goos, 2004) is vital for the success of women and equity. Women associate perceived identity compatibility and perceived social support with a greater sense of belonging in STEM (Rosenthal et al., 2011).

In our poster we report on a case study with one secondary mathematics preservice teacher, Maria, a confident woman, and high achiever with an interest in, but no prior experience with, coding. Maria was in her third semester of a 16-month teacher education program that focused on pedagogies which made use of various educational technologies. Maria was introduced to Scratch ©, a block-based and user-friendly coding environment. A member of the research team met with Maria weekly to support her learning and progress. We analyse Maria's experiences through the lens of Hannula's (2002) framework for analysing attitude and changes in attitude.

BLOGS AND LEARNING JOURNALS: MATHEMATICS TEACHER CANDIDATES' REFLECTIONS ON LEARNING TO TEACH

Keywords: Preservice Teacher Education; Teacher Beliefs; Instructional Vision

This poster describes our shared exploration of teacher candidates' (TC) engagement in two kinds of *personal writing space* across two courses in our secondary mathematics education program. In our courses, *learning journals* are semi-private student-instructor writing spaces where TCs relate to the subject of mathematics, while *blog entries* prompt candidates to "go public" with their ideas about teaching. In support of our program's balance between reflection and enactment, we explore the potential of these two formats, extending Cohen's (2016) ideas on writing in mathematics by analyzing writing as a space for mathematics TC learning. We use writing to facilitate opportunities for TCs to develop critical, antiracist perspectives that center students' humanity (Gutiérrez's 2002; 2018; Love, 2019), and to respond to Felton-Koestler's (2020) call for mathematics teacher educators to attend to sociopolitical issues in TC learning.

We sought to understand how secondary mathematics TCs in our Noyce program (NSF, n.d.) used writing to learn about teaching toward equity and antiracism, asking: *When teacher candidates engage in writing as a reflective practice, how do they write about mathematics, equitable mathematics teaching, and/or teaching toward antiracist classrooms?* We selected three Noyce scholars, Rhianna, Valerie, and Yolanda, who took our two courses simultaneously in Fall 2020, and analyzed the ways they used these different writing spaces for their learning.

Journals enabled these TCs to capture ideas about the beauty of mathematics, express empathy with students, and consider parallels between their own needs and those of students. Yolanda wrote about "explor[ing] content through an intrinsic perspective," noting "In K-12, math was always about numbers and solutions." She valued "see[ing] mathematics as what it is – beautiful worlds that we can visit and engage with." Rhianna used her own experiences to express empathy with students. For instance, she used her feeling that topological equivalence was "foreign" to imagine that her students might find *fraction* equivalence similarly foreign. Finally, Valerie mused that a reflective journal could be as valuable for her students as it was for her, saying "I really like this format of thought collection" and that she wanted her students, too "to have something personal they made and look back on how they constructed knowledge…."

Blogs allowed TCs to reflect on emerging ideas through the lens of classroom practices. Valerie asked, "how do we develop students' disciplinary agency?" reflecting that "it starts with knowing… Know the strengths of your students. Know the ways they like to play and work. Then, put it all together." She returned to this idea in processing a teaching moment when a student made and revised a conjecture as he articulated his way of thinking. Rhianna described how videos, chats, and nearpod assignments gave her knowledge of her students and "the work, emotions, and explanations my students had about their own identity, what it meant to be smart, … and differences correlated to real world events mathematically and socio emotionally." Lastly, Yolanda aimed to use her understanding of students to help them connect to the power and beauty of math: "I want my students to recognize their power as mathematicians and participate in math that is personally and socially meaningful to them. It is because of this that I must also know where my students come from, their backgrounds, and how they are positioned in society."

Palabras clave: Maestros mentores, formación de maestros, estudio de lecciones, experiencias de campo

Esta investigación se contextualiza en una innovación que utiliza el estudio de lecciones (Lewis et al., 2019) para establecer conexiones entre los cursos de métodos y las experiencias clínicas. A pesar de que varias investigaciones han reconocido la importancia de las experiencias de campo en la formación de los candidatos a maestros de matemáticas (Bieda et al., 2015), son pocas las investigaciones que se focalizan en determinar el conocimiento de los mentores de las experiencias de campo. Utilizamos cuatro situaciones hipotéticas para explorar cómo los mentores utilizarían su conocimiento para lidiar con posibles problemas que se presentan en el estudio de lecciones. Los datos se analizaron utilizando las estructuras discursivas descritas por Horn (2010) y el modelo de Toulmin (1958).

El diseño utilizado fue el estudio de caso (Yin, 2003). Participaron tres mentores de candidatos a maestros de matemáticas a nivel secundario (grados 7 a 12). El proceso de recopilación de la información se llevó a cabo mediante un grupo focal en el que los participantes reaccionaron a cuatro situaciones hipotéticas de posibles actuaciones en el proceso de estudio de lecciones. Específicamente, preguntamos ¿Cómo los maestros mentores fomentarían la participación de todos los participantes del equipo? ¿Cómo llamarían la atención a un candidato a maestro que rompe el protocolo en el momento en que se está implementando la lección de investigación? ¿Cómo fomentarían discusiones fundamentadas en las observaciones en la fase de reflexión? ¿Cómo incorporarían las preocupaciones de los candidatos a maestros que desean cambiar completamente la lección de investigación?

Lo resultados demuestran que, para motivar la participación de los candidatos a maestros en las lecciones de estudio, los mentores crearían un ambiente adecuado, estimularían la comunicación por medio de preguntas y el involucramiento en la clase desde el inicio de la experiencia de campo, pero también dejarían espacios para la reflexión. En casos inesperados en los que los candidatos a maestros rompan los protocolos convenidos, tratarían de establecer un balance entre explorar las razones por las cuales no se respetan y permitir las actuaciones inesperadas. Establecerían de antemano los criterios para realizar las observaciones y en la etapa de reflexión no permitirían datos que no provengan de observaciones. Los cambios a la lección de investigación estarían limitados a cambios en la forma de enseñar ya que los contenidos matemáticos no son negociables.

Encontramos que los mentores de futuros maestros utilizan principalmente el conocimiento que han adquirido en su práctica para dar respuesta a las situaciones hipotéticas. Ese mismo conocimiento lo quieren transmitir a los candidatos a maestros que supervisan a través del ejemplo y de crear un ambiente participativo que permita la discusión y la reflexión. Se necesita más investigación para establecer los aspectos que permiten que estas comunidades de estudio de lecciones sean verdaderos espacios para crecimiento profesional cuando hay personas con diferentes experiencias y conocimientos previos.

Keywords: Mentor Teacher, teacher education, Lesson Study, field experiences.

The context of this study is an innovation using Lesson Study (LS) (Lewis et al., 2019) to establish connections between methods courses and clinical experiences. Although several researchers have recognized the importance of field experiences in mathematics teacher education (Bieda et al., 2015) there are few that focuses on determining mentors´ knowledge. We use four hypothetical situations to explore how mentor teachers would use their knowledge to manage problems that could surface during Lesson Study. Data was analyzed using the discursive patterns described by Horn (2010) and the Toulmin´s (1958) model.

We used a case study design (Yin, 2003). Three mentors of high school math teacher candidates (grades 7-12) participated. We collected data through a focus group in which participants reacted to four hypothetical situations of possible actions in the lesson study process. Specifically, we asked: How would mentor teachers encourage the participation of all team members participating in LS? How would they draw attention to a teacher candidate who breaks the LS protocol when the research lesson is implemented? How would they encourage discussions based on observations during the reflection phase? How would they incorporate the teacher candidates' concerns who want to change the research lesson completely?

The results show that to motivate the participation of prospective teachers in LS, the mentors would create a suitable environment, foster communication through questions and class involvement from the beginning of the field experience, but also leave room for reflection. In unexpected cases where the prospective teachers break agreed LS protocols, they would try to find a balance between exploring the reasons why the protocols are not followed and allowing unexpected actions. They would establish in advance the criteria for making the observations and at the reflection stage they would not allow data that did not come from observations. Changes to the research lesson would be limited to changes in the way of teaching since the mathematical contents are non-negotiable.

We found that mentor teachers primarily use the knowledge that they have acquired in their practice to respond to the hypothetical situations. They want to share that knowledge to the prospective teachers whom they supervise through example and create a participatory environment that allows for discussion and reflection. More research is needed to establish the aspects that allow these communities of LS to be true spaces for professional growth when there are participants with different experiences and knowledge.

UNDERSTANDING THE EVOLUTION OF A TEACHER'S PHILOSOPHY OF MATHEMATICS: PART I, HIS INITIAL CONCEPTIONS

José N. Contreras
Ball State University
jncontrerasf@bsu.edu

Teachers' beliefs and conceptions about the nature of mathematics affect their instructional practices (Thompson, 1992). Thus, considerable research has been done to understand the development of teachers' beliefs and conceptions using mostly qualitative methodologies (Cooney, 1985; Eggleton, 1995; Fernandes & Vale, 1994).

The goal of this research is to understand the evolution of a teacher's philosophy of mathematics and the impact of his philosophy on his classroom practice. In this poster, I will report on the teacher's conceptions about mathematics as he entered the teacher education program (thereafter called his initial conceptions) and the critical experiences that, from his own perspective, influenced those conceptions. As a main research method, I'm using the biographical approach, a particular method of narrative inquiry.

To better understand teachers' knowledge, thoughts, and conceptions, researchers have used narrative, biographical research, and self-study methodologies (e.g., Butt, Raymond, McCue, and Yamagishi, 1992; Elbaz, 1990; Fernandes 1995; Frost, 2010; (Hamilton et al., 2008; Kelchtermans, 1993, 1994; Knowles, 1992; Suazo-Flores et al. 2019).

The biographical approach involves the use of heuristic tools such as critical events and formative experiences. Damian Torres, the participant of the study, is writing a journal of reflections in which he reflects on his evolving philosophy of mathematics and provides answers to questions or discuss issues related to the nature of mathematics.

Damian Torres's initial conceptions about the nature of mathematics included a utilitarian view, a platonic view, a logical view, and a problem-solving view. He saw mathematics as a service subject because it is used to solve daily-life problems faced by ordinary people, and advanced practical problems faced by some people having a professional degree such as engineers, architects, etc. In addition, he conceived of mathematics as a tool to describe the physical world and that the goal of scientists was to discover the mathematical laws that govern nature and the universe. He also held a platonic view about the nature of mathematics. He thought that mathematics was a finished, immutable, and absolute body of knowledge. He said that mathematical formulas and theorems were true yesterday, are true today, and will be true tomorrow. The work of past mathematicians consisted of discovering the theorems and procedures. Damian also viewed mathematics as a logical, objective, and rational discipline. He stated that the solutions to mathematical problems, including the proofs of mathematical theorems, can always be checked because the solutions and the proofs are based on logical reasoning rather than on personal opinion or physical instruments subject to error. Finally, Damian Torres also conceived of mathematics as problem solving. He mentioned that mathematics provides problems to practice and the solutions to these problems involve applying appropriate formulas and theorems. In addition, he stated that mathematics helps develop our thinking and reasoning skills and that also provides the tools to solve problems in the real world. Damian Torres said that that some factors that shaped his initial conceptions include his experiences in solving daily-life problems and the problems and theories posed and described in mathematics and science textbooks.

WHAT AN ANGLE MEASURE MEASURES FOR PROSPECTIVE TEACHERS

Hamilton L. Hardison
Texas State University
HHardison@txstate.edu

Keywords: Geometry and Spatial Reasoning, Measurement, Angularity

Angle measure is a central topic in mathematics curricula at a variety of levels (Barabash, 2017). Yet, how individuals reason about angles and their measures has been the focus of fewer research studies in comparison to other geometric attributes like length and area (Smith & Barrett, 2017). Some researchers have argued that productive ways of reasoning about angularity can be engendered through principles of quantitative reasoning (e.g., Hardison & Lee, 2019; Hardison, 2020; Moore, 2013). More specifically, by working to foster a conception of angularity as a quantity—a measurable attribute of an object (Thompson, 2011). Attributes must be conceptualized in order to be quantified. Therefore, it is important to attend to the attribute(s) an individual holds in mind when considering an angle's measure. Openness and amount of rotation are two common characterizations of the angular attribute appearing in the literature, both of which can be conceived in relation to a circle. In this poster, I report on 19 prospective teachers' (PTs) conceptions of the attribute characterized by an angle's measure. At the time of the study, the participants were enrolled in an undergraduate geometry content course for middle and secondary PTs at a large public university in the United States. Data for the study included PTs responses to two prompts. In the first prompt, PTs provided a typed response to the question: "When you measure a line segment in inches, you're measuring its length; when you measure an angle in degrees, what are you measuring?" In the second prompt, PTs were provided with multiple copies of an angle model and asked to indicate (by drawing, shading, etc.) what exactly they would be measuring; multiple copies of the angle model were provided in the event that PTs wished to indicate more than one option for what they were measuring. Responses to the first prompt were coded based on the objects and attributes referenced. Responses to the second prompt were coded based on the characteristics of the drawings produced. For both prompts, responses could receive multiple codes.

PTs responses to the first prompt indicate relatively little consistency in the verbal characterization of the attribute that an angle's measure references. The most frequent responses included statements of uncertainty (21% of responses; e.g., "I don't know" or "I am not sure") or references to an angle as an object without nominalization of an attribute (21% of responses; e.g., "you are measuring the angle two lines make with each other"). Attributes mentioned included width (16%), opening (11%), rotation (11%), tilt (5%), distance (5%), area (5%), and position (5%). Other non-attribute responses included radius (5%) and radians (5%). Circles were mentioned in 16% of responses. For the second prompt, the 19 PTs produced a total of 44 drawings indicating what they thought they were measuring (an average of 2.3 drawings per PT). In these drawings, curved inscriptions suggesting circles were prominently featured with 48% of responses including a shaded circular sector and 39% of responses indicating a circular arc without a shaded region. Few responses indicated attention to linear attributes like side length (2%) or distance between the sides of the angle model (2%). The differences in PTs responses to these two tasks suggest that prospective teachers should be supported through opportunities to develop verbal characterizations of angle measure that are consistent with their mental imagery of angle measure. Further results and implications will be shared via the poster.

TOPICS CHOSEN BY PRE-SERVICE ELEMENTRY TEACHERS ENGAGING IN SELF-DIRECTED LEARNING IN A GEOMETRY CLASS

Susanna Molitoris Miller
Kennesaw State University
smolitor@kennesaw.edu

Keywords: Pre Service Teacher Education, Geometry and Spatial Reasoning, Measurement, Culturally Relevant Pedagogy

Self-Directed Learning (SDL) is a pedagogical approach described as "a process in which individuals take the initiative, with or without the help of others, in diagnosing their learning needs, formulating learning goals, identifying human and material resources for learning, choosing and implementing appropriate learning strategies, and evaluating learning outcomes" (Malcolm Shepherd Knowles, 1975, p. 18). Participating in SDL allows learners to draw from their own *mathematical funds of knowledge* (Velez-Ibanez & Greenberg, 2005) while also developing informal learning skills similar to those used by teachers throughout their careers (Kyndt et al., 2016; Wagner, 2011; McNally et. al, 2009).

This study explores themes among the types of self-directed learning projects completed by elementary education majors as part of a content course for pre-service teachers (PSTs). PSTs were told to learn something related to geometry and measurement and to then present a project as an "artifact" of that learning. Projects were assessed according to six criteria: clear communication of the mathematics, accuracy of the mathematics, a statement of why they chose the project, a statement of what they learned that they did not know before, inclusion of contextual information and references, and overall organization and neatness. Students were provided with a list of 100+ starter ideas but no structured steps. We assume, given the option to explore anything they like, that PSTs chose projects that felt relevant to them.

Data were collected at a large university outside of a major city in the Southeastern U.S. which attracts a diverse student population. The projects analyzed for this study were generated by 113 PSTs over the course of three semesters and seven course sections. Each PST completed a series of three mini projects each which could be related or unrelated to one another. PSTs were permitted to work with a partner.

The project set was reviewed for themes, and inductive codes were generated. Some themes occurred more than others, and some projects merited multiple codes. We will not report the frequency of each theme in order to not marginalize project types which were less common but equally important. Themes included:

- Companions – involved their child, pet, friends, or other relatives
- Art – analysis of existing art or generation of new mathematical art
- Work – unpacking or exploration of how concepts apply in their job
- Sports / Hobbies – technical components of soccer, dance, track, cheer, etc.
- Crafts / Baking / DIY projects – how mathematics plays a role in creating
- Scavenger Hunt – identifying concepts in everyday life
- Travel – Planning travel or observing concepts while away
- Wonderment – extending a topic via history, related topics, or a challenge problem
- Practice – exploring or practicing a concept from class to better understand it

While the specific applications of these themes varied from student to student, these general trends help identify areas of mathematics that are relevant to PST populations.

INFUSING PROOF AND JUSTIFICATION, MATHEMATICAL MODELING AND TECHNOLOGY: THE CASE OF MATHEMATICAL SERIES

Shahabeddin Abbaspour Tazehkand
University of Central Florida
Shaha8@ucf.edu

Farshid Safi
University of Central Florida
Farshid.Safi@ucf.edu

Keywords: Reasoning and Proof, Modeling, Technology, Preservice Teacher Education

Study has shown that teachers believe proof is a subject that not all students could learn (Knuth 2002). However, this is not the case for mathematical modeling or technology. This study aims to focus on enriching preservice teachers' knowledge about proof and justification by infusing other mathematical practices. To do this, we intentionally integrate frameworks from different subjects to build a structure in which the goal of learning and teaching proof and justification could be achieved. Since there are different definitions and frameworks for each mathematical practice that is mentioned, this is indeed a very challenging task. The content that we chose for this purpose is arithmetic and geometric series, which helps the purpose of the study since it is connected to a very rich context.

While it seems clear why mathematics is essential in any society, it is not clear how educators should prepare students to use mathematics when using it to make sense of everyday life's challenges in solving real-life issues (Abassian et al., 2020). Mathematical modeling represents how students use mathematics and apply it to solve those real-world and everyday life problems. The definition that we chose for this study is the models and modeling perspective (MMP)/contextual modeling. According to Lesh & Doerr (2003), MMP extends the goal of problem-solving to develop the applications of mathematics in real-world situations in order to make a deeper understanding of mathematical concepts.

Although there are different definitions for mathematical proofs, researchers consistently indicate that proof and proving have a central role in mathematical practice (Zazkis, Weber & Mejia-Ramos, 2014). Mathematics educators also agree that in K-12 school mathematics, curriculum proof needs to have a central place (Stylianides & Stylianides, 2006) because, in mathematics itself, the proof has a central role, and K-12 mathematics should maintain that structure for students. Since the focus of tasks in this study is on mathematical sequences and series, we chose to work with Stylianides' (2008) analytical framework of reasoning and proving. The mentioned framework has three components: mathematical, psychological, and pedagogical, which suits the purpose of our study and working with preservice teachers.

Common Core State Standards for Mathematics (CCSSM, 2010) states that technology is a powerful tool to help students understand and solve real-world problems and situations that are modeled mathematically. The role of technology is emphasized in Principles and Standards for School Mathematics (NCTM 2000). The technology principle says, "Technology is essential in teaching and learning mathematics; it influences the mathematics taught and enhances students' learning." In this study, we use Mishra Koehler's (2006) framework that was introduced for research in preparing teachers to integrate technology in classrooms.

Using the different frameworks, this study will lead to a chain of tasks in investigating mathematics sequences and series. Those designed tasks will help preservice teachers by providing them opportunities to explore how proofs are constructed through a productive challenge.

Student Learning

THE EVOLUTION FROM LINEAR TO EXPONENTIAL MODELS WHEN SOLVING A MODEL DEVELOPMENT SEQUENCE

EVOLUCIÓN DE MODELOS LINEALES A EXPONENCIALES AL RESOLVER UNA SECUENCIA DE DESARROLLO DE MODELOS

Luis E. Montero-Moguel
University of Texas, San Antonio
Universidad de Guadalajara

guadalupe.carmona@utsa.edu

This article describes the results of an investigation based on a Models and Modeling Perspective [MMP]. We present the evolution of the models built by university students when solving a model development sequence designed to promote their learning of the exponential function. As a result, we observed that students' thinking was modified, expanded, and refined, as they developed different iterations of their models. Students' models evolved by creating, first, linear models that required direction; second, models where there was no dissociation between linear and exponential behavior; then, situated exponential models; and finally, sharable, and reusable exponential models.

Keywords: Modeling, College-level mathematics, Exponential function

In the research literature (Ärlebäck, Doerr & O'Neil, 2013; Ärlebäck & Doerr, 2018) it is mentioned that high school and undergraduate students have difficulties with the learning of the exponential function because it is a mathematical object whose learning requires a high cognitive transfer capacity. In addition, its understanding implies also understanding other concepts. For example, learning the exponential function requires students to develop covariational reasoning (Carlson, Jacobs, Coe, Larsen, & Hsu, 2002; Thompson & Carlson, 2017). Research by Ärlebäck and Doerr (2018) and Ärlebäck, Doerr and O'Neil (2013) shows the importance of designing Model Eliciting Activities [MEAs] for students to develop knowledge related to the exponential function. Technology can support the learning of the exponential function because it allows the use of different representations and the connection between them to interpret, describe and predict phenomena, in addition to simplifying calculations. Due to its dynamic nature, technology can also support students to delve into the concepts such as variation (Stillman, Blum & Kaiser, 2013) and therefore to develop their covariational reasoning.

The problem addressed in this research was to better understand how a model development sequence can contribute to the expansion and refinement of the knowledge of exponential function developed by undergraduate students in business administration and accounting [LAEC]. The research question posed was: How did LAEC students' models and covariational reasoning - related to the exponential function- evolve when solving a model development sequence based on real-life problems, with the support of technology?

Conceptual framework

The conceptual framework of this research was based on the MMP proposed by Lesh and Doerr (2003) and the covariational reasoning framework proposed by Carlson et al. (2002).

Models and Modeling Perspective

According to the MMP, learning mathematics is a process of developing conceptual systems, which are continually modified, extended and refined based on the student's interactions with their environment (e.g., teachers and peers) and by solving problems (Lesh, 2010). Solving problems implies “differentiating, integrating, reorganizing, adapting or extending interpretation systems that are in intermediate stages of development” (Lesh, 2010, p. 27). Cycles of Modeling are interpretations that students exhibit when solving MEAs, in which the ways of thinking are repeatedly expressed, tested, and revised (Lesh, 2010; Sevinc & Lesh, 2018). From the MMP, models are defined as:

> Conceptual systems (consisting of elements, relations, operations, and rules governing interactions) that are expressed using external notation systems, and that are used to construct, describe, or explain the behaviors of other system(s)—perhaps so that the other system can be manipulated or predicted intelligently.
>
> A mathematical model focuses on the structural characteristics (rather than, for example, physical or musical characteristics) of the relevant systems. (Lesh and Doerr, 2003, p. 10)

In this way, the MMP proposes structuring experiences for the student, in which they express, test and refine their ways of thinking during the process of building a mathematical model to solve a situation that is presented to them. These situations, intentionally designed for students to generate models using specific mathematical ideas, are called Model Eliciting Activities [MEAs], and they are situated in everyday contexts (Doerr, 2016; Lesh & Doerr, 2003; Aliprantis & Carmona, 2003). As in everyday life, these situations are open and can be solved in many ways. Therefore, students generate various approaches and levels of sophistication of mathematical thinking that are explicitly expressed in the models they build.

Lesh, Cramer, Doerr, Post and Zawojewski (2003) propose a standard organizational scheme for model development curricular sequences composed of a MEA, a Model Exploration Activity [MXA] and a Model Adaptation Activity [MAA].

A proposal to analyze the types of models that students build when solving a MEA is the “MEA Quality Assessment Guide” (Lesh, 2010, p. 33) designed to help teachers and students evaluate the quality and level of sophistication of the models they develop in response to MEAs. The evaluation is proposed in terms of the relevance of the model developed by the students in solving the situation that has been presented to them in the MEA, identifying five levels. The solution: a) requires redirection, b) requires major extensions or refinements, c) requires only minor editing, d) is useful for these specific data given. and e) is sharable and reusable.

Conceptual framework for covariational reasoning

Learning exponential functions implies that students develop a covariational reasoning. That is, "the cognitive activities involved in the coordination two varying quantitative while attending to the ways in which they change in relation to each other" (Carlson et al., 2002, p. 124). The conceptual framework proposed by Carlson et al. (2002) is oriented to the study of covariational reasoning that students develop when solving problems that contain situations that involve the use of two quantities that change simultaneously. Four of the five levels of covariational reasoning identified by Carlson are shown in Table 1.

Table 1: Four levels of covariational reasoning from Carlson et al. (2002, p. 358)

Level 1 (L1). Coordination
At the coordination level, the images of covariation can support the mental action of coordinating the change of one variable with changes in the other variable (MA1).
Level 2 (L2). *Direction*
At the direction level, the images of covariation can support the mental action of coordinating the direction of change of one variable with changes in the other variable. The mental actions identified as MA1 and MA2 are *both* supported by L2 images.
Level 3 (L3). *Quantitative Coordination*
At the quantitative coordination level, the images of covariation can support the mental actions of coordinating the amount of change in one variable with changes in the other variable. The mental actions identified as MA1, MA2 and MA3 are supported by L3 images.
Level 4 (L4). *Average Rate*
At the average rate level, the images of covariation can support the mental actions of coordinating the average rate of change of the function with uniform changes in the input variable. The average rate of change can be unpacked to coordinate the amount of change of the output variable with changes in the input variable. The mental actions identified as MA1 through MA4 are supported by L4 images.

Based on these two theories, Montero-Moguel & Vargas-Alejo (2021) proposed a classification of models called "Guide for the evaluation of models related to the concept of function" [GEMF] that allows describing the evolution of the models and the covariational reasoning developed by the students when solving MEAs where the concept of exponential function underlies.

Methodology

The research was qualitative because the interest was to study the development process of students' concept of exponential function in order to identify and describe the evolution of the models developed during the model development sequence. The research participants were 10 first-semester university-level students (women and men). The students were in a course focusing on mathematics applied to business. Before they were exposed to the model development sequence designed for this study, the students had not covered the topic of exponential function as part of in this course.

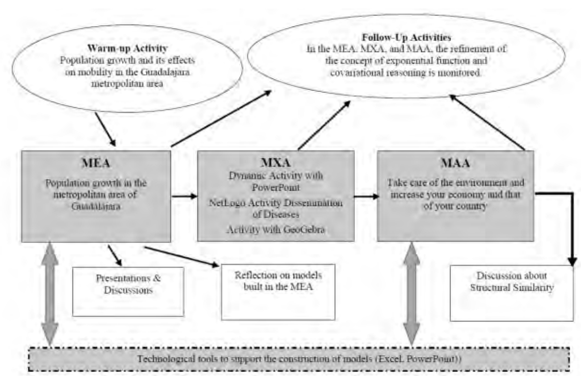

Figure 1: Didactic sequence diagram

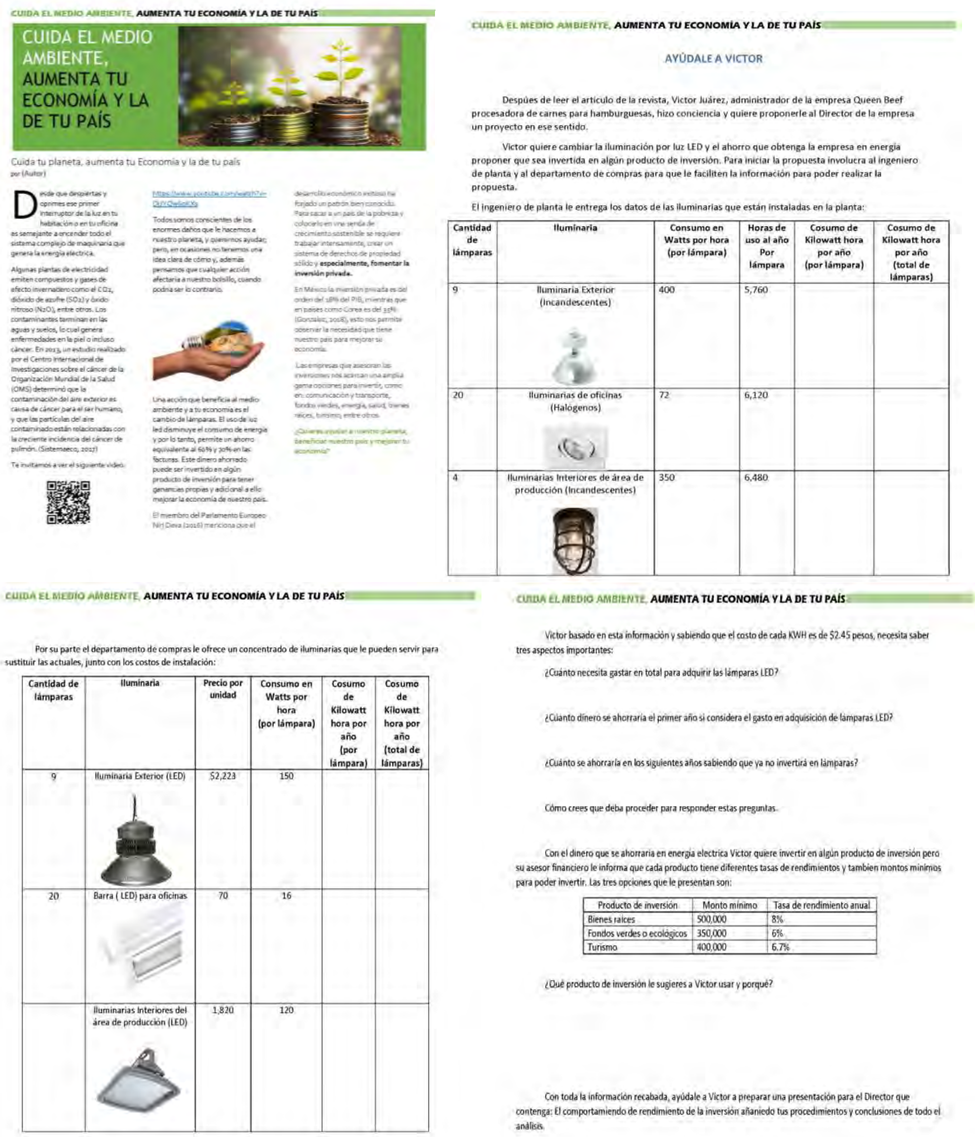
The model development sequence was designed based on the proposal of Lesh et al. (2003). It was made up of three activities (Figure 1): a) MEA in the context of population growth

(Montero-Moguel &Vargas Alejo, 2021), b) MXA divided into three parts, PowerPoint activity, NetLogo activity, and GeoGebra activity, c) MAA in the context of taking care for the environment and investments.

