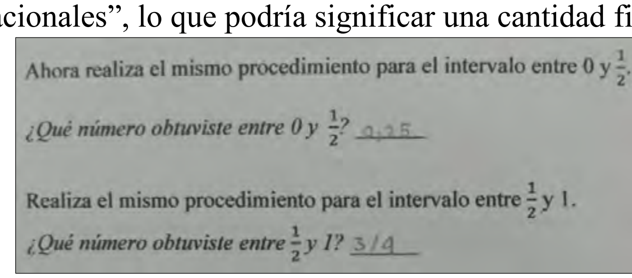
Paola continúa solucionando las preguntas (ver Figura 8) que conllevan a efectuar el mismo procedimiento para hallar un número entre 0 y 1/2 (ver Figura 9), y otro entre 1/2 y 1. Los números que ha encontrado ella hasta el momento son: 0.25, 1/2 y 3/4; es decir, el segmento unitario fue dividido en cuatro partes iguales. Finalmente, los estudiantes responden la pregunta que aparece en la Figura 10. Se observa en esta imagen que Paola se acerca a un pensamiento afín con lo denso, pues contempla que cada vez se obtienen mitades y que esto tiene un proceso infinito. Mientras que Néstor, al parecer, no considera la infinidad sino "varios números racionales", lo que podría significar una cantidad finita.



Ahora realiza el mismo procedimiento para el intervalo entre 0 y $\frac{1}{2}$.

¿Qué número obtuviste entre 0 y $\frac{1}{2}$? 0,25

Realiza el mismo procedimiento para el intervalo entre $\frac{1}{2}$ y 1.

¿Qué número obtuviste entre $\frac{1}{2}$ y 1? 3/4

Figura 8: Registro 2 de Paola (Nivel 2)

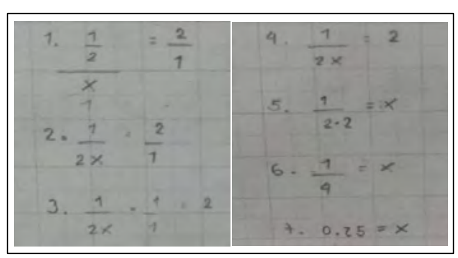


Figura 9: Registro 3 de Paola (Nivel 2)

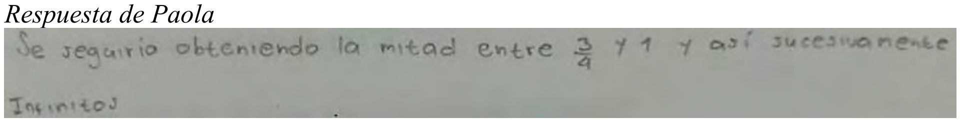
5. ¿Qué sucede si continúas realizando el mismo procedimiento entre $\frac{3}{4}$ y 1? Y así sucesivamente, ¿cuántos números racionales se obtendrían?

Respuesta de Paola



Respuesta de Néstor

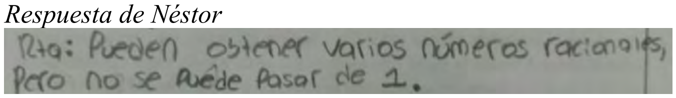


Figura 10: Registro de Paola y Néstor en la pregunta 5 (Nivel 2)

Actuaciones asociadas con el Nivel 3. Para este nivel se diseñaron tres lecciones de aprendizaje concernientes a progresiones aritméticas y progresiones geométricas para comprender la propiedad de densidad de los racionales en los números reales. En una de las lecciones el estudiante lee un breve párrafo sobre la definición de progresión aritmética. En seguida, el estudiante debe hallar cinco medios aritméticos entre 4 y 22 usando el término n-ésimo de una sucesión: $u = a + (n - 1)d$, donde a es el primer término, n el número de términos y d la diferencia entre un término y otro. En la Figura 11 se muestra la resolución de Paola al ejercicio –en un registro algebraico– y concluye que $d = 3$, y escribe los términos hallados.

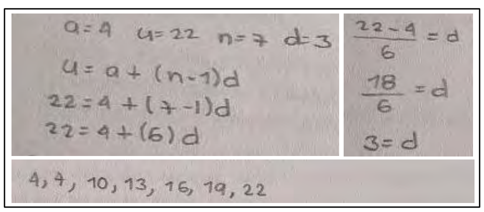

Figura 11: Registro de Paola (Nivel 3)

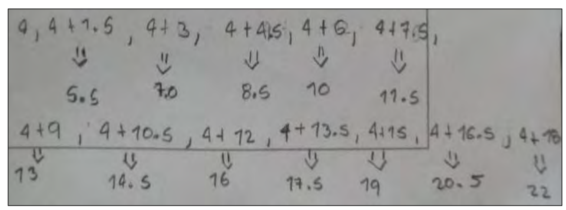

Figura 12: Registro de Néstor (Nivel 3)

Posteriormente, el estudiante debe responder la siguiente situación: *Si d, de la pregunta anterior, se redujera a la mitad, ¿cuáles serían los nuevos medios aritméticos entre 4 y 22?* En la Figura 12 se muestra que Néstor solo utiliza el primer término para encontrar los nuevos medios aritméticos. Él suma 1.5 a 4, luego suma el doble de 1.5 a 4, en seguida, el triple de 1.5 a 4, y así hasta llegar a 22. Néstor hace uso de representaciones de sumas de números decimales en un registro aritmético. Finalmente, se les solicita a los estudiantes hallar la media aritmética entre a y u usando la expresión para hallar el término n-ésimo de una sucesión. Sin embargo, Paola y Néstor no pudieron resolver este punto de la actividad porque les parecía difícil.

Actuaciones identificadas en el Nivel 4. Para este escenario se diseñó una lección de aprendizaje inspirada en actividades de Tovar (2011). Se espera que el estudiante pueda aprender la densidad de los irracionales en los reales, a partir de la continuidad de la recta con respecto a la no correspondencia entre los números racionales y los puntos de la recta. Néstor exploró en GeoGebra c a diagonal de un cuadrado de lado 1 se "traslada" sobre la recta numérica y observa que el punto x está entre 1.2 y 1.6 (ver Figura 13). Luego se le pidió escribir cuatro intervalos en donde esté ubicado este punto. Para ello, él efectuó varios zooms en la pantalla de GeoGebra y anotó dos intervalos (ver Figura 14). Ambos estudiantes observaron que el punto x no corresponde a un racional y que cada vez son más pequeños los intervalos que lo encierran.

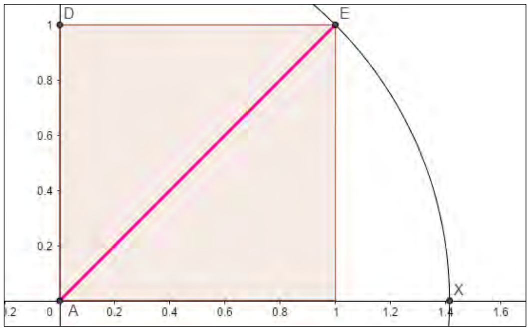

Figura 13: Registro 1 de Néstor (Nivel 4)

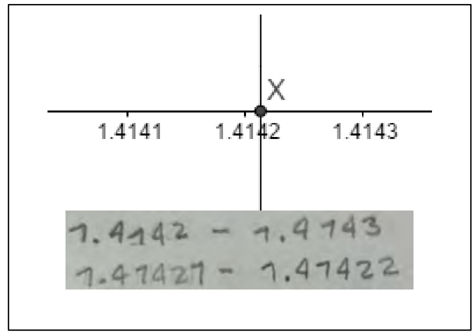

Figura 14: Registro 2 de Néstor (Nivel 4)

Por último, hallaron la diagonal del cuadrado por medio del Teorema de Pitágoras, y luego concluyen que entre dos números racionales se encuentra $\sqrt{2}$. No obstante, ambos estudiantes seguían pensando en la presencia de un sucesor, en este caso para $\sqrt{2}$ cuando se les cuestionó por ello, pero no respondieron cuál podría ser. Esto lleva a pensar que al ser $\sqrt{2}$ un irracional, les es difícil encontrar un supuesto sucesor pese a que ellos afirman su existencia.

Conclusiones

El diseño y elaboración de la THA implicó la búsqueda y análisis de temas de la matemática escolar que pudieran guiar al estudiante al aprendizaje de la propiedad de densidad. Temas como semejanza de triángulos, progresiones aritméticas y geométricas, propiedad de continuidad y diagonal de un cuadrado, ayudaron a los estudiantes no solo en su proceso de aprender sino en su proceso de comprender la propiedad de densidad. Sin embargo, ambos estudiantes conservaron la idea de la existencia de un sucesor en un conjunto que no sea el de los números naturales. En la última fase de este primer ciclo, aunque los estudiantes mejoraron sus habilidades para hallar números intermedios en un intervalo, todavía se les dificultaba hacer una conciencia metaconceptual sobre la no existencia de un sucesor en los números reales. Este aspecto se tendrá en cuenta para el refinamiento de la trayectoria de aprendizaje en el segundo ciclo de actividades. Por otro lado, los estudiantes emplearon varias representaciones semióticas como las escrituras fraccionaria y decimal. El lenguaje coloquial fue uno de los registros semióticos más usados por los estudiantes para expresar con sus propias palabras sus pensamientos. Finalmente, las hipótesis planteadas mostraron que es viable que el estudiante pueda mitigar las dificultades sobre la propiedad de densidad. Se sugiere que estas hipótesis se encuentren más encaminadas en la identificación de características que hace que un conjunto sea denso como de uno discreto, lo que conllevaría, posiblemente, a la comprensión de un sucesor único en los números naturales.

Agradecimientos

Backward transfer is when learning about a new topic influences an individual's prior ways of reasoning about a topic they previously learned about. This study looked at how quadratic functions instruction differentially influenced students' prior ways of reasoning about linear functions. Specifically, we compared students at three levels of reasoning about linear functions, low-, mid-, and high-level, using a pre/posttest design that bracketed a two-week quadratic functions math program. Results showed that students at different reasoning levels experienced different backward transfer effects, that particular mathematical reasoning processes were most involved in the effects, and that the effects spanned two dimensions of productiveness of mathematical reasoning. Results from this study are significant for better understanding the construct of backward transfer, and have implications for teaching quadratic functions.

Keywords: algebra and algebraic thinking; cognition; learning theory

The study reported in this article integrates two ideas that thus far have not yet been intentionally studied together. The first idea is that when individuals learn about a new concept (C_2), that learning may have the unintended side-effect of influencing the individuals' ways of reasoning about a previously-encountered concept (C_1) (i.e., a concept they previously learned about and already developed ways of reasoning about). We call this effect *backward transfer* (BT) (Hohensee, 2014). A number of studies have reported a variety of BT effects (e.g., Bagley et al., 2015; Hohensee, 2014; Melhuish & Fagan, 2018; Van Dooren, 2004). Importantly, these studies have also shown there can be different BT effects for different students.

The second idea is that students develop ways of reasoning that are more or less productive. Greeno (1989) characterized *productive ways of reasoning* about problem situations as when reasoning is deeply embedded in a problem situation and when that reasoning accounts for the essential properties and relations of that problem situation.

Our study examined the interplay between these two ideas. To explain what we mean, imagine two students with different pre-established ways of reasoning about C_1, who participate in the same learning experiences about C_2. How the BT effects on those students' ways of reasoning about C_1 might compare is an open question. Our study set out to make these kinds of comparisons.

Insights these comparisons reveal would be consequential for the development of BT theory because research thus far has only looked at *what* effects are produced (e.g., Hohensee, Gartland, Willoughby, & Melville, 2021), without trying to account for *how* those effects are different across students. Insights would also be consequential for future research on BT because, once more is known about differences in BT effects across students, future research can examine how to address the differences (e.g., find ways to promote backward transfer that enhances productiveness of ways reasoning about C_1).

Theoretical Perspective

Our theoretical perspective has three parts: part one is about mathematical reasoning in general, part two is about what productive mathematical reasoning is (and is not), and part three is about BT effects on mathematical reasoning. It is the relationship between productiveness of mathematical reasoning and BT effects on reasoning that is the topic of our study.

Mathematical Reasoning

Our theoretical perspective on mathematical reasoning aligns with Jeannotte and Kieran's (2017) view that all mathematical reasoning is made up of thought and communicational elements that are organized on two interrelated dimensions, a process dimension and a structural dimension.[1] The process dimension refers to the steps taken by thought or communicational elements to reach an intended mathematical goal. Jeannotte and Kieran specify nine such processes: generalizing, classifying, comparing, identifying a pattern, validating, justifying, proving, formal proving, and exemplifying. Of the nine processes, classifying, comparing, and identifying a pattern were most central to our study.

One type of reasoning important for our study was *quantitative reasoning*. As we conceive it, quantitative reasoning requires the processes of *classifying* and *comparing*. Classifying is defined as the process of inferring "a class of objects based on mathematical properties and definitions" (Jeannotte & Kieran, 2017, p. 11). For an example of a falling rock, two quantities that could be classified are the distance and time the rock falls. Additionally to measure a particular quantity, comparisons must be made between amounts of a quantity and a standard of measure for that quantity (e.g., compare a meter stick to the distance a rock falls).

A second type of reasoning important for our study was *covariational reasoning*. As we conceive it, covariational reasoning requires the process of *comparing*. Comparing is defined as "the search for similarities and differences [to infer a] narrative about mathematical objects or relations" (Jeannotte & Kieran, 2017, p. 11; parenthetical added). During covariational reasoning, what is being compared are the ways "two varying quantities . . . change in relation to each other" (Carlson et al., 2002). For the falling rock example, corresponding differences in distance and time could be compared. Note that while quantitative and covariational reasoning are tied to classifying and/or comparing, other process likely also play a role (e.g., making *generalizations* during quantitative reasoning, justifying one's covariational reasoning, etc.).

Productiveness of Mathematical Reasoning

Our theoretical perspective on productiveness of mathematical reasoning aligns with Greeno (1989), who characterizes productiveness on four dimensions, two of which are the following: (a) the degree to which reasoning is deeply embedded in the problem situation, and (b) the degree to which reasoning accounts for essential properties and relations in a problem situation.[2] According to our interpretation of these dimensions, when comparing students, those who engage in *more* of a particular kind of reasoning (e.g., more of the same kind of classifying or comparing) in ways that are relevant to a particular problem situation, are more deeply embedded in the problem situation. Similarly, we interpret those students who engage in the kinds of classifying and/or comparing that is more relevant to the problem situation, as better accounting for the essential properties and relations of the problem situation. Thus, these are two ways students' reasoning can be categorized in terms of its productiveness.

Backward Transfer Influences on Mathematical Reasoning

Finally, our theoretical perspective on how BT influences mathematical reasoning is based on Lobato's (2012) perspective on forward transfer, which is that transfer is "the influence of a learner's prior activities on her activity in novel situations" (p. 233). BT, which is "the influence that constructing and subsequently generalizing new knowledge has on one's ways of reasoning about related mathematical concepts that one has encountered previously" (Hohensee, 2014, p. 136), aligns with Lobato's perspective on forward transfer because we too were interested in studying *all* influences. However, our definition of BT also departs from Lobato's definition of forward transfer because we were interested in influences on reasoning about previously-encountered concepts by new knowledge, rather than in the opposite direction.

A number of other mathematics education researchers have observed this phenomenon (e.g., Bagley et al., 2015; Lima & Tall, 2008; Melhuish & Fagan, 2018; Van Dooren et al., 2004). However, to our knowledge no studies have specifically examined the relationship between BT effects and productivity of mathematical reasoning. In this study, we were driven by the following research question: *In what ways are BT effects similar and/or different for students whose prior ways of reasoning are more productive (e.g., deeply embedded in a problem situation) compared to students whose prior ways of reasoning are less productive (e.g., not grasping as essential properties or relations of a problem situation)?*

Methods

Setting and Participants

Our study took place during a summer mathematics program in the Mid-Atlantic region of the United States. Participants were recruited from an organization that helps students of color enhance their college readiness. The students' grade-level ranged from 9th to 11th grade. Our study was centered around a two-week summer math program on quadratic functions. The program took place at a local university and was taught by the primary investigator. Students had two 60-minute lessons per day. This study focused on data from four students whose reasoning about linear functions represented varying levels of productiveness.

Procedure

The study began on the first day of the math program with a linear functions paper-and-pencil pre-assessment. The students had previously learned about linear functions, and as the assessment showed, came in with varying levels of productiveness in reasoning about linear functions. Students were also interviewed about their solution methods on the assessment. Next, students participated in 16 lessons about quadratic functions that focused on covariational reasoning (i.e., the math program). At the end of the program, students took a linear functions paper-and pencil post-assessment and were interviewed again about their solution methods.

Assessments. The assessments assessed the students' abilities to reason about various linear function problems. There were three main problems on the assessment each containing several sub-questions. The first problem made use of graphical representations, the second made use of tabular representations, and the third made use of pictorial representations. Two versions, A and B, of the linear functions assessment were developed. The versions varied in context and in numerical values, but not in structure or in mathematical intent. Students were randomly assigned to one version for their pre-assessment and the other version for their post-assessment.

Math program instructional pattern. The math program was designed as a two-week course on quadratic relationships. The principle investigator, a university professor who was previously a high school mathematics teacher, was the instructor for the course. The focus of the program was to develop students' abilities to reason covariationally with quadratic functions. An inquiry-oriented instructional approach was utilized and quadratic functions were represented with tables and with SimCalc dynamic software.

Data Set

Our data set consisted written responses to the pre- and post-assessments, and video/audio recordings and transcripts from semi-structured interviews.

Data Analysis

We began by reviewing the assessments and the interviews in order to identify four students, of varying levels of productiveness in reasoning about linear functions. We looked for at least one student from each of the following categories: higher-, mid- and lower-level linear function reasoners. We also looked for students who appeared to exhibit changes in ways of reasoning from pre- to post-assessment. We ended up choosing one high-level, one low-level, and two mid-level linear function reasoners.

During analysis, each member of the research team analyzed one student's data, taking a grounded theory approach (Strauss & Corbin, 1998). During open coding, each research team member went sub-question by sub-question through the written and interview responses for their student, looking for changes in ways of reasoning from pre- and post-assessment. Each new change in reasoning became a new code. When each student had been analyzed, we compared the codes and consolidated those that were similar. For each student, a second member of the research team reviewed the coded changes in ways of reasoning f to triangulate the data. During axial and selective coding, each team member identified associations between categories of changes in ways of reasoning and organized and integrated the categories into a story for each student and presented the story to the group for feedback. Finally, the team interpreted each change in reasoning in terms of Jeannotte and Kieran's (2017) mathematical reasoning processes and Greeno's (1989) dimensions of productive reasoning.

Results

In this section, we present each student's changes in ways of reasoning, starting with Rashana, the higher-level linear function reasoner, followed by Layla, the lower-level linear function reasoner, followed by Yolanda and Damien, the mid-level linear function reasoners. For each student, we state the core category and several subcategories of how their reasoning changed from pre- to post-assessment. Then, we illustrate the core category and one subcategory.

Rashana

Rashana, the highest-level linear function reasoner of the four students, changed some of her ways of reasoning linear functions from the pre- to post-assessment. There was a core category we called *improved quality of the responses*, and four subcategories we called (a) *expansion of covariational reasoning*, (b) *more quantities notice*, (c) *exploration of relationship between quantities*, and (d) *different representations used*. Each subcategory represents a dimension on which Rashana's reasoning became more productive from pre- to post-assessment.

Core category: Improved quality of responses. From pre- to post-assessment, Rashana improved the quality of several responses. Interestingly, however, on the six problems that we coded her response as having improved from pre- to post-assessment, the correctness of her answers did not change. For example on problem 3(a) of the pre-assessment, Rashana correctly solved a problem about a plant growing at a constant rate by first finding the equation $y = 1.6(x+1) + (-.2)x$. This equation was technically correct. However, Rashana indicated she was uncertain about why the $(-.2)x$ was needed, other than that the equation did not work without adding that expression. In contrast, on problem 3(a) of the post-assessment, Rashana correctly solved a similar problem by representing the data set with a table, without any uncertainties.

Subcategory: More quantities noticed. We subcategorized some changes in Rashana's ways of reasoning as *more quantities noticed*. For example, on 3(d) of the pre-assessment Rashana noticed the following quantities for a plant growing at a constant rate: the changes in the day, and changes in the height. In contrast, on problem 3(d) of the post-assessment, Rashana again noticed the changes in the day and the changes in height, but also changes in the changes in the day and the changes in the changes in height.

Applying Jeannotte and Kieran's (2017) conceptualization of mathematical reasoning to this subcategory, we interpreted the change to notice more quantities as an increase in the process of *classifying* (i.e., classifying more quantities). Also, applying Greeno's (1989) conceptualization of productivity of reasoning to this subcategory, we interpreted this a productive change in favor of becoming more deeply embedded in the problem on the post-assessment problem.

In sum, Rashana, who represented a high-level linear function reasoner, nevertheless exhibited BT changes in her ways of reasoning that considering correctness alone did not reveal.

Layla

Layla, the lowest-level linear function reasoner of the four students, also changed some of her ways of reasoning about linear functions from the pre- to post-assessment. There was a core category we called *mixed changes in quantitative reasoning*, and three subcategories we called (a) *new ways of reasoning with quantities* (b) *new ways of reasoning with changes in quantities*, and (c) *new ways of finding and reasoning about rates of change.* In contrast to Rashana, Layla's responses in several instances became less productive from pre- to post-assessment, although at times there were also more productive aspects.

Core category: Mixed changes of quantitative reasoning. From pre- to post-assessment, Layla's ways of reasoning changed on six responses. Moreover, four of the six were less correct from pre- to post-assessment, and the other two stayed at similar levels of correctness. However, we did observe some productive development in her ability to reason quantitatively. For example, on problem 1(a) of the pre-assessment, Layla *correctly* applied the slope formula to a linear graph representing gas left in a car's gas tank vs the distance the car traveled. However, her explanation lacked evidence of quantitative reasoning: "So basically, I started out by finding the total amount. So I did the slope equation for these two first and then I found out that that was the total number of gas use between point A and point C."

On problem 1(a) of the post-assessment, Layla *incorrectly* divided corresponding values of gallons used by distance driven. However, her explanation had more reasoning with quantities:

> So, I said the gas in Car 1 is decreasing as the miles driven increases. The gas in Car 1 has decreased drastically by point C. So, basically, I did the distance driven over the gallons left in the tank . . . Those were the changes. The changes in the - oh my gosh - the changes in the um, we were just talking about this! The changes in, um, I would say the changes in gallons.

We interpreted this excerpt as evidence of Layla trying to reason with several quantities, distance driven, gallons of gas in the tank and changes in the gallons. Most changes in Layla's ways of reasoning similarly reflected increased attempts at quantitative reasoning.

Subcategory: New ways of reasoning with changes in quantities. We subcategorized some changes in Layla's ways of reasoning as *new ways of reasoning with changes in quantities*. For example, on problem 2(a) of the pre-assessment, Layla used the slope formula to correctly determine that for a table displaying the additional cost for extra megabytes of data used on a cell phone plan "it increased by .75 cents, each time you used a megabyte." In this response, reasoning with the changes in quantities involved multiplicatively comparing changes in one quantity and changes in the other quantity (i.e., by dividing).

On problem 2(a) of the post-assessment, Layla found changes in additional megabytes used and changes in additional cost between rows of the table to "find the constant rate of additional, that used. But that wasn't really working for me." Thus, Layla went from multiplicatively comparing changes in quantities on the pre-assessment, to looking for additive patterns in the changes in each quantity separately. Altogether, changes in how Layla reasoned with changes in quantities were observed on five problems.

Applying Jeannotte and Kieran's (2017) conceptualization of mathematical reasoning to this subcategory, we interpreted changes in reasoning about changes in quantities as primarily a change in the process of *comparing* (i.e., going from multiplicatively comparing to additively comparing). Also, applying Greeno's (1989) conceptualization of productivity of reasoning to this subcategory, we interpreted this an unproductive change toward grasping *less* of the essential properties and relations for the post-assessment problem than the pre-assessment problem.

In sum, Layla, who represented a low-level linear function reasoner, exhibited BT changes in her ways of reasoning that were mostly not productive but did reflect increased attempts at quantitative reasoning..

Yolanda

Yolanda, one of the mid-level linear function reasoners, also changed her ways of reasoning from pre- to post-assessment. There was a core category we called *greater focus on changes in quantities*, and three subcategories we called (a) *more changes in quantities found*, (b) *more changes in quantities represented*, and (c) *changes in reasoning about changes in quantities.* Like Rashana, each subcategory represents a dimension on which Yolanda's reasoning became more productive from pre- to post-assessment.

Core category: Greater focus on changes in quantities. From pre- to post-assessment, Yolanda's reasoning changed in favor of a *greater focus on changes in quantities*. For example, on problem 3(d) of the pre-assessment, Yolanda focused only on the changes in the height for the growing plant, recording magnitudes of each change in height, and adding brackets to indicate where each change in height applied. On problem 3(d) of the post-assessment, Yolanda again focused on the plant's height, adding brackets to indicate where the changes in height applied. She also focused on the changes in days and the changes in changes in the days. We found evidence of this increased focus on changes in quantities on five problems.

Subcategory: Changes in reasoning about changes in quantities. We subcategorized some changes in Yolanda's ways of reasoning as *changes in reasoning about changes in quantities.* For example, on problem 1(b) of the pre-assessment, Yolanda compared changes in the gallons left in the tank from points D to E and from points E to F (see Figure 6), saying:

> Car 2 does not use the same gas at the same rate between D and E as it does between E and F due to the reason that D to E takes up 1.50 gallons while E to F took up only .75 gallons.

In contrast, on 1(b) of the post-assessment, Yolanda tried to iterate a difference in one quantity to go from one data point to the other:

> So one way I found out, well made me confident, was I just did the pattern again and again on the whiteboard I had. And since I just did 42 times like 42 times 9, 42 times 8 to try to get to 408 but I didn't come to that number.

Thus, Yolanda went from comparing two changes for the same quantity (i.e., between points D and E and points E and F), to iterating a difference in one quantity to go from one value of the quantity to another (i.e., iterating 42 miles to go from 42 to 408 miles). Changes in how Yolanda reasoned about changes in quantities were observed on three problems.

Applying Jeannotte and Kieran's (2017) conceptualization of mathematical reasoning to this subcategory, we interpreted changes in reasoning about changes in quantities as a change in the process of *comparing* (i.e., how Yolanda compared changes in quantities). Also, applying Greeno's (1989) conceptualization of productivity of reasoning to this subcategory, we interpreted this a productive change in favor of grasping more of the essential properties and relations for the post-assessment problem. We claim this because iterating a change in one quantity repeatedly is more consistent with a constant rate of change than comparing static changes in a particular quantity. In sum, Yolanda, who represented a mid-level linear function reasoner, exhibited productive changes in her ways from pre- to post-assessment but that, like Rashana, did not impact correctness.

Damien

Finally, Damien, one of the mid-level linear function reasoners, also changed his ways of reasoning from pre- to post-assessment. There was a core category we called *improved covariational reasoning* and three subcategories we called (a) a *change in reasoning about different quantities*, (b) *better understanding of rates of change*, and (c) *change in the stability of correct application of the slope formula*. Overall, Damien's reasoning appeared to change in favor of an increased ability to reason covariationally in a more productive manner.

Core category: Improved covariational reasoning. From pre- to post-assessment, Damien improved his ability to reason covariationally. In particular, on each of the five problems we coded as having changed responses from pre- to post-assessment, despite not all responses becoming more correct, Damien provided evidence of improved covariational reasoning. For example, on problem 1(a) of the pre-assessment, which was about the graph of the gas remaining in the tank of the car and the distance driven, Damien wrote down the correct slope formula, but incorrectly calculated the slope by dividing Δx by Δy instead of vice versa. Trying again, he subtracted Δx from Δy rather than dividing Δy by Δx. When asked what his calculation meant, Damien struggled to reason covariationally, replying, "for each, um, mile driven, 30 gallons are wasted." This incorrect response suggested he did not have a clear understanding of the meaning of slope. Understanding slope is an important aspect of reasoning covariationally.

On problem 1(a) of the post-assessment, Damien used the slope formula to correctly calculate that the slope between points A and B and between points B and C was -0.031, and correctly wrote "per mile driven 0.031 gallons of gas are used." In the interview, Damien confirmed, by interpreting the slope, that there had been somewhat of a productive change in his covariational reasoning, saying "It's negative 0.031 because that's how much is decreasing by." This response suggests Damien was reasoning more covariationally.

Subcategory: Better understanding of rates of change. We subcategorized some changes in Damien's ways of reasoning as indicating a *better understanding of rates of change*. For example, on problem 2(a) of the pre-assessment, Damien was asked to consider the cell phone data table. Damien correctly applied the slope formula but was unclear about why that worked: "I don't know how to describe it, but, um . . . when I was in slope intercept in eighth grade and I just remember doing this for every question that I would get that would be like this." In contrast, on problem 2(a) of the post-assessment, Damien correctly found and correctly interpreted the rate of change:

> I found out that the one megabyte of data costs 0.75 cents. So they said that they wanted to know how much, um, an additional 51 MB of data would cost. So I've taken 0.75 and multiply . . . Since one megabit of data is 75, well .75, I want it to multiply that by 51 times.

This excerpt suggested Damien had a better understanding of the rate of change.

Applying Jeannotte and Kieran's (2017) conceptualization of mathematical reasoning to this subcategory, we interpreted changes in reasoning in favor of better understandings of rates of change as a change in the process of *comparing* (i.e., rates of change are multiplicative comparisons between changes in one quantity and the corresponding changes for a related quantity). Also, applying Greeno's (1989) conceptualization of productivity of reasoning to this subcategory, we interpreted this a productive change in favor of better grasping the essential properties and relations of a problem situation.

In sum, Damien, who like Yolanda was a mid-level linear function reasoner, exhibited productive changes in his ways of reasoning from pre- to post-assessment. However, in contrast to Yolanda, whose reasoning changed primarily in favor of a greater focus on changes in quantities, Damien's reasoning changed primarily in favor of improved covariational reasoning.

Discussion

The results from this study can be summed up with the following five points. First, three of four students' level of correctness remained stable from pre- to post-assessment, while one student's level of correctness dropped. Second, all students, including the student whose level of correctness dropped, showed at least some productive changes in reasoning from pre to post (i.e., most BT effects were productive). Third, productiveness was impacted on both of Greeno's (1989) productiveness dimensions. Fourth, BT effects largely involved changes in quantitative reasoning and somewhat involved covariational reasoning. Fifth, the reasoning process that appeared most involved in BT was the process of comparing.

Significance. This study is significant because it provides new insights into how BT influences mathematical reasoning processes and productiveness, as well as into how the reasoning of students at different levels is influenced by BT. With respect to reasoning processes, this study is significant because it showed that particular reasoning processes (i.e., *classifying* and *comparing*) can be influenced by BT. Moreover, it showed that BT can influence the amount that reasoning processes are used (e.g., classifying more quantities) and the ways reasoning processes are used (e.g., comparing different quantities).

With respect to mathematical reasoning productiveness, this study is significant because it showed how productiveness can be influenced by BT. Although other studies have reported productive and unproductive BT effects on mathematical reasoning (e.g., Hohensee, 2014), this study was the first to show that these effects can manifest themselves on two of Greeno's (1989) dimensions of productiveness.

Finally, with respect to students who represent different reasoning levels, this study is significant because it showed that BT can influence the reasoning of students at all levels. This finding challenges our previous theory about BT (Hohensee, 2014), that BT primarily affects mid-level reasoners, and that high-level reasoners know too much and low-level reasoners too little to be influenced by BT. It is also significant that our study unpacks ways that students at different levels are influenced by BT. To our knowledge, our study is the first to do so.

Implications. We mention two implications for practice. An implication from our finding that our lower-level linear function reasoner, whose reasoning became less correct from pre to post but who also showed some new quantitative reasoning, is that perhaps it could be useful for this level of reasoner, if teachers revisited an old topic after covering the new topic. By reasoning more quantitatively, these learners may be more ready to further their thinking of the old topic.

A final implication is that emphasizing quantitative and covariational reasoning during quadratic functions instruction should be promoted. Our results suggest that this emphasis productively influences most students' ways of reasoning about linear functions.

Notes

[1] The structural dimension, which is about whether the mathematical reasoning is deductive, inductive, or abductive, was not examined.

[2] Creativity and flexibility, the other two dimensions of productiveness of reasoning, were not examined.

Jennifer A. Czocher
Texas State University
czocher.1@txstate.edu

In this paper we address the question, how do quantitative reasoning and covariational reasoning present as students build structural conceptions of real-world situations. We use data from an exploratory teaching experiment with an undergraduate STEM major to illustrate the explanatory roles quantitative reasoning and covariational reasoning play in, (a) coordinating more than two interdependent quantities, (b) conceiving of real-world situations in more than one way, (c) constructing networks of quantitative relationships, and (d) creating a mathematical expression. We make the case that looking at mathematical model construction through the lens of quantitative reasoning and covariational reasoning may provide insights into students' mathematical decisions as they structure complex real-world scenarios.

Keywords: Mathematical Modeling, Quantitative Reasoning, Covariational Reasoning

Mathematical Modeling plays a central role in supporting students' views of relevance of mathematics to the real world. Many scholars as well as curricular materials have advocated for the importance of including mathematical modeling into the mathematics curriculum because it would motivate the use of mathematics in the world outside of a classroom, for students (Blum & Niss, 1991, Zibek & Connor, 2006; CCSSI, 2010). In addition, empirical studies have also shown that incorporating mathematical modeling in the teaching of mathematics can positively impact both students' learning of mathematics and affective factors which influence students' learning such as interest, motivation, and self-efficacy (e.g., Czocher, 2017; Rasmussen & Blumenfeld, 2007; Schukajlow et al., 2012; Zbiek & Conner, 2006). Despite the field's desire to motivate the learning of mathematical modeling and its inclusion to curricula, mathematical modeling remains highly challenging for students (Stillman, Brown, & Galbraith, 2010; Jankvist & Niss, 2017; Blum, 2011; Blum & Leiss, 2007).

The challenges students experience while engaging in mathematical modeling are multifaceted. Mathematical modeling involves translating between real-world and mathematics in both directions simultaneously. This translation requires the appropriate mathematical and real-world knowledge (Blum, 2011), so that the modeler can associate the appropriate mathematics with the real-world situation. Existing research on mathematical modeling investigates students' mathematical modeling activities, informing the field about challenges students face in given content areas or real-world scenarios. These studies focus on how students simplify the real-world situation, identify important parameters and variables from the simplified situation, transform these identifications into a mathematical representation, and check the validity of the mathematical representation created against real world constraints. However, these studies have given little attention to describe a modeler's model evolution in terms of quantities and relations among those quantities.

The literature on mathematical modeling is clear that mathematical knowledge alone is insufficient for choosing viable mathematics to represent a real-world situation. The modeler, would also need an understanding of the entities present in the real-world situation, how these entities contribute to the aspects that needs to be modeled, and relations among these entities.

That is, the modeler may have to conceive the real-world situation through quantities and relations among those conceived quantities. Before the field of mathematical modeling can promote this kind of understanding among modelers, the field would first need an idea of how quantitative relations are established during model construction. Conceiving of a real-world situation through quantities and establishing relations among those quantities involves quantitative reasoning and covariational reasoning. Therefore, the purpose of this paper is to discuss how covariational reasoning and quantitative reasoning is present in the construction of mathematical models of real-world situations. We first present research that bridges mathematical modeling and quantitative reasoning, Next, we provide our theoretical orientation that was used towards the analysis of data. Next, we present four examples of how quantitative reasoning covariational reasoning is present in model construction. Finally, we discuss implications.

Mathematical Modeling and Quantitative Reasoning

Thompson (2011) claimed that "mathematical modeling is simply mathematics in the context of quantitative reasoning" (p. 52). By this Thompson means, in mathematical modeling a modeler uses mathematical notation and methods to express a relationship among quantities that were constructed by the modeler. Larson (2013) in her study with linear algebra college students explored the role of quantities and quantitative reasoning in mathematical model construction. Larsen operationalized a mathematical model as a system that consists of elements, relationship among elements, and operations that describe how these elements interact. Larsen made the case that quantities act as "elements" in students' mathematical model. Further, she stated that quantitative reasoning provides a language to describe (i) how students consider quantities that are relevant, (ii) how students express the relationship among these quantities, (iii) use these relationships to operate on these quantities, and finally (iv) how these operations would give rise to new quantities that are also "elements" of the students' model. Larsen claims that quantitative reasoning is a central mechanism in model development because *products* (derivation of new quantities by operating on identified quantities) of one stage at model development become the *objects* at the next stage.

Czocher & Hardison (2020) presented methodological approaches for understanding the quantities that modelers identify as situationally relevant in a given modeling tasks and how the conception of these quantities are manifested as observations through external inscriptions and utterances the students' make. They formulated eight observable criteria that can be used as indications that the modeler engaged in the process of quantification. Further, they defined the construct *modeling space* (Czocher & Hardison, 2019) as the set of mathematical models the modeler constructs within a given modeling task to conceptualize students' mathematical model. Collectively, contributions lead the mathematical modeling field in a new path to trace the genesis of students' quantities and to understand how the meanings students attribute to these quantities may change over time in the context of mathematical modeling. In this paper we contribute to the existing conversation that bridges mathematical modeling and quantitative reasoning. In particular, we address the following question: Given that quantitative and covariational reasoning are foundational to mathematical modeling, how do they present in students' conceiving of mathematical structure within a real-world situation?

Theoretical Orientation

We take on the cognitive perspective on mathematical modeling (Kaiser, 2017). In this perspective, mathematical modeling is considered to be the cognitive processes involved in constructing a mathematical model of real-world scenarios. We view *mathematical model* an individual constructs as an external representation of the relationship between the quantities the individual conceived as relevant to the real-world situation she is given to model. We take on Thompson's (2011) view on quantity, where quantity is a mental construction of a measurable attribute of an object. Thompson (2011) defines *quantification*, the mental construction of quantities, as "the process of conceptualizing an object and an attribute of it so that the attribute has a unit of measure, and the attribute's measure entails a proportional relationship with its unit" (p.37). *Quantitative reasoning* (QR) refers to conceiving and reasoning about quantities and the relations among the conceived quantities. A *quantitative operation* is a "mental operation by which one conceives a new quantity in relation to one or more already-conceived quantities" (Thompson, 1994, p.10). Examples of quantitative operations include combining two quantities additively or multiplicatively and comparing two quantities additively or multiplicatively. Each quantitative operation creates a relationship among the quantities operated upon with the quantitative operation and the result of operating. As Thompson (1994) noted, "Conception of complex situations are built by constructing networks of quantitative relationships" (p.11).

Carlson and colleagues (2002) define *covariational reasoning* (CR), a form of quantitative reasoning, to be "the cognitive activities involved in coordinating varying quantities while attending to the ways in which they change in relation each other" (p. 354). Carlson et al. (2002) identified five mental actions students exhibited when engaging in covariational reasoning. These five mental actions include, *coordination* of quantities, coordinating the *direction of change* of quantities, coordinating the *amounts of change* of quantities, coordinating *average rate of change* of one quantity with respect to the other quantity, and coordinating the *instantaneous rate of change* of one quantity over the interval of the domain. Similarly, Thompson and Carlson (2017) proposed six major levels of covariational reasoning. These levels are smooth continuous variation, chunky continuous variation, coordination of values, gross coordination of values, pre coordination of values, and no coordination of values. Moore et al (2020) extend the work of QR and CR by introducing the construct *abstracted quantitative structure*: "a system of quantitative relationships a person has interiorized to the extent they can operate as if it is independent of specific figurative material" (p.752, Moore et al., 2020) as means to explain the construction of a concept. Borrowing ideas from these constructs, we define a *structure for real-world situation* to be the network of quantitative relations among the quantities one constructed as relevant to model a real-world situation. By network of quantitative relations, we mean the set of quantitative relations that was created as a result of operating on conceived quantities. We call this way of understanding about the real-world situation as *a structural conception for the real-world situation.* Students' structural conception of a real-world situation will be analyzed by seeking instances of quantitative and covariational reasoning while they engage in mathematical modeling activities.

Methods

We present data from an exploratory teaching experiment (Steffe & Thompson, 2000) conducted with an undergraduate STEM major at a large university in the United States of America. We used a teaching experiment methodology because it afforded us means to build explanatory accounts of students' mathematical reasoning while they conceive of real-world situations through quantities and relations among those quantities. The overall goal of the exploratory teaching experiment was to investigate how students use quantitative reasoning and covariational reasoning to construct mathematical models of complex real-world scenarios.

Our participant Baxil, a non-native English speaker, participated in a total of ten clinical interview sessions comprising the teaching experiment. Baxil was an undergraduate mathematics major who at the time of the experiment was enrolled in a differential equations course. Each session was approximately an hour long. In this report, we draw data from three teaching sessions where Baxil engaged in the *Baker's Yeast Task*, *The population Dynamics Task*, and *The Fruit Ripening Task*. We focus on these tasks because they provide illustrations of how conceiving of quantities, operating on conceived quantities, reasoning about conceived quantities that change in tandem are present in the structuring for real-world scenarios and because they offer insights into networks of quantitative relations that can be built up into models.

> *The Baker's Yeast Task*: Baker's yeast is a type of fungus that reproduces through budding. Each cell reproduces once every 30 minutes. To grow yeast for baking bread, you have to proof it first (allow it to form a colony) in a bowl of warm water. Suppose that in a particular bowl, after six hours, the surface of the water is covered in yeast cells. Can you come up with an expression that gives the number of cells present after 6 hours if we start with n cells initially?
>
> *The Population Dynamics Task*: Suppose in a laboratory setting, we are looking at large populations of breeding stock in which species give birth to new offspring but also die after some time. Suppose that the given population has a birth rate of α% and, the death rate of the population due to natural causes is β%. If P is the population of species at any given time, write a mathematical expression for the rate at which the population changes with time.
>
> *The Fruit Ripening Task*: There is a surprising effect in nature where a tree or bush will suddenly ripen all of its fruit or vegetables, without any visible signal. If we look at an apple tree, with many apples, seemingly overnight they all go from unripe to ripe to overripe. This will begin with the first apple to ripen. Once ripe, it gives off a gas known as ethylene (C_2H_4) through its skin. When exposed to this gas, the apples near to it also ripen. Once ripe, they too produce ethylene, which continues to ripen the rest of the tree in an effect much like a wave. This feedback loop is often used in fruit production, with apples being exposed to manufactured ethylene gas to make them ripen faster. Develop a mathematical model that captures the dynamics of the ethylene gas produced.

The primary goal of the exploratory teaching experiment was to build accounts of Baxil's mental activities as he reasoned quantitatively and covariationally to construct mathematical models of the task scenarios. Since we did not have direct access to Baxil's mental activities, we created second-order accounts (Steffe & Thompson, 2000) of inferences we made from Baxil's observable activities including his language, verbal descriptions and discourse, written work, and his mathematically salient gestures. Each episode was video recorded, and his written work was digitized.

We conducted both ongoing analysis and retrospective analysis (Steffe & Thompson, 2000). The ongoing analysis involved testing and formulating hypothesis during the teaching experiment based on ways Baxil was reasoning with the quantities he conceived as relevant to model the situations. After the completion of the teaching experiment, we revisited the data to perform an in-depth retrospective analysis. Our retrospective analysis consisted of two phases: observing and describing Baxil's mathematical modeling activities and constructing and refining accounts of Baxil's use of quantitative reasoning and covariational reasoning to mathematically structure the task scenarios. The two phases of the retrospective analysis of Baxil's engagement in the three tasks, comprised of five rounds of data analysis to arrive at examples that could serve for theory-building. First, we watched the videos or subsets of videos without interruption to observe patterns in Baxil's activities. Second, we paid closed attention to Baxil's utterances, gestures, and written work and described his mathematical modeling activities for the three tasks. Third, we identified instances where Baxil was reasoning with conceived quantities (Thompson, 2011; Czocher & Hardison, 2020), operating on the conceived quantities (Thompson, 1994), and engaging in covariational reasoning (Carlson et al, 2002; Thompson and Carlson, 2016). Fourth, we constructed annotated transcripts of such instances that provided rich descriptions of Baxil's mathematical modeling activities. Finally, we constructed and refined explanatory models of Baxil's structuring of the three task scenarios.

Findings

Coordination of three interdependent quantities

In the fruit ripening task, Baxil conceived ripeness as "readiness to eat" the fruit. When the teacher-researcher (TR) asked to draw an ethylene gas production-time graph, Baxil sketched Figure 1. He reasoned "I would say increasing slowly at the beginning, then increasing faster as they are ready to eat because after you're ready to eat, it will produce more instead if it didn't ripe yet." Here, Baxil conceived of a relation among gas production and time where, as time goes on, the rate at which ethylene gas produced increases because as fruits are ripening, they produce more gas. The TR probed his rationale for why the ethelyne gas production would be faster as the fruit ripens. Baxil explained "When you're not ready to eat, it's just like a little bit amount of the gas, I would think, but after it's ready, it goes faster because everywhere have the gas". Baxil engaged in coordination of three interdependent quantities (amount of ethelyne gas produced, gas production, and time), while maintaining pairwise coordination between amount of gas vs. time and gas production vs. time, and production of gas vs. amount of gas.

Figure 1: Baxil's graph for ethylene gas produced vs time.

There can be more than one way of conceiving a real-world scenario.

In the fruit ripening task, The TR asked Baxil to construct a mathematical expression for the amount of ethylene gas produced. He presented two expressions to represent the same scenario and discussed the merits of each:

i. Amount of gas produced by the apple which is ready to eat = $e^{rate\ of\ gas*\ time}$

Olanoff, D., Johnson, K., & Spitzer, S. (2021). *Proceedings of the forty-third annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Philadelphia, PA.

ii. Amount of gas produced by the apple which is ready to eat = $rate^{time}$

In expression (i), Baxil conceived of rate of gas to be the "percentage of gas inside the apple". By that, Baxil meant the ripeness to ethylene conversion rate. Whereas in the second expression, he indicated that rate would be "the rate of gas that affect the (ripeness of the apple)". Baxil further indicated that the amount of gas, as represented in the first expression, would be increasing slowly. Whereas in the second expression, the amount of gas would increase quickly. This interpretation was evident in his following explanation:

> May I make an example like the raw apple there is a little bit of gas like I say 10% of them I guess, so it might be a 20% of them and the next there is something like that and there is a 40% then a 60% it doesn't add to 100% that's the second equation thinking and for the first equation I was thinking if it is 10% the rate won't be changing... I mean not the rate the like the amount then I say like its 10% it might be and depend on the tense it will be increasing by one-tenth, two-tenth, third-tenth, four-tenth... something like that.

Here Baxil conceived two distinct measurable attributes of the same object, apple. One was by how much the apple produces the gas and the other being by how much the gas affects the apple. As a result, he constructed two expressions that, despite being mathematically equivalent, behaved different to him in terms of quantities and quantitative operations.

Constructing a network of quantitative operations

Baxil initially conceived of the population dynamics scenario in terms of a birth rate and a death rate. Baxil was thinking about the population changing continuously along 1-second chunks of time, indicating chunky continuous variational reasoning. This was evident when he reasoned "every second have some people die and every second have people born". While he was reasoning about how the population changes, he was also coordinating the quantities population, people born, and people dead simultaneously. This was evident when he reasoned "Because if someone is born, so the population is growing as well. That means the principle is changing too. But when people die…the population, it's also going down." By principle, Baxil meant initial population during any time chunk. He also indicated that the quantities birth rate (α) and death rate (β) will be non-varying.

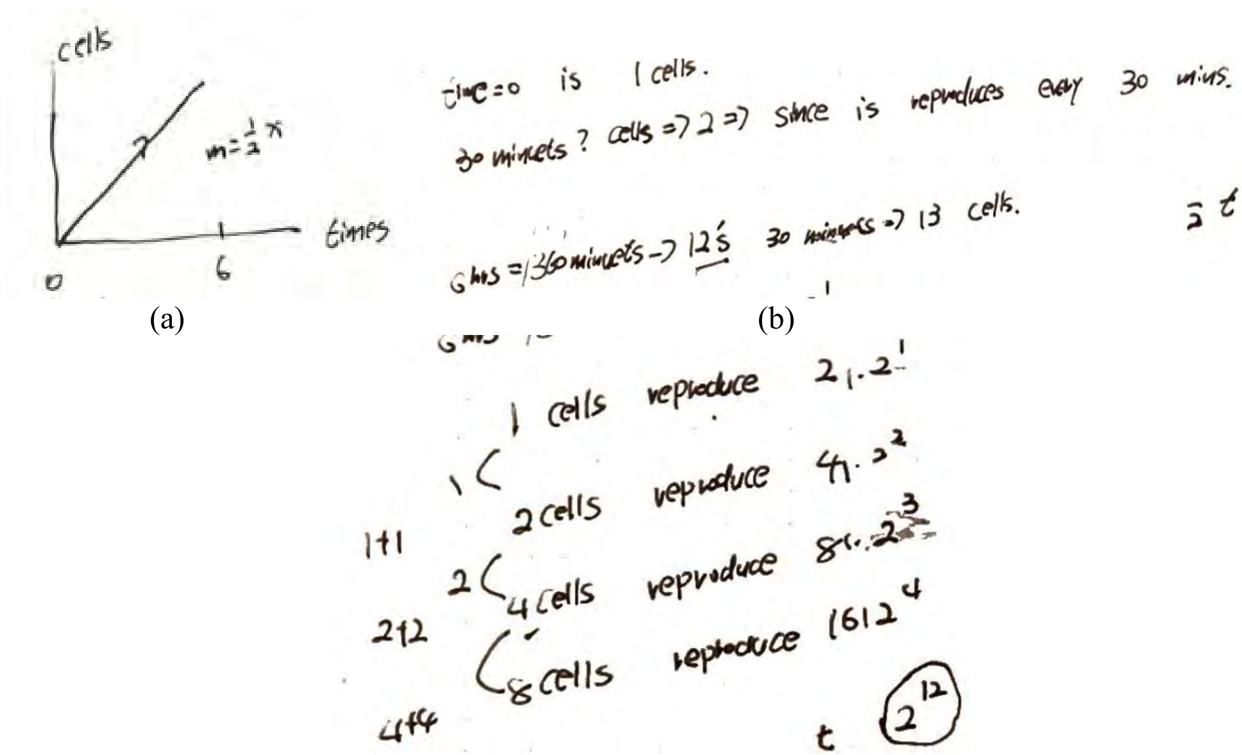
Baxil's final model for this real-world scenario was $P'(t) = P(t)\alpha - P(t)\beta,$ where $P(t)$ is the population over time, $P(t)\alpha$ is the "percentage of people to be born" and $P(t)\beta$ is the "percentage of people that will be dead." Here, he constructed the quantities "percentage of people be born" and "percentage of people be dead" via the multiplicative combination of the quantities (α, $P(t)$) and (β, $P(t)$) respectively. Baxil also gave evidence of thinking of rate of change of population as the net rate of change by meaningfully adding the percentage of people that can be born and subtracting the percentage of people that would die. By additive combination of two quantities, he created an expression for $P'(t)$, which itself is a multiplicative combination of population and time. Baxil was also aware that all of the quantities he constructed, were implicitly dependent on time itself. Therefore, Baxil expressed a network of quantitative operations as a network of arithmetic operations, by operating on the quantities $P(t), t, \alpha, \beta, \alpha P(t), \beta P(t),$ and $P'(t)$.

QR and CR supports in constructing a mathematical expression for a real-world situation.

Baxil's initial conception of the Baker's Yeast scenario was that the "number of cells" and "time" share a linear relationship. He drew the graph in Figure 2(a) reasoning as "because times is increasing…then the cells is also increasing". At this instance, there is evidence to claim that

Baxil was reasoning covariationally, where not only did he coordinate the quantities “number of cells” and “time”, but he also established a directional relationship between them.

The TR then asked him what happens to the number of cells at each 30-minute mark, to which Baxil constructed the representation in Figure 2(b). Although he reasoned that at the end of the first 30 minutes there would be 2 cells “because it reproduces every thirty minutes”, at the end of the 6 hours, he reasoned as “six hours has 360 minutes, which is 12 of thirty minutes, there for 12+1=13 cells”, attempting quantitatively coordinate how the number of cells would change at the end of every 30 minutes. The TR intervened, asking what happens to the 2 cells after at the end of an additional 30 minutes, Baxil answered that 2 cells become 4 cells “because both [cells] reproduce”. As a result, Baxil produced the representation in Figure 2(c) and deduced that at the end of six hours there would be 2^{12} cells. He then wrote down 2^{2t} as the number of cells produced after t hours of time, given that he starts with 1 cell. He attained this structure through coordinating the amounts of change of time and number of cells. Baxil established a quantitative relationship between the number of cells and time through coordinating the direction of change and amounts of change of those quantities. Through his quantitative and covariational reasoning, Baxil was able to structure the Baker’s yeast scenario.



(a) (b)

(c)

Figure 2: (a) Baxil’s graph for how number of cells varies with time from $t = 0$ to $t = 6$, (b) Baxil’s explanation for the number of cells present at the end of 6 hours and (c) Baxil’s final model when starting with 1 cell.

Conclusion and Discussion

In the fruit ripening task Baxil coordinated three interdependent quantities to reason how production of ethylene gas changes with time and brought in two distinct structures, in his perspective, to build a model for the scenario. In the Population Dynamics task, Baxil was able to establish a structure for the situation through reasoning with the quantities: rate of change of prey population, the population of prey, the birth rate, and death rate of prey, through coordinating the direction of change of the quantities population of prey and time and engaging in quantitative operation to produce other quantities. And finally, In the Baker's Yeast task, Baxil was able to establish a structure for the situation through coordinating the value and direction of change of quantities time and number of cells. Although initially his coordination of the amounts of change of these two quantities of these two wasn't representative of the situation (from the TR's perspective), through TR's intervention, he was able to conceive how the number of cells would increase every thirty minutes. Being able to internalize this quantitative coordination, helped him to create a mathematical expression that would predict the number of cells at time t. In conclusion, Baxil structured these three scenarios through conceiving quantities, operating on those conceived quantities, and through engaging in covariational reasoning to discuss how those conceived quantities are related.

A primary goal of the work in QR and CR is describing students' learning of specific mathematical ideas and their attendant reasoning processes. We make the case that QR and CR influences a modelers' structuring for real-world situations. This is because, the manner in which one choses to operate on two or more already conceived quantities, establishes a relationship among the old quantities and the newly created quantity (that resulted by operating on the old ones). This newly constructed quantitative relation influences the construction of other new quantities and operations on those quantities. This way, multiple conceptions of real-world situations can originate through engaging in quantification and covariational reasoning. Therefore, having a structural conception of the real-world situation provides students the opportunity to realize how seemingly different real-world situations can be mathematically modeled using the same mathematics and how the same situation can be modeled using different mathematics, depending on the conceived quantities and the operations performed on them. Looking at QR and CR in model construction allows researchers to pay close attention to get an understanding of the quantities the modeler conceived and the modeler's reasoning about those quantities. This understanding will provide a better picture about the mathematical decisions the modeler makes to mathematize complex situations, particularly during the simplifying and specifying phases of modeling (Zbiek & Conner, 2006; Blum, 2011) that precede the formal mathematical expression of a model. We believe attending to the quantitative and covariational rationales for these decisions will open opportunities for appropriate intervention when necessary.

STUDENT STRUGGLE DURING COLLABORATIVE PROBLEM-SOLVING IN ONE MATHEMATICS CLASSROOM

In solving mathematics problems in collaboration, students encounter a range of mathematical and social struggles. As teachers cannot possibly respond to every such struggle, they may need to respond to those with which students require most support. Yet, little is known about students' success in overcoming the various types of struggle they encounter. In this study, we examined the types of struggle students experienced as they worked together in solving a cognitively-demanding problem. We analyzed the relative proportions of the various types of struggle they encountered, their success in overcoming each type, and the resources they leveraged in doing so. While students overcame many mathematical struggles, they had less success overcoming struggles related to reaching consensus or having their questions answered by peers. We argue that teachers may merit from support in learning to attend to these latter, more social struggles.

Keywords: Problem Solving, Middle School Education, Teacher Educators

Conceptual Framework

Struggle is of crucial importance to student learning (Hiebert & Grouws, 2007; NCTM, 2014). Indeed, if students already know all they need to know to solve a problem, the problem is unlikely to result in much struggle or any new learning. Struggle is a sign that one's prior knowledge is inadequate for solving a problem and that something new needs to be learned. When struggling, students may identify gaps in their understanding, which can result in new learning if addressed (Loibl & Rummel, 2014). Research even shows that, when given the chance to struggle in solving a problem before a lesson on the underlying concepts, students develop richer understandings of these concepts than when given the lesson without first having had opportunities to struggle (Kapur, 2010).

Recent research has described the mathematical, or cognitive, struggles students encounter when solving challenging mathematics problems, as well as teachers' responses to such struggles (Warshauer, 2015). In today's mathematics classroom, however, students are likely to encounter not only individual, cognitive struggles, but also a host of other struggles related to the collaborative context in which they are increasingly being asked to solve problems (NCTM, 2014). When solving problems in collaboration with others, students encounter various social struggles, such as the struggle to have their questions answered or ideas taken up by their peers (Langer-Osuna, 2011). If not overcome, these social struggles may limit students' opportunities to engage substantively with the mathematics under consideration and to benefit in their learning as a result. In solving problems collaboratively, students may also encounter struggles that reside at the intersection of the mathematical and the social. For example, they may struggle to explain a solution strategy of theirs to a peer or to understand a peer's explanation (Franke et al., 2015). If granted the opportunity to work through such struggles, both the student providing an explanation and the student listening to one may develop important mathematical understandings (Ing et al., 2018; Webb et al., 2009).

Olanoff, D., Johnson, K., & Spitzer, S. (2021). *Proceedings of the forty-third annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Philadelphia, PA.

Prior research has examined teachers' responses to these various cognitive struggles (Warshauer, 2015), social struggles (Dunleavy, 2015), and struggles to engage with one another's mathematical thinking (Franke et al., 2015). Given the many demands on their time and attention when teaching, teachers cannot possibly attend and respond to every such struggle that students encounter. They may thus need to respond to those struggles students have the hardest time overcoming. And yet, knowledge of the relative success students have in overcoming the various types of struggle they encounter remains underspecified. Moreover, little is known about the resources students call upon when struggling or which of these resources prove most helpful in overcoming their struggles.

As a first step to addressing these perceived research needs, the current study involved an analysis of video portraying students' collaborative mathematical work. The study is part of a broader project seeking to unpack the nature of students' struggles, both productive and unproductive, in learning mathematics. We examined the types of struggle a group of four students encountered as they worked together to solve a cognitively-demanding problem (Stein et al., 1996) over the course of a lesson. We analyzed the number and proportion of each type of struggle encountered by the group as a whole and by each individual student in the group. We also examined the extent to which students overcame each type of struggle they encountered and the resources they drew upon in doing so. Specifically, we examined the following research questions:

1. What types of struggle do students in one classroom encounter when solving a cognitively-demanding mathematics problem in collaboration?
2. How successful are the students in overcoming the various types of struggle they encounter?
3. What resources do the students leverage to overcome these struggles?

Methods

Study Context

The data we examined in this study consisted of one classroom video portraying a group of four 7th-grade students solving a cognitively-demanding mathematics problem collaboratively. We chose this video from a large collection of videos collected from the same school district. This particular district is a large, metropolitan district serving students from diverse racial, linguistic, and cultural backgrounds. The district uses a task-based curriculum comprised of challenging tasks designed to be solved using multiple solution strategies and representations, and for which an existing solution strategy should not be immediately apparent (Stein et al., 1996). Moreover, the district has a strong focus on and commitment to the tenets of Complex Instruction (Cohen & Lotan, 2004). For example, in each of the district's middle-school mathematics classrooms, teachers strive to delegate authority to students. They also assign students group roles to ensure that they all contribute substantively to the group's problem-solving efforts and to disrupt a pattern whereby only the voices of high-status students are heard.

Clip Selection

We chose to analyze video as the analysis we describe below would not have been feasible to conduct in a classroom in real time. The video we analyzed for this study was chosen through an iterative process. To begin, the first author viewed 83 videos in their entirety, each about 45-minutes in length. These videos portrayed groups of 3-4 students solving challenging mathematics tasks and were collected as part of a separate research study. The videos were collected with an iPad placed on a tripod, while audio was collected using a table mic. Following data collection, audio from the table mic was synced with the video from the iPad. In viewing these 83 videos, the first author flagged videos in which students appeared to be struggling often, for sustained periods of time, and in varying ways. This struggle was evidenced by students' disagreements, questions, and expressions of confusion. Altogether, this process yielded a collection of 30 classroom videos. Next, the first author revisited notes he had written describing the audio- and video-quality of the videos, dropping those that were of inadequate quality (e.g., in which a student was out of view or students were hard to hear). This left 19 videos. Finally, he read through descriptions he had written for each of these 19 videos, choosing eight that portrayed a variety of different types and magnitudes of struggle. This collection of eight videos became the focus of a larger research program examining struggle.

Together, the two authors of the present study narrowed down this collection of videos from eight to three for detailed analysis. Our selections were guided by a set of criteria rooted in literature on productive struggle and the use of classroom video (Sherin et al., 2009; Warshauer, 2015). The criteria specified that the videos portray substantial student discussion of the mathematics, a range of resources being called upon, and various types of struggle.

In applying these criteria, we identified three videos, one that we analyzed in depth for this paper. We chose to analyze this video first as we had developed some familiarity with it through a separate analysis and believed this familiarity would facilitate the process of applying codes as part of the current analysis. This video portrays a group of four students solving the Mathematics Assessment Resource Service, or MARS, task referred to as Design a Garden (Figure 1).

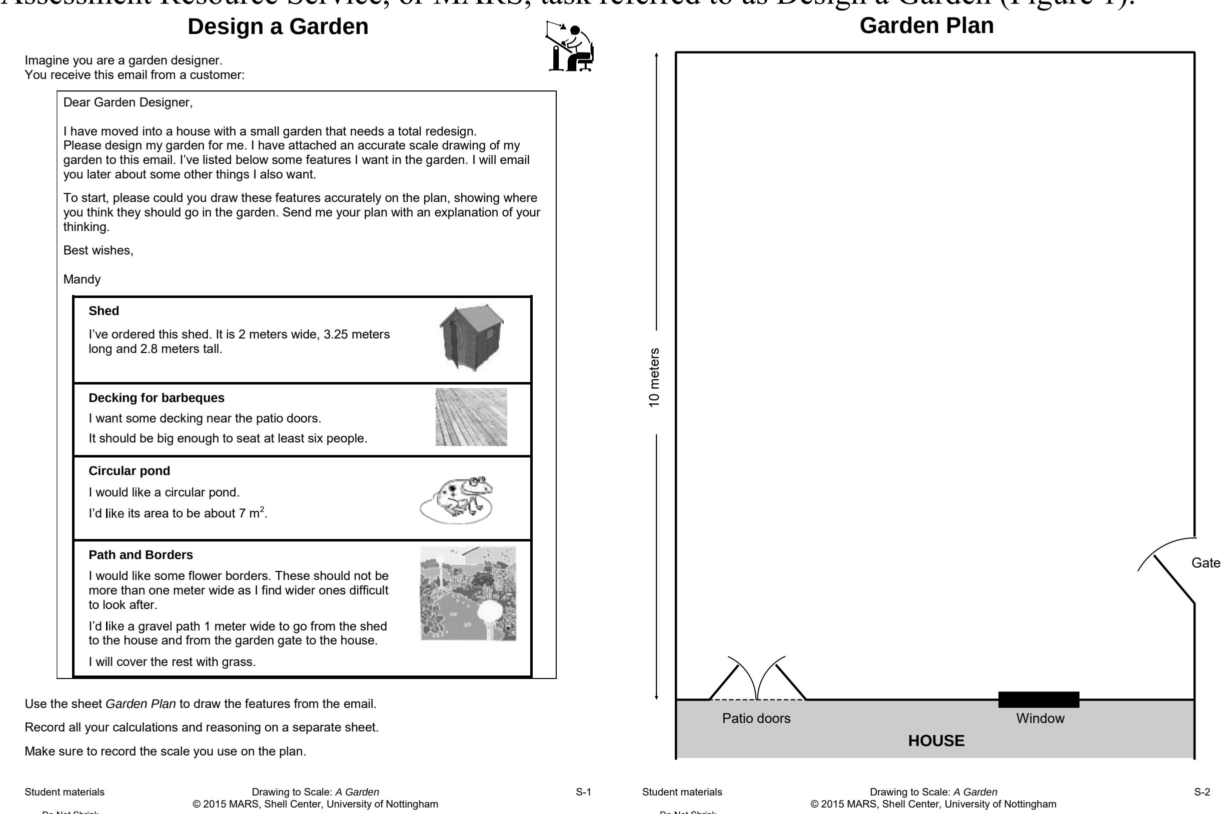

Figure 1. The Design a Garden Task

For this task, students were asked to create a scale drawing of a garden containing the following items: a) a shed, b) a deck (i.e., a patio), c) a circular pond, and d) a path and some borders. We analyzed the 45 minutes and 14 seconds of video portraying students solving this particular problem, excluding a brief warm-up activity at the start of the lesson. This 45:14 of video begins with the teacher launching the Design a Garden task, during which time she asked students to identify all the different items they might find in a garden. Students then used the remaining time to work together to design their garden, ensuring that they included each of the items the task asked them to include. Although each student had their own copy of the task in front of them, they worked together throughout, cognizant that they needed to arrive at consensus regarding where they placed the various items in their design, as well as the dimensions of each item.

Data Analysis

We began our analysis of this video by applying codes to a 12-minute sample, which represented about 10% of the total duration of all three videos we ultimately selected. We did this to refine our coding procedure and establish inter-rater agreement before then splitting off to each code part of the video. Ultimately, however, we decided that we would both code the entire video together.

We coded the video in three phases. First, the two authors independently parsed the 12-minute sample of video into segments that captured any instance in which a student in the video encountered a “roadblock,” which we defined as an impediment or obstacle that slowed students’ progress. Although it was common for more than one student to be involved in particular roadblocks, we created roadblock segments one student at-a-time, as it was too challenging to create segments for multiple students simultaneously. We did not distinguish smaller roadblocks from more substantive ones, instead creating segments for any impediment students encountered, regardless of its magnitude. Next, we met to compare our segments and to arrive at consensus regarding the start and end times for each one. This resulted in a collection of segments for each of the four students in the 12-minute video-clip. In the second phase of coding, we independently applied the following codes to each segment: 1) type of struggle encountered (cognitive, socio-cognitive, social, or materials) and 2) struggle overcome (yes or no). *Cognitive* struggles consisted of individual, mathematical struggles like the struggle to understand the problem or implement a procedure for solving it. *Socio-cognitive* struggles consisted of students struggling to explain a strategy to a peer or to reach consensus regarding a particular approach for solving the problem. *Social* struggles consisted of struggles related to group dynamics, including the struggle to have one’s questions or ideas taken up. Finally, the *materials* code captured students’ struggles to access or use a material (e.g., a ruler, a calculator). We applied a series of rules for determining whether or not a struggle was overcome, which varied somewhat depending on the type of struggle under consideration. As an example, if a student repeatedly asked a question that was not answered, we determined that this struggle, a social struggle, was not overcome. As another example, the socio-cognitive struggle to reach consensus was overcome if students ultimately reached agreement regarding the idea over which they were in disagreement. If the conversation shifted to a different topic before such agreement was reached, we determined that the struggle was not overcome. In cases were a student acknowledged understanding something mathematical that had previously puzzled them, we determined that they had overcome a cognitive roadblock. After applying these codes in this second phase of coding, we came together to compare our codes and discuss, then resolve, any disagreements. For the vast majority of segments, we had applied the same codes independently. In the third phase of coding, we independently applied codes for the various resources students asked for or were offered related to each roadblock we identified previously. These resources consisted of: a) a peer, b) the teacher, c) a tool, d) the problem itself, e) students' multiple mathematical knowledge bases or MMKBs (e.g., linguistic resources) (Turner et al., 2012), and f) notes/the board. We then met to discuss and resolve any disagreements in these code applications.

We then repeated the steps described here with the remainder of the video.

Examining the coded data. After coding all the data, we each independently examined the coded data, then wrote and shared analytic memos documenting our observations. Our analysis of the coded data was guided by several conjectures. First, we conjectured that the students would encounter different types of roadblocks and that different students would encounter these roadblock types to varying degrees. To evaluate this conjecture, we examined the relative proportions of each type of roadblock encountered by the group, as well as the relative proportions of each type of roadblock each student encountered. Second, we conjectured that students would have more success overcoming certain types of roadblocks than others. To evaluate this conjecture, we examined the proportion of each type of roadblock that students overcame. Third, we anticipated that calling upon certain resources might prove more helpful to students in overcoming the roadblocks they encountered. To evaluate this final conjecture, we identified which resources were called upon most for those roadblocks that students overcame.

Findings

Overall, students encountered 107 roadblocks in the 45:14 of video we analyzed. Of these 107 roadblocks, 30 (28.0%) were *cognitive*, 48 (44.9%) were *socio-cognitive*, 16 (15.0%) were *social*, and 13 (12.1%) were related to students accessing or using *materials*. Hence, a full 59.9% of the struggles students encountered (i.e., socio-cognitive and social) were related to the collaborative nature of their work.

In terms of the number of roadblocks each individual student encountered, and for which we had evidence, Student 1 encountered 25, Student 2 encountered 32, Student 3 encountered 13, and Student 4 encountered 37. Table 1 portrays the number and proportion of each of the four types of roadblock each individual student encountered. The proportion of cognitive roadblocks each student encountered was fairly similar, although for Student 3, the total *number* of cognitive roadblocks he encountered was smaller than was the case for the other students. Moreover, while Students 1, 2, and 4 encountered a similar number and proportion of socio-cognitive roadblocks, Student 3 grappled with far fewer socio-cognitive roadblocks. Lastly, the number of social roadblocks Student 3 encountered was the same as the number encountered by Students 1, 2, and 4 combined.

Table 1: Number & Proportion of Each Type of Roadblock Encountered by Each Student

	Student 1	Student 2	Student 3	Student 4
Cognitive	10 (40.0%)	8 (25.0%)	3 (23.0%)	9 (24.3%)
Socio-cognitive	13 (52.0%)	17 (53.1%)	1 (7.7%)	17 (45.9%)
Social	1 (4.0%)	3 (9.4%)	8 (61.5%)	4 (10.8%)
Materials	1 (4.0%)	4 (12.5%)	1 (7.7%)	7 (18.9%)
Total	25	32	13	37

Note. Percentages show the proportion of the total number of roadblocks each student encountered for each roadblock type (e.g., 10/25 or 40% of Student 1's roadblocks were cognitive).

With regard to students' success in overcoming roadblocks, we found that students overcame more cognitive and materials roadblocks than either socio-cognitive or social roadblocks (Table 2).

Table 2: Number & Proportion of Each Type of Roadblock Overcome or Not Overcome

Type of Roadblock	Overcome	Not Overcome	Total
Cognitive	15 (50.0%)	15 (50.0%)	30
Socio-cognitive	2 (4.2%)	46 (95.8%)	48
Social	4 (25.0%)	12 (75.0%)	16
Materials	11 (84.6%)	2 (15.4%)	13

Specifically, students overcame half of the *cognitive* roadblocks they encountered and a full 84.6% of the *materials* roadblocks they encountered. This latter number is likely as high as it is in part because it includes certain materials roadblocks that were fairly easy to overcome (e.g., accessing an eraser). One such roadblock, however, involved students figuring out how to use a SAFE-T compass to draw the circular pond in their garden design. This roadblock was, in our view, harder to overcome than the roadblock of finding an eraser, yet was ultimately overcome. Unlike most of the materials roadblocks, the cognitive roadblocks were more challenging. One such roadblock involved Student 2 trying to find the radius of a circle with the area being given, something the student ultimately overcame with support from Student 1, who located a website that calculated the circle's radius when the area was entered. Regarding the *socio-cognitive* roadblocks, the vast majority of these involved three students – Students 1, 2, and 4 – trying to reach consensus regarding the inclusion, dimensions, and placement of various objects in the garden. For one such roadblock, Student 1 suggested placing the patio in a particular location in the garden, which Student 4 disagreed with. To convince Student 1 to place the patio in a different location, Student 4 pointed out that the existing garden plan included a pair of patio doors, and that the patio should be placed by these doors, something Student 1 immediately agreed with. This was one of only two socio-cognitive roadblocks that was overcome. Another such struggle regarded whether or not to add stairs to the patio. While Student 4 wanted to include stairs, the other students, especially Students 1 and 2, disagreed, pointing out that the problem did not say to include stairs and that they had seen patios before that did not have stairs. This particular struggle re-surfaced multiple times, yet consensus was never reached and the struggle remained unresolved. In terms of *social* roadblocks, students overcame one-fourth of this type of roadblock. However, further analysis revealed that Student 3, who encountered most of the social roadblocks, overcame only one-eighth of these. For Student 3, the social roadblock repeatedly encountered involved having their ideas heard and questions responded to.

Lastly, we examined the types of resources students called upon both when successful in overcoming a roadblock and when unsuccessful in doing so. As shown in Table 3, when students overcame a roadblock, the resource they most often called upon was one another (i.e., peers). At times, a peer's support was asked for, while at other times, a peer offered support that was unsolicited. As an example, for the socio-cognitive struggle mentioned above, in which Students 1 and 4 sought to reach consensus regarding the placement of the patio, Student 4 pointed out the patio doors to Student 1. In this example, Student 1 had asked Student 4 if they agreed with Student 1's idea, and as such, the peer resource was asked for. Although the peer resource was often called upon when roadblocks were overcome, it was also called upon often when students did not manage to overcome a roadblock.

Table 3: Resources Leveraged in Overcoming Each Roadblock

	Peer	Teacher	Tool	Problem	MMKBs	Notes/board
Overcome	18 (56.3%)	2 (6.3%)	15 (46.9%)	3 (9.4%)	0 (0.0%)	3 (9.4%)
Not overcome	63 (84.0%)	9 (12.0%)	11 (14.7%)	23 (30.7%)	9 (12.0%)	3 (4.0%)

Note. There were 32 roadblocks overcome and 75 not overcome; totals here exceed these numbers, as multiple resources were called upon for certain roadblocks. Percentages represent the proportion of roadblocks overcome, or not overcome, when a given resource was called upon (e.g., for 18/32 or 56.3% of the roadblocks overcome, students called upon the peer resource).

Noteworthy is that one resource – students' multiple mathematical knowledge bases (MMKBs) – was called upon only when students were engaged in a disagreement and striving to reach consensus. As an example, when discussing whether or not to add stairs to the patio, Student 2 referenced knowledge of their home patio, specifically, that this patio had no stairs and was so low from the ground that stairs were not needed. Lastly, we think it is worth noting that, for the 32 roadblocks students overcame, the teacher was accessed as a resource only twice.

Discussion

In this study, we examined three research questions: 1) What types of struggle do students in one classroom encounter when solving a cognitively-demanding mathematics problem in collaboration? 2) How successful are the students in overcoming the various types of struggle they encounter? 3) What resources do the students leverage to overcome these struggles? We anticipated that students would encounter a variety of different types of struggle, experience greater success in overcoming certain types of struggle, and call upon certain resources more than others when striving to overcome their struggles.

We found that the majority of the struggles, or "roadblocks," students encountered were related to the collaborative context in which they solved the Design a Garden problem. Specifically, 59.9% of their struggles were either socio-cognitive or social in nature. This suggests that, if teachers are asked to train their attention primarily on students' cognitive (i.e., individual, mathematical) struggles, as prior work has sought to do (Warshauer et al., 2021), teachers may miss a significant part of the struggle picture. These findings also suggest that teacher educators may find it beneficial to support teachers in attending to a greater range of different types of struggle that students encounter.

This seems particularly important given the potential association between social, socio-cognitive, and cognitive struggles. Of the roadblocks that Student 3 encountered, 61.5% were social in nature. Moreover, this student overcame only one of the eight social struggles they encountered. Unlike Students 1, 2, and 4, few of Student 3's struggles were mathematical in nature. While the majority of the roadblocks Students 1, 2, and 4 grappled with were cognitive or socio-cognitive, this was not the case for Student 3. This suggests that, unless a student overcomes the social struggles they encounter during collaborative problem-solving, they may lack opportunities to grapple with the mathematical struggles that seem likely to result in them arriving at important mathematical insights (Webb, 1991). Given that so few of Student 3's social struggles were overcome, it may be important for teachers to attend and respond to (Jacobs et al., 2010) social struggles like a student struggling to have their questions heard and ideas taken up, perhaps more so than the other types of struggle we describe here. Existing research provides guidance in this regard, describing practices (e.g., Shuffle Quizzes) teachers may enact to ensure all students are included in a group's mathematical conversations (Dunleavy, 2015).

Teachers may also wish to attend and respond to students' socio-cognitive struggles given how few of the struggles of this type students overcame. Prior work provides guidance regarding the sorts of moves teachers might make to help students engage with each other's strategies (Franke et al., 2015). Why so few socio-cognitive roadblocks were ultimately overcome is not immediately apparent. However, we think this may be related to the particular nature of the socio-cognitive roadblock with which these students engaged most: deciding whether or not to include stairs in the garden design. Although this was related to the problem, it was less mathematical than, say, the struggle to reach consensus regarding the solution to a problem, something that would likely be less open to debate. Moreover, we imagine that a discussion of the solution to a problem may do more to merit students' mathematical understandings than a discussion of whether or not to include stairs in the design of a garden. As such, some socio-cognitive roadblocks appear more worthy of students' time than others. Finally, we find it noteworthy that, despite referencing the problem itself and calling upon their out-of-school knowledge, students did not overcome many of their socio-cognitive struggles related to reaching consensus. This suggests that such roadblocks may be difficult to overcome even if students call upon the sorts of resources teachers might hope that they call upon.

Of the various types of roadblocks students encountered, they had most success overcoming cognitive and materials roadblocks. Indeed, students overcame half of their cognitive roadblocks, often with the support of their peers and rarely with the support of the teacher. In our view, this suggests that, rather than intervening right away when students appear to be grappling with a mathematical struggle, it may be best to leave the students to continue grappling, as there is a good chance that they will overcome the struggle on their own, without the teacher's support.

Limitations and Future Directions

The purpose of this analysis was to make visible the complexity of students' struggles in the course of one lesson. The patterns discernable in this video, however, cannot broadly predict what students' struggles may look like in other contexts. For instance, in the classroom observed in this video, like many others in this district, norms appeared to have been established whereby students understood they were to rely on each other for support. This may explain, in part, the degree to which students turned to each other as a resource and suggests that students in classrooms where such norms are not yet present may call upon their peers with lesser frequency.

Additionally, while certain resources (e.g., students' multiple mathematical knowledge bases) did not appear to be called upon much when students overcame a particular roadblock, we do not believe this suggests that these resources are not helpful with regards to overcoming struggle. It is possible that such resources would prove more helpful with problems involving contexts other than designing a garden. We think this is an area worthy of further examination.

Lastly, there are some limitations to our coding procedure. For instance, when students ultimately reached agreement, we determined that a socio-cognitive roadblock to reach consensus had been overcome. However, such agreement could have been reached as a result of one student leveraging their status or overpowering a peer. It is important to distinguish such instances from instances when agreement is reached as a result of a more equitable exchange, yet our coding procedure does not capture such distinctions. Future work could examine the role of students' status, power, and positioning in overcoming struggles like the struggle to reach consensus.

ENACTED TASK CHARACTERISTICS: SETTING AN INFRASTRUCTURE FOR STUDENTS' QUANTITATIVE REASONING

Syracuse University
waraja@syr.edu

In this study, we explored enacted task characteristics (ETCs) that supported students' quantitative reasoning (QR). We employed a design-based methodology; we conducted a teaching experiment with eight secondary school students. Through ongoing and retrospective analyses, we identified ETCs which supported students' quantitative reasoning. The ETCs can set the infrastructure for students' QR when students are: (a) identifying changing attributes of the tasks or situations, (b) coordinating the change among quantities, and (c) making generalizations about quantitative relationships. ETCs play an important role in development of students' meaningful understanding when tasks are designed with focus on quantitative reasoning and representational fluency.

Keywords: Enacted Task Characteristics, Quadratic Functions, Representational Fluency, Functional Thinking, Quantitative Reasoning

Rational and Research Aim

This research aims to identify sets of enacted task characteristics that support students' co-development of representational fluency and functional thinking in learning about quadratic functions within a quantitative context. Historically, quadratic functions have been identified as one function family students develop less sophisticated reasoning. Scholars reported that students often develop an unsophisticated understanding of quadratic functions, such as (a) conceiving a graph as an object (a pictorial entailment) (Ellis & Grinstead, 2008; Zaslavsky, 1997); (b) only articulating the parameters of quadratic functions with an unsophisticated understanding (Ellis & Grinstead, 2008; Even, 1998); (c) providing inappropriate generalization (Ellis & Grinstead, 2008); (d) conceiving of quadratic growth as exponential (Altindis & Fonger, 2018; Altindis & Fonger; 2019; Fonger & Altindis, 2019); and (e) depending heavily on algebraic representations, which limits the development of a robust understanding of quadratic functions (Ellis & Grinstead, 2008).

Developing greater sophisticated reasoning in learning about quadratic functions requires co-development of representational fluency and functional thinking. *Representational fluency* (RF) is defined as "the ability to create, interpret, translate between, and connect multiple representations—is a key to a meaningful understanding of mathematics" (Fonger, 2019, p. 1). *Functional thinking* (FT) is a creative thinking style about functions, creating patterns, and generalizing the functional relationships within concrete representations of functions (Blanton & Kaput, 2011; Stephens et al., 2017). In this study, FT included two types of reasoning about functions: correspondence and covariational reasoning. *Correspondence reasoning* is understanding the relationship between the x and y values by looking at the x and the y as corresponding dependent and independent values or quantities (Confrey & Smith, 1991; 1994; 1995). According to Thompson and his colleagues, covariational reasoning is being able to think about "two quantities' values varying" and the two quantities "varying simultaneously" (Thompson & Carlson, 2017, p. 425).

Although we learn about the meaningful understanding grounds within the co-development of RF and FT from the literature (Even, 1998, Altindis & Fonger, 2019), we are still left with an inquiry on what type of enacted task characteristics may support the co-development of RF and FT. This study is guided by the research question: How can secondary school students be supported to develop a sophisticated understanding of quadratic functions?

Theoretical Framework and Background Literature

We networked the theory of quantitative reasoning (QR) (Thompson, 1994) with a theory of representations (Kaput, 1987a; 1987b) to support students' sophisticated understanding of quadratic functions. Quantitative reasoning sets a foundation for students' algebraic and covariational reasoning. Thompson's quantitative reasoning theory is based on Piaget's work on the mental images that learners create or *mental constructions* (Thompson, 1994). The creation of mental constructions is a demanding process for students to conceptualize quantities, quantification, and relationships among quantities (Thompson, 2011). According to Piaget (1967), *images* are conceptualizations that people must create, not something that already exists in their understanding of functions or the world. Piaget (1967) theorizes that a given subject's mental operation of a function and their mental image are connected and that the subject makes sense of an object by interacting with it. Following this logic, students might form an image of a function through reasoning about quantities that covary (Thompson, 1994). According to Thompson, when students try to grasp the concept of functions as equations that vary, they often focus on one variable as the source of the variation, usually the dependent variable. According to Thompson (1994), students' ability to build an image of changing quantities involves several layers: first, perceiving a change in one quantity; second, shifting into conceiving the two quantities as coordinated; and, finally, constructing an image of the two changing quantities as they covary simultaneously. These categories are based on Piaget's constructivist theory of learning.

Representations have been a focus of the mathematics education research community for decades. Scholars have explored students' understanding of mathematics regarding their representational activity, particularly their translations between and among representations—creating, interpreting, and transforming representations (e.g., Adu-Gyamfi & Bosse, 2014; Janvier, 1987a;1987b). In general, the relationship between mathematics and representations is understood as cause and effect—as long as teaching and learning mathematics exists, representations and their role will exist within it. In this study, we will focus on external (concrete) representations. Throughout this study, the word representation refers to the concrete representations of functions: graphs, tables, symbolic equations, and diagrams.

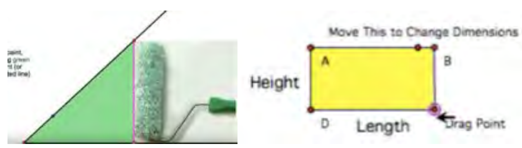
In the current study, we intend to network the theory of QR and the theory of representations to support students' sophisticated understanding of quadratic functions. We set the design principles and instructional supports, by the affordances of QR and representations, as follows: (a) creating opportunities for students to construct mental images of covarying quantities; (b) getting students to focus on quantitative operations rather than numerical operations; (c) emphasizing the role of concrete representations in quantitative processes; (d) grounding students' RF within the meaning of quantities; and (e) getting students to present the models of quantities in their minds via concrete representations.

Methodology

In the present study, we employed a design-based research methodology (Cobb et al., 2017). We conducted a teaching experiment with eight Turkish American middle and high school students in the 8^{th}, 9^{th}, and 10^{th} grades from urban and suburban school districts. The teaching experiment consisted of eight instructional lessons for two weeks lasting 45 to 60 minutes. We networked theories of quantitative reasoning (Thompson, 1994; 2011) and representations (Kaput, 1987a;1987b; Dreyfus, 2002) in designing a well-crafted learning ecology framework: enacted task characteristics, small and whole group dynamics, and teacher' pedagogical moves. In this research report, we will be focusing on enacted task characteristics. The data sources are enhanced transcription of small and whole group interactions. We are both the teacher researcher (TR) in this teaching experiment.

Tasks

In the present study, we used two tasks: the paint roller task and the growing rectangle task (see Figure 1). Both these tasks were created by Amy Ellis and her colleagues (2011; 2015). The context of these tasks may help students construct a much more profound understanding of quadratic functions as "a conception of two quantities varying simultaneously" (Thompson & Carlson, 2017, p. 444). With these tasks, students may notice attributes of the situation, such as seeing the paint roller's length and the size of the area being painted. Students may conceive of the triangle's height increasing and note that the area is also growing continually. These tasks include dynamic situations, diagrams, and videos that can help students see how a change in length affects a change in the area using color-coding that might help make the change in variables more visible to students (Johnson et al., 2018).



(a) (b)

Figure 1: (a) The Paint Roller Task (b) Growing Rectangle

Analyses

We used Cobb and Whitenack's (1996) techniques, which drew from Corbin and Strauss's (2008) constant comparison method. In the initial analysis, using phase one, we identified regularities in participants' interactions in small- and whole-group settings by creating enhanced transcriptions, structured and extended memos, and researcher journals. In the episode-by-episode analysis, we created the initial coding schema by coding the enhanced transcriptions of day 1 to day 8 using phase two. Then we re-coded to refute or agree with the codes or form the top-level codes—an emergent coding schema—using phase three. We then formed a developed coding schema—a learning-ecology framework—using phase four. In the analysis of analyses, we coded using the predetermined analytical frameworks of RF and FT—using phase five. Then we identified shifts in students' understanding of quadratic functions concerning the supports students received during the teaching experiment and verified the learning-ecology framework by coding 25% of the data using phase six.

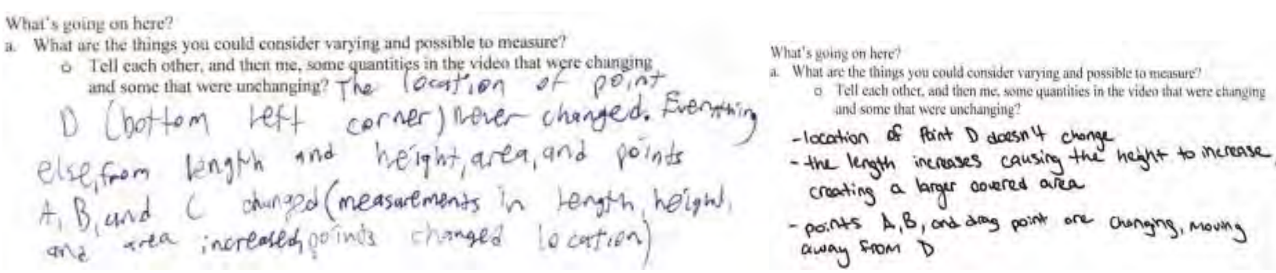
Result

Enacted Task Characteristics

We define ETCs as the instances in which students are given opportunities to articulate, talk about, answer, and discuss quantitative relationships within tables, graphs, and symbolic equations during small- and whole-group interactions (King, 2011; Stein et al., 2007). In other words, ETCs are statements and questions about a problem or a set of problems that encourage students to articulate, talk about, discuss, and create representations to present quantitative relationships. ETCs are a form of instructional support; the characteristics cluster around promoting students' QR and RF. ETCs can set the infrastructure for students' QR when students are: (a) identifying changing attributes of the tasks or situations, (b) coordinating the change among quantities, and (c) making generalizations about quantitative relationships.

Identifying changing attributes of tasks. One of the enacted task characteristics is asking students to identify attributes of a situation or their tasks—identifying relevant quantities and units to measure the quantities. Students were asked or prompted to identify quantities by looking at the task's attributes and identifying relevant quantities. After tracing appropriate quantities within the task context, they were prompted to think about a unit to measure the quantities.

Asli and Yener watched a video in the following vignette —featuring a growing rectangle being sketched via dynamic geometry software. Student handouts were structured so that students were asked to think and talk to each other about varying quantities and possible ways to measure those quantities. The task was structured to ask students to identify varying quantities; for example, the question in Figure 2: "What are the things you could consider varying and possible to measure?"



(a) (b)

Figure 2: (a) Yener's and(b) Asli's Varying Quantities of the Growing Rectangle

See the vignette below, which is the conversation students had in responding to the question on the task: "What are the things you could consider varying and possible to measure?"

6 Asli: Location of point D does not change.
7 Yener: Yeah. [Figure 2 (a) shows Yener's written answer: The location of point D (bottom left corner) never changed. Everything else, from the length and the height, area and the points A, B, and C changed (measurements in length, height, and area increased, points changed location)]
8 Researcher: Can you talk to each other?
9 Asli: We just wrote down when we talked about before we got the paper. [Figure 2 (b).]

Asli and Yener identified the rectangle's corner; D (D is a point on the rectangle) was not changing (line 6–7). Asli referred to it as point D's location; Yener stated that D is at the "bottom left corner," not changing (Figure 2). They agreed that everything else is changing on the task. Asli noticed that "the length increases causing the height to increase, creating a larger covered area" (see Figure 2 (b)). Asli also recognized that the corners of the rectangle are changing, so she wrote, "Points A, B, and drag points are changing, moving away from D." Yener agreed with Asli that A, B, and C changed. Length, height, and area changed as well. Yener recognized that the change in height, length, and area increases when the locations of A, B, and C (corners of the rectangle) change (line 7). Hence, we concluded that creating a foundation for students' QR might involve getting students to determine what is changing or varying in a dynamic task context. The tasks' structure, along with necessary tools, supports students in identifying varying relevant quantities. Students begin to recognize constant and variable quantities and how to measure them. This is evidence to suggest that enacted task characteristics should include questions or prompts that direct students' attention toward identifying relevant varying quantities on a task and noticing that the quantities are changing together.

Coordinating change among quantities. Another ETC is the coordination of change among quantities: probing, asking, or reinforcing students to coordinate changes among quantities. The tasks were structured to ask students how a change in one quantity affects the change in another in order to get students to coordinate the change between quantities. For example, one of the ETCs asks students: "How does the change in height affect change in area?" In the following vignette, Asli and Yener investigated the relationship between the height, length, and area of the growing rectangle task.

10 Yener: How does change in height is affect the change in area? If the height changes, the length changes.
11 Asli: The change in height increases the area covered. Because it contributes to the formula to get the area.
12 Yener: When the height changes, the area changes. Here is the area changes too.
13 Researcher: Can you be more specific? About how the height changes, the length changes. This also be an area.
14 Asli: When the length is increasing, the heights increase.
15 Yener: Increase Uhm. I think they might increase by the same amount. Yeah, they probably started over different, and then they increased amount each time the height and length.
16 Yener: Oh, I found this when height changes by 2, length changes by 3. That means that is constant.
17 Asli: Okay. So, what I wrote is the change in height increases the area covered because it contributes to the formula necessary to calculate the area [Figure 3 (a)].
18 Yener: Mine is same thing with height is affecting the change. [Figure 3 (b); he wrote: "The change in height is affecting the change in area by contributing to the formula for area therefore affecting the area."]

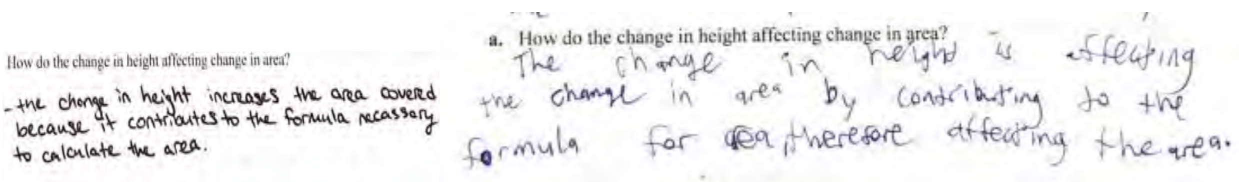


Figure 3: (a) Asli and Yener's (b) Response to "How Do the Change in Height Affecting Change in Area?

For this type of ETC, students are asked to see how the change in one quantity affects the change in another quantity (Figure 3). These questions (e.g., how does change in height affect the change in area?) form a foundation upon which students can coordinate change in quantities. For instance, Yener read the question (line 10): "How does change in height is affect the change in area?" Then he coordinated height with the length such that if the height changes (line 12), the length changes. Asli built on Yener's reasoning by stating (line 11), "The change in height increases the area covered."

Yener and Asli engaged in the task jointly; Yener agreed with Asli's statement, which encouraged Asli to justify her statement (line 11). She said, "Because it contributes to the formula to get the area." Asli's justification is about the corresponding reasoning. Yener said: "Increase, Uhmm. I think they might increase by the same amount, Yeah, they probably started over different, and then they increased amount each time the height and length." Yener noticed that the growing rectangle's height and length started with a different amount that changed in magnitude or amount each time (line 15). Then Yener said: "Oh, I found this when height changes by 2, length changes by 3. That means that is constant." Asli read her written responses: "Okay. So, what I wrote is the change in height increases the area covered because it contributes to the formula necessary to calculate the area" (line 17).

In responding to the task characteristics, students not only respond to questions on the tasks, but they also attempt to justify their responses. As we saw from Asli, she read her answer and even explained it (line 17). Furthermore, Yener read his response by comparing and contrasting his answer for the same question with Asli's (line 18).

Observing the results of this student exchange, we can infer that this student's ability to reason about relevant quantities and coordinate changes in quantities develops when prompted to consider how a change in one quantity affected change in another quantity. In other words, asking students about how a change in one quantity may affect the change in another can be an effective way to support healthy peer deliberation and the development of more advanced reasoning.

Generalization. Lastly, ETC involved structuring tasks to ask students to generalize the relationship between quantities. In terms of this study, a generalization is a form of support that pushes students to think about a pattern representing the relationship between quantities (e.g., the length of the paint-roller and its area). With ETC, students were asked to answer the same focus questions[1] in small- and whole-group settings in their handouts and had individual writing time for answering the same problem in their journal. The below vignette is taken from a whole-group interaction when students explored the relationship between the paint roller's length and the area covered by the paint roller. ETCs were structured with a focus question to allow the students to look for a pattern about the quantitative relationships.

And in the vignette below, the students were exploring the focus question: "What is the relationship between the length of the paint roller and the amount of the area being covered?"

The focus question is designed to prompt students to coordinate a change in the paint roller's length and a change in the area it is covered. In other words, the question itself states that there is a relationship between the length of the paint roller and the area covered, which pushes students to generalize about the relationship.

Consider the vignette below:

31 Researcher: So, we will present the focus question ["What is the relationship between the length of the paint roller and the amount of the area being covered?"]. I will ask this group to present first. Yener. Ready.

32 Yener: I did not finish everything. But I have my answer.

33 Researcher: Okay. So, when someone is presenting, we want to ask questions, and we want to compare their thinking with ours—what they have on there. All right?

34 Yener: Wait. So, I just answer the focus question?

35 Researcher: Okay. Yeah. We are just answering the focus questions. But we are providing some evidence for our thinking.

36 Asli: Do you want to start first?

37 Yener: Okay, I'll do it first.

38 Yener: So, the focus question is, what's the relation between the length of the paint roller and the amount of area covered? And my answer is that every time the length increases by one centimeter, the amount the area changes by or the change in the change of area, it increases by 1 centimeter.

The focus Question: What is the relationship between the length of the paint roller and amount of the area covered?

Figure 4: A Focus Question for the Paint Roller Task

As we see with the above vignette, the TR stated that as a classroom community, students were trying to answer the focus question, which was about generalizing the relationship between quantities (line 31). Subsequently, the student's attention was directed to the relationship between the growing triangles' length and area (line 34). The paint roller task creates a growing triangle; the students' attention is directed to how the growing area is related to its length. As we see, the TR asked Asli and Yener if they could present, and when they agreed to present, she restated that as a community, they were trying to answer the focus question (line 31–33). Yener confirms that they were just answering the focus question by saying, "Wait. So, I just answer the focused question" (line 34). The TR oriented Yener toward answering the focus question and providing evidence to the claim they made in answering the focus question (line 33). Yener read the question (Figure 4): "What is the relationship between the length of the paint roller and amount of the area being covered?" and answered it by saying, "And my answer is that every time the length increases by one centimeter, the amount the area changes by or the change in the change of area, it increases by 1 centimeter" (line 38).

We concluded that having students answer the same focus questions about covarying quantities in social (small- and whole-group settings) and individual contexts (journals and individual handouts during writing time) might provide students with opportunities to articulate their thinking a more sophisticated understanding of their reasoning.

To use this ETC, the students' handouts and journals center on a focus question. For example, "What is the relationship between the length of the paint roller and the amount of the area being covered?" Students' handouts are designed to aid students in answering the focus question. Additionally, the TR's prompts in whole- and small-group settings, along with students' journals, center on answering the same focus questions. ETCs are a form of support in small- and whole-group settings where students are encouraged to generalize quantitative relationships.

In this example, we see that ETCs ask students to generalize the relationship by getting students to answer the focus question in small- and whole-group settings centered around identifying a pattern between quantities. Thus, ETCs are pushing students to generalize a relationship between quantities. The study suggested that enacted task characteristics that help support students' learning can include setting a focus question about quantitative relationships, which provides opportunities for students to generalize the quantitative relationships. Setting a focus question (see Figure 4) that asks students to explore the relationship among quantities is a form of support that may reinforce advanced reasoning about quantitative relationships. The findings suggest that the focus question provides students opportunities to articulate quantitative relationships in individual, small, and whole-group settings. Students benefited from the focus questions about quantitative relationships because students could answer the questions on their own, then discuss the same quantitative relationship in small- and whole-group settings where everyone articulated their thinking about the situation.

Discussion and Conclusion

We analyzed ETCs in the context of setting infrastructure for students' QR. Enacted task characteristics are purposefully designed elements that contribute to students' meaningful understanding of quadratic functions. Such characteristics allow students to talk, articulate and discuss quantitatively rich tasks while learning about quadratic functions. This study's findings parallel prior literature that posits that enacted tasks' design characteristics are a form of instructional support in learning and teaching about mathematics (King et al., 2011; Stein et al., 2007). In particular, the findings indicated that enacted task characteristics could effectively support student learning by setting infrastructure for students' QR. Thus, the present study's significance is in showing that the task characteristics should be designed with an emphasis on QR and RF and that these kinds of task characteristics can support students in co-developing RF and FT.

The findings showed that enacted task characteristics supported students' learning when ETCs enabled students to notice changing quantities and identify these quantities' attributes when learning about quadratic functions. The task characteristics made quantities and quantitative relationships visible to students. They provided opportunities for students to measure the magnitude of the quantities in the tasks, which effectively aligns with the prior research (e.g., Johnson et al., 2018). As the findings corroborate previous research on making quantities and their relationships visible to students, they further the literature by showing how task characteristics should be emphasized when focusing on RF and FT. Specifically, we found three salient task characteristics that enabled students to form foundations for QR. These characteristics include, typically, stating, probing, or asking students about (a) identifying changing attributes of the tasks, (b) coordinating change among quantities, and (c) generalizing the quantitative relationships.

First, we found that task design characteristics that direct students' attention to covarying quantities support students' meaningful understanding. Furthermore, such features support students' development of robust quantitative reasoning. Second, the current findings also focus on purposefully designing tasks to allow students to coordinate the change in one quantity with the change in another quantity. Lastly, the present results demonstrated that creating tasks with features, such as focus questions, that allow students to explore quantitative relationships is an effective form of support for students that further helps them form generalizations about quantitative relationships. While prior literature focused on making quantities visible to students (e.g., Johnson et al., 2018), this study builds on previous literature by suggesting that designing tasks with prompts, statements, or questions that redirect students' attention towards recognizing coordination among quantities can provide effective support for students' meaningful learning. This study also suggests that designing tasks with focus questions that require students to articulate or seek a generalized pattern about a quantitative relationship is beneficial to students' to develop quantitative reasoning skills.

Note

[1] For example, “What is the relationship between the length of the paint roller and the amount of the area being covered?”

TEACHING PRODUCTIVE STRUGGLE IN CALCULUS

Sarah E. Hanusch

Students often lack the cognitive and metacognitive strategies to maximize their learning. However, instruction may help students use these strategies. We redesigned a calculus course to teach students metacognitive strategies, with three components: frequent in-class discussions, corrections on exams, and a student essay on metacognitive strategies. We used a mixed method study design to qualitatively analyze the students' essays and quantitatively measured changes in students' attitudes towards mathematics using a pre-post assessment. We found the students attitudes improved at a practical and statistically significant level ($p<0.0001$) over the course.

Keywords: Affect, Emotion, Beliefs, and Attitudes. Calculus. Metacognition.

Introduction

To learn new ideas, a learner needs two types of knowledge: knowledge of the subject, and knowledge about learning itself (Alexander, 2005). In our experience, most college courses have curricula filled with subject matter knowledge, but do not provide our students with enough guidance about learning. We attempted to remedy this in a first-semester calculus course.

Calculus is difficult for many students, and often serves as a gatekeeper to other STEM courses (Bressoud, et al. 2013). Many students leave calculus with less confidence in their mathematical abilities than before they started, and less desire to continue taking mathematics.

We redesigned a first-semester calculus course by adding three components: (i) frequent class discussions on metacognition; (ii) allowing students to correct their midterm exams and improve their scores; and (iii) assigning students to read articles and watch videos on metacognitive topics, and write a reflective essay on these materials.