The MEA and MAA were designed with the same structure to elicit students' conceptions of exponential function, including three parts: a newspaper designed for this MEA, context questions, and a situation. The newspaper and the situation of the MAA are shown in Figure 2.



CUIDA EL MEDIO AMBIENTE, AUMENTA TU ECONOMÍA Y LA DE TU PAÍS

CUIDA EL MEDIO AMBIENTE, AUMENTA TU ECONOMÍA Y LA DE TU PAÍS

Cuida tu planeta, aumenta tu Economía y la de tu país
por (Autor)

Desde que despiertas y oprimes ese primer interruptor de la luz en tu habitación o en tu oficina es semejante a encender todo el sistema complejo de maquinaria que genera la energía electrica.

Algunas plantas de electricidad emiten compuestos y gases de efecto invernadero como el CO_2, dióxido de azufre (SO_2) y óxido nitroso (N_2O), entre otros. Los contaminantes terminan en las aguas y suelos, lo cual genera enfermedades en la piel o incluso cáncer. En 2013, un estudio realizado por el Centro Internacional de Investigaciones sobre el cáncer de la Organización Mundial de la Salud (OMS) determinó que la contaminación del aire exterior es causa de cáncer para el ser humano, y que las partículas del aire contaminado están relacionadas con la creciente incidencia del cáncer de pulmón. (Sistemaeco, 2017)

Te invitamos a ver el siguiente video.

Todos somos conscientes de los enormes daños que le hacemos a nuestro planeta, y queremos ayudar, pero, en ocasiones no tenemos una idea clara de cómo y, además pensamos que cualquier acción afectaria a nuestro bolsillo, cuando podría ser lo contrario.

Una acción que beneficia al medio ambiente y a tu economía es el cambio de lámparas. El uso de luz led disminuye el consumo de energía y por lo tanto, permite un ahorro equivalente al 60% y 70% en las facturas. Este dinero ahorrado puede ser invertido en algún producto de inversión para tener ganancias propias y adicional a ello mejorar la economía de nuestro país.

El miembro del Parlamento Europeo Nirj Deva (2016) menciona que el desarrollo económico exitoso ha forjado un patrón bien conocido. Para sacar a un país de la pobreza y colocarlo en una senda de crecimiento sostenible se requiere trabajar intensamente, crear un sistema de derechos de propiedad sólido y **especialmente, fomentar la inversión privada.**

En México la inversión privada es del orden del 18% del PIB, mientras que en países como Corea es del 35% (González, 2018), esto nos permite observar la necesidad que tiene nuestro país para mejorar su economía.

Las empresas que asesoran las inversiones nos acercan una amplia gama opciones para invertir, como en: comunicación y transporte, fondos verdes, energía, salud, bienes raíces, turismo, entre otros.

¿Quieres ayudar a nuestro planeta, beneficiar nuestro país y mejorar tu economía?

CUIDA EL MEDIO AMBIENTE, AUMENTA TU ECONOMÍA Y LA DE TU PAÍS

AYÚDALE A VICTOR

Despúes de leer el articulo de la revista, Victor Juárez, administrador de la empresa Queen Beef procesadora de carnes para hamburguesas, hizo conciencia y quiere proponerle al Director de la empresa un proyecto en ese sentido.

Victor quiere cambiar la iluminación por luz LED y el ahorro que obtenga la empresa en energía proponer que sea invertida en algún producto de inversión. Para iniciar la propuesta involucra al ingeniero de planta y al departamento de compras para que le faciliten la información para poder realizar la propuesta.

El ingeniero de planta le entrega los datos de las iluminarias que están instaladas en la planta:

Cantidad de lámparas	Iluminaria	Consumo en Watts por hora (por lámpara)	Horas de uso al año Por lámpara	Cosumo de Kilowatt hora por año (por lámpara)	Cosumo de Kilowatt hora por año (total de lámparas)
9	Iluminaria Exterior (Incandescentes)	400	5,760		
20	Iluminarias de oficinas (Halógenos)	72	6,120		
4	Iluminarias Interiores de área de producción (Incandescentes)	350	6,480		

CUIDA EL MEDIO AMBIENTE, AUMENTA TU ECONOMÍA Y LA DE TU PAÍS

Por su parte el departamento de compras le ofrece un concentrado de iluminarias que le pueden servir para sustituir las actuales, junto con los costos de instalación:

Cantidad de lámparas	Iluminaria	Precio por unidad	Consumo en Watts por hora (por lámpara)	Cosumo de Kilowatt hora por año (por lámpara)	Cosumo de Kilowatt hora por año (total de lámparas)
9	Iluminaria Exterior (LED)	$2,223	150		
20	Barra (LED) para oficinas	70	16		
	Iluminarias Interiores del área de producción (LED)	1,820	120		

CUIDA EL MEDIO AMBIENTE, AUMENTA TU ECONOMÍA Y LA DE TU PAÍS

Victor basado en esta información y sabiendo que el costo de cada KWH es de $2.45 pesos, necesita saber tres aspectos importantes:

¿Cuánto necesita gastar en total para adquirir las lámparas LED?

¿Cuánto dinero se ahorraría el primer año si considera el gasto en adquisición de lámparas LED?

¿Cuánto se ahorraría en los siguientes años sabiendo que ya no invertirá en lámparas?

Cómo crees que deba proceder para responder estas preguntas.

Con el dinero que se ahorraria en energia electrica Victor quiere invertir en algún producto de inversión pero su asesor financiero le informa que cada producto tiene diferentes tasas de rendimientos y tambien montos minimos para poder invertir. Las tres opciones que le presentan son:

Producto de inversión	Monto mínimo	Tasa de rendimiento anual
Bienes raices	500,000	8%
Fondos verdes o ecológicos	350,000	6%
Turismo	400,000	6.7%

¿Qué producto de inversión le sugieres a Victor usar y porqué?

Con toda la información recabada, ayúdale a Victor a preparar una presentación para el Director que contenga: El comportamiendo de rendimiento de la inversión añaniedo tus procedimientos y conclusiones de todo el análisis.

Figure 2: Newspaper and situation of the MAA

The GEMF was used to analyze the data, it allowed to analyze the models built by the students when they solved the model development sequence (Table 2).
The experimentation lasted three sessions of three hours each. It was important to collect data from different sources to support the phenomenon studied, including: student worksheets, audio recordings, video recordings, and teacher's log.

Table 2: Classification of models

Model T1. The model requires direction
The model is not associated with the function (exponential, in this case) that allows to better describe, interpret, predict and control the situation. Students associate a linear behavior to the situation. Students need additional comments from their classmates or questions that encourage reflection by the teacher, that allow them to redirect their way of thinking. In relation to covariational reasoning, students show level 1 of Carlson et al. (2002, p. 358): "the images of covariation can support the mental action of coordinating the change of one variable with changes in the other variable (MA1)".
Model T2. The model requires major extensions or refinements
The model is associated with the (exponential) function that best describes the situation; however, students are unable to dissociate linear behavior. The student needs to work further to obtain greater extensions or refinements. Regarding covariational reasoning associated with the function that best describes the situation, the student shows coordination and direction of the variables. Students' reasoning relates to level 2 of Carlson et al. (2002, p. 358): " the images of covariation can support the mental action of coordinating the direction of change of one variable with changes in the other variable ".
Model T3. The model is situated
The model is associated with the (exponential) function that best describes the situation. It is only useful for the context of the situation presented. The student's conceptual system is extended and refined by differentiating between exponential and linear behavior. In relation to covariational reasoning associated with the function that best describes the situation, students exhibit coordination, direction, and quantification of the variables. Students' reasoning relates to level 3 of Carlson et al. (2002, p. 358): "the images of covariation can support the mental actions of coordinating the amount of change in one variable with changes in the other variable".
Model T4. The model is sharable and reusable
The tool not only works for the proposed problem, but it would also be easy for others to modify and use it in similar situations outside the context of the situation posed. Regarding covariational reasoning associated with the function that best describes the situation, students exhibit coordination, direction, quantification, and average rate of change of the variables. Students' reasoning relates to level 4 of Carlson et al. (2002). The images of covariation can support the mental actions of coordinating the average rate of change of the function with uniform changes in the input variable. The average rate of change can be unpacked to coordinate the amount of change of the output variable with changes in the input variable. (Carlson et al., 2002, p. 358)

Results Analysis and Discussion

A qualitative data analysis was conducted based on the following modeling cycles.

First Modeling Cycle

Models were developed during teamwork as students solved the MEA. The four teams built model T1 (Require Direction) and included only tabular representations. The students did not recognize an exponential pattern, they focused on solving the situation using linear models. Their level of covariational reasoning was level 1 (coordination) based on Carlson et al. (2002).

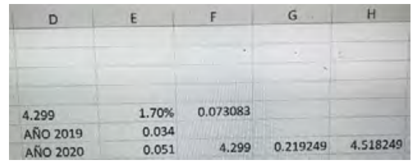
Models T1. Teams A and D multiplied the data included in the MEA (the initial population of 4.299 million times the growth rate of 1.7%) and obtained the value of 0.073803 (million people) that they assumed constant (Figure 3a). Team C detected that the growth for the years 2019, 2020 and 2021 was 0.073, 0.074 and 0.075 million inhabitants, respectively; they thought that the population increased 0.001 million people per year, that is, they believed that the growth was constant (Figure 3c). Team B model was characterized by the use of the "rule of three". A member of the team commented the following.

S4: Let's see, then we need to get the 1.7, so… would it be like a rule of three?

AÑO	2018	2019	2020	2021	2022
POBLACIÓN INICIAL	4.299	4.373	4.447	4.520	4.594
CRECIMIENTO ANUAL	0.073803	0.073803	0.073803	0.073803	0.073803
POBLACIÓN FINAL [POBLACIÓN INICIAL + CRECIMIENTO]	4.373	4.447	4.520	4.594	4.668

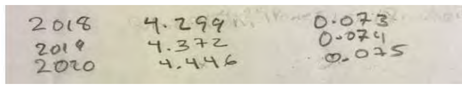
Nota: Datos en millones de habitantes

a) Teams A and D model



D	E	F	G	H
4.299	1.70%	0.073083		
AÑO 2019	0.034			
AÑO 2020	0.051	4.299	0.219249	4.518249

b) Team B model



2018	4.299	0.073
2019	4.372	0.074
2020	4.446	0.075

c) Team C model

Figure 3: Models first modeling cycle of the equipment

Second Modeling Cycle

These models were developed by students after they self-evaluated their first model and interacted with the teacher. Three types of models emerged.

Models T2. Teams B and D built tabular and graphical representations. The teams did not dissociate the exponential growth from the linear. Covariational reasoning level 2 from Carlson et. al (2002)

Models T3. Team A built an exponential and situated model (Figure 4a). The representations were tabular. Covariational Reasoning Level 3 from Carlson et. al (2002).

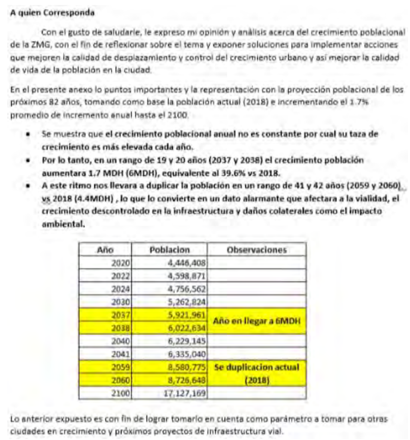
Models T4. Team C built an exponential model, integrated algebraic representations; the model was sharable and reusable (Figure 4b). Covariational reasoning level 4 from Carlson et. al (2002).

Third Modeling Cycle

These models were developed after each team of students engaged in a whole class discussion. Prior to this, students wrote their letters individually as a homework assignment.

Models T3. Students S4 and S5 included graphical and tabular representations in their models; they expressed that growth was not constant and it depended on the rate of 1.7%. The model was situated.

Models T4. Eight students included tabular, graphical, verbal, and algebraic representations in their models, which are modifiable and reusable for similar situations outside the context of the population growth situation.



A quien Corresponda

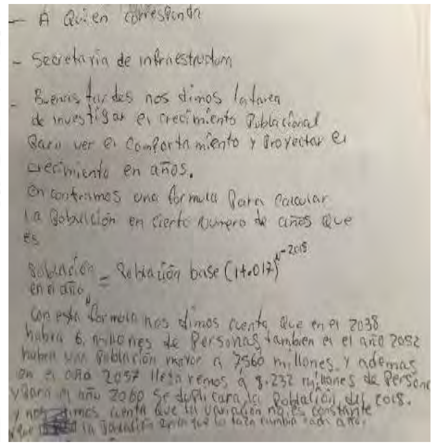
Con el gusto de saludarle, le expreso mi opinión y análisis acerca del crecimiento poblacional de la ZMG, con el fin de reflexionar sobre el tema y exponer soluciones para implementar acciones que mejoren la calidad de desplazamiento y control del crecimiento urbano y así mejorar la calidad de vida de la población en la ciudad.

En el presente anexo lo puntos importantes y la representación con la proyección poblacional de los próximos 82 años, tomando como base la población actual (2018) e incrementando el 1.7% promedio de incremento anual hasta el 2100.

- Se muestra que **el crecimiento poblacional anual no es constante por cual su taza de crecimiento es más elevada cada año.**
- **Por lo tanto, en un rango de 19 y 20 años (2037 y 2038) el crecimiento población aumentara 1.7 MDH (6MDH), equivalente al 39.6% vs 2018.**
- **A este ritmo nos llevara a duplicar la población en un rango de 41 y 42 años (2059 y 2060) vs 2018 (4.4MDH) , lo que lo convierte en un dato alarmante que afectara a la vialidad, el crecimiento descontrolado en la infraestructura y daños colaterales como el impacto ambiental.**

Año	Poblacion	Observaciones
2020	4,446,408	
2022	4,598,871	
2024	4,756,562	
2030	5,262,824	
2037	5,921,961	Año en llegar a 6MDH
2038	6,022,634	
2040	6,229,145	
2041	6,335,040	
2059	8,580,775	Se duplicacion actual (2018)
2060	8,726,648	
2100	17,127,169	

Lo anterior expuesto es con fin de lograr tomarlo en cuenta como parámetro a tomar para otras ciudades en crecimiento y próximos proyectos de infraestructura vial.



- A Quien corresponda
- Secretaria de infraestructura
- Buenas tardes nos dimos la tarea de investigar el crecimiento Poblacional para ver el comportamiento y proyectar el crecimiento en años.
En contramos una formula para calcular la Población en cierto numero de años que es
Población en el año n = Población base $(1+.017)^{n-2018}$
Con esta formula nos dimos cuenta que en el 2038 habra 6 millones de personas tambien en el año 2052 habra una población mayor a 7.560 millones y ademas en el año 2057 llegaremos a 8.232 millones de personas y para el año 2060 se duplicara la población del 2018. y nos dimos cuenta que la variación no es constante [illegible] la población ya que la taza cambia cada año.

a) Model team A b) Model team C

Figure 4: Example of models built in the second modeling cycle

Fourth Modeling Cycle

Models were developed when the students solved the MAA. The students exhibited model T4. The characteristics of the fourth modeling cycle were the following.

5. Two students (S4 and S5) improved their models from Model T3 to T4. They included a diversity of representations in their models.
6. Eight students (S1, S2, S3, S6, S7, S8, S9, and S10) affirmed their model T4.
    - a. Four students (S3, S8, S9, and S10) mathematized based on only one investment rate to explain the situation.
    - b. Four students (S1, S2, S6, and S7) mathematized based on the three investment rates.
        - i. Three students (S1, S2, and S6) proposed the choice of only one investment product (green funds) (Figure 5).
        - ii. One student (S7) proposed a combination of different investment products.

CAMBIO DE ILUMINARIA INCANDESCENTE A LED – CUIDA EL MEDIO AMBIENTE E INVERSION

Con el ahorro en 10 años ($602,825), podemos invertir en 3 opciones de inversión que a continuación represento de forma tabular y grafica .
T = Inversión Inicial (1 + % de Rendimiento)
En conclusión, por sentido común la inversión en bienes raíces genera mejores rendimientos, sin embargo, el fondo del proyecto además de ahorrar recursos económicos también están los recursos naturales, por lo que en mi punto de vista sugiero reinvertir lo ahorrado en este concepto para seguir desarrollando tecnologías y acciones que promuevan la sustentabilidad ambiental.

	Año	Bienes Raices	Ambiental	Turismo
AHORRO POR CONSUMO	1	$ 34,464	$ 34,464	$ 34,464
	2	$ 97,615	$ 97,615	$ 97,615
	3	$ 160,767	$ 160,767	$ 160,767
	4	$ 223,918	$ 223,918	$ 223,918
	5	$ 287,069	$ 287,069	$ 287,069
	6	$ 350,220	$ 350,220	$ 350,220
	7	$ 413,371	$ 413,371	$ 413,371
	8	$ 476,523	$ 476,523	$ 476,523
	9	$ 539,674	$ 539,674	$ 539,674
	10	$ 602,825	$ 602,825	$ 602,825
RENDIMIENTOS DE INVERSION	11	$ 651,051	$ 638,995	$ 643,214
	12	$ 703,135	$ 677,334	$ 686,310
	13	$ 759,386	$ 717,974	$ 732,292
	14	$ 820,137	$ 761,053	$ 781,356
	15	$ 885,748	$ 806,716	$ 833,707
	16	$ 956,608	$ 855,119	$ 889,565
	17	$ 1,033,136	$ 906,426	$ 949,166
	18	$ 1,115,787	$ 960,811	$ 1,012,760
	19	$ 1,205,050	$ 1,018,460	$ 1,080,615

Ambiental	6.0%

Figure 5: Example of models from the fourth modeling cycle

Figure 5 is an example of the model T4 built by the students in the fourth cycle, during which students dissociated the linear and exponential behavior and included different representations (verbal, tabular, graphical, and algebraic). Regarding the linear function, students used it to describe energy savings and identified a constant growth. Regarding the exponential function, students included an analysis of three types of investment instrument at ten years, which allowed them to propose a form of investment portfolio. A summary of the evolution of the linear to exponential models built by the students can be observed in Table 3.

Table 3: Scheme showing the evolution of the models

Team	Student	Type of Model built by the students			
		First cycle MEA (Team)	Second cycle MEA (Team)	Third cycle MEA (Individual)	Fourth cycle MAA (Individual)
A	S1	T1	T3	T4	T4
	S2	T1	T3	T4	T4
B	S3	T1	T2	T4	T4
	S4	T1	T2	T3	T4
	S5	T1	T2	T3	T4
C	S6	T1	T4	T4	T4
	S7	T1	T4	T4	T4
	S8	T1	T4	T4	T4
D	S9	T1	T2	T4	T4
	S10	T1	T2	T4	T4

Conclusions

This analysis allowed us to address the research question, how did LAEC students' models and covariational reasoning - related to the exponential function- evolve when solving a model development sequence based on real-life problems, with the support of technology?

The evolution of the models developed by students was observed in each modeling cycle. In the first cycle, all the teams built T1 models. They identified variables, but did not understand the type of relationship between them. The ideas and procedures associated with the situation were linear. The teams gave more importance to the answers obtained for the situation than to the construction of models.

In the second cycle, three types of models were built (T2, T3, and T4) characterized by various attributes, including: a) Model T2: Teams B and D used language associated with the linear function to describe the exponential function. They failed to dissociate linear behavior from exponential. b) Model T3: Team A exhibited coordination, direction, and quantification of the variables. This team dissociated linear behavior from exponential; the model was situated. c) Model T4: Team C exhibited coordination, direction, quantification, and average rate of change between the variables. This team not only dissociated linear behavior from the exponential, but they also built useful models for a specific client (sharable) who was interested in solving the situation, and any similar situation with different initial conditions (reusable).

In the third modeling cycle, the students individually reconstructed the models, based on the group discussions generated in class. They all participated in the evaluation and self-evaluation of their models. Students' progress in developing their knowledge and skills to mathematize evolved to situated (T3), and shareable and reusable models (T4). In the fourth modeling cycle, the students, individually, transferred their knowledge obtained by performing the MEA and MXA, which allowed them to deepen their knowledge regarding concepts such as: variation, exponential function, variables and use of different representations. When solving the MAA, the refinement of ideas was noted, all the students built sharable and reusable models (T4).

EVOLUCIÓN DE MODELOS LINEALES A EXPONENCIALES AL RESOLVER UNA SECUENCIA DE DESARROLLO DE MODELOS

THE EVOLUTION FROM LINEAR TO EXPONENTIAL MODELS WHEN SOLVING A MODEL DEVELOPMENT SEQUENCE

En este artículo se describen resultados de una investigación basada en la Perspectiva de Modelos y Modelación [PMM]. Se presenta la evolución de los modelos construidos por estudiantes universitarios al resolver una secuencia de desarrollo de modelos creada para propiciar el aprendizaje de la función exponencial. Como resultado, se observó que el *pensamiento de los estudiantes se modificó, amplió y refinó, ya que los modelos evolucionaron. Primero, se construyeron modelos que requerían dirección por ser lineales; después, modelos donde no se exhibía disociación entre comportamiento lineal y exponencial; enseguida, modelos exponenciales situados; y finalmente, modelos exponenciales compartibles y reutilizables.*

Palabras clave: Modelación, Matemáticas de nivel universitario, Función exponencial

En la literatura de estudios de investigación (Ärlebäck, Doerr y O'Neil, 2013; Ärlebäck y Doerr, 2018) se menciona que los estudiantes de nivel superior tienen dificultades con el aprendizaje de la función exponencial porque es un objeto matemático cuyo aprendizaje requiere una alta capacidad cognoscitiva de transferencia, ya que su comprensión implica entender otros conceptos. El aprendizaje de la función exponencial requiere que los estudiantes desarrollen un razonamiento covariacional (Carlson, Jacobs, Coe, Larsen y Hsu, 2002; Thompson y Carlson, 2017). Investigaciones realizadas por Ärlebäck y Doerr (2018) y Ärlebäck, Doerr y O'Neil (2013) muestran la importancia del diseño de Actividades Provocadoras de Modelos [MEAs, por sus siglas en inglés] para que los estudiantes desarrollen conocimiento relacionado con la función exponencial. La tecnología podría apoyar el aprendizaje de la función exponencial debido a que posibilita el uso de distintas representaciones y la conexión entre ellas para interpretar, describir y predecir fenómenos, además de simplificar cálculos. Debido a su carácter dinámico la tecnología puede apoyar a los estudiantes a profundizar en conceptos como variación (Stillman, Blum y Kaiser, 2013) y por lo tanto a desarrollar su razonamiento covariacional.

El problema que interesó abordar en esta investigación fue conocer cómo una secuencia de desarrollo de modelos puede contribuir a la ampliación y refinamiento del conocimiento sobre la función exponencial de estudiantes de licenciatura en administración de empresas y en contaduría [LAEC]. Por lo tanto, la pregunta de investigación que se planteó fue ¿Cómo evolucionaron los modelos y el razonamiento covariacional−relacionados con la func exponencial− de estudiantes de LAEC al resolver, con el apoyo de tecnología, una secuencia de desarrollo de modelos compuesta por problemas cercanos a la vida real?

Marco Conceptual

El Marco conceptual de esta investigación se estructuró con base en la PMM propuesta por Lesh y Doerr (2003) y el razonamiento covariacional propuesto por Carlson et al. (2002).

La Perspectiva de Modelos y Modelación

De acuerdo con la PMM, aprender matemáticas es un proceso de desarrollo de sistemas conceptuales, que se modifican de manera continua; se extienden y refinan a partir de las interacciones del estudiante con su entorno (e.g., los profesores y compañeros) y al resolver problemas (Lesh, 2010). Resolver problemas implica "diferenciar, integrar, reorganizar, adaptar o extender sistemas de interpretación que se encuentran en etapas intermedias de desarrollo." (Lesh, 2010, p. 27) Los ciclos de modelación son interpretaciones que los estudiantes exhiben al resolver las MEAs, en las cuales las formas de pensamiento se expresan, prueban y revisan repetidamente (Lesh, 2010; Sevinc y Lesh, 2018). Desde la PMM, los modelos se definen como:

> Sistemas conceptuales (que consisten en elementos, relaciones, operaciones y reglas que gobiernan las interacciones) que se expresan mediante sistemas de notación externa, y se usan para construir, describir o explicar los comportamientos de otros sistemas –Quizás de tal forma que otro sistema pueda ser manipulado o predicho de manera inteligente.

> Un modelo matemático se enfoca en las características estructurales (más que, por ejemplo, en características musicales o físicas) de los sistemas relevantes. (Lesh y Doerr, 2003, p. 10)

De esta manera, la PMM propone estructurar experiencias para el alumno, en las cuales exprese, pruebe y refine sus formas de pensamiento durante el proceso que desarrolla al generar un modelo matemático para resolver una situación problemática que le es presentada. Estas situaciones diseñadas intencionalmente para que los alumnos generen modelos utilizando ideas matemáticas específicas se llaman Actividades Provocadoras de Modelos (MEAs), y están situadas en contextos cotidianos (Doerr, 2016; Aliprantis y Carmona, 2003). Tal como sucede en la vida cotidiana, estas situaciones son abiertas y se pueden resolver de muchas maneras. Por tanto, los estudiantes generan varias aproximaciones y niveles de sofisticación de pensamiento matemático que quedan expresados de manera explícita en los modelos que generan en sus soluciones.

Lesh, Cramer, Doerr, Post y Zawojewski (2003) proponen un esquema organizacional estándar para secuencias curriculares de desarrollo de modelos compuesto por una MEA, una Actividad de Exploración de Modelos [MXA] y una Actividad de Adaptación de Modelos [MAA].

Una propuesta para analizar los tipos de modelos que los alumnos construyen al resolver una MEA es la “guía de evaluac alidad MEA” (Lesh, 2010, p. 33) dise ada para ayudar a los maestros y estudiantes a evaluar la calidad y nivel de sofisticación de los modelos que desarrollan en sus respuestas a las MEAs. La evaluación se propone en términos de la pertinencia del modelo desarrollado por los estudiantes al resolver la situación problemática que se le ha presentado en la MEA, identificando cinco niveles: a) Requiere redirección, b) Requiere mayores extensiones o refinamientos, c) Sólo requiere ediciones menores, d) Útil para estos datos específicos dados y e) Compartible y reutilizable.

Marco conceptual de razonamiento covariacional

El estudio de las funciones exponenciales implica que los alumnos desarrollen un razonamiento covariacional, es decir “actividades cognitivas implicadas en la coordinación de dos cantidades que varían mientras se atiende a las formas en que cada una de ellas cambia con respecto a la otra” (Carlson et al., 2002, p. 124). El marco conceptual propuesto por Carlson et al. (2002) se orienta al estudio del razonamiento covariacional que desarrollan los estudiantes al resolver situaciones problema que implican el uso de dos cantidades que cambian simultáneamente. Cuatro de los cinco niveles de razonamiento covariacional identificados por Carlson se observan en la Tabla 1.

Tabla 1: Cuatro niveles de razonamiento covariacional de Carlson et al. (2002, p. 358)

Nivel 1 (N1). ***Coordinación***
En el nivel de coordinación, las imágenes de la covariación pueden sustentar a la acción mental de coordinar el cambio de una variable con cambios en la otra variable (AM1).
Nivel 2 (N2). ***Dirección***
En el nivel de dirección, las imágenes de la covariación pueden sustentar a las acciones mentales de coordinar la dirección del cambio de una de las variables con cambios en la otra. Las acciones mentales identificadas como AM1 y AM2 son sustentas por imágenes de N2.
Nivel 3 (N3). ***Coordinación cuantitativa***
En el nivel de la coordinación cuantitativa, las imágenes de la covariación pueden sustentar a las acciones mentales de coordinar la cantidad de cambio en una variable con cambios en la otra. Las acciones mentales identificadas como AM1, AM2 y AM3 son sustentadas por las imágenes de N3.

Nivel 4 (N4). ***Razón promedio***
En el nivel de la razón promedio, las imágenes de covariación pueden sustentar a las acciones mentales de coordinar la razón de cambio promedio de una función con cambios uniformes en los valores de entrada de la variable. La razón de cambio promedio se puede descomponer para coordinar la cantidad de cambio de la variable resultante con los cambios en la variable de entrada. Las acciones mentales identificadas como AM1 hasta AM4 son sustentadas por imágenes de N4.

A partir de estas dos teorías se propuso en Montero-Moguel y Vargas Alejo (2021) una clasificac los denominada "Guía de evaluac los relacionados con el concepto de func [GEMF] que permite describir la e los modelos y el razonamiento covariacional desarrollado por los estudiantes al resolver MEAs donde subyace el concepto de función exponencial.

Metodología

La investigación fue de tipo cualitativa, porque interesaba analizar el proceso de desarrollo de conocimiento de los estudiantes para lograr identificar y describir la evolución de los modelos que ellos desarrollan al resolver la secuencia de desarrollo de modelos para elucidar el concepto de función exponencial. Los participantes de la investigación estaban conformados por 10 alumnos (mujeres y hombres) de primer semestre de nivel universitario. Los alumnos estaban cursando la materia de matemáticas aplicadas a los negocios. Previo a la experimentación, los alumnos no habían visto el tema de función exponencial en el curso.

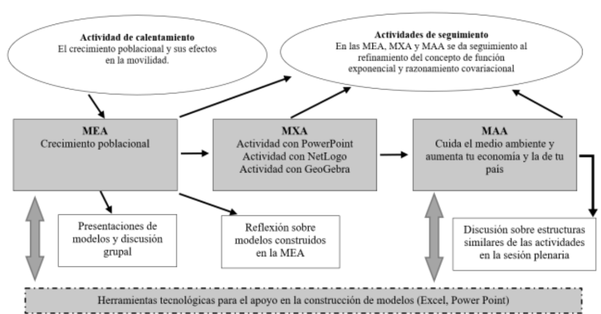

Figura 1: Esquema de secuencia didáctica

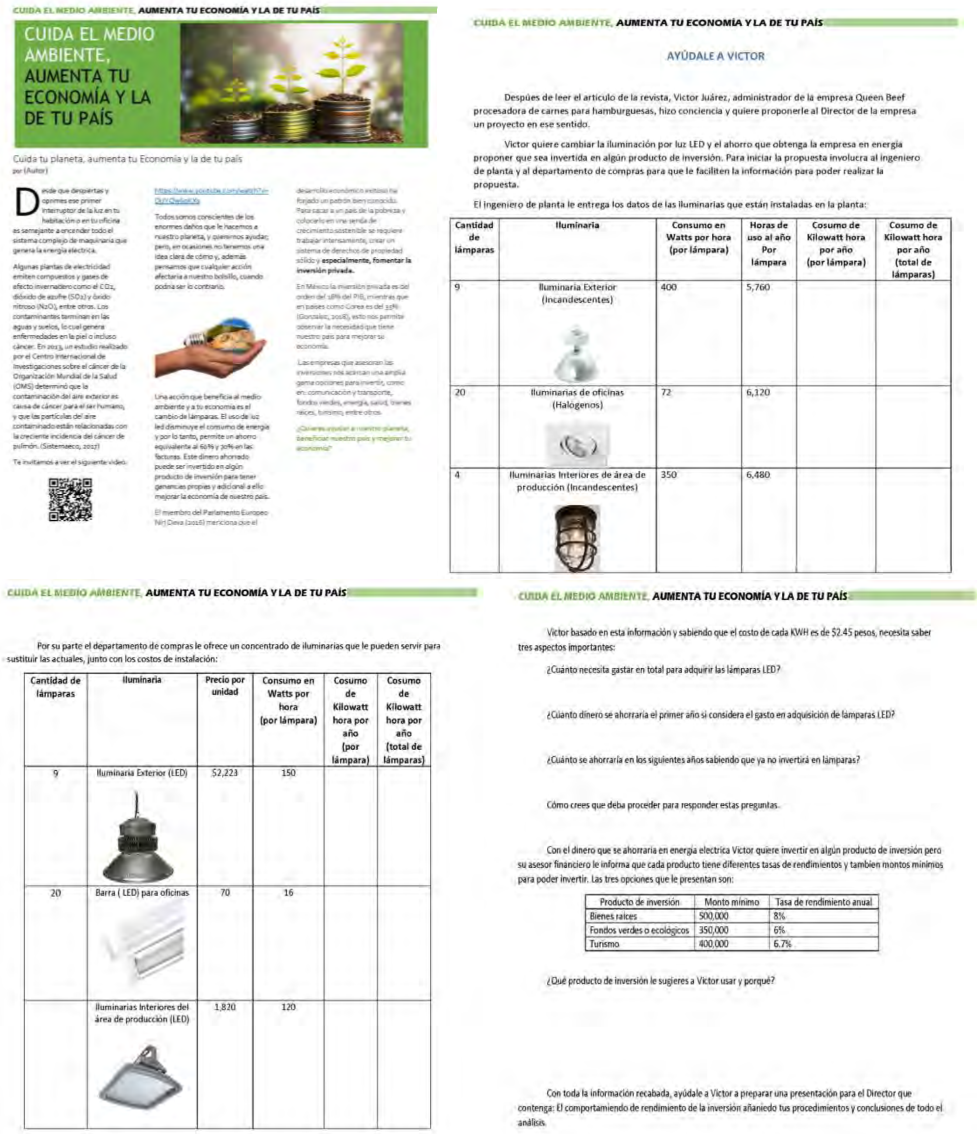
La secuencia de desarrollo de modelos se diseñó con base en la propuesta de Lesh et al. (2003). Se conformó por tres actividades (Figura 1): a) MEA en el contexto del crecimiento poblacional (Montero-Moguel y Vargas Alejo, 2021), b) MXA dividida en tres partes, actividad con PowerPoint, actividad con NetLogo y actividad con GeoGebra y c) MAA en el contexto del cuidado del medio ambiente e inversiones.

La MEA y la MAA fueron diseñadas con la misma estructura para elucidar las concepciones de los estudiantes de función exponencial, incluyendo tres partes: nota periodística diseñada exprofeso, preguntas de contexto y situación problema. La nota periodística y la situación problema de la MAA se presentan en la Figura 2.



CUIDA EL MEDIO AMBIENTE, AUMENTA TU ECONOMÍA Y LA DE TU PAÍS

CUIDA EL MEDIO AMBIENTE, AUMENTA TU ECONOMÍA Y LA DE TU PAÍS

Cuida tu planeta, aumenta tu Economía y la de tu país
por (Autor)

Desde que despiertas y oprimes ese primer interruptor de la luz en tu habitación o en tu oficina es semejante a encender todo el sistema complejo de maquinaria que genera la energía eléctrica.

Algunas plantas de electricidad emiten compuestos y gases de efecto invernadero como el CO_2, dióxido de azufre (SO_2) y óxido nitroso (N_2O), entre otros. Los contaminantes terminan en las aguas y suelos, lo cual genera enfermedades en la piel o incluso cáncer. En 2013, un estudio realizado por el Centro Internacional de Investigaciones sobre el cáncer de la Organización Mundial de la Salud (OMS) determinó que la contaminación del aire exterior es causa de cáncer para el ser humano, y que las partículas del aire contaminado están relacionadas con la creciente incidencia del cáncer de pulmón. (Sistemaeco, 2017)

[illegible]

Todos somos conscientes de los enormes daños que le hacemos a nuestro planeta, y queremos ayudar; pero, en ocasiones no tenemos una idea clara de cómo y, además pensamos que cualquier acción afectaría a nuestro bolsillo, cuando podría ser lo contrario.

Una acción que beneficia al medio ambiente y a tu economía es el cambio de lámparas. El uso de luz led disminuye el consumo de energía y por lo tanto, permite un ahorro equivalente al 60% y 70% en las facturas. Este dinero ahorrado puede ser invertido en algún producto de inversión para tener ganancias propias y adicional a ello mejorar la economía de nuestro país.

El miembro del Parlamento Europeo Nirj Deva (2016) menciona que el desarrollo económico exitoso ha forjado un patrón bien conocido. Para sacar a un país de la pobreza y colocarlo en una senda de crecimiento sostenible se requiere trabajar intensamente, crear un sistema de derechos de propiedad sólido y **especialmente, fomentar la inversión privada.**

En México la inversión privada es del orden del 18% del PIB, mientras que en países como Corea es del 35% (González, 2018), esto nos permite observar la necesidad que tiene nuestro país para mejorar su economía.

Las empresas que asesoran las inversiones nos acercan una amplia gama opciones para invertir, como en: comunicación y transporte, fondos verdes, energía, salud, bienes raíces, turismo, entre otros.

¿Quieres ayudar a nuestro planeta, beneficiar nuestro país y mejorar tu economía?

CUIDA EL MEDIO AMBIENTE, AUMENTA TU ECONOMÍA Y LA DE TU PAÍS

AYÚDALE A VICTOR

Despúes de leer el articulo de la revista, Victor Juárez, administrador de la empresa Queen Beef procesadora de carnes para hamburguesas, hizo conciencia y quiere proponerle al Director de la empresa un proyecto en ese sentido.

Victor quiere cambiar la iluminación por luz LED y el ahorro que obtenga la empresa en energia proponer que sea invertida en algún producto de inversión. Para iniciar la propuesta involucra al ingeniero de planta y al departamento de compras para que le faciliten la información para poder realizar la propuesta.

El ingeniero de planta le entrega los datos de las iluminarias que están instaladas en la planta:

Cantidad de lámparas	Iluminaria	Consumo en Watts por hora (por lámpara)	Horas de uso al año Por lámpara	Cosumo de Kilowatt hora por año (por lámpara)	Cosumo de Kilowatt hora por año (total de lámparas)
9	Iluminaria Exterior (Incandescentes)	400	5,760		
20	Iluminarias de oficinas (Halógenos)	72	6,120		
4	Iluminarias Interiores de área de producción (Incandescentes)	350	6,480		

CUIDA EL MEDIO AMBIENTE, AUMENTA TU ECONOMÍA Y LA DE TU PAÍS

Por su parte el departamento de compras le ofrece un concentrado de iluminarias que le pueden servir para sustituir las actuales, junto con los costos de instalación:

Cantidad de lámparas	Iluminaria	Precio por unidad	Consumo en Watts por hora (por lámpara)	Cosumo de Kilowatt hora por año (por lámpara)	Cosumo de Kilowatt hora por año (total de lámparas)
9	Iluminaria Exterior (LED)	$2,223	150		
20	Barra (LED) para oficinas	70	16		
	Iluminarias Interiores del área de producción (LED)	1,820	120		

CUIDA EL MEDIO AMBIENTE, AUMENTA TU ECONOMÍA Y LA DE TU PAÍS

Victor basado en esta información y sabiendo que el costo de cada KWH es de $2.45 pesos, necesita saber tres aspectos importantes:

¿Cuánto necesita gastar en total para adquirir las lámparas LED?

¿Cuanto dinero se ahorraría el primer año si considera el gasto en adquisición de lámparas LED?

¿Cuánto se ahorraría en los siguientes años sabiendo que ya no invertirá en lámparas?

Cómo crees que deba proceder para responder estas preguntas.

Con el dinero que se ahorraria en energia electrica Victor quiere invertir en algún producto de inversión pero su asesor financiero le informa que cada producto tiene diferentes tasas de rendimientos y tambien montos minimos para poder invertir. Las tres opciones que le presentan son:

Producto de inversión	Monto mínimo	Tasa de rendimiento anual
Bienes raices	500,000	8%
Fondos verdes o ecológicos	350,000	6%
Turismo	400,000	6.7%

¿Qué producto de inversión le sugieres a Victor usar y porqué?

Con toda la información recabada, ayúdale a Victor a preparar una presentación para el Director que contenga: El comportamiendo de rendimiento de la inversión añaniedo tus procedimientos y conclusiones de todo el análisis.

Figura 2: Nota periodística y situación problema de la MAA

Para el análisis de los datos se utilizó la GEMF que permite analizar los modelos construidos por los estudiantes al resolver la secuencia de desarrollo de modelos (Tabla 2).

La experimentación tuvo una duración de tres sesiones de tres horas cada una. El investigador fungió como profesor-investigador. Fue importante colectar datos de distintas fuentes que ayudaran a describir el fenómeno estudiado: hojas de trabajo de los estudiantes, audios, videos y bitácora del docente.

Tabla 2: Clasificación de modelos

***Modelo T1.* El modelo requiere dirección**
El modelo no está asociado a la función (exponencial, en este caso) que permite describir, interpretar, predecir y controlar mejor la situación problema. Los estudiantes asocian un comportamiento lineal a la situación; necesitan comentarios adicionales de sus compañeros o preguntas que propicien la reflexión por el profesor, que les posibiliten redireccionar su manera de pensar. En relación con el razonamiento covariacional, los estudiantes exhiben el nivel 1 de Carlson et al. (2002, p. 358): "las im enes de la covariación pueden sustentar a la acción mental de coordinar el cambio de una variable con cambios en la otra variable".
***Modelo T2.* El modelo requiere mayor extensión o refinamiento**
El modelo está asociado a la función (exponencial) que describe mejor la situación problema. Sin embargo, los estudiantes no logran disociar el comportamiento lineal de su sistema conceptual. El estudiante necesita trabajar más en la resolución del problema que le permita mayor extensión o refinamiento. Respecto al razonamiento covariacional asociado a la función que describe mejor la situación problema, los estudiantes exhiben coordinación y dirección de las variables. Se puede considerar que alcanzaron el nivel 2 de Carlson et al. (2002, p. 358): "las im nes de la covariación pueden sustentar a las acciones mentales de coordinar la dirección del cambio de una de las variables con cambios en la otra".
***Modelo T3.* El modelo es situado**
Está asociado a la función (exponencial) que describe mejor la situación problema es útil únicamente para el contexto de la situación problemática presentada. El sistema conceptual de los estudiantes se amplía y refina al diferenciar entre un comportamiento exponencial y lineal. En relación con el razonamiento covariacional asociado a la función que describe mejor la situación problema, los estudiantes exhiben coordinación, dirección y cuantificación de las variables. Se puede considerar que alcanzaron el nivel 3 de Carlson et al. (2002, p. 358): "las im nes de la covariaci pueden sustentar a las acciones mentales de coordinar la cantidad de cambio en una variable con cambios en la otra".
***Modelo T4.* El modelo es compartible y reutilizable**
La herramienta no sólo funciona para el problema propuesto, sino que también sería fácil para otros modificarla y utilizarla en situaciones similares fuera del contexto de la situación problemática planteada. Respecto al razonamiento covariacional asociado a la función que describe mejor la situación problema, los estudiantes exhiben coordinación, dirección, cuantificación y razón de cambio promedio de las variables. Se puede considerar que alcanzaron el nivel 4 de Carlson et al. (2002). Las imágenes de covariación pueden sustentar a las acciones mentales de coordinar la razón de cambio promedio de una función con cambios uniformes en los valores de entrada de la variable. La razón de cambio promedio se puede descomponer para coordinar la cantidad de cambio de la variable resultante con los cambios en la variable de entrada (Carlson et al., 2002, p. 358).

Análisis de resultados y Discusión

El análisis de los datos se hizo con base en los ciclos de modelación siguientes.

Primer Ciclo de Modelación

Se desarrolló durante el trabajo en equipo para resolver la MEA. Los cuatro equipos construyeron *modelos T1* (Requieren dirección) e incluyeron únicamente representaciones tabulares. Los alumnos no reconocieron un comportamiento exponencial. Se centraron en resolver la situación problema mediante modelos lineales. Su nivel de razonamiento covariacional fue del nivel 1 (coordinación) de acuerdo con Carlson et al. (2002).

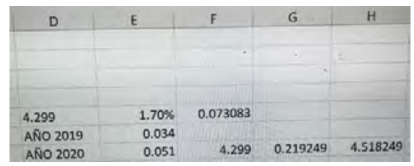
Modelos T1. Los Equipos A y D multiplicaron los datos contenidos en la MEA (la población inicial de 4.299 millones por la tasa de crecimiento de 1.7%) y obtuvieron el valor de 0.073803 (millones de personas) que supusieron constante (Figura 3a). El equipo C detectó que el crecimiento para los años 2019, 2020 y 2021 era de 0.073, 0.074 y 0.075 millones de habitantes, respectivamente; pensaron que la población aumentaba 0.001 millones de personas por año. Es decir, los estudiantes creyeron que el crecimiento era constante (Figura 3c). El modelo del equipo B se caracteriz or el uso de "la regla de tres". Un integrante del equipo come o siguiente.

S4: A ver, entonces tenemos que sacar el 1.7, ¿entonces… sí sería como una regla de tres no?

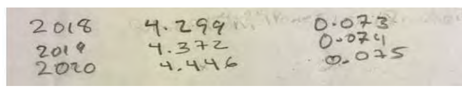
AÑO	2018	2019	2020	2021	2022
POBLACIÓN INICIAL	4.299	4.373	4.447	4.520	4.594
CRECIMIENTO ANUAL	0.073803	0.073803	0.073803	0.073803	0.073803
POBLACIÓN FINAL [POBLACIÓN INICIAL + CRECIMIENTO]	4.373	4.447	4.520	4.594	4.668

Nota: Datos en millones de habitantes

a) Modelo equipos A y D



b) Modelo equipo B



c) Modelo equipo C

Figura 3: Modelos primer ciclo de modelación de los equipos

Segundo Ciclo de Modelación

Se desarrolló posterior a la autoevaluación del primer modelo e interacción con el profesor. Emergieron tres tipos de modelos.

Modelos T2. Los Equipos B y D construyeron representaciones tabulares y gráficas. Los equipos no disociaron el crecimiento exponencial del lineal. Nivel de razonamiento covariacional 2 de Carlson et. al (2002)

Modelos T3. El equipo A construyó un modelo exponencial y situado (Figura 4a). Sus representaciones fueron tabulares. Nivel de razonamiento covariacional 3 de Carlson et. al (2002).

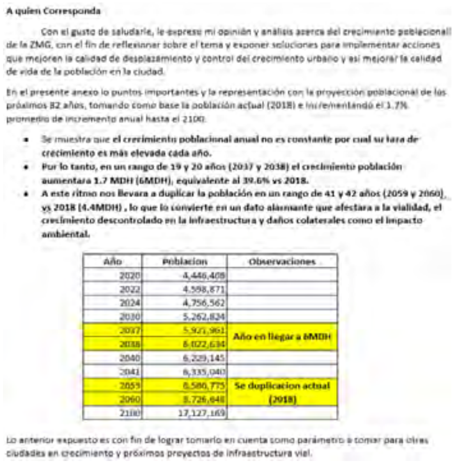
Modelos T4. El equipo C construyó un modelo exponencial, integró representaciones algebraicas. Su modelo es compartible y reutilizable (Figura 4b). Nivel de razonamiento covariacional 4 de Carlson et. al (2002).

Tercer Ciclo de Modelación

Se desarrolló después de la sesión plenaria. Los alumnos realizaron sus cartas de forma individual como tarea extra a los trabajos de clase.

Modelos T3. Los alumnos S4 y S5 incluyeron representaciones gráficas y tabulares en sus modelos; expresaron que el crecimiento no era constante y que dependía de la tasa del 1.7%. El modelo de los alumnos fue situado.

Modelos T4. Ocho alumnos incluyeron representaciones tabulares, gráficas, verbales y algebraicas en sus modelos, los cuales son modificables y reutilizables para situaciones similares fuera del contexto de la situación problemática de crecimiento poblacional.



A quien Corresponda

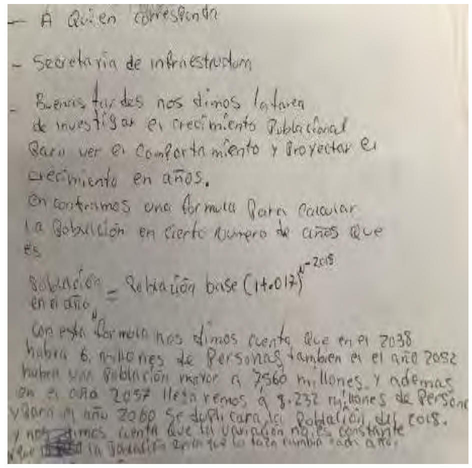
Con el gusto de saludarle, le expreso mi opinión y análisis acerca del crecimiento poblacional de la ZMG, con el fin de reflexionar sobre el tema y exponer soluciones para implementar acciones que mejoren la calidad de desplazamiento y control del crecimiento urbano y así mejorar la calidad de vida de la población en la ciudad.

En el presente anexo lo puntos importantes y la representación con la proyección poblacional de los próximos 82 años, tomando como base la población actual (2018) e incrementando el 1.7% promedio de incremento anual hasta el 2100.

- Se muestra que **el crecimiento poblacional anual no es constante por cual su tasa de crecimiento es más elevada cada año.**
- **Por lo tanto, en un rango de 19 y 20 años (2037 y 2038) el crecimiento población aumentara 1.7 MDH (6MDH), equivalente al 39.6% vs 2018.**
- **A este ritmo nos llevara a duplicar la población en un rango de 41 y 42 años (2059 y 2060) vs 2018 (4.4MDH), lo que lo convierte en un dato alarmante que afectara a la vialidad, el crecimiento descontrolado en la infraestructura y daños colaterales como el impacto ambiental.**

Año	Poblacion	Observaciones
2020	4,446,408	
2022	4,598,871	
2024	4,756,562	
2030	5,262,824	
2037	5,921,961	Año en llegar a 6MDH
2038	6,022,634	
2040	6,229,145	
2041	6,335,040	
2059	8,586,775	Se duplicacion actual (2018)
2060	8,726,648	
2100	17,127,169	

Lo anterior expuesto es con fin de lograr tomarlo en cuenta como parámetro a tomar para otras ciudades en crecimiento y próximos proyectos de infraestructura vial.



- A Quien corresponda
- Secretaria de infraestructura
- Buenas tardes nos dimos la tarea de investigar el crecimiento poblacional para ver el comportamiento y proyectar el crecimiento en años.

Encontramos una formula para calcular la población en cierto numero de años que es

$$\text{Población en el año } n = \text{Población base}(1+.017)^{n-2018}$$

Con esta formula nos dimos cuenta que en el 2038 habra 6 millones de personas también en el año 2052 habra una población mayor a 7.560 millones y ademas en el año 2057 llegaremos a 8.232 millones de personas y para el año 2060 se duplicara la población del 2018. Y nos dimos cuenta que la variación no es constante por que la tasa cambia cada año.

a) Modelo equipo A b) Modelo equipo C

Figura 4: Ejemplo de modelos construidos en el segundo ciclo de modelación

Cuarto Ciclo de Modelación

Se desarrolló cuando los estudiantes resolvieron la MAA. Los alumnos exhibieron modelos T4. Las características del cuarto ciclo de modelación fueron las siguientes.

1. Dos estudiantes (S4 y S5) pasaron de Modelo T3 a T4. Incluyeron en sus modelos una diversidad de representaciones.
2. Ocho estudiantes (S1, S2, S3, S6, S7, S8, S9 y S10) se mantuvieron en el modelo T4.
    - a. Cuatro estudiantes (S3, S8, S9 y S10) matematizaron con base en sólo una tasa de inversión para explicar la situación.
    - b. Cuatro estudiantes (S1, S2, S6 y S7) matematizaron con base en las tres tasas de inversión.
        - i. Tres estudiantes (S1, S2 y S6) propusieron la elección de sólo un producto de inversión (fondos verdes) (Figura 5).
        - ii. Un estudiante (S7) propuso una combinación de diferentes productos de inversión.

Año	Bienes Raices	Ambiental	Turismo

Figura 5: Ejemplo de modelos del cuarto ciclo de modelación

La Figura 5 es un ejemplo del modelo T4 construido por los estudiantes en el cuarto ciclo, en la cual se observa que los estudiantes disociaron el comportamiento lineal y exponencial e incluyeron diferentes representaciones (verbal, tabular, gráfica y algebraica). Respecto a la función lineal, la utilizaron para describir el ahorro de la energía e identificaron un crecimiento constante. Respecto a la función exponencial, los estudiantes incluyeron el análisis de los tres tipos de instrumentos de inversión a diez años lo que les permitió proponer un plan de inversión. En resumen, la evolución de los modelos lineales a exponenciales construidos por los estudiantes se puede observar en la Tabla 3.

Tabla 3: Esquema que muestra la evolución de los modelos

Equipo	Alumno	Tipo de Modelo construido			
		Primer ciclo MEA (equipo)	Segundo Ciclo MEA (Equipo)	Tercer Ciclo MEA (Individual)	Cuarto Ciclo MAA (Individual)
A	S1	T1	T3	T4	T4
	S2	T1	T3	T4	T4
B	S3	T1	T2	T4	T4
	S4	T1	T2	T3	T4
	S5	T1	T2	T3	T4
C	S6	T1	T4	T4	T4
	S7	T1	T4	T4	T4
	S8	T1	T4	T4	T4
D	S9	T1	T2	T4	T4
	S10	T1	T2	T4	T4

Conclusiones

Respecto a la pregunta de investigación ¿Cómo evolucionaron los modelos y el razonamiento covariacional−relacionados con la func encial− de estudiantes de LAEC al resolver, con el apoyo de tecnología, una secuencia de desarrollo de modelos compuesta por problemas cercanos a la vida real? La evolución de los modelos construidos se pudo observar en cada ciclo de modelación. En el primer ciclo todos los equipos de estudiantes construyeron modelos T1. Identificaron variables, pero no entendieron el tipo de relación que había entre las mismas. Las ideas y procedimientos asociados a la situación fueron lineales. Los equipos dieron más importancia a las respuestas obtenidas para la situación que a la construcción de modelos.

En el segundo ciclo se construyeron tres tipos de modelos (T2, T3 y T4) caracterizados por varios atributos, entre los que se pueden mencionar los siguientes: a) Modelos T2: los equipos B y D usaron lenguaje asociado a la función lineal para describir la función exponencial. No lograron disociar el comportamiento lineal del exponencial en su sistema conceptual. b) Modelo T3: El equipo A exhibió coordinación, dirección y cuantificación de las variables. Disoció el comportamiento lineal del exponencial, el modelo fue situado. c) Modelo T4: El equipo C exhibió coordinación, dirección, cuantificación y razón de cambio promedio entre las variables. No sólo disoció el comportamiento lineal del exponencial, sino que, además, construyó modelos útiles para un cliente (compartibles) interesado en resolver la situación y cualquier situación parecida (reutilizable), con condiciones iniciales distintas.

En el tercer ciclo de modelación los estudiantes, de manera individual, reconstruyeron los modelos con base en las discusiones grupales generadas en clase y participaron en la evaluación y autoevaluación de los modelos. Su progreso en cuanto al desarrollo de su conocimiento y habilidades para matematizar evolucionó a los modelos situados (T3) y compartibles y reutilizables (T4). En el cuarto ciclo de modelación los estudiantes, de manera individual, transfirieron su conocimiento obtenido al realizar la MEA y la MXA, las cuales les permitieron profundizar en su conocimiento respecto a conceptos como: variación, función exponencial, variables y uso de diferentes representaciones. Al resolver la MAA se notó el refinamiento de ideas, ya que todos los estudiantes construyeron modelos, compartibles y reutilizables (T4).

PRODUCTIVE STRUGGLE LEADING TO COLLECTIVE MATHEMATICAL CREATIVITY

Ayman Aljarrah
Acadia University
ayman.aljarrah@acadiau.ca

Jo Towers
University of Calgary
towers@ucalgary.ca

In this article we show how students' productive struggle on a mathematical task can lead to collective mathematical creativity. We use observable (co)actions and interactions from a video record that features three Grade 6 students in a problem-solving session to document the emergence of collective creativity leading to a solution. We discuss some key features of the task and the learning environment and present implications for classroom practices aimed at helping students to capitalize on their mathematical struggles.

Keywords: Elementary school education, Problem solving, Number concepts and operations

In this paper we show how elementary students' productive struggle on a mathematics task can lead to collective mathematical creativity and what that process might look like in practice. We discuss some key features of the task and the learning environment and present implications for classroom practices aimed at helping students to capitalize on their mathematical struggles.

Literature Review

Productive Struggle

In the field of mathematics education, Boaler (2016) described a vision of mathematics learning where students are offered opportunities to engage in productive struggle, to thrive, and to become mathematical problem solvers. Lesh & Zawojewski (2007) noted that such a productive way of thinking involves iterative cycles of "expressing, testing, and revising mathematical interpretation—and of sorting out, integrating, modifying, revising or refining clusters of mathematical concepts from various topics within and beyond mathematics" (p. 782). There is an extensive literature discussing ways to support students in this kind of productive struggle in the mathematics classroom. The NCTM (2014) noted that effective teaching values productive struggle as a means to deepen conceptual understanding and "embraces a view of students' struggles as opportunities for delving more deeply into understanding the mathematical structure of problems and relationships among mathematical ideas" (p. 48). In recent years, many authors (e.g., Townsend et al., 2018; Warshauer, 2015) have emphasized the socioemotional dimension of learning and have focused on the importance of building supports for, and valuing, struggle in the classroom. It is widely recognized that without appropriate supports students can spend a lot of time in unproductive struggle and that, for those students, timely intervention is key in nudging them forward from unproductive to productive struggle (Jonsson et al., 2014). Some studies, though, report that students are able to sustain productive struggle, given supports such as an appropriate task, successful strategy choice, and relevant tools. For example, in a study using GeoGebra, Granberg (2016) reported that the majority of the students were able to engage in productive struggle that enabled them to solve problems together. Successful students did this by observing knowledge gaps between their prior knowledge and the target knowledge, correcting incorrectly recalled information, and reconstructing partly forgotten knowledge.

Creativity—Individual and Collective

While some see creativity as confined to special people, particular arts-based activities, or undisciplined play, scholars generally agree that creativity involves the combination of originality and task appropriateness or effectiveness (Beghetto & Kaufman, 2013; Runco & Jaeger, 2012). The word *creativity*, both in its origins and in most of its different uses, reflects a kind of newness, originality, or novelty; it indicates bringing something new and fruitful into being. Craft (2001) claimed that creativity in learning environments enables learners to generate and expand ideas, suggest hypotheses, apply imagination, and look for alternative, not-yet imagined approaches. In the field of mathematics education, Levenson (2011) characterized collective mathematical creativity using characteristics of individual creativity—namely, fluency, flexibility, and originality—and concluded that working as a collective may encourage students to persevere and try new ideas and that teachers can promote the emergence of creativity in their classrooms by encouraging diversity, supporting interactions, and allowing for a certain amount of instability (Levenson, 2014).

Theoretical Framing

Building on this scholarship, herein we draw on the first author's work on collective creativity in mathematics learning environments (Aljarrah, 2017, 2018, 2020; Aljarrah & Towers, 2019), and the work of the second author on the emergence of collective mathematical understanding (Martin & Towers, 2009, 2011; Martin et al., 2006). We bring these theoretical frameworks together to document and analyze the trajectory from productive struggle to the emergence of collective creativity.

Collectivity and Emergence

The second author and colleagues (Martin et al., 2006) laid the groundwork for the present study of collective creative acts in mathematics learning environments. They argued that doing and understanding mathematics are creative processes that should be considered at both the individual and the collective levels. Drawing on improvisational theory, Martin and Towers (2009) suggested that, when students are working together, acts of mathematical understanding "[can] not simply be located in the minds or actions of any one individual, but instead [emerge] from the *interplay* of the ideas of individuals, as these [become] woven together in shared action, as in an improvisational performance" (p. 2, emphasis in original). Martin et al. (2006) used the notion of coaction "to describe a particular kind of mathematical action, one that whilst obviously in execution is still being carried out by an individual, is also dependent and contingent upon the actions of the others in the group" (p. 156).