Literature Review

Calculus Attitudes and Instruction

Calculus 1 is a required course for many programs of study in STEM fields. For the last 40 years, educators, politicians and students have called for calculus to move from "a filter to a pump" (Steen, 1988; Bressoud, Mesa & Rasmussen, 2015). Unfortunately, according to the *Characteristics of Successful Programs in College Calculus* (CSPCC) study (Bressoud, et al., 2015), little progress in improving retention rates has occurred over this time.

The CSPCC study found that many students lose interest in mathematics during their first calculus course (Sonnert & Sadler, 2015), and the students reported decreased confidence in their mathematical abilities and decreased enjoyment from mathematics. This finding was confirmed with the *Mathematics Attitudes and Perceptions Survey*, where Code, et al. (2016) found that during a full year calculus sequence, students' attitudes moved away from expert-like orientations. However, pedagogical factors including "classroom interactions that acknowledge students" can lead to improvements in students' attitudes during calculus (Mesa, et al., 2015).

Metacognitive Instruction

To effectively learn new material in any domain, students should have sufficient knowledge of cognitive and metacognitive strategies for learning (Alexander, 2005; Dunlosky, et al., 2013; Winne & Hadwin, 1998), which is comparable to a teacher having both subject matter knowledge and pedagogical knowledge (Shulman, 1987). Unfortunately, students vary widely in their knowledge of appropriate learning strategies (Askell-Williams & Lawson, 2005ab; Askell-Williams, Lawson & Murray-Harvey, 2007; Askell-Williams, Lawson & Skrzypiec, 2012).

However, students can improve their knowledge of cognitive and metacognitive strategies via instruction (Hattie, 2009). The instruction in these strategies can be integrated into other instruction for just-in-time intervention, and result in meaningful increases to student knowledge of cognitive and metacognitive strategies (Askell-Williams, Lawson & Skrzypiec, 2012).

Methodology

The redesign was implemented in two sections of a calculus 1 course, taught by the second author. Six sections of this course were offered, but only two participated in the redesign. The students were not aware of this redesign or this study when they enrolled in the course.

In the two redesign sections, 56 students were enrolled. However, only 46 students are included in our analysis. The other students either elected not to participate, did not correctly fill out the consent form, or did not complete both the pre- and post-surveys.

The goal of the redesign was to alter the students' attitudes about learning mathematics, especially the mindset of the students, and their attitudes toward failure (Dweck, 2006). The redesign had three components. The first component was in-class talks and discussions on productive failure and mindset. Some talks were planned, specifically those given on the first and last day of class, and on the days when exams were returned. An instance of this occurred prior to the instructor handing back the first exams, when the instructor said:

> Before you get your exam back, I want you to think about how you're going to frame your score in your mind, and how you're going to put into practice everything that we've talked about up to this point regarding mindsets and productive mistakes. If you flip your exam over and see a good score, are you going to attribute that to you being a "math person?" That your score is solely the result of your "natural talent?" Or did you score well because you put in the time, hard work, and effort? One of these framings leads to a fixed mindset, and the other a growth one.

This example is typical of the pre-planned talks given throughout the semester.

In addition, mini discussions occurred spontaneously and with greater frequency both in class and office hours. For example, mistakes that the instructor made at the board, and mistakes that the students made while working on in-class problem sets provided opportunities to talk about the importance of mistake-making and struggle for learning.

To encourage the students to return to their mistakes and make them productive, the students could correct mistakes on their exams and return them for partial credit. These exam corrections made up the second component of the redesign.

The third component of the redesign consisted of assigned YouTube videos and online readings on metacognition, mindsets, and productive failure. At the end of the semester, the students wrote a reflective essay that discussed the videos, readings, and class discussions. This assignment was inspired by blog posts from Matt Boelkins (2017) and Stan Yoshinobu (2016).

Data collection

To assess the redesign, we utilized a mixed methods design. We qualitatively analysed the students' essays using a constant comparative method to develop themes (Creswell, 2007).

Also, we gave the students the Mathematics Attitudes and Perceptions Survey (MAPS) twice (Code, et al., 2016). The pre-test was administered during the first week, and the post-test was administered during the penultimate week. This survey assesses the attitudes of students towards mathematics along seven dimensions: beliefs about growth mindset, the applicability of mathematics to the real world, confidence, interest in studying mathematics, persistence in problem solving, making sense of mathematics, and the nature of answers in mathematics. The MAPS assessment was validated with both undergraduate and mathematician groups, and expert consensus was achieved on all items, except two growth mindset indicators.

We processed the data by matching pre-test to post-test and eliminating the participants who did not have both. The survey included a filter question to ensure the participants were reading the questions carefully, and we removed one participant who answered that question incorrectly. Then for each survey item we recorded a 1 for a response that indicated a positive attitude towards mathematics, and 0 for neutral or negative responses, as specified by Code, et al. (2016).

Results

Quantitative Results

The MAPS survey data was analysed with paired t-tests. The difference between the pre-test and post-test was calculated for each student for the overall survey, and within all seven subcategories. The mean of these differences was computed, and we ran a paired t-test. The difference between pre-test and post-test was highly significant (p=0.0000001), with a mean score increase of 3.478 points on a 31-point survey. Furthermore, (see Table 1), each of the

Table 1: Means of differences and p-values for each paired t-test.

Category (points)	Mean of Differences	Standard Deviation	p-value
Overall (31)	3.478	3.897	0.0000001*
Growth Mindset (4)	0.565	1.003	0.000203*
Real World (3)	0.652	0.924	0.000009*
Confidence (4)	0.500	1.457	0.012238
Interest (3)	0.217	0.841	0.043187
Persistence (4)	0.543	1.005	0.000321*
Sense Making (5)	0.435	1.377	0.018831
Answers (6)	0.304	1.171	0.042408

* indicates significance at the 0.01 level

seven subcategories showed a significant improvement in attitudes at the 0.05 level. The categories of growth mindset, real world applicability and persistence in problem solving were also significant at the 0.01 level. Thus, this course resulted in a significant positive change in attitude for the students involved. Furthermore, previous results have shown a significant negative change on this instrument after taking a full year calculus sequence (Code, et al., 2016).

Qualitative Results

The constant comparative analysis resulted in two major themes: the transition from fixed to growth mindsets and adopting the belief that struggle can be productive. Note that all student names are changed to pseudonyms to protect their privacy.

The transition from a fixed mindset to a growth mindset was a topic in many of the essays. Several students acknowledged that they previously held a fixed mindset about mathematics, such as Taylor who said

> Coming into this class this semester I was suffering from a fixed mindset. I believed that I lacked the ability to be good at math no matter what I did. Since I already made up my mind that I was never going to understand math, I didn't put in the work needed to get better at it. I now understand that this is not the case. I now understand that I can be successful in calculus if I work hard and apply a growth mindset. … The mental switch from a fixed mindset to more of a growth mindset is the reason for that success.

Taylor's quote is representative of several students' beliefs that they previously felt they were "not a math person", that they were "naturally worse at math than other people" or that they "had hit [their] ceiling in mathematical ability." Yet all these students acknowledged that these beliefs started to change due to the redesign.

The other major theme from the analysis was the students' growing belief that struggles and failures can be productive. Abby expresses this belief writing "This course has truly taught me how to learn from my mistakes and almost laugh at the failures because it's usually easy for me to get it correct on my next try." Another student, Bradley said "If we embrace our failures and learn from them rather than dwelling on them and pitying ourselves, we can learn faster and improve our success." Several students echoed the sentiments from these quotes that they now find failure to be a normal learning experience.

For many students, normalizing failure led to a focus on learning rather than grades. For instance, Maddie said "I know that all I focus on is getting good grades and I have this fear of failing. I should look at it in a way of learning and understanding why it is that I failed." Similarly, Carrie said "there we many times throughout the class that I didn't do so well on my exams, but through these productive failures I feel I have learned new things."

One concern is that several students seemed to conflate productive struggles with test corrections. We observe this in Andrew's statement "the circumstances that have been given to me during this calculus class have been amazing. In other math classes I get the test back look it over once and put it away but with the corrections I look through it thoroughly and figure out my mistakes." We find it concerning that some of the students seem to associate the concept of making struggles productive to this single task, but we also understand that it was a valuable opportunity for the students to experience productive failure.

Conclusions and Implications

Although the primary goal of calculus is for students to learn the concepts and applications of differential and integral calculus, it is a crucial course for recruiting and retaining students in STEM majors (Bressoud, et al., 2013). Furthermore, we believe that changing attitudes about mathematics is a mechanism for recruitment. As such, the redesign of teaching metacognition alongside calculus concepts was successful in changing attitudes about mathematics.

While the redesign was successful, it may not be possible to scale this to larger sections. In particular, the exam corrections were time consuming, and would not be easily scalable.

Furthermore, we acknowledge that we cannot separate the redesign from possible conflating variables, such as the charisma of the instructor, the previous knowledge of the students, and the scheduling of the course. It was not possible to have an additional section of the course to serve as a control group, due to logistical constraints. As such, we cannot claim that the redesign alone caused the change in attitudes. However, due to the overwhelming changes in attitudes recorded by surveys, we are confident that the redesign contributed to this result.

A CASE OF UNITS COORDINATION STAGE CHANGE IN MIDDLE SCHOOL

Amy J. Hackenberg
Indiana University
ahackenb@iu.edu

Patricia A. Walsh
Indiana University
pawalsh@iu.edu

Jonathan Rojas Valero
Indiana University
jrojasv@iu.edu

A case study of a 7th grade student, Emily, was conducted to understand her change from units coordination stage 1 to 2 over the fall semester of 7th grade. Emily participated in a unit-long classroom design experiment conducted that semester by two of the authors, where units coordination stage change was not an explicit goal. Units coordination refers to how students conceive of relationships between discrete units, like 1s, or measurement units, like lengths, as they solve problems. Students at stage 1 can coordinate two different types of units as they solve a problem, such as the number of packages in a crate containing 6 boxes with 8 packages in each box. However, these students are essentially in a "one's world" and do not create structures like six 8s. In this paper we carefully document Emily's stage change. We also consider tasks in the unit that may have supported this significant change.

Keywords: Number Concepts and Operations, Rational Numbers, Learning Theory

Students enter middle school operating at three different stages of units coordination (Steffe, 2017). Units coordination refers to how students conceive of relationships between discrete units, like 1s, or measurement units, like lengths. Students who are operating at stage 1 can learn to coordinate two different types of units as they solve a problem. Consider the problem of how many packages are in a crate if it contains 6 boxes with 8 packages in each box. Students at stage 1 can track a box of 8 packages, and then another, and another, until they accumulate six 8s (Steffe, 1992). However, the result, 48 packages, is only 48 ones for them—they do not create the structure that observers can see, six 8s. Furthermore, if students are to build on this result to solve another problem, they have to keep re-establishing the 48 as six 8s. In contrast, students operating at stage 2 create the 48 packages as six 8s (Ulrich, 2016a). Yet like stage 1 students, stage 2 students do not maintain the 48 as six 8s: 48 becomes 48 ones. In contrast, students operating at stage 3 maintain the 48 as six 8s as they work on solving more problems.

Units coordination influences students' reasoning in many mathematical domains that are the focus of middle school, such as proportional reasoning (Shin, et al., 2020) and equation writing (Hackenberg & Lee, 2015). Students at stage 1 are basically pre-fractional (Hackenberg, 2013), which puts them at a great disadvantage in working on these domains. Steffe (2017) estimates about 30% of incoming 6th grade students are at stage 1, while a recent study found 61% of 6th grade students were at stage 1 (Zwanch & Wilkins, 2021). Therefore, the field needs to understand how changes in units coordination stage occur, especially from stage 1 to stage 2.

To our knowledge, only one study has addressed stage change (Norton & Boyce, 2015). These researchers supported a 6th grade student to shift from stage 1 to 2 by engaging the student in fairly rapid questions about the number of different types of units in a "embedded units" problem similar to our Crate Problem (shown in the Method section). We did not engage in this approach because we did not intend, necessarily, to promote a shift in units coordination stage. However, our study implies another possible avenue for promoting stage change.

The purpose of this paper is to show evidence of a student, Emily, who entered 7th grade at stage 1 of units coordination. During fall semester she transitioned to stage 2. That semester she participated in a unit on proportional reasoning co-taught by the first and second authors; the second author was Emily's classroom teacher at the time of the study. In this paper we document how we assessed Emily's units coordination stage at the start and end of the semester to demonstrate a case of change in stage. We do not claim that the classroom unit caused this stage change. However, we consider tasks in the unit that may have supported this significant change.

Our research question is: What was Emily's stage of units coordination at the start and end of the first semester of her 7th grade?

Theoretical Frame: Units Coordination and Fractions Knowledge

Students' units coordination stages influence their fractions knowledge (Steffe & Olive, 2010). We view students' fractions knowledge in terms of schemes, where a scheme is a goal-directed organization of mental actions that includes an assimilatory mechanism, activity, and a result (Steffe, 2010b). For example, students at stage 1 often construct parts-within-wholes fraction schemes because they have not yet constructed a disembedding operation where they can take a part out of a whole and mentally keep the whole intact (Hackenberg, 2013).

When students are at stage 2 of units coordination, they can construct disembedding operations, and so they have the tools to construct a *partitive unit fraction scheme* (Steffe, 2010a). For students who have constructed this scheme, one-fifth of a unit means a part that can be iterated five times to make the unit. Norton and Wilkins (2013) found that 6th and 7th grade students who constructed a partitive unit fraction scheme went on to construct more advanced fractions operations and schemes in a relatively short period of time. So, evidence of a partitive unit fraction scheme implies that a student is operating at stage 2.

Method

This paper is part of a larger study, a design experiment to investigate how to differentiate mathematics instruction with a regular-level 7th grade class with 18 students. Before the unit began, we sought to develop initial understanding of students' units coordination stages and fractions knowledge and to select six focus students, two operating at each stage. Toward this end we administered two written assessments of students' units coordination stages (e.g., Norton, et al., 2015), and a written assessment of students' fractions knowledge (Wilkins, et al., 2013). We used results of these assessments to select 16 students for 40-minute interviews prior to the start of the unit. Following the interviews, we had 5 students at stage 1, 9 at stage 2, and 4 at stage 3. Emily was one of the focus students at stage 1.

For this paper we have developed a second-order model of Emily. A second-order model is a researcher's constellation of constructs to describe and account for another person's mathematical activity (Steffe & Olive, 2010). To make the model, we repeatedly reviewed video of Emily's interviews; video of her activity during the unit; and her written work. We wrote summaries, interpretations, and conjectures. We debated interpretations at bi-weekly research meetings with a 6-member research team, coming to consensus through discussion. We also compared Emily to other middle school students at stage 1 (e.g., Ulrich, 2016b). Our model of Emily is a description of her schemes and operations, with accounts of accommodations (re-organizations) that occurred and interactions that were involved in the accommodations.

Two of the interview tasks we used to assess students' units coordination stages are:

Tiles Problem. Cara is putting down square paving tiles for a walkway with 4 tiles in each row. Her bag holds 60 tiles. She puts down 6 rows of tiles. How many rows with 4 tiles in each row can she make with the rest of the tiles?

Crate Problem. There are 4 cans of juice in a package and 8 packages in a box. A crate contains 6 boxes. How many cans of juice are in a crate and can you draw a picture to show how you know?

With these problems we assessed whether students had constructed 4 tiles or cans as a composite unit (unit of units) by iterating 4 multiple times, tracking the numbers of items and the number of rows or packages. We also assessed whether students could use that coordination in further problem solving. If a student did not, that was evidence of coordinating two types of units in activity only, a characteristic of stage 1.

Findings

Now we provide evidence of Emily's units coordination stage from her initial interview at the start of fall semester, and then from her follow up interview at the end of the semester.

Emily's Initial Interview: September 11

Tiles Problem. In her initial interview, Emily worked on the Tiles and Crate Problems. On the Tiles Problem, she initially divided 60 by 6. Although in our view this gave her 10 rows of 6 tiles, she then subtracted 4 (tiles) from the 10 (rows). So, she did not appear to view the 10 as a number of rows, and she was certainly not thinking of the rows as consisting of 4 tiles each.

When prompted to draw a picture, Emily drew 4 tiles individually in a row. When asked if she could put down 6 of those rows, Emily drew only the first two tiles in the next row for a total of 6 tiles, rather than 6 rows. When explaining, she said, "Oh, 6 rows!" She continued her drawing to make 6 rows of 4, and she said she could have "done 6 times 4" to get 24.

When Emily drew 2 tiles onto her initial 4 tiles to make 6 tiles, rather than 6 rows, she again showed that she was not organizing the tiles into groups of 4. This response is characteristic of students who have not constructed composite units (Steffe, 1992). However, when explaining she seemed to realize that 6 rows meant 6 groups of 4 tiles. Her subsequent activity showed that she could conceive of 4 as a composite unit and coordinate two types of units (tiles and rows).

The interviewer asked what the 24 meant. Emily said, "how many she's put down so far" and subtracted 24 from 60. She was "not really sure" about the result, 36: She thought it was too much for rows, so then it must be tiles. The interviewer asked how she would get the number of rows, stating again there were 4 tiles in each row. Emily said, "36 divided by 6 maybe?"

This response is striking because it shows Emily was not structuring the remaining tiles into composite units of 4. Even though she had drawn rows of 4 tiles and she and the interviewer had repeatedly talked about rows of 4, in this moment Emily suggested dividing by 6. This response is evidence that Emily's coordination of tiles and rows of 4 tiles was transient, and therefore that she was making the coordination of the two types of units in activity. It also shows the lack of a feedback system between multiplication and division, a characteristic of stage 1 (Steffe, 1992).

Crate Problem. Emily initially drew separate pictures of pairs of adjacent units: a rectangle with 4 circles for cans of juice (a package), another rectangle with 8 rectangles inside (a box), and another rectangle with 6 rectangles inside (a crate). When asked how the pictures were related, she said, "inside the box is packages and inside this crate is boxes and inside those boxes are packages and inside those packages are cans." When asked to show those relationships in a picture, she drew a second picture: a large rectangle (crate) with 6 rectangles (boxes) inside, with 8 small squares (packages) in each of those, and with 4 circular juice cans in one of the squares.

From this point on, Emily's work on the problem was characterized by conflation of all units, sometimes repeatedly and after questioning and reference to her drawings. For example, at one point she found 32 as the number of cans in all 8 packages in a box. However, she then insisted for a sustained period (1.5 min) that 32 was the number of cans in one package, not one box. When asked whether 32 was the number of cans in one package or eight, she said, "Oh yeah, eight packages." Then she tried to use the 32 to find the total number of cans in the crate by multiplying it by 4 and by 32, and she re-insisted that the 32 was the number of cans in a single package. Under questioning she remarked, "If you think about it, there *are* cans in the boxes," as though she was understanding this anew, 14.5 min into her work on the problem.

So, even though Emily had drawn cans within packages within boxes in her second picture, she was not reasoning with a box as eight 4s. Once she made that coordination, the box was 32 ones, and she had to re-establish the coordination after working on another part of the problem. Her work on the Tiles and Crate Problems is solid evidence that she was coordinating two types of units in activity, and so was at stage 1. Written assessments confirmed this conclusion.

In addition, Emily did not show evidence of a partitive unit fraction scheme. When we posed the One-Fifth Problem (below), Emily drew a copy of the bar and then another copy next to it—a bar consisting of 2 parts. When asked to draw a bar that consisted of 5 of those parts, she did so. But when asked what the answer to the problem was, she said it was the 2-part bar (Figure 1a).

One-Fifth Problem. This rectangle is a candy bar. This bar is 1/5 of another bar. Draw that bar.

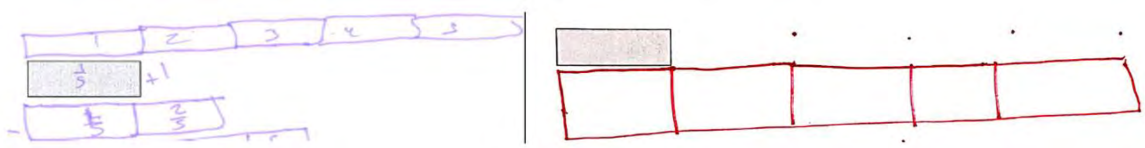

Figure 1a and b: Emily's work on the One-Fifth Problem

Emily's Final Interview: December 19

In her final interview, Emily worked mostly on problems to assess her understanding of the proportional reasoning unit. We did not pose problems to assess units coordination alone because we did not expect to see stage changes after 3 months. However, we did pose fractions problems, including the One-Fifth Problem.

This time, Emily drew a copy of the given bar. Then she spanned the given bar with her fingers and iterated that length four times to the right, drawing a 5-part bar (Figure 1b). Although the fourth part does not look equal, the dots above show she was making equal parts. When asked how she had done the problem, she said, "because it's one-fifth and that means there's 5 whole parts to it." This response was dramatically different from her initial interview, demonstrating clear evidence of a partitive unit fraction scheme. She also solved a related problem in a similar way. Her work is strong evidence that she had constructed a partitive unit fraction scheme, which implies a transition to stage 2 of units coordination.

Conclusions

We have shown evidence that Emily experienced a change in units coordination stage during the fall semester of her 7th grade. Although we cannot claim that specific interventions caused this change, we have identified a task that may have been influential. During the proportional reasoning unit, Emily's class worked on determining how to make two cars travel at the same speed but for different distances and times. Emily's drawings of the journeys underwent a change from not showing relative size to showing it (Hackenberg, et al., 2019), and she sustained this change. It is possible that this work was one factor in her units coordination stage change. We look forward to more investigations of what promotes stage changes in units coordination.

STRUGGLING WITH PRODUCTIVE STRUGGLE: IMPLICATIONS FOR STUDENTS WITH DIVERSE COGNITIVE RESOURCES

Angela R. Crawford
Boise State University
angelacrawford1@boisestate.edu

The perspectives in mathematics education and special education are in tension when it comes to productive struggle. This study describes how struggle surfaced for the students and teacher/researcher in teaching experiments using learning trajectories with three students with diverse cognitive profiles. The students' activity helps to illustrate the relationships between struggle and mathematics learning. I share how students' struggle led to my own challenge in navigating tensions between mathematics education and special education. I consider how my focus on productive struggle without attending to cognitive difference reflected ableist thinking. Finally, I suggest implications of these observations for reframing productive struggle.

Keywords: Students with Disabilities; Instructional Activities and Practices; Learning Trajectories and Progressions

The perspectives of mathematics education, with a commitment to student thinking, and special education, with a commitment to explicit teaching, are often in tension—no less so when it comes to the idea of productive struggle. However, there is agreement that combinations of instructional approaches are beneficial for students (Alfieri et al., 2010; NMAP, 2008; Woodward, 2004). A number of researchers are investigating the mathematical thinking of students with learning disabilities as they engage with constructivist-based tasks (e.g., Hunt & Tzur, 2017; Xin & Tzur, 2016), but questions remain as to how best combine approaches. I conducted teaching experiments (Confrey & Lachance, 2000; Steffe et al., 2000) using a learning trajectory (LT) approach (Sarama & Clements, 2009) with three students with learning challenges, herein referred to as cognitive differences. I explored how primarily constructivist tasks and productive struggle might be supplemented with explicit support to generate learning. I drew on Hiebert and Grouws' (2007) definition of productive struggle as expending effort to make sense of mathematics.

Method

Participants

A purposeful sample of three elementary-aged girls with different learning strengths and challenges participated in this research. Table 1 provides information about these students.

Table 1: Participant information

Name	Age	Parent's description	Neuropsychological evaluation
Miranda	10	Insightful, creative. Likes to plan time to include rewards and breaks. Miranda says she wants to be interested or intrigued	Strengths: fluid reasoning, auditory memory. Difficulties: attention, inhibiting behavior; compromises accuracy for speed.
Eva	9	Great sense-of-humor, honest, loves pets, very active. Has trouble with	Strength: auditory processing. Difficulties: anxiety, speech-sound

		self-control, appropriate behavior. Very anxious about math.	disorder, mixed expressive-receptive language disorder, ADHD.
Macey	11	Compassionate, fun. Does well with hands-on and informal situations. Learns slowly and gradually, does not have a-ha moments.	Strengths: fluid and visual-spatial reasoning. Difficulties: executive functions, abstract reasoning, expressive language.

As the teacher/researcher, I am a participant in this research. I am a white, cisgender woman with over 16 years working in general education and intervention. My disciplinary commitments tend toward the mathematics education perspective, but having taught many students who struggle, I know things are not simple in practice. Therefore, in this research, I committed to supporting student progress rather than rigid use of a single instructional approach.

Teaching Experiments

The teaching experiments (Confrey & Lachance, 2000; Steffe et al., 2000) involved 45-minute individualized sessions, once or twice weekly, over 2-6 months during the COVID-19 pandemic. The conjecture guiding the experiments (Confrey & Lachance, 2000) was instruction based on a LT can center on constructivist-based tasks and support efficient progress when supplemented appropriately with reflection prompts and explicit guidance. Data sources include video and transcripts, artifacts, and planning and reflection protocols. Rigor was ensured through regular consultation with critical colleagues for their interpretations.

Retrospective Analysis

I used a three-level analysis (Simon, 2019) beginning with coding each data source for activity and strategies as indicators of student thinking. The next level of analysis involved identifying patterns and change over time, and the final level involved using the previous analyses to make inferences informing the guiding conjecture. I ensured rigor and trustworthiness through regular discussion with critical colleagues and sharing interpretations with parents as a form of member checking.

Findings

Miranda

The teaching experiment with Miranda was based on an equipartitioning LT (EPLT; Confrey et al., 2014) and reflective abstraction prompts (Simon et al., 2018). The struggle that surfaced for Miranda was sustained attention to tasks, and she resisted repeating tasks with varying number sets or contexts, a key aspect of reflective abstraction. She also wanted to figure things out without my support and did not want me to ask questions that would direct her thinking.

In a moment of insight, Miranda would enthusiastically rush through a task using sound reasoning but confuse the role of specific digits in some way and not quite "close the loop" on the idea. If she learned her solution was not right, Miranda would declare she was too confused and bored to continue. For example, when Miranda had an insight that sharing *a* objects among *b* persons results in *a/b* of an object per person, she said enthusiastically, "Mind blown!" I asked what would happen if four people shared three things. She tried to figure it out mentally but had a hard time keeping the numbers straight. When I pressed her to notate her thinking, she declared writing and drawing were boring, and only wanted to do it in her head. I tried to ask her questions to provide structure. However, Miranda then said she was too confused and bored, and she would not re-engage in the task meaningfully until the next session.

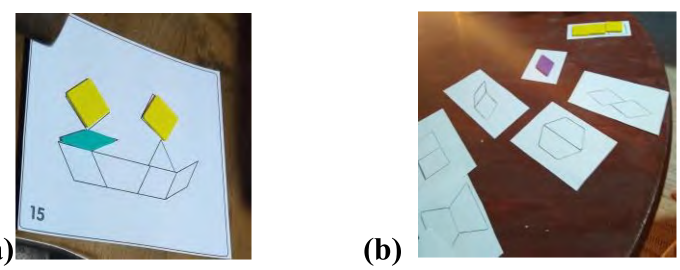
Miranda's effort to make sense of the math was productive in one sense—she would have moments of insight that were temporarily intriguing enough for her to pursue. However, it was unproductive in the sense that the process was not efficient. It was a struggle to find enough variety to sustain Miranda's motivation. Through trial-and-error, I landed on the approach of explicitly summarizing her activity from the previous session and explaining the conceptual idea at the heart of the task. I gave her feedback on where her thinking had gone astray. At this point, Miranda would solve one or two more related tasks and then express a desire to move on.

Eva

Eva had high levels of anxiety and often refused to participate during math class. Her activity in counting, arithmetic, and spatial reasoning was consistent with what is typically seen in children 4-6 years old (Clements & Sarama, 2021). I selected the shape composition LT as the focus for the teaching experiments (Clements & Sarama, 2021). The struggle that emerged for Eva was engaging with any challenge. She would look at a task and within seconds decide she could not do it. Then, she would jump up and run to the yard or play with her dogs.

Eva's first task is shown Figure 1a. Eva appeared to recognize the outlines for two squares because she quickly found these shapes and placed them at the top of the picture. Next, she used trial-and-error to find the right shape and orientation for the rhombus. Then, her attention moved to the connected shapes along the bottom, and she abandoned the task and would not return.

Because Eva would not engage with challenges, I chose to provide a very graduated increase in difficulty with extensive, explicit feedback that I viewed as eliminating struggle. Over the next few sessions, I provided outlines that gradually increased the quantity, combination, and orientation of shapes and the proportion of shared sides (see Figure 1b). I also provided Eva with extensive positive feedback. Each time she filled in a picture, I explicitly pointed out a mathematical feature of her activity: "Nice work, Eva! I noticed that … you saw that this large shape was made of two smaller shapes. Maybe you noticed this outline has three sides? Oh, you did! Great! And I saw you solve a problem—you turned this one to make it fit just right!" This approach led to fewer instances of giving up and gradual progress in the shape composition LT.



(a) (b)

Figure 1: (a) abandoned shape composition task; (b) scaffolded shape composition tasks

Macey

Macey's sessions focused on the EPLT (Confrey et al., 2014). Macey quickly took on each task, working until she felt she had achieved a satisfactory solution. However, her progress was slow, and we spent many sessions repeating variants of tasks. Macey struggled to make connections, see relationships, and construct new mathematical understanding. I used reflection prompts to guide her attention toward new ideas. However, prompts such as "What do you notice?" were typically too general. She seemed look for any feature she could describe, not one related to the mathematical ideas. For example, I asked Macey to share a whole "French fry" among an increasing number of sharers. She partitioned the whole each time, named the size of the share, and taped it to a piece of paper. When I asked her what she noticed, she said the denominator counted by ones and the numerators all stayed one. Then, I asked a more focused question, “Do you notice anything about the size of the share and the denominator?” She did not have an answer, so I became more directive: “Look at this denominator and this share. Now look at the next denominator and this share. Do you notice something? No? Can you compare this share to the one before? Which is a bigger sized share?”

I intentionally set up situations to be perturbations of her current conceptions to help her re-construct ideas. However, these situations were unproductive. Typically, Macey would look at the representations for a few seconds and then move some manipulatives or pencils or papers around, sit back in her chair, and look at something else in the area. It did not appear to be avoidance; my intuition tells me it was so inaccessible that she lost her place, maybe forgot what was expected, and was waiting for guidance. While I cannot be sure my interpretation is correct, I feel confident characterizing this as unproductive struggle. Faced with unproductive struggle, I often switched to explicit instruction to see if it supported progress. I would directly point out a relationship we had been exploring and explain the idea I wanted Macey to see. Then I would ask her to point to features of the representations I was describing and ask her to restate what I had just explained. My hope was that by guiding her attention explicitly, and with enough repetition of the idea, Macey would come to internalize the idea rather than remain lost.

Discussion

My purpose for the teaching experiments was to describe conditions under which constructivist approaches supplemented by reflection prompts and explicit guidance supported students’ learning and productive struggle. During the sessions, I frequently experienced struggle in deciding on the “right” course of action to support student learning. I wanted to provide opportunities to construct understanding through sense-making but, concerned we were not making progress, I felt I began to rely heavily on explicit guidance. However, during the retrospective analysis, I saw the increased support and explicitness was intentional and individualized, not a refutation of the conjecture or abandonment of the commitment to positioning students as active learners. In each case, the students actively engaged in the mathematical tasks without premature guidance (DeCaro & Rittle-Johnson, 2012). Explicitness was inserted within a constructivist framework to support attention to features relevant to the underlying mathematical ideas and connections.

Once I saw the pattern of purposeful, individualized explicitness, I also realized struggle was productive for all three students. Until then, my notion of productive struggle had nuances of ableist thinking. Ableism describes practices and attitudes that compare individuals to a standard of “normal” resulting in practices serving “standard” people (Stop Ableism, 2021). I had resisted “too much” explicitness because I viewed productive struggle narrowly as *expending effort to make sense of mathematics*. Viewed in this way, it established a standard reflecting cognitive strengths and needs of typically-achieving students. I had de-valued other forms of struggle such as with attention, anxiety, abstraction, or combinations of those.

These observations have two implications. First, disciplinary commitments can be re-framed as a commitment to recognizing and navigating complexity. Following on this, another implication is a more inclusive view of struggle would recognize the struggle that surfaces from cognitive difference. We can support students’ productive engagement by intentionally and purposefully planning for struggle in multiple forms—sense-making, attending, processing, remembering, reasoning, etc. From this perspective, a more inclusive definition of productive struggle is *expending effort that leads to greater levels of engagement with mathematical sense-making*. This small change in syntax and vocabulary may have large effects semantically, and those effects may better serve our goal of inclusivity.

THAT'S CRAZY
AN EXPLORATION OF STUDENT EXCLAMATIONS IN HIGH SCHOOL MATHEMATICS LESSONS

Sarina Simon
Boston University
simons21@bu.edu

Leslie Dietiker
Boston University
dietiker@bu.edu

Rashmi Singh
Boston University
rashmis@usc.edu

In this study, we explore the relationships between the types of student exclamations in an enacted lesson (e.g., "Wow!") and the varying dramatic tensions created by the unfolding content. By analyzing student exclamations in six specially-designed high school mathematics lessons, we explore how the dynamic tension between revelations of mathematical ideas at the moment and what is yet to be known connects with the aesthetic pull to react by the student. As students work through novel problems with limited information, their joys and frustrations are expressed in the form of exclamations.

Keywords: Emotions, Classroom Discourse, Mathematical Story, Exclamations, Tension

Historically, mathematics is not perceived as a popular subject among young people (COAG, 2008). National surveys show that students lose interest in mathematics as they progress in school and that by Grade 8, most report their experiences in mathematics class as unengaging and boring (Mullis et al., 2012, 2016; National Center for Education Statistics, 2015). However, students' experiences in mathematics classrooms are largely understudied (Martínez-Sierra & García González, 2014, 2015; Larkin & Jorgensen, 2015; Lewis, 2013). These studies explained students' emotions in the classroom either analyzing their interview responses (Martínez-Sierra & García González, 2014, 2015) or their responses in surveys and interviews (Dietiker, 2015; Lewis, 2013). Larking and Jorgensen (2015) allowed students to use an iPad as a video diary tool to record their experiences in the classroom. However, in this brief, we are analyzing students' experiences by observing their exclamations at different points of the lesson using the transcript, video recordings and the observation notes of each lesson.

Teachers designed lessons for Mathematically Captivating Learning Experiences (MCLE) to spark student engagement by attracting and maintaining students' attention and enhancing their curiosity and creativity. This is accomplished by withholding information from students, increasing the tension during the lesson. As tension rises and falls during the lesson, students feel compelled to shout exclamations expressing their reactions to the tension. Unlike traditional lessons, where teachers usually disclose the information too soon limiting the tension build up, MCLEs encourage students to explore relationships between mathematical ideas and make meaning. The purpose of this paper is to address: *What is the relationship between students' exclamations and the build-up of tension throughout these MCLE lessons?*

Theoretical Framework

Teachers designed lessons using the Mathematical Story Framework (Dietiker, 2015) with different aesthetic reactions. The framework considers the characters, setting, and plot within the context of a mathematics classroom. The characters are typically the students and those interacting with the lesson while the setting is the lesson materials such as, on a graph, paper, or computer screen. The plot describes how the content unfolds. We used Freytag's five-stage model (1863) to describe the development of mathematical stories and associated a degree of tension to each stage (Figure 1).

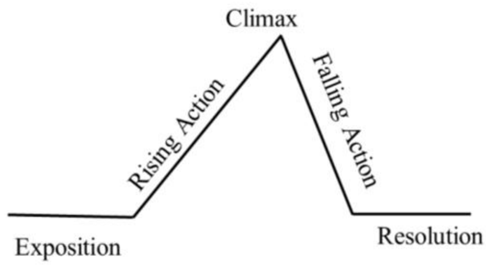

Figure 1. Freytag's Model of story development

The first stage, an *exposition,* is usually in the form of a Do Now or introductory problem that sets the narrative of the lesson. The story begins at equilibrium, that is students know the tools required to solve the given problem and there is either none or the lowest tension. The equilibrium is later disrupted as the story develops and the tension begins to rise and is propelled by a crisis during the *rising action*. At this stage, the ratio of what is unknown to known begins to increase and students wrestle with a concept and continuously make efforts to restore the equilibrium. The tension reaches its peak at the *climax* where students possibly have many questions they have yet to figure out. In the *falling action* stage*,* the level of tension quickly falls towards the *resolution*. Students use the new insights to help uncover answers and thereby creating a new equilibrium. During these stages, certain student exclamations arise. This model helps us identify the types of students' exclamations associated with the level of tension at certain points of the lesson.

Method

The students in this study were from six high school classrooms from the Northeastern region of the United States studying topics from Algebra One to AP Calculus AB. All students willingly participated in the study and the exclamations were recorded anonymously. Researchers monitored a focus group during the lesson to observe the levels of tension. The video and audio were recorded and the tone of a students' response was noted in the transcript.

We used thematic analysis to identify and analyze the patterns of meaning in a data set (Braun & Clarke, 2006). Throughout this data analysis process, the first author reviewed the lesson transcripts and noted the context and timestamp of each exclamation, and identified a pattern that relates to the levels of tension in a lesson. Four themes emerged around the tension that aligned with the Freytag model (see Table 1).

Findings

A thematic analysis of the data suggested that students' exclamations varied with levels of tension because of the information disclosed at that point in the lesson. This table shows the generalization of the exclamations found in the MCLE database organized by relative tension and their occurrence in a lesson related to the Freytag model. Areas of *low tension* occurred when students solved familiar problems, typically during the exposition of the lesson. We found students groaning or saying, "this is boring" as they applied known facts and procedures.

Growing tension occurred when teachers introduced a new problem where students could not directly apply previous knowledge. At this point, students began to question their understanding and made connections from previous mathematical ideas to make sense of this new problem. The tension grew until the point of *highest tension* (*climax* of the mathematical story) where vital information was disclosed to students. This is where students exclaimed shouts (see Table 1) in disbelief. The mathematical story ended with students saying, "wow" and *relieving tension* as they learned the applications of this new skill or topic.

Table 1: Students' Exclamations Categorized by Tension in MCLEs

Tension	Student Examples	Description	Moment in Freytag's Model
Low Tension	"This is boring" ** groans	Students are completing problems using prior knowledge in the form of a Do Now.	Exposition
Growing Tension	"I think I see a pattern" "Oh!!!! Wait"	Students are working through the investigation and a relationship or key piece of information is disclosed.	Rising Action
High Tension	"I'll bet money" "That's Trippy!"	Students react in disbelief with a new solution or tool.	Climax
Relieving Tension	"Wow"	Students are making sense of this new mathematical concept or idea.	Falling Action

The following is a breakdown of students' exclamations in an Algebra 2 class in correlation to the tension regarding the Introduction to Inverses lesson.

Low Tension "Yeah." Students worked on the Do Now problem individually and occasionally checked answers with their group members. In this scenario, the "yeah" was an affirmation to the group that the answer was correct and no follow-up discussion was needed.

Growing Tension "I'm having a brain aneurysm" In this scenario students were plugging values for *x* into the functions $h(x) = (5x - 27)/2 + 1$ and $k(x) = (2(x - 1) + 27)/5$ and $h(k(x))$. You also heard students say "Oh Jesus Christ!" and "Woah there!" Up until now, the students only had to compose functions like $f(x) = 2x + 5$. The tension built because they were using their prior knowledge on this new situation. Later in the lesson when the teacher checked the students' work and left them saying "interesting." Then students said, "We definitely did something wrong then. She does not say 'interesting' often. The tension rose as they double-checked their work and ensured everything was correct.

High Tension "Oh my god, everything cancels out!" During a full class discussion, the teacher wrote $h(k(x)) = (5((2(x - 1) + 27)/5) - 27)/2 + 1$ on the board and had students simplify it. Students said "Oh! oh! Oh!" and "I see it!" as students figured out that the solution simplified to x. Students said, "All that time it was x? So why do we need to go over this as a class?" This was a high-tension moment because the students did not yet understand and were wondering what was so special about the solution $h(k(x)) = x$. At this moment the teacher claimed that this was a special relationship called inverses. Soon after a student exclaimed, "Wait! IT'S THE SAME THING!" referring to the fact that the composition of a function of a variable (x) and its inverse is always the variable (x). This was the highest point of tension because students were starting to see the relationship between a function and its inverse.

Relieving Tension "I'm even curious" Students were working together to see if two functions were inverses using composition. They were given a list of functions and tried to match the two that were in fact inverses of one another.

There were certain instances where students become frustrated and say, "this is boring" or "I give up" but with some input and encouragement from the teacher, students were re-engaged or followed along enough until they were convinced that a process worked. For example, in one lesson, students were given the near-impossible task of finding logarithms without using a calculator! Many students initially found the process tedious and boring. However, by the end of the lesson, students said "Ohhh!" and "I get it now!" The students struggled through the tension and were rewarded with a positive outcome.

Discussion

In some instances, an exclamation was heard at multiple points of tension. For example, a student said, "Ah" to convey that they made a mistake. This was a low tension moment and was quickly resolved. However, in another lesson, a student said "Ah" in confusion and frustration. This is a high tension moment because the student struggled with the concept. These claims were grouped according to the tension in the lesson.

This study focuses on MCLE lessons because the aesthetics of the design are controlled for each lesson. So, the moment of tension when these exclamations occur aligns with parts of Freytag's Model of story development (see Fig.1). The more students engaged with the tensions in the MCLE lessons, the more they were able to voice their confusions, understanding, and emotions. These findings are useful for practitioners and researchers because it gives the insight to create future lessons focused on tension buildup and the Mathematical Story Framework. In the MCLE Research project, we have found that these lessons are significantly more interesting to students than the traditional lessons from the same teacher. A future study could focus on examining ways these exclamations differ in MCLE designed lessons than traditional mathematics lessons.

INTERPRETACIÓN DE GRÁFICAS EN CONTEXTO POR ESTUDIANTES UNIVERSITARIOS

INTERPRETATION OF GRAPHICS IN CONTEXT BY UNDERGRADUATE STUDENTS

En este artículo se presentan los resultados de una investigación relacionada con la interpretación de gráficas de funciones a trozos asociadas a situaciones problema. Se diseñó una secuencia de actividades basada en NetLogo. Se implementó en un ambiente online, mediante el uso de la plataforma Zoom. El marco teórico que se utilizó para analizar los resultados fue la teoría de razonamiento covariacional de Carlson. Los participantes en este estudio fueron 15 estudiantes de cuarto trimestre de nivel universitario. Como resultado se observó que los estudiantes lograron exhibir el Nivel 3 de razonamiento covariacional.

Palabras clave: Matemáticas de nivel universitario, Pre-Cálculo, Funciones a trozos, Tecnología.

Introducción

Varios investigadores (Carlson, Jacobs, Coe, Larsen y Hsu, 2002; Doerr, Ärlebäck y Staniec, 2014; Stroup, 2005) han identificado que, en distintos niveles educativos, los estudiantes exhiben dificultades para interpretar funciones asociadas a situaciones cercanas a la vida real.

El objetivo de esta investigación fue conocer, según la teoría de razonamiento covariacional de Carlson, et al. (2002), como interpretaban los estudiantes universitarios gráficas de velocidad contra tiempo en el contexto del tránsito vehicular. La investigación se llevó en el ambiente virtual Zoom, con ayuda de NetLogo y hojas de trabajo elaboradas ex profeso. La pregunta de investigación fue ¿cómo los estudiantes universitarios interpretaron y externalizaron su conocimiento sobre la función a trozos al resolver situaciones donde ésta subyace?

Marco Conceptual

El razonamiento covariacional se define como "las actividades cognitivas en coordinación de dos cantidades que varían mientras se atienden a las formas en que cada una de ellas cambia con respecto a la otra" (Carlson et al., 2002).

Para su estudio, Carlson et al. (2002) desarrolló un marco que describe cinco acciones mentales de los estudiantes asociados a cinco niveles de desarrollo del razonamiento covariacional. Tres de las acciones mentales (Carlson et al., 2002) son: a) AM1-Coordinación del valor de una variable con los cambios en la otra, b) AM2-Coordinación de la dirección del cambio de una variable con los cambios en la otra variable, c) AM3-Coordinación de la cantidad de cambio de una variable con los cambios en la otra variable. Tres de los niveles de razonamiento covariacional (Carlson et al., 2002) son: a) Nivel 1. Coordinación, b) Nivel 2. Dirección, c) Nivel 3. Coordinación Cuantitativa. Un estudiante ha obtenido un nivel, si sustenta las acciones mentales del nivel considerado y las asociadas a los niveles inferiores.

Metodología

La investigación fue de tipo cualitativa y se realizó en el ambiente virtual Zoom, debido a la pandemia del COVID-19. La población de estudio estuvo conformada por 15 estudiantes, de 19 a 22 años de edad, del cuarto trimestre de la carrera de física e ingeniería. Se organizaron en tres equipos (A, B y C). La secuencia de actividades se apoyó en a) simulaciones con el programa Traffic Basic de NetLogo (Figura 1) y b) una hoja de trabajo (Figura 2) que contiene un problema de una función a trozos en el contexto de tránsito vehicular.

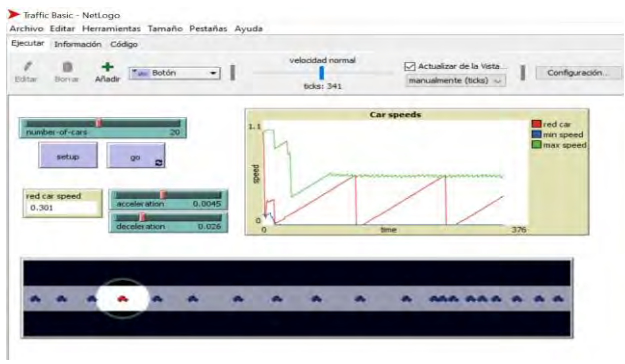

Figura 1: Simulación del Programa Traffic Basic de NetLogo

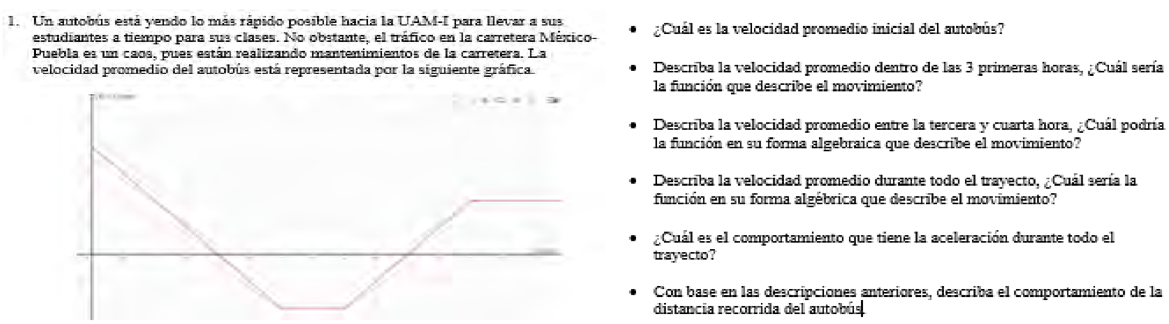

Figura 2: Hoja de Trabajo

Fases de implementación de la secuencia de actividades

Fase 1. Implementación de las simulaciones de Traffic Basic de NetLogo mediante Zoom. El objetivo fue identificar y analizar cómo el estudiante interpretaba y explicaba la gráfica (dinámica) que se desplegaba al simular el fenómeno de tránsito vehicular.

Fase 2. Resolución de la hoja de trabajo en equipos. El objetivo fue identificar y analizar cómo el estudiante interpretaba y explicaba una gráfica, sin el apoyo de la simulación.

Fase 3. Cierre de la sesión. El objetivo fue revisar si el estudiante refinó su lenguaje y comprensión para describir las gráficas.

Se recolectaron videos, respuestas de los estudiantes y notas del profesor. La duración de la actividad fue de 2 horas. Se analizó el nivel de desarrollo del razonamiento covariacional mediante los aportes de Carlson et al. (2002), donde, AMi son las acciones mentales y Ni son los niveles de razonamiento covariacional, para $i = 1,2,3$.

Resultados y Discusión

Fase 1: Implementación de las Tres Simulaciones de Traffic Basic de NetLogo

Primera Simulación. El profesor solicitó a los estudiantes describir la primera simulación (Figura 3) y la gráfica, con el objetivo de identificar sus acciones mentales.

Los estudiantes describieron, cualitativamente, la gráfica de velocidad promedio contra tiempo mediante el uso de conceptos distintos. C_2 co fico e idiendo la velocidad", "se mueve hacia arriba en un tiempo determinado" (posible AM1 y AM2). Mientras que, B_4 dijo: "Su rapidez aumenta hasta llegar a un máximo, se detiene, luego baja". Es posible que B_4 usó rapidez como sinónimo de velocidad; de acuerdo con Yildiz (2016) esto es común.

Segunda Simulación. El objetivo consistió en provocar un segundo episodio para que describieran el movimiento del auto en términos de las variables observadas en la gráfica.

El profesor modificó el parámetro de la aceleración, realizó la segunda simulación (Figura 3) y solicitó a los estudiantes describir la forma de la gráfica.

El estudiante B_2 aseveró que, en el último tramo del gráfico, la aceleración es constante. B_1discre l decir: "¡no!¡no es la acelerac elocidad, ahí la velocidad es constante y la acelerac n vale cero durante el tiempo transcurrido!" (posible AM1 y AM2).

Se pudo observar de nuevo la dificultad para describir la gráfica en términos de las variables involucradas en la gráfica. B_2 describió en términos de aceleración. B_1corrigió a B_2 y describió la gráfica en términos de la velocidad. Sus descripciones fueron cualitativas.

Tercera Simulación. El profesor realizó la tercera simulación (Figura 3), al cambiar la cantidad de automóviles, y pidió describir en términos de las variables observadas en la gráfica. C_1y B_2 dijeron: "la gr fica es de la velocidad contra el tiempo" (AM1). C_3 comentó que el auto "cambia su velocidad en cada tiempo" (AM1 y posible AM2). Podemos decir que C_1 y B_2 exhibieron N1 al identificar las variables involucradas en la simulación y C_3 pareció exhibir N2 al identificar las variables involucradas y la relación entre ellas.

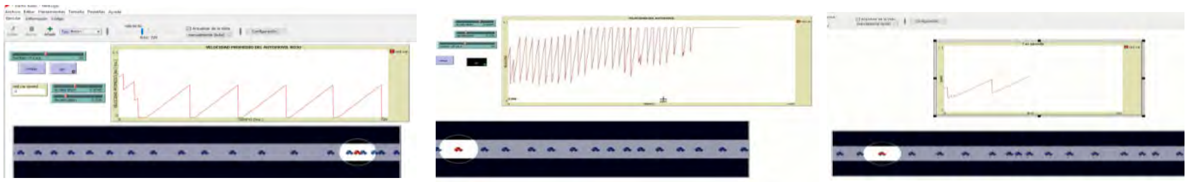

Figura 3: De izquierda a derecha, primera, segunda y tercera simulación en NetLogo

Fase 2: Implementación de la Hoja de Trabajo

Equipo A. Los estudiantes lograron identificar, verbalmente, las variables en el contexto del problema (AM1). Les fue difícil interpretar qué ocurría con el autobús, cuando su velocidad era negativa. De acuerdo con Stroup (2005) interpretar gráficas que incluyan velocidades negativas es complejo. Podemos decir que exhibieron N1.