One of the most important ideas in the study of collectivity in learning settings is the notion of emergence. In our analysis of data later in this paper, we concentrate on three key features of collective emergence adopted from improvisational theory and already articulated in the mathematics education literature (e.g., Martin & Towers, 2009, 2011; Martin et al., 2006): (1) potential pathways, (2) collective structure and striking a groove, and (3) etiquette and the group mind. Noteworthy here is that the actions and interactions of a group working as a collective are usually prompted and constrained by a common purpose that guides the development of a collective structure. In referring to the development of such a collective structure, Martin and Towers (2011) adopted Berliner's (1994, 1997) expression *striking a groove*.

> Striking a groove involves 'the negotiation of a shared sense of the beat,' and is a subtle and fundamental process to allow the performance to develop to its fullest…. The 'groove' is the

> underlying element of the structure that allows the improvisation to proceed in a coherent and productive way, and it is the responsibility of all the players to collectively maintain the groove. (Martin & Towers, 2011, p. 257)

Martin and Towers (2011) also borrowed the expression "etiquette" from Becker (2000) to refer to a number of conventions (group norms) that "govern the ways in which an improvisational performance develops and group flow[1] emerges" (Martin & Towers, 2011, p. 258). Based on the study of improvisational theater, Sawyer (2001) noticed that actors use guidelines (principles) to create better conversations. Three simple, yet overarching, principles were proposed by Sawyer (2001) as rules of improv: (1) Yes, and…, (2) Don't write the script in your head, and (3) Listen to the group mind. According to Sawyer (2001), the "Yes, and …" rule implies that every student should accept the material introduced by preceding student(s) and add something new to it. The second rule, "Don't write the script in your head," is intended to keep all improvisers, moment by moment, within the scene. It means do not plan in advance by foreshadowing or pre-determining where the problem-solving is going, for to do so shines the spotlight on oneself and results in "a lack of the necessary outward focus, toward the group creativity" (Sawyer, 2001, p. 17). Hence, an outward focus requires adherence to the third rule—listening to the group mind—being willing to abandon personal motivations to further the emerging collective structure.

Collective Creativity

Sawyer (2003) also asserted the improvised and the collective nature of group creativity. According to him, group creativity is: (1) unpredictable, in that each moment emerges from preceding flow of the performance, (2) collective, in that members of the group influence each other from moment to moment, and (3) emergent, in that the group demonstrates properties greater than the sum of its individuals. Based on the above ideas, and the first author's study of the nature of collective creativity in mathematics learning settings (Aljarrah, 2018), we define collective creative acts as particular kinds of "(co)actions and interactions of a group of curious learners while they are working collaboratively on an engaging problematic situation. Such acts, which may include (1) summing forces, (2) expanding possibilities, (3) divergent thinking, and (4) assembling things in new ways, trigger the new and the crucial to emerge and evolve" (p. 136). Below, we elaborate on the four metaphors for creativity, first proposed by Aljarrah (2018), that form core of our definition of collective creative acts:

Summing forces: This metaphor encompasses the ways in which learners coordinate their efforts to enable productive steering (Aljarrah, 2019) towards a mathematical understanding "that is not simply located in the actions of any one individual but in the collective engagement with the task posed" (Martin et al., 2006, p. 157).

Expanding possibilities: Expanding might be understood as broadening the learners' horizon by gaining new insights based on previous insights. It is a kind of stretching of the space of the possible as a result of the evolving and the growth of the learners' basic insights.

Divergent Thinking: Divergent thinking requires students to consider many potential pathways, look in many directions, journey outside a known content universe, go beyond the problem's clearly given conditions and information, and think outside-the-box (Aljarrah, 2019).

Assembling (things in new ways): This metaphor implies looking for associations and making connections. It is a vision of creativity based on an assumption that many educative things are with(in) the reach of learners in their learning environment.

In our analysis, we show how collective creativity emerges from productive struggle by detailing the students' pathways to collective creativity in pursuit of a solution to a mathematical problem.

Methods

The data described below are part of a broader, design-based research study exploring collective creativity in elementary mathematics learning environments (Aljarrah, 2018). Two mathematics teachers and 25 of their sixth-grade students in a Canadian school setting participated in the study. Students participated in problem-solving sessions in their regular mathematics classroom and in small groups under task-based interview conditions with the first author. Video-recordings of these group activities formed the core of the data.

The processes of analysis followed Pirie's (1996) advice to "sit, look, think, look again" (p. 556) supported by Powell et al.'s (2003) analytical model for studying the development of mathematical thinking, which consists of seven interacting, non-linear phases: (1) viewing the video data, (2) describing the video data, (3) identifying critical events, (4) transcribing, (5) coding, (6) constructing a storyline, and (7) composing a narrative (p. 413). Following Flanagan (1954), an event was considered to be critical if it was helpful in triggering and/or explaining the emergence of collective creativity in elementary mathematics learning environments. These events were transcribed and the key features of collaborative emergence (Martin & Towers, 2011) together with the first author's definition of collective creativity and metaphors for creativity as outlined in the previous section, were used to code the students' collaborative practices that were effective in the emergence of new and crucial ideas. For the purpose of this article, we selected one video excerpt that best displayed the way that productive struggle led to the emergence of collective mathematical creativity.

Findings

In order to explain how students' productive struggle on a mathematical task can lead to collective mathematical creativity, we use a video excerpt that features a group of sixth grade students, who were assigned the pseudonyms Maddie, Adam, and Frank, engaged in a problem-solving session with the first author. The first author introduced the following task to the group and asked them to work on it together: *What are the possible combinations to obtain a sum of one dollar using pennies, nickels, dimes, and quarters such that the four different types of coins are included in each combination?* Due to space limitations, we focus on describing three collective creative acts, namely, summing forces, expanding possibilities, and divergent thinking, which resulted from the group's productive struggle on the assigned mathematical task. (Note: In the transcript we use dashes to show an interruption of one speaker by another).

Productive Struggle Leading to Summing Forces

The presence of multiple potential pathways was evident at the beginning of the scene. The students started by negotiating the task, and a variety of ideas and suggestions were put forward as possible approaches to find all combinations to obtain a sum of one dollar. Quite quickly, one potential pathway garnered attention. Adam suggested getting "the basic ones [i.e., one penny, one nickel, one dime, and one quarter]." Maddie gave the sum of those basic ones: "Okay, there is forty-one—" and Frank suggested that they could "use all pennies" to make up the rest of the dollar (i.e., fifty-nine cents). He also started to pool the group's thoughts and ideas on their shared document. For example, he wrote down the expression 41¢ = 1 penny + 1 nickel + 1 dime + 1 quarter and labelled it as a fixed amount. He also wrote down 59¢ and under it he wrote 59 pennies as a first suggestion to make 59¢. Maddie noted that they "need at least one of each, though still." Frank responded by pointing to their shared document and explaining, "Yes, those are forty-one—" (he was trying to remind her that they already had one of each coin in their basic combination to a total of forty-one). Maddie agreed that they could "have all pennies," so Frank continued the discussion by wondering, "So, forty-one, um, that means there is, um, how many?" Adam responded "fifty-nine." Maddie was still doing the calculation in her head while she was whispering "fiftyyyyyy, um—" so Frank stressed Adam's answer by completing Maddie's whispering, "Nine, yes, fifty-nine." Frank summarized and rearticulated their initial thoughts by stating, "Okay, so fifty-nine left. Out of fifty-nine, how many can we make? So, one of them is fifty-nine pennies, um— [while he was looking to Adam and Maddie]." Our interpretation of Frank's pause and questioning look towards Adam and Maddie is that the space was open equally to all suggestions. As such, it was impossible to predict the direction of the group's unfolding interaction. None of the students seemed to be trying to force his/her ideas on the group, and none of them tried to convince the others to follow a specific strategy. To this point, what we found of particular noteworthiness was the group's collective engagement in "summing forces." They tried to understand the problem and to consider the conditions of it. Thus, decisions about where to start and how to proceed emerged from their interactions as a group. They listened respectfully to each other and responded thoughtfully to the wonderings and suggestions that emerged through the conversation. The respectful collaboration between the students set them on a pathway towards the mathematics that emerged.

Productive Struggle Leading to Expanding Possibilities

As the interaction continued, the task the students set for themselves shifted from finding all possible combinations to obtain a sum of one dollar to finding all possible combinations to obtain a sum of 59 cents. From here on, a collective structure started to evolve. This conceptual structure was located in, and stemmed from, the actions and doings of the group as a collective. Those acting and doings "determine[d] both the nature of the potential that [was] created, and also how the potential [was] then developed into a coherent performance" (Martin et al., 2006, pp. 159–160). Take as an example the occasion just mentioned above, where Frank initiated a space for a conversation to navigate potential pathways to proceed: "Okay, so fifty-nine left. Out of fifty-nine, how many can we make? So, one of them is fifty-nine pennies, um— [while he was looking to Adam and Maddie]." This opening prompted Adam to suggest making a table within which to arrange the group's choices, and, on their shared piece of paper, he drew an initial table with four columns and a few rows. Maddie pulled the paper toward her side of the table, labeled the columns of Adam's table (1¢, 5¢, 10¢, & 25¢), and started to suggest, with effective participation from Frank, some possible combinations to total fifty-nine cents (see Table 1). At this moment we see the students striking a groove (Berliner, 1994, 1997). Maddie and Frank needed no explanation of Adam's table, nor did Adam attempt to offer an explanation. Maddie didn't seek Adam's permission (and nor did he show any sign that such seeking was expected) to take control of the shared document containing Adam's blank table. Maddie added column headings, and these were not contested in any way. Maddie and Frank then began suggesting possible combinations of coins that would sum to 59. This kind of synchronous participation is characteristic of the coactions that are needed to sustain a collective structure. The metaphor of growth—of expanding possibilities—seems to characterize the students' participation in this episode as they built on and expanded the ideas, concepts, and approaches already developed.

Productive Struggle Leading to Divergent Thinking

While trying to lay out all possible combinations to a total of fifty-nine cents in their shared table, the students engaged in an interactional conversation to find an effective way to do this. Their interaction and conversation supported them in considering many potential pathways, looking in many directions. For example, Frank started to fill the table with some possible combinations while whispering, "Um, fifty-nine pennies—." But suddenly, a different potential pathway seemed to present itself to Adam who suggested trying to "get the total amounts [of combinations]; we can get the total amount for, like, if we change this (the fifty-nine) to fifty, and then we had some sort, like, the two combinations of nine (i.e., nine pennies; and four pennies and one nickel)—." Maddie, still wedded for the moment to the idea of finding combinations that made 59 not 50, tried to make sense of Adam's suggestion. She asked him to "wait, wait, wait," and then to "continue." Adam explained his suggestion by stating, "You could change the number to fifty [instead of fifty-nine], and then go from fifty, because it is easier to go from fifty and then multiply the answer by two." While Adam was explaining to Maddie "why [he would] multiply the answer (i.e., the number of combinations to a total of 50 cents) by two," Frank continued filling their existing shared table while whispering words like "forty-seven, um, forty-nine."

Two possible pathways were now in play and the group faced a choice about which pathway to follow. As the students negotiated their varied suggested strategies to proceed, Maddie pondered the options. The "Yes, and" rule, sometimes called the "Do not deny" rule, does not mean that you must agree with everything that comes from fellow learners, but it does mean that you have to listen to them thoughtfully, and fully respect, embrace, and respond to their contributions, which is what Maddie did when faced with the two potential pathways. Maddie made a commitment to their existing strategy, saying to Adam, "Okay, let us actually listen to him (i.e., to Frank)." Following Maddie's suggestion, the group suspended Adam's suggestion (to begin with 50 instead of 59) in favor of trying the strategy that Frank was still pursuing—to lay out all potential options to combine two or more types of coins, and then to find all possible combinations to obtain a sum of 59 cents under each option. They inferred that there were eleven options that were the basis of all possible combinations totaling 59 cents: pennies and nickels;

nickels and dimes; dimes and quarters; pennies and dimes; pennies and quarters; nickels and quarters; nickels, dimes, and pennies; nickels, dimes, and quarters; pennies, dimes, and quarters; quarters and dimes; and all (i.e., pennies, nickels, dimes, and quarters). For a while, all subsequent actions of the group were about developing a fast (or an effective) strategy to find all possible combinations that met these criteria (a collective goal). All the three students' contributions were critical in keeping the mathematics moving forward. Most speaking turns followed the "Yes, and…" rule, and listening to the group mind was evident throughout the whole problem-solving session with this group. Though Adam had interjected a new suggestion (to find combinations to sum to 50, then multiply by two), which could have destabilized the group process, the group collectively agreed to shelve Adam's idea for now and continue working on their present strategy. Although the group elected to listen to the group mind, they later returned to test Adam's suggestion but at the end of their second consideration of his mathematical idea, Adam was willing to abandon his personal motivations and to defer to the group mind (Martin & Towers, 2011) as the group returned once again to using 59 cents as their focus for generating combinations.

The metaphor of divergent thinking characterizes the students' collective process during this part of their problem-solving journey. Two competing solution paths emerged and were given consideration and one was agreed upon and pursued by the group. The group showed that it valued divergent thinking by re-considering the rejected proposal a second time, before ultimately letting it go.

Discussion

In the above extracts we can see that engaging in productive struggle, when viewed through the lens of improvisational concepts such as emergence of multiple pathways, collective structure and striking a groove, and etiquette and group mind, is an iterative process. The students began by considering multiple potential pathways and establishing an etiquette of working together and listening to group mind. At this stage of their problem solving the metaphor of summing forces can be used to describe their actions. At each point during the scene when the group faced or was confronted by a challenge, all the members of the group were eager to contribute their ideas and thoughts and to listen responsively to the others' contributions. The *momentum* that helped students to overcome such challenges and make remarkable progress should be attributed to the whole group as a result of the interaction between their ideas, thoughts, representations, metaphors, gestures, and words.

They gradually refined their problem-solving through striking a groove resulting in a collective structure of focus. Here, the metaphor of growth and of expanding possibilities characterizes their creative process. Students' creative acts were not just about finding their route around/through the problem. Even though they settled on an initial strategy, they still continued to generate alternative possible pathways. By continuing to explore (play with) ideas and thoughts, new spaces of possibility were opened. Learning was not just about zeroing in on a final end product or conclusion but about participating in a continuous process of growing (coming to understand). Later, although the collective structure could have been disrupted as they once again considered competing pathways to a solution, the metaphor of divergent thinking, which characterizes their creative process during this part of their collaboration, helps us to recognize the value of continually seeking out divergent views while still retaining the capacity as a group to defer to group mind to keep the collective moving towards a creative solution. In this data extract, we see students iteratively scope out multiple potential pathways to a solution, 'agree' (without ever discussing rules of engagement) on a way of working together (an etiquette) that allows them to defer to the group mind, develop a collective structure of engagement that affords insight into a credible route to solving the problem, create and reject further potential solution pathways, and again defer to the group mind to coalesce on a solution. This iterative process, we believe, is characteristic of the creative process, and we anticipate that it would be evident in other data extracts featuring collaborating groups who are able to sustain productive struggle in the pursuit of mathematically sound problem-solving.

Implications for Classroom Practice

The iterative process leading from productive struggle to collective creativity suggests a number of implications for classroom mathematics learning. We note that the task offered to this group of students was rich enough to allow for the possibility of multiple potential solution pathways to emerge. According to Martin and Towers (2011), although there exists the potential for many different directions for the 'performance' to take at any point of the scene, it is at the start that "the potential is unlimited…[and] it is here that the widest range of choices are open to the actors" (p. 256). However, for students to sustain productive struggle, the task also needs to afford the possibility of multiple potential pathways to emerge at many points in the solution so that the possibility of better alternative pathways can emerge during problem-solving.

In addition, the learning environment (and this includes structures such as resources offered to students) needs to afford the emergence of collective structure and striking a groove. As we have noted elsewhere (Martin et al., 2006), offering single piece of paper for students to share has proved fruitful in promoting the growth of collective mathematical understanding in that it becomes a place to 'pool' thinking. As we saw in the data presented here, the shared document enabled the emergence of the initial solution idea by providing a single focus for striking a groove based on which "a collectively created structure start[ed] to emerge" (Martin & Towers, 2011, p. 269). Finally, our data suggests that the kind of teaching that supports productive struggle is teaching that models and encourages the kind of etiquette and valuing of group mind that generate good improvisational performances. These students had learned such etiquette in a classroom that valued genuine collaboration, mathematical argumentation, and problem solving.

Conclusion

The students in this problem-solving session are good examples of *attentive and responsive listeners*. Their conversation was fundamentally creative; it required "trust among the group; the ability to listen and to respond to each other; the ability to work without a script or a director" (Sawyer, 2001, p. 196). Thus, they were able to struggle productively by listening to and watching what others were saying and doing and responding accordingly. No comment or gesture was ignored, i.e., mathematical ideas and actions stemming from any one of them became "taken up, built on, developed, reworked, and elaborated by others and thus emerge[d] as shared [structures] for and across the group, rather than remaining located within any one individual" (Martin et al., 2006, p. 157).

As VanLehn et al. (2019) concluded, though, it is not easy to create environments in which this kind of collaborative productive struggle can be sustained and in which there are opportunities for students to "work hard together to solve challenging, open-ended problems that afford many mathematical insights and discussions" (p. 8) and in which successful pedagogy "engages the students in mathematically meaningful, productive, collaborative behavior" (p. 8). Jardine et al. (2003) reminded us though that "children like to work hard—if that work is meaningful, engaging, and powerful" (p. 102). They used the expression "hard fun" to describe this kind of learning, which is rich in productive struggle, recognizing that it is the kind of learning that is called for to thrive in this rapidly changing and challenging world.

Note

[1] A property of the collective, where "everything seems to come naturally; the performers are in interactional synchrony" (Sawyer, 2003, p. 44). Sawyer (2003) suggested this expression based on Csikszentmihalyi's (1990) conception of flow. According to Sawyer (2003), "Csikszentmihalyi intended flow to represent a state of consciousness within the individual performer, whereas group flow is a property of the entire group as a collective unit" (p. 43).

STEM integration holds significant promise for supporting students in making connections among ideas and ways of thinking that might otherwise remain "siloed." Nevertheless, activities that integrate disciplines can present challenges to learners. In particular, they can require students to shift epistemological framing, demands that can be overlooked by designers and facilitators. We analyze how students in an 8th grade mathematics classroom reasoned about circles, across math and coding activities. One student showed evidence of shifting fluently between different frames as facilitators had expected. The dramatic change in his contributions gauge the demands of the activities, as do the contributions of other students, who appeared to work within different frames. Our findings have relevance for the design and facilitation of integrated STEM learning environments to support students in navigating such frame-shifts.

Keywords: Integrated STEM / STEAM, Computational Thinking, Geometry and Spatial Reasoning, Middle School Education

Introduction

The "STEM" and "STEAM" labels in education (Takeuchi et al, 2020) signal possibilities for integrative experiences involving multiple disciplines. These experiences can be valued as *workforce preparation,* recognizing that interdisciplinarity is increasingly vital in professional STEM fields (National Science Foundation, 2020; Nersessian, 2017). Or, they can reflect the observation that problems in the world of work are seldom confined to a single school subject area (Lesh, Hamilton, & Kaput, 2007). Alternatively, a case for integrative STEAM activities can be based in goals such as enhancing students' motivation and engagement, and increasing the sense of relevance of STEM subjects (National Science and Technology Council, 2018). Recognizing the motivation for engaging in them, the *value* of such integrative STEM activities hinges on learners' successfully constructing productive relations among the integrated disciplines. Lehrer & Schauble (2020) warn that this can be a challenging proposition indeed, showing how activities that promise to connect mathematics with other STEM disciplines can unfold in ways that diverge from teachers' intended learning goals, or can raise thorny questions that participants may not be equipped to navigate. Connecting with the PME-NA conference theme of *productive struggle*, Lehrer and Schauble's (2020) work highlights the challenges (and opportunities) involved in making struggles over mismatches between disciplinary ways of knowing in integrative STEAM activities into productive inter- and meta-disciplinary experiences for learners.

Charting a course for this line of work calls for rich descriptions of the classroom experience of integrative STEAM activities that engage learners at the intersection of epistemic practices fundamental to different disciplines. Integrative STEAM activities of this kind position learners as *boundary crossers* (Akkerman & Bakker, 2011) with epistemic agency to connect mathematical practices of representation and inquiry with those of other disciplines. The construct of boundary crossing is widely studied in the context of professional and organizational learning. To conceptualize what kinds of learning might be possible by positioning students as boundary crossers, and to calibrate the challenges involved, we draw (with caveats) on that literature of professional boundary crossing and interdisciplinarity. A useful review by Akkerman and Bakker (2011) outlines essential themes that are foundational to our analysis. Boundary crossing research typically studies professional practices in which individuals and groups find themselves at the intersection of communities that are concretely embodied in disciplinary and institutional practices that play critical roles in their work lives. In such settings, boundary crossers can pioneer new directions of organizational and professional growth.
In classroom settings, institutional and disciplinary forces are present in very different ways from how they appear in professional settings. Nevertheless, research from the professional context offers us models for how learners might be supported to negotiate tensions at the intersections of disciplines, models that can offer guidance through target stances and forms of interaction. Table 1, below, describes analogies that we leverage between professional STEM and classroom STEM education contexts.

Table 1: Tracing the key concepts of boundary crossing and epistemic cultures and frames—between professional STEM and STEM education contexts

Key Concept	Manifestation in Science & Technology Studies and organizational research	Manifestation in educational activity designs and analyses
Boundary Crossing	Shared problems and enterprises create the need for transdisciplinarity. Stable procedures and institutional structures emerge that reflect the interface between distinct disciplinary cultures (Osbeck & Nersessian, 2017).	Activity designs create the need for students to construct connections across subject areas. Diverse participation reflects the interface between distinct ways of thinking. New hybrids prove their *viability* by being useful in practice (Brady, Eames, & Lesh, 2015).
Epistemic Cultures and Epistemic Frames	Epistemic cultures (Knorr Cetina, 1999) have characteristic discourses and representations for concepts relevant to their shared enterprise. Shifts appear in boundary crossing, facilitated by boundary objects and by "creoles" (Galison, 1997) to mediate the boundary.	In talk and interaction, different participants interpret activity settings using interpretive frameworks built out of disciplinary and everyday knowledge resources. Breakdowns in activity can reflect clashes between these epistemic frames (Hall & Stevens, 2015) and provoke repair, negotiations, and shifts.

In this paper, we analyze a classroom episode, in which we describe the distinct *epistemological frames* (Scherr & Hammer, 2009; Thoma, Deitrick, & Wilkerson, 2018) and the *shifts* between such frames, which the facilitators assumed students would navigate. Understanding the demands we are making of students as designers and facilitators of integrative

STEAM activities, and learning how to support students are two critical issues of research and praxis for making such activities scenes for productive struggle in mathematics education.

Theoretical and methodological approaches

The *framing* of a situation or interaction reflects participants' determination of "what is going on" there (Goffman, 1974). Faced with a barrage of information that is overwhelming and often conflicting, humans have to make snap decisions about what "kind" of situation they are in, in order to determine what is relevant, what the rules are, and how they should act. Framing is both interactional and individual; contexts can invite particular frames, but frame signaling can be ambiguous (Wisittanawat & Gresalfi, 2020) or can suggest different frames to different people (Hand, Penuel, & Gutierrez, 2012). It is remarkable, then, that this can be mostly done unthinkingly and without uncertainty rising to conscious experience, especially since framing is a matter of shared agreement and coordination (Goffman, 1974).

In designed or otherwise exceptional environments, however, questions and even disputes about framing can come to occupy the foreground (DeLiema, Enyedy, & Danish, 2019). Novel settings make it possible for multiple candidate framings to emerge, as people look for contextual clues about the tools, participation structures, language, and interactions that are appropriate. Such settings can offer different frames for different people (Hand, Penuel, & Gutierrez, 2012), or make it ambiguous to both participants and outside observers what is actually going on (Gresalfi, Brady, Knowe, & Steinberg, 2020).

Within learning environments, such indeterminacy in framing can be seen as a liability, making it more difficult for individual students to participate or more challenging for teachers to facilitate a student group in activities that require coordination. On the other hand, moments that provoke frame indeterminacy can also offer the potential to bring together different interpretations of shared experience, and thus could also offer powerful learning opportunities. Goffman's (1974) extended analysis of frames and their transformations shows how frame breaks and frame disputes surface fundamental assumptions about the "primary frameworks" that underlie social interactions in various contexts. They thus offer an opportunity to see and discuss the consequences of these underlying frameworks. In the context of frames governed by disciplinary ways of seeing and acting, frame breaks and frame disputes offer a setting where the nature and consequences of epistemic frameworks that are fundamental to the philosophy of a discipline can be made palpable and experiential.

Setting and Participants

We focus our analysis on one session from an 8th grade mathematics classroom at an urban public-school in the southeastern United States. The teacher, Ms. T, has been a co-design partner with the authors in an NSF-funded project (CAMPS, NSF#1742257), to design and study learning environments that integrate mathematics, computer science, and art. To this point in the project, Ms. T and the authors had collaborated in an informal-learning setting, a summer "Code Your Art" camp. In the 2018-19 school year, at Ms. T's initiative, the project team worked to adapt activities and ideas from "Code Your Art" camp to Ms. T's math class on "Code Fridays." Throughout the school year, the research team worked with her to co-design and co-facilitate coding activities on many Fridays, using the NetLogo (Wilensky, 1999) modeling environment. Ms T's school is a community middle school serving a racially and economically diverse population, and the class that experienced Code Fridays sessions comprised 34 students.

On the day in question, Ms. T reviewed practice problems for a high-stakes state assessment before moving on to coding. Facilitators' in-the-moment decisions about how to transition from this phase to the Code Fridays activity created an opportunity for integration across math and computation around *circles* in a sequence of two conversations. Students reasoned very differently about circles across these two instructional moments, leading to the appearance that they did not make connections between the same set of ideas as they switched activities. One possible interpretation is that students demonstrated a failure to "transfer," in that resources and ideas leveraged in one activity were not leveraged in the second. Instead, we argue that the different resources students brought to bear on questions about circles suggested differences in their epistemological framing (Scherr & Hammer, 2009; Thoma, Deitrick, & Wilkerson, 2018) of the two activities, and revealed mismatches between some students' framing and facilitators' expectations. Recognizing the roles of framing and frame-expectations focuses our attention on features (and shortcomings) of our design and facilitation, rather than on shortcomings in students' thinking.

Methods of Analysis

We apply epistemological frame analysis to our focal episodes, to understand how students experienced and responded to signals for framing of two successive activities about circles. Data analyzed in this paper include video from two sources, a camera in back of the room positioned to capture the teacher's projected computer, and a second camera set up in the front to capture students' talk, gestures, and interaction at their tables. Through multiple viewings of the record, we narrowed our focus to two brief episodes involving circles—one from the math exam practice and the other from the coding session. We used discourse analysis, including an analysis of gesture, to investigate how different epistemological framings were recruited with respect to expected framings across the two activities.

Findings

We found that across the two focal activities, distinct epistemological framings of circles emerged. We identified one student, Mateo (a pseudonym), who navigated the shift between these two activities successfully (i.e., as the teacher and researchers had expected). We studied the forms of expression and argumentation that he exhibited, as a measure of the difference in framing. We also identified other students in the class, whose contributions appeared to come from frames less well aligned with the expectations of the facilitators. These students did not appear to lack conceptual sophistication or resources; rather, their framing prevented them from participating in the discussion as the facilitator intended. Our goal in the analysis was to gauge the nature of the epistemological discontinuity between these mathematics and coding activities: both the success that Mateo had in constructing compelling accounts across the two settings, and the challenges other students faced, help to characterize this discontinuity between activities.

Mathematics activity: Mapping given numbers to elements of the area formula

The class session began with a review of practice problems for the state exam. Problem 37 asked for the area of a semicircle, given that its diameter measured 6 units. Mateo volunteered to share his work:

Mateo: So, uh, since we know the formula for the area of a circle is, pi times uh radius squared, so for half the circle, we just need to do, uh one-half of pi times radius squared. So, I did…so I did for the radius I found that it was 3 because the radius is half of that, the the diameter. So I did uh uh 3? Uh, squared? which is 3 times 3 which is 9, and I did 9 times, uh, 3.14, divided by two, so I got 14.13.

Mateo's contribution suggested he framed the problem as a challenge of *mapping* given elements of the figure to their meanings in a memorized formula, and enacting the operations called for by that formula. His explanation took care to unpack each element in the memorized area formula (the relation of a semicircle's area to that of a circle; the value of p; the meaning of r and its relation to the diameter; and the meaning of squaring), which was sensitive to classmates who might have missed any of these elements. Moreover, his use of pronouns (e.g., "we know," "we just need," "I did") suggested that Mateo was positioning this mapping against a backdrop of communal and normative mathematical knowledge, which authorize his procedure. Finally, Mateo's manner of pointing and gesture-writing in the air with his pencil as he provided his explanation (Figure 1) is an instance of what McNeill (1992) calls an *observer-viewpoint* gesture. Together these features suggest he is visualizing a figure and that his reasoning was occurring in a mapping between recognized inscriptions and arithmetic calculations.

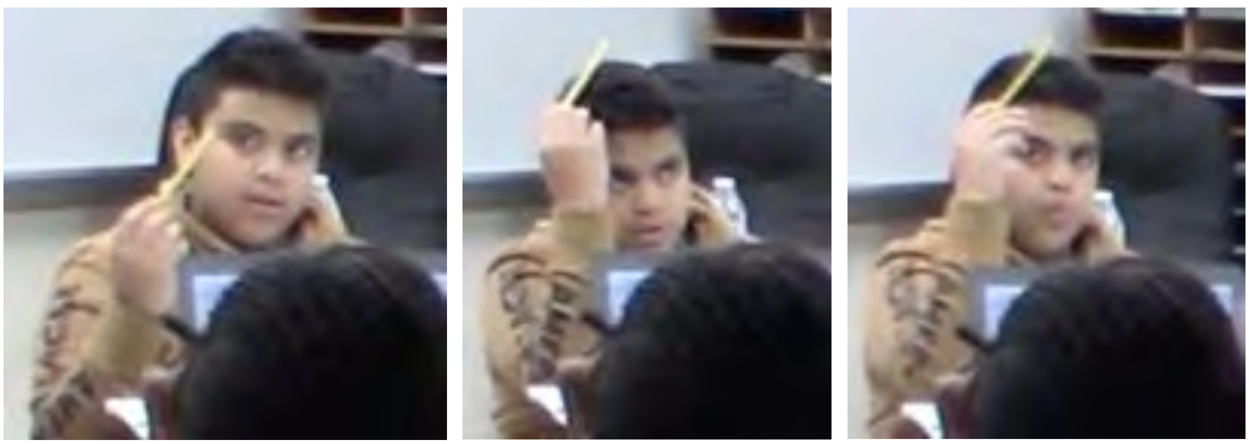

Figure 1. Mateo wrote in the air with his pencil as he described steps to calculate the area of the semicircle.

Mateo's contribution expressed a coherent framing, but his was not the only framing possible. In volunteering an alternative solution, ("I have another way") Edgar made a contribution that framed the activity in terms of voicing diverse strategies for sense-making, a framing valued in Ms. T's classroom at other times:

Edgar: Well, what I do is I multiply uh 6 times the 3.14, and from that I think I got the uh, it was like, yeah, 18.84, then then I multiply it, multiply that number by 6, again, and I get, like, 113.04, and then I divide it by 4 and then half.

Edgar's solution was both correct and well-reasoned. As he later explained, squaring the diameter (twice the radius) and then dividing by a factor of 4 ("since I multiplied twice...times two times two") accommodated the givens of the problem. And with a calculator, his method was no more computationally cumbersome than Mateo's. Yet Edgar's approach appeared to be out of sync with the framing of the activity assumed by the teacher (and the students who followed her lead). Edgar's reasoning was questioned ("Where'd you get the four from?") and critiqued ("you added a bunch of unnecessary steps") by other students. Moreover, Ms. T reinforced these responses, saying "[Edgar], don't confuse yourself. On the test, you don't have that much time to go through all those steps, ok? Stick to the formula…."

Edgar's status in this classroom was quite high; indeed, he had been celebrated minutes earlier for using "a process of elimination" to reason about multiple-choice responses. Yet Edgar's own first-person pronoun use positioned his work as an *idiosyncratic* approach ("What I do," "Then I multiply"), in contrast with Mateo's normative "we." Finally, faced with the responses of classmates and Ms. T, Edgar explained "that's how I've been doing it…because I have no idea…." Overall, the differential rhetorical success of Mateo and Edgar suggest that Edgar's solution was received as less responsive to the "epistemic game" (Shaffer, 2006) of efficiently filling the "epistemic form" (Collins & Ferguson, 1993) of the formula.

Coding activity: Reasoning from the intrinsic perspective of the turtles.

On turning to Coding, the class was introduced to NetLogo *turtles* (agents that can move). The researcher leading the activity, CB, set the stage by creating 100 turtles on the projected computer, noting they were "piled up" at the center of the screen. With students following along, he typed forward 5, to be run by all turtles.

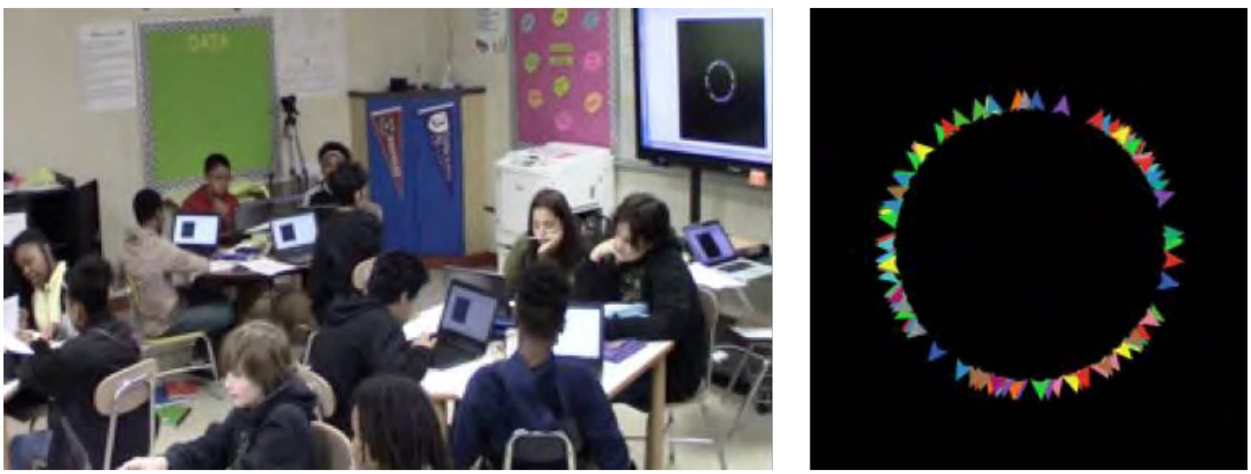

Figure 2. When student created 100 randomly-oriented turtles and executed forward 5**, a circle was formed.**

The turtles each moved forward 5 steps from the center of the screen and created a circle (Figure 2), which surprised the class. Making a connection to the first half of the session, CB asked, "By the way, since you guys were just talking about circles, what's the RADIUS of this circle?" Students shouted out three answers: "Three-sixty!" "Five!" and "Two point five!" CB then asked the class to discuss their reasoning in groups and different groups came to different conclusions. Marissa and Elena shared first and then Mateo joined the discussion:

Marissa: 2.5
CB: 2.5? And why?
Elena: The the the diameter is 5, all the way across. And the radius is half of that.
CB: Ok, so IF the diameter was 5, then the radius would be 2.5, for sure. How…what is the diameter of this guy?
Mateo: 10.
CB: 10. Why?
Mateo: Because if all the patches are going forward five, all facing in different directions/

CB: /turtles//
Mateo: //Ah turtles. So, they're all going 5 in every direction. The diameter's going to be 10.

<u>Figure 3</u>. Mateo gestured to show the movement of two oppositely-oriented turtles and the diameter they made.

The class's discourse about the circle of turtles illustrates the discontinuity between the two activities and the CB's expectations about how students would shift their framing to participate. On one hand, Marissa and Elena's group reasoned within the epistemic frame of mapping given values to formulas, as provided by the prior math activity. They interpreted the number 5 as mapping to the turtle-circle's *diameter*, as had happened earlier in Problem 37. Thus they argued for a radius of 2.5. In contrast, Mateo's explanation revealed a different epistemic frame and a new form of reasoning, distinctive to the context of agent-based programming. From the group of 100 turtles, he selected an imagined pair facing in opposite directions. With two hands, he gestured to simulate their movement, and then gestured (Figure 3A-B) to show how they would produce a line segment passing through the center of the circle, 10 steps long. Finally, (Figure 3C) he interpreted this to be the diameter of the circle formed by all the turtles.

Each of Mateo's moves arises from successfully constructing and operating a mathematization of the computational agent-based environment. First, the selection of two turtles from the *agentset* of 100 relies on a characteristic feature of computational simulations, which use randomization to present a finite sample of an infinite outcome space. The "circle" is only *suggested* by the turtles' bodies, and yet the "professional vision" (Goodwin, 1994) of a mathematically-attuned user of this representation can reason from the particular sample of turtles to imagine two of them oriented with precisely opposite headings. Next, Mateo uses a peculiar species of communicative character-viewpoint gesture (McNeill, 1992; Ochs et al. 1994), in which he embodies the *pair* of turtles with his hands, positioning his own head as the invisible center of the constructed circle. This gestural achievement stabilizes the mathematical objects (center, radial points, radius, diameter) that are necessary to align the situation and enable a link with the forms of reasoning about circles used Problem 37 can be applied effectively.

Conclusions and implications for future work

Mateo was successful in reasoning across the two activity contexts. But to do so, he had to make a substantial leap between epistemic frames. The differences in reasoning showed in the "embodied modeling" approach he employed (cf, Wilensky & Riesman, 2006) and in the different gestural resources that he recruited. The connection that CB assumed would be straightforward, in fact required a significant conceptual reorganization. Many students in this class exhibited strong and flexible resources for reasoning about circles, across each of the two activity contexts, as shown in Edgar's example. Nevertheless, differences and shifts in the discourse and forms of reasoning demanded by the two activities suggested that the "circle" in the math problem and the "circle" formed by the NetLogo turtles were substantially different kinds of objects. We take this example as indicating a challenge for the design and facilitation of activities that aim to provide STEM integration. Specifically, we must recognize that in moving across disciplinary contexts, we may be unknowingly asking students to bridge between epistemic frames, to carry ideas and resources from one domain to the other.

STEM integration has high potential. Indeed, treating the circle from an agent-based perspective offered Mateo a significant resource for mathematically conceptualizing it. Mateo's gestures suggest that he was able to use the turtles to imagine a circle as a *set* or a *locus* of *points* (turtles), and to infer that relations among those turtles/points gave rise to a property of the circle (its diameter). Utilizing a "point-set perspective" is typically viewed as a notable achievement in mathematics. Reasoning in this style, (Figure 3) Mateo leveraged the relation between two turtles and the vacated "center" (his head), as an embodied support for describing the emergent circle's diameter. His description was compelling in the classroom discourse, but it is not clear that his turtle-based reasoning and means of bridging computational and mathematical worlds were fully shared. Providing disciplinarily hybridized learning environments where students can reap the benefits of bridging the disciplinary divide between mathematics and computer science is a challenge for both research and praxis.

CHARACTERIZING OPPORTUNITIES FOR MATHEMATICAL AND SOCIAL PARTICIPATION: A MICRO-ANALYSIS OF EQUITY IN SMALL-GROUP ZOOM INTERACTIONS

Heather Fink
University of California, Berkeley
hfink@berkeley.edu

This study focused on issues of equity related to small-group participation in a distance learning calculus class. Equity is defined as the fair distribution of opportunities for students to participate and learn. I examined how opportunities for mathematical and social participation were constructed through acts of positioning for four students. Findings suggest that creating fair opportunities requires: 1) conceptualizing opportunities for participation as connected to students' positionings and developing identities, 2) acknowledging that what counts as an opportunity for one student does not necessarily count as an opportunity for another student, and 3) leveraging both mathematical and social contributions in creating equitable, supportive, and intellectually rich learning communities.

Keywords: Classroom discourse; Equity, inclusion, and diversity; Online and distance education

Educational inequities constrain the opportunities students have to participate and learn in math classes (Cobb & Hodge, 2002; Esmonde, 2009). Often rooted in societal-level biases, inequities are promulgated by patterns of marginalization (e.g., racialization, sexism) that distribute power unfairly through classroom interactions (Esmonde & Langer-Osuna, 2013; Gutiérrez, 2012; Martin, 2009). Inequities occur when some students are positioned as having more to contribute than others (Herbel-Eisenmann, Wagner, Johnson, Suh, & Figueras, 2015) and/or face additional barriers to participation (Leyva, Quea, Weber, Battey & López, 2020). Pursuing equity requires studying classroom interactions at a micro-scale to understand how inequities play out for individual students in specific classroom contexts (McDermott & Roth, 1978). Equity is conceptualized as the fair distribution of opportunities for students to engage in meaningful ways, supporting the development of rich content knowledge and positive identities (Esmonde, 2009; Schoenfeld, 2014). This study focuses on micro-level issues of equity related to small-group participation in math. I examine how opportunities for mathematical and social participation were constructed through acts of positioning in a distance learning calculus class.

Small-group learning tasks hold potential to address issues of equity by engaging all students in meaningful content while also supporting students in building positive identities as thinkers, learners, and community members (Boaler & Staples, 2008; Cohen & Lotan, 2014). While potential benefits are substantial, implementing successful small-group learning is not easy (Barron, 2003), and working with virtual learning constraints makes it even harder (Wong, 2020). In video-conferencing platforms like Zoom, students face additional physical and social barriers to interaction (e.g., background distractions, ambiguous body language, and limited visibility of student work). For some students, Zoom breakout rooms have been the only opportunity to interact with people outside of their immediate families, exacerbating the necessity for small-group interactions to support both students' academic and social needs.

This study explored the interactions of four students working on a small-group task, focusing on the construction of opportunities for mathematical and social participation. Specific research questions are: *1) How did each student contribute during the task? 2) How were students invited to contribute? 3) How did group participants respond to students' contributions?*

Theoretical Framework

This study is informed by sociocultural and situated theories that consider learning as occurring through participation in cultural activities (Lave & Wenger, 1991; Vygotsky, 1978). Classroom participation is defined broadly and includes more than content-related talk. Non-verbal forms of communication are believed to be valuable for learning (Esmonde, 2009), and "off-task" or social participation is deemed relevant and potentially productive (Gholson & Martin, 2014; Langer-Osuna, Gargroetzi, Munson, & Chavez, 2020). Learning is defined as changes in students' participation in collective classroom practices (Lave & Wenger, 1991). Students' participation in learning activities is a function of the opportunities they are given to participate (Gresalfi, Martin, Hand, & Greeno, 2009); if opportunities to participate are unfairly distributed, then learning will be inequitable as well. Opportunities to participate are shaped by the roles and responsibilities students are assigned through acts of positioning (van Langenhove & Harré, 1999). Through positioning, racialized and gendered narratives (i.e., storylines) come into play (Esmonde & Langer-Osuna, 2013; Reinholz & Shah, 2018). As students interact, expectations are negotiated for what each student can and should do, distributing power among students (Herbel-Eisenmann et. al., 2015). Equitable learning processes require that each student be positioned as a valuable contributor to their own and their peers' learning. Students positioned with competence and authority have more opportunities to participate in consequential and influential ways, and therefore have better access to rich mathematical learning and identity development (Cohen & Lotan, 2014; Gresalfi et al., 2009; Langer-Osuna, 2011).

Methods

Data Collection

Participants. Classes used Zoom for fully distanced learning at the time of observation (Feb. 2021). The focal group consisted of four 12th grade students in a Calculus AB course at an urban public high school: Yonas, Guadalupe, Hosein, and Elijah (pseudonyms). Guadalupe is the only student in the group who identifies as female, and Elijah is the only student who identifies as White. Ms. B was the calculus teacher. Mr. K was a student teacher. Ms. F was the researcher (began daily observations Sept. 2020). Participants are shown in Figure 1 (with permission).

Figure 1: Participants in the Focal Group on Zoom

Task. Students joined Zoom breakout rooms to work on a Related Rates problem. They had not yet received formal instruction on this topic. The teacher wanted students to think about the underlying ideas before formalizing solving strategies. Students were instructed to work with their teams. The problem read: *1. A ladder leans against a wall. It begins to slide down the wall.*

Olanoff, D., Johnson, K., & Spitzer, S. (2021). *Proceedings of the forty-third annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Philadelphia, PA.

Does the top of the ladder move at the same rate as the bottom of the ladder? 2. Suppose the bottom slides away from the wall at a rate of 1 ft/sec. How fast is the top of the ladder sliding down the wall when the bottom of the ladder is 6 ft from the wall? Assume the ladder is 10 ft.

Video. Video of the focal group was recorded using Zoom functionality. The video was approximately 10 minutes long, the amount of time the students spent working on the task.

Data Analysis

Video was transcribed for speech and salient expressions/gestures, then divided into *contributions*. A contribution was uninterrupted speech by one person of a single *type* (defined below). Sometimes a single talk-turn contained two contributions, such as when Yonas began reading the problem aloud (contribution 1), then shared mathematical reasoning (contribution 2). All talk was coded as either a mathematical or social contribution. Codes were assigned to every contribution based on *acts of positioning* (van Langenhove & Harré, 1999), operationalized into three categories: contribution types, contribution invitations, and contribution responses.

Contribution types. Each contribution is an act of positioning (Gholson & Martin, 2014). The contributing student positions themself through the type and content of their contribution. Did the student contribute sound mathematical reasoning? Or did they contribute a comment that made everyone smile? Contribution *types* were coded as: Asks a question, Makes a comment, Shares mathematical reasoning, Shares solution with reasoning, Shares solution without reasoning, Expresses agreement, Expresses disagreement, or Reads the problem aloud.

Contribution invitations. Each contribution invitation is an act of positioning (Langer-Osuna, 2011; Radinsky, 2008), including explicit and implicit prompts. Students position themselves and each other depending on how contributions are prompted. Was a student called on by name to contribute a math idea? Or did they interrupt another student to share an idea with seemingly no invitation at all? Contribution invitations were coded as one of the following: Participant actions, Silence, or Interruptions. Invitations were coded as *Participant action* when the words or actions of someone in the group prompted a contribution from someone else, either explicitly or implicitly. The person whose actions invited the contribution was also coded. Invitations were coded as *Silence* if a contribution was made when no one was speaking and was not connected to previous contributions. *Interruptions* were coded when someone cut off another person's contribution, indicating a lack of invitation.

Contribution responses. Participants' responses to contributions are acts of positioning as well (Anderson, 2009; Hand, 2010). Students are positioned by their peers and teachers through the reactions they get to the contributions they make. Is the contribution met with explicit affirmation? Is the validity of the contribution challenged? Or is the contribution ignored? Contribution responses were coded as: Positive (verbal agreement or smile), Negative (verbal disagreement or interruption), or Neutral (silence or no change in facial expression).

Findings

Collectively, findings address the central question of how opportunities for mathematical and social participation were constructed for each student. Findings are organized by the specific research question: *1) How did each student contribute during the task? 2) How were students invited to contribute? 3) How did group participants respond to students' contributions?*

Contribution Types

Findings in this section address the question: *How did each student contribute during the task?* Contributions were quantified by totaling the number of words spoken and the number of contributions made by each student, shown in Table 1. Words and contributions were categorized as either mathematical or social. The number of words metric provides insight into the amount of airtime occupied by each student without any indication of contribution quality.

Table 1: Number of Mathematical & Social Words and Contributions by Student

	Yonas	Guadalupe	Hosein	Elijah
# of Mathematical Words Spoken	454	55	227	213
# of Social Words Spoken	9	130	1	0
TOTAL # of Words Spoken	**463**	**185**	**228**	**213**
# of Mathematical Contributions	23	4	10	10
# of Social Contributions	2	9	1	0
TOTAL # of Contributions	**25**	**13**	**11**	**10**

Yonas spoke more than twice as many words as his peers, resulting in a total of 25 contributions, 23 of which were mathematical. Hosein and Elijah both spoke over 200 words, resulting in 10 mathematical contributions each. Hosein had a one-word social contribution as well. Unlike her peers, Guadalupe's social words and corresponding social contributions more than doubled her math words and math contributions. Table 2 shows the types of contributions for each student.

Table 2: Number of Mathematical & Social Contributions by Type by Student

# of Contributions by Type			Yonas	Guadalupe	Hosein	Elijah
	Mathematical	Asks a question		1	3	
		Makes a comment	7		2	1
		Shares mathematical reasoning	7		3	1
		Shares solution with reasoning	2	1	1	2
		Shares solution without reasoning		1		
		Expresses agreement	3	1	1	4
		Expresses disagreement	1			2
		Reads the problem aloud	3			
	Social	Asks a question		2		
		Makes a comment	2	7	1	

All students shared at least one solution with mathematically valid reasoning and each expressed verbal agreement with a peer at least once. Yonas and Elijah were the only students who expressed disagreement, and Guadalupe and Hosein were the only students who asked questions. Based on this data, it appears Yonas contributed the most in terms of the quantity of math interactions, and Guadalupe contributed the most in terms of social interactions. Hosein and Elijah both made considerable math contributions, while Guadalupe shared some math ideas too.

Contribution Invitations

Findings in this section address the question: *How was each student invited to contribute?* Invitations were categorized as either mathematical or social. From there, invitations were determined to be connected to participants' actions, silence, or interruptions. The number of invitations by type and by student are presented in Table 3.

Table 3: Invitations to Contribute by Type and by Student

	Mathematical				Social			
	Participant Actions	Silence	Interruptions	Total	Participant Actions	Silence	Interruptions	Total
Yonas	12	10	1	23	2	0	0	2
Guadalupe	4	0	0	4	8	1	0	9
Hosein	4	5	1	10	1	0	0	1
Elijah	6	2	2	10	0	0	0	0

Table 3 shows that invitations for Yonas's and Hosein's mathematical contributions were relatively balanced between participant actions and silence (Yonas: 12 participant actions vs. 10 silence; Hosein: 4 participant actions vs. 5 silence). The relatively high number of silence invitations suggest that Yonas and Hosein were comfortable initiating math contributions without an explicit prompt. Yonas and Hosein also had one interruption each, but both students apologized. When Guadalupe was speaking, Yonas said, "Oh my god. Wait. Sorry, sorry. I just had a theory." When Yonas was speaking, Hosein said, "Um, Yonas? I'm sorry to interrupt. I have an idea." Elijah's math contributions were most often connected to other participants' actions (6 out of 10 invitations). Elijah also made the same number of contributions when the room was silent as when someone else was speaking, suggesting that if Elijah had a thought to share, he shared it regardless of what other people were doing. Unlike Yonas and Hosein, Elijah offered interruption apologies. All of Guadalupe's math contributions were prompted by other people's actions; she made no math contributions while the group was silent, nor interrupted anyone. These data suggest that Guadalupe was not as comfortable as her peers initiating math contributions on her own. Participants' actions dominated Guadalupe's invitations for social contributions as well. However, she did make one social contribution that occurred during silence, suggesting she was more comfortable initiating social contributions than mathematical.

The majority of all contributions were prompted by participants' actions; participants included Ms. F (researcher), Ms. B (teacher) and Mr. K (student teacher) in addition to the four students. Ms. F was there the entire time. Ms. B visited the group once for 28 seconds, and Mr. K visited the group once for 33 seconds. Ms. B's and Mr. K's visits overlapped by 8 seconds. Figure 1 provides a closer look at the invitations that were attributed to *participant actions*. The figure contains two rectangles per student, one for math invitations (purple) and one for social invitations (blue). The top two rectangles show data for Yonas (bold outlined name). Orange arrows point away from Yonas representing the number of times Yonas's actions prompted a contribution from someone else. For example, the orange arrow from Yonas to Hosein in the top left rectangle shows that Yonas's actions prompted two math contributions from Hosein. Blue arrows point toward Yonas representing the number of times someone else's actions prompted a contribution from Yonas. For example, the blue arrow pointing from Hosein to Yonas shows that Hosein's actions prompted three of Yonas's math contributions. The thickness of arrows corresponds to the number of invitations, also shown as a number next to each arrow.

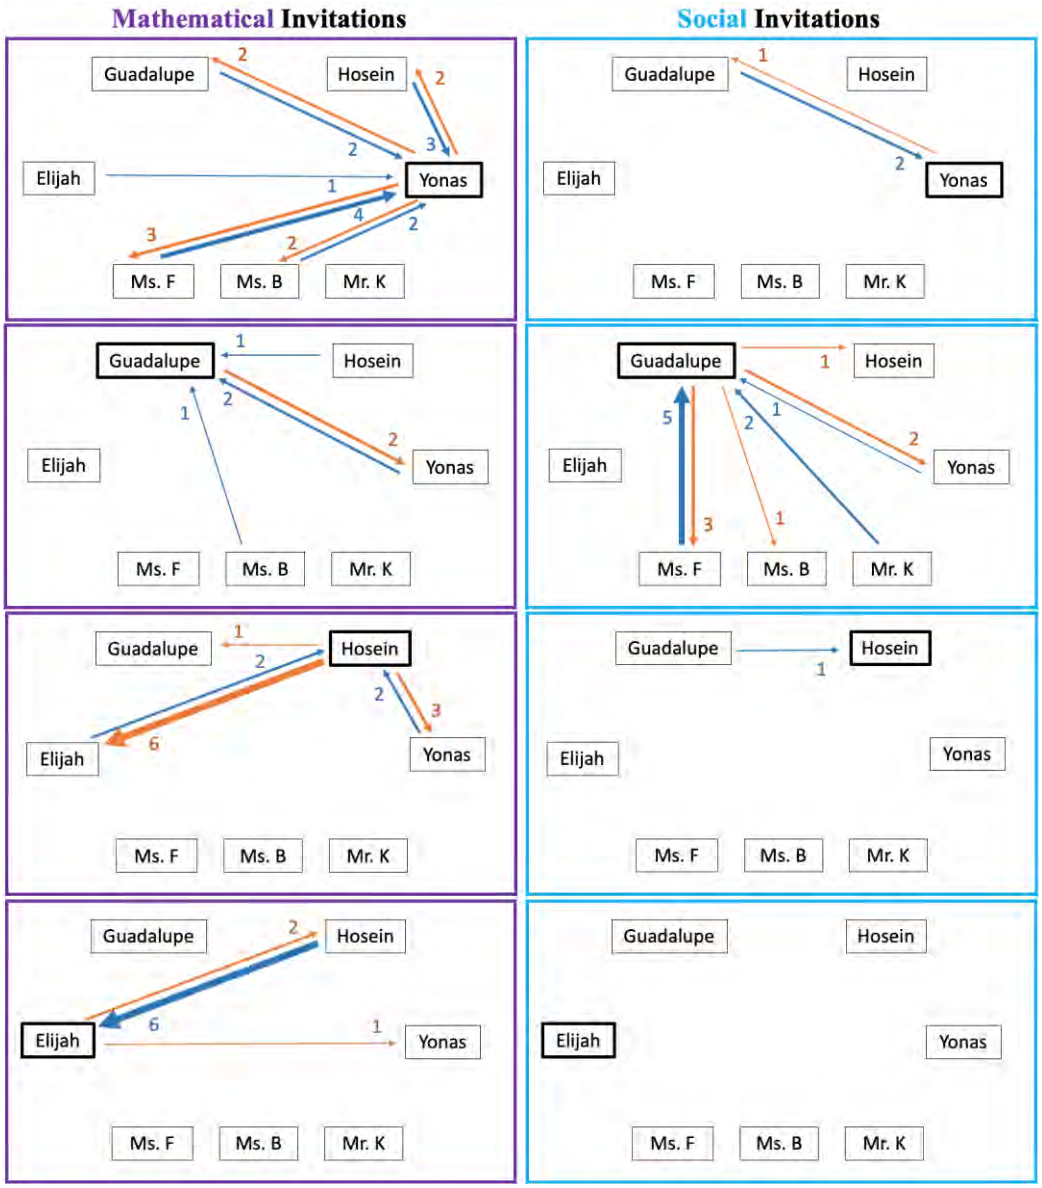

Figure 1: Participant Action Invitations *by* and *to* each Student

The top two rectangles show that Yonas connected through participant action invitations with everyone except Mr. K. Interactions between Yonas and others were relatively balanced and reciprocal; he interacted roughly the same amount with each person, and invitations *by* and *to* each person were relatively even. Elijah was an exception, with just one interaction with Yonas.

The next two rectangles, highlighting Guadalupe's interactions, show that she was connected to everyone except Elijah, and most of her interactions were social. In fact, Guadalupe was involved in *all* of the social contributions that took place during this task; she either made the contribution or her actions invited someone else to make a social contribution. Most of Guadalupe's social interactions involved adults, Ms. F in particular, and can be characterized as friendly, casual, and often humorous. For example, when Ms. F first entered the breakout room, Guadalupe greeted her with, "[Ms. F], oh my God! I get so excited!" *Ms. F's appearance in the group invited Guadalupe's contribution*. In response to Mr. K's sleepy appearance, Guadalupe teased, "[Mr. K], you look hecka bored." *Mr. K's appearance invited Guadalupe's contribution.* And, in response to Yonas's virtual whiteboard drawing, Guadalupe commented with sarcasm, "very sturdy looking ladder!" *Yonas's drawing invited Guadalupe's contribution.* Guadalupe made only four mathematical contributions, the fewest in the group. Her first math contribution was invited by Hosein's direct question, "[Guadalupe], what are you thinking about [the problem]?" The second contribution was an expression of agreement (i.e., "I agree with you,") in response to an explanation shared by Yonas just after Ms. B joined the room. The third contribution was invited by Ms. B's question to the group, "Are you guys saying yes or no?" Guadalupe's final mathematical contribution was a question she asked Yonas about what he was doing, invited by Yonas's virtual white board drawing.

The next row of rectangles shows that most of Hosein's interactions occurred with Yonas and Elijah. Two of Hosein's math contributions were prompted by Elijah's actions and two by Yonas's. The bottom two rectangles highlight the very limited scope of Elijah's interactions. Elijah interacted almost exclusively with Hosein with six of his contributions prompted by Hosein's actions. There were several back-and-forth math conversations between Hosein and Elijah which sometimes included Yonas peripherally, but never Guadalupe. One example occurred toward the end of the discussion when Hosein asked the group, "So, does that mean that the top falls twice as fast as the bottom?" *Silence invited Hosein's contribution.* Elijah responded right away, "Um. I don't think it's twice as fast because it's six verses eight." *Hosein's question invited Elijah's contribution.* Hosein explained further, "No, but it has to move an additional four on the bottom compared to the eight that it has to move at the top." *Elijah's comment invited Hosein's contribution.* Elijah contemplated Hosein's response, saying, "Hmm… True. Hmm… Interesting." *Hosein's comment invited Elijah's contribution.* This 2-person exchange illustrates the type of back-and-forth conversation Elijah engaged in with only Hosein.

Contribution Responses

Findings in this section address the question: *How did participants respond to each student's contributions?* Every contribution received a response from each person who was in the room at the time of the contribution, coded as positive, negative, or neutral based on participants' words and actions. Each contribution received 4-6 responses, depending on how many people were there. The four students and Ms. F were in the room the entire time. Ms. B and Mr. K were there for less than a minute each. Table 4 shows responses for each student's contributions.