Equipo C. Los estudiantes describieron el movimiento del autobús representado por la función a trozos, por ejemplo, mencionaron que, entre la tercera y cuarta hora, la velocidad del autobús es invariante y es igual a -1 (Figura 4). Exhibieron AM1, AM2 y AM3, pues identificaron, relacionaron y coordinaron las variables v, t. Podemos que exhibieron N3.

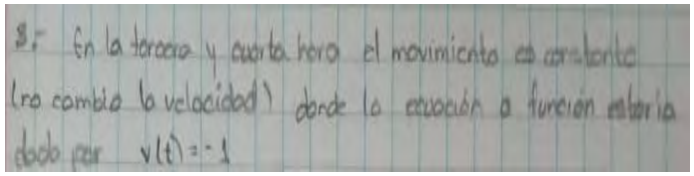

Figura 4: Respuesta del Equipo C

Equipo B. Los estudiantes interpretaron que la velocidad por debajo del eje del tiempo era negativa y, por ende, el autobús iba en reversa (Figura 5 derecha). Describieron, verbalmente, que cuando la recta intersecaba al eje del tiempo, entonces el autobús se había detenido por completo. Podemos decir exhibieron AM1, AM2 y AM3, pues identificaron, relacionaron y coordinaron las variables v, t (Figura 5 izquierda). Podemos decir que exhibieron N3.

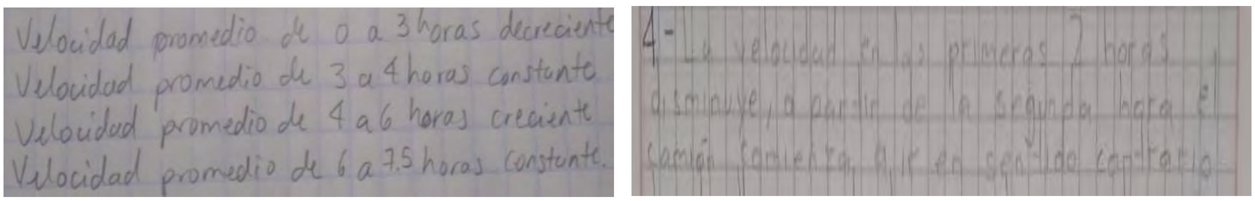

Figura 5: Respuesta del equipo B

Fase 3: Cierre de la sesión

Los estudiantes presentaron al final de la sesión sus respuestas. Su duda principal fue sobre la interpretación de las velocidades promedio negativas del autobús durante su recorrido. El profesor promovió la comprensión del problema a partir de la discusión grupal realizada con base en las distintas respuestas. En general, se observó la dificultad para describir la aceleración y sobre todo la distancia recorrida a partir de la gráfica de velocidad –lo cual coincide con lo encontrado por Stroup (2005). En esta discusión los estudiantes comentaron al profesor que no estaban acostumbrados a resolver problemas de contexto, por lo que se les había hecho difícil la actividad, pero les había gustado.

Conclusiones

Podemos concluir lo siguiente como respuesta a la pregunta de investigación planteada en este reporte: ¿Cómo los estudiantes universitarios interpretaron y externalizaron su conocimiento sobre la función a trozos al resolver situaciones donde ésta subyace? Se observó el surgimiento de diferentes tipos de descripciones al utilizar NetLogo y la hoja de trabajo. Los estudiantes denotaron mayor experiencia asociada a una descripción de gráficas estáticas en lápiz y papel fuera de contexto, que para analizar el movimiento del vehículo rojo con base en la simulación, y construcción simultánea de la gráfica. Durante la primera fase fue difícil para los estudiantes describir la gráfica en términos de las variables involucradas. Sus descripciones fueron de tipo cualitativo, asociadas a conceptos como aceleración y rapidez. No obstante, los estudiantes C_1 y B_2 exhibieron N1 y C_3 pareció exhibir N2. En la segunda y tercera fase emergieron descripciones cuantitativas, además de las cualitativas. Los estudiantes de los equipos B y C exhibieron un nivel de razonamiento covariacional más cercano al N3, al exhibir acciones mentales AM1, AM2 y AM3. Las respuestas denotan que al equipo A le fue difícil describir la gráfica e interpretarla en términos del contexto de la situación, sin embargo, exhibió N1 pues identificó las variables del problema. El equipo B por su parte exhibió más facilidad para representar de manera algebraica su interpretación de la gráfica, pero dificultad para describirla por escrito en términos del contexto de la situación. El equipo C exhibió descripciones en términos del contexto de la situación. Concluimos al igual que investigadores señalados en este documento, que aún en el nivel universitario los estudiantes requieren vivir experiencias donde razonen sobre eventos dinámicos para mejorar su razonamiento covariacional y, en particular, algo que observamos es la necesidad de brindarles experiencias donde puedan discutir conceptos como velocidad, velocidad promedio y rapidez.

Reconocimiento

La investigación tuvo apoyo de CONACYT a través de las becas de estudiantes de posgrado.

INTERPRETATION OF GRAPHICS IN CONTEXT BY UNDERGRADUATE STUDENTS

This article presents the results of an investigation related to the interpretation of graphs of piecewise functions associated with problematic situations. A sequence of activities based on NetLogo was designed. It was implemented in an online environment, using the Zoom platform. The theoretical framework used to analyze the results was Carlson's theory of covariational reasoning. The participants in this study were 15 college-level fourth-trimester students. As a result, it was realized that the students managed to exhibit Level 3 of covariational reasoning.

Keywords: College Level Math, Pre-Calculus, Piecewise Functions, Technology.

Introduction

Several researchers (Carlson, Jacobs, Coe, Larsen & Hsu, 2002; Doerr, Ärlebäck & Staniec, 2014; Stroup, 2005) have identified that, at different educational levels, students have difficulties interpreting functions associated with situations close to real life.

The objective of this research was to know, according to the covariational reasoning theory of Carlson, et al. (2002), how university students interpreted velocity versus time graphs in the context of vehicular traffic. The research was carried out in the Zoom virtual environment, with the support of NetLogo and worksheets elaborated on purpose. The research question was, how did university students interpret and externalize their knowledge about the piecewise function when solving situations where it underlies?

Conceptual Framework

Covariational reasoning is defined as "the cognitive activities involved in coordinating two varying quantities while attending to the ways in which the change in relation to each other" (Carlson et al., 2002, p. 354).

For their study, Carlson et al. (2002) developed a framework that describes five mental actions of students associated with five levels of development of covariational reasoning. Three of the mental actions (Carlson et al., 2002) are: a) AM1-Coordinating the value of one variable with changes in the other, b) AM2- Coordinating the direction of change of one variable with changes in the other variable, c) AM3-Coordinating the amount of change of one variable with changes in the other variable. Three of the levels of covariational reasoning (Carlson et al., 2002) are: a) Level 1. Coordination, b) Level 2. Direction, c) Level 3. Quantitative Coordination. A

Student has obtained a level, if he supports the mental actions of considered level and those associated with the lower levels.

Methodology

The research was qualitative and was carried out in the Zoom virtual environment, due to the COVID-19 pandemic. The study population consisted of 15 students, from 19 to 22 years old, from the fourth trimester of the physics and engineering career. They were organized into three teams (A, B and C). The sequence of activities was supported by a) simulations with NetLogo Traffic Basic program (Figure 1), and b) a worksheet (Figure 2) containing a problem of a piecewise function in the context of vehicular traffic.

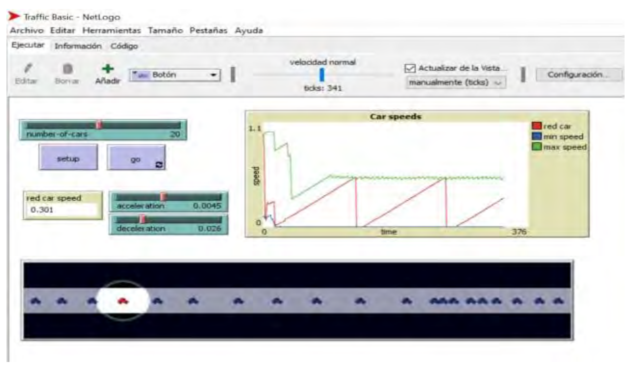

Figure 1: NetLogo Traffic Basic program simulation

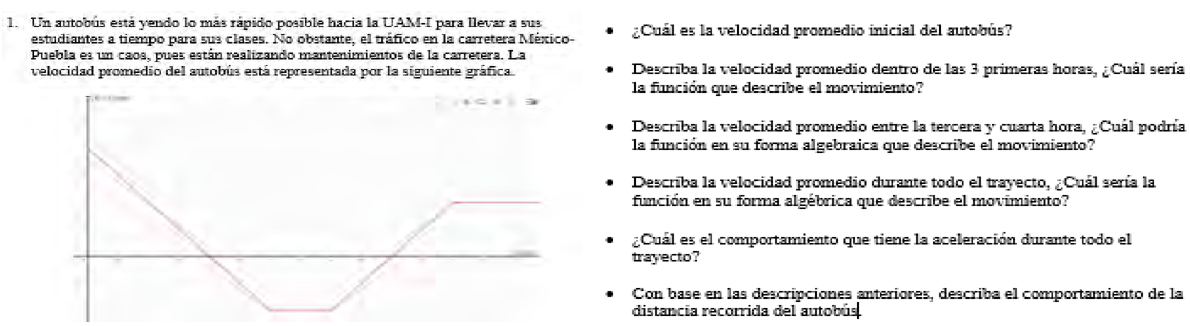

Figure 2: Worksheet

Implementation phases of the sequence of activities

Phase 1. Implementation of NetLogo Traffic Basic simulations using Zoom. The objective was to identify and analyze how the student interpreted, and explained the graph (dynamics) that was displayed when simulating the phenomenon of vehicular traffic.

Phase 2. Resolution of the worksheet in teams. The objective was to identify and analyze how the student interpreted and explained a graph, without the support of simulation.

Phase 3. Closure of the session. The objective was to check if the student refined the language and understanding of it to describe the graphs.

Videos, student responses, and teacher notes were collected. The duration of the activity was 2 hours. The level of the students' development of covariational reasoning was analyzed using the contributions of Carlson et al. (2002), where AMi are the mental actions, and Ni are the covariational reasoning levels, for $i = 1,2,3$.

Results and Discussion

Phase 1: Implementation of the three NetLogo Traffic Basic simulation

First Simulation. The teacher asked the students to describe the first simulation (Figure 3) and the graph, to identify the mental actions.

Students described qualitatively, the graph of average velocity versus time using different concepts. C_2 commented "graphic is measuring the velocity", "moves upward at a certain time" (possible AM1 and AM2). While, B_4 said: "his speed increases up to a maximum, stops, then lower". It´s possible that B_4 used speed as a synonym for velocity; according to Yildiz (2016) this is common.

Second Simulation. The aim was to cause a second episode to describe the movement of the car in terms of the observed variables in the graph.

The teacher changed the parameter of acceleration, performed the second simulation (Figure 3) and asked students to describe the shape of the graph.

Student B_2 stated that, in the last section of the graph, the acceleration is constant. B_2 disagreed, he said: "No! It´s not the acceleration, it´s the velocity, there the velocity is constant, and the acceleration is zero during the elapsed time!" (possible AM1 and AM2).

We were able to observe again the difficulty of describing the graph in terms of the variables involved in the graph. B_2 described the graph in terms of acceleration. B_1 corrected B_2 , and described the graph in terms of velocity. The descriptions of them were qualitative.

Third Simulation. The teacher made the third simulation (Figure 3) and, changing the number of cars, asked to describe in terms of the variables involved in the graph. C_1 and B_2 said: "the graph is of velocity versus time" (AM1). C_3 said the car "changes its velocity in each time frame" (AM1 and possible AM2). We can say that C_1 and B_2 exhibited N1 when identifying the variables involved in the simulation, and C_3 seemed to exhibit N2 when identifying the variables involved and the relationship between them.

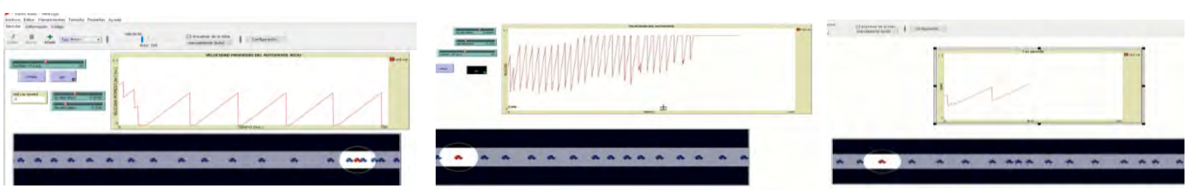

Figure 3: From left to right, first, second and third simulation in NetLogo

Phase 2: Worksheet implementation

Team A. Students were able to verbally identify the variables in the context of the problem (AM1). It was difficult for them to interpret what was happening with the bus, when its velocity was negative. According to Stroup (2005), interpreting graphs that include negative velocities is complex. We can say that the students of Team A exhibited N1.

Team C. Students described the movement of the bus represented by the piecewise function, for example, mentioned that, between the third and fourth hour, the velocity of the bus is invariant, and is equal to -1 (Figure 4). They exhibited AM1, AM2 and AM3, as they identified, related and coordinated the variables v, t. We can say they exhibited N3.

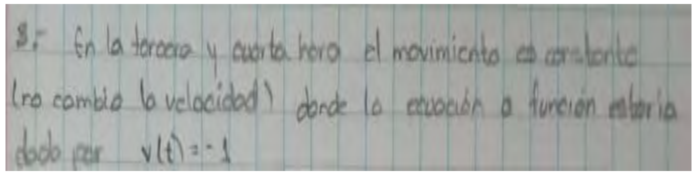

Figure 4: Team C responses

Team B. Students interpreted the velocity below the axis of the time was negative and, therefore, the bus was reversed (Figure 5, right). They verbally described that when the line intersected the time axis, then the bus had come to a complete stop. We can say they exhibited AM1, AM2 and AM3, as they identified, related and coordinated the variables v, t (Figure 5, left). We can say that they exhibited N3.

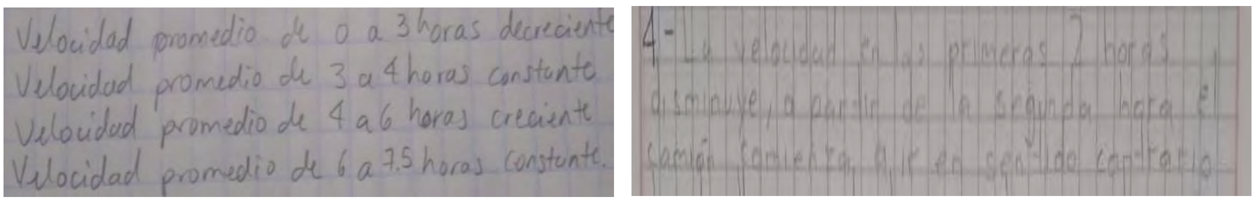

Figure 5: Team B responses

Phase 3: Closure of the session

Students presented their answers at the end of the session in a group discussion. The main question was about the interpretation of the negative average velocities of the bus during its journey. The teacher promoted the understanding of the problem based on the different students' answers. In general, it was observed the difficulty to describe the acceleration, and especially the distance traveled by the bus from the velocity graph – which coincides with what was found by Stroup (2005). At the end of the group discussion, the students commented to the teacher that they didn´t use to solve context problems, so the activity had been difficult for them, but they liked it.

Conclusions

We can conclude the following in response to the research question posed in this report: how did university students interpret and externalize their knowledge about the piecewise function when solving situations where it underlies? Different types of descriptions came up when using NetLogo and the worksheet. The students demonstrated a better experience associated to static graphic descriptions on pen and paper, out of context, than to analyze the movement of the red vehicle based on the simulation, and simultaneous construction of the graph. During the first phase it was difficult for the students to describe the graph in terms of the variables involved. Their descriptions were qualitative, associated with concepts such as acceleration and speed. However, students C_1 and B_2 exhibited N1, and C_3 appeared to exhibit N2. In the second and third phases, quantitative descriptions emerged, in addition to qualitative ones. The students of teams B and C exhibited a level of covariational reasoning closer to N3, they exhibited mental actions AM1, AM2 and AM3. The answers indicate that it was difficult for team A to describe the graph and interpret it in terms of the context of the situation, however, it exhibited N1 because it identified the variables of the problem. Team B, on the other hand, exhibited more facility to represent algebraically their interpretation of the graph, but difficulty to describe it in writing in terms of the context of the situation. Team C provided descriptions in terms of the context of the situation. We conclude, like the researchers mentioned in this study, that even at the university level, students must live experiences where they reason about dynamic events to improve their covariational reasoning and, in particular, something that we observe is the need to provide them with experiences where they can discuss concepts such as velocity, average velocity and speed.

DEVELOPING STUDENTS' UNDERSTANDING OF PROOF THROUGH REVISING PROOFS BASED ON PEER CRITIQUES

Brooke Krejci
Winona State University
brooke.krejci@winona.edu

Kimberly Conner
University of Northern Iowa
kimberly.conner@uni.edu

This study focuses on the critiquing process as an opportunity to engage high school geometry students with all aspects of the third Common Core Standard for Mathematical Practice (SMP3): construct viable arguments and critique the reasoning of others. We report on the types of critiques students provided one another and the extent to which students addressed each type of critique when revising their arguments. Nearly half of students' critiques related to the clarity of a claim or need for a mathematical justification. Students consistently revised draft arguments based on peer critiques, but at times did so in ways that decreased the generality of the argument or inserted mathematically incorrect justifications. Findings suggest that the broader instructional sequence can afford opportunities to discuss the key components of proof by drawing on students' ideas while maintaining shared authority throughout.

Keywords: Reasoning and Proof, Geometry and Spatial Reasoning, Standards, Instructional Activities and Practices

Introduction

Although research on the teaching of proof in secondary geometry has typically focused on the construction of a proof, this is but one component of the third Common Core Standard for Mathematical Practice (SMP3): Construct viable arguments and critique the reasoning of others (CCSSI, 2010, p. 6). Specifically, SMP3 calls for students to pose conjectures and investigate their validity, construct arguments that use definitions and previously established results as justifications for claims, communicate to others, and respond to peer arguments. Analysis of the types of reasoning and proof opportunities found in U.S. textbooks highlighted a difference in number of exercises that asked students to pose a conjecture versus construct a proof, as well as a lack of specific exercises asking students to critique the reasoning of others (Otten et al., 2014). These findings suggest that students may not engage in all aspects of SMP3 within a single proof task without modifications by the teacher. The present study investigated one way teachers could modify proof tasks to allow for varied reasoning-and-proving around a single diagram or context. In this paper, we focus on a subset of that practice: asking students to provide written critiques to one another and then revise their draft proofs in response to peer feedback.

Theoretical Perspective and Literature Review

Our study is based on the perspective that mathematics learning occurs through discursive practices (e.g., Pimm, 1987; van Oers, 1996). While classroom discourse is commonly studied within the context of oral communications between teachers and students, students can also engage in discourse with one another through reading and responding to each other's written work (Pimm, 1987). Within proof instruction, the classroom teacher or textbook is commonly viewed as the audience and authority for determining whether a students' constructed argument of a conjecture can be considered a proof (e.g., Herbst & Brach, 2006; McCrone & Martin, 2009; Otten et al., 2017). This view contrasts with Stylianides' (2007) definition of proof, wherein the classroom community plays a central role in determining the set of accepted statements, forms of reasoning, and modes of expression used in the proving process. Drawing on this definition of proof, we contend that it is important for students to develop their understanding of proof through engaging in varied reasoning-and-proving activity.

One way that teachers can communicate to students their role as a member of the mathematics community is by having them revise their arguments based on peer feedback. Through the process of revising their mathematical argument, students have the opportunity to make changes to their argument in ways that increase its validity, precision, amount of detail, and/or level of convincingness (Jansen, 2020). In order to be able to provide peer critiques, students must first make sense of the peer's argument, so they can pose questions or comments to clarify or improve the argument (CCSSI, 2010). Reading other students' arguments also has the potential to provide insights that students can incorporate into their own arguments and reinforce the idea that there are multiple ways to prove a mathematical conjecture. Students' evaluations of written arguments can also shed light on their understanding of proof, including aspects that may not be reflected in their own constructed arguments (Bieda & Lepak, 2014; Healy & Hoyles, 2000; Stylianides & Stylianides, 2009). While there are multiple potential benefits to this practice, peer feedback also has the potential to reinforce incorrect ideas about proof, such as the idea that examples are sufficient justifications for general claims (e.g., Knuth et al., 2009; Lee, 2016). The research questions guiding this study were 1) Which aspects of students' draft proofs did their peers attend to when providing written critiques? 2) In what ways did students take up their peer feedback, or not, when revising their argument?

Methods

This study took place across three geometry classes, taught by the first author, located in a rural high school in the Midwest region of the United States. Our analysis focuses on thirteen students' written work across four proof tasks. The first task was the Exterior Angle Theorem, presented as a diagram with specific angle measurements. Task two focused on the diagonals of parallelograms. The third task investigated the quadrilateral formed by connecting the midpoints of rectangles' sides. Task four involved classes of polygons that are similar (see Conner & Krejci, 2020 for specific prompts). For each task, students (1) formed a conjecture based on a provided geometric context; (2) constructed a draft argument; (3) exchanged papers and provided written critiques/feedback to their peers; (4) revised their argument based on the peer feedback. The task concluded with a whole class discussion of one proof based on students' ideas.

Data and Analysis

Students' critiques were open-coded (Strauss & Corbin, 1998) and then collapsed into the following categories: requests for justification (e.g., "why does this work?"), clarification of vocabulary or notation (e.g., "which angles are you referring to?"), feedback focused on the structure of the argument (e.g., "how does ____ help prove your conjecture?"), suggestions (e.g., "add how each triangle = 180") , counterexamples related to a claim, comments about the generality of a claim (e.g., "if only most angles and sides are congruent, does it always work?"), requests for examples, and compliments. After establishing the coding scheme, each researcher individually coded the remaining papers and then met to resolve any discrepancies.

We analyzed the extent students took up the peer critiques in their revised argument by identifying changes in the revised argument that appeared to be in response to each critique. When determining whether a student addressed a critique in their revised argument, we qualitatively categorized the ways in which students addressed the different types of critiques without attending to whether it improved the argument. Since students directly progressed through writing their draft argument, giving peer critiques, and writing their final argument without any additional input from the teacher, we could reasonably assume that the changes between their draft and final arguments were either a direct result of the peer critiques or an indirect result of reading their peer's draft argument. In our analysis process, we focused only on changes that appeared to be connected to the peer feedback.

Results

Critiques Provided

Table 1 reports the overall percentage of critiques within each category. Students provided clarity and justification critiques across all four tasks; in contrast, suggestion and counterexample critiques occurred most frequently in the Diagonals of a Parallelogram task while structural critiques surfaced predominantly in the Exterior Angle Theorem task. These findings show that students can attend to important aspects of proof, even when they are not provided specific directions about what to attend to during the critique/feedback process.

Table 1: Types of Critiques Students Provided Across All Tasks

	Clarity	Justify	Structure	Suggestion	Compliment	Counterex.	Example	General
Overall	23.6%	21.1%	13%	13%	8.9%	8.1%	6.5%	4.1%

Aspects of peer critiques students attended to as they revised arguments

Students addressed the majority of their peers' critiques, ranging from 60% (generality) to 83% (clarity). When revising their arguments, some changes improved the overall argument while others resulted in decreased generality of the claim or the use of incorrect justifications.

Clarity. Students addressed 24 of the 29 critiques related to the clarity of mathematical claims and diagrams when revising their arguments. For example, in the Midpoints of a Rectangle task, one group critiqued, "What triangles are you talking about?" for clarity around what Joe, Cody, and Taylor were referring to when they said "The triangles around the rhombus are all congruent because..." The students clarified this phrase in their revised argument by saying, "we know that the triangles EAF, GBF, GCH, and EDH are all congruent to each other..." in reference to their diagram. Clarity critiques typically involved a small change in wording, making them accessible for students to address during the revising process.

Justification. Of the 26 justification critiques provided, students addressed 15 of them when revising their argument. Students' new justifications fell into three categories: specific examples, mathematically incorrect justifications, and, rarely, mathematically correct justifications. For example, one group's conjecture for the Midpoints of a Rectangle task included the claim that "the inside shape [formed by connecting the midpoints of the sides of a rectangle] is a rhombus it has 4 congruent sides." Based on the critique, "how do you know shape is a rhombus? (is there a theorem?)", the students added the following claim to their revised argument: "We know the inside shape is a rhombus because rhombus opposite angle theorem." The rhombus opposite angle theorem is an incorrect justification as it can only be used *once* a rhombus has been established, and not vice versa. This example is illustrative of a pattern we encountered across multiple arguments: namely, students used an incorrect justification or did not provide a justification at all in instances where their claim required multiple steps to sufficiently justify.

Structure. Students addressed 11 of the 16 critiques students provided that related to the structure of the argument. For example, Cody addressed two structural critiques he received for the Exterior Angle Theorem task by explaining how the properties in his draft argument could be used to solve for the missing angles C and D (Figure 1). Although his revised argument does not fully explain how he could use the equation D = 180 - C to prove that B + A = D, it comes closer to connecting the equation with his conjecture. The way that Cody revised his argument to address the structural critiques was representative of the broader data: students addressed the critiques in a mathematically appropriate, but incomplete way.

<table>
<tr><th>Draft Argument (Cody)</th><th>Critiques (Kim)</th><th>Revised Argument (Cody)</th></tr>
<tr><td>A triangle = 180° and a line = 180°</td><td>Give more explanation as to why this matters</td><td rowspan="2">We know how to solve one [missing angle] because there are 180° in a triangle so you add up the two angles and subtract them from 180° that is how you get the third angle in the triangle. After that we know a line is also 180° and because the angle we just solved is on that line, we take 180° minus that number to get the outside angle.</td></tr>
<tr><td>So if D = 180 - C then B + A = D</td><td>How does “D = 180 - C” help your argument?</td></tr>
</table>

Figure 1: Draft and revised claims from Cody’s Exterior Angle task

Discussion

The lesson structure used in this study (conjecture - construct draft argument - provide written critiques - revise argument) offers a way for students to engage in multiple facets of SMP3. We found that having students provide written critiques to their peers surfaced many of the key aspects of proof, such as the need for claims to be clear and include mathematical justifications. Students’ ability to provide meaningful critiques occurred even in instances when they struggled to write arguments that adhered to all aspects of a proof. This finding is consistent with prior literature that has shown students are better at evaluating arguments than constructing them (Bieda & Lepak, 2014; Healy & Hoyles, 2000).

The process of having students revise their arguments based on peer critiques communicates the message that students play an important role as a member of the audience for whom a proof is written and furthers the sharing of authority among both students and the teacher. There was clear evidence that changes between students’ draft and final argument were due to peer critiques, demonstrating students’ ability to make sense of the peer feedback and find ways to incorporate it into their revisions. Students’ revisions in response to peer critiques ranged from those that improved the overall argument to ones that resulted in a decrease of the generality of a claim or the inclusion of a mathematically incorrect justification. This finding highlights the role of content knowledge (e.g., Cirillo & Hummer, 2021) and strategic proof understanding (Weber, 2001) needed to be able construct an argument that adheres to all aspects of a proof. For example, students’ addition of mathematically incorrect justifications may point to gaps in their content knowledge, whereas their inclusion of examples as justification could suggest incomplete understanding of the generality of the claim being proven. The differences between types of critiques that students were able to address may point to the complexity of the skills and knowledge needed to address the critique. Specifically, it may be that students are better able to attend to structural critiques once they have established the main ideas in the argument with appropriate justifications. Even though this process did not consistently result in airtight proofs, we do not discredit the value of having students revise their arguments based on peer feedback. Rather, the revision process can serve as an opportunity for the teacher to assess students’ base arguments and level of understanding in order to progress them towards a mathematically sound proof (Stylianides, 2007).

THINKING ABOUT CONSTANT RATE OF CHANGE: A CASE STUDY OF ALEXI

Ishtesa Khan
Arizona State University
Ishtesa.khan@asu.edu

This paper presents the results of a study where a student's thinking about the idea of constant rate of change and her thinking about the foundational ideas for understanding the constant rate of change were investigated. The idea of constant rate of change involves students' quantitative reasoning, covariational reasoning, and proportional reasoning. The result of the exploratory teaching interviews also discusses how the participant thinks about quantities, the relationship between quantities, representation of quantities, changes in quantities, rate, ratio, and proportionality in relation to the idea of constant rate of change.

Keywords: constant rate of change, changes in a quantity, students' thinking, ratio of changes.

Introduction and Theoretical Background

Learning the idea of a constant rate of change associates with the concept of quantities, representation of quantities in a context, rate, ratio, proportionality, changes in quantities, and linear functions. A student engages in quantitative reasoning (Thompson, 1988, 1990, 1993, 1994 & 2011) as she conceives quantity as a measurable attribute of an object and conceives measuring it as a multiplicative comparison of two fixed quantities. When two quantities vary in relation to each other, the mental operations that support the dynamic images in students' thinking is referred to as covariational reasoning (Carlson et al., 2002; Thompson & Carlson, 2017). Proportional reasoning as a theory is based on the idea of ratio and rate and requires a conceptualization of multiplicative comparison of the measures of two quantities. A ratio is a multiplicative comparison of the measures of two non-varying quantities, and a rate is the proportional relationship between two varying quantities' measures (Thompson & Thompson, 1994). A student engages in proportional reasoning when she conceives the invariant relationship of quantities in a dynamic situation or applies her understanding of proportionality in a mathematical context. Therefore, a student conceptualizes the idea of constant rate when she envisions two quantities in a situation vary smoothly and continuously, and the changes in one quantity is a simultaneous result of changes in another quantity; and as the quantities covary the ratio of the changes in the values of two quantities remain proportional.

In this paper, I will present the results of exploratory teaching interviews (Steffe & Thompson, 2000) that was designed to address students' thinking about the idea of constant rate of change and other foundational ideas to understand the constant rate of change.

The primary research question I want to consider here is- how do students think about the idea of constant rate of change in a context in association with foundational ideas like quantities, representation of quantities, rate, ratio, and changes in the quantities?

Methods

For this study, I used an exploratory teaching interview (ETI), one of the teaching experiment elements (Steffe & Thompson, 2000). An ETI is a one-on-one interview consist of an interviewer, a student, and video/audio recording devices and was a convenient choice for this study as the spontaneous nature of proposing on-moment hypotheses would provide the groundwork to construct a model of students' thinking of the idea of constant rate of change. The participant, Alexi (pseudonym) was a precalculus student in a large south-western university in the United States, during the time of the interview. She participated in three 1.5 hours interviews. The interviews were held in zoom, and I used the zoom video recordings to analyze the data. The data analysis methods used in this study are qualitative analysis supported by grounded theory (Strauss & Corbin, 1994) and conceptual analysis (Glaserfeld, 1995; Thompson, 2008) to construct a model of Alexi's thinking. The tasks I used in this study had a dynamic nature. I presented two primary contexts- *the candle burning* context and *the circle* context (Carlson, M.P., Oehrtman, M., & Moore, K.C, 2016). The contexts used for the tasks in this study are-

- *Context 1.* The Candle Burning Problem- A 14-inches candle is lit. Using an applet, students identify the fixed and varying quantities where the applet shows how the candle's burned length and the remaining length of the candle covary as time changes. Students use variables, expressions, formulas, and graphs to represent the relationship between quantities in the context. Students think about changes in the quantities and constant rate of change as we present a situation where a candle burns at a constant rate of 1.8 inches per hour.
- *Context 2.* The Circle- Students think about the relevant ideas- quantities, the relationship between quantities, representation of the quantities, ratio and rate, and constant rate of change when a circle's circumference varies with respect to the circle's radius. Students are allowed to use an applet after they try conceptualizing the context.

Results

In Context 1, Alexi could imagine the length of the candle varying at different moments since the candle is lit and identified the candle's length before and after it was lit as quantities. She thinks she can associate numbers to the attribute of an object, and the numbers make them measurable. I probed her asking if it is possible to measure a quantity without associating numbers. Then she thought about comparing two objects with respect to one another, and she could measure attributes of one object in terms of the other without associating any numbers. In context 1 & 2, Alexi spontaneously mentioned the relationship between quantities. She noticed that the candle's remaining length decreases as the burned length of the candle increases and the circle's circumference increases or decreases as the circle's radius increases or decreases. She was careful identifying the independent and dependent quantities and how changes in the dependent quantity depend on the changes in independent quantity from the applets' visual effect. In both contexts, Alexi was natural in identifying independent and dependent varying quantities and fixed quantities and how two quantities are changing together (increasing or decreasing values of dependent quantity as there is a change in the independent quantity). She also represented the quantities and relationship between the quantities in both contexts using variables, expressions, and formulas.

In the candle burning context, the applet was set in a way that the burned length of the candle is 5 inches, and the remaining length of the candle is 9 inches. She was asked to think about the change in the values of the burned length of the candle from 5 inches to 12.40 inches is and the corresponding change in the values of the remaining length of the candle. Alexi exhibited her thinking with an analogy of the variables x_1 & x_2. She thinks x_1 is the value of the quantity from where the quantity has changed to a new value. She used hand swiping motion to say,

> "I think about it as x_1 as it (the quantity) has changed to get to x_2, so if we take x_2 and subtract x_1, it will give us the amount x_1 had to move to get to x_2. If we think about x_1 and subtracting x_2 from it, we would be going backward instead of figuring out how much x has changed from x_1 to get to x_2."

She later clarified that she thinks a change in x from x_1 to x_2 means x is moving from x_1 towards x_2. She exhibited her thinking about change in a quantity's value from one reference point to a new point as she mentioned that the candle's remaining length since it is lit decreases as the candle's burned length since it is lit increases.

In the circle context, she initially thinks about $0.56 - 0.5$ as the change in radius when it increases to 0.56 cm from 0.5 cm and $2\pi * (0.56 - 0.5)$ as the corresponding change in circumference when the radius increases to 0.56 cm from 0.5 cm. With little probing Alexi mentioned that $2\pi(0.56)$ cm and $2\pi(0.5)$ cm are values of the circumference when the radius of the circle is 0.56 cm and 0.5 cm respectively, and the difference between the values of the circumference represents the change in the values of the circumference when radius has changed from 0.5cm to 0.56 cm. However, she thinks about $2\pi * 0.06$ cm as a value of circumference when the radius is 0.06 cm not a change in the values of the radius. Alexi was asked to determine the rate of change of the circle with respect to any change in the length of the radius. She thinks that she compares the difference between two values of the circumference with respect to the difference between two values of the radii when she is thinking about the rate of change of the circumference with respect to any change in the length of the radius. She figured the numerical value of the rate of change in this situation is 2π. The answer 2π made her think that this is the resulting ratio of any circumference and corresponding radius of the circle. She exhibited thinking the formulas $C = 2\pi r$ and $\Delta C = 2\pi\Delta r$ represent the same relationship between the circumference and the radius. The following excerpt presents Alexi's response justifying why both formulas represent the equivalent relationship between the circumference of the circle and the radius of the circle-

Alexi: I think they represent the same thing because ΔC is still a circumference and Δr is still radius. We just got them differently. The 2π is always the same. No matter what C and r is C/r is 2π.

Interviewer: You mean ΔC and C represent the same quantity?

Alexi: Yes, we just got ΔC from subtracting two circumferences instead of C.

Interviewer: When you subtract a new value of the circumference value from a previous circumference value, do you think the difference is a value of the circumference? For example, if you have two values of the circumference of the circle and the difference is $c_2 - c_1$, what does the value of $c_2 - c_1$ mean to you?

Alexi: To me, this is a circumference value that we got from subtracting two circumferences. I understand how it's a change, but I also think that we got it from two circumference values so that it is still a circumference. We just got it in a different way.

Interviewer: When you have a change from quantity's two values, do you think the change represents a value of the quantity?

Alexi: Yes.

She thinks the rate of change of the circumference of the circle with respect to any change in the length of the radius is a constant rate of change because both ratios $\frac{C}{r}$ and $\frac{\Delta C}{\Delta r}$ results into a constant 2π.

Next, Alexi was presented with a modified candle burning context where a candle burns at a constant rate of 1.8 inches per hour. 5.6 hours after being lit, the candle is 9.92 inches tall. She thinks that the candle burns at a constant rate of 1.8 inches means every hour the candle burns 1.8 inches. She imagines the candle is getting shorter as time goes by, and as the unit of time gets smaller, she imagines the candle is getting less visibly shorter.

She started thinking that the candle before it is lit is 9.92 inches tall, and since it is lit the change in time is 5.6 hours, and the change in height of the candle is 9.92 inches since it is lit. However, after I insisted her on drawing a diagram of the context, and then she noticed before the candle was lit the candle would be taller than 9.92 inches after 5.6 hours being lit. She thinks as the candle burns 1.8 inches every hour, it burns 5.6 times as large as 1.8 inches after 5.6 hours being lit. She thinks 5.6*1.8 inches is the candle's length that burnt off in 5.6 hours and that is the change in length of the candle since it is lit. She thinks the changes in the time since the candle is lit and the changes in the candle's length since it is lit is proportional as 'anything happens to one side of the ratio, the same happens to the other side, that's what make them proportional.'

Reflecting on her thinking to each context, Alexi summarized what she thinks about two quantities varying at a constant rate-

> "Two things (quantities) work together or vary at a constant rate means they are moving at a constant rate, but like they are moving proportionally. If one of the quantities is moving an equal amount, the other side of the ratio will move as well proportionally."

She provided an example to support her answer as she thinks if it were 2 hours since the candle is lit the burnt length of the candle would be 2 times as large as 1.8 inches; if the time changes 1/3 of 1 hour, the candle's burned length would be 1/3 times as large as 1.8 inches.

Discussion

The findings suggest that Alexi conceives a quantity as a measurable attribute of an object and the multiplicative comparison of two fixed quantities makes a quantity measurable. Alexi showed consistency in thinking about variation of varying quantities and covariation between two covarying quantities across the contexts and her thinking aligned with 'smooth-continuous variation/covariation' discussed by Thompson & Carlson (2017). Alexi's responses about changes in a quantity or changes in quantities' values revealed her thinking that she struggles to separate any change in a quantity's value from a varying value of the quantity. She thinks the change in a quantity's value is another value of the quantity that results from taking the difference of two values of the quantity. She successfully identified desired answers in the problems with a little probing; however, her meanings for a 'change in a quantity's value' create opportunities for researchers to design tasks that will support students' thinking about changes in a quantity's values in a productive way.

Alexi's responses in the study indicate that she connects the idea of proportionality with the idea of ratio. She thinks there is a constant rate if two quantities covary proportionally. She thinks about two quantities vary at constant rate if the value of one quantity is always the same number of times as large as the other quantity's value. Alexi confuses the concept of rate with the concept of constant rate of change. When she reveals her thinking about the concept of constant rate of change, it does not involve thinking about changes in one quantity's value being proportional to the corresponding changes in the other quantity's value. Her thinking is parallel to how she thinks about changes in a quantity's value being the same as a new value of the quantity. The result of the study indicates Alexi's struggle to connect the foundational ideas like rate, ratio, changes in a quantity to construct a productive meaning of the idea of constant rate of change.

CONFIDENCE AND PARTICIPATION IN A CALCULUS REVIEW PROGRAM: A CASE STUDY

Jana Elle Vandenberg
Arizona State University
jevanden@asu.edu

Carla van de Sande
Arizona State University
carla.vandeseande@asu.edu

Staying engaged in school is especially challenging in these times. This paper presents work from a review program that is designed to help students stay connected while not attending classes and to encourage them to adopt a growth mindset. Every day during the break between semesters before students take Calculus 2 they are texted Calculus 1 review questions. Students are given opportunities such as the ability to try the problem again if they answer incorrectly, use hints, and answer challenge problems to push themselves. Each student interacts with the program in a unique way and understanding student choices can help us create a program that benefits all students. Furthermore, with specific knowledge about the student's background, the program can be improved to help similar students thus allowing for more targeted support for minority and first-generation students.

Keywords: Undergraduate Education. Calculus. Technology. Equity, Inclusion, and Diversity.

Introduction

Just like physical skills, cognitive skills grow rusty over time unless they are regularly used and practiced. This means that school breaks can have negative consequences on student learning. Indeed, by a conservative estimate, summer vacation sets K-12 students back by one month of instruction; that is, it causes them to lose one month of grade-level equivalent skills relative to national norms (Cooper, Nye, Charlton, Lindsay, & Greathouse, 1996). Although this "summer gap" effect has been documented for many school subjects, it is most pronounced for mathematics which requires a strong foundation of prior knowledge, and this phenomenon extends into higher education too. We now know that having breaks between sequential closely related mathematics courses significantly lowers performance in the second course at the university level (van de Sande & Reiser, 2018).

The Keeping in School Shape (KiSS) program was created to help students prepare for Calculus 2 by sending them a daily Calculus 1 review problem via text message or email. The program uses retrieval practice as well as push technology to engage with students in a variety of ways. (Roediger & Butler, 2011) (van de Sande & Reiser, 2020) Since the first year it was launched the program has grown to include a variety of features such as challenge problems and theme days aimed at fostering a growth mindset (Dweck, 2008) as well as furthering students review capabilities. Furthermore, the charity aspect of the program aims to motivate the students. The most recent session of the KiSS program held during the winter break of 2020 also included three surveys: an entry survey, an exit survey, and an extended feedback survey. These three surveys were used to interpret the activity of specific students throughout the program and gain insight into the students as a whole. This paper will first introduce the program and its features, then follow one student's path through the program.

The Program

Every day starting the Monday after the end of the Fall 2020 semester students who had enrolled in the program were sent a message either via email or text. When they clicked on this message, they were taken directly to the first daily problem where they viewed the problem and rated their confidence. They rated their confidence by picking one of the following five options which have been assigned a number for data analysis: not at all (1), not very (2), meh (3), somewhat (4), and super duper! (5). The student then clicked next and was presented with the daily Calculus 1 review problem along with five multiple choice options. If they answered correctly on their first attempt, they could view the solution, exit, or attempt a related challenge question. If they opted for a challenge question, they then could view its solution or exit (Figure 1).

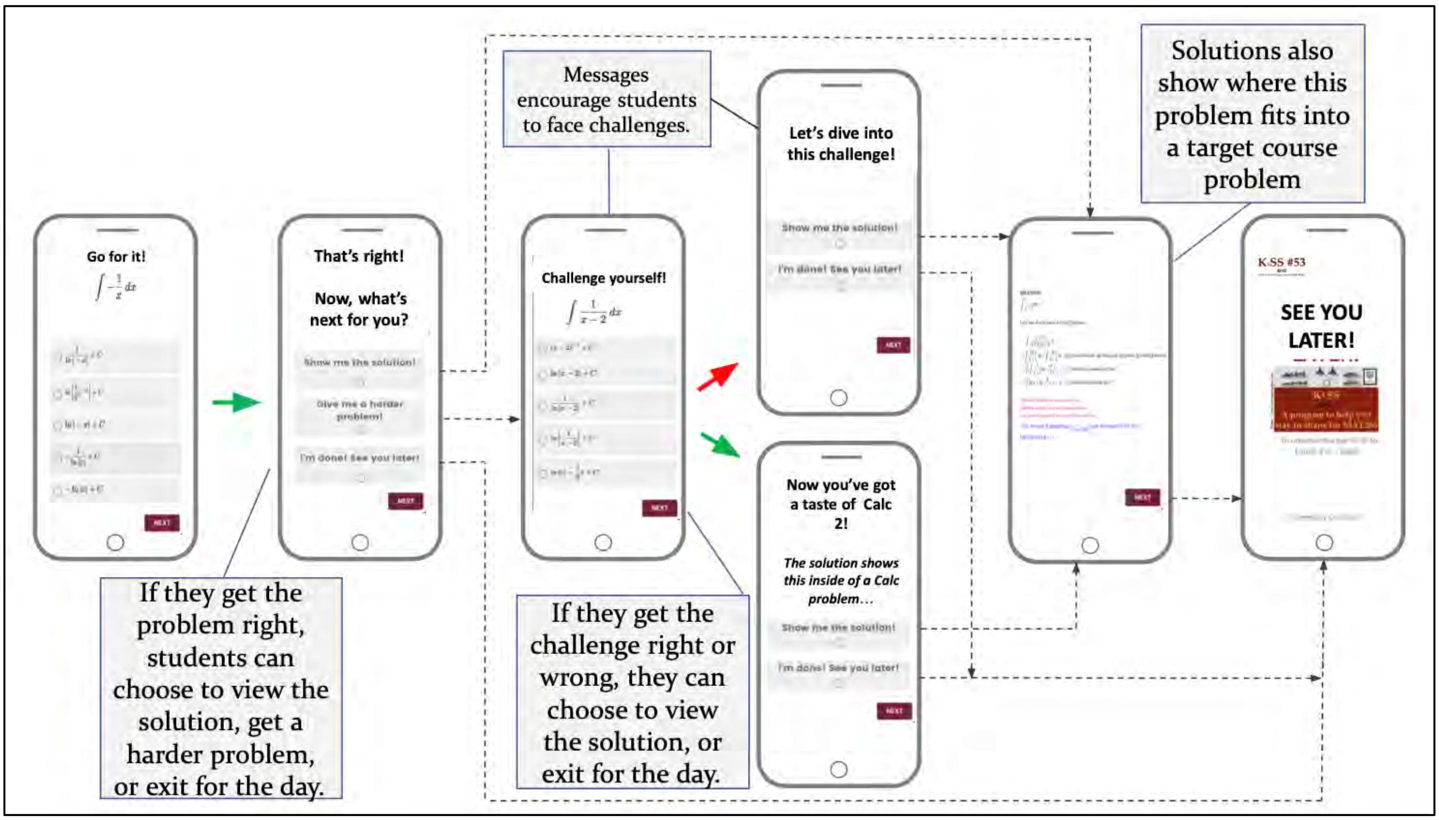

Figure 1: Path through daily review problem if student answers problem correctly

If the student answered incorrectly, they could choose to see a hint or see the solution. If they chose to see a hint, they could attempt the problem again. If they got the problem correct or incorrect on this second try, they could view the solution to the problem or exit.

There are two days of the week where the KiSS program does not follow the above explained schedule, namely 2's-days and trivia days which are held on Tuesdays and Sundays, respectively. On 2's-days, students had the option of doing an additional review problem similar to the initial problem regardless of their accuracy, or, if they answered correctly they could opt to do up to two related challenge problems. On trivia days students were given the option to only complete a math related trivia question or to complete their normal daily review followed by the math related trivia question.

Finally, there is the charity aspect of the KiSS program. Whenever a student answered a question correctly, they were allowed to select one of five good causes to receive a point. At the end of the program, the second author donated money to the charity with the most points.

Analysis

We will now follow one specific student, "John," who identified as a black and Asian male (pronoun: he/his) and a first-generation college student studying Electrical Engineering on his path through the program and responses in the extended feedback survey. John completed 19 of the 33 possible problems in the 2020 KiSS Winter Break program. Of the 19 questions he answered, he answered 14 correctly and five incorrectly and had an average confidence rating of 2.95 on a scale of one to five. So, while he answered 73.7% of the questions he attempted correctly, his confidence rating was very low, suggesting that he underestimate his capabilities.

When asked about his mindset regarding math, John stated in the extended feedback survey that that he felt he could "improve through hard work. If [he] finds the concept difficult, it means [the] will have to practice more." This mindset is evident in how John acted when he answered a question incorrectly. As shown in Figure 2, which depicts his confidence rating for each of the problems he answered and in which the problems he answered incorrectly are colored red, this happened five times. Every time John answered incorrectly, he chose to view the hint and try again, thus giving himself more practice. After viewing the hint and attempting the question again, John got the question correct three out of five times, suggesting that the hints themselves (or how he used them), were helpful to some extent. In addition, consistent with a belief that he could improve with effort, John viewed the problem solution regardless of whether he got the daily question right or wrong on the second attempt.

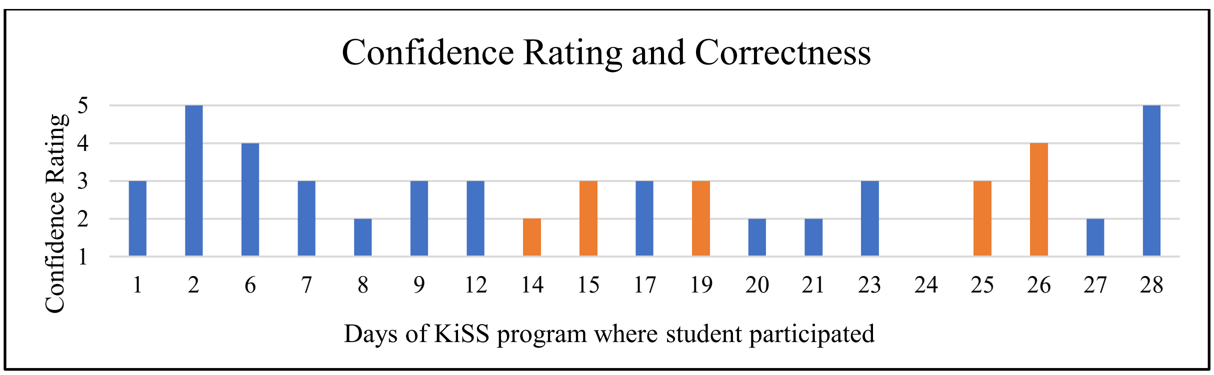

Figure 2: Student's confidence rating and correctness for each initial daily review question he answered

In the KiSS program students had the option on normal days to push themselves by answering a challenge question if he answered the first daily question correctly. John answered a total of 14 questions correctly, 12 of which were normal daily review days and two of which were 2's-days. On normal review days John only took the opportunity to attempt a challenge question three out of 12 times (25% of the time). Of those three times, he answered the challenge question correctly twice. On the other nine regular program days, John chose to view the solution eight times and exited once. This behavior is still consistent with a growth mindset at some level, since, even if he chose not to regularly push himself with a challenge problem, he still wanted to learn more from the daily problem rather than just exiting for the day. Furthermore, reviewing the solution even though he answered the question correctly suggests that he was still not confident with either himself or the material. John stated that the reason he "sometimes" did the challenge problem after getting the daily review problem correct "depend[ed] on the day/energy level". This suggests that John might be cognizant of the fact that he could push himself more but is not always motivated to for a variety of reasons. However, John may have been open to trying a question of similar difficulty.

To examine this dynamic, we can look at John's choices on the two 2's-days he participated in. On the first 2's day he participated in, John answered the initial daily review problem correctly and then chose to view the solution and do the related daily review problem which he also answered correctly. This is one of the few days on which John chose not to view the solution and instead exited, perhaps because, after getting the initial and related problem correct, he felt very confident in the way he was solving the problems. John's tendency to favor repetition over challenge, is evident in that he chose to do a second related problem of the same difficulty rather than trying the more difficult challenge problems. On the second 2's-day that John participated in, he again got the initial daily review problem correct. This time he chose to try a challenge problem, and after getting this challenge problem wrong, he clicked to see a solution. He then clicked to try the related challenge problem, but did not complete it. We infer from the fact that he viewed the second challenge problem but did not attempt it that he perhaps found it intimidating. This behavior is indicative of a fragile growth mindset since John chose to confront a second challenging problem – after not succeeding on a similar problem the first time – but then retreated (Dweck, 2008). The second 2's-day was the last day John engaged with the program mathematically, even though there were five more days with problems. He did participate in the extended feedback survey which was sent out between the last two days of the program, indicating that he was still receiving notifications for the questions. It is possible that John stopped participating at the end of the program because he got busy as the semester neared, or that his confidence was shaken after his participation in the second 2's-day on which he was unsuccessful in answering the challenge questions.

Discussion

Since every student has a unique experience within the KiSS program, there is much to be learned by studying one student's choices. The student discussed in this paper was a first-generation college student who identified as "black and Asian." Historically, first generation and minority students have more difficulty in higher education and specifically in Science, Technology, Engineering and Mathematics. Moreover, demographics have been known to be a factor in how students understand their own capabilities (Leslie et al., 2015; Litzler et al., 2014). John exhibited low confidence in his mathematical abilities and did not always choose to challenge himself. He also always generally chose to view the solution, suggesting that, even though he got the question correct, he was either still not confident in his ability or with the concepts and skills used in the question. Since confidence is often tied to success in STEM fields (Litzler et al., 2014), it is important that a program such as the KiSS program helps students build confidence.

To help students with a similar background and confidence level as John, the KiSS program could include the option to do a related daily problem that is not more challenging every day. This would allow these students to practice more and build their confidence which could lead to them attempting more challenging problems once they are more confident. We could also continue to foster a growth mindset by including hints for the challenge problems so that students have more support when they attempt a challenge problem (Dweck, 2008).

It is important to note the extended feedback surveys conducted with the option to answer the survey online, or via a Zoom interview or phone call. Had John chosen to speak via Zoom or phone, there could have been more chance for dialogue. Despite this limitation, case studies such as this help us understand how to expand the KiSS program to best serve our students.

This study examined how transfer mathematics students reflected on their experiences with remote, online-instruction caused by the COVID-19 pandemic. Using a model of knowledge-sharing communities, we sought to better understand any challenges they faced and adjustments they made to support their learning. Through qualitative data analysis of semi-structured individual interviews with two transfer mathematics undergraduates, we found that students were aware of the difficulties they faced with a new class structure and with building community. To attend to these challenges, students exhibited a high level of agency in generating virtual communities to simulate the level of connectivity that in-person instruction affords; they perceived these communities as salient to their learning. Our findings can potentially inform instructors on practices that better support community building.

Keywords: Undergraduate Education, Online and Distance Education, Technology

Introduction

The landscape of higher education has shifted to an online and remote setting as a result of the COVID-19 pandemic. This drastic pivot in instruction became the impetus for challenges and adversities students had likely never encountered in their learning. One such challenge was the increased difficulty in community building and fostering interpersonal relationships. Integration into a community, both academically and socially, has been shown to strengthen individuals' commitment to education and their respective institutions; conversely, the lack thereof increases the likelihood of departure from a student's institution (Tinto, 2019). This poses a problem for university retention, particularly for transfer students during COVID-19. Transfer students tend to come from low-income households, identify with marginalized communities, and follow non-traditional paths to universities (Berger & Malaney, 2003). They arrive at universities already facing social challenges related to community building (Rhine et al., 2000), and this adversity is likely exacerbated by the remote learning environment brought upon by COVID-19. This study attempted to understand how transfer mathematics students perceived online instruction and engaged in community building to potentially inform mathematics instructors on practices that fostered connectivity and community. The research question of this study was: How did transfer mathematics students adjust to challenges at their new university during online remote learning?

Framing

This study used Yoon and Rolland's (2012) model of knowledge sharing in virtual communities as the conceptual framework to understand the processes in which the mathematics transfer students created and engaged with communities during this period of online remote instruction. This model is founded on self-determination theory, which concerns how people determine their choices motivated by psychological needs in the absence of external influence (Deci & Ryan, 1985). Yoon and Rolland's model investigated the effect of "psychological needs – perceived competence, perceived autonomy, and perceived relatedness – on knowledge-sharing behaviors in virtual communities," while also looking at the role of familiarity and anonymity with these needs (2012, p. 1133). Specifically pertinent to this study, perceived relatedness (the feeling of connection to others) and competence influenced knowledge-sharing behaviors. Our study involved virtual communities in which knowledge-sharing and online interaction were a means of learning, so this work helped us understand how students recognized their needs and were motivated to create a virtual community.

Methods

This study was conducted as part of a larger project exploring students' experiences in a set of mathematics courses supporting their transition to the university. Eleven undergraduate students in a Minority-Serving Institution in California participated in the study, and we used purposeful sampling (Patton, 2002) to select the two transfer students. One self-identified as male (Nathan – a pseudonym, used for all proper nouns), and one self-identified as female (Ava). In Fall 2020, both students took three mathematics courses: Course A (a transition to higher mathematics course, which introduced students to mathematical proof writing), Course B (an academic and career advising course), and Course C (an elective course that provided a space to further develop proof-writing and learn the expectations for higher level mathematics courses). The latter two courses were taken by the same set of transfer mathematics students and were specifically created in an attempt to ease the transition to the university.

In the subsequent quarter, we conducted and video/audio-recorded semi-structured interviews via Zoom (Rubin & Rubin, 2011). Students were asked to reflect on their experiences related to their enrollment in the set of courses, with special interest to how COVID-19 affected their learning experiences. The interview protocol included questions pertaining to academic and social challenges that students faced as a result of the remote-online format.

We qualitatively analyzed students' responses by watching the videos of the interviews, writing memos, and coding. Using descriptive, open coding (Strauss & Corbin, 1990), we identified themes around students' experiences with community during remote instruction brought upon by COVID-19 and generated these initial codes: Anticipation of Worsened Instruction and Connections, Instructor Challenges, Instructor Adjustments, Student Adjustments, and Impact. We then regrouped and categorized the coded data into two larger themes: *Challenges with Online Instruction* and *Student-Generated Community.*

Findings

We found that collectively, in the era of COVID-19, incoming mathematics transfer students transitioning into a four-year university yearned for and sought to develop a mathematics community. The findings are organized on the final two themes related to students' experiences during online instruction: the challenges of online instruction and the subsequent response of the student-generated online community.

Challenges with Online Instruction

Class Structure. Instructors' structure and effort varied between courses. For instance, the Course C instructor posted recorded lectures online and used designated class time as office hours, while Nathan's Course B instructor held optional synchronous lectures and posted recordings online. Regarding synchronous lectures, Nathan explained:

> [Online lectures] go faster than they would if it was an-in person class, so ...you're still writing things down, and they ask if there's any questions, but you're not even finished writing down...so your brain hasn't caught up to see if you can ask the question.

The online setting largely impeded the (often nonverbal) feedback between instructor and students, so feedback had to come and be elicited actively and intentionally. Additionally, some instructors seemed uninterested in mitigating these challenges. Nathan said positive things about his instructors' effort, whereas Ava mentioned that one of the professors engaged students as minimally as possible in the online format. When asked to elaborate, she said, "it was just [my Course A professor's] screen [in lectures] so, I actually don't know [what] my professor looks like. Actually, even during office hours, it was his name, it wasn't his face." Even though this professor hosted office hours, as mandated by the university, he did not appear to demonstrate much effort into building connections or increasing his approachability with his students, according to Ava. COVID-19 challenges may have impeded further interaction with students.

Community. Though both students felt that class sessions had worse instruction compared to in-person, they expressed concerns about their social needs too. Ava stated, "I didn't think I would meet as many people...and...was really nervous definitely about the social aspect because friends...and making those kinds of connections are really important to me." Ava emphasized the importance of making connections and anticipated that developing friendships with her peers would be a challenge. Similarly, Nathan acknowledged that the online format posed difficulties for both students and professors within the class sessions. He shared, "It is also hard on teachers, I think, to create a sense of community...because the majority of students aren't going to have their cameras on and they're not going to ask questions verbally. They'll just put it on the chat." Given the difficulties posed by online instruction, class activities were not a significant contributor to students' sense of community.

Student-Generated Community

Emergence. In-class structures did not foster the same level of community that may have naturally emerged from sharing the same physical space, so students actively invested time and effort outside of designated class time to engage with the course content. In particular, students used social media to create a learning community that would not have existed otherwise. Both Nathan and Ava noted Discord – an online platform with text and video chat, often used by gamers – as an integral piece to their experience. Discord was first used in Course B class, when a student created a channel for the class. Nathan explained, they "were kind of able to bond, and so [they] created some other channels." This online community emerged out of the desire for community and to have a more accessible space to engage with their coursework with other students. The students even invited their Course B instructor, Delilah, to join the channel, Nathan shared that this created a "simulated classroom environment in a way." In other words, the Discord channels provided aspects of an in-person classroom that the actual class sessions did not. Students were aware of the primary role they had in creating community in this online setting. Nathan said, "my classmates, I think, have done a pretty good job of creating a sense of community, even if the teachers aren't necessarily facilitating that – …it's been kind of more student-driven just because of the Discord server."

Impact. The transfer students perceived the presence of an online student community as beneficial. Both students spoke at length about its academic and social benefits; Ava explained it connected a "network of people…who were all going through the same thing and [struggling] to find the answers.". Students' mutual struggle served as a catalyst for meaningful interactions, and, as a result, Nathan considered his classmates "genuine friends, which is cool because...that is hard to do strictly online." Ava expressed even more pronounced sentiments, describing someone she met through Course B as being "her best friend in the whole world," who she stayed in contact with through Discord despite no longer having a class together. Moreover, the use of Discord led to transfer students' inclusion into larger online communities associated with the university. Ava shared that, after being exposed to Discord and integrating into the Course B created community, she was now in a larger student-run server that has existed for a few years. She described it as: "nothing official but has like a couple thousand or a couple hundreds of people in there and that's just everybody, just any student [at the university]." Both students felt that a student-generated online community in which mutual-participating was required had a positive impact in their remote, academic transition to their receiving four-year institution.

Discussion & Conclusions

During COVID-19, schools have transitioned to remote learning, often leaving students challenged to find their alternative means for making connections with other students. Using a qualitative analysis approach allowed us to examine how transfer students in these mathematics courses developed an online knowledge-sharing community. It is crucial that educators focus on this population of transfer students, as nearly 84% of those who utilize the community college pathway are underrepresented minoritized students and 50% of U.S. of transfer students intend on pursuing a STEM degree after community college (Starobin & Lanaan, 2005; Zhang 2019).

Moreover, examining the transfer mathematics student experience is of importance because there is currently very little research on supports that may assist them in their academic and social transition to a four-year university. Yoon and Rolland (2012) provided a theoretical lens to examine the relationship between relatedness and knowledge-sharing. The exacerbated social need imposed by COVID-19 prompted students to adapt and build an online community that fostered relatedness amongst the students and was conducive of knowledge-sharing interactions. Transfer students enrolled in the cohort-style courses supported each other by creating servers on Discord for themselves. On Discord, these students participated in a virtual community, where they shared important mathematics concepts pertinent to their coursework. We believe that these knowledge-sharing interactions contributed to the perceived competence of all members of the community. Future research can attend to the ways that knowledge-sharing activities influence perceived competence and relatedness.

NURTURING STUDENTS' UNDERSTANDING OF AREA THROUGH VARIATION: A CASE STUDY

Pingping Zhang
Winona State University
pzhang@winona.edu

Azita Manouchehri
The Ohio State University
manouchehri.1@osu.edu

The theory of variation (Marton & Booth, 1997) has been mostly used as a task/instructional design principle in classroom settings. In other words, studies tend to look at what is made possible to discern rather than how the discernment may happen in the interaction with the students (Kullberg et al., 2017). The purpose of this paper is to shed a light on how a 7th grade student's understanding of area progressed when prompts guided by the theory of variation were provided within a one-on-one interview setting. The concept development framework (Zhang & Manouchehri, 2016) was used to identify the student's understanding for the concept of area. The results suggested that the student's understanding significantly shifted through a series of prompts.

Keywords: Learning Theory, Measurement, Middle School Education

Various methods have been suggested by the mathematics education community to develop children's understanding of area, such as using multiple representations and real-world situations, connecting between the formulas for calculating area and the visual relationships (Barrett, Clements, & Sarama, 2017), and scaffolding along the concept developmental stages (Battista, 2012; Zhang & Manouchehri, 2016). This paper will focus on achieving such goal through the theory of variation (Marton & Booth, 1997) and unpack Jazzy's case where she worked on an area problem.

The Theory of Variation

Marton's theory of variation (Marton & Booth, 1997) posits that learning is the process of developing an awareness of critical aspects and features of a target knowledge. Such a process can benefit from a change in the presentation, or a variation, of the critical aspects and features, which could promote effective discernments towards these aspects and features. Marton and Pang (2006) identified four patterns of variation, including *contrast* (looking at different values of the same aspect), *generalization* (looking at different appearance of the same value), *separation* (changing the values of some aspects while keeping the other aspects the same), and *fusion* (looking at all the critical aspects at the same time). These four patterns provide a general idea on how to construct activities to promote learning of the targeted knowledge.

The theory of variation has been mostly used as a task/instructional design principle in classroom settings. In other words, studies tend to look at *what* is made possible to discern rather than *how* the discernment may happen in the interaction with the students (Kullberget al., 2017). Hence, the purpose of this paper is to shed a light on how a student's understanding of area progressed when prompts guided by the theory of variation were provided within a one-on-one interview setting.

Framework for the Concept of Area

The concept development framework used to identify the student's understanding for the concept of area in this paper was developed by Zhang and Manouchehri (2016). According to

Zhang and Manouchehri, the framework breaks the development into three phases: heap, complex, and concept. In the *heap* phase, the learner associates an object with another because of physical context instead of any mathematical property of the objects. In the *complex* phase, objects are related in one's mind not only by their impressions, but also by concrete relationships between them. In the *concept* phase, the relationships between objects are abstract and logical. Each phase further contains various stages; see the full framework in Zhang and Manouchehri (2016).

The concept formation framework is composed of three major components: non-measurement reasoning, unit area, and formula. This paper mainly reveals the shift of the formula component under the prompts guided by the theory of variation.

Methods

Participant and Data Collection

Jazzy was enrolled in an extracurricular program and routinely participated in one-on-one interviews with the authors from grade 6 to 8. In these interviews, she was asked to solve various mathematical problems while giving detailed explanation of her thinking process. There was no time limit on each problem and each interview was video recorded and there was no time limit on each problem. She had access to markers, poster paper, and a calculator during the interviews. In general, the interview protocol restricted the interviewers from giving any explicit instructions and only allowed them to ask clarification questions. Jazzy was in 7th grade when she completed the interview episode in this paper.

Contexts

Jazzy was asked to solve the problem below. This was one of the problems where she concluded that she couldn't solve within a short period of time.

Table 1. Compare Triangle problem

	Consider the graph on the left: Which triangle has a bigger area, triangles BEC or triangle BFC?

Jazzy spent a total of 2.5 minutes solving the problem. She first asked for numbers before attempting to solve it, then stated that triangle ABE and triangle CDF (part of the outer area of each target triangle) looked very different so she couldn't tell. As a follow up of her initial request, the interviewer provided her two hypothetical numbers, where BC was 10 units long and AB was 5 units long, and asked her whether she could solve the problem with the given information. Jazzy explained that she needed to further figure out the lengths of AE and DF, hence there was not enough information to answer the question. At this point, the interviewer acknowledged her conclusion and started the second part of the interview, which last 8 minutes. Jazzy attempted to solve the problem in terms of both non-measurement (comparing the outer areas) and measurement (finding the lengths of sides) reasonings before the interviewer stepped in, which revealed an understanding at a lower Complex stage for the concept of area, i.e., comparing parts randomly and (attempt at) using incorrect formula.

Results

Since little of what Jazzy knew was revealed in the first part of the interview, the interviewer started by asking her how to find the area of a triangle. Jazzy almost immediately wrote down the formula, $\frac{1}{2}bh$. The interviewer continued to ask what the formula meant for her and asked her to draw a picture to show how the formula worked (visually). Jazzy drew a right triangle and labeled the two legs as height and base (Figure 2.1) and explained that you multiplied them together and then multiplied by a half. The interviewer asked Jazzy why we multiplied them together and multiplied it by one half. She immediately drew a triangle to form a rectangle (Figure 2.2) and explained that the area of a rectangle was height multiplied base and the triangle was only half of the rectangle, hence you multiplied it by one half.

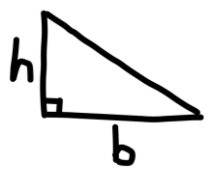

Figure 2.1: Jazzy's Illustration of the Triangle Formula

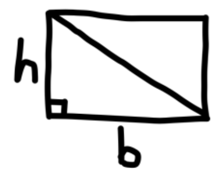

Figure 2.2: Jazzy's Explanation of the Triangle Formula

The interviewer followed up her response by asking whether the formula was only true for right triangles. Jazzy hesitantly said no. The interviewer asked her to draw a scalene triangle and show the formula still works. This time she drew an isosceles triangle; she acknowledged that it was not scalene but the interviewer encouraged her to continue with it. She identified the height of the triangle and marked the height and the base correctly, then shaded the left half of the triangle, drew it on the top-right side to complete the rectangle, and explained that "this side can be flipped here to make a rectangle" (Figure 3.1).

Since the second example Jazzy chose was plausible for her argument, the interviewer drew another example (Figure 3.2) and asked whether this case would be true according to her reasoning. Jazzy hesitantly said no, "but the formula is supposed to work, I don't know why."

Figure 3.1: Triangle Formula for a Non-right Triangle

Figure 3.2: Example Provided by the Interviewer

At this point the interviewer acknowledged her responses and redirected her to the original question (Table 1) by asking whether we could use the formula here. Jazzy thought for a few seconds and said "oh, I see." She drew the heights of both triangles and marked them as 5, then stated that the base for both was 10, hence they had the same area.

The interviewer continued asking whether they would still have the same area if the given numbers were different, such as 30 units and 40 units instead of 5 units and 10 units. Jazzy proceeded to conclude that the areas would be the same because the base would be 40 and the heights would be both 30. The interviewer finally asked what if we didn't have the measurements. She promptly answered that it wouldn't matter because the base and height would always be the same between the two triangles.

The interviewer moved on to provide a follow-up problem, where the two triangles were imbedded in a trapezoid instead of a rectangle (Figure 4.1). Being asked to compare the areas between triangle ABC and triangle BCD, Jazzy answered that they would be the same after thinking for 4 seconds. She further drew the heights of the two triangles and explained that they were the same since the base was also the same.

At last, the interviewer drew a different trapezoid (Figure 4.2) with two triangles inside and asked the same question. Jazzy was able to quickly conclude it would be the same because of the same base and the same height, which marks the end of the interview.

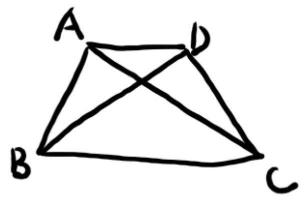

Figure 4.1: A Varied Problem Provided by the Interviewer

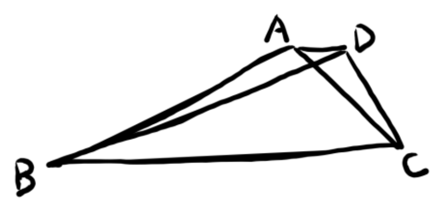

Figure 4.2: A Different Trapezoid Provided by the Interviewer

Discussion and Conclusion

Jazzy's initial understanding of the area formula was at a lower Complex stage, i.e. only used under specific occasions, which was revealed by her explanations on a right triangle and an isosceles triangle. The lower stage of understanding is possibly why she knew the formula but couldn't use it to solve the problem even with the given measurements.

The first example provided by the interviewer (Figure 3.2) was a generalized version of the two triangles in the original problem (*generalization*). Although Jazzy didn't have enough time to figure out how to adjust her reasoning to fit the new situation, she was able to make the connection between the generalized triangle to the two triangles in the problem. When the interviewer provided different measurements or even omitted the measurements (*contrast*), Jazzy focused on the fact that the base and the height were the same. Such focus was extended to the last two examples provided by the interviewer (Figure 4.1 and Figure 4.2), where the rectangle was replaced by a trapezoid (*separation*). This is considered as an understanding at the highest Concept stage for the concept of area. A potential *fusion* question could be to ask her to look at the three forms of reasoning, non-measurement, measurement, and formula, and make sense of her final answer with the two initial (failed) approaches.

In conclusion, Jazzy's stage of understanding for the concept of area significantly shifted through a series of prompts guided by the theory of variation. When the interviewer provided various measurements, she forced Jazzy to contrast her current understanding of the problem. In doing so, Jazzy was able to notice the target aspect (same base and same height) and retain the observation when one condition was changed (triangles inside of a trapezoid instead of a rectangle). For future study, it would be beneficial to test whether the improved understanding can transit under a different context in a problem-solving setting.

However, it is worth noticing that although Jazzy didn't figure out how the formula works for a scalene triangle, it did not restrain her from using the formula in a generalized way. It is plausible to argue that understanding how the formula (visually) works is not necessary to solve this problem, hence the interviewer did not focus on that part. Problems requiring such understanding to solve can be used to study those discernments.

CALCULUS INSTRUCTION AND FEMALE SENSE OF BELONGING

Casey Griffin
University of Delaware
crgrif@udel.edu

Women continue to be underrepresented in undergraduate science, technology, engineering, and mathematics (STEM) majors. Low sense of belonging and poor instruction in introductory STEM courses, especially Calculus, have been identified as key contributors to women leaving STEM. Incorporating active learning has potential to support female students in developing a stronger sense of belonging and persisting in STEM. This study investigates the instructional experiences and sense of belonging of female students enrolled in two versions of introductory Calculus – a standard course and a non-standard course infused with active learning. Females in the active learning course reported significantly higher sense of belonging and greater impact of instruction on their sense of belonging than female students in the standard course.

Keywords: Affect, Emotion, Beliefs and Attitudes; Calculus; Gender; Undergraduate Education

Problem, Perspective, and Purpose

Women continue to be underrepresented in undergraduate science, technology, engineering, and mathematics (STEM) majors (e.g., Chen et al., 2013; PCAST, 2012; Seymour & Hunter, 2019). Fewer females than males enter STEM majors, and more females than males switch out of STEM majors (Pryor et al., 2009; Eagan et al., 2013). In fact, women are 1.5 times more likely to leave the STEM pipeline compared to men (Ellis et al., 2016).

Sense of belonging can play a crucial role in females' decisions to persist in STEM (Shapiro & Sax, 2011). Sense of belonging is a "sense of being accepted, valued, included, and encouraged by others (teachers and peers) in the academic classroom setting and of feeling oneself to be an important part of the life and activity of the class" (Goodenow, 1993, p. 25). Research indicates that female students typically report a lower sense of belonging than male students in STEM courses (Shapiro & Sax, 2011; Rainey et al., 2018).

Rainey et al. (2018) conducted an interview study with 201 college seniors who were categorized as either STEM majors or STEM leavers about their sense of belonging in STEM. Students, especially females, cited interpersonal relationships as a major contributor to their feelings of belonging in STEM. Here, an interpersonal relationship means "feeling socially connected or similar to those around them in their STEM major" (p. 7).

Calculus is a critical course for STEM majors and a key juncture at which students decide whether to persist in STEM (Ellis et al., 2014; Rasmussen et al., 2013; Seymour & Hunter, 2019). Students have reported poor instruction in their foundational STEM courses as a major reason for leaving STEM -- citing Calculus in particular (Rasmussen et al., 2013; Seymour & Hunter, 2019). Seymour and colleagues (Seymour & Hewitt, 1997; Seymour & Hunter, 2019) report that students prefer teaching that is engaging and interactive and are less tolerant of poor teaching (i.e., instruction that is boring and lacks engagement) now than they were 20 years ago.

One approach that offers promise in addressing students' concerns about poor instruction and developing their sense of belonging is active learning. Active learning opportunities engage students in "the process of learning through activities and/or discussion in class, as opposed to passively listening to an expert" (Bonwell & Eison, 1991, p. iii). Using group work, class discussions, and student response systems (e.g., clickers) are some ways in which instructors can provide active learning opportunities. Instruction that includes active learning offers opportunities for students to interact with each other and their instructor, thus creating potential for building interpersonal relationships and thus strengthening their sense of belonging. Moreover, research indicates that students who engage in active learning have higher levels of achievement and persistence than students without these opportunities (Freeman et al., 2014; Lahdenperä et al., 2017; Rasmussen et al., 2019) and that women learn better in an active and collaborative learning environment (Shapiro & Sax, 2011; Kogan & Laursen, 2014).

This study compares female students' sense of belonging in two versions of introductory Calculus at the same university, and investigates how instruction might impact their sense of belonging. I address the following research questions: (1) How does female students' sense of belonging in an active learning Calculus course compare to female students' sense of belonging in a standard Calculus course? and (2) How do female students in an active learning Calculus course and a standard Calculus course characterize the impact of the instruction on their sense of belonging?

Methods

Setting and Participants

This study was conducted at a mid-sized R1 research university in the mid-Atlantic region of the U.S. during the Fall 2020 semester. The university offers two pathways for Calculus I – a standard one-semester course and a two-semester Integrated Calculus course designed to incorporate active learning. Both courses are taken primarily by freshmen, are coordinated, and use the same textbook (Stewart, Clegg, & Watson, 2021).

The standard Calculus course is typically taught in a large auditorium with lecture as the primary means of instruction. Students enrolled in this course typically intend to major in STEM. The course is coordinated in the sense that there is a common textbook and common exams. In the Fall 2020 semester, a mix of permanent and temporary faculty taught 8 sections of the course, each capped at 100 students. Due to the COVID-19 pandemic, the course was taught in a synchronous virtual format over Zoom. For the remainder of this paper, this course will be referred to as C-S.

The active learning Calculus course is typically taught in a classroom in which students sit at round tables and work together on math problems during class. Students are typically freshmen who need Calculus for their intended major but have not yet mastered all of the pre-calculus prerequisites. The first semester of the course, which is the focus of this study, develops differential Calculus, weaving in necessary pre-calculus topics as they arise. The second semester (which is not the focus of this study) develops integral Calculus, again weaving in necessary pre-calculus topics. The course is highly coordinated. In addition to common textbooks and exams, instructors teach from common lesson plans specifying which problems students work on each class, and whether they will be discussed as a whole class or in small groups. In the Fall 2020 semester, the university offered 2 sections taught by permanent faculty, each capped at 50 students. However, due to the COVID-19 pandemic, this course was also taught synchronously via Zoom. To maintain opportunities for group work, instructors used Zoom's breakout room functionality. For the remainder of this paper, this course will be referred to as C-A.

Participants were students enrolled in one of two sections of C-S taught by the same instructor and students enrolled in either section of C-A. These students received an email inviting them to participate by completing a survey about their experience in the course. In C-S, 77% (N=158) of 198 students and in C-A, 88% (N=80) of 91 students completed the survey. For this study, only students who were freshmen and self-identified as female were considered, resulting in a final sample size of 44 C-S students and 37 C-A students.

Data Collection and Analysis

The survey was distributed and completed electronically using Qualtrics, a web-based survey tool, during the eleventh week of the fourteen-week semester. To collect information about students' sense of belonging in the course, Good et al.'s (2012) Mathematical Sense of Belonging (MSoB) instrument was incorporated into the survey. The MSoB portion consists of 30 Likert items asking students to indicate the extent to which they agree with statements about their feelings of belonging in the course on a scale of 1 (Strongly Disagree) to 8 (Strongly Agree). To collect information about how students experienced the instruction, students were asked to indicate how often they experienced each of eight instructional strategies, and to identify the three most frequently used strategies. The strategies were chosen based on typical active learning instructional practices (e.g., group work), as well as strategies known to be used in at least one of C-S or C-A (e.g., lecture). To investigate how students characterized the impact of the instruction on their sense of belonging, students were asked to rate the type of impact (positive, neutral, negative) each instructional strategy had on their ability to form interpersonal relationships, a key component of sense of belonging.

Mean responses were calculated for sense of belonging and tested using IBM SPSS Statistics (Version 27) predictive analytics software. Independent samples t-tests were used to determine differences in mean responses between C-S and C-A students with $p<0.05$. To capture students' perceptions of the instruction they experienced, frequencies were computed to determine the percentage of students who reported experiencing each strategy. These proportions were tested with a two-sample proportion z-test with $p<0.05$ to determine significant differences between strategies used in the two courses. Effect size was calculated using Cohen's (1988) benchmarks for d. Finally, to investigate the relationships between the types of instructional strategies and students' abilities to form relationships, frequencies were computed to determine the percentage of students who reported each type of impact.

Results

Students' responses to the MSoB portion of the survey were used to measure their sense of belonging. Results showed a statistically significant difference ($t=3.581$, $df[79]$, $p=0.001$) with females in C-A (Mean=6.95, StDev=1.07) reporting a higher average sense of belonging than females in C-S (Mean=5.97, StDev=1.34). The effect size is large (Cohen, 1988, $d=0.80$), suggesting a substantive difference between the two groups.

To understand how students perceived their Calculus instruction, they were presented with eight instructional strategies and asked to identify the three most frequently used. In each course, only two strategies were selected by more than 55% of students. The percentage of students who identified each of these strategies as most frequently used is presented in Table 1. C-S students were significantly more likely to report working on problems individually and lecture; C-A students were significantly more likely to report group work and their instructor asking for their responses. These data indicate students perceived very different forms of instruction in the two courses, with C-A students reporting more opportunities for active learning.

Students were asked to indicate the type of impact (negative, neutral, positive) that each instructional strategy had on their ability to form relationships with their classmates and with their instructor. Table 2 presents the percentage of students indicating each type of impact for the two most frequently reported instructional strategies in each course. In terms of their ability to form relationships with classmates, less than 40% of C-S students reported that the most frequent instructional strategies had a positive impact. The majority of C-S students reported a mostly neutral impact (57% for individual work and 55% for lecture). In contrast, the vast majority of C-A students reported a positive impact (98% for group work and 78% for soliciting student responses). In terms of their ability to form relationships with the instructor, C-S students reported the most frequent instructional strategies had a mix of positive and neutral impacts. In contrast, students in C-A reported a mostly positive impact. Thus, a higher percentage of C-A students reported a positive impact of the most frequent instructional strategies on their ability to form interpersonal relationships, a key component of sense of belonging.

Table 1: Percent of Female Students in C-S and C-A Selecting Each Instructional Strategy as One of the Three Most Frequently Used.

	C-S	C-A	*z*	Cohen's *d*
Students work on math in groups	20%	97%	-6.94***	2.72
Students work on math individually	93%	8%	7.65***	2.78
Instructor asks for student responses	16%	81%	-5.85***	1.72
Instructor lectures	84%	41%	4.03***	1.13

Asterisks denote the p-values (for p<0.05, ** for p<0.01, and *** for p<0.001 significance levels).*

Table 2: Percent of Female Students in C-S and C-A Indicating What Type of Impact Each Instructional Strategy Had on Their Ability to Form Relationships.

		Relationships with Classmates			Relationships with Instructor		
	Impact	Positive	Neutral	Negative	Positive	Neutral	Negative
C-S	Individual Work	37%	57%	2%	48%	45%	5%
	Lecture	34%	55%	12%	66%	32%	2%
C-A	Group Work	98%	3%	0%	73%	27%	0%
	Student Reponses	78%	22%	0%	94%	3%	3%

Note: Percentages may not add to 100%, as students were able to select "This does not happen in my class" as a response to this question.

Conclusions

Female students in the active learning Calculus course (C-A) reported a significantly higher sense of belonging, more opportunities for active learning during class instruction, and more positive impacts of instruction on their ability to form relationships (a key contributor to sense of belonging) than their female counterparts in the standard Calculus course (C-S). While this study's design does not allow for causal claims, these findings suggest a link between opportunities for active learning and female students' sense of belonging in Calculus. Perhaps increasing opportunities for active learning in introductory STEM courses like Calculus will help retain more female students in STEM. Further research should investigate these potential relationships, including the kinds and frequency of active learning opportunities needed to make an impact.

DEVELOPMENTAL MATHEMATICS STUDENTS' PERCEPTIONS OF (RE)LEARNING OUTCOMES: THE VALUE OF ALGEBRA ALL OVER AGAIN

Kristen Amman
Rutgers University
kristen.amman@gse.rutgers.edu

Juan Pablo Mejía Ramos
Rutgers University
jpmejia@math.rutgers.edu

We report findings from an exploratory study on developmental mathematics students' perceived experience re-learning content they had already studied in middle- or high-school. Our findings suggest that these experiences are largely shaped by students' expected and perceived learning outcomes associated with that content. We describe how six of those learning outcomes depend on students' confidence in their previous understanding of the content to be re-learned, and how those learning outcomes influence students' modes of engagement during (and emotional reactions to) their re-learning experience.

Keywords: Affect, Emotion, Beliefs, and Attitudes; Algebra and Algebraic Thinking; Developmental Education; Undergraduate Education

Developmental (or remedial) education courses are commonly offered at U.S. colleges and universities for students that are deemed underprepared for "college-level" work in mathematics, reading, or writing. Traditional developmental courses are often nestled within a sequence, meaning that a student needs to pass multiple courses before enrolling in a credit-bearing course of the same subject. The Conference Board of the Mathematical Sciences Survey (CBMSS) found that in Fall 2015 approximately 41% of all two-year college and 11% of all four-year college and university mathematics and statistics enrollment was in developmental courses. Despite this sizable enrollment, only an estimated 50% of students beginning at public two-year institutions and 58% of students beginning at public 4-year institutions pass or earn some credit for all the developmental mathematics courses (DMCs) they attempt to take (Chen, 2016). Reasons for these failure rates have been proposed at various levels, but most research has focused on entry and exit problems with the developmental course sequence such as placement and attrition (e.g. Bahr, 2008a; Bahr 2012a; Bailey, Jeong & Cho, 2010). Grubb (2001) referred to this approach as contributing to the "black box" problem of teaching and learning in DMC (Grubb, 2001). These studies give us a broad sense of the paths students take to credit-bearing courses, but leave the reasons for rates of attrition, passing, and graduation obscured. Accordingly, he called for more research that characterizes student experiences in developmental mathematics programs and identifies aspects that appear to be critical to the formation of end-of-course outcomes over time. This exploratory study began to fill this gap in the literature by describing student experiences with content through the theoretical lens of *relearning,* or the experience of trying to learn about something one has already tried to learn about before. Relearning is an interdisciplinary phenomenon that has been studied more narrowly in the fields of cognitive psychology and preservice teacher education. This study utilizes an expanded conceptualization that cuts across these fields in order to characterize student experiences with a critical and highly critiqued component of developmental mathematics courses: repeated content.

Theoretical Framework: Relearning

Student experiences in DMCs involve significant amounts of time learning about content students have seen before, either from a previous K-12 mathematics course or from a previously-attempted DMC (Ngo & Velasquez, 2020; Fay, 2020). This similarity to content seen before is a point of *concern* for developmental math educators. Stigler, Givvin and Thompson (2010) summarize student experiences in DMCs as being, "presented the same material in the same way yet again" (p. 4). Likewise, Ngo (2020) described them as "high school math all over again," after finding that approximately 2/5 of all students in DMCs had demonstrated some degree of proficiency with course content in high school. Despite this distinctive and recurring feature, there are almost no studies that focus on student perceptions of their experience learning about content seen before, or "relearning". Thus far, usage of the term "relearning" for the purposes of research has been unnecessarily restrictive. For over 100 years, relearning has been used in studies of memory in cognitive psychology to describe the experience of committing to memory what one has already memorized (Ebbinghaus, 1885; Nelson, 1985; Bahrick, 1979). Recently the concept of 'successive relearning' has been applied to college classrooms to maximize retention of course material (Dunlosky & Rawson, 2015; Janes et al., 2020; Rawson, Dunlosky & Janes, 2020). This usage focuses on content that is considered to be learned when it is memorized and is capable of being demonstrated in one experimental session. Likewise, Zazkis (2011) proposed the term 'relearning' to better describe the experiences of preservice teachers in their mathematics content courses, in which pre-service teachers "revisit and reconstruct" what was previously learned (p. 12). According to this definition, students are only relearning if they are expanding the "domain of applicability" of their content understanding, or correcting "prior misleading learning" (Zazkis & Rouleau, 2018).

We suggest that these prior conceptualizations are instances of the same underlying phenomenon which also exists in DMCs. At the most basic level, relearning requires three things: some (mathematical) content, a "time 1" (T1) representing a past occurrence when an individual tried to learn about that content, and a "time 2" (T2) representing a most recent time when that individual tried to learn about that same content again. While the content at T1 and T2 need not be identical, it does need to cross a threshold of similarity such that the learning goals with respect to that specific content at T2 are essentially the same as those at T1. Although the name re-*learn*ing suggests some degree of mastery of the content at T1, we make no such assumption. The goal of this exploratory work was to utilize the lens of relearning to describe student experiences with content seen before. Using a conceptualization that cuts across these fields will help us better understand both context-specific features of DMC that contribute to its unique and troubling outcomes, as well as suggest avenues for future research among other fields that share this phenomenon.

Methods

This was a multiple-case study in which three Intermediate Algebra students participated in one-hour, semi-structured interviews before and after learning about a topic they indicated they had seen before in a previous algebra class (Equations of a Line and Polynomials). Simon and Zarah were students of Instructor A and had never previously taken an algebra course in college. At the time of data collection (in Spring 2020), Simon was an 18-year-old, first-year student, while Zarah was a 19-year-old, second-year student. Valeria (a 20-year-old, third-year student at the time of the study) was in Instructor B's class and had previously taken three algebra courses in college. Both Instructor A and B were recommended by the head of the department for their quality of instruction, and as many participants as possible were recruited through an online survey. All course meetings in which these topics were covered were observed and recorded. In interview 1, students were asked to describe their past history learning about the topic, confidence in their current understanding, and to predict what the experience of learning about the topic again would be like. In interview 2, after the topic had been taught, students were asked to describe what it was actually like to learn about the topic again, including how predictions aligned with what actually occurred. Discussions were anchored in problems gathered from field notes or student work as often as possible. A discussion of instructor interviews and student follow-up interviews is beyond the scope of this report, so the results reported here focus student interviews from the Spring 2020 semester. Interviews were transcribed and analyzed using a modified thematic analysis. While data collection was guided by specific theoretical propositions, the novelty of the research called for a more exploratory approach. Coding proceeded in five stages beginning with in vivo coding (Creswell, 2007) and progressing to a modified thematic analysis (Braun & Clarke, 2012) as familiarity with the dataset increased.

Results

Student descriptions of their experience with relearning, both expected and perceived, were centered around multiple types of learning outcomes. This was *not* a grade or an indication of passing/failing. In asking what was learned in a relearning scenario, we mean to answer the question: what was the value of students' learning experience in terms of their understanding of content *this time around*? The answer to this question requires one to reference, in some way, the content that was learned before which a feature unique to relearning scenarios. Zazkis' notion of reconstruction is an example of such a learning outcome in the field of teacher education. Unlike Zazkis, however, we found that students described more than one learning outcome both when talking across sub-topics and comparing expected and perceived outcomes across interviews (interview 1/I1 and interview 2/I2 below). Students described six types of learning outcomes:

- Gain a Deeper Understanding: Seeing previously-learned material in a new way and using this shift in perspective to gain a "deeper" understanding than they did before. (Zarah, I2)
- Confirm my Understanding: Feeling they already know the content and seeing relearning it as verifying their understanding is adequate. (Simon, I2; Zarah, I1, I2; Valeria, I2)
- Jog my Memory: Experiencing relearning a given content as simply refreshing their memory of material they feel they understood well at some point, but have since forgotten. After the class is completed, they do not feel like they require further practice. (Simon, I1, I2; Zarah, I1, I2; Valeria, I1, I2)
- Reconstruct Memory with Guidance: Reconstructing their memory of previously-learned material with the guidance of an instructor to avoid remembering things "incorrectly". After the class is completed, they require further practice. (Zarah, I2)
- Fix Past Mistakes: Addressing what students identify as inadequate understandings of course material gained from past experiences. (Valeria, I2)
- Accept What I Don't Understand: While perceiving to hold an inadequate understanding of course material gained from past experiences, students see themselves as being unable to address this understanding and either accept or avoid it. (Valeria, I1; Simon, I2)

While the codes are not ordered hierarchically, they were each associated with a degree of confidence in the student's perception of their current understanding of the re-learned material. 'Reconstruct my Memory with Guidance', for example, was associated with a lower degree of confidence, as students felt that they understood the material enough to partially rely on memory, but not well enough to do so without significant assistance from an instructor. Crucially, discussions of their expected and perceived learning outcomes were associated with particular methods of engagement with re-learned material and affective dispositions while re-learning. For example, in Interview 2, Valeria described different anticipated learning outcomes for sub-topics within the polynomials unit. She sometimes found herself frustrated with the experience of going over content that she already understood (confirm my understanding) to the point where she saw little value in paying attention during class.

> Valeria: Polynomials is just like, a thing to me like I honestly could care less. So when I know, I know. I'm like, I'm kind of getting lazy with this, cause this is like the third time of taking this class…Like if, like when she starts doing examples and I do them on my own and get the right answers, like maybe she'll do five and I get the first three right then I'm like I don't really need to pay attention any more. So then I'll just either like daze off or like go on my phone to be honest.

However, for other sub-topics that she found more difficult, Valeria's experience was dominated by avoidance behaviors and anxiety gained from her past history with algebra. When discussing factoring techniques she remarked, "If [a polynomial] has a number in front of the x^2 one then I'll usually just sit there and just stare at it, but if it doesn't then I can usually just do it...I think it just scares me or something. It just like scares me." Valeria went on to suggest that her difficulties with this type of factoring could only be resolved if she had learned about them in a different way the first time they were introduced (Accept what I don't understand). As her case illustrates, due to their previous experience with algebra, developmental mathematics students were frequently making judgments about what they expect to get out of their re-learning experience often based only on perceived similarity of content (to what they've seen before) and their confidence in understanding the material at that time.

Discussion

Given that some learning outcomes may be more or less desirable than others, the results provided here will be useful to DMC instructors seeking to understand the potential impacts of their pedagogy on student understanding, and how this may vary significantly from other courses in which students are learning new mathematics for the first time. The fact that student perceptions of their learning outcomes shifted not only by topic within an interview, but across interviews as they gained more information casts doubt on literature that attempts to classify students as one particular type or as having one type of learning need. Although descriptors such as "brush up" experiences were noted, they were not useful as static descriptors of student experiences as has been done in previous literature on DMC (Grubb & Gabriner, 2013; Cox & Dougherty, 2019). Instead, students described multiple types of expected learning outcomes depending on their confidence in their previous understanding of material to be re-learned. Crucially, these expectations informed student methods of engagement with and attitudes towards course material in ways that may be unseen by instructors or placement instruments working with views of students as being of monolithic "types". Placement measures may need to be sophisticated enough to provide heavy advising and the ability to re-place if the shift between expected and perceived learning outcomes the student experiences is actually harmful for their future learning. Finally, the interdisciplinary nature of the conceptualization of relearning used here means that the findings of this study have implications across the field of teacher education as well. It remains an open question the realm of potential learning outcomes possible across relearning contexts and the degree to which theories of conceptual change that have been employed in teacher education could be useful in improving the pedagogy of DMC as well.

In one classroom of a Title 1 high school, students (n=12) were separated into groups and participated in a three-part study in which played and designed content for a 3D motion-capture video game, The Hidden Village (THV). This paper provides case-studies from group's work provided evidence of students' intuitions, insights, and explanations (including their gestures) of how students conceptualized the geometric transformations and how students embodied their ideas about geometry and how those ideas "traveled" (via directed actions) within and between student groups.

Keywords: Embodiment, Geometry, Collaborative Construction, Transfer

Introduction

The Hidden Village (THV) is a 3D motion-capture video game that allows players to embody mathematics learning (Swart et al., 2020). In the game, players perform movements (*directed actions*, see Nathan, 2017) prior to reading and evaluating a geometric conjecture. In effect, participants, nascent of the directed actions' relevance, are primed through body movements that are representative of both the structure of a geometric object(s) and enactive of the geometric transformation(s) of the object(s). A recent re-design of THV includes new modules that allow players to generate their own content (i.e., create new conjectures and new directed actions) to be played in the game. In the current study, students, working in groups, were invited to participate in a 3-day program to play THV, then collaboratively design their own series of directed actions for a given conjecture, and then play their conjecture and those designed by their peers. Researchers hypothesized that *directed actions* would foster mathematical insights crucial for students' insights and proofs. In this study, we present case study analyses in which students' verbal explanations, gesture production and the subsequent actions they designed to simulate geometric transformations can communicate concepts to their peers in a classroom setting.

Theoretical Background

The theory of *Gesture as Simulated Action* (GSA; Hostetter & Alibali, 2019), asserts that gestures, as spontaneous co-articulations with speech or thought, serve to activate perceptual-motor processes in the brain. In mathematics learning, Abrahamson & Sánchez-García (2016) effectively demonstrated how relative positioning of one's hands helped participants better understand concepts of ratio and proportion. According to Nathan's (2017) theory of *Action-*

Cognition Transduction (ACT), sensorimotor experiences feedforward and feedback to a predictive cognitive architecture that inductively and deductively reasons about the behaviors of ideomotor systems. ACT is a part of a larger framework called *Grounded and Embodied Cognition* (GEC; Nathan & Walkington, 2017), which proposes that body movement complements learners' verbal expressions (often seen in spontaneous gesture) by grounding understanding via the physical relationships that are the origins of mathematical thinking.

THV leverages the actions, gestures, and other body-based resources in a physically interactive social settings like collaborative game play to create opportunities for players to embody their ideas. When other groups perform the directed actions designed by their peers, we can observe the embodied transfer of ideas across groups via movement (Alibali & Nathan, *in press*). In collaborative settings, we hypothesize that these socially supported actions provide a physical medium by which their ideas "travel" between players. Moreover, we hypothesize these actions become a type of physical vocabulary that students invoke in subsequent explanations as *dynamic depictive gestures* as they mentally and physically simulate transformations of mathematical objects through multiple states (Garcia & Infante, 2012). We explore these hypotheses in multiple cases to demonstrate how embodied mathematical ideas travel within and between student groups through the creation of directed actions for game play.

Methods

Materials

The Hidden Village Game Module. THV delivers an embodied geometry curriculum in which a 3D motion capture sensor detects players enacting an in-game avatar's movements and records players' reasoning about geometry conjectures (i.e., ever false or always true). Figure 1 shows the 5 main parts to each level of game play.

Figure 1: One level of THV gameplay.

The Hidden Village Conjecture Editor Module. Students add new conjectures and design what they consider to be mathematically relevant directed actions by manipulating the sequences of poses of the avatar (Figure 2). Student groups use the Pose Editor to generate 2-3 poses (starting, intermediate, and target pose) to collaboratively co-create directed actions for each conjecture and players can preview the movements as animations. User-generated content is stored in an online database and accessible for others to play in the game module.

Figure 2: The THV Conjecture (authoring conjectures) and Pose Editors (for creating directed actions) and an example of a directed action sequence (far right).

Participants and Procedure

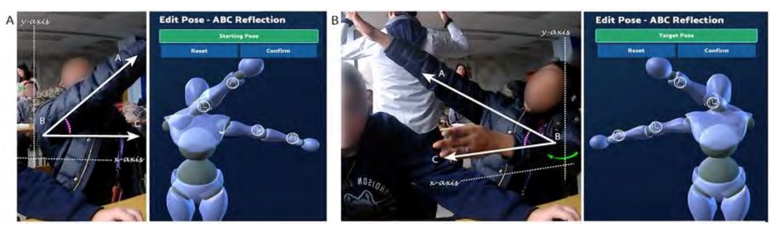
In this study, 12 students in a Title I high school in the midwestern United States were randomly assigned to groups of three or four to participate in a three-day embodied mathematics curriculum focused on geometric thinking. This paper focuses on three of the student groups.

On Day 1, group members took turns playing six conjectures in THV game module. On Day 2, student groups collaboratively constructed their own directed actions for a newly-assigned conjecture. On Day 3, student groups took turns playing the new THV curriculum (8 conjectures; 3 repeated from day 1, 3 newly designed by student groups, and 2 transfer conjectures.

Results

Within-Group Analysis

Upon noticing that the student's initial discussion of the conjecture produced a sequence of directed actions that produced the desired outcome of the geometric transformation,



Transcript 3**:** (*N.B. S1 indicates Student #1;* brackets [...] indicate gestures.)

[1] S1: Oh, wait. This is not the starting pose. Is that the starting pose? [Uses arms to make ∠ABC on the left
[2] side of the body] We are going like, this is the angle [shifted arms directly to the right side of
[3] her body by performing a reflection across the body vertical axis]... Boom! That's the angle!

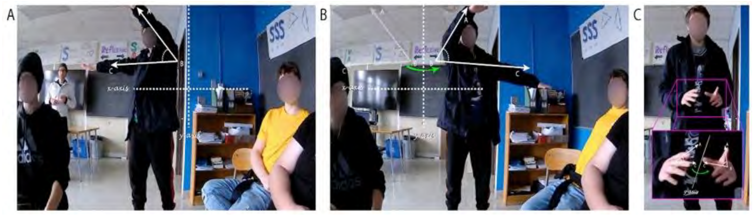
Figure 5: For *ABC Reflection* conjecture, Student 1 in Group 1 embodies the starting pose physically (also shown as designed in THV Pose Editor, panel A) and S1 performs the entire directed action, finishing on the target pose.

This transcript indicates the starting and target poses (see Figure 5) the student group used for the *ABC Reflection* conjecture. S1 embodied the idea of "using your body as the midline" through this directed action as they narrated their actions, shifting the angle from the right side over the body to the left side, which solidified their understanding of a reflective transformation.

Between-Groups Analysis

Students in Group 4 played the *ABC Reflection* conjecture as designed by Group 1. One player per group performed the directed actions while the other group members observed.

Researchers analyzed students' speech and gestures to track how Group 1's ideas traveled to peers (RQ2).



Transcript 4: (*N.B. S3 indicates Student #3;* brackets [...] indicate gestures.)

[1] S3: False. Because it can be proportionally the same, have the same angles [using hands to make an
[2] angle] while being in different locations. [S3 then, selects the correct multiple-choice answer]

Figure 6: S3 3 in Group 4 performs the directed actions (Panels A & B) for *ABC Reflection*. In Panel C, S3 provides intuition and rationale, gesturing the reflection.

In the process of proving the conjecture, S3's spontaneous gesture enacted an embodied conceptualization of the ∠ ABC that results from the transformation. In effect, this gesture is a truncated version of the authoring group's directed actions and complements S3's rationale.

Discussion

These case studies show the promises of an embodied, collaborative mathematics curriculum by demonstrating instances of how mathematical ideas "travel" through embodied actions. Students created content that explored embodied ways of reasoning those ideas were shared when their peers performed those directed actions during game play. This study provides preliminary evidence that directed actions can serve as a malleable factor that scaffolds cognition through its connections to the body, leaving historical traces that learners can feel, reinforcing their mathematical reasoning and complement their verbal explanations as conceptualization occurs. Embodied cognition offers promising ways to foster the transfer of mathematical ideas through students' collaboratively constructed movement.