Table 4: Responses to each Student's Contributions

	# of Mathematical		Positive		Negative		Neutral		# of Social		Positive		Negative		Neutral	
	Contributions	Responses	#	%	#	%	#	%	Contributions	Responses	#	%	#	%	#	%
Yonas	23	95	9	9%	3	3%	83	87%	2	9	5	56%	0	0%	4	44%
Guadalupe	4	18	0	0%	1	6%	17	94%	9	39	17	44%	0	0%	22	56%
Hosein	10	40	8	20%	2	5%	30	75%	1	5	4	80%	0	0%	1	20%
Elijah	10	40	0	0%	2	5%	38	95%	0	0	n/a	n/a	n/a	n/a	n/a	n/a

The majority of responses to math contributions were neutral for all four students. However, Yonas and Hosein received at least some positive responses to their math contributions (Yonas: 9 positive; Hosein: 8 positive), mostly in the form of verbal agreement (e.g., "yeah"). Neither Guadalupe nor Elijah received positive responses for any math contributions. On the other hand, all students received at least one negative response. When Yonas interrupted Guadalupe to share an idea, this counted as a negative response for Guadalupe. Negative responses also occurred when someone disagreed with an idea that was shared. For example, in the Elijah-Hosein conversation shared previously, Elijah responded negatively to Hosein's suggestion that the top of the ladder fell twice as fast as the bottom by disagreeing with Hosein. Then Hosein responded negatively to Elijah by further supporting his initial claim. Elijah was eventually convinced by Hosein's explanation and, consequently, responded positively to Hosein's final contribution.

Social contributions received more positive responses than math contributions, most coming in the form of smiles and laughs and many involving the adults. For example, shortly after Mr. K joined the room, Guadalupe accused him of looking “hecka bored.” (See Figure 1 in Methods.) Guadalupe then admitted that she sometimes turns off her camera in class so she can lie in bed. She clarified by saying, "but not in this class. Never in this class." Smiling, Hosein responded, "Never." (This was Hosein's one and only social contribution.) Laughing, Yonas responded, “Jeez, does that actually happen?” Guadalupe, Hosein and Yonas all received positive responses to these social contributions from everyone except Elijah. There were big smiles and chuckles from Ms. F and Mr. K, but Elijah's expression did not change. In fact, Elijah did not smile once during the task. Even though Yonas and Hosein did not speak many social words, they indicated their support of Guadalupe's numerous social contributions through their frequent smiles.

Discussion

The goal of this study was to examine how opportunities for mathematical and social participation were constructed through acts of positioning during a small-group task. Students in the same classroom were positioned differently through their contributions. Yonas was positioned as a collaborative, talkative math contributor who shared his thinking freely, had easy access to the conversational floor (Erickson, 2004), and engaged in social interactions either directly with Guadalupe or indirectly by listening and smiling. Guadalupe was positioned as a jovial, caring, social contributor who brought smiles to participants' faces and shared math ideas when asked explicitly. Hosein was positioned as an inquisitive and polite math contributor who offered his own ideas and asked other people for theirs. Elijah was positioned as a deep-thinking math contributor who shared ideas and opinions freely and was oblivious to social norms.

These various positionings had implications for the opportunities students had to contribute to the group's collective learning experiences. Opportunities for mathematical and social participation looked different for different students. What counted as an *opportunity* for one student to participate did not count as a genuine *opportunity* for another. For example, silence in the breakout room constituted a clear opportunity for Yonas, Hosein, and Elijah to offer mathematical contributions, but not Guadalupe. If someone else was talking, that too counted as an opportunity for everyone except Guadalupe, though Yonas's and Hosein's interruption apologies suggest the opportunity was not as clear as it was for Elijah. Guadalupe's threshold for math contributions was much higher than it was for her peers; she needed an explicit invitation to share her mathematical ideas. However, Guadalupe's threshold for social participation was low; the appearance of an adult was enough to prompt a greeting or a light-hearted joke from her. The opposite was true for Elijah. Elijah's threshold for math contributions was the lowest of all four students, yet the threshold for social contributions was the highest. In fact, the threshold was so high that it was never reached in this episode. It is unclear what an opportunity for social participation might look like for Elijah since he did not participate in any social interactions.

Prior research shows that classroom participation is a function of the opportunities students have to participate, and opportunities are shaped by classroom contexts (e.g., how competence is constructed and how tasks are designed) (Gresalfi et al., 2009). However, to understand how opportunities for participation are differentially constructed within a single classroom, looking beyond classroom-level contextual factors is needed. This study suggests that constructing fair opportunities to participate requires: 1) conceptualizing opportunities for participation as deeply connected to students' positionings and developing identities in classroom communities, 2) acknowledging that what counts as an *opportunity* for one student to participate does not necessarily count as an *opportunity* for another, and 3) leveraging both mathematical and social contributions in creating equitable, supportive, and intellectually rich learning communities.

Working toward participatory equity – cultivating classrooms with *fair* (not necessarily the *same*) opportunities to participate (Esmonde, 2009; Secada, 1989) – requires taking into account that calculus classes are historically White, male-dominated spaces, in which females and racially minoritized students face additional barriers to participation (Leyva et. al., 2020). Opportunities to participate for Guadalupe, a woman of color, were undoubtedly different from those of her White and/or male peers. Exploring how racialized and gendered discourses shape students' opportunities to participate is an important direction for future research.

GESTURE INDICATES PRODUCTIVE STRUGGLE IN PROOF WRITING: CASE STUDIES FROM A BASIC TOPOLOGY COURSE

Keith Gallagher
University of Nebraska Omaha
keith.gallagher87@gmail.com

Many students struggle with proof writing. However, struggle is not universally bad: researchers have distinguished between productive and unproductive forms of struggle and have identified productive struggle as essential for learning mathematics. Yet, in practice, recognizing when learners are engaged in productive struggle or unproductive struggle can be challenging. In this report, I argue that students' gesture production may indicate engagement in productive struggle. I observed three undergraduate students from an introductory point-set topology course, collaborating in pairs to complete proof tasks. I present evidence from the students' work on two proof tasks that undergraduate students' gesture frequently when they are engaged in productive struggle and that gesture is rare during engagement in unproductive struggle.

Keywords: Cognition, Communication, Reasoning and Proof, Undergraduate Education

Writing proofs is known to be challenging for mathematics students (Alcock & Weber, 2010; Azrou & Khelladi, 2019; Harel & Sowder, 1998; Iannone & Inglis, 2010; Leron, 1983, 1985; Moore, 1994). Hiebert and Grouws (2007) identified that allowing students to struggle with mathematics was an important feature of effective mathematics teaching; still, not all struggle is beneficial to students' learning. In this paper, I present evidence that undergraduate students' uses of gestures when working on proof tasks can be used as an indicator of engagement in productive struggle.

Vygotsky (1978) defined the *zone of proximal development*: "the distance between the actual developmental level as determined by independent problem solving and the level of potential development as determined through problem-solving under adult guidance, or in collaboration with more capable peers" (Vygotsky, 1978, p. 86). To support students' learning of new material, educational tasks should be designed so that the concepts involved fall into the students' zone of proximal development: they should be challenging to students, but achievable through appropriate scaffolding and support from peers or a teacher. Hiebert and Grouws (2007), in a meta-analysis of effective teaching practices for conceptual understanding, echoed this idea, referring to the notion of *struggle*, defined as "effort to make sense of mathematics, to figure something out that is not immediately apparent" (ibid., p. 387). In this paper, I will refer to this kind of struggle as *productive struggle*, and distinguish it from *unproductive struggle*, or "needless frustration or extreme levels of challenge created by nonsensical or overly difficult problems... [or] the feelings of despair that some students can experience when little of the material makes sense" (Hiebert & Grouws, 2007, p. 387).

Gesture use is known to be directly connected to cognition and perception (Alibali et al., 2014; Bernard et al., 2015; Goldinger et al., 2016; Hostetter & Alibali, 2008; Lakoff, 2012; Lakoff & Núñez, 2000; McNeill, 1992, 2005; Straube et al., 2011; Varela et al., 1993; Wilson, 2002). Research on undergraduate students' gesture use has shown that the use (or lack of use) of gestures influences strategy choices in problem solving (Alibali et al., 2011) and that gesture use can support recognition of important ideas in the construction of proofs (Gallagher, 2020; Pier et al., 2019; Williams-Pierce et al., 2017) and communication about ideas related to proof (Kokushkin, 2020).

In this paper, I present evidence that undergraduate students' use of gestures when working on tasks related to proof may be indicative of engagement in productive struggle.

Theoretical Framework

To frame this work, I utilize Sfard's theory of commognition as well as the notion of productive struggle.

Commognition is a portmanteau of the words *communication* and *cognition*; Sfard described it in the following way:

> Once we adopt the claim that thinking may be usefully defined as the individualized form of the activity of communicating, thinking stops being a self-sustained process separate from and, in a sense, primary to any act of communication and becomes an act of communication in itself, although not necessarily interpersonal. This self-communication does not have to be in any way audible or visible and does not have to be in words. In the proposed discourse on thinking, cognitive processes and interpersonal communication processes are thus but different manifestations of basically the same phenomenon. (Sfard, 2008, pp. 82-83)

The crux of the theory of commognition is that thinking and communicating are intrinsically linked. Rather than thinking of cognition as *preempting* communication or communication *following from* cognition, commognition adopts the perspective that these two actions are indeed one and the same. Furthermore, thinking can be conceptualized as *self-communication*; thus, commognition encompasses the practices of internal thought and "thinking out loud" as acts of communicating ideas with oneself.

In line with Sfard's assertion above, I assume that self-communication does not need to take the form of speech, and I include the production of gestures during self-communication as a form of commognition. Gestures are known to be produced spontaneously during thought, particularly when students are initially orienting to a problem or trying to communicate complex information (Alibali et al., 2014; Bernard et al., 2015; Hostetter & Alibali, 2008; Lakoff, 2012; Lakoff & Núñez, 2000; Straube et al., 2011).

With this in mind, in this work I associate gesture use with the concept of *productive struggle*, using the definition from Hiebert and Grouws (2007) given in the introduction to this paper. In the results that follow, I will show that gesture does not always occur spontaneously. Rather, I will argue that spontaneous gesture use occurs concurrently with productive struggle and can be used to distinguish productive struggle from unproductive struggle in undergraduates working on proof-related tasks.

Methods

Four undergraduates were recruited from a general topology course for a teaching experiment to gain insight into the ways undergraduates leverage examples, diagrams, and gestures when writing proofs in general topology. The author served as the researcher leading the teaching experiment. A total of 9 one-hour sessions comprised the teaching experiment, during each of which the students were asked to prove a true statement and disprove a false statement, although they only engaged with only one of these tasks during some sessions due to limitations on time. Each session was video recorded, and each video was transcribed. Videos and transcripts were then coded for instances of students engaging in productive struggle and unproductive struggle (operationalized definitions provided later in this section) and instances of students producing gestures.

A descriptive case study methodology (Cohen et al., 2013; Yin, 2003) was used to analyze the behaviors of Stacey, Tom, and Rachel, specifically focusing on when and how they used gestures while reasoning about proof tasks. The fourth student was excluded from this analysis, as he attended only one session, and participated very minimally in that session. As the students worked collaboratively to complete the proof tasks in a given session, and different groups of students were present during each session, I consider each session to constitute one "case" in this case study.

In this paper, I assume that the meaning of *struggle* is self-evident, but I distinguish between unproductive struggle and productive struggle. For the purposes of this paper, I claim that students are engaged in *unproductive struggle* any time they give visual or audible signs of focusing on the task under consideration but are not performing an action (such as drawing a diagram, considering an example, or writing notation) or proposing ideas or making conjectures (statements or questions like "I think I need to take the union of these sets" or "What happens if I take the intersection here?"). In other words, students are engaged in unproductive struggle when they appear to be thinking about a problem but seem to be unable to interact with the ideas involved in its statement or its solution. Most often, this is evidenced by students staring at the board in silence or expressing sentiments like "I'm not sure what to do here." In contrast, students are said to be engaged in *productive struggle* any time they are performing an action or proposing an idea or conjecture related to the task under consideration but seem to be uncertain about the usefulness or consequences of those actions, ideas, or conjectures. Examples of productive struggle include consideration of examples, drawing diagrams, attempting to write logical statements to move forward in a proof, and thinking aloud about the meaning of notation.

For this paper, I use the definition of *gesture* given by Rasmussen, Stephan, and Allen (2004) as "movement made by the hand with a specific form: the hand(s) begin at rest, moves away from the position to create a movement, and then return to rest" (p. 303). Gestures may be further divided into deictic gestures (pointing) and representational gestures (movements made to depict an idea, object, or action), though in this paper I do not consider these kinds of gestures separately.

Results

Throughout all nine sessions, instances of struggle were evident from all participants. I present results from two tasks: the prove task from Session 1 and the disprove task from Session 2. Stacey was present for all three (indeed, all nine) sessions; she was joined in Session 1 by Tom, and in Session 2 by Rachel.

Session 1

The students engaged in unproductive struggle when they were faced with notation they had used before but were unaccustomed to working with. In Session 1, Stacey and Tom struggled to get started on the following task, which was written on a chalkboard: *Let $f: S \to T$ be a function, and let $\{U_i\}_{i\in I}$ be a family of subsets of T. Prove that $f^{-1}(\bigcap_{i\in I} U_i) = \bigcap_{i\in I} f^{-1}(U_i)$.* After some initial thought, Stacey expressed the general proof strategy: "First, we have to prove that the first one is a subset of that [pointing from $f^{-1}(\bigcap_{i\in I} U_i)$ to $\bigcap_{i\in I} f^{-1}(U_i)$], and then we have to prove that this one is a subset of that one [pointing from $\bigcap_{i\in I} f^{-1}(U_i)$ to $f^{-1}(\bigcap_{i\in I} U_i)$." Tom suggested to start by proving the inclusion $f^{-1}(\bigcap_{i\in I} U_i) \subseteq \bigcap_{i\in I} f^{-1}(U_i)$, which he indicated by drawing the relation "⊆" in the air with his finger. Stacey wrote "Let $x \in f^{-1}(\bigcap_{i \in I} U_i)$" on the board.

The students then spent the next full minute in silence, both staring at the problem on the board, motionless. At the end of that minute, Stacey wrote "$\{1,2,3\}$" on the board and stated that "the intersection of all of those subsets would be the null set, 'cause there's nothing that would be common to every single one of them," a statement Tom agreed with. I interpreted this as Stacey's attempt to consider an example in which $T = \{1,2,3\}$, and that she has taken the family of subsets $\{U_i\}_{i \in I}$ to be the power set of T. She indicated that she knew the family of subsets did not need to contain *all* subsets of T, but she clarified that she was "just trying to figure out something to think about, I'm a little bit lost."

After another minute of silent consideration, Stacey turned to Tom and asked, "Do you understand... what an inverse of an intersection would even look like?" She proposed, as another attempted example, that if the intersection was the set $(2,3]$, then the "inverse" of that intersection might be "all of the other elements other than this?" Both students continued to stare at the board in silence.

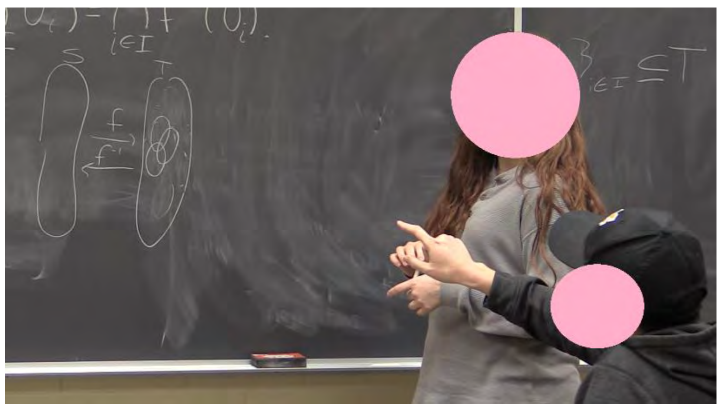

Figure 3: Tom pointing to Stacey's diagram.

I then prompted the students to draw a picture to represent the situation, and Stacey drew a standard set-theoretic diagram. Almost immediately, Tom pointed at the subsets of T in the diagram (Figure 1), claiming that "x is gonna be a point inside all three, in the intersection." Stacey considered this suggestion for a moment, then replied "... Is it?" In response, Tom began to explain his reasoning, but after pointing to the notation for $f^{-1}(\bigcap_{i \in I} U_i)$, he paused and second guessed his suggestion, pointing to the set S and saying "It's gonna be in this"; Stacey agreed, elaborating, "It's not in this [pointing to the text $\{U_i\}_{i \in I}$ in the problem statement], it's in the inverse of the intersection of that." Tom continued, explaining that for each U_i, $f^{-1}(U_i)$ represented a subset of S, first pointing to the notation $f^{-1}(U_i)$ and then tracing the outline of the corresponding subset of S with his finger in the diagram, and he noted that taking the intersection of those subsets would result in "only one area," tracing out a smaller region in the overlap of those sets. "Yeah, and x is *in* that area," Stacey concluded.

The remainder of the students' time spent on this task continued in a similar fashion, with Tom and Stacey pointing to notations from the problem statement and to regions of their diagram and using dynamic representational gestures to indicate elements being mapped between the sets S and T (Figure 2). Although they did not write a formal proof due to time constraints on the session, Tom and Stacey were able to articulate the key ideas of this proof and construct an oral and visual argument that appeared to convince both of them why this statement was true.

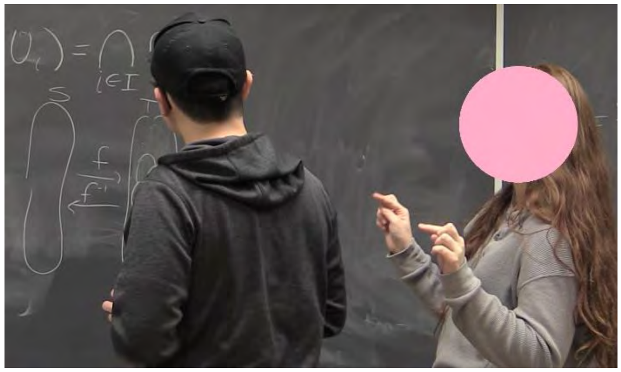

Figure 4: Stacey's dynamic representational gesture indicating a point mapping from T to S via f^{-1}.

Session 2

Stacey and Rachel worked together in Session 2 and did not experience the same immediate struggle that Stacey and Tom experienced in Session 1. Rather, they were able to discuss, relatively comfortably, the notions of symmetry, transitivity, and reflexivity that were necessary to work on the following task: *Disprove: Every relation* C *that is both symmetric and transitive must be reflexive.*

Upon reading the problem, Stacey immediately began by writing "$\{(1,2),(2,1),$'' at which point she paused and pointed with her index finger to the corresponding components of her writing as she read aloud, "So we have one-two... two-one... we have *a* related to *b*... it'd be one-one, if that was symmetric," and Rachel suggested adding $(2,2)$: "[pointing to where Stacey had written $(1,2)$ and $(2,1)$] I think you have to have both anyway, because it's 'for all.'" Stacey continued, "[pointing sequentially to each digit in $(1,2)$] We could do one to two, and then [writing] two to three, and then one-three, and that'd be transitive" (Figure 3).

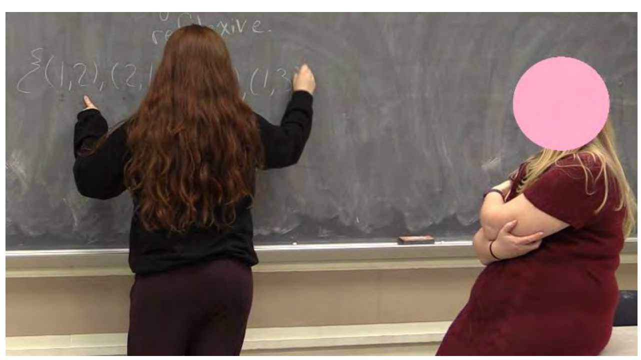

Figure 5: Stacey referencing element $(1,2)$ while adding element $(1,3)$.

After two minutes of work, Stacey and Rachel presented the relation $\{(1,2),(2,1),(2,3),(1,3),(3,1),(3,2)\}$ as their counterexample (the reader will note, however, that they did not specify a set on which to define this relation), at which point I informed them that, although their relation was symmetric on a certain set, it was not transitive, and thus could not serve as a counterexample to the given statement. Inspecting their work, Rachel pointed to the pair $(3,2)$, and Stacey pointed to the pair $(2,3)$ as she announced disappointedly "Then we'd need three-three, and we can't" throwing her hands into the air. Rachel replied, "No, we can have three-three," reminding Stacey that the reflexive property would not be satisfied unless their relation contained *all* of $(1,1), (2,2)$, and $(3,3)$ – although they would later realize that all three of these pairs must be present for their relation to possess the transitive property (Figure 4).

Figure 6: Rachel realizing that $(1, 1)$ must be included in the relation.

After adding $(1,1), (2,2)$, and $(3,3)$ to their relation, both students backed away from the board and stared at their work, both silent and standing still. Rachel explained "We need to have one that's not like, one-one, two-two, or three-three, but it still satisfies symmetric and transitive, which I don't think that we can." Reading over the definition of the reflexive property, Rachel noticed that they had not specified a set for their relation, and she wrote $X = \{1,2,3\}$ under their relation. "We need something to not be in there, like one-one, two-two, or three-three... exactly where I'm stuck." Both students continued staring at the board, no longer writing nor gesturing. Near the end of this session, Rachel suggested a viable solution to their problem – but both students rejected it. She proposed, "I mean, if you threw a four into X... but then you'd just have to make more elements," referring to a misconception expressed by both students during this session that if $4 \in X$, then 4 would have to be related to the other elements in X, and thus would need to appear as a component of some ordered pairs in their relation. Stacey agreed, and they continued to stare at the board in silence (Figure 5).

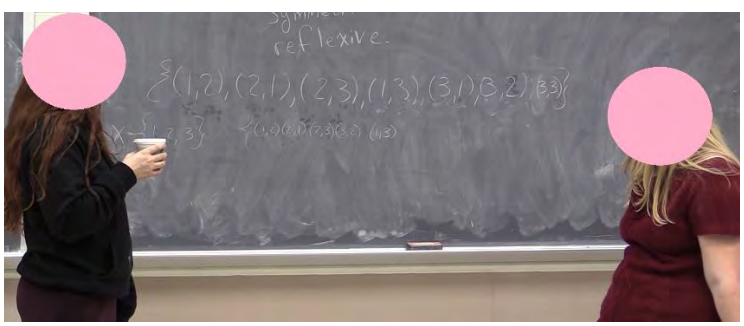

Figure 7: Stacey and Rachel near the end of Session 2, confused about how to prevent this relation from satisfying the reflexive property.

Discussion

Throughout the data presented, and indeed, throughout the data corpus, the study participants produced significantly more gestures during times of productive struggle than during times of unproductive struggle. In fact, during times of unproductive struggle, students seldom produced gestures, which is in sharp contrast to periods of productive struggle, during which gestures were commonplace.

Sfard's theory of commognition treats thought and communication as two sides of the same coin. Taking this perspective and treating unproductive struggle and productive struggle as two distinct forms of cognitive activity, I note that, in these data, these corresponded to two distinct forms of communication. In addition to distinct modes of verbal communication – silence versus speech – these data also show distinct forms of nonverbal communication: stillness versus gesture. In this comparison, stillness may be thought of as a form of nonverbal silence.

Consider Stacey's and Tom's behaviors from Session 1. Stacey and Tom initially seemed unable to make any progress on the task, as evidenced by them taking little action and seeming to be confused by the terminology, notation, and concepts involved in the task. Although Stacey attempted to generate examples, those examples were inappropriate to model the conjecture, and they did not seem to provide Stacey or Tom with any advantages. However, when I suggested that Tom and Stacey draw a picture to represent the situation, they began to negotiate meaning for the various pieces of notation used in the statement of the conjecture and to develop intuition for the scenario it described, eventually gaining personal insights into why the statement was true.

Stacey and Rachel were not immediately hindered in Session 2. In fact, they were able to produce an equivalence relation on the set $\{1,2,3\}$ and competently discuss the concepts of symmetry and transitivity that were necessary to produce an appropriate counterexample. However, both students seemed to lack a complete understanding of the definition of reflexivity (or perhaps of relations more generally), which caused them to struggle as they tried to violate this property. Throughout their discussion, however, Stacey and Rachel produced numerous pointing gestures as they negotiated how to make their relation satisfy the symmetric and transitive properties and as they discussed why the relation they had chosen also satisfied the reflexive property. When they tried to identify a way to violate the reflexive property, they became "stuck," and their gestures ceased.

Conceptualizing gestures as a component of cognition gives a window into students' mental activities. These results show that the students in my sample produced gestures when they were engaging in a meaningful way with the content of a given proof task, and, conversely, that they did not gesture when they were not participating in such engagement. To be clear, I do not mean to imply that productive struggle will *always* be accompanied by gestures, but rather that *when* a student produces gestures, these may act as an indication that the student is engaged in productive struggle.

Conclusion

Struggle is essential in the process of learning mathematics. Unproductive struggle, however, prohibits learners from making learning gains and increases their frustration, leading to a decrease in motivation. Educators should strive to engage their students in productive struggle, as this is the part of the problem-solving process during which students grow their understanding, make connections, and feel like their efforts might be rewarded with success.

In this paper, I framed students' gesture use as a way for teachers to discern whether students are engaged in productive struggle or unproductive struggle. With this tool, teachers can determine, at a glance, whether a task that has been set may be beyond the zone of proximal development for their students, and whether they may need to intervene to prevent students from losing motivation or simply let their students continue to work and develop their ideas.

However, as online instruction becomes more prevalent, researchers should attend to other means for distinguishing productive struggle from unproductive struggle, as gestures are not only more difficult to notice in the online environment, but may also be less frequent due to the inefficiency of pointing in such settings. Indeed, as reports from teachers and students indicate some students struggling to learn in the online environment, and as some classrooms transition back to in-person instruction, educators must be hypervigilant to notice signs of students struggling, and gestures serve this purpose well.

People often view mathematics as abstract, cold, and irrelevant to real-life, and their school experiences influence such views. In this case study, we investigated the mathematics learning experiences of two women who participated in an afterschool girls STEM club 26 years ago. We explored their experiences in and out of school and how such experiences informed their images of mathematics. Data were collected from a survey, focus group interviews, and individual interviews. Using qualitative analysis, we learned that their school mathematics experiences influenced the participants' images of mathematics. The findings also revealed the participants' continuous and discontinuous learning experiences between school and out-of-school mathematics. This study suggests creating spaces to develop curricula that bridge the gap between school and out-of-school learning experiences.

Keywords: Attitudes, Belief, Informal education, Integrated STEM

Introduction

People's experiences with learning mathematics in schools inform their images of mathematics (Sam & Ernest, 2000). The public often describes mathematics as difficult, cold, abstract, and primarily masculine (e.g., Darragh, 2018, Epstein et al., 2010, Ernest, 1996). In a *Journal of Research in Mathematics Education* commentary, Stephan et al. (2015) reported "grand challenges" for mathematics education, including "changing the public's perception about the role of mathematics in society," "achieving equity in mathematics education," and "changing perceptions about what it means to do mathematics" (p. 139). These challenges necessitate altering the public's image of mathematics. Sam and Ernest (2000) conceptualized the image of mathematics as "a mental representation or view of mathematics, presumably constructed as a result of social experiences, mediated through school, parents, peers or mass media" (p. 195). Researchers suggested that the widespread and narrow public image of mathematics may have resulted from instruction in mathematics education that portrays the subject as isolated from out-of-school experiences (e.g., Darragh, 2018; Sam & Ernest, 2000).

Reconstructing the public image of mathematics requires widespread support from many stakeholders. Specifically, the mathematics education community is responsible for supporting the public to see mathematics as "normal and ordinary but at the same time important and useful" (Darragh, 2018, p. 203). Researchers have found that in contrast to the image of school mathematics; out-of-school mathematics, including everyday mathematics and mathematics learning in designed informal environments, is often viewed as useful and real (Civil, 2007; Cooper, 2011; Nunes, 1999; Pattison et al., 2017). Exploring out-of-school mathematics could be a way to disseminate alternative images of mathematics (Nemirovsky et al., 2017). Therefore, informal mathematics learning has the potential to address the described grand challenges to change the public image of mathematics. However, limited extant literature has reported continuities and discontinuities between people's mathematical experiences in in- and out-of-school contexts. Conducting such a study has the potential to inform school mathematics teaching and broaden the public image of mathematics.

We investigated two women's in-school and out-of-school mathematics learning experiences to: (a) examine how these experiences informed their images of mathematics, and (b) identify continuities and discontinuities across their experiences. The women had participated in an afterschool STEM program, *Girls Excelling in Math and Science* (*GEMS*), in fifth and sixth grades. The two participants had different mathematics learning experiences as well as different views of mathematics. The following research questions guided this study:

- How did the participants' mathematics experiences inform their images of mathematics?
- How did the participants' descriptions of mathematics reflect continuities and discontinuities between their in-school and out-of-school experiences?

Literature Review and Theoretical Perspectives

School contexts typically have highly regulated learning environments. Below, Bronkhorst and Akkerman (2016) summarized key characteristics at school:

> (a) learning is intended; (b) students and teachers as main actors, with teachers as knowledgeable others; (c) what and how one learns is formalized in a curriculum; (d) validation of learning by assessment; (e) cumulative qualification; (f) school building; (g) mandatory attendance. (p. 22)

Unlike in-school learning, out-of-school learning often has more flexibility regarding time and space and is not constrained by the school schedule, national or state standards, and standardized tests. Informal learning is usually voluntary and allows students to bring in their cultural knowledge and personal experiences (Copper, 2011). In this section, we synthesize literature on in- and out-of-school mathematics learning as well as continuities and discontinuities between school and out-of-school contexts.

In- and Out-of-School Mathematics Learning

Out-of-school learning refers to curricular and non-curricular learning experiences that are provided for students outside of the school environment (Resnick, 1987). Resnick mentioned several discontinuities between in- and out-of-school learning. For example, school environments often focus on individual performance, independent thinking, symbolic representations, and generalized skills and knowledge. In contrast, learning out of school typically involves collaborative engagement, tools, and is situated in authentic environments. School mathematics learning frequently focuses on preparing students for standardized tests, and providing isolated instruction with limited opportunities to make connections between mathematics and daily life experiences (Copper, 2011). Students often view school learning as completing assignments required by teachers, which at times diminishes their motivation and interest in learning mathematics (Nunes et al., 1993).