In the months surrounding the most polarizing election in modern American history, youth produced and posted over 1,200 digital media clips on a chosen issue of concern through the educational web-based platform *Let's Talk About Election 2020.* Amongst other pressing topics, students created media related to COVID-19, Black Lives Matter, and climate change.
Given that quantitative literacy has been posed as both a civil rights priority of this millennium (Moses & Cobb, 2001) and fundamental to a contemporary democracy (Ball, Goffney & Bass, 2005; Steen, 1997), the question of how youth engage in quantitative reasoning in their civic lives has received scant attention. The body of curricular resources that examines social injustices through the lens of mathematics is growing but its use remains uncommon in math classrooms (e.g., Gutstein, 2006; Berry III, Conway IV, Lawler & Staley, 2020). Still, youth engage with quantitative data nearly every moment of every day. This study contributes insight into the ways that young people use quantitative reasoning as they engage in myriad forms of civic activity beyond the mathematics classroom. The study asked, in digital media created for *Let's Talk About Election 2020* around Black Lives Matter, COVID-19, and climate change, *what forms of quantitative reasoning did youth use in their civic argumentation, and how were these shaped by topic?*

To answer this question, transcripts from digital media segments were coded using an *a priori* set of codes defining three forms of quantitative reasoning – reasoning around a) quantity, b) relationships and change, and c) uncertainty (de Lange, 2006). Emergent coding was used to examine patterns in the use of these forms of reasoning across the three topics.

Findings show that all three forms of quantitative reasoning were present across topics. Widely evidenced mathematical practices included a) reasoning around relations of change over time, b) conceptions of scale, magnitude and normalcy, and c) set building activity surrounding notions of "we" in evoking empathy and compelling community action. Furthermore, across media segments, youth composers consistently mixed quantification and humanization. In doing so, segments cycled between mathematical practices of pattern recognition, abstraction and generalization that can be valuable for social problem solving, and narrative forms that invoked the particularities of diverse lived experiences and perspectives that can otherwise be lost in abstraction. Whereas single stories and mathematical models can each mislead in isolation, pairing them lent sophistication and texture to these media segments, suggesting the importance of quantitative civic reasoning for both mathematics learning and civic life.

Insight from this work can support mathematics educators working to bring together youth civic learning and mathematics. Specifically, we spotlight forms of quantitative civic reasoning that youth already employ outside the math classroom that can provide curricular inroads to bridge mathematics classrooms and students' civic lives.

STUDENTS' REASONING IN A MODELING TASK: MODELING DANCE WITH MATHEMATICS

Nicolette Colona
Towson University
ncolon3@students.towson.edu

Melike Kara
Towson University
mkara@towson.edu

Kimberly Corum
Towson University
kcorum@towson.edu

Keywords: Modeling, Mathematical Representations, Geometry and Spatial Reasoning

There is a growing emphasis on the inclusion of mathematical modeling tasks in school mathematics where students are engaged in analytical thinking, reasoning, critical thinking, and problem-solving skills (National Council of Teachers of Mathematics, 2000). Modeling tasks are helpful in revealing student thinking and they enable students of differing performance levels to interpret, invent, and find solutions (e.g., Batista, 2017; Carmona & Greenstein, 2007; Koellner-Clark & Lesh, 2003; Mousoulides, Pittalis, Christou, & Sriraman, 2010). Mathematical modeling helps students connect mathematics to the real-world. Furthermore, modeling tasks can support student interest in the learning of mathematics, make mathematics relevant and meaningful to students, provide opportunities to improve students' problem-solving skills, and improve student achievement in mathematics (Asempapa & Foley, 2018). In our modeling task, students analyze various dance moves that have different geometric concepts embedded in each move (e.g., angles, lines, shapes, symmetries) and then generalize their findings to develop a model that could be used for future dance analysis. Students are engaged in mathematical modeling throughout this task because they are using mathematics to represent, analyze, make predictions or otherwise provide insight into the dance world.

We implemented the *Modeling Dance with Mathematics* task with two different groups of students. The first group consisted of 40 university students who are prospective teachers. The implementation with the first group was one 50-minute virtual session that took place in October 2020. The second group consisted of six high school students enrolled in an honors geometry course. The implementation with the second group was two 45-minute virtual sessions that took place in January 2021. Students analyzed five specific dance positions to better understand geometry as represented in human motion. They then created models using their knowledge of geometric concepts to support their analysis of additional dance moves. The goal of the task was to help students deepen their understanding of geometric shapes and describe the relationship between different figures and shapes. The activity sequence for this task consisted of three parts: (1) recording notices and wonders for three dance moves, (2) analyzing the five dance moves provided in picture form, and (3) developing an analysis guide (model) for future dance moves.

The common themes in students' analysis across both implementations included: angles formed in the dance moves and shapes formed in the dance moves. These themes also occurred as the most common themes in students' models that were created to be used as analysis guide for future dance moves. When completing the task, students made mathematical assumptions of angles, lines, and shapes that were formed by the body parts of the dancer and analyzed different dance moves. The results indicated that all of the students were able to create models to analyze dance moves and notice the mathematics of a real-life situation by applying their current knowledge of geometric concepts. The results of this study could help teachers in planning and implementing similar modeling tasks, especially when anticipating patterns of student solutions and preparing questions to assess and advance student thinking.

THE INFLUENCE OF A VALUES AFFIRMATION INTERVENTION ON STUDENTS' MATHEMATICAL, SOCIAL, AND EPISTEMOLOGICAL EMPOWERMENT

Carrie O. Bala
Utah State University
carrie.bala17@gmail.com

Keywords: Affect, Emotion, Beliefs, and Attitudes; Culturally Relevant Pedagogy; Equity, Inclusion, and Diversity; High School Education

Purpose of the Study

The purpose of this study is to better understand the varying impacts of educators' attention to identity construction on the mathematical, social, and epistemological empowerment of tenth grade Emergent Bilinguals and native English-speaking students. To attend to this purpose, I will address the following research questions.

1. When controlling for language identity, to what degree does a values affirmation intervention predict students' mathematical, social, and epistemological empowerment?
2. Following a values affirmation intervention, how do the perceptions of students with differing language identities relate to their mathematical, social, and epistemological empowerment?
3. Following a values affirmation intervention, how do students' mathematical, social, and epistemological empowerment profiles differ between outcome measures and personal survey responses?

Proposed Conceptual Relationships

In the context of the mathematics classroom, students' intersecting mathematical, cultural, racial, gender, and academic identities develop through critical reflection on personal strengths, values, and social positions. Critical consciousness development is the mechanism through which identity construction expands to motivation, action, and empowerment. This conceptual framework, displayed in Figure 1, details a flow of influence from identity construction to critical consciousness development to empowerment.

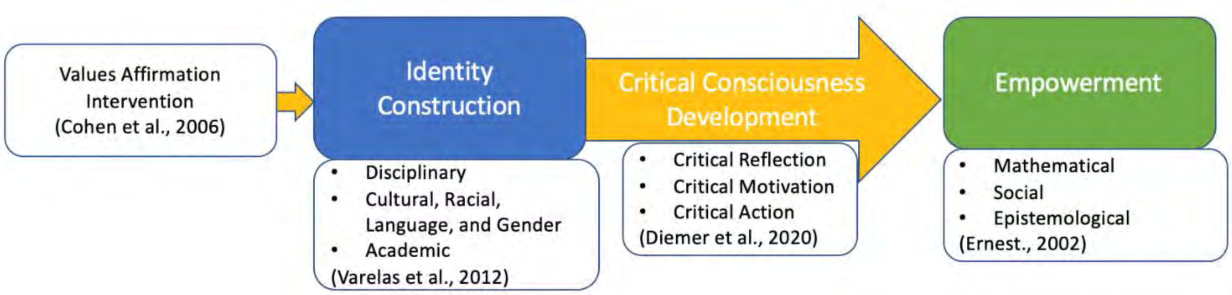

Figure 1: The Critical Identity Construction and Empowerment Framework (Crit-IC-E)

This framework informs the mixed methods transformative study design, which incorporates a values affirmation intervention intended to bolster positive student identity construction and measures to assess critical consciousness and empowerment. I will utilize quantitative, qualitative, and integrated methods to analyze students' empowerment. Approximately 150 tenth-grade Emergent Bilingual and native English-speaking students will be recruited from a western high school to participate in the proposed study.

PERSIST AND THRIVE!: A REVIEW OF LITERATURE ABOUT BLACK GIRLS IN MATHEMATICS

Olanrewaju T. Oriowo
University of North Carolina at Charlotte
ooriowo@uncc.edu

Keywords: Equity, Inclusion and Diversity, Gender

The academic performance of Black girls is often absent or scarcely represented in scholarly literature, thus creating a false or incomplete impression of their ability to achieve in mathematics (Young et al., 2018). This deficit narrative about the academic capabilities of black students, especially black girls, invades classrooms, colleges and universities. Deficit narratives could influence how Black girls position themselves in relation to mathematics, placing them at risk of disidentification (Brand et al., 2016; Ellis et al., 2016; Pringle et al., 2012). The purpose of this literature review is to determine the factors that mar the mathematical experiences of Black girls as well as the strategies and supports dedicated to supporting their persistence.

This literature review begins with an examination of the dominant views of Black learning that positions Black students as deficient and inferior to their White and Asian counterparts (e.g., Boaler, 2002; Gholson & Martin, 2019). While many ascribe these views to all black students, there are some researchers who have been able to identify perspectives that vary across gendered lines (e.g., Beekman & Ober, 2015; Marra et al., 2009). I address the complexity of the achievement (or rather, opportunity) gap, highlighting the research of scholars who look beyond the existence of a gap to the sources and contributing factors (e.g., Davis & Martin, 2018; Ellington et al., 2010; Malloy & Jones, 1998,). Next, I present literature on the dehumanization of Black girls in academic spaces (e.g., Joseph et al., 2019; Chambers et al., 2016; Young et al., 2018). The humanity of Black girls is yet to be realized in the United States as Black women and girls continue to be positioned as lacking in intelligence (Joseph et al., 2019), as disruptive in classrooms (Chambers et al., 2016), and as possessing a limited range of emotions (Gholson & Martin, 2019). Turning attention specifically to the mathematics classroom, I illuminate the various ways in which mathematics' learning spaces have been shown to be unwelcoming to Black girls (e.g., Felton-Koestler, 2015; Sleeter, 1997; Darragh, 2014). Some believe that mathematics is sterile, objective and neutral, yet a growing body of work shows that neutrality in mathematics is a myth as cultural values and expectations are expressed in the teaching thereof (Nortvedt & Buchholtz, 2018; Gutiérrez, 2013). Black girls have had to enact coping strategies to stave off feelings of isolation and exclusion (Alexander & Hermann, 2016; Gholson & Martin, 2019).

Key findings from this review of the literature include that Black girls are collaborative learners and should be afforded opportunities to work as a collective unit (e.g., Gresalfi &Hand, 2019; Kang et al., 2018), teachers play an important part in how Black girls experience mathematics instruction (Meaney & Evans, 2012; Pringle et al., 2012), and that positive mathematics identities could improved learning experiences (e.g., Fellus, 2019; Grayven & Heyd-Metzuyanim, 2019; Tao & Gloria, 2018). Although there is a growing body of asset-based studies, more research is needed that attends to high-achieving Black girls and women who are thriving in mathematics, highlighting the attributes, characteristics, and structural or institutional supports that made this possible, as well as the role that mathematics educators play.

DO VISUAL FRACTION MODELS HELP STUDENTS COMPARE FRACTIONS? EVIDENCE FROM ELEMENTARY STUDENTS' WRITTEN WORK

Jinqing Liu
Indiana University
Jinqliu@iu.edu

Erik Jacobson
Indiana University
erdajaco@indiana.edu

Both learning and teaching fractions can be challenging. To build students' conceptual understanding of fractions, visual models (e.g., circle model, fraction bar) are broadly promoted (Van de Walle et al., 2019) because they are theorized to communicate students' mental models (Cramer & Whitney, 2010) and make abstract mathematical concepts more accessible (McKendree et al., 2002). The phrase "visual model" or "visual fraction model" is used 19 times in the U.S. Common Core State Standards for Mathematics (CCSSM), indicating the broad consensus regarding the importance of visual models for meaningful mathematical learning. However, while the effectiveness of visual models for fractions has been well documented in small-sample studies in contexts with high involvement from university mathematics educators (e.g., Empson & Levi, 2011; Petit et al., 2015), to date, little is known about how students use visual models to justify the sizes of fractions at scale. Even less has been published after the wide adoption of the CCSSM. Accordingly, we aimed to answer RQ1: To what extent do 4th graders choose visual models to explain fraction comparison? RQ2: How effectively are such models used? RQ3: What constraints are encountered?

We designed an open-ended task that provided students with choices to explain their solutions: *Write the fractions 2/3, 3/4, and 3/8 in order from smallest to largest. Use pictures, words, or symbols to explain.* This task was administered to 214 fourth graders from seven schools in five counties of a U.S. Midwestern state. We coded whether students' justification included a visual model and categorized the models by type (e.g., fraction bar, set model, number line, etc.). For each type, we calculated the corresponding accuracy rate (correct here means order the fractions in a correct order) to determine how well it supported fraction reasoning. We analyzed incorrect responses to identify error patterns.

We found that among the 214 students, 93 (43%) used visual justification, and their accuracy rate (AR) was 28%. This rate was the same as that of those who used non-visual justification, so we found no correlation between accuracy and the choice of visual justifications for fraction comparison. However, sixteen of the 48 students (AR 33%) who used a rectangle or fraction bar model and five of the ten students (AR 50%) who employed a number line only produced the correct fraction order, suggesting that the rectangle and number line models may support students' fraction comparison more effectively than other visual models. Analysis of students' incorrect responses revealed that many students experienced constraints (1) with equal partitioning (e.g., by partitioning the circle horizontally instead of radially); (2) with referring to the same whole (e.g., by using non-congruent shapes modeling fractional area); and (3) with sector area in circle models (e.g., by drawing radial shares so inaccurately the resulting conclusion was incorrect).

Overall, we found that although visual fraction models are supposed to support students' fractional reasoning and are emphasized in the CCSSM, less than half of fourth graders in this study elect to use such models and their accuracy is not higher than students who do not. We conjure that students' units coordination (Wilkins et al., 2020) and teachers' fraction instruction

(Watanabe, 2002) may impact students' use of fraction visual models. We call for more research on fraction visual models in the CCSSM era. (c.f., Lee & Lee, 2020).

Classroom environments that incorporate the use of groupwork as part of a broader, reform-oriented approach to mathematics teaching and learning have resulted in learning gains, improved relationships among students, and positive mathematics identities (Boaler, 2006, 2008; Boaler & Staples, 2008; Staples, 2008). However, the students who most often have opportunities to participate in groupwork—in particular—and classroom discourse more broadly are those whose voices align with the dominant discourse of math classrooms (Lubienski, 2002; Nasir & Vakil, 2017; Zevenbergen, 2000). To invite more students into doing mathematics requires better alignment of the practices of mathematics to a wider range of students.

On this poster we will share initial data and analysis of African American students' perceptions of groupwork in a 6th-grade classroom where a white teacher implemented Complex Instruction (CI), a pedagogical approach designed to minimize status differences and establish more equitable classrooms (Cohen & Lotan, 1997; Lotan, 2003). Over four weeks the teacher used "groupworthy" tasks related ratio reasoning (Lappan et al., 2014) as a context to introduce students to the use of group roles to scaffold students' interactions in small groups. After the CI intervention, we interviewed 12 students to learn how their perceptions of productive and equitable group processes aligned with the interactions we observed among groups. We created hypothetical sample dialogues based on common occurrences we observed in within-group interactions and asked students to react to the dialogues.

Our poster will share our analysis of the student interviews alongside excerpts of group discussions that we used as a basis for our interview protocol. This project prioritizes the experiences of students, and the types of interactions that they perceive as equitable and collaborative, to determine how students learn collaboration and learn mathematics through collaboration. This work can shift power for determining what constitutes mathematical activity towards students of color, better aligning the discipline with those who have been historically marginalized.

The Design & Pitch Challenges in STEM (D&P; Confrey et al., 2019) is a novel curricular framework that situates mathematics learning within entrepreneurial pitch competitions. Leveraging features of project-based learning (PBL), design-based learning (DBL), and entrepreneurial-based learning (EBL), the framework was built to generate excitement and interest math by engaging students in authentic, math-focused entrepreneurial design challenges. In this poster, we report preliminary results from a study of students' experiences participating in the Keep It Real challenge, one of the nine D&P Challenges in STEM. In this challenge, students were tasked with inventing an app that uses data representations to help people manage their "phubbing" behavior, the act of ignoring (or snubbing) someone while using your phone ("phubbing" = "phone" + "snubbing"). Using a case study methodology (Yin, 1994), we explored the following research question: *How and to what extent does the Keep it Real challenge create opportunities for students to engage with the process of building and inventing statistical representations?* We collected data from a variety of sources, including daily written work samples and video data. We then analyzed these data using a grounded theory (Glasser & Strauss, 1967) approach.

During the competition, students drew on their interests and experiences to invent apps that would help users monitor their phubbing and incentivize improvement. As students considered how to incorporate data representations in their app designs, they defined statistical questions (e.g., how much is a user phubbing? Is a user's phubbing improving over time?); identified and considered how to quantify relevant data (e.g., phubbing as the number of minutes someone uses their phone after hearing the user's name or the number of times they access their phone during designated social events); and built prototypes of data representations using hypothetical data (e.g., line graphs to show changes in number of phubs by day, or bar graphs to show minutes spent phubbing by app or by day/week). Overall, the design challenge created a purpose for students' statistical reasoning and provided a lens through which they could make informed decisions about what questions their data representations should answer, what data were relevant to answering those questions, and how to best represent those data to effectively inform users' behaviors. Despite opening the space for students to invent novel data representations, students exclusively relied on traditional middle grades representational forms, such as circle graphs, line graphs, and bar graphs. Given the ages of the participating students and based on our conversations with them during the study, it is likely that students drew on the statistical representations with which they were familiar. This lack of variation or novelty in students' representations could limit the potential of the challenge for introducing and teaching new forms of data representation, though the findings indicate viability for motivating mathematics learning through entrepreneurial pitch competitions. More work is needed to better understand how to support students' engagement with a broader range of data representations without limiting their freedom to innovate within the entrepreneurial environment of the D&P Challenges in STEM.

PARTICIPANT REASONING IN A MULTIVARIATE SOCIAL JUSTICE CONTEXT RELATED TO PARTICIPANT IDENTITY AND LIVED EXPERIENCES

Jennifer M. Seat
Middle Tennessee State University
jms2dr@mtmail.mtsu.edu

Keywords: Data Analysis and Statistics; Social Justice; Affect, Emotion, Beliefs, and Attitudes

Over the past twenty years, Teaching Mathematics for Social Justice (TMSJ) has emerged as a well-documented phenomenon of practice in mathematics education. Thinking about the knowledge and experience of the participant becomes a crucial element of planning a productive experience in the TMSJ context, with one important consideration being the role of the lived experiences in how participants work with social justice tasks. Findings from the literature of statistics education can be helpful in understanding how lived experiences can influence student interaction in a social justice context. Investigations by Wroughton et al. (2013) and Queiroz et al. (2017) have demonstrated that statistical content and student experience cannot be separated. Another critical linkage that has emerged is the dependence of TMSJ on data (Frankenstein, 2012; Skovsmose, 2012). The use of data sets in TMSJ can be fixed, meaning that activities direct attention in a single direction to focus student attention. However, an interesting finding from early childhood data literacy offered that questions about data can limit the ability of students to process information (Schwartz & Whitin, 2006). This limitation may also be happening in TMSJ tasks as well. One teaching strategy from statistics education that could remove the stress of a fixed point in a social justice lesson would be to facilitate a social justice lesson guided as an investigation. MacGillivray and Pereira-Mendoza (2011) indicated that when students design authentic investigations, there are significant implications for both the written and verbal communication of statistical ideas. These statistical ideas are interesting when combined with ideas like lived experiences in social justice tasks, which becomes the focus of this research brief. The question that guides the current investigation is: ***In what ways do student identities and lived experiences influence the interpretation of an open statistical task in a TMSJ context?***

To investigate this question, a task-based interview (Goldin, 1997) was designed to examine the ways in which students interacted with a multivariate social justice data set. Initial design work showed that participant background was influential in the interpretation of the task. To continue and refine the research task, participants from a mid-sized public university were used. The task was posed using CODAP (https://codap.concord.org/) to explore how participants interacted with a dataset refined from the GSS survey (https://gssdataexplorer.norc.org/variables/vfilter) concerning the prompt: *Use the data provided to find a noticeable difference or demonstrate there is no noticeable difference between groups represented in the data*. The interviews were initially analyzed based on self-identification data provided by participants to identify relevant incidents from each interview. These relevant incidents were combined to generate an aggregate set of data that was analyzed for themes. This poster highlights the preliminary themes from this aggregate set. These themes offer insight into how students use experience and identity as an entry-point for data-based tasks in social justice contexts.

Introduction

Flow is an optimal psychological state first described by Csikszentmihalyi (1975, 1990, 2000). According to Csikszentmihalyi, when in flow, a person is completely engaged in activity and experiences various psychological characteristics, such as out of self-consciousness and enjoyment of the progress. Csikszentmihalyi (1991) explained that there are nine factors that consist of flow experience: challenge-skill balance, concentration, clear goals, feedback, sense of control, action-awareness merging, loss of self-consciousness, time distortion and autotelic experience. Studies found that the flow experience had a significant influence on efficiency and performance while engaging in different activities (Joo et al., 2011; Kiili & Ketamo, 2017). There are two goals for this research. First, we develop the Mathematics Flow State Scale (MFSS) to measure students' flow experiences in mathematics classrooms, adopted from the original Flow State Scale (FSS), and, second, we examine the validity and reliability of MFSS.

Methods

Two samples were collected for this study. For the first sample, we collected data from 374 fourth grade students. The second sample includes 503 fourth, fifth, and sixth grade students. MFSS was developed from the original Flow State Scale (Jackson & Marsh, 1996) to assess the degree of flow state students experience in mathematics classroom. To refine the original 36 items, we conducted Exploratory Factor Analysis (EFA) using the first sample. After the modification with the result of EFA, we ran Confirmatory Factor Analysis (CFA) to test the nine factors describe elementary school students' flow experience when learning mathematics using AMOS 20 (Arbuckle, 2011).

Results

After applying the EFA 12 times, 10 items were deleted for comprehensive reasons. All remaining 26 items had acceptable factor loading (0.4 to 0.85). To examine the factor structure of MFSS, we conducted the CFA three times with the one-factor model, the nine-factor model, and the eight-factor model to compare and select the best fitting model. Results showed that the eight-factor model with 24 items was the most suitable form of MFSS.

Discussion

The goal of this study was to develop and validate the psychometric properties of the MFSS. Results showed that the psychometric properties including reliability and validity of MFSS were acceptable, which suggests that the MFSS can be used in mathematics classroom to test elementary school students' positive experience (i.e., flow) when learning mathematics. Measuring students' positive affect would contribute valuable information to mathematics education research and practice as it can advance current knowledge about students' emotions and motivation in learning mathematics in a positive perspective.

Keywords: Algebra and Algebraic Thinking; Technology; Elementary School Education

The field of *early algebra* (Stephens et al., 2017) has established itself as a promising developmental pathway to support students' later learning of formal algebra. Early algebra is not pre-algebra or algebra earlier, it is not a natural extension of number (Blanton et al., 2015), and there is evidence that it can begin alongside development of number, including prior to it (Venenciano et al., 2020). Blanton and colleagues (2015) describe 5 big ideas of early algebra: "(a) equivalence, expressions, equations, and inequalities; (b) generalized arithmetic; (c) functional thinking; (d) variable; and (e) proportional reasoning" (p. 43). Moreover, there have been important advances in the use of games to engage students in inquiry-oriented learning contexts with success (e.g., Trujillo et al., 2016). This study investigates the impact of a game-based early algebra intervention on 4th and 5th grade students' early algebra knowledge.

Participants included 457 fourth and fifth grade students across 10 schools and 28 teachers' classrooms in a mid-sized school district in the Southwestern US. Around 64% of the students self-reported as Hispanic/Latinx, 18% as White, 13% as Multi-racial and the rest as Asian, Black/African American or Native American. About 55% reported as Female and 45% Male. Data is from a pre/post-assessments of students' early algebra knowledge (Engledowl, 2020), pre/post-surveys of mathematics anxiety, total gameplay time, grade level, gender, and race.

The intervention focused on two key ideas of early algebra that overlap with Blanton et al.'s (2015) big ideas: write and interpret expressions, and express patterns and relationships between quantities. Teachers implemented 3 inquiry-oriented lessons that each involved three phases: 1) gameplay, 2) a supplemental activity, and 3) another gameplay session. Each lesson was associated with one of two games and an interactive tool. Data was analyzed using a 2-level hierarchical linear model, with students (Level 1) nested within teachers (Level 2), using the R package *lmerTest* (Kuznetsova et al., 2017). Assessment scores were converted to latent person-ability logit scores using Rasch analysis (Bond & Fox, 2015) and the eRm package in R (Mair & Hatzinger, 2007). Students' mathematics anxiety was measured as a composite score with the same items as OECD (2014), and demographics were dichotomous.

Preliminary findings show that the null model's intraclass correlation (ICC) indicated about 35.2% of the variance in post-test scores could be explained by classroom membership—teachers played a major role in students' knowledge. Full model analysis revealed that all independent variables except for *Gender* and *Time* were statistically significant (all $p < .10$). Although we found expected results, such as no differences on gender, and that grade level, pre-test, and anxiety (e.g., Ashcraft & Krause, 2007) are significant predictors, a shocking result was that total time students played *Agrinautica* was not a significant predictor. Analysis is ongoing to further explore contextual factors at both student and teacher levels.

> I heard a thing about: "Chew mint gum when you study, and then chew the same gum, when you take the test. And all those things will come back." … It's like that but in reverse for me. …When I'm sitting [at home] at my desk with my computer, I'm in lay-back-have-fun-play-a-video-game mode, not sit-forward-and-take-notes-for-a-college-math-class. … As opposed to pre-COVID: My dorm is a working space or, and so is the cafeteria. I've got spots and layouts that, like the only thing I ever knew in my dorm was working. So that was naturally a workspace. (Kaleb, Interview, April 17, 2020)

The ideas Kaleb, a mathematics undergraduate student, shared with us in an interview after instruction had shifted online in response to the coronavirus pandemic brought to our attention how space affects students' learning experiences. Upon directing our attention to matters of space, we noticed that other undergraduates majoring and minoring in mathematics whom we also interviewed after the shift to online instruction—as part of a longitudinal study of students' development of agency and autonomy—were telling similar stories.

To make greater sense of the stories that were shared with us, we draw on human geography to distinguish between *space* and *place*, that is, to distinguish between the purely physical and the physical married with human experience (Entrikin, 1991; Tuan, 1977). Although geographers are not in agreement as to the exact relation between space and place, we draw on humanistic geographers to define place as a space–time configuration with associated human activities and experiences (Agnew, 2011; Sack, 1997). This distinction allows us to situate the pandemic as: (a) a collapse of *spaces*, that is, describe how an abundance of class spaces (e.g., classrooms, help rooms, the instructor's office) became a single space (i.e., home), and (b) a collision of home and class *places* to capture how two worlds collided—as exemplified by Kaleb's words.

Using the terminology of space and place, we will share spatial and "platial" aspects of three undergraduate students' experience taking mathematics classes during the pandemic. In particular, we will illustrate how these students (a) found on-campus spaces important, (b) suffered from problems of motivation and concentration by the distractions offered by being home, and (c) engineered their homes to make them more conducive to their learning.

On top of adumbrating the utility of a spatial/"platial" lens for understanding important aspects of students' experiences during the pandemic, we will also discuss implications for instruction. Specifically, by posing three example questions, we intend to show how attending to space and place can offer valuable insights for equitable instruction during the pandemic: (a) Who has what access to synchronous online class places? (b) What other places are students in while in online class during the pandemic? and (c) What places are students in while taking monitored exams?

Chapter 12:

Teaching & Classroom Practice

USING TEACHER AND STUDENT NOTICING TO UNDERSTAND ENGAGEMENT DURING SECONDARY MATHEMATICS LESSONS

The purpose of this paper is to present a framework that illustrates teachers' and students' ways of noticing mathematical engagement. This framework offers clarity about the complexity of engagement, and it includes three elements: evaluations of the presence of engagement, descriptions of the nature of engagement, and features of the classroom that support or constrain engagement. We interviewed 30 sets of high school math teachers and focus groups of their students and asked them to reflect on students' engagement during a videotaped lesson from their classrooms. Results illustrate cases of how noticing of engagement between teachers and students can be shared. Cases of partially and minimally shared noticing of engagement suggest opportunities for teachers to learn about students' perspectives or how to communicate with students about their intentions to engage them.

Keywords: mathematics engagement, teacher noticing, student noticing, motivation

Engaging secondary students in mathematics lessons is an enduring challenge, as students' mathematics engagement has been found to decrease as they move through years of schooling (e.g., Collie et al., 2019). Engagement is a complex construct, involving affective, behavioral, cognitive, and social factors (Fredricks et al., 2004; Middleton et al., 2017), each impacting student learning and performance differently. In a nationally representative sample of high school students in the United States, behavioral and cognitive engagement explained more of the variance in students' mathematics achievement scores than affective or emotional engagement (Sciarra & Seirup, 2008). This study highlights that the nature of engagement matters for students' learning and performance, even though it was not specific to mathematics learning.

Teaching practice shapes the learning environment that students experience (Anderson et al., 2004), and the learning environment impacts students' engagement (Shernoff et al., 2017). However, according to Pedler et al., (2020), teachers face challenges understanding how to engage students because engagement is such a complex phenomenon. According to Erickson, to teach effectively, "one needed to 'learn' the children one was trying to teach" (Erickson, 2011, p.18). So, perhaps one approach for teachers to learn more about students' engagement is for teachers to become "students of our students" (Ritchart & Church, 2020, p. 11).

In this study, we investigated what mathematics teachers noticed about their students' engagement and how their students exhibited similar or different noticings about their engagement. Building upon research on specialized noticing practices of mathematics teachers (Jacobs et al., 2010; van Es et al., 2017) and research on students' noticing of mathematics (Hohensee, 2016; Lobato et al., 2013), the purpose of this study is to investigate what teachers and their students noticed about mathematics engagement while viewing video recorded events from their classrooms. We offer a framework to demonstrate that noticing of mathematics engagement involves evaluating whether or not students were engaged (presence of engagement), describing the nature of students' engagement (dimensions of engagement), and interpreting what happened in the classroom to elicit students' engagement (features of engagement).

Teachers' and Students' Noticing

Noticing is a process of identifying events as noteworthy, using evidence to discuss these events, and providing interpretations of these events (van Es & Sherin, 2002). What a person notices influences their reasoning about the event (van Es & Sherin, 2002; Lobato et al., 2013). Across teacher noticing literature (e.g., van Es & Sherin, 2002; Jacob et al., 2010; van Es et al., 2017), researchers consider *interpreting* to be higher quality noticing compared to *evaluating* or merely *describing*.

Different targets for noticing suggest a need for alternative frameworks for illustrating ways of noticing. Researchers have studied what teachers notice about their students' mathematical thinking (Jacobs et al., 2010) or equity in the mathematics classroom (van Es et al., 2017), as well students' different centers of focus of noticing during mathematics lessons (Hohensee, 2016; Lobato et al., 2013). For this study, we investigate a different target of teachers' and students' noticing: mathematics engagement. Additionally, previous research studies examined teacher and student noticing separately, while we investigate them in relation to each other.

Mathematics Engagement

Academic engagement is a psychological investment in and effort directed towards learning from academic tasks (Jansen, 2020; Newmann et al., 1992). Engagement is a complex meta-construct (Fredricks et al., 2004) that includes affective, behavioral, and cognitive dimensions (Appleton & Lawrenz, 2011; Bobis et al. 2016; Fredricks et al., 2004; Helme & Clarke, 2001; Middleton et al., 2017), and a social dimension (Middleton et al., 2017; Jansen & Bartell, 2013; van Uden et al., 2013; Wang, et al., 2016). Behavioral engagement includes effort or time on task. Cognitive engagement is concentration or connections made while learning. Affective engagement is an emotional state of investment, such as interest. Social engagement is participation in the learning process. When describing student engagement in the classrooms, teachers and students could focus on different *dimensions of engagement* (affective, behavioral, cognitive, or social).

Recent prior research reveals teachers' thinking about what students will find engaging in mathematics classrooms and how these interpretations may guide their instruction (Bobis et al., 2016; van Uden, et al., 2013). We named interpretations of what will engage students as interpretations of *features* that engage students. Researchers have explored whether teachers determine engagement to be present or not (Skilling et al., 2016), or teachers' *evaluations* of the presence of engagement (or disengagement). In terms of describing engagement, when reflecting on engagement generally, teachers tended to focus on relatedness or sense of belonging in the classroom (Herman, et al., 2000; van Uden et al., 2013). However, when teachers were asked to focus on particular students or to consider a situated case of engagement, they tended to focus primarily on behavioral or overt emotional engagement (Bobis et al., 2016; Skilling et al., 2016).

Previous research on students' perspectives have uncovered the motivators that drive their engagement (Daniels & Arapostathis, 2005; Jansen & Bartell, 2013; Middleton, 1995). These motivators range from interest and reward (Daniels & Arapostasis, 2005; Middleton 1995) to interpersonal relationships in the classroom (Daniels & Arapostasis, 2005; Jansen & Bartell, 2013). Cognitive and social engagement appear to be prominent in students' perceptions of their own engagement.

Research Questions

To understand teachers' and students' noticing of mathematics engagement, we designed this study to answer the following research questions: *What do teachers and their students notice about elements of engagement (presence, dimensions, features) when asked to reflect on a shared mathematical experience? In what ways do they agree or disagree on these elements?*

Methods

Context and Participants

To address our research questions, we analyzed student and teacher interview data collected for the Secondary Mathematics in-the-Moment Longitudinal Engagement Study (SMiLES). SMiLES is a three-year mixed-methods study funded by the National Science Foundation that explored engagement in high school classrooms across two states (one state in the Southwestern region and one in the Mid-Atlantic region of the United States). Data analyzed for this study comes from 6 high schools (3 in each state) collected during the Fall 2018 to Spring 2019 academic year. Data for SMiLES were collected during Algebra 1 or Integrated Math 1 lessons.

Regarding our participants, we recruited teachers for this study by soliciting nominations of teachers from district curriculum supervisors and mathematics coaches. We invited nominated teachers to participate in the study, and 16 teachers participated (11 female, 5 male) in the SMiLES project during the Fall 2018 to Spring 2019 academic year. Teachers self-reported their races: 14 identified as white, one identified as Asian-American, and one identified as Hispanic/Latinx. They averaged 10.8 years of teaching experience with a range of 1 to 27 years. Student demographics for the schools in the Southwest were: 85-94% low income, 2-5% white, 1-15% Black, 74-96% Latinx, and 0-5% Asian, Native American, or Multi-Racial, and student demographics for the schools in the Mid-Atlantic were: 9-30% low income, 24-57% white, 27-46% Black, 7-24% Latinx, and 0-5% Asian, Native American, or Multi-Racial.

Students were selected to participate in focus group interviews from each class period that we observed. The criteria we used to select students for the focus groups was based on an analysis of students' responses to a mathematics engagement survey administered by the research team at the beginning of the semester. A cluster analysis of this data identified motivational profiles of students (Tarr et al., 2019). Three clusters were identified across the sample and the students invited to participate in the interviews: (1) strongly aligned with one of the profiles (2) had parent consent, and (3) had given assent. The average number of students who participated in a focus group was 2.45 with a range from 1 to 3 students.

Data Collection and Analysis

The dataset for this analysis consists of 30 sets of interviews with teachers and their students, with multiple class periods studied for most teachers. Interviews were conducted one-on one with teachers and in a focus group for the students. Prior to the interview, the research team identified a video clip that showed a representative example of student engagement from an observed lesson in the SMiLES dataset for that class. Each video clip was between 90 seconds and three minutes in length and had been experienced by the teacher and students in the focus group. Interviews took place two to three weeks after each observation. We conducted these interviews as video viewing sessions (c.f., Erickson, 2007), during which participants commented upon what they noticed in a video regarding the nature of engagement during that activity. These interviews were not treated as stimulated recall (e.g., Lyle, 2003), as we did not expect participants to be able to recall their experience after multiple weeks and we did not intend to capture participants' decision making in those moments.

We employed a case study approach (Yin, 2017) when analyzing these sets of interviews. We defined a case as a teacher's noticing and their students' noticing of a recorded classroom activity. Data for the case consisted of a set of interviews: the teacher interview and corresponding student focus group interview about the classroom activity. We analyzed these interview episodes to identify three elements of engagement reported by teachers and their students: the *presence of engagement, dimensions of engagement* and *features which elicit engagement or disengagement*. We defined *presence of engagement* as the indication by the teacher and students of whether students were engaged or disengaged. We defined *dimensions of engagement* as the type of engagement reflected in how a teacher or student described the nature of engagement, according to six categories of dimensions: affective, behavioral, cognitive, instrumental, social, and relatedness. We defined *features that elicit engagement or disengagement* to be teachers' and students' self-reports of what appeared to support (or constrain) students' engagement (or disengagement). Features are interpretations that the teachers and students provided about what happened in the lesson that engaged or disengaged students. These features were coded using an emergent process (Saldaña, 2013) from listening to voices of both the students and the teachers. We also analyzed for the *presence of engagement*; whether teachers and students determined that students were or were not engaged during the event in the video clip. We then identified ways in which sets of teachers and their students agreed or disagreed about what they noticed with respect to presence of engagement, dimensions of engagement, and features which elicit engagement or disengagement.

The elements of engagement in this study (presence, dimensions, and features) parallel the noticing stances described by van Es and Sherin (2002): *describe, evaluate, and interpret*. The participants' characterization of presence of engagement is a form of *evaluation* of whether or not students were engaged. When teachers or students talked about the ways in which students were or were not engaged, this aligns with *describing* engagement. (We coded participants' descriptions of engagement according to dimensions.) We considered *interpretations* of these video clips to be when teachers or students reasoned about the features that brought about students' engagement or disengagement.

During analysis, it became clear that there were cases in which teachers and their students noticed and agreed about engagement in various intersections of these elements. Our stance was that high quality noticing of engagement between teachers and their students occurred when they shared perspectives on engagement. *Strongly shared noticing* occurred when a teacher and their students agreed on all three elements (presence, dimensions, and features). *Partially shared noticing* occurred when a teacher and their students agreed on any two of those three elements. *Minimally shared noticing* was agreement between a teacher and their students on any one of those three elements. A *disagreement* on noticing any of the elements of engagement could provide an opportunity for teachers' learning about how to engage their students. Either a teacher could learn more about their students in order to engage them or the teacher could communicate rationales more explicitly so that students could learn more about their teachers' intentions for engaging them in particular activities.

Results

Through the process analyzing interview data, we examined ways that elements of engagement (presence, dimension, and feature) intersected and what these intersections revealed about how teachers and their students thought about engagement in secondary mathematics classrooms. To this end, we built a framework (see Fig. 1) that organizes our results and helps to describe the ways our participants noticed engagement in their math class.

This framework, organized as a Venn diagram, recognizes each element of engagement -- presence, dimension, and feature -- as a set which can intersect and interact with the other elements. What teachers and their students notice can then be described through these elements and whether and how they intersect. Each of the outer circles (no intersections) represents when a teacher and their students notice and agree only on one element. We describe this as "Minimally Shared Noticing of Engagement." If a teacher and their students similarly noticed two out of the three elements of engagement, then they would fall into one of the intersections of two elements: "Partially Shared Noticing of Engagement." Finally, the innermost intersection ("Strongly Shared Noticing of Engagement") indicates that a teacher and their students exhibited shared noticing on all three elements of engagement. The complement of this Venn diagram also exists and would include cases where a teacher and their students did not notice similarly or agree on any of the three elements of engagement. We present two cases here: "Strongly Shared Noticing of Engagement" and "Minimally Shared Noticing of Engagement – Presence."

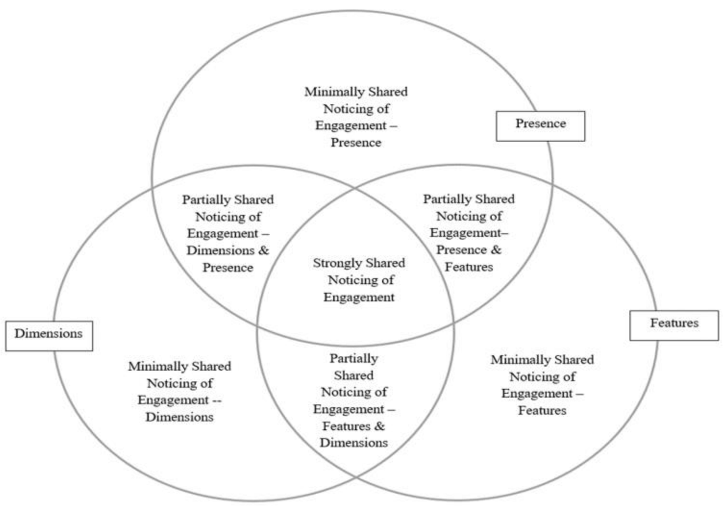

Figure 1: Framework for the Elements of Engagement

Case 1: Case of Strongly Shared Noticing of Engagement

Julie and her students represent a case of a teacher and her students expressing shared noticing of mathematics engagement according to all three elements in our framework: presence, dimensions, and features (see Table 1). In the activity captured on our video recording, we observed that Julie shifted out of a whole-group discussion and had students move into working in smaller groups during the mathematics lesson. When reflecting on the video, Julie and her students evaluated students' engagement similarly; they agreed that the students were engaged. They interpreted the opportunity to work in small groups as the feature which elicited this engagement and in describing this feature, they described engagement in terms of social engagement. Thus, we interpret this case as one of strongly shared noticing of engagement in a secondary mathematics classroom.

Julie attended to the social dimension of engagement (engagement through student interactions and discourse with and around mathematics) when she explained that she knew students were engaged because they were interacting with each other to make sense of the mathematics. She explained that by providing the opportunity for students to work in groups, she avoided a potential pitfall of whole-class discussion: the same students answering all the questions. She said, “That's why I try to throw it out to them, because they're not communicating with me. I don't want to know just what three people know -- I want to know what everybody knows.” She went on to explain that small group work allows her to engage in formative assessment by listening to conversations and to assess each student’s knowledge. She said, “That's why I kind of, like I said, threw it back to them, circulated so that I could hear and talk to each group.” In her reflection on the classroom video, Julie described students interacting with each other around the mathematics, and she interpreted the students’ interactions to mean they were engaged.

Table 1: Julie and her students, Case of Strongly Shared Noticing of Engagement

Elements of Engagement		Summary
Presence	Agreed: Engagement	This teacher and her students expressed shared noticings for all elements [presence, dimensions, and features]. They agreed students were engaged and have some agreement about what engages students and why.
Dimensions	Agreed: Social	
Features	Agreed: Students worked and talked together in groups about mathematics	

Julie’s students interpreted engagement in the video similarly to Julie. When reflecting on the video, the students said that the class was engaged, and explained that this was the case because of the interactions they were observing – indicating that they also connected social engagement with the presence of students being engaged. They also noticed instances of engagement similar to Julie’s. Katie noted, “I think that the whole class was into the activity just because of all the talking that was going on. We were all discussing what was going on the board and arguing over the correct answer, which is definitely our class.” Luna agreed with Katie, “[Student 1] was talking, but then [Student 2] started, and then people were there and over here started talking about what answer was right … yeah … that's when everybody was engaged.” Both Luna and Katie interpreted that engagement was evident through discussing and arguing over the answer indicating the social dimension of engagement.

This case is an example of a strongly shared noticing of engagement between an instructor and their students. Both Julie and her students interpreted the video as indicative of social engagement by focusing on the interactions that students had around the mathematics. This indicates that Julie and her students noticed the same elements of engagement: when students have the opportunity to work together on mathematics, the activity can be engaging. Julie’s decision to put students in groups suggested that she considered what her students needed to engage. It might be the case that when a teacher and her students have a shared perspective on what engages students (features) and why and how students engage (dimensions), students are more likely to be engaged.

Case 2: Case of Minimally Shared Noticing of Engagement – Presence

Jacob and his students represent a case of agreement on the presence of engagement with disagreement on the dimensions and features of engagement (See Table 2). When reflecting on the video clip, both Jacob and his students evaluated that students were not engaged; however, they associated this lack of engagement with different dimensions of engagement and features of the classroom. This video viewing session illustrates an opportunity for Jacob to improve his teaching practice, as both the teacher and the students agreed that students were disengaged.

Table 2: Jacob and his students, Case of Minimally Shared Noticing of Engagement – Presence

<table>
<tr><th colspan="2">Elements of Engagement</th><th>Summary</th></tr>
<tr><td>Presence</td><td>Agreed:
Disengagement</td><td rowspan="3">Although the teacher and students agreed that students were not engaged [presence], the teacher did not notice similarly to his students in terms of why and how students engaged [dimensions] or what engaged or disengaged students [features]</td></tr>
<tr><td>Dimensions</td><td>Disagreed:
Teacher – Cognitive
Students – Behavioral, Social</td></tr>
<tr><td>Features</td><td>Disagreed:
Teacher – Pressing for explanations
Students – Whiteboards</td></tr>
</table>

During the video recording, we observed that students first solved problems by writing on their desks with dry erase markers while Jacob and the classroom aide walked around to answer questions. Then Jacob brought the class together to discuss the answer to the problem they were working on: *Solve the system of equations: y = -4x -14 and y = 8x+2.* Students found an answer of (1.33, 8.67), but they observed that this ordered pair did not exactly satisfy the equations. In response to this, Jacob spent time explaining to the class that, when plugging an ordered pair in to check a solution, students should use a fraction representation rather than rounded decimals because the fractions are exact. During this whole class discussion, Jacob provided a few opportunities for students to call out answers, but primarily explained through direct instruction.

When Jacob described students' disengagement, his focus was on the challenges the students faced and how he handled them,

> ...they're willing to work until they're done with the problem and then they go away from the engagement. But I think in terms of just trying to explain with the fraction and things like that it was really … I was just challenging them to think on their own. … I was trying to challenge them to think about it and doing some prodding and things like that to steer them in the right direction.

Jacob explained that he noticed that student engagement was low, especially after they finished the problem they were working on. He described how he tried to engage students cognitively by pressing them to think about why the approximation did not yield the same answer as the exact fraction. When these justifications were not correct, he tried to steer them in the correct direction. Jacob's description of engagement focuses on the cognitive dimension; students could be engaged when they are asked to actively think about their own work.

When Jacob's students were interviewed about if they thought their classmates were engaged, they expressed that they did not think so, and both described evidence of this disengagement in terms of behavioral and social dimensions. Nikia said, "I feel like most of them wasn't [engaged]…you know how he said, 'So what'd everybody get?' Only one person answered. Then everybody was just looking down like this, playing with their markers." She decided they were not engaged because they were not paying attention. Ashiya agreed with Nikia on the presence, dimension, and feature of engagement, but provided an example from before the class discussion, "Whiteboards, yeah, it's a lot of talking. But you'll do the work. While you're doing the work, you'll talk to somebody. Then when you're done, you'll sit there and wait for [the teacher or the aide] to come around and say that's correct or they'll help you if it's not correct… but what Nikia was saying, it is a lot of talking." Although both students recognized their classmates' behavioral disengagement, Ashiya mentioned that sometimes when Jacob and the class aide were busy answering questions, students sometimes helped each other, recognizing the potential for social engagement, but she did not comment on whether or not helping each other was engaging.

Although Jacob and his students did not agree on the features or dimensions of engagement seen in the video clip, they did agree on the absence of student engagement. This indicates that Jacob and his students had a shared understanding of when students are not engaged, even if the dimensions and features were different. This is a case of minimal shared understanding, but we recognize the potential for teacher learning if there is a shared noticing about presence of engagement. If Jacob used this opportunity to learn about what students thought about how and why they were disengaged, he potentially could find ways to increase engagement in the classroom.

Discussion

We offer a framework for teacher and student noticing of mathematics engagement aligned with noticing stances of evaluating, describing, and interpreting (van Es & Sherin, 2002), as illustrated by these cases. Both teachers and students were capable of going beyond evaluating whether or not students were engaged (presence) to describe the nature of students' engagement. Both teachers and students also articulated features of engagement to interpret what may have elicited engagement in the classroom.

This study extends previous work on noticing by investigating noticing of engagement in contrast to noticing mathematical thinking (Jacobs et al., 2010; Hohensee, 2016; Labato et al., 2013) or noticing related to equity in mathematics teaching and learning (van Es et al., 2017). Additionally, previous research on teachers' noticing (e.g., Jacobs et al., 2010; van Es et al., 2017; van Es & Sherin, 2002, 2008) and students' noticing (Hohensee, 2016; Labato et al., 2013) did not compare what teachers noticed with what their students noticed. This study also demonstrates that teachers are capable of noticing a range of dimensions of engagement beyond behavioral and affective engagement, as seen in previous research studies (Bobis et al., 2016; Skilling et al., 2016), as these teachers also noticed cognitive and social engagement.

We conjecture that when a teacher and their students have a more strongly shared understanding of engagement, students' engagement is likely to be stronger, but this could be explored in future research. To establish a shared understanding of engagement, a teacher could (a) strive to understand their students' perspectives and adjust their teaching to align better with students' views or (b) more explicitly provide meaningful, explanatory rationales to students. When perspectives on engagement are not shared, this is an opportunity for teachers to learn about their students. When a teacher provides an explanatory rationale for their instructional choices, this can support students' autonomy and motivation (Reeve, 2009).

This study offers a framework for characterizing teacher and student noticing of mathematics engagement, and it investigates the potential for examining whether and how students and their teachers share noticing practices. The evidence provided in this study shows that teachers and students *can* share common descriptions, interpretations, and evaluations across this framework, and that differences in shared noticing can align with different elements of engagement. Our framework illustrates how elements of mathematics engagement can provide insight on the complex construct of engagement and how it may reveal opportunities for teachers to learn how to further engage their students in the future.

Several researchers have promoted reimagining functions and graphs more quantitatively. One part of this research has examined graphing "conventions" that can at times conflict with quantitative reasoning about graphs. In this theoretical paper, we build on this work by considering a widespread convention in mathematics teaching: putting related, derived graphical objects (e.g., the graphs of a function and its inverse or the graphs of a function and its derivative) on the same set of axes. We show problems that arise from this convention in different mathematical content areas when considering contextualized functions and graphs. We discuss teaching implications about introducing such related graphical objects through context on separate axes, and eventually building the convention of placing them on the same axis in a way that this convention and its purposes become more transparent to students.

Keywords: Mathematical Representations, High School Education, Undergraduate Education

Graphs are a foundational mathematical construct used ubiquitously across science, technology, engineering, and mathematics (STEM). Modeling quantitative relationships through graphs has been promoted as essential in STEM education (National Governors Association Center for Best Practices & Council of Chief State School Officers, 2010; National Research Council, 2012). Yet, there are two important issues that lie at the intersection of graphs and modeling contexts. First, there is a tension between (a) the power of *contextualizing* mathematics for conceptual understanding and quantitative reasoning and (b) the power of *abstraction* in mathematics to see general structures and underlying ideas (Freudenthal, 1968; Mitchelmore & White, 2007; van den Heuvel-Panhuizen, 2003). Second, there is a tension between (a) using conventions in displaying graphs for communicative or illustrative purposes, and (b) conflicts those conventions may have with perceiving and understanding deeper quantitative relationships (Moore & Silverman, 2015; Moore et al., 2014; Moore et al., 2019).

Previous research work, discussed in the next section, has made strides in bringing quantitative and covariational reasoning to bear on students' graphical thinking. In this theoretical paper, we contribute to this area by examining the convention of graphing related, derived objects (e.g., the graphs of a function and its inverse, or the graphs of a function and its derivative, or input and output vectors) onto the same set of axes in connection with contextualization versus abstraction. To do so, we use example cases from across different mathematical areas to describe how this convention, which is appropriate for abstract situations, conflicts with contextualization and quantitative reasoning. We then offer implications that our theoretical exploration has for teaching mathematical topics involving this graphing convention.

Literature Review

Graphs play a central role in representing quantities and quantitative situations mathematically, and they are used extensively across STEM fields to model a wide variety of phenomena (e.g., Angra & Gardner, 2017; Beichner, 1996; Planinic et al., 2012; Rodriguez, Bain, Towns, et al., 2019; Rodriguez, Bain, & Towns, 2019). Unfortunately, research from both mathematics and science education shows clearly that students have difficulties using graphs with quantitative situations (e.g., Bajracharya & Thompson, 2014; Beichner, 1994; McDermott et al., 1987; Testa et al., 2002; Woolnough, 2000). One prominent tendency is for students to see graphs as "pictures" or "shapes" rather than as a depiction of a relationship between quantities (Beichner, 1994; Leinhardt et al., 1990; McDermott et al., 1987; Moore & Thompson, 2015). Other challenges include confusing "slope" with "height" (Hale, 2000; McDermott et al., 1987; Planinic et al., 2012), making incorrect assertions based on the visual look of a graph (Aspinwall et al., 1997), understanding changing rates (Carlson et al., 2002), and making local versus global interpretations (Leinhardt et al., 1990; Monk, 1994). One key issue is that many conventions, such as x residing on the horizontal axis or a *vertical* line test, end up being considered as essential requirements for graphs by students (Moore & Silverman, 2015; Moore et al., 2019).

In order to promote better understanding, several researchers have focused on conceptually-rich and quantitatively-founded ways of approaching graphs in mathematics education. Some early work in this area focused on using videos and computers to track information such as distance and velocity to produce graphs (Beichner, 1996; Zollman & Fuller, 1994), or using motion detectors to embody graphical activity (Beckmann & Rozanski, 1999; Berry & Nyman, 2003). Since then, a significant portion of research has focused on re-imagining functions and graphs at the fundamental level through covariation (e.g., Carlson et al., 2002; Castillo-Garsow et al., 2013; Ellis et al., 2016; Moore & Thompson, 2016; Paoletti & Moore, 2018; Thompson & Carlson, 2017). Several studies have reported on improved student understanding and reasoning about functions, graphs, and coordinate systems when students develop these covariation-based ways of thinking (Ellis, 2011; Ellis et al., 2016; Moore, 2014; Moore et al., 2013).

In particular, Moore and Thompson (2015) contrast *static thinking*, in which students think of the graph as a static object (like a "wire"), with *emergent thinking*, in which students imagine the covariational relationship between x and y as tracing out the graph. In emergent thinking, a graph involving quantities communicates an evolving "story" between the quantities (Rodriguez, Bain, Towns, et al., 2019). However, a barrier to thinking this way is students' adoption of certain conventions as being necessary for graphs to be mathematically correct. For example, Moore et al. (2019) explain that students state that a sine curve snaking up the y-axis does not suggest a function, because of the vertical line test, despite the fact that the graph perfectly well represents the functional relationship $x = \sin(y)$. Moore and colleague's work suggests that confronting these conventions directly can help students develop a stronger sense of how graphs can portray quantitative relationships (Moore et al., 2014; Moore et al., 2019). Our paper builds on the existing literature by considering an important convention in mathematical graphing activity, described in the next section, and its conflict with representing quantitative relationships.

Theoretical Perspective: Conventions in Graphing

This study uses the lens of "conventions" in terms of graphical activity. Hewitt (1999, 2001a, 2001b) described what he called "arbitrary" aspects of mathematics, consisting of social conventions that do not necessarily have to be done that way, but on which some consensus has been reached. Some examples Hewitt provided were the names of shapes, the usage of the symbols x and y as coordinates, or terminology for operations (1999, p. 4). Other examples in the context of graphing could include using perpendicular axes (unlike Descartes' early conventions, Katz, 2009), having "up" be the positive direction, or using uniform scaling. Thompson (1992) proposed the importance of students becoming aware of these conventions they were using. He used the phrase "convention qua convention" to mean when one understands "that approaches other than the one adopted could be taken with equal validity" (p. 125). He explained that problems arise when conventions are not properly understood as conventions (see also Thompson, 1995). Moore et al. (2019) then built on these ideas by providing a definition of "convention," which we use in this paper: a convention is a combination of a concept, a community, and a representational practice.

The precise convention we highlight in this paper is the common practice of placing a graphical object and a related, derived graphical object on the same set of axes. Here, by "object" we mean the literal "thing" that is placed on the axes, such as a function's graph, a curve, or a vector arrow. Applying Moore et al.'s (2019) definition, we see the "community" as the mathematical community, the "concept" as graphical objects related in some key way, and the "practice" as placing these related objects on the same set of axes. As examples, it is common to graph a function and its inverse function on the same set of axes (e.g., Blitzer, 2018; Sullivan & Sullivan, 2020), or to place the graphs of a function and its derivative on the same set of axes (e.g., Hass et al., 2020; Rogawski et al., 2019; Stewart et al., 2021).

Conventions in mathematics also have connection to abstraction in mathematics (Dreyfus, 2020; Ferrari, 2003). A core practice of mathematics is abstracting similar structures from different contexts (Brousseau, 1997, 2002). This practice results in decontextualized objects, for which certain conventions might be adopted to track them in the absence of concrete quantities, such as using x primarily as the "input/independent" variable, or placing the output primarily on the vertical axis. Such conventions in communicating about abstract structures may be perfectly valid in the abstract space, but may conflict with reasoning within a quantitative context.

The goal of this theoretical paper is to examine cases of this convention across mathematics content areas to show how it may problematically intersect with contextual graphs that represent quantities. We explain how not understanding this convention *as* a convention can lead to issues in making sense of contextualized or quantitative interpretations of a graphical system. We then describe teaching implications based on our theoretical investigation and attempt to situate this convention more appropriately within learning about representing related graphical objects.

Conflicts between the Convention and Contextualization in Case Content Areas

In this section, we unpack the convention described in the previous section in three distinct mathematical content area cases. The primary purpose of this section is to show, theoretically, the conflicts that can arise between this particular convention and contextualization. The next section then discusses the pedagogical implications that may help address this conflict.

Case 1: Graphing Inverse Functions

One key concept in mathematics is inverse functions. Students are exposed to inverse functions each time they learn about a new function (e.g., exponential, trigonometric). A common convention of inverse functions is to graph the function and its inverse on the same set of axes, where the inverse is a reflection of the original graph over the $y = x$ line. Figure 1 shows common types of images students see in textbooks and in classrooms. In abstraction, this convention can make sense to examine how the features of the two graphs relate to each other.

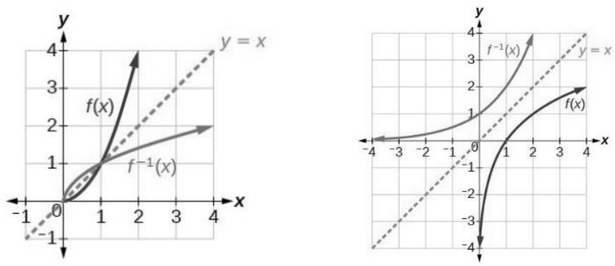

Figure 1: Common types of images of functions and inverses on the same set of axes

The problem with this convention is in moving to a contextualized situation. For example, if one examines a function converting Euros to U.S. Dollars, D(E) = 1.3E (Teuscher et al., 2018), one might create a graph with Euros on the horizontal axis and U.S. Dollars on the vertical axis. The point (50,65) on the graph suggests that an input of 50€ gives an output of \$65. However, if the inverse function is graphed as a reflection across the D = E line on the same axes, then the new graph conflicts with the quantitative meanings of the two axes. The point (50,65) reflects to the point (65,50), now suggesting, according to the axes, that 65€ corresponds to \$50, which is incorrect (Figure 2). To accurately interpret the placement of the two graphs on the same axes, a student must make *both* axes simultaneously represent *both* the D and E quantities, tracking which version of the axis label matches which graph is being examined. For novice learners of inverse functions, this may be quite sophisticated reasoning, obscuring the actual quantitative relationship that exists for a function and its inverse (see also Duval, 2016). Thus, the convention of placing two related graphical objects (graphs of a function and its inverse) on the same axes may conflict with contextualizing the functions and graphs through quantities.

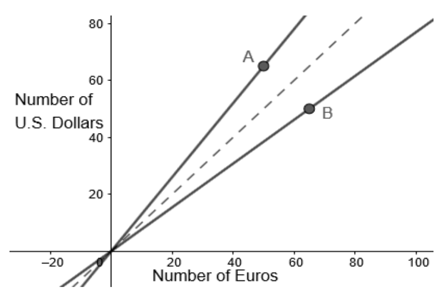

Figure 2: Graphs of function and inverse in the context of money

Case 2: Graphing Derivatives of Functions

This convention also appears in the practice of placing the graph of a function and the graph of its derivative on the same axes. Calculus textbooks and instructors often do this, as exemplified in Figure 3 taken from Stewart et al. (2021, p. 164) and Hughes-Hallett et al. (2012, p. 106). If the variables x and y represent nothing more than pure numbers, this practice is appropriate, since one can put the numeric outputs of f and f' on the same *unit-less* axes.

Olanoff, D., Johnson, K., & Spitzer, S. (2021). *Proceedings of the forty-third annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Philadelphia, PA.

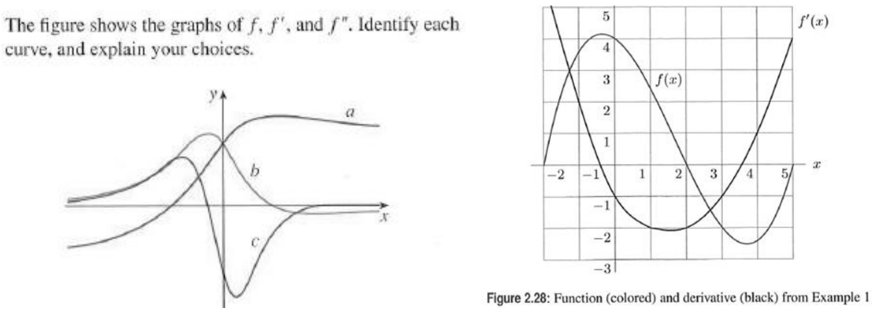

Figure 3: Function and derivative graphs on the same axes

As with inverse functions, the problem arises when trying to contextualize these functions. For example, suppose $f(x)$ represents the temperature in degrees Celsius as a function of time, with x in units of minutes. Then the output of the derivative, f', is the rate of change of temperature in degrees per minute, which is a fundamentally different quantity than the output of f as temperature. When placing f and f' on the same axes, some confusion arises: What quantity is represented by the vertical axis? Is it the temperature? The rate of change? Both? In fact, it would require *both* quantities being on the vertical axis simultaneously. For example, Figure 4, taken from Hass et al. (2020, p. 150), shows a position function (s) and its derivative function (velocity, v). Note the label "s, v" on the vertical axis, meaning that single axis is simultaneously representing two quantities. When looking at $s = 5\cos(t)$ or $v = -5\sin(t)$, one must constantly shift the vertical axis between position and velocity quantities and their associated units. While experts can likely make such subtle shifts without much problem, and it may even be a goal for students to eventually do such thinking, this convention again conflicts with contextualizing functions and their derivatives and examining them quantitatively, especially for novices.

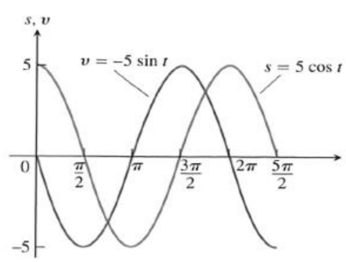

Figure 4: The vertical axis representing two quantities simultaneously

Case 3: Graphing Matrix Operations

One common way to think about matrix-vector multiplication in linear algebra is as a matrix performing a geometric transformation on a vector. In this perspective it is common to show the original vector and the transformed vector on the same set of axes (e.g., Poole, 2015), as in Figure 5. When working in the abstract world of vectors as geometric arrows or lists of unit-less numbers, this convention can help to illustrate the transformation that is represented by a particular matrix.

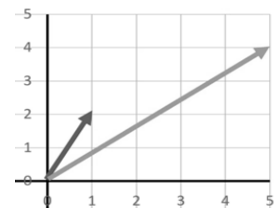

Figure 5: A vector and a transformed vector on the same set of axes

However, yet again, contextualizing vectors and matrices can possibly come into conflict with this convention. As an example, the second author collaborated with two secondary teachers to develop a set of tasks to help students better understand the structure of matrix multiplication and how matrix multiplication can be used to model real-world phenomena. The tasks used the context of two basketball players, Joaquin and Raul, who played the same position but averaged different numbers of points and rebounds each quarter, with Joaquin averaging 6 points and 3 rebounds per quarter and Raul averaging 2 points and 5 rebounds per quarter. The students were asked: The basketball coach wants his centers to combine for 20 points and 14 rebounds, because that might help them win the game. What number of quarters could the coach play Joaquin and Raul to average 20 points and 14 rebounds? This problem gives rise to the matrix equation: $\begin{bmatrix} 2 & 6 \\ 5 & 3 \end{bmatrix}\begin{bmatrix} J \\ R \end{bmatrix} = \begin{bmatrix} 20 \\ 14 \end{bmatrix}$, with solution $\begin{bmatrix} J \\ R \end{bmatrix} = \begin{bmatrix} 1 \\ 3 \end{bmatrix}$.

From a mathematical standpoint, we can think about this as a 2-by-2 matrix that transforms the vector $\begin{bmatrix} 1 \\ 3 \end{bmatrix}$ to the vector $\begin{bmatrix} 20 \\ 14 \end{bmatrix}$. However, the vector $\begin{bmatrix} 1 \\ 3 \end{bmatrix}$ is in units of *quarters played* for each player, $\begin{bmatrix} \text{1 J quarter} \\ \text{3 R quarters} \end{bmatrix}$, while the output vector has units of *points* and *rebounds*: $\begin{bmatrix} \text{20 points} \\ \text{14 rebounds} \end{bmatrix}$. When plotting these two vectors on the same axes, we again see a complication with what quantities the axes represent. The horizontal axis must simultaneously represent "Joaquin quarters" *and* "points" while the vertical axis must simultaneously represent "Raul quarters" *and* "rebounds" (Figure 6). Like with function inverses and derivatives, this is likely difficult for novices learning about matrix-vector multiplication, and we see that the convention of placing related graphical objects on the same axes once again can be at odds with contextualization.

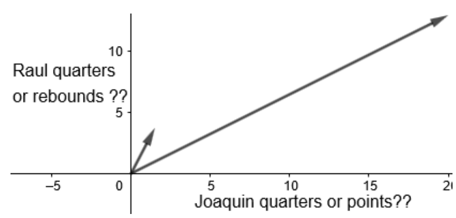

Figure 6: Conflict in the Quantities on Each Axis

When the Convention Does *Not* Conflict with Contextualization

To be clear, the convention of placing related, derived graphical objects on the same axes does not *always* conflict with contextualization. For example, consider certain graphical transformations, such as a vertical shift given by $f(x) + 4$ or a vertical stretch given by $2f(x)$ (Figure 7). If the function and graph represent a quantitative context, such as x representing the price of a good and $f(x)$ representing the amount sold of that good, then the transformations typically retain those same quantitative meanings. The function $f(x) + 4$ can represent that an additional fixed 4 units are sold at all price levels, and 2*f*(*x*) can represent that twice as many units are sold at each price level. In both of these cases, the vertical axis retains the same quantity "amount sold" and there is no conflict with the convention and the context.

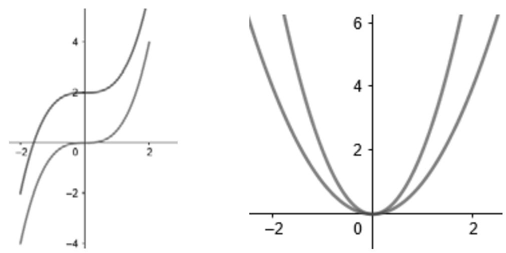

Figure 7: Transformations graphed on the same axes

Teaching Implications

We have explained how the practice of placing related, derived graphical objects on the same axes can often conflict with using quantitative contexts for functions and graphs. The answer should not be to avoid contextualization to sidestep the conflict and teach solely with abstract pure-numeric functions (Ferrari, 2003). But, it also cannot be to avoid the abstract convention, because it is a common practice. To address the dilemma, instruction should use context, but then help students see the convention *as* a convention (Moore et al., 2019; Thompson, 1992). To this end, we offer the following suggestions, based on Brousseau's (1997; 2002) idea of contextualizing mathematics in order to then re-decontextualize it. Thus, we take the stance that teaching using contextualized quantitative situations is crucial, but that students must be guided toward a comprehension and usage of the abstract convention we have described.

The first step must involve the teacher identifying whether a mathematical topic wherein two related graphical objects are commonly placed on the same axes actually conflicts with contextualization, or not, as we did in the previous section. Thus, the previous section contributes as a model for that type of conceptual analysis. If a potential conflict is identified, we recommend that the graphical representations of the two related objects initially be placed on *separate* axes. To use inverse functions as an example, if the class is learning that the function D(E) = 1.3E has an inverse function E(D) = D/1.3, then the two graphs should be placed initially on two separate axes (Figure 8). Doing so initially avoids the conflict between quantitative reasoning and using a single set of axes and permits the students to track how each graphical object (function or inverse, in this case) relates to the context's quantities. With each graph separate, students can develop quantitative reasoning about the overall context, without the difficulties described in the previous section, such as identifying the rate that one currency accumulates as the other currency accumulates (see also Moore, 2016; Moore & Thompson, 2015; Thompson & Carlson, 2017). Thus, in the first step, the focus is on quantitatively understanding each mathematical object *in its own right*, at the global level.

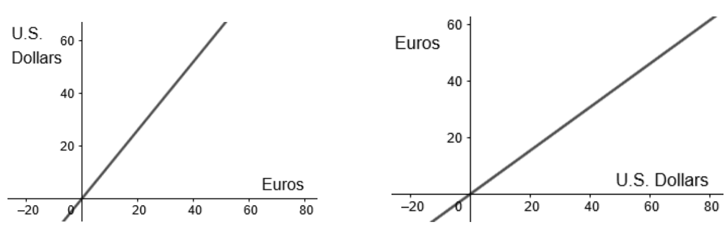

Figure 8: First, Begin with Related Objects on Separate Axes

The second step acts as an intermediate between the initial contextualization and the abstracted, decontextualized convention. In this step, students are asked to compare the two graphical objects to identify specific connections, differences, or relationships. A key part of this step is to explicitly ask the students to place the two sets of axes near each other in a way that facilitates comparisons between the two graphical objects. For example, suppose students are investigating the graphs of a function and its derivative, where $f(x)$ represents the temperature as a function of time. As per step one, the students have represented the graphs of f and f' on separate axes and have examined the behaviors of the temperature and the rate of change separately. The teacher could ask, "Compare the graph of f with the graph of f'. What connections do you see between them? I encourage you to put the derivative graph directly underneath the function graph to help compare them." Such placement allows some connections to become clearer, such as what behavior for f is associated with f' being positive, negative or zero (Figure 9). The key feature of this step is that, while still on separate axes, the students are now thinking about the benefits of placing the graphs more closely to each other. The physical placement gets the students one step closer to the convention, while still maintaining a focus on the quantitative relationships.

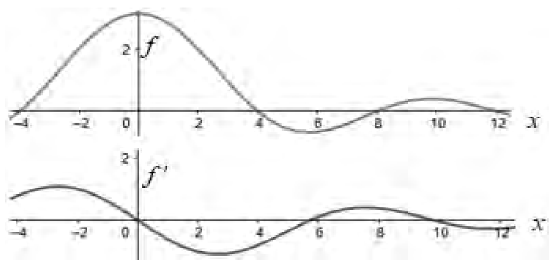

Figure 9: Second, Place Graphs in a Way to Examine Specific Connections

The third step then moves to the abstract convention and its purposes, while explicitly attending to quantitative difficulties associated with the convention. In this step, the teacher can place the two graphical objects on the same axes and ask the students what the advantages and disadvantages of doing so might be. To use matrix-vector multiplication as an example, suppose a teacher has used the quarters-played / points-rebounds context, has started with the vectors on two different axes (step one), and has had the students compare the two vectors by placing the two axes close to each other (step two). The teacher then places the two vectors on the same axes, and asks, "What might be the benefit of putting the two vectors on the same axes? But what might be confusing about doing that?" This step helps students identify the benefits of seeing directly how one vector can be thought of as a transformed version of the other. Yet, the discussion also helps students see the difficulties in thinking about one vector as representing one pair of quantities (quarters played) while the other vector represents a different pair of quantities (points and rebounds). By now seeing this convention *as* a convention (Thompson, 1992), the students can see why it is used in the first place, when they might choose to use it, and what cognitive work they need to do to make sure they can quantitatively interpret graphs superimposed on top of each other.

In conclusion, we believe these three steps address the problems described in the previous section by allowing the concepts to be taught with contextualization and quantitative reasoning, but then gradually transitioning to the abstract convention (Brousseau, 1997; 2002). Such a sequence of steps makes the convention of placing the graphical objects on the same axes more reasonable, but also helps students be aware of the challenges associated with it. We believe these steps put students in a better position to develop the sophisticated abstract thinking that goes along with assigning multiple (conflicting) quantities on the same axis. Students can use this convention appropriately both within and outside mathematics. That is, not only can they better appreciate the convention for abstract graphical objects, but they can also better reason about contexts that *are* represented with multiple quantities on the same axis, such as the position and velocity graphs in Figure 4, or the “double *y*-axis” graphs shown here in Figure 10.

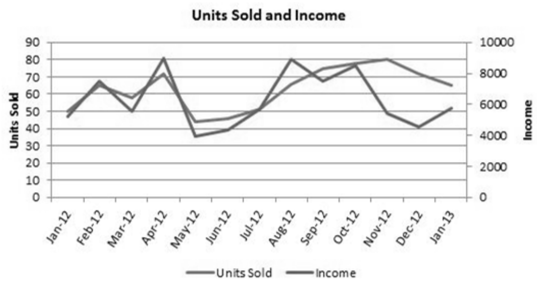

Figure 10: Double *y*-axis Graphs with Two “Vertical Axis” Quantities

Productive use of student mathematical thinking is a critical yet incompletely understood dimension of effective teaching practice. We have previously conceptualized the teaching practice of building on student mathematical thinking and the four elements that comprise it. In this paper we begin to unpack this complex practice by looking closely at its first element, establish. Based on an analysis of secondary mathematics teachers' enactments of building, we describe two critical aspects of establish—establish precision and establish an object—and the actions teachers take in association with these aspects.

Keywords: Classroom Discourse, Communication, Instructional Activities and Practices

The Association of Mathematics Teacher Educators [AMTE] Standards (2017) argued that an important component of whole-class instruction is the "intentional discussion of selected and sequenced student approaches... to move students through a trajectory of sophistication toward the intended mathematics learning goal of the lesson" (p. 16). This argument is supported by other related recommendations (National Council of Teachers of Mathematics [NCTM], 2014) that have highlighted the importance of productively using students' mathematical thinking as part of whole-class instruction. There are many different ways that teachers can productively use students' mathematical thinking, however, and these ways are determined, at least in part, by the nature of the thinking itself (Stockero et al., 2020). It has been posited that some instances of student thinking are of particular importance and that using them productively can be especially advantageous (Leatham et al., 2015).

That said, taking advantage of such instances requires coordinating a complex collection of teaching practices, and there is evidence that certain aspects of these practices do not occur naturally in whole-class instruction (Stockero et al., 2020). To better understand and improve teachers' ability to engage in complex practices, Grossman and her colleagues (2009) suggested that practices be decomposed into their "constituent parts" (p. 2069) for the purpose of helping teachers develop these practices. We have previously conceptualized the teaching practice of *building on student mathematical thinking* and the four elements that comprise it (see Van Zoest et al., 2016). In this paper we begin to further decompose this complex practice by looking closely at its first element, *establish*.

Theoretical Framework

Before describing the teaching practice of building, we first introduce the type of instances of student thinking that this practice is intended to take advantage of. As we have described elsewhere in greater detail (Leatham et al. 2015), MOSTs (**M**athematically Significant Pedagogical **O**pportunities to Build on **S**tudent **T**hinking) occur at the intersection of three critical characteristics of classroom instances: student mathematical thinking, significant mathematics, and pedagogical opportunity. Particularly relevant to this paper, MOSTs are observable instances of student mathematical thinking that provide sufficient evidence to "make reasonable inferences about student mathematics" (Leatham et al., 2015, p. 92).

When we say *building on student mathematical thinking* we mean the teaching practice that takes advantage of the opportunity that a MOST provides (Van Zoest et al., 2016). More specifically, we define *building on a MOST* (hereafter referred to as *building*) as making a MOST "the object of consideration by the class in order to engage the class in making sense of that thinking to better understand an important mathematical idea" (Van Zoest et al., 2017, p. 36). As we unpacked that definition in the context of our collective experience with analyzing teaching (our own and that of others), we theorized that building is comprised of four elements: (1) *establish* the student mathematics of the MOST as the object to be discussed; (2) *grapple toss* that object in a way that positions the class to make sense of it; (3) *conduct* a whole-class discussion that supports the students in making sense of the student mathematics of the MOST; and (4) *make explicit* the important mathematical idea from the discussion.

As part of our ongoing research, we have been investigating these elements. The current paper focuses on the first element and addresses this research question: What are necessary components of the *establish* element of building as revealed through teachers' attempts to enact the practice?

Literature Review

Productively using student thinking during whole-class discussion involves teachers capturing the essence and relevant details of student contributions (a central purpose of the *establish* element of building). Thus, research on productive whole-class discussions sheds some light on this important facet of teaching, although it has seldom been the direct focus of studies. For example, van Zee and Minstrell (1997) described a *reflective toss*, which is a teacher response that "elicit[s] further thinking by *catching the meaning of the student's prior utterance* and throwing responsibility for thinking back to the students" (p. 241, italics added). Another example comes from the work of Webb et al. (2014), who identified teacher moves that facilitate students "referencing *the details of another student's idea*" (p. 88, italics added) as an important aspect of promoting students' productive engagement with their peers' mathematical thinking. Implicit in these findings is the need for the meaning and details of student contributions to be available for reference. Knowing more about capturing the essence and relevant details of student contributions (and thus about aspects of *establish*) is critical to understanding productive use of student mathematical thinking during whole-class discussion.

One significant contribution to understanding this preliminary facet of productively using student thinking is Staples' (2007) model of a teacher's role in supporting collaborative inquiry. A key component of this model, which was conceptualized through her longitudinal study of one high school teacher, is the work a teacher needs to do to *establish and monitor a common ground*. Staples identified a variety of instructional strategies that a teacher may use to establish student ideas as the common ground. One strategy was repeating student contributions and using multiple modes of communication (e.g., verbal, written) to provide students with a variety of opportunities to access one another's ideas. Another strategy involved publicly recording ideas in a structured way on the board to provide some permanence of student contributions and to facilitate students' development of an idea throughout an inquiry. Later she further elaborated by indicating that the goal of such practice is "not perfect use of vocabulary or formal sentences, but rather clear enough expression of ideas so that both the teacher and other students can consider the contribution" (Staples & King, 2017, p. 40). Our study builds on Staples' work in this area by investigating the *establish* element of building with multiple teachers who were conducting whole-class discussions around the same tasks and often the same student thinking. Broadening the pool of teachers and simultaneously focusing on comparable situations across them provided a rich data set that allowed us to more fully identify necessary aspects of *establish* and the subtleties that are involved in teachers accomplishing it.

Methods

In order to study our theorized practice of building we enlisted 12 teacher researchers—practicing secondary mathematics teachers who desired to more productively use their students' mathematical thinking. These teachers enacted the building practice in their classrooms using four mini tasks (see Figure 1) that were designed to elicit particular MOSTs, resulting in 27 building enactments. We compared these enactments to our initial conceptualization of building by coding transcripts of the enactments for actions that seemed to either facilitate or hinder the overall practice of building. Analysis of these coded data led to refinement of the four elements of building, including identifying necessary aspects of each and a variety of associated subtleties. With respect to the focus of this paper—*establish*—our analysis revealed both aspects of this practice and actions teachers might take to effectively position student contributions to become the object of discussion.

(a) Percent Discount The price of a necklace was first increased 50% and later decreased 50%. Is the final price the same as the original price? Why or why not?	**(c) Points on a Line** Is it possible to select a point B on the y-axis so that the line $x + y = 6$ goes through both points A and B? Explain why or why not. 
(b) Variables Which is larger, x or $x + x$? Explain your reasoning.	**(d) Bike Ride** On Blake's morning bike ride, he averaged 3 miles per hour (mph) riding a trail up a hill and 15 mph returning back down that same trail. What was his average speed for his whole ride?

Figure 1: The Four Mini Tasks Used in Creating Instantiations of Building

Results

We describe here two aspects of *establish*: *establish precision* and *establish an object*. (A third identified aspect, *establish intellectual need*, is beyond the scope of this paper.) In order to effectively position a student contribution (a MOST) to become the object of discussion teachers must establish (a) precision—the student contribution must be clear, complete, and concise so that the class can focus on making sense of that contribution, and (b) an object—the contribution must take on a measure of permanence and identity so that it can clearly be referred to during the remainder of building. In the following sections we elaborate on these two aspects, describing actions teachers take in association with each aspect. Note that although students might spontaneously take actions that contribute to making the contribution precise or an object, we focus here on the actions teachers take to ensure that these aspects are satisfied. Those teacher actions initiate the work, even though the actor could be students or the teacher.

Establish Precision

The first aspect of *establish* requires that the teacher ensure that the student contribution is clear, complete, and concise. Precision is important because making imprecise thinking the object of consideration is likely to hamper building (Peterson et al., 2020). By carrying out this aspect, the teacher establishes what it is the class is going to make sense of during the *conduct* element of building.

Of course, not all student contributions are imprecise; some are stated precisely to begin with. Precise contributions, however, were more the exception than the rule in our data. Analysis of the building enactments revealed a number of ways that student contributions were not precise enough for students to engage in making sense of them. In the following sections, we consider three actions that might be needed to establish the precision of a student contribution: clarifying, expanding, and honing.

Clarifying. Clarifying is about making clear WHAT the student has said. We discuss here two types of situations where clarifying actions may be needed. First, student contributions often need to be clarified because students use informal language or pronouns with vague referents (Peterson et al., 2020). For example, during a Percent Discount (Figure 1a) enactment, as a student was sharing their solution, they said, “Like you’re subtracting it.” The teacher followed up with, “Okay, subtracting what?” and the student replied, “50 percent.” We see here that the teacher’s question helped to make clearer this part of the student contribution by making the referent explicit. This type of clarifying also occurs when details that are naturally left out of a contribution due to conversational conventions, such as the prompt the student was responding to, are added in.

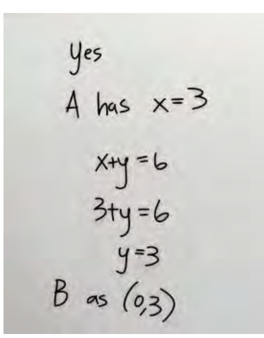
Second, student contributions need to be clarified when students share the substance of their reasoning, but the logical structure of those ideas are not clearly articulated. For example, consider this student contribution during a Variables (Figure 1b) enactment: “I believe that x plus x is larger because if x is just one value, x plus x would be double the value, which in this case makes it larger,” and the teacher’s response, “You were thinking x plus x is larger than x, because when you add the values, it makes it double, so it’s larger?” Without changing the logic of the student’s contribution, the teacher clarified the logical structure. By confirming with the student that the clarification was accurate, the teacher has clarified the contribution for other students in the class and kept the focus on the student contribution.

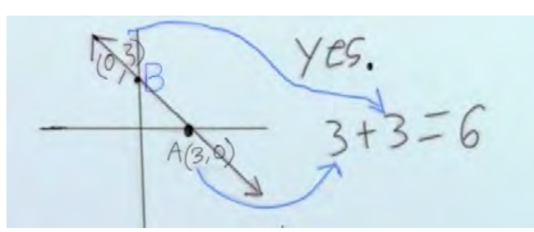
Expanding. Expanding is about making the contribution complete and involves adding something to the contribution that is needed to position the class to engage in making sense of it. The most common expansion situation that we saw in the enactments we analyzed was when a student provided an answer without reasoning. Student contributions that are merely an answer need to be expanded because the class will not be able to fully make sense of the contribution without the underlying reasoning behind that answer. For example, in response to Variables (Figure 1b), a student initially simply stated, “x + x is greater than x.” Although the teacher knew the student had reasoning for their answer from monitoring students’ work, without expanding the student’s contribution to include the reasoning, the class would be left guessing about what exactly they were to make sense of. When asked to share their explanation for their answer, the student elaborated, “So x plus x will be 2x, and x will be just 1x.” This expansion provided the necessary fodder for a sense-making discussion. This teacher expanded further when they responded, “So you’re saying 2x is bigger than 1x, is that what you’re saying?” This response seems to be important as it makes explicit the critical reasoning that was missing. As mentioned above, confirming that an inference is accurate keeps the focus on the student's contribution.

Student contributions also need to be expanded when reasoning is present, but a piece of information needed to make the contribution complete is missing. For example, during a discussion about Bike Ride (Figure 1d), a student wrote (a+b)/c on the board and explained that c represented the number of speeds. Although it is possible to infer what a and b represented, asking the student to explicitly define these variables made the contribution more complete. There was nothing unclear about what the student said, but their explanation did not provide all the information the class would need to make sense of it. In both these latter examples, rather than counting on students to guess the missing information or to infer the implicit information, the expansion made that information explicitly available, and resulted in a more complete contribution—one the class was better positioned to collaboratively make sense of.

Honing. Honing is about making the student contribution concise and involves reducing it to its essence. Sometimes a student contribution contains extra verbiage or extraneous information that is unnecessary for, and may even interfere with, making sense of the student contribution. Making these contributions concise requires removing unnecessary information that might distract students from the main sense-making opportunity. For example, during a Variables (Figure 1b) enactment, a student explained part of their reasoning as, "Because they have the same shirt, so they can be added together, so x plus x will be 2x." The teacher response honed the student contribution by taking up the "so x plus x will be 2x" piece of the student contribution and omitting the part about "the same shirt."

More often, honing is a matter of capturing ideas within a student contribution more succinctly by using symbols or other shorthand. For example, in a Points on a Line (Figure 1c) enactment, a student explained, "I put 'yes' because A has the point, like, its x equals 3," to which the teacher commented, "All right, so, 'Yes, A has x equals 3,'" as they wrote that same information on the board (Figure 2a, lines 1 and 2). The student continued their explanation, "And then the equation is x plus y equals 6, so then I just plugged in the x, which is 3, plus y, equals 6 and figured out y, it needs to be 3, and then just put point B as (0,3)." The teacher listened and carefully captured what the student was saying on the board (Figure 2a). In this case, the teacher made the student contribution more concise by the use of mathematical symbols. In a different Points on a Line enactment, part of a student explanation included, "3 plus 3 equals 6 where the first 3… come[s] from A and the second 3 comes from B." In Figure 2b, we see how, rather than writing down what the student said in words, the teacher concisely captured their contribution by drawing lines from the 3s in each of the two points on the line to the corresponding 3 in the equation. All of these honing actions contribute to making the student contribution more precise by making it appropriately concise.





(a) (b)

Figure 2: Two Illustrations of Teachers Establishing Precision through Honing

Establish an Object

Beyond establishing what the student contribution is (just described in Establish Precision), *establish* also entails the work of ensuring that the student contribution is established as an object, as a "thing" that can be considered. The initial goal of establishing a contribution as an object is to support making the *grapple toss* as efficient and effective as possible; it is much easier to toss an object—and for students to then engage with it during the *conduct* element—when the object is well-defined. We have come to see objects as well-defined when they have a high degree of both permanence and identity.

Our analysis of building enactments revealed a number of teacher actions that have the potential to contribute to establishing the student contribution as an object. In the following sections we describe two main sets of teacher actions that seem to contribute to this aspect of *establish*: re-presenting the object, which makes it more permanent, and referring to the object, which contributes to the identity of the object.

Re-presenting the Object. Re-presenting happened most frequently in the enactments we analyzed when student contributions were first made public orally (as opposed to students initially sharing their work at the board or on a document camera). In order to set these contributions apart from the ongoing conversation, teachers can re-present them. Re-presentation acts serve to demarcate a student contribution from the ongoing discussion and thus give it a degree of permanence, a staying power that often does not exist with the numerous passing comments of classroom discourse. These re-presentation acts signal a pause in the ongoing dialogue and begin to create space for a new kind of activity—one that will make the student contribution the object of consideration.

One option is for the teacher to re-present the oral student contribution orally. Two common forms of re-presentation occurred in our data: repeating and revoicing. Consistent with the definitions of others (e.g., Chapin et al., 2009; Forman et al., 1998), repeating is when the entire object is restated with no replacement in language and revoicing is when the student contribution is paraphrased without changing its meaning. One benefit of re-presenting through revoicing is that the re-presentation may be a more precise object than the original. One risk of re-presenting through revoicing is that a poorly executed revoicing may result in an object that is less precise.

Another way to re-present an oral student contribution is to switch to a written presentation (as the teachers did in Figure 2). Creating a public record of an oral student contribution by, for example, inviting the student to write what they said on the board or by acting as scribe themselves, is a way for the teacher to take the somewhat ephemeral spoken word and make it more tangible. That is, the student contribution becomes something the teacher and students can hold on to, can refer to, can operate on. It creates, in essence, a physical object that can be referred to in the *grapple toss* and pursuant discussion. Creating a public record sets the MOST apart from other verbal contributions during a whole-class discussion, giving it a permanence that is difficult to achieve otherwise.

Referring to the Object. Another way that teachers establish the student contribution as an object involves referring to the thinking AS an object. In other words, treating the student contribution as an object makes it more of an object. Such referring creates a sense of identity for the object. But student contributions are complex entities (often several sentences in length). We have found a number of ways that teachers refer to student contributions, some of which have more potential than others to contribute to making the student contribution an object.

One way a teacher may refer to a student contribution as an object is to use a pronoun (i.e., that, this, it) for which everyone would likely know that the referent is the student contribution. For example, during a Percent Discount (Figure 1a) enactment, a student contributed, “Because you’re adding fifty and then you’re taking away fifty percent,” and the teacher responded, “Say it again, what you just said.” Members of the classroom would likely recognize that the “it” in “say it again” was referring to the entirety of the students’ contribution, which helps to make the contribution an object. Furthermore, students would likely recognize that the phrase “what you just said” was also a somewhat generic way of referring to the student contribution.

A second way of referring to the object is to name it. We have seen teachers name student contributions by characterizing the nature of the thinking (e.g., this claim, this reasoning), attributing that thinking to the student by name (e.g., Tray’s thinking)—and sometimes by doing both (e.g., Jaden’s claim). Naming, a form of *metatalk* (Leinhardt and Steele, 2005), is a way of marking the student contribution so the class can access it again when the name is used.

A third way of referring to the object is for a teacher to point to or make a gesture toward a public record of the student contribution. The action of pointing at the board contributes to the student contribution being the object that the class is to focus on as the discussion continues.

The aforementioned ways of referring to a student contribution (pronouns, generic terms, naming, and pointing) vary in their potential to contribute to making a student contribution an object. Referring to the object by name seems to have the most potential for making the student contribution an object because a) the name reduces the potential for ambiguity in the referring, and b) because the name makes the student contribution easily identifiable for future reference.

Although we are not claiming that any particular subset of objectifying actions is necessary for “sufficiently” establishing the student contribution as an object, our analysis of teaching enactments suggests that re-presenting the contribution by creating a precise public record of it and referring to it by name (based on the nature and/or the contributor) provide a strong foundation for the *grapple toss*. Given the difficulties students have in focusing on making sense of a specific contribution (Franke et al., 2015; Webb et al., 2014), the more scaffolding we can provide in that regard, the more likely they are to maintain this focus.

Discussion & Conclusion

Establish is comprised of three aspects (see Figure 3), two of which were discussed in this paper: establish precision and establish an object. The goal of establish precision is to ensure that the student contribution is clear, complete, and concise, accomplished respectively by clarifying, expanding, and honing actions. The goal of establish an object is to ensure that the student contribution achieves a measure of permanence and identity, accomplished respectively by re-presenting and referring actions. In other words, we want the class to know exactly what the student contribution is and also position that contribution as an object that can easily be referred to and acted upon throughout the remaining elements of building.

Element	Establish						
Aspect	Precision			An Object		Intellectual Need	
Action	Clarifying	Expanding	Honing	Re-presenting	Referring		

Figure 3: Establish Broken Down by Aspects and Associated Actions

We conclude with several observations about these aspects of *establish*. First, whereas the work of establishing precision operates on the pieces of the student contribution in order to create a clear, complete, and concise object, the work of establishing an object operates on the object as an entity, re-presenting and referring to the entire object in order to make it more of an object. For instance, when expanding, one adds a piece to the object, and when honing, one removes a piece from or replaces a piece of the object. In contrast, when re-presenting through revoicing, one paraphrases the entire object, and when referring through naming, one names the entire object.

Second, the *establish* element of building is a teacher practice—it is always the teacher's responsibility to *ensure* that the student contribution is a precise object. The teacher does not always need to be the one who makes a student contribution a precise object, but they DO always need to consider WHETHER the contribution is precise and a well-defined object and take action if it is not. That said, there are many different ways that both the teacher and the contributing student carry out *establish* actions. For example, although the desired action might be "clarify," the teacher might invite the contributing student to clarify or they themselves might provide the clarification with a confirmation from the contributing student. As we have discussed elsewhere (Van Zoest et al., 2021), it is helpful to disentangle the actor from the action in order to unpack critical nuances of teacher responses to student mathematical thinking.

Third, although we have discussed these aspects and associated actions of *establish* discretely, generally they do not occur as such in practice. That is, teachers often accomplish multiple aspects of *establish* simultaneously. We see this in Figure 2a, where the teacher is engaged in honing (as discussed), as well as re-presenting by creating a public record of the student's oral contribution and clarifying the reasoning of the contribution by placing each piece of the logic on a separate line.

Finally, the individual actions we have identified are not new—they have been discussed to some degree in the literature. Furthermore, others have observed relationships between these actions and broader teacher practices, noting that it is valuable to consider actions (e.g., clarifying) with respect to "the purpose that those techniques are serving" (Boerst et al., 2011, p. 2854). Our work here illustrates the importance of coordinating a collection of actions in order to accomplish a particular purpose, in this case to *establish* a student contribution as part of the broader teaching practice of building on that contribution.

Unpacking *establish* has allowed us to better understand the complexity and craft of this critical element of building, better positioning us to work with teachers to develop their abilities to productively use student mathematical thinking.

NOTICING FOR EQUITY IN WRITTEN WORK: EXPLORING ONE TEACHER'S STUDENT WORK ANALYSIS PRACTICES

Miriam Leshin
Stanford University
mleshin@stanford.edu

Attending to students' thinking and using it to inform instruction has been shown to be an effective teaching practice. Although research on teacher noticing has explored how teachers attend to and interpret thinking in the moment and through video, less is known about the ways in which teachers notice students' thinking in written work, as well as the cultural dimensions that shape noticing. While work on "noticing for equity" has begun to explore the latter, it focuses on noticing of participation. This qualitative case study asks if equitable noticing extends to students' work. Analysis of one equity-oriented math teacher's student work analysis practices revealed that she a.) attended to the details of students' strategies with a learner stance, b.) contextualized their understandings, c.) interpreted their understandings through a strengths-based lens, and d.) planned to respond by identifying aspects of work to share with the class.

Keywords: Teacher Noticing; Equity, Inclusion, and Diversity

Introduction

Research has shown that when teachers attend closely to their students' mathematical thinking, they can use it to inform instruction, leading to gains in achievement (Carpenter et al., 1989). When teachers deeply understand students' thought processes, they can build on their prior knowledge and leverage student-generated strategies for class learning. Studies on "teacher noticing" of thinking and of classroom activity have explored what teachers attend to and how they interpret it (Jacobs et al., 2010; Sherin & van Es, 2005). Although teacher noticing has been studied primarily in the midst of teaching or in video, teachers can also attend to students' thinking by examining their written work (Kazemi & Franke, 2004). Less is known about what and how teachers notice thinking in work, as well as the ways in which that noticing is shaped by teachers' pedagogical commitments (Erickson, 2011), dispositions (Hand, 2012), and immersion in dominant discourses about mathematics (Louie, 2018). While work on "noticing for equity" has begun to explore these cultural dimensions of noticing, it focuses on noticing of participation (van Es et al., 2017; Wager, 2014). This study asks if equitable noticing might extend beyond participation—as noticed in-the-moment or on video—to students' written work. Given that student work is accessible and can be looked at outside of instruction, it is an untapped resource for making sense of thinking. Understanding equitable ways of noticing thinking in written work may support teachers in their practice, teacher educators training novice teachers, and researchers documenting equitable math pedagogies. While noticing of thinking and noticing for equity have been theorized separately, illuminating connections between the two may support future study of their intersections. This qualitative case study uses think-aloud protocols to explore one equity-oriented math teacher's student work analysis process, investigating the following questions:

1. What and how does an equity-oriented teacher notice when examining their students' written work?
2. In what ways do a teacher's pedagogical commitments and dispositions inform their noticing when examining their students' written work?

Conceptual Framework

This study draws on three bodies of literature to examine the ways in which an equity-oriented teacher's pedagogical commitments and dispositions shape what and how they notice when looking at work (figure 1). The teacher noticing literature has included several studies involving student work analysis related to the construct of noticing children's mathematical thinking. Scholars have recently extended the noticing literature towards theories of equitable mathematics pedagogy, utilizing "noticing for equity" to document equity-oriented teachers' noticing of participation. In these studies, scholars argue that teachers' commitments to equitable pedagogy shape their equitable noticing of participation. In exploring noticing for equity in written work, this study suggests pedagogical commitments also shape noticing of thinking.

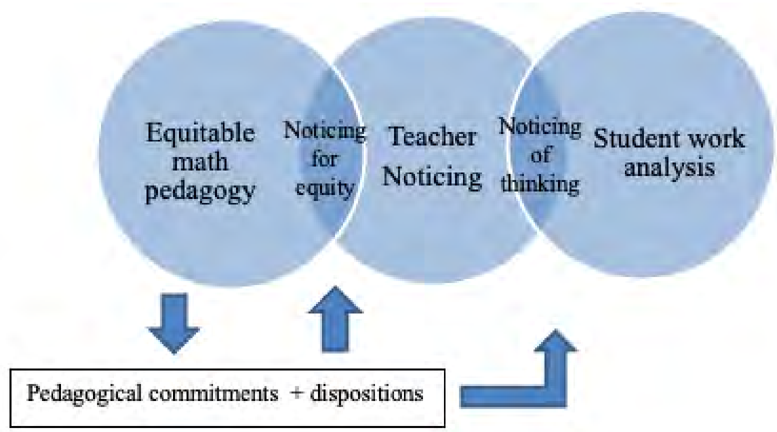

Figure 1: Conceptual Framework

Teacher Noticing

The teacher noticing literature builds on Goodwin's (1994) concept of "professional vision," defined as "ways of seeing and understanding events" that are distinct to a social or professional group (p. 606). In their study of noticing mathematical thinking, Jacobs and colleagues (2010) conceptualized noticing as three interrelated cognitive processes: attending to details of students' strategies, interpreting students' understandings, and planning to respond based on those understandings. The authors found that teachers improved their noticing through professional development in which they analyzed video and written work from their own students and anonymous students. The teachers attended to more details of a student's thinking and used robust evidence to interpret their understanding and to plan to respond (Jacobs et al., 2010). Similarly, Sherin and van Es (2005) found that teacher participants in video clubs shifted from an evaluative to an interpretive stance. Goldsmith and Seago (2011) found that teachers engaging in professional learning with video or work attended more deeply to mathematical details, used evidence from artifacts to support claims, and noticed more potential in students' thinking.

Student Work Analysis & Noticing of Children's Thinking

Other researchers have examined the affordances of student work analysis without using the noticing construct. In their study of a workgroup in which teachers collectively analyzed their own students' work, Kazemi and Franke (2004) found that teachers learned to attend more closely to their students' thinking, becoming more detailed in their descriptions of students' strategies, developing an appreciation for students' unique mathematical ideas, and finding ways to elicit and build on students' thinking. Additionally, researchers have found that student work can serve as a resource to deepen teachers' knowledge around student thinking and to strengthen instruction (Ball & Cohen, 1999). Despite these affordances, researchers have identified constraints in looking at student work. Goldsmith and Seago (2011) found that when looking at anonymous work, teachers attended closely to students' reasoning and remained open to multiple possible interpretations, but they focused more on lesson details rather than the specifics of thinking when looking at their own students' work. Accordingly, researchers advocate for an inquiry-based approach to looking at work to support teachers to focus on the details of thinking and to carefully draw on their knowledge of students and context (Little et al, 2003).

Equitable Mathematics Pedagogy & Noticing for Equity

The teacher noticing literature has focused on noticing as a cognitive process; however, Louie (2018) argues that scholars ignored two aspects of Goodwin's professional vision: noticing is culturally situated and is not politically neutral. Erickson (2011) identifies a teacher's "pedagogical commitments" as the tacit and explicit ontological assumptions about teaching and learning that shape noticing. Hand (2012) posits that what teachers notice is informed by their "dispositions," which are the perspectives they have developed through both their teaching experiences and life experiences. Building on Hand, Louie (2018) argues that teachers' immersion in dominant ideologies shapes what and how they notice. The dominant mode of instruction in math classrooms is knowledge transmission from teacher to student (Boaler, 2016), which corresponds to similarly narrow definitions of ability (Louie, 2017). Narrow notions of ability are not applied equally, as racialized discourses that position white and Asian students above Black and Latinx students persist in and beyond classrooms (Shah, 2017). Teachers, particularly white teachers, are immersed in these ideologies, which may shape their noticing.

Emerging work on "noticing for equity" considers these cultural dimensions of noticing. R. Gutiérrez (2007) argues that achieving equity means no longer being able to predict, based on group membership, students' achievement, participation, and ability to mathematically critique the world. One line of inquiry on equitable pedagogy works to expand conceptions of mathematical activity and ability (Louie, 2017) through practices like Complex Instruction—a form of groupwork that combines multi-dimensional content with attention to status (Cohen & Lotan, 2014), including teachers noticing students' strengths (Jilk, 2016). Building on this work, van Es and colleagues (2017) define "noticing for equity": "How mathematics teachers notice aspects of classroom activity that have consequences for whether or not particular groups of students feel more or less empowered to take up these practices [i.e. engagement in mathematical reasoning]" (p. 252). In their study, the authors found that teachers' equitable instructional practices were connected to particular forms of "noticing for equity" around participation, such as attending to issues of status and positioning, attending to individual students' histories to inform interactions, and attending to the energy and flow of the class (van Es et al., 2017). Similarly, Wager (2014) found that teachers' positionality toward equitable pedagogy was connected to noticing of participation. These studies examined noticing of participation in-the-moment or in video; less is known about equitable noticing of thinking in students' work.

Methods

Study Context & Participant

I identified Ms. D[1] as "equity-oriented" due to her pedagogical commitments (Erickson, 2011), her implementation of equitable math pedagogies, and her dispositions (Hand, 2012) toward pushing back on dominant discourses about mathematics for Black and Latinx students. Ms. D, who identities as a white woman, is National Board Certified and has taught at public and charter schools in California for the past 23 years. Originally trained as a science educator, she became fascinated with her students' thinking when she began teaching middle school mathematics 20 years ago and has since engaged in significant professional learning around listening to and learning from students' thinking. While Ms. D is not representative of the broader teaching force, she does represent, as Shulman (1983) writes, "images of the possible."