Learning in school is not necessarily disconnected from out-of-school learning; in particular, some intended continuity efforts strengthen school learning by bridging learning between school and out-of-school spaces (Bronkhorst & Akkerman, 2016). The out-of-school contexts provide a rich environment for authentic and experiential learning (Nielsen et al., 2009). Authentic mathematics is introduced in the classroom to remedy the common disengagement in school mathematics, wherein students are expected to develop formal mathematics by mathematicizing their informal mathematical activities (Bonotto, 2005). In doing so, school activities further engage students and provide opportunities for them to consolidate knowledge and develop deeper understandings (Nielsen, 2009). Some researchers have suggested fostering informal learning as a supplemental formal learning method (e.g., Xiao & Carroll, 2007). Other researchers have proposed that the schooling system should incorporate informal curriculum to bridge learning in formal and informal contexts (e.g., Hung et al., 2012).

The term "informal learning environment" is often used as a general reference for a learning setting which is different from school. Though there is not an agreed-upon definition of informal learning environment in the literature, it often refers to everyday activities such as family discussions, pursuing one's hobbies, or daily conversations and designed environments such as museums, science centers, or afterschool programs (e.g., Civil, 2007, National Research Council, 2009). Nemirovsky et al. (2017) stated that designed informal mathematics learning environments are "intentionally designed to support mathematics learning, whether because they are structured through programs with regular schedules and assigned educators or because they host technologies, tools, or exhibits designed to engage the user with mathematics" (p. 970). In this study, we use the terms *informal mathematics* and *out-of-school mathematics* interchangeably to refer to mathematics practices in everyday life, in professions, and in designed informal learning environments.

Continuities and Discontinuities between In-School and Out-of-School Settings

Researchers have found that people use flexible strategies in diverse settings to solve mathematical problems outside of school, which are significantly different from those taught in school (Lave, 1988; Nunes et al., 1993; Saxe, 1988). Nunes (1999) suggested that school mathematics, concepts, methods, and procedures are the goals for instruction, solving problems for the teacher's sake. As such, "informal mathematics education is an emerging field of learning with a unique potential to disseminate alternative images about the nature of mathematics and to realize the potential for everyone to engage with mathematics in creative and diverse ways" (Nemirovsky et al., 2017, p. 975).

Bronkhorst and Akkerman (2016) synthesized 186 empirical studies to investigate continuity and discontinuity in students' learning across school and out-of-school contexts. They found that both continuity and discontinuity can result from different educational intentions, but it also occurs as a given. Due to the fundamental role in students' learning, the school is responsible for establishing the continuity for students' learning across contexts. There are possibilities and challenges for schools to develop this continuity. First, introducing out-of-school practices in school might be a challenge for teachers who usually have limited expertise in out-of-school teaching practices, while on the other hand this can be an opportunity for teachers to engage in a new practice. Second, a challenge for teachers adopting informal practices is to ensure that all required content and standards are met. Third, in order to extend schools' influence, some informal learning contexts provide opportunities to supplement school education, such as a tutoring center, that intentional continuity limits students' experiences differing from school.

Akkerman and Bakker (2011) claimed that discontinuities result from boundaries, which can be seen as socio-cultural differences between different contexts. As learners engage in different practices, learning is not necessarily bounded in a particular stable domain. Rather, learning involves crossing boundaries between multiple practices, in which a learner should be approached as a whole person who participates in school and many other places. Our theoretical perspective is informed by learning as crossing boundaries between in-school and out-of-school contexts (e.g., Akkerman & Bakker, 2011; Bronkhorst & Akkerman, 2016), which provides a lens to explore each participant as a whole person with interconnected identities when they engage in different practices.

Methods

In this study, the designed informal learning environment particularly refers to an afterschool STEM program–*GEMS*. *GEMS* was initiated in 1994 by a mother who aimed to help her daughter and other girls develop positive dispositions towards mathematics and science. The first *GEMS* club was started at an elementary school in Virginia; at that time, most participants were white and from working class families. The mother and her daughter's fifth-grade classroom teacher co-led the club; fifth and sixth grade girls were enrolled by teacher's recommendation, parental request, and/or voluntarily.

This study draws its data from a larger study of the original *GEMS* participants in 1994-1995. In the current study, we used a collective case study approach (Yin, 2017) to understand two participants' descriptions of their mathematics learning experiences in formal and informal settings and to explore their images of mathematics. We aimed to explore across the two cases to draw case-specific characteristics. As such, the goal of this case study was not to generalize the image of mathematics from the two cases. Instead, our goal was to identify the possible impact of mathematics experiences on the participants' images of mathematics (Simons, 2009).

Data Collection

Based on information-oriented sampling (Yin, 2017), Kate and Stella (pseudonyms) were selected from the larger study because of their different experiences and views on mathematics. Kate expressed her positive experiences with school mathematics; she identified herself as "naturally good in mathematics." In contrast, Stella, consistently reported struggling with mathematics in and out of school, saying, "I had always been awful at math."

Reflecting on Yin's (2017) emphasis on the role of theory in guiding case study research, we developed data collection protocols based on relevant literature. For instance, building on the literature on mathematical identity (Boaler, 2002), we designed an interview question, which asked the participants to describe themselves as math learners. We also built from Sam and Ernest's (2000) work that proposed that adults' images of mathematics are influenced by their mathematics teachers. The data sources included surveys, focus group interviews, and individual interviews.

Data Analysis

Data analysis involved a review of the three data sources to derive relevant themes across cases regarding mathematics experiences and conceptions of mathematics in- and out-of-school. Drawing on Akkerman and Bakker (2011) and Bronkhorst and Akkerman's (2006) foundational work on continuities and discontinuities crossing boundaries, we conceptualized continuities when individuals make connections between their participation in various contexts(Bronkhorst & Akkerman, 2006) in which individuals might change roles across contexts. Discontinuities refer to an individual's experiences, interests, and perspective in one context that conflict with his/her experiences in another context. We followed a qualitative content analysis protocol, which allowed coding to be both data driven and theory driven (e.g., Schreier, 2012).

The first author reviewed all data and developed the primary codes. Using the primary codes, the two members of the research team then independently coded each participant's survey, focus group interview, and individual interviews. The researchers also wrote research memos to record the emerging new codes and suggestions for revising the codebook. The third researcher oversaw the coding process and tracked the discrepancies between the first two researchers' codes. Then the authors discussed and resolved these divergences. Any unresolved divergences, confusions, ambiguities were brought to the whole research team and discussed in the team meeting until a consensus was reached.

Findings

In this section, we report our findings to highlight Kate and Stella's mathematics learning experiences, how they influenced their views of mathematics, and continuities and discontinuities within their mathematical learning experiences across settings.

Kate's Description of Mathematics

Math is binary. In Kate's descriptions, mathematics is objective and a natural aptitude. She explicitly mentioned her positive learning experiences in elementary and secondary mathematics classrooms, saying "when I was growing up, I knew I could do the math and science as well as the boys....I was interested in math and science at an early age. It just came naturally to me." Kate perceived mathematics as a neutral and objective subject (i.e., right and wrong answers). The objective aspect of math gave her autonomy when she interacted with math. She stated:

> I liked knowing there was an answer, and that you just had to go through the steps to get it right or wrong. And you know why you got the grade you did in math and science. I knew that if I studied, I would get it right. I could and can control it.

Kate compared math and science with other subjects in which there is no right or wrong answer; the learners then need to rely on evaluation from authorities, which from her perspective is subjective. She stated that "in English, instead [of a right or wrong answer], you could write an essay and the teacher may or may not like it depending on what day she reads it."

Even though Kate enjoyed the binary right and wrong aspect of mathematics and considered herself a natural mathematics learner, she was also hindered by this aspect of mathematics. She was hesitant to share her answers in the class as she did not want to present wrong answers. She said, "but you completely second guess about yourself. I do not want to raise my hands just because if I am wrong that's gonna feel really bad in front of everyone."

Discontinuities between school and GEMS broaden the image of mathematics. Kate described the nature of mathematics learned in a formal space as "rigid of structure" and objective ("there is a right answer") while the mathematics learned in the informal learning space was flexible and more subjective. The discontinuities of mathematics within GEMS and the classroom broadened her image of mathematics.

Kate connected her mathematics learning experiences with her daily life activities and experiences. Meanwhile, she acknowledged that she was not able to perceive the continuity in formal classroom mathematics and her daily-life activities in her childhood, "I remember we got our first computer. We're going to have fun games. They're so much fun. It was always learning without making it feel like you're learning. It was always the problem-solving games. This is super fun!"

Kate acknowledged that she engaged in those games without realizing she was learning mathematics (i.e., logic and reasoning). She distinguished between her mathematics learning experiences in the mathematics classroom and in *GEMS*. She mentioned:

> [in a mathematics class], it's gonna look really bad, if I get this wrong in front of everybody. I think one thing that helped in GEMS [that] it was okay if you were not super confident, like yes, I know this. And then they [leaders] were like you're close, but you're not quite there.

This indicated that her learning experiences in these two spaces were discontinuities in terms of being open to share her answers for two reasons. First, the mathematics content presented in the *GEMS* was different from the school mathematics content; it was more subjective, and it did not necessarily depend on "Yes or No type of answers." She stated,

> [Math] was just fun and group kind of thing and, what if add this in and how does that affect? It was not obviously a rigid structure. It's not like a question/answer. So, that definitely helped in a way that builds confidence.

Second, Kate described that the learning environment in the *GEMS* was safer ("it's okay not to get the right answer") and less judgmental ("everybody here they like the same thing as you do") than the classroom learning environment. Kate mentioned that *GEMS* made her realize that mathematics can be learned in a fun way, which aligned with her childhood experiences of learning mathematics with computer games. She stated that she never felt she was learning "rigid structure[s]" and "just question/ answer" in *GEMS*, but it was like building something as a group and having a product at the end. Specifically, she mentioned:

> There was not that big of a, I guess, a fear of that as much as you have in class, it was just a smaller group of people and everybody kind of understood we all like this and we all love doing this, and it's okay to not get it right.

Kate enjoyed the discontinuities of mathematics between school and *GEMS*; in fact, she intentionally sought out these discontinuities. When she was in high school, she joined an after-school math club and expected to do activities similar to *GEMS*. But when she got there, she found that "it was just sitting there doing mathematics problems. I don't need another math class after school, no thanks."

Stella's Description of Mathematics

Math is multifaceted. Stella struggled a lot in basic mathematics, in particular, numbers, but she perceived mathematics as multifaceted, including logic, process, language, statistics, and spatial design. She described her early school years, saying *"*I always sucked with numbers. I was awful at the times table. I was a straight A student except for any math class that I had; I was constantly getting Cs [in math]. *"* Stella said she was traumatized by mathematics:

> I had always been awful at math, especially after third grade where I always failed the multiplication table timed quizzes and tests because I didn't understand the concepts. I don't think I passed a single one of those tests besides the 5s, maybe the 9s because of logic. I was traumatized by math.

In elementary and middle school, people surrounding her did not understand her difficulties, which exacerbated her struggles in mathematics. She said,

> I really struggled in elementary school. And my mother did not get it at all because I was a straight A student in any of the language arts and I really did well in writing. But I just could not understand math and they didn't have, I guess, it wasn't something that was really talked about or knew. So, nobody really thought to be like, hey, this girl has a learning disability because I was doing so well everywhere else. I really grew to hate math because of it.

In high school, Stella was often quiet in math classes. In spite of her hard work on algebra, Stella mentioned that she performed poorly. She said that it was incomprehensible for her at the time to get "such a bad grade." However, she performed well in geometry and got an A. Because she did not want to take extra mathematics classes, she opted to take a programming course instead of trigonometry or calculus. For Stella, programming was not related to mathematics, just logic and languages, "even if it is like math in that it is a logical process, I did not have to do any of the calculation and numbers, that was really hard for me."

Supports discontinuities in mathematics learning. Stella portrayed herself early on as a person who struggled with mathematics. To avoid being called on to do numerical problems in the class, she would make sure to raise her hand and be overly participating in any process- and logic-related questions. The discontinuities between mathematical results and process provided opportunities for her to enhance her strength (i.e., logical thinking and conceptual understanding). Stella mentioned that in GEMS, her teacher helped her address these discontinuities.

Unlike in the mathematics classroom, Stella was not nervous in *GEMS*, "[The teacher] was so good and motivated everyone involved. You can ask questions, there was definitely no stupid question." *GEMS* did not focus on memorizing rather promotes application of math which released Stella's struggles, she said "*GEMS* made me think that that math wasn't as scary. I learned that I understood applied math in a way that I didn't get from memorizing times tables." Even though she was traumatized by numbers and did not like math, she developed confidence in math, "[in *GEMS*] I learned that I even though I was bad at writing down equations on paper, I was decent at applied math. I ended up doing computer programming in high school because I felt comfortable with applied math." At home, Stella's father also supported her conceptual understanding by encouraging Stella to use tools, she recalled "he would even let me use my fingers and he gave me an Abacus so I could use that. It really helped because it took the numbers out of the math and I could understand."

The discontinuities between learning mathematics that focus on getting correct results and understanding concepts supported Stella to appreciate different foci of mathematics. Rather than hindering her development, the discontinuities redeemed her struggles in mathematics and provided room for her to develop her confidence and interests, which impacted her course selection and later career decision. Looking back, she laughs, "even with all my math issues, I ended up going into STEM."

Kate and Stella's Explorations of Continuities In and Out-of-School

Even though Kate experienced discontinuities in her mathematics learning between formal and informal learning environments, Kate's learning experiences in informal settings and everyday life indicated that her descriptions of the nature of mathematics were somewhat continuous as she described mathematics presented in informal classrooms and everyday life as "fun-type" learning. Kate wants her daughter to engage with more mathematical toys because she wants her daughter to choose a STEM-related career: "She has blocks we are building, for her it's just let's stack them down, and right now she accesses the construction all that comes in and knocks it over, but you do not realize this in a way you are engineering but something you are building blocks." Kate also mentioned that her experiences in *GEMS* are parallel with this because in *GEMS* she "never thought [they] were learning, [they] tried fun experiments" without realizing they were "actually learning bigger concepts."

Stella consistently experiences mathematics struggles across different settings. She said, "I still really struggle with the [math], when I'm on the phone with somebody and I need to read off a credit card number, I always mess it up" she added, "I still cannot do basic math like a *normal* person." However, she accepts these continuities and uses resources to overcome the challenges. She depends on Excel and other software when she is doing finances in her personal and professional life. In *GEMS*, continuities of mathematics struggles did not hinder her development. Being with friends and gaining support from her teacher, Stella felt a sense of belonging and being involved, "it was no stupid questions for me [in *GEMS*]. If she [the teacher] could see that you were not understanding it, she would explain it a different way. She had like a million different ways to explain something until you understood it."

Discussion

In this study, we sought to answer two research questions: How did the participants' descriptions of mathematics experiences inform their images of mathematics? How did the participants' descriptions of mathematics reflect continuities and discontinuities between their in-school and out-of-school experiences? For the first research question, we learned that participants' school experiences influenced Kate and Stella's images of mathematics. Kate reported liking mathematics and referred to happy memories of doing mathematics across her experiences at school, home, and her professional life. Stella, who explicitly reported not liking mathematics, referred to school experiences wherein she remembers struggling or feeling defeated. These findings are aligned with existing literature that reports that schools and mathematics teachers greatly influence people's image of mathematics (Sam & Ernest, 2000). Though Kate and Stella hold different attitudes toward mathematics, their views of mathematics are aligned with the public image of mathematics. School mathematics for the two participants was perceived as difficult, cold, abstract, and masculine (e.g., Darragh, 2018, Ernest, 1996, Epstein et al., 2010). Kate and Stella perceived that people either can do school mathematics naturally or not. Kate said that she liked math since she was young while Stella described how she "was awful" in math. Kate's mathematics experiences were pleasant, she enjoyed doing mathematics at school, with her family, and at *GEMS*. Yet, for Stella, school mathematics, especially elementary mathematics, was difficult and unpleasant. In contrast, Stella enjoyed doing mathematics that was related to logic and application, such as her experiences doing mathematics at *GEMS* or with her family.

Concerning findings related to the second research question, we identified continuities and discontinuities in both participants' in-school and out-of-school experiences. A continuity we identified is that when participants reported having uplifting experiences with mathematics in school, the confidence continues in other learning contexts. We identified a discontinuity when Stella reported not liking school mathematics, but doing mathematics in her daily life. The two participants' descriptions of their professional mathematics activities were uplifting and reflected confidence. It appears that even though school experiences had a profound influence on the participants' images of mathematics, their experiences in other learning contexts, particular positive learning experiences, also impact on their construction on alternative images of mathematics.

Future studies could design school mathematics interventions and study their influences on students' images of mathematics. We learned from the participants that doing mathematics in their professions is doable and enjoyable, which prompted us to think that designing activities that resemble those done by professionals might be a way to bridge in-school and out-of-school mathematics, which could broaden students' images of mathematics. Participants reported using mathematical practices and concepts in their daily lives. Curriculum designers might use those practices and concepts to develop K-12 curricula.

A HYPOTHETICAL LEARNING TRAJECTORY FOR THE UNDERSTANDING OF NUMBER DENSITY IN HIGH SCHOOL STUDENTS

UNA TRAYECTORIA HIPOTÉTICA DE APRENDIZAJE PARA LA COMPRENSIÓN DE DENSIDAD NUMÉRICA CON ESTUDIANTES DE BACHILLERATO

Mayra Suárez-Rodríguez

asacrist@cinvestav.mx

During their school life, students learn mathematical topics that can be considered essential for the understanding of the property of density in the set of real numbers. Therefore, we detected a need to design and elaborate a Hypothetical Learning Path to include topics to help promote the learning of this property. This report shows results of a first stage of an educational experiment as part of an ongoing research. It describes how through the trajectory, high school students are able to recognize ways of finding numbers in an interval using various semiotic representations. We also describe some difficulties that students had to recognize the non-existence of a successor in real numbers.

Keywords: Learning Trajectories and Progressions, Number Concepts and Operations, Mathematical Representations, High School Education

Introduction and Research Questions

It has been seen that many students, from the beginning of their elementary school to the end of high school, even university school, show a deficiency in understanding the density property in the set of real numbers (Tirosh et al., 1999). In elementary school, the student only has one opportunity to learn about the density property of decimal numbers (Ávila & García, 2008). For example, in Mexico, the teacher shares with his sixth-grade students (around 12 years old) a unit related to this property using the number line (SEP, school year 2020-2021). In the project by Vamvakoussi and Vosniadou (2010), high school students between 12 and 17 years of age show difficulty in understanding the density property in real numbers. Some students in this project believe that there is no other number between 0.005 and 0.006, or between 1/3 and 2/3. That is, for them, these pairs of numbers are “consecutive” each. Students seem to believe in the existence of a successor in real numbers. And other participants in the study refer that there is a finite number of decimals between 0.005 and 0.006.

On the other hand, Vamvakoussi and Vosniadou (2010) have noted how there are students who are affected by the symbolic representation of the extremes of an interval. The authors observed that students tend to express that there are no fractions between decimals, that there can only be decimals; and vice versa. For this reason, it is important, as Duval (2004) points out, that different representations are handled throughout the students’ school journey. According to Duval, teaching and learning mathematics implies that some cognitive activities (conceptualization, reasoning, comprehension, among others) require, in addition to natural language or that of images, the use of different registers of semiotic representation. For this author, in mathematics there are different writing systems for numbers, symbolic notations for objects, relations and operations, as well as a variety of graphs; each of the above activities constitutes a different semiotic form.

In order to overcome the difficulty that students must understand the density property in real numbers, a Design Based Research is being carried out (Cobb & Gravemeijer, 2008), in which a Hypothetical Learning Trajectory (HLT) was designed as a didactic proposal using various representation registers. Simon (1995) proposes that a HLT is a sequence of activities to attend to some mathematical concept, in which these activities are built from one or more hypotheses that support the student in the construction of new knowledge.

Considering the above and the problems that are generated to understand the density property, the following research questions were elaborated:

a) How to design a HLT to promote the learning of the density property in the set of real numbers?

b) How do high school students understand the property of density in real numbers using semiotic representations that can be produced during HLT?

Theoretical framework

Vamvakoussi and Vosniadou (2004) indicate that understanding the density property of rational numbers is a gradual process: from the discrete to the dense. The authors conclude that prior knowledge about natural numbers supports the student to use the property of the discrete to solve tasks related to rational numbers, in effect restricting the understanding of the density property. Using the ideas of Ni and Zhou (2005), the act of counting by a child is his first approach to a representation of the natural number, of the discrete; this representation persists in the child to such an extent that in problems related to fractions or decimals he considers properties of the natural numbers to solve them. Vamvakoussi and Vosniadou, in 2004, carried out an investigation to find out how much ninth-grade students (around 15 years of age) know about the number density, later, the authors elaborated five categories based on the responses of the participants (see Table 1).

Table 1: Categories of thinking about the quantity number of numbers in an interval

Naive thinking about the discrete	It is thought that there is no other number between two *consecutive false* rational numbers. Vamvakoussi and Vosniadou (2004) created this expression to refer that exists a successor of a rational number.
Advanced thinking about the discrete	It is thought there is a finite quantity of numbers between two consecutive false rational numbers.
Mixed thinking between discrete and dense	In some cases, it is thought that between two rational numbers there is an infinity of numbers; and in other cases, that there is a finite number.
Naive thinking about the dense	It is understood that there is an infinity of numbers in an interval, but this situation is not justified by using the density property. The symbolic representation of the extremes of an interval influences the way of thinking; it is believed there can only be an infinite number of decimal numbers between decimals and an infinity of fractions between fractions, but not an infinity of fractions between decimals or otherwise.
Advanced thinking about the dense	There is a sophisticated understanding of the density property; that is, it is understood that there is an infinite number of numbers between two rational numbers, regardless of their symbolic representation and this is justified through the use of the density property.

To understand the property of density in real numbers, it is necessary to consider that the real number has different representations (Apóstol, 2006). However, Duval (1983) points that this task is not easy for a student, it is difficult for him to recognize the same mathematical object through various contexts of representation. As happened in the study done by Neuman (2001), seventh grade students (around 13 years old) did not accept that there could be a fraction between 0.3 and 0.6, since for them fractions and decimals were different mathematical objects that did not have any relationship. For Duval (1983), learning a mathematical concept requires the resource of several semiotic systems of representation, which implies a deeper mathematical thinking by the student.

Relevant aspects of an HLT

Complementing the definition of a HLT, Simon and Tzur (2004) describe that this expression refers to the predictions (hypotheses) that the researcher, or the teacher, think about how a student can challenge the proposed scenarios in a learning trajectory. The path becomes "real" (real trajectory) when the student's conceptions or ideas are known during the socialization of activities (Simon, 1995). For Simon, during the trajectory, the researcher can modify various aspects, including the duration and the design of the learning lessons, this as a result of the interactions that arise with the students. Thus, a HLT provides the researcher with a rational criterion to decide the design that he is considering, as well as the best hypothesis of how the learning process can advance in the student. Following the author's discourse, three essential components of a HLT are considered: a) *the objectives*, understood as the set of statements of which it is expected to carry out the fulfillment of the actions, b) *the route of the learning activities*, in which students progress, made up of increasingly complex levels with instructional activities that promote the passage from one level to another, and c) *hypotheses by the researcher*, understood as the conjectures that a researcher plans about the learning process.

Methodology

Our research methodology is situated in the context of Design Based Research (DBR), with a qualitative approach of a case study. DBR is a methodological approach in which the researcher tries to examine, in a systematic and detailed way, how students do proposed tasks, and analyzes teaching strategies and tools (Cobb & Gravemeijer, 2008). In terms of these authors, a DBR tries to experiment to support learning, through the design of an HLT. Cobb and Gravemeijer recommend testing and improving the conjectures or hypotheses outlined in the trajectory, which is why they suggest the execution of several cycles of analysis and design of activities. In the present investigation, we focus on a HLT for the learning of the number density, whose refinement contemplates two cycles. At this moment, the investigation is completing the first cycle of design and analysis.

Participants

The current population is made up of four students aged between 15 and 17, who are in high school in Colombia. Due to the COVID-19 pandemic, the activities have been carried out individually and hybrid, some at the student's home and others virtually, over a period of three months. This report will show the participation of two students, Néstor and Paola (pseudonyms), who completed the proposed HLT route.

HLT design

The educational experimentation corresponding to the first cycle has three phases, the first and third consist of the application of a pretest and posttest respectively, and the second consists of the HLT. This report will show results of the first and second phases, and on the conclusions section some details the last phase.

First and second phase. Students solve a pretest and a posttest –with four questions–, each test lasts 30 minutes and measure how much they know about the discrete property of natural numbers and the density of real numbers. Through the pretest and the posttest, it is investigated whether at the end of the implementation of the HLT there have been changes in the way of reasoning of the student regarding the property of the discrete of the natural numbers, which is why the same questionnaire is used. The questions in this questionnaire were inspired by questions asked by Suárez-Rodríguez and Figueras (2020).

Second stage. In preparing this phase there are three objectives:

1. *Establish the stages of the HLT*. These stages are specified as levels of learning lessons, exactly four (see Table 2); however, it does not mean that the student depends on a previous level to complete the next. Each level lasts approximately one hour and 30 minutes.

2. *Define the hypotheses for each level*. The learning hypotheses are raised based on topics that students have studied in their school life and that it is believed that they can guide them to the understanding of density (see Table 2). McMullen and Van Hoof (2020) mention that although this property is not studied in class, there are moments in school mathematics that can provide opportunities to talk about it.

3. *Reach a metaconceptual awareness*. The student is expected to achieve metaconceptual awareness and can identify the characteristics that make a set dense. A student assumes a metaconceptual awareness when he reflects on some of his assumptions that they are not true, and that they also limit the way he interprets the new information (Vosniadou, 1994).

Table 2: HLT Levels and Hypotheses

Levels	*Hypotheses*
Level 1. First approaches to number density.	From two situations: one related to everyday life and the other related to a hypothetical scenario, it is thought that the student can have his first approaches to the property of density.
Level 2. Approach to number density through the similarity of triangles.	It is contemplated that by using triangle similarity students can learn about the density property of rational numbers.
Level 3. Approach to number density from arithmetic progressions and geometric progressions.	It is possible that by finding arithmetic and geometric halves in an interval the student understands the density property of rational numbers in the set of real numbers.
Level 4. Approach to numerical density through the property of continuity.	Using the continuity property, students are believed to understand the density property of irrational numbers in the set of reals.

Results

Pretest results

For the analysis of the responses given to the pretest by the students, the characterization made by Vamvakoussi and Vosniadou in 2004 was considered (Table 1).

Naive thinking about the dense. Figure 1 shows Néstor's response to the first item of the pretest. The process of infinite subdivisions in an interval was the representation that this student elaborated the most. It is observed how he uses decimal writing as a semiotic representation in an arithmetic register; and how he uses colloquial language to refer that there are infinite numbers between 0 and 1, and to express that the numbers follow the "same cycle". This last sentence suggests that he does not consider the irrational numbers in the interval, since the numbers that he writes are numbers in periodic decimal writing.

1. How many numbers are there between 0 and 1? Explain your answer.

Rta: Para mi, los números que hay son infinitos. Porque sigue el mismo ciclo; y porque no tienen un final. los: Ejemplo. 0.111111....
0.111112....
0.111113....

Figure 1: Naive thinking about dense (example)

Naive thinking about the discreet. Figure 2 shows Paola's responses to the fourth item of the pretest. It is appreciated that Paola answers the questions according to her natural number knowledge. Apparently, Paola believes in the existence of "several successors" (0.2, 0.11, 0.111) in decimal numbers. The difficulty of her to perceive the equivalence between 0.1 and 0.10 is also appreciated, since she indicates that 0.2 is the successor of 0.1, but that if the number were 0.10, her successor would be 0.11.

4. Pedro wants to draw a line where he can locate decimal numbers. He starts with the number 0.1. Then he places the 0.2. At that point, Laura interrupts him and says that the number that "follows" 0.1 is 0.11.
a. Who is right, Pedro or Laura? Neither of them? Or both? Explain your answer.

Pedro tiene la razón, ya que después de 0,1 sigue 0,2, Laura tendría razón en el caso que fuera 0.10.

b. Is there a number that follows 0.1? If your answer is yes, write the number that you think follows 0.1. But if your answer is not affirmative, explain why.

Si, existe un número que le sigue a 0,1.
0,11, 0,111, 0,111...

Figure 2: Naive thinking about discrete (example)

HLT Learning Lesson Results

Some actions of Paola and Néstor during the HLT are described.

Actions related to Level 1. In this first scenario, the students solved two learning lessons whose purpose is to have a first approach to density. In one of the lessons, the student must describe the movements that a frog makes (first the frog jumps halfway, then it jumps half of what was left, and so on). In Figure 3 it is seen that Néstor answers the question by approaching a thought related to the dense; however, his expression "too many times" can mean something finite. He uses a common language representation in his response. In the question in Figure 4, Néstor performs the procedure to find the following terms of the given sequence and uses semiotic representations such as fractional and exponential writing in an arithmetic register. In the last question (see Figure 5), he claims that there is an infinity of fractions between 0 and 1, but he does not justify with the density property.

2. How many times does the frog jump between points A and B? Explain your answer.

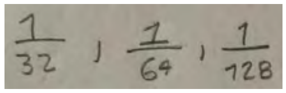
Rta: demasiadas veces; Por que la rana tarde o temprano va a llegar a su destino. [B]

4. Considering the previous question, how many fractions can you find between 0 and 1? Explain your answer.

Rta: se pueden encontrar infinitas fracciones Porque hay una infinidad de números.

Figure 3: Néstor's Record 1 (Level 1) **Figure 5: Néstor's Record 3 (Level 1)**

3. If 1 is the distance between A and B, that is, the interval from 0 to 1, the sequence of terms that the frog performs is: 1/2, 1/4, 1/8, 1/16 ...
Now find the next three terms of the sequence. Describe your procedure.



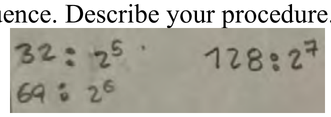


Figure 4: Néstor's Record 2 (Level 1)

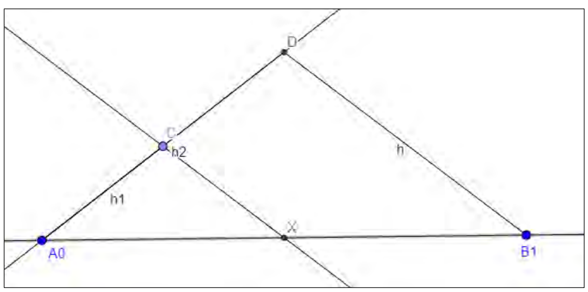
Actions identified in Level 2. The learning lesson of this session is inspired by activities done by Tovar (2011). It is believed that by using similarity of triangles the student can understand the property of density to find middle terms in an interval. At first, the student reads the instructions so that he can construct similar triangles on a number line in GeoGebra. The image in Figure 6 shows the exercise carried out by Paola in which is observed that between "A0 and B1" (that is, between 0 and 1) she located the point *x*. She is asked to find this point. After thinking about it several times, Paola concludes that she must use proportions, as shown in Figure 7. She uses graphical representations of similar triangles in a geometric register, and in an algebraic register she finds the value of *x*. In the exercise instructions, the values of the segments, $\overline{AC}$ = 1 y $\overline{AD}$ = 2, are described for the resolution of this.



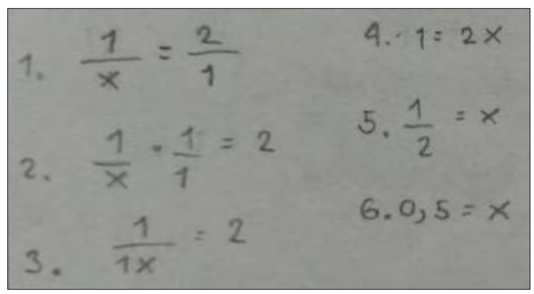


Figure 6: Paola's graph (GeoGebra) **Figure 7: Paola's Record 1 (Level 2)**

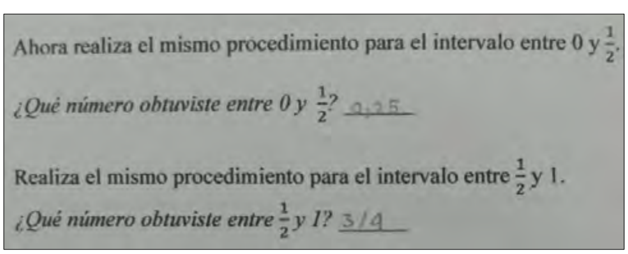
Paola continues to solve the questions (see Figure 8) that lead her to carry out the same procedure to find a number between 0 and 1/2 (see Figure 9), and another between 1/2 and 1. The numbers that she has found up to moment are: 0.25, 1/2 and 3/4; that is, the unit segment was divided into four equal parts. Finally, the students answer the question that appears in Figure 10. It is observed in this image that Paola approaches a thought related to the dense, since she contemplates that each time halves are obtained and that this has an infinite process. While Néstor, apparently, does not consider infinity but "several rational numbers", which could mean a finite quantity.



Ahora realiza el mismo procedimiento para el intervalo entre 0 y $\frac{1}{2}$.

¿Qué número obtuviste entre 0 y $\frac{1}{2}$? 0,25

Realiza el mismo procedimiento para el intervalo entre $\frac{1}{2}$ y 1.

¿Qué número obtuviste entre $\frac{1}{2}$ *y 1?* 3/4

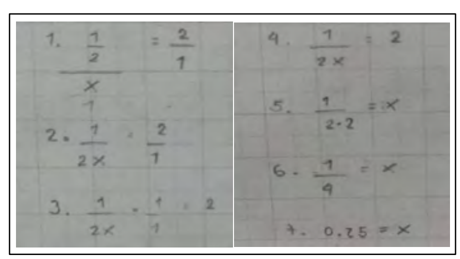


Figure 8: Paola's Record 2 (Level 2) **Figure 9: Paola's Record 3 (Level 2)**

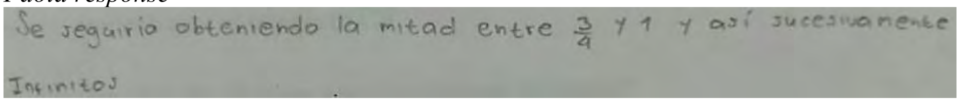
5. What happens if you continue to perform the same procedure between 3/4 and 1? And so on, how many rational numbers would you get?

Paola response



Néstor response

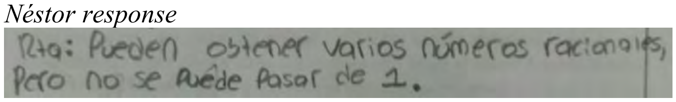


Figure 10: Record of Paola and Néstor in question 5 (Level 2)

Actions associated with Level 3. For this level, three learning lessons concerning arithmetic progressions and geometric progressions were designed to understand the density property of rational in real numbers. In one of the lessons the student reads a short paragraph about the definition of arithmetic progression. Next, the student must find five arithmetic means between 4 and 22 using the nth term of a sequence: $u = a + (n - 1)\, d$, in which a is the first term, n is the number of terms and d the difference between one term and another. In Figure 11 Paola's resolution to the exercise is shown –in an algebraic register – and she concludes that $d = 3$, and writes the terms found.

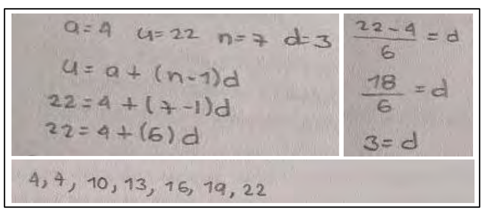

Figure 11: Paola's Record (Level 3)

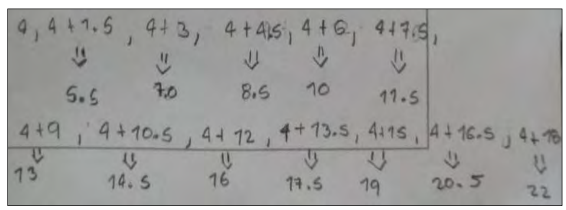

Figure 12: Néstor's Record (Level 3)

Subsequently, the student must answer the following situation: If d, from the previous question, were reduced by half, what would be the new arithmetic means between 4 and 22? Figure 12 shows that Néstor only uses the first term to find the new arithmetic means. He adds 1.5 to 4, then double 1.5 to 4, then triple 1.5 to 4, and so on until he reaches 22. Néstor makes use of representations of additions of decimal numbers in an arithmetic register. Finally, students are asked to find the arithmetic mean between a and u using the expression to find the nth term of a sequence. However, Paola and Néstor could not resolve this point of the activity because it seemed difficult to them.

Actions identified in Level 4. For this scenario, a learning lesson inspired by activities by Tovar (2011) was designed. It is expected that the student can learn the density of irrationals in reals, from the continuity of the line with respect to the non-correspondence between the rational numbers and the points of the line. Néstor explored in GeoGebra how the diagonal of a square with side 1 "translates" on the number line and observes that point x is between 1.2 and 1.6 (see Figure 13). Then he was asked to write four intervals where this point is located. To do this, he made several zooms on the GeoGebra screen and noted two intervals (see Figure 14). Both students observed that the point x does not correspond to a rational and that the intervals that enclose it are getting smaller and smaller. Finally, they found the diagonal of the square using the Pythagorean Theorem, and then concluded that between two rational numbers lies $\sqrt{2}$. However, both students were still thinking about the presence of a successor, in this case for $\sqrt{2}$, when they were questioned about it, they did not answer what it could be. This leads us to think that since $\sqrt{2}$ is irrational, it is difficult for them to find a supposed successor even though they affirm its existence.

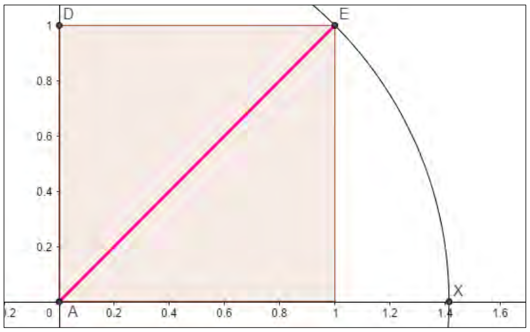

Figure 13: Néstor Record 1 (Level 4)

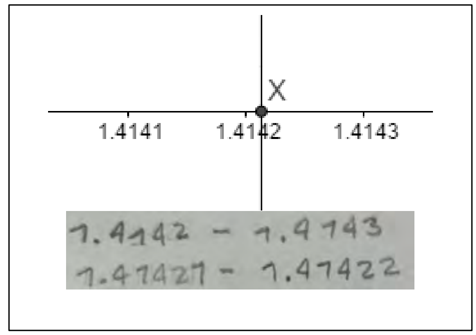

Figure 14: Néstor Record 2 (Level 4)

Conclusions

The design and development of the HLT involved the search and analysis of school mathematics topics that could guide the student to learn the number density. Topics such as similarity of triangles, arithmetic and geometric progressions, property of continuity and diagonal of a square, helped the students not only in their learning process but in their process of understanding the property of density. However, both students retained the idea of the existence of a successor in a set other than that of natural numbers. In the last phase of this first cycle, although the students improved their skills to find intermediate numbers in an interval, it was still difficult for them to make a metaconceptual awareness about the non-existence of a successor in the real numbers. This aspect will be considered for the refinement of the learning trajectory in the second cycle of activities. On the other hand, the students used various semiotic representations such as fractional and decimal writing. Colloquial language was one of the semiotic registers most used by students to express their thoughts in their own words. Finally, the hypotheses raised showed that it is feasible for the student to mitigate the difficulties on the density property. It is suggested that these hypotheses are more aimed at identifying characteristics that make a set dense as a discrete one, which would possibly lead to the understanding of a unique successor in natural numbers.

A HYPOTHETICAL LEARNING TRAJECTORY FOR THE UNDERSTANDING OF NUMBER DENSITY IN HIGH SCHOOL STUDENTS

UNA TRAYECTORIA HIPOTÉTICA DE APRENDIZAJE PARA LA COMPRENSIÓN DE DENSIDAD NUMÉRICA CON ESTUDIANTES DE BACHILLERATO

asacrist@cinvestav.mx

Durante su vida escolar, el estudiante aprende temas de las matemáticas que podrían considerarse esenciales para la comprensión de la propiedad de densidad en el conjunto de los números reales. Por ello se contempló la necesidad de diseñar y elaborar una Trayectoria Hipotética de Aprendizaje para incluir temas que ayuden a propiciar el aprendizaje de esta propiedad. Este informe muestra los resultados de la primera experimentación educativa de una *investigación que aún está en curso. Se expone la delineación de la trayectoria en la que el estudiante, de bachillerato, logra reconocer formas de hallar números en un intervalo usando varias representaciones semióticas. Así mismo, se describen algunas dificultades que tiene el estudiante para reconocer la no existencia de un sucesor en los números reales.*

Palabras clave: trayectorias de aprendizaje y progresiones, conceptos de números y operaciones, representaciones matemáticas, educación media superior

Introducción y Preguntas de Investigación

Se ha visto que muchos estudiantes, desde que inician su educación primaria hasta que terminan con la educación media superior, incluso con la universitaria, muestran deficiencia para comprender la propiedad de densidad en el conjunto de los números reales (Tirosh et al., 1999). En la primaria, el estudiante solo tiene una oportunidad para aprender acerca de la propiedad de densidad de los números decimales (Ávila y García, 2008). Por ejemplo, en México, el docente comparte con sus estudiantes de sexto de primaria (alrededor de 12 años) una unidad relacionada con esta propiedad usando la recta numérica (SEP, ciclo escolar 2020-2021). En el proyecto de Vamvakoussi y Vosniadou (2010), estudiantes de secundaria (y bachillerato) entre 12 y 17 años de edad, muestran dificultad para comprender la propiedad de densidad en los números reales. Algunos estudiantes de este proyecto creen que no hay otro número entre 0.005 y 0.006, o entre 1/3 y 2/3. Es decir, para ellos, estos pares de números son "consecutivos" cada uno. Al parecer, los estudiantes creen en la existencia de un sucesor en los números reales. Y otros participantes del estudio mencionado, refieren que hay una cantidad finita de decimales entre 0.005 y 0.006.

Por otro lado, Vamvakoussi y Vosniadou (2010) han notado cómo hay estudiantes que se ven afectados por la representación simbólica de los extremos de un intervalo. Las autoras observaron que estudiantes tienden a expresar que no hay fracciones entre decimales, que solo puede haber decimales; y viceversa. Por ello, resulta importante, como señala Duval (2004), que se manejen representaciones diferentes a lo largo el trayecto escolar de los estudiantes. Según Duval, enseñar y aprender matemáticas conlleva a que algunas actividades cognitivas (conceptualización, razonamiento, comprensión, entre otras) requieran, además del lenguaje natural o el de las imágenes, la utilización de diferentes registros de representación semiótica. Para este autor, en matemáticas se encuentran distintos sistemas de escritura para los números, notaciones simbólicas para los objetos, relaciones y operaciones, así como también una variedad de gráficas; cada una de las actividades anteriores constituye una forma semiótica diferente.

Con miras a superar la dificultad que tienen los estudiantes para comprender la propiedad de densidad en los números reales, se está llevando a cabo una Investigación Basada en el Diseño (Cobb y Gravemeijer, 2008), donde se diseñó una Trayectoria Hipotética de Aprendizaje (THA) como una propuesta didáctica utilizando diversos registros de representación. Simon (1995) plantea que una THA es una secuencia de actividades para atender algún concepto matemático, donde dichas actividades se construyen a partir de una o varias hipótesis que apoyen al estudiante en la construcción de nuevos conocimientos.

Teniendo en cuenta lo anterior y la problemática que se genera para comprender la propiedad de densidad se elaboraron las siguientes preguntas de investigación:

a.) ¿cómo diseñar una THA para promover el aprendizaje de la propiedad de densidad en el conjunto de los números reales?, y
b.) ¿cómo estudiantes de bachillerato comprenden la propiedad de densidad en los números

reales usando representaciones semióticas que se pueden producir durante la THA?

Marco Teórico

Vamvakoussi y Vosniadou (2004) plantearon la hipótesis de que la comprensión de la propiedad de densidad de los números racionales es un proceso gradual: de lo discreto a lo denso. Las autoras concluyen que el conocimiento previo sobre los números naturales apoya al estudiante al uso de la propiedad de lo discreto para solucionar tareas vinculadas con los racionales, en efecto restringe la comprensión de la propiedad de densidad. Recurriendo a las ideas de Ni y Zhou (2005), el acto de contar por un niño es su primer acercamiento a una representación del número natural, de lo discreto; esta representación perdura en el niño a tal grado que en problemas vinculados con fracciones o decimales él toma en cuenta propiedades de los números naturales para solucionarlos. Vamvakoussi y Vosniadou, en el 2004, realizaron una investigación para conocer qué tanto saben los estudiantes de noveno grado (alrededor de 15 años de edad) acerca de la propiedad de densidad, posteriormente, elaboraron cinco categorías con base en las respuestas de los participantes (ver Tabla 1).

Tabla 1: Categorías del pensamiento sobre la cantidad de números en un intervalo

Pensamiento ingenuo sobre lo discreto	Se considera que no hay otro número entre dos números racionales *consecutivos falsos* (expresión instaurada por Vamvakoussi y Vosniadou, en 2004, para referir que existe un sucesor en los números racionales.)
Pensamiento avanzado sobre lo discreto	Se cree que hay un número finito de números intermedios entre dos números racionales consecutivos falsos.
Pensamiento compuesto entre lo discreto y lo denso	En algunas situaciones se piensa que entre dos números racionales hay una cantidad infinita de números, y en otros, que hay una cantidad finita.
Pensamiento ingenuo sobre lo denso	Se contempla que hay una infinidad de números en un intervalo, pero no se justifica la situación usando la propiedad de densidad. La representación simbólica de los extremos de un intervalo influye en la forma de pensar; se cree que solo puede haber una infinidad de decimales entre decimales, pero no fracciones; de igual modo sucede con fracciones entre fracciones.
Pensamiento avanzado sobre lo denso	Hay una comprensión bastante sofisticada de la propiedad de densidad, es decir, se pone de manifiesto que se entiende que entre dos números racionales hay una infinidad de números, independientemente de su representación simbólica, y se justifica con la propiedad de la densidad.

Para comprender la propiedad de densidad en los números reales es necesario tener en cuenta que el número real tiene diversas representaciones (Apóstol, 2006). No obstante, Duval (1983) recalca que esta tarea no es sencilla para un estudiante, le cuesta reconocer el mismo objeto matemático a través de varios contextos de representación. Como sucedió en el estudio hecho por Neuman (2001), estudiantes de séptimo grado (alrededor de 13 años edad) no aceptaban que podía haber una fracción entre 0.3 y 0.6, pues para ellos las fracciones y los decimales eran objetos matemáticos distintos que no tenían relación alguna. En términos de Duval, el aprendizaje de un concepto matemático requiere del recurso de varios sistemas semióticos de representación, lo que implica un pensamiento matemático más profundo por el estudiante.

Aspectos relevantes de una THA

Complementando la definición de una THA, Simon y Tzur (2004) describen que esta expresión se refiere a las predicciones (hipótesis) que tiene el investigador, o el profesor, sobre cómo un estudiante puede desafiar los escenarios propuestos en un camino de aprendizaje. El camino se vuelve "real" (trayectoria real) cuando se conoce las concepciones o las ideas del estudiante durante la socialización de las actividades (Simon, 1995). Para Simon, durante el recorrido de la trayectoria, el investigador puede ir modificando varios aspectos, entre ellos la duración y el diseño mismo de las lecciones de aprendizaje, esto como resultado de las interacciones que van surgiendo con los estudiantes. Así, una THA le proporciona al investigador un criterio racional para decidir el diseño que él está considerando, así como la mejor hipótesis de cómo puede avanzar el proceso de aprendizaje en el estudiante. Siguiendo el discurso de Simon, se consideran tres componentes esenciales de una THA: a) *los objetivos*, entendidos como el conjunto de enunciados de los que se espera llevar a cabo el cumplimiento de las acciones, b) *la ruta de las actividades de aprendizaje*, en la cual los estudiantes progresan, constituida por niveles cada vez complejos con actividades instruccionales que fomentan el paso de un nivel a otro, e c) *hipótesis planteadas por el investigador*, entendidas como las conjeturas que planea un investigador sobre el proceso de aprendizaje.

Metodología

Nuestra metodología de investigación se sitúa en el contexto de la Investigación Basada en el Diseño (IBD), con un enfoque cualitativo de un estudio de casos. La IBD es un enfoque metodológico en el que el investigador intenta examinar, de manera sistemática y minuciosa, cómo los estudiantes afrontan tareas propuestas, y también analiza estrategias y herramientas de enseñanza (Cobb y Gravemeijer, 2008). En términos de estos autores, en una IBD se intenta experimentar para apoyar el aprendizaje, a través del diseño de una THA. Cobb y Gravemeijer recomiendan ir probando y mejorando las conjeturas o las hipótesis que se esbozan en la trayectoria, razón por la cual sugieren la ejecución de varios ciclos de análisis y diseño de actividades. En la presente investigación, nos enfocamos en una THA para el aprendizaje de la propiedad de densidad, cuyo refinamiento contempla dos ciclos. En este momento la investigación está culminando el primer ciclo de diseño y análisis.

Participantes

La población de la investigación en curso está conformada por cuatro estudiantes con edades entre 15 y 17 años, quienes cursan la educación media vocacional (bachillerato) en Colombia. Debido a la pandemia de COVID-19, las actividades se han realizado de manera individual e híbrida, algunas en casa del estudiante y otras de manera virtual, durante un periodo de tres meses. En este informe se mostrará la participación de dos estudiantes, Néstor y Paola (pseudónimos), quienes completaron la ruta de la THA propuesta.

Diseño de la THA

La experimentación educativa correspondiente al primer ciclo tiene tres fases, la primera y tercera constan de la aplicación de un pretest y postest respectivamente, y la segunda se constituye de la THA. En este informe se mostrarán resultados de la primera y segunda fase, y en el apartado de las conclusiones se mencionarán detalles breves de la última fase.

Primera y segunda fase. Los estudiantes resuelven un pretest y un postest –de cuatro ítems– con una duración de 30 minutos cada uno, y miden qué tanto saben sobre lo discreto de los números naturales y lo denso de los números reales. A través del pretest y el postest se indaga si al final de la implementación de la THA ha habido cambios en forma de razonar del estudiante respecto a la propiedad de lo discreto de los números naturales, razón por la cual se utiliza el mismo cuestionario. Las preguntas de dicho cuestionario se inspiraron en preguntas hechas por Suárez-Rodríguez y Figueras (2020).

Segunda fase. En la preparación de esta fase se tienen tres objetivos:

1. *Establecer las etapas de la THA*. Se concretan estas etapas como niveles de lecciones de aprendizaje, exactamente cuatro (ver Tabla 2); sin embargo, no significa que el estudiante

dependa de un nivel anterior para completar el siguiente. Cada nivel tiene una duración de una hora y 30 minutos aproximadamente.

2. *Definir las hipótesis para cada nivel*. Se plantean las hipótesis de aprendizaje con base en temas que han cursado los estudiantes en su vida escolar y que se cree que pueden guiarles a la comprensión de la densidad (ver Tabla 2). McMullen y Van Hoof (2020) mencionan que si bien esta propiedad no se profundiza en clase, hay momentos de la matemática escolar que pueden proporcionar oportunidades para hablar de ella.
3. *Alcanzar una conciencia metaconceptual*. Se espera que el estudiante pueda lograr una conciencia metaconceptual para que pueda identificar las características que hacen que un conjunto sea denso. Un estudiante asume una conciencia metaconceptual cuando reflexiona sobre algunas de sus suposiciones y que estas no son ciertas, y que además limitan la forma en que interpreta la nueva información (Vosniadou, 1994).

Tabla 2: Niveles e hipótesis de la THA

Niveles.	*Hipótesis*
Nivel 1. Primeros acercamientos a la propiedad de densidad.	A partir de dos situaciones: una relacionada con la cotidianidad y otra vinculada con un escenario hipotético, se piensa que el estudiante puede tener sus primeros acercamientos a la propiedad de densidad.
Nivel 2. Acercamiento a la propiedad de densidad a través de la semejanza de triángulos.	Se contempla que usando semejanza de triángulos los estudiantes puedan aprender sobre la propiedad de densidad de los números racionales.
Nivel 3. Aproximación a la propiedad de densidad a partir de progresiones aritméticas y progresiones geométricas.	Es posible que hallando medios aritméticos y geométricos en un intervalo el estudiante comprenda la propiedad de densidad de los números racionales en el conjunto de los reales.
Nivel 4. Aproximación a la propiedad de densidad por medio de la propiedad de continuidad.	Se cree que usando la propiedad de continuidad los estudiantes comprenden la propiedad de densidad de los números irracionales en el conjunto de los reales.

Resultados

Resultados del pretest

Para el análisis de las respuestas dadas al pretest por los estudiantes se tuvo en cuenta la caracterización hecha por Vamvakoussi y Vosniadou en 2004 (ver Tabla 1).

Pensamiento ingenuo sobre lo denso. En la Figura 1 se muestra la respuesta de Néstor al primer ítem del pretest. El proceso de subdivisiones infinitas en un intervalo fue la representación que más elaboró este estudiante. Se observa cómo él usa la escritura decimal como representación semiótica en un registro aritmético; y cómo él usa lenguaje coloquial para referir que hay infinitos números entre 0 y 1, y para expresar que los números siguen el "mismo ciclo". Esta última frase hace pensar que él no toma en cuenta a los números irracionales en el intervalo, pues los números que él anota son números en escritura decimal periódica.

1. ¿Cuántos números hay entre 0 y 1? Justifica tu respuesta.

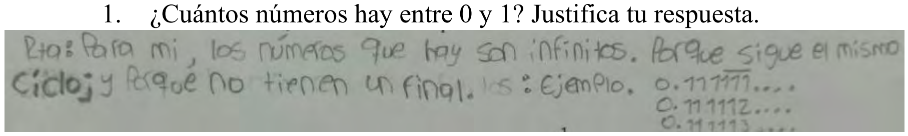

Figura 1: Pensamiento ingenuo sobre lo denso (ejemplo)

Pensamiento ingenuo sobre lo discreto. En la Figura 2 se muestran las respuestas de Paola al cuarto ítem del pretest. Se aprecia que Paola responde a las preguntas de acuerdo con sus conocimientos de número natural. Al parecer, Paola cree en la existencia de "varios sucesores" (0.2, 0.11, 0.111) en los números decimales. También se aprecia su dificultad para percibir la equivalencia entre 0.1 y 0.10, pues ella indica que 0.2 es el sucesor de 0.1, pero que si el número fuera 0.10, su sucesor sería 0.11.

4. Pedro quiere dibujar una línea donde pueda ubicar números decimales. Inicia con el número 0.1. Después coloca el 0.2. En ese momento, Laura lo interrumpe y dice que el número que "sigue" de 0.1 es 0.11. a. ¿Quién tiene la razón, Pedro o Laura?, ¿ninguno de los dos?, o ¿ambos? Justifica tu respuesta.

Pedro tiene la razón, ya que después de 0,1 sigue 0,2, Laura tendría razón en el caso que fuera 0.10.

b. ¿Existe un número que le sigue a 0.1? Si tu respuesta es afirmativa, escribe el número que crees que sigue a 0.1. Pero si tu respuesta no es afirmativa explica por qué.

Si, existe un número que le sigue a 0,1.
0,11 , 0,111 , 0,111...

Figura 2: Pensamiento ingenuo sobre lo discreto (ejemplo)

Resultados de las lecciones de aprendizaje de la THA

Se describen algunas actuaciones de Paola y Néstor durante la puesta en marcha de la THA.

Actuaciones vinculadas con el Nivel 1. En este primer escenario los estudiantes solucionaron dos lecciones de aprendizaje cuya finalidad es tener un primer acercamiento a la densidad. En una de las lecciones, el estudiante debe describir los movimientos que efectúa una rana (primero salta a la mitad, luego salta la mitad de lo que quedó, y así sucesivamente). En la Figura 3 se contempla que Néstor responde la pregunta acercándose a un pensamiento afín con lo denso; no obstante, su expre masiadas veces" puede significar algo finito. Él usa una representación de lenguaje común en su respuesta. En la pregunta de la Figura 4 se aprecia que Néstor realiza el procedimiento para hallar los siguientes términos de la sucesión dada, y usa representaciones semióticas como las escrituras fraccionaria y exponencial en un registro aritmético. En la última pregunta (ver Figura 5), aunque él afirma que hay una infinidad de fracciones entre 0 y 1, no justifica con la propiedad de densidad.

2. ¿Cuántas veces saltará la rana entre los puntos A y B? Explica tu respuesta.

Rta: demasiadas veces; Por que la rana tarde o temprano va a llegar a su destino. [B]

Figura 3: Registro 1 de Néstor (Nivel 1)

4. Teniendo en cuenta la pregunta anterior, ¿cuántas fracciones puedes encontrar entre 0 y 1? Justifica tu respuesta.

Rta: se Pueden encontrar infinitas fracciones Por que hay una infinidad de números.

Figura 5: Registro 3 de Néstor (Nivel 1)

3. Suponiendo que 1 es la distancia entre A y B, es decir, el intervalo de 0 a 1, la sucesión de términos que realiza la rana es: $\frac{1}{2}, \frac{1}{4}, \frac{1}{8}, \frac{1}{16} \ldots$
Ahora, halle los siguientes tres términos de la sucesión. Describe su procedimiento.

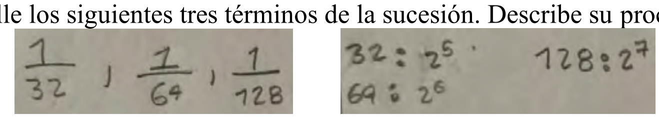

Figura 4: Registro 2 de Néstor (Nivel 1)

Actuaciones identificadas en el Nivel 2. La lección de aprendizaje de esta sesión está inspirada en actividades hechas por Tovar (2011). Se cree que al usar semejanza de triángulos el estudiante puede comprender la propiedad de densidad para hallar términos medios en un intervalo. Al principio, el estudiante lee las instrucciones para que pueda construir triángulos semejantes sobre una recta numérica en GeoGebra. La imagen de la Figura 6 muestra el ejercicio realizado por Paola en la que se observa que entre "A0 y B1" (es decir, entre 0 y 1) 1 punto *x*. Se le pide que halle este punto. Después de pensarlo varias veces, Paola concluye que debe usar proporciones, como se nota en la Figura 7. Ella emplea representaciones gráficas de triángulos semejantes en un registro geométrico, y en un registro algeraico halla el valor de *x*. Cabe mencionar que en las instrucciones del ejercicio están descritos los valores de los segmentos, $\overline{AC}$ = 1 y $\overline{AD}$ = 2, para la resolución de este.

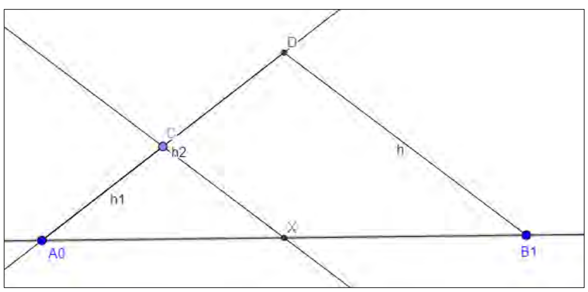

Figura 6: Gráfica de Paola (GeoGebra)

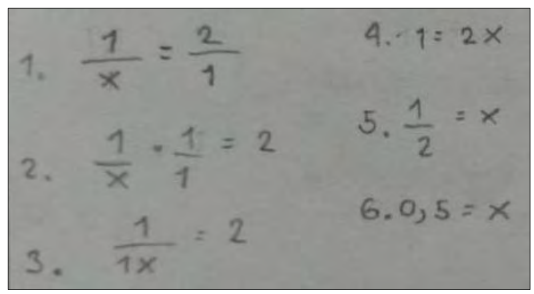

Figura 7: Registro 1 de Paola (Nivel 2)