Ms. D's fascination with students' thinking and commitment to equity are integrated into her teaching philosophy. She believes it is her responsibility to "create the conditions that promote equity," defining equity as all students having access to multiple approaches to mathematical content, different ways of participating, a supportive relationship with their teacher, and collaborative relationships with classmates (Interview 1). This resonates with Ms. D's philosophies: 1.) mathematics consists of different ways of thinking; 2.) people learn through participation and interaction, and 3.) building relationships with and among students helps establish a learning community in which students' identities within and beyond the classroom are acknowledged. Relatedly, Ms. D aims to address power in her classroom, implementing Complex Instruction (CI) and working to center her Black and Latinx students' voices.

Data Collection

I used a case study design (Yin, 2009) and grounded theory analysis (Strauss & Corbin, 1994) to illustrate one teacher's practice of looking at student work. Data was collected during the 2019-2020 school year, which was Ms. D's first year at a public middle school, where she teaches sixth grade mathematics. The district in which she teaches is 8% Asian, 24% African American, 32% White, 21% Latinx, and 15% multi-ethnic/other. As a result of COVID-19 and the shift to remote learning, the majority of data collection took place over Zoom. Because this study centers around student work analysis, the primary data source consisted of three think-alouds, in which Ms. D made sense of her students' work, each followed by a short interview protocol. Students' work samples consisted of individually completed "Cool Downs" (i.e. exit tickets), which prompted students to represent their thinking in multiple ways. For the first think-aloud, which was video recorded in person, work samples came from the 20 students who were present and whose families had consented. For the second and third think-alouds, which were recorded via Zoom, work samples came from 19 (think-aloud 2) and 16 (think-aloud 3) of the 20.

Secondary data sources were used to contextualize Ms. D's noticing, given that teachers' philosophies and dispositions may shape their noticing (Erickson, 2011; Hand, 2012). Prior to the think-alouds, a semi-structured interview (Glesne, 2005) was conducted to gather information about Ms. D's context, philosophies, conceptions of equity, and experience with equitable pedagogies. The original design involved observing Ms. D's class the day of each think-aloud. One observation was conducted on the day of think aloud 1, during which fieldnotes were generated (Emerson et al., 2011). Due to the shift to online learning, no additional observations were feasible. Instead, Ms. D's weekly digital materials were consulted as artifacts.

Data Analysis

In the first phase of analysis, I identified Ms. D's pedagogical commitments. I engaged in line-by-line open coding of the interview transcript, from which bottom-up codes of Ms. D's pedagogical commitments and conceptions of equity emerged (Emerson et al., 2011). I refined these codes through visual diagraming and coding of observation fieldnotes, constructing a pedagogical commitments codebook which I then used to focus code the transcript.

In the second phase, I analyzed how Ms. D made sense of work in the think-alouds. I constructed time-indexed content logs (Derry et al., 2007) of the recordings and transcribed dialogue and movement of work. I broke the transcript into idea segments—separated by a change in an idea or turn—which served as the unit of analysis for three rounds of coding: open coding; a priori coding using Jacobs and colleagues' (2010) noticing framework; and focused coding for connections to equitable math pedagogy literature. I constructed a codebook based on commonalities across the rounds and used it for a fourth round of coding. To generate themes, I wrote analytic memos and constructed diagrams of Ms. D's think-aloud process and relationships among codes. I then mapped each theme back to its related codes and excerpts, confirming that each theme was supported by evidence from at least two think-alouds. Finally, I looked for counterexamples of themes, expanding one theme to account for its complexity.

Findings

My analysis showed that Ms. D noticed students' mathematical thinking in ways that potentially promote equity. Although she engaged in the three cognitive processes of the Jacobs et al. (2010) framework, she did so through the lens of her pedagogical commitments. As she attended to the details of students' strategies, she maintained a learner stance, acknowledging her uncertainty with their thinking. As she interpreted understanding, she contextualized it within the learning environment, drawing on her knowledge of students and critically reflecting on the opportunities to learn that she had provided. These noticings supported Ms. D to engage in a strengths-based interpretation of students' understandings, recognizing strengths and partial understandings. Finally, her expansive definition of mathematical understanding supported Ms. D to notice aspects of students' work to share with the class as part of her plans to respond.

As has been found in studies of noticing thinking, Ms. D engaged in three intertwined cognitive processes as she looked at students' work: she attended to the details of students' strategies, interpreted their understanding, and made plans to respond (Jacobs et al., 2010). She engaged in these three processes in all think-alouds and in at least two of the three for every piece of work. For example, when looking at student G's work in think-aloud 1, Ms. D described G's thinking in detail, noting how she broke the 12 apart, recognizing her expression as equivalent, and wondering if she meant 16 instead of 12 (figure 2). As she attended to these details, Ms. D interspersed interpretations of G's understanding, determining that she understands how to write an expression with parenthesis and how an expression connects to a rectangle's area. Finally, Ms. D identified areas of growth (e.g. understanding partial shading of a rectangle). This example reflects a pattern across think-alouds: Ms. D attended to the details of a student's work, moved between interpreting and attending, and then made a plan to respond.

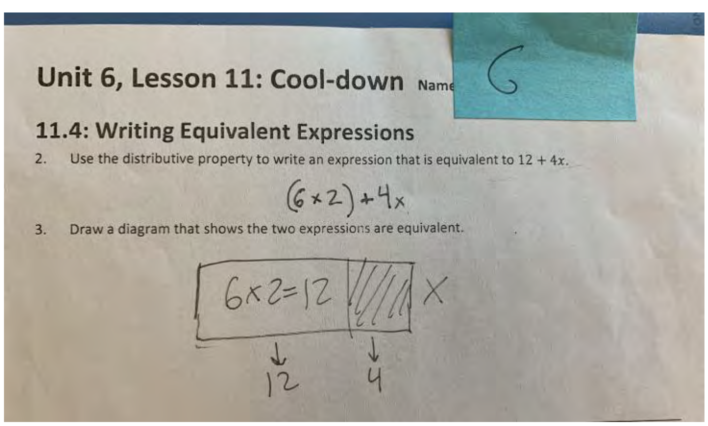

Figure 2: Photo of G's work

Attending to students' strategies: Maintaining a learner stance

As Ms. D attended to the details of students' strategies, she did so with a learner stance, in which she attempted to deeply understand students' thinking, expressed fascination with it, and acknowledged her uncertainty around the particulars of students' strategies. In the third think-aloud, Ms. D spent four minutes attempting to decipher how one student may have found the area of a parallelogram, testing out multiple possible strategies. She was fascinated by his work regardless of its accuracy, which was a trend throughout the think-alouds and which aligned with her assumption that all work showcased deep thinking and was worth paying attention to. It was common for Ms. D to comment that a student was "thinking about something," even if she wasn't clear on what that something was. This comfort with uncertainty, rather than seeking resolution, shaped Ms. D's process of attending to thinking. She consistently acknowledged her own uncertainty around a student's strategy, sometimes phrasing it as a question she planned to ask the student, such as, "but what does she mean by height and base?" (Think-aloud 3). Ms. D interacted with the work as a learner, naming uncertainties and framing them as wonderings.

Attending & interpreting: Contextualizing students' thinking

As Ms. D moved from (and between) attending to the details of students' strategies and interpreting which aspects of the concept they understood, she contextualized students' thinking in two ways. To make sense of their thinking and interpret their progress, she drew on her knowledge of her students as people and as mathematical thinkers. At times, she referenced a student's prior mathematical thinking, such as their facility with mathematical vocabulary or their mastery of particular strategies. For example, in think-aloud 1, Ms. D drew on her knowledge of student J's strengths (i.e. mastery of using tape diagrams to represent equations) and her areas of growth (i.e. area) to interpret her understanding. Additionally, Ms. D drew on her knowledge of students as people to understand their progress. In think-alouds 2 and 3, Ms. D spoke about J's challenges with distance learning—feeling overwhelmed by technology and missing interaction—and celebrated her completion and understanding amidst these struggles.

Importantly, Ms. D drew not only on her knowledge of students to interpret their work but also on her role in shaping their opportunities to learn. When noticing a student's partial understanding, Ms. D critically reflected on the extent to which she had provided that student access to the learning opportunities necessary to develop that understanding. In think-aloud 2, for example, Ms. D noted that students' struggles with language precision were likely related to lack of discussion during distance learning. Rather than attributing these struggles to individual students, Ms. D situated them within the learning environment and her role as an educator. Additionally, Ms. D referred back to the directions she had written for each problem as she processed students' work. For example, she acknowledged that the term "diagram" is vague, that there doesn't have to be a question in a student's word problem, and that describing a strategy doesn't require a numerical answer. In all three cases, Ms. D's critique of her directions widened the space of understanding, allowing for different kinds of representations and strategies.

Interpreting understanding: Applying a strengths-based lens

Ms. D's learner stance on and contextualization of thinking comprised an expansive notion of mathematical understanding, supporting her to interpret students' understanding through a strengths-based lens. For each problem on the cool down, Ms. D attended to each student's work and sorted them into two piles: understanding and partial understanding. Although she sorted along this binary, the piles were fluid and did not correlate with categories of "right" or "wrong." Instead, Ms. D sought out evidence that students understood the concepts—even if they had a computational error—and sometimes moved students across piles based on evidence from a later problem. This fluid and conceptual sorting enabled Ms. D to recognize partial understandings of the learning objective in each piece of work, articulating what that student understood and what they did not understand yet. Additionally, Ms. D recognized strengths outside of the objective, such as writing an equivalent expression (even if doesn't use the distributive property), writing a numerical expression (even if it doesn't have a variable), and drawing a tape diagram (rather than a rectangular diagram). For this last strength, Ms. D's critical reflection on the directions supported her to recognize this student's tape diagram as a strength. Ms. D's recognition of partial understandings and strengths thus enabled her to notice a range of aspects of work.

Plan to respond: Identifying aspects of work to share with the class

Although Ms. D's plans to respond included many typical of formative assessment (e.g. feedback and small-group instruction), a portion of her plans involved using students' work as a tool for learning. As Ms. D recognized different ways of thinking and partial understandings, she identified aspects of students' work to share with the class. Her practice of noticing work to share took on two forms: highlighting exemplars and leveraging mistakes for class learning.

In think-aloud 3, Ms. D commented on many aspects of student thinking that she planned to "highlight" in class the following week. For example, Ms. D noticed and planned to share K's use of units and A's use of mathematical vocabulary. Both noticings were supported by Ms. D's contextualization of students' thinking. For K, Ms. D recognized his precision with units, even though that wasn't part of the objective. For A, Ms. D critically reflected on her directions, noting that A did not need an exact answer. Additionally, Ms. D noticed and planned to highlight different ways of thinking. For example, Ms. D recognized two students' creative ways of finding a parallelogram's area: T cut a parallelogram in half and Si chose a base from which to draw a height. In planning to highlight T's and Si's work, Ms. D affirmed the use of approaches that differed from most of the class. Ms. D's practice of highlighting student work was observed prior to school closure. During the observation, eight students shared aspects of their cool down, ranging from using arrows to communicate thinking, substituting to test out possibilities, and incorporating vocabulary. When selecting work to highlight, Ms. D not only considered students' approaches, but also their identities within and beyond the classroom. In interviews, Ms. D expressed a desire to "elevate students' status" in the classroom, particularly her female students of color and her quieter students, as she was aware that students' identities may relate to their perceived status. The eight students who shared their work, for example, came from a range of identities. In recognizing her students as multi-layered people with different personalities and backgrounds, Ms. D worked to elevate those who may have less power in class or in the world.

In addition to noticing aspects of work to highlight, Ms. D also planned to leverage student work as a learning opportunity for the class. While highlighting involved students sharing exemplar aspects of their work, leveraging involved Ms. D organizing an instructional activity around student work that showed partial understanding. In think-aloud 2, for example, Ms. D planned to respond to students' word problems by repurposing them for the class's learning, saying: "Already as I'm reading these, I'm excited to use these as an assignment for next week, which ones make sense, which ones don't, and have the kids try to see if they can come up with an expression [for each]" (Think-aloud 2). Ms. D aimed to leverage students' work as a tool for learning, positioning them as mathematical thinkers whose ideas are worthy of discussion.

Taken together, Ms. D's approach to looking at work with a learner stance, a critical lens on context, and a strengths-based interpretation supported her to identify aspects of work to plan to share with the class (figure 3). This plan to respond by leveraging and highlighting students' work has the potential to expand students' ideas about mathematics and about each other.

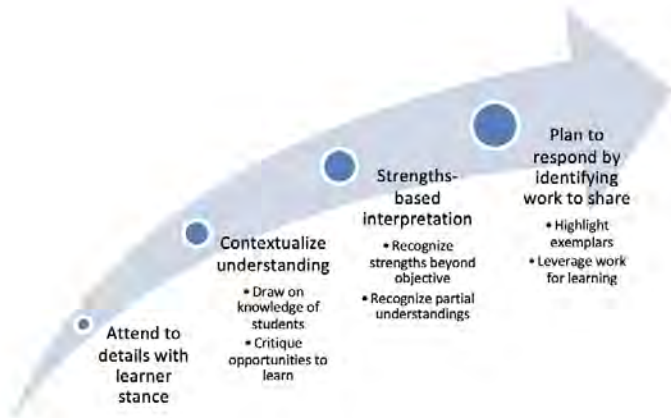

Figure 3: Visual representation of the major features of Ms. D's noticing process

Discussion and Implications

Ms. D's case illustrates that there are ways of attending, interpreting, and planning to respond to work that potentially promote equity. This case also shows that pedagogical commitments shape noticing, as Ms. D simultaneously utilized her expansive notions of mathematical understanding, as well as her ideas about status and positioning. This intertwining of multiple commitments supported her to a.) notice a range of thinking and b.) plan to highlight the work of students who may have been perceived as low-status in the classroom, the world, or both.

Ms. D's learner stance, her critical lens on context, and her commitments to expansive notions of mathematics supported her to notice a range of ways of thinking. Ms. D's inquiry lens resonates with studies showing this approach yields deep understanding of thinking, which can inform instruction and contribute to teacher learning (Kazemi & Franke, 2004). Despite being immersed in deficit discourses about students (Louie, 2018), Ms. D's commitments and her professional learning may have supported her to notice diverse strengths. The widening of understanding is important to equitable pedagogy, as math is accessible to more students when it is represented in multiple forms and different ways of thinking are valued (Boaler, 2016).

Noticing a range of thinking enabled Ms. D to plan to highlight multiple work samples, potentially expanding who is seen as competent. Ms. D's highlighting practice resonates with the CI routine of "assigning competence" (Cohen & Lotan, 2014), in which teachers position low-status students as competent. Importantly, Ms. D also attended to students' race and gender identities, which she believed may intersect with their perceived status. Put another way, Ms. D saw students' "social identities" in the world as potentially connected to the "practice-linked identities" they developed in the classroom (Esmonde & Langer-Osuna, 2013, p. 1). This practice of positioning students with attention to status and identity suggests teachers can "notice for equity" when looking at work, which resonates with van Es and colleagues' (2017) findings that attending to status and positioning was embedded in equitable noticing of participation.

This study has implications for practice and research. Teachers may take up these ways of attending and interpreting when looking at work to expand students' ideas about math and each other. Teacher educators may support novice teachers with attending to and selecting work outside of class as an entry point to implementing Smith and Stein's (2011) five practices. Future professional learning may support teachers to consider students' mathematical ideas and their statuses/identities when selecting their students' work. Finally, future research on student thinking might theorize the ways in which equity-oriented teachers simultaneously take into account the mathematical significance of students' ideas and students' statuses and identities.

Note

MOVES TEACHERS USE TO RESPOND TO STUDENTS' NON-CANONICAL APPROACHES FOR SOLVING EQUATIONS

A historical review of mathematics textbooks suggests a canonical method to solving equations that teachers often see as "the" way to solve equations. In this paper, we examine data from a nationally-distributed sample of 524 secondary mathematics teachers who responded to scenario-based survey items that represent the instructional situation of solving equations. The items featured scenarios in which students presented non-canonical solution methods and asked participants to share how they would respond. Using a framework that draws on systemic functional linguistics, we describe the linguistic resources teachers used. While closed moves are frequently used to avoid discussion of non-canonical solutions, our results suggest that teachers find ways to make regular use of: (1) closed moves for accommodating non-canonical solutions and (2) open moves when steering the conversation back to the canonical method.

Keywords: Algebra and Algebraic Thinking, Classroom Discourse, Research Methods

Background and Framework

While policy documents have been crafted to provide numerous visions for mathematics instruction in the U.S. (NCTM, 1991, 2014)—such visions have yet to become a regular state of affairs in actual classrooms. This is nowhere less true than teachers' instructional practices of responding to students' mathematical contributions (Milewski & Strickland, 2016) where teachers tend to be overly evaluative and propagate standard teaching routines—praising only those contributions that correctly carry out previously-demonstrated procedures while dismissing contributions that do not use expected methods even if they present correct solutions (Ball, 1997; Crespo, 2002). Furthermore, when teachers demonstrate a stalwart commitment to a single procedure, they cue students to learn rotely—undermining the development of conceptual understanding and flexible thinking (Hiebert & Carpenter, 1992).

In the case of solving equations in Algebra 1, a historical review of the mathematics textbooks suggests a long-standing canonical method (Buchbinder et al., 2015) that teachers expect students to use to solve equations (Buchbinder et al., 2019a). This method has been described by scholars as containing the following steps: (1) use the distributive property to clear out grouping symbols (when applicable), (2) simplify expressions on each side of the equation, (3) use the addition and subtraction properties of equality to isolate the variable from the constants, and (4) use the multiplication and division properties of equality to solve for the unknown variable (Buchbinder et al., 2015; Star & Seifert, 2006).

While many teachers prefer to spend class time on the canonical method (Buchbinder et al., 2019a), they sometimes have to make on-the-spot decisions about how to handle non-canonical solutions offered by students (Mason, 2015; Schoenfeld, 2008). This study investigates the linguistic resources teachers use when responding to non-canonical solutions in the instructional situation of solving equations: including those responses that manage to make use of students' alternative contributions as well as those that do not. In this paper, we examine data collected from a nationally-distributed sample of 524 secondary mathematics teachers who responded to a set of scenario-based survey items that each featured an embedded, rich-media representation of the instructional situation of solving equations (Chazan & Lueke, 2009). Within these items, teachers were asked to share how they would respond to scenarios in which a student presents a non-canonical solution for an equation on the board if such a situation would occur in their class.

Theoretical Framework

While teachers' instructional decisions are commonly modeled as expressions of individual characteristics, such as a teacher's resources, orientations, and goals (Schoenfeld, 2010), other factors need to be taken into consideration. Phenomena such as cultural scripts (Hiebert & Stigler, 2000) and lesson signatures (Givvin et al., 2005) provide evidence that the norms of teaching can be distinguished across cultural lines, which suggests that teaching is as much a socially-shaped activity as it is individual.

The theory of practical rationality (Herbst & Chazan, 2012) accounts for teachers' decision making using both individual and social resources. It does this using the two primary building blocks of (1) Brousseau's (1997) notion of didactical contract, and (2) Herbst's (2006) notion of instructional situation. Brousseau's concept of didactical contract identifies relationships between the teacher, their students, and the content in ways that tacitly regulate the ways that the teacher and students are expected to act within instructional exchanges (Herbst, 2003). Author's notion of instructional situation takes note of the way the didactical contract is shaped within the set of recurring situations within a course of study. For example, the theory posits the set of norms for solving equations in algebra differs from the set of norms for doing proofs in geometry and these differences impact both the teachers' and students' understanding of what kind of work is necessary for the teacher to claim the student has learnt what is expected of them (Herbst, 2006; Herbst & Chazan, 2012). In this way, the normative and routine nature of these instructional situations create a stable social resource that can be used by teachers and students to know how to act within a given situation.

In the case of the instructional situation of solving equations, the canonical method represents or activates the norms of the situation (Buchbinder et al., 2019a; Chazan & Lueke, 2009). To be clear, the norms of the situation are not deterministic, even for teachers with strong preferences for the canonical method. For example, when faced with the circumstance of having a shy student at the board presenting a non-canonical solution, a teacher who might normally feel quite strongly about adhering to the situational norms may respond in ways that accommodate the student's work to avoid embarrassing the student. Teachers have resources they can use to navigate such circumstances. For example, at least some portion of the reform literature has aimed to delineate specific linguistic resources teachers can use to shift their practices of responding to supporting students' mathematical contributions (e.g., O'Connor & Michaels, 2019).

Research Questions

In our prior work (Buchbinder et al., 2019b), we have shown that when confronted with non-canonical student solutions in the instructional situation of solving equations, teachers' responses can be parsed into one of three broad categories—those responses where the teacher: a) ***complies with the norm*** by finding a way to move quickly back to the canonical method , b) ***repairs the task*** by finding a way to make slight accommodations for a non-canonical solution, for example, by ensuring each step of the students' solution was justified before moving on, and, c) ***repairs the situation*** by making large accommodations for a non-canonical solution such as switching the focus of the lesson towards that solution. In this paper, we ask: what are the various linguistic resources teachers use to: (a) ***comply*** with the norms of that situation?, (b) ***repair the task***?, and (c) ***repair the situation***?

Methodology and Data Sources

Participants

Data used in this paper come from a nationally-distributed sample of 524 secondary mathematics teachers from 47 states who were invited by email and received an honorarium for participation. The sample of teachers included 59.6% female, 40.1% male, and 0.36% other or no answer; 83.58% White, 7.3% Black, 2% Hispanic, 2.8% Asian, 0.89% Other. The teachers had an average of 14.32 years of experience (*SD*=8.68) ranging from 1 to 40 years. Participants were invited to partake in a total of 27 open-ended scenario-based instruments—one of which, the Algebra-Equations Decision Instrument, we focus on here.

Instrument

As part of their participation in the Algebra-Equations Decision Instrument, each participant was provided with four rich-media, scenario-based items; each containing a classroom scenario that played out across several storyboard frames. Such multimedia representations have been found effective at gauging participant teachers' decision-making (Herbst & Chazan, 2015). Each scenario begins with a teacher posing a solving equations task and includes a moment in which a student is called to the board to share their work and the student subsequently describes a solution. In all cases, the students' solution was both mathematically correct and non-canonical.

For example, in one item, the teacher poses the problem 4x + 2 = 5x - 3, and a student volunteer approaches the board to share their solution where they *solve by graphing* (see Figure 1a). In another item, the teacher poses the problem 5(x + 2) = 56 - 2 (x +2), and a student shares a solution in which they *attended to structure* of the equation, meaning that the student solves by treating the term (x+2) as a quantity, instead of distributing first (see Figure 1b).

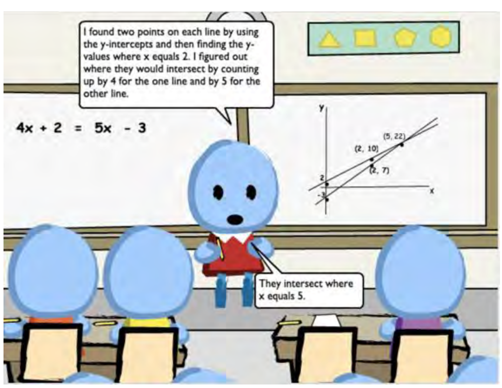

Figure 1a. **A frame from one of the items where a student elects to *solve by graphing***

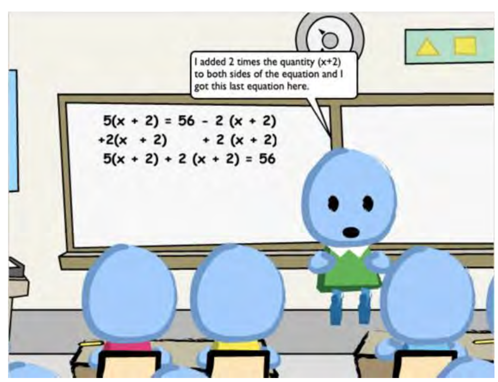

Figure 1b. **A frame from one of the items where a student elects to attend to structure.**

After viewing each scenario, study participants were asked to respond to the following open-ended prompt: "Please describe the action you would do next and your reasons for doing this action". Participants' open-ended responses are the focus of our analysis for this paper.

Data Corpus and Analytical Method

In total, the corpus contains 2,087 participant responses: some included a single "next action" (n=1,530), while others included a more detailed sequence of moves (n=463), or no action (n=94), i.e. restating of the scenario but not addressing the prompt. Among the single actions responses, some avoided addressing the students' solution (n=251) by naming some other action such as, "I would apologize to the class for my poor time management.". The present analysis focused on those responses that managed to address the students' solution with a single "next action" (n=1,279) and proceeded in two parallel phases. In phase one, we coded responses according to the degree the participant indicated they would direct the class towards the canonical method or towards the offered non-canonical solution provided by the student in each scenario: (a) ***comply*** with the norms of that situation?, (b) ***repair the task***?, and (c) ***repair the situation***?.

In phase two, we used a previously-established coding scheme that augments a framework developed by teachers, who were conducting action research, (Authors, 2020) with functional classifications drawn from the linguistic framework by Eggins and Slade (2005). The Eggins and Slade framework comprises two functional systems of choice which organize responding moves according to how they shape the discourse. The first functional system of choice (***open/close)*** distinguishes between moves that prolong or curtail the discussion of the prior contribution; the second distinguishes between moves that demonstrate a willingness to accept the contribution (***support***, ***confront***) or defers responsibility for responding by asking other students to react to the contribution (***invite***).

Altogether, the combination of these systems of choice produce the following six codes for actual utterances: curtail the interaction by supporting the student contribution (***close-support***), curtail the interaction by confronting the contribution (***close-confront***), defer responsibility for responding by suggesting other students curtail the interaction (***close-invite***), extend the interaction by supporting the contribution (***open-support***) extend the interaction by confronting the contribution (***open-confront***) and defer responsibility for responding by suggesting other students prolong the interaction (***open-invite***). Details about the first and second phases of the coding can be found in our earlier work (Buchbinder et al., 2019b & Milewski & Strickland, 2020), but will also be illustrated with examples in the results section. After both phases of coding were complete, we examined patterns in the frequency of overlap of codes to help answer the research questions.

Analysis and Results

From the 1,279 responses we coded, 599 (47%) contained descriptions of actions that ***comply with the norms*** of the situation—finding ways to move quickly back to the canonical method. Of these 599 responses, the majority (n=404, 67%) represent actions that could be coded as ***close-confront***. Some of these *close-confront* responses took on the form of telling (e.g., *I would work through it using another method that is more routine*) while others took the form of a negative evaluation (e.g., *Since the bell rang I would make a note to bring up the same problem next class period and start off by solving it the right way -- meaning the way the students were used to*). Still others took a softer form, soliciting the class for a different solution (e.g., *I would ask if anyone in the class solved the problem a different way so that we could discuss the more* *traditional method).* Of course, ***close-confront*** moves are not the only way that teachers can manage to comply with the norm (see Table 1).

Table 1. **Examples of responses distinct from *closed-confront* that teachers used to *comply with the situation***

Linguistic Code	Participant Response Example	% of responses
Close-Support	*I would explain while that works there's a much simpler way to solve the equation.*	*17%*
Close-Invite	*Have someone else share their method and show how it shows the same thing as what orange just did*	*5%*
Open-Support	*I would ask [the student]: 'why did you not divide (x+5) by 9 also on the right side?' ((common mistake))…*	*5%*

From the 1,279 total responses, 430 (34%) contained descriptions of actions that represent mild breaches of the norms of the instructional situation (repair the task)—providing some slight accommodations for the student's non-canonical solution. Nearly a third of those 430 responses (n=156, 36%) fit into the linguistic category of open-support. Some represented the teacher asking the student to clarify or justify aspects of the student's non-canonical solution (e.g., *Have the student explaining reiterate the step and make sure the class understands*) while others represented the teacher resolving the uncertainty in the room by some reassurance about the mathematical appropriateness of the method (e.g., *I would explain that as long as the same action is performed to each side of the equation that method is valid*). That said, teachers sometimes found other ways, beyond open-support moves, to repair the task (see Table 2).

Table 2. **Examples of responses distinct from *open-support* that teachers used to *repair the task***

Linguistic Function	Participant Response Example	% of responses
Open-Invite	*It's not clear what 'dividing everything by 9' means so prompt students to ask questions of the student.*	*27%*
Close-Support	*Go over how each term changes when you divide it by 9.*	*22%*
Close-Invite	*I would ask the students for homework to write down whether or not they thought the solution on the board was correct and if they could get the same solution algebraically.*	*7%*

From the 1,279 responses, the remaining 250 (20%) responses contained descriptions of actions that implied breaches of the instructional situation (repair the situation)—making large accommodations for the student's non-canonical solution. Nearly half (n=135, 54%) of those 250 responses were coded as close-invite. Some of these responses represented the teacher asking other students to evaluate the contribution (e.g., *I would ask the students to discuss at their tables what was on the board and see if they agree or disagree with what is on the board*) while others represented the teacher requesting other students or the class take up the strategy on another problem (e.g., *I would give them another problem similar to the one [that student] did and see if they can duplicate the process*). Again, not all of the responses describing actions that breach the situation were categorized as close-invite (see Table 3).

Table 3.* Examples of responses distinct from *close-invite* that teachers used to *repair the situation

Linguistic Function	Participant Response Example	% of responses
Open-Invite	*I would have students discuss in pairs what they think Blue did.*	*20%*
Close-Support	*I would answer the students questions about why certain procedures were done in the problem.*	*14%*
Open-Support	*I would ask the student (with help from the class) to justify using mathematical properties or concepts each step.*	*7%*

In this section, we have shown that the modal teacher response to students' non-canonical solutions ***comply with norms*** of the situation (47%) and the preponderance of those responses take up the form of moves that could be coded as ***close-confront*** (67%). We have also shown that teachers sometimes elect to make small accommodations for students' non-canonical solutions (***repair the task***, 34%), and when they manage to do so they tend to use moves that were coded as ***open-support*** (36%). That said, nearly half of the responses that ***repaired the task*** were accomplished with moves that were coded as ***open-invite*** (27%) or ***close-support*** (22%). Finally, in 20% of the responses, we see teachers make sweeping accommodations for students' non-canonical solutions by ***repairing the situation***; and in the majority of those responses, teachers elected to use moves that could be coded as ***close-invite*** (54%).

Discussion, Conclusion and Significance

Despite reformers' calls for teachers to embrace the open discussion of multiple students' solutions, our research has reported that teachers favor canonical solution methods over non-canonical one. The theory of instructional situations and practical rationality has suggested teachers are often operating in contexts in which they feel responsible for maintaining the norms of the situation, which favors the canonical method. That said, we see in this data some promise in that a small majority of teachers' responses (54%) deviate from the norms of the situation by making some kind of accommodations for students' non-canonical methods. Yet, teachers' willingness to use ***open*** and/or ***supportive*** moves is mostly restricted to those instances when they are making only slight accommodations of students' non-canonical solutions (***repair the task***). In contrast, when a teacher takes the risk of making a significant accommodation for a students' non-canonical solution (***repair the situation***), they tend to use ***closed*** moves—albeit they often elect to use ***closed invitations.*** Yet even the invitational nature of these more-accommodating moves allow the teacher to maintain some semblance of control of the situation by sanctioning a narrow platform from which students can react to the non-canonical solution presented (e.g., requesting students evaluate, add on to, or replicate the method). These results support our prior hypotheses (Chazan & Lueke, 2009) that even when teachers are willing to engage with students' non-canonical solutions, there are important tensions in doing that.

While the analysis we have reported herein focuses on the response set as a whole, we have reason to believe that the breaches to the instructional situation represented across these items, i.e., the types of non-canonical student solutions, are not equivalent in terms of their likeliness to be perceived by teachers as reasonable approaches to take up in whole class discussion (Buchbinder et al., 2019a). Drawing from a recent use of the instrument administered to a set of secondary teachers prior to their involvement in professional development focused on facilitating whole class discussion, we have noticed that when aggregating teachers' responses according to item, some items (such as the type of solution featured in Figure 1b) seemed to also have greater numbers of closed responding moves than others (such as the type of solution featured in Figure 1a). Further, such items also contained more comments like the following, in which teachers remark on the represented method in ways that suggest they have concerns about it.

> The approach [the student represented in Figure 1b] took may be a bit confusing for students (such as [those who used] order of operations) and may lead to more anxiety and apprehension ... I think [the teacher] did a nice job hearing [the student] out, but should also show the [order of operation] approach ...and see if that helps to clarify some confusion.

To further explore teachers' rationality about particular kinds of non-canonical work, future work could interrogate patterns that exist when looking across teachers' responses to different items.

In closing, one of the primary ways that reformers have sought to further teachers' openness towards student-generated solutions is by suggesting alternative discursive moves that encourage teachers to use more open or invitational responding moves. The results from the analysis of the second and third parts of the research question cast some suspicion on the efficacy of such prescriptions. These results suggest that teachers can and do find ways to make regular use of ***closed*** moves to make accommodations for the students' non-canonical solutions (***repair the situation***)—in which they, in some serious way, take the risk of abandoning the canonical solution method. These results also suggest that teachers make regular use of ***open*** moves to ***repair the task***—steering the conversation back to the canonical solution method. These findings are reminiscent of earlier work in the field that looked critically at reform recommendations (Chazan & Ball, 1999; Cohen, 1990). In closing, we suggest that more work is needed to understand teachers' practical rationality in order to better understand which suggestions teachers may be more inclined to take up.

Generalization is a critical component of mathematics learning, but it can be challenging to foster generalization in classroom settings. Teachers need access to better tools and resources to teach for generalization, including an understanding of what tasks and pedagogical moves are most effective. This study identifies the types of instruction, student engagement, and enacted tasks that support generalizing in the classroom. We identified three categories of Classroom Supports for Generalizing (CSGs): Interactional Moves, Structuring Actions, and Instructional Routines. The three categories operate at different levels to show how teachers, students, tasks, and artifacts work in interaction to mutually support classroom generalizing.

Keywords: algebra and Algebraic Thinking, Classroom Discourse, Instructional Activities and Practices

Understanding Classroom Generalization

Generalization is a central component of mathematical learning, with researchers arguing that it serves as the origin of mathematical ideas (Vygotsky, 1986; Peirce, 1902). The importance of generalization is reflected in national standards documents across North America (Council of Chief State School Officers, 2010; Ontario, 2005; Secretaría de Educación Pública, 2017), as well as in curricular materials (e.g., Hirsch et al., 2007). However, research shows pervasive student difficulties in creating and understanding correct general statements (e.g., adez & Kolar, 2015; English & Warren, 1995), creating further challenges in fostering success in many domains, including function, geometry, and combinatorics (e.g., Ellis & Grinstead, 2008; Pytlak, 2015; Lockwood & Reed, 2016).

Although students' challenges with generalizing is well documented, less is known about how to better support generalization, particularly in classroom settings. The majority of research on generalizing has occurred in laboratory settings, such as clinical interviews and small-scale, researcher-led teaching experiments. The field knows less about how productive generalization occurs in school settings with practicing teachers teaching everyday topics. Furthermore, the limited research on teachers' abilities to foster generalization shows that effectively supporting generalization is challenging for teachers (e.g., Callejo & Zapatera, 2017; Mouhayar & Jurdack, 2012). Teachers need support in learning how to help students generalize, including increased access to research-based tools and resources that build on the field's knowledge of students' productive generalizing. In response to these needs, this paper investigates the state of student generalizing in middle-school and secondary classrooms. In particular, we addressed the following questions: What are the opportunities for generalizing in classroom settings? Specifically, what types of instructional moves, student engagement, and enacted tasks support classroom generalizing?

Literature Review and Theoretical Framework

Researchers have identified both cognitive activities and pedagogical strategies that can foster generalization. The cognitive activities include visualizing properties beyond what is perceptually available (Becker & Rivera, 2007; Yeap & Kaur, 2008), attending to particular characteristics or relationships above others (Rivera & Becker, 2007), identifying relationships between tasks, representations, or properties (Cooper & Warren, 2008; Johanning, 2004), and describing general relationships or processes verbally or in written form (Ellis, 2007; Rivera & Becker, 2008). Research on pedagogical strategies has identified potentially productive moves to foster generalization, which includes having students consider big numbers (Zazkis et. al, 2008), showing variation across tasks (Mason, 1996), guiding students to reflect on their mathematical operations (Doerfler, 2008; Ellis, 2007), providing access to physical or visual representations (Amit & Neria, 2008), emphasizing similarity across contexts (Radford, 2008), and ordering tasks in a progressive sequence (Ellis, 2011; Steele & Johanning, 2004).

There are two caveats to consider in relation to the above findings concerning teachers supporting generalizing. The first is that the bulk of these studies were conducted in small-scale laboratory teaching settings, and the degree to which their findings might translate to whole-classroom activity is not well understood. A couple of studies, however, did detail the classroom factors influencing how middle-school students engaged with a generalization problem (Jurow, 2004; Koellner et al., 2008). For instance, Koellner and colleagues found that working with an open-ended problem with multiple entry points, having opportunities to visualize a concrete representation, and being able to work collaboratively fostered students' generalizing, along with the teacher's discursive moves of pushing for algebraic generalizations without supplying answers. The second caveat is that although many of the above studies have addressed specific instructional moves, fewer have explicitly addressed to the role that interaction can play in fostering generalizing. There are two notable exceptions. Ellis (2011) identified a number of generalizing-promoting actions representing how teachers and students can interact to foster generalizing, including publicly generalizing, encouraging justification, building on ideas, and focusing attention on mathematical relationships. This study, however, was situated in a teaching experiment setting rather than a classroom setting. In a classroom-based study, Jurow (2004) introduced the notion of participation frameworks to account for how students generalized in small groups. Both studies suggest that generalizing can occur as a consequence of processes distributed across tasks, students, and tools.

Defining and Situating Generalizing

While definitions of generalization vary, most characterize it as a claim that some property holds for a set of mathematical objects or conditions larger than the set of original cases (Carraher et al., 2008). For instance, Radford (2006) described generalizing as identifying a commonality based on particulars and then extending it to all terms, and Harel and Tall (1991) characterized generalization as the process of applying a given argument to a broader context. These definitions situate generalization as an individual, cognitive construct, but as seen with Jurow's (2004) work, one can also consider generalizing as a collective act distributed across multiple agents (Ellis, 2011; Tuomi-Gröhn & Engeström, 2003). This perspective attends to how social interactions, tools, and classroom environments can shape students' generalizing actions, positioning generalization as a fundamentally social practice. We follow this perspective to define generalizing as an activity in which learners in specific sociomathematical contexts engage in at least one of the following actions: (a) identifying commonality across cases, or (b) extending reasoning beyond the range in which it originated (Ellis, 2011).

We use the symbolic interactionist perspective, considering classroom learning to be a social process that occurs in interaction (Bauersfeld, 1995). From this perspective, learning is examined through the lens of multiple processes of interactions, in which students' interactions with tasks, artifacts, one another, and with their teacher all co-contribute to the activity of generalizing. This can occur through conversation, shared problem-solving activity, and negotiated meaning of problems and solutions. We view the learning environment as a system, made up of mutually interacting agents, and then consider how that system supports students' shared construction of meaning as they generalize. Reflecting the foci of our research questions, the symbolic interactionist perspective enables us to privilege both individual students' reasoning and the processes of interaction that supported that reasoning (Blumer, 1969; Voigt, 1995).

Methods

We conducted a series of classroom observations in one middle-school and two high-school classrooms. Prior to scheduling the observations, we asked each teacher to choose a unit that they thought would offer opportunities to observe generalizing. Mr. J was a third-year teacher who taught advanced algebra and precalculus, Ms. R was a sixth-year teacher who taught high-school algebra, and Ms. N was a third-year teacher who taught sixth-grade mathematics. In each classroom we conducted videoed observations with two cameras. One camera focused on the teacher and whole-class setting, and the other recorded a focus group of three to four students, capturing the entirety of their engagement including conversations, gestures, and written work.

In Mr. J's tenth-grade advanced algebra class we observed a three-day unit on exponents and roots, culminating in the development of the rule $\sqrt[b]{x^a} = \left(\sqrt[b]{x}\right)^a$. In Ms. R's ninth-grade algebra class we observed a four-day unit on using algebraic symbols and equation solving techniques to represent word problems. In Ms. N's sixth-grade class we observed a four-day unit on the coordinate plane, basic properties of quadrants, determining horizontal and vertical distances between points, and determining reflections over the *x*- and *y*-axes. We also interviewed each teacher twice after the observed units in order to explore their definitions of generalization, their beliefs about generalization, and their beliefs about how to foster generalization in the classroom. For the purposes of this paper, we draw specifically on the classroom observation data in order to determine student opportunities to generalize in classroom settings.

To analyze the data, we relied on both transcripts and video recordings, considering the participants' talk, gestures, intonations, and use of tools, drawings, and physical objects. We first coded all instances of generalization using Ellis et al.'s (2017) RFE Framework, and then turned to Ellis' (2011) categories of generalizing-promoting actions as an initial scheme to code instances of classroom interaction that supported the generalizations. In addition to using the generalizing-promoting actions categories, we revisited all classroom interactions to identify those that potentially contributed to the generalizations but were not captured by existing codes. We coded actions as fostering generalizing if generalizing occurred in direct response to an action, if a generalization mirrored or responded to a new idea introduced by an action, or if we could identify a conceptual chain linking the ideas or structure introduced by an action and a generalization that followed it. A number of interaction instances yielded novel codes, which contributed to the Classroom Supports for Generalizing (CSG) presented in this paper. Three members of the project team then independently re-coded every transcript, collaboratively resolving any discrepancies through consensus. Following the approaches others have used to investigate discourse (e.g., Pierson & Whitacre, 2010), the codes do not distinguish between teachers' and students' utterances. This is consistent with the interactionist framework, in which the students and teachers jointly contribute to a shared understanding (Cobb & Bauersfeld, 1995).

Results: Classroom Supports for Generalizing

We found three major CSG categories: (a) Interactional Moves, (b) Structuring Actions, and (c) Instructional Routines (Figure 1). Interactional Moves refer to the questions, initiations, responses, or ideas that people, task prompts, artifacts, or representations can introduce into the conversation. These moves are not limited to teacher moves; students can also initiate questions, share ideas or strategies, or encourage one another to generalize, justify, or share. In addition, specific task prompts or even one's use of a representation can constitute an Interactional Move, if they play an in-the-moment role of fostering generalizing during a classroom conversation.

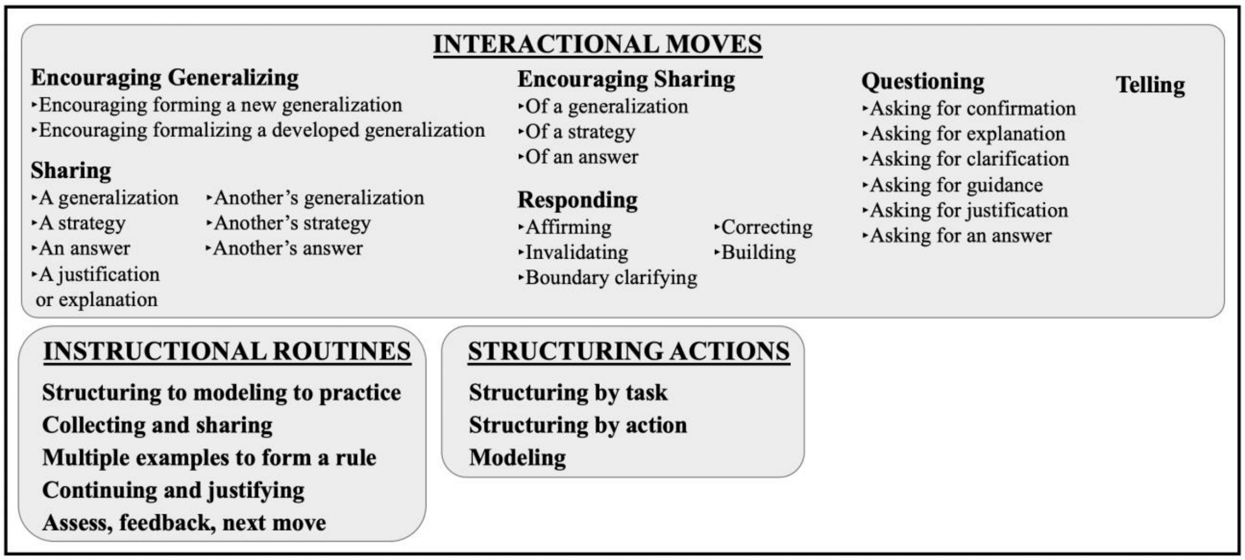

Figure 1: Interactional Moves, Instructional Routines, and Structuring Actions

In contrast to Interactional Moves, which are spontaneous and localized, Structuring Actions typically address the aspects of a teacher's instruction that are more systematic and intentional. They are the actions one employs to implicitly or explicitly structure students' activity in a manner designed to lead to a generalization. This can include developing and implementing task sequences with the aim of fostering a generalization, explicitly drawing students' attention to sameness across problem types or ideas, or choosing to organize a series of representations in a manner that highlights a generalizable feature. It can also include modeling the process of developing a generalization for other members of the community, an action that students may sometimes engage in as well as teachers.

The third category, Instructional Routines, depicts the patterned and recurrent ways that instruction unfolds in a classroom (Horn & Little, 2010). Following the work of those who have studied professional routines in teaching (e.g., Leinhardt et al., 1987; Rösken et al., 2008), we consider these routines to entail a stable schematic core with a more fluid shell, allowing for variable responses to demands of the moment. The Instructional Routines we identified were those stable, repeatable series of pedagogical moves that fostered student generalizing. These are processes such as collecting a range of student strategies to share for whole-class discussion and to serve as a source for forming a generalization (*collecting and sharing*), or visiting a small group, assessing their progress towards a generalization, providing feedback and guidance based on their progress, and then leaving them with a specific next step to achieve (*assess, feedback, next move*). Each of the routines we identified appeared repeatedly in one teacher's class but not in others', indicating that many routines may be somewhat teacher specific.

Developing a Generalization in Interaction: Horizontal Distance

Due to length constraints, rather than defining and discussing each CSG, we instead offer an extended data episode illustrating the manner in which multiple CSGs operate together in order to support the classroom development of a generalization. This episode draws from Ms. N's 6th-grade classroom and takes place during a lesson about the horizontal and vertical distance on a coordinate plane. The excerpt illustrates one of Ms. N's Instructional Routines, *multiple examples to form a rule*. In this routine, a teacher shares and discusses multiple examples of the same phenomenon, and then directs students to consider what remains invariant across the examples with the aim of developing a mathematical rule as an articulation of the invariance.

In launching the routine, Ms. N projected a coordinate plane on the board and placed a magnetic dart at the point (7, 5). She then asked a student to place a second dart a horizontal distance of 8 units from the first dart. The student placed the dart at the point (-1,5), and Ms. N encouraged the students to note the ordered pairs of the two points. She then repeated this process, placing a dart at (-1, 1) and asking a student to place a second dart at a horizontal distance of 3 units away. The student placed the dart at (-4, -1), and Ms. N again asked the students to attend to the ordered pairs of the two points. Ms. N then repeated this process a third time, placing the dart at (7, -4) and asking a student to place the second dart a horizontal distance of 10 units away. The student placed the dart at (-3, -4). At this point, Ms. N also engaged in the Structuring Action CSG of *structuring by action*: She wrote the three pairs of ordered pairs together on the board in a manner that made it visually salient that the *y*-values of each pair of ordered pairs was the same (Figure 2). The written representation itself played the role of *encouraging generalizing (forming)* by directing students' attention to the structure of each pair of points.

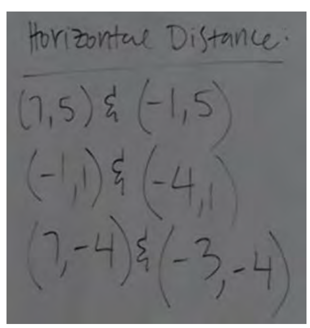

Figure 2: Ms. N's Representation of Three Pairs of Ordered Pairs

In the following table (Table 1), we provide each classroom member's utterance with the accompanying CSG it represents. The excerpt begins with Ms. N explicitly asking the students what the ordered pairs have in common:

Table 1: First Excerpt Utterances and CSGs

Utterance	CSG
Ms. N: Who can tell me what looked at these two ordered pairs to start [points to the first pair]. What do they have in common? What are these ordered pairs have in common?	Encouraging Generalizing (forming)
Ari: They both have the same *y*-axis coordinate?	Sharing (a generalization)
Ms. N: *y*-coordinate. Good. What is their *y*-coordinate?	Questioning (asking for answer)
Ari: Five.	Sharing (an answer)
Ms. N: Five. All right, what do these two points (points to the next pair) have in common? Rayna?	Encouraging Generalizing (forming)
Rayna: They have the same *y*-coordinate?	Sharing (a generalization)
Ms. N: What is the *y*-coordinate?	Questioning (asking for answer)
Rayna: One.	Sharing (an answer)
Ms. N: They both have a one in common in the *y*-coordinate place, and what do these two points have in common (points to the last pair)? Wesley.	Encouraging Generalizing (forming)
Wesley: They both have the same *y*-axis coordinate which is negative four.	Sharing (a generalization)
Ms. N: Perfect. So, what do they *not* have in common? What are they not sharing?	Encouraging Generalizing (forming)
Parker: *x*-coordinate.	Sharing (a generalization)
Ms. N: Their *x*-coordinates, right? So that is going to be a pattern that you will always notice whenever we are talking about horizontal distance between two points.	Sharing (a generalization)

Ms. N was *structuring by action* throughout the above exchange by explicitly drawing students' attention to sameness across the three pairs of ordered pairs. This occurred not only through the above exchange, by also by Ms. N's actions of finger pointing and underlining the *y*-coordinates of each ordered pair on the board. Those actions were to support the generalization that when determining a horizontal distance, each pair of points will have the same *y*-value. Ms. N then *encouraged generalizing* by asking the class, "Is it possible that I could look at these ordered pairs and without even plotting them, know the distance between them?" Jonah proposed the idea that you can simply take the sum of the absolute value of the *x*-values of each pair of points to find the difference:

Jonah: You just need to add them together. You can get how many things you go over. Because the top [pointing to (7, 5) and (-1, 5)] like if you, you add them together, but you get rid of the negative sign, it equals eight. Second [pointing to (-1, 1) and (-4, 1)] you move five.

Ms. N: Okay. So be careful with, with saying add them together. I think I know what you mean. But be careful with say add them.

With this proposal Jonah *shared* a generalization. He subsequently added that he meant the absolute value: "Absolute value. Just add them together." In response, Ms. N asked the students to consider the second case Jonah mentioned, with (-1, 1) and (-4, 1). In doing so, Ms. N engaged in a form of *responding* that was *boundary clarifying*: Her intent was to help the students determine when Jonah's generalization would work and when it would not. The students determined that it worked for the first and third pair, but not the middle pair of (-1, 1) and (-4, 1);

they concluded this by physically counting the number of units between the two points on the coordinate plane. In the next excerpt, the students and Ms. N together began with Jonah's incorrect generalization and transformed it into a correct one (Table 2):

Table 2: Second Excerpt Utterances and CSGs

Utterance	CSG
Ms. N: So what, what happened with your theory? I like the theory, it's almost there. But we need to tweak it a little bit going.	Encouraging Generalizing (forming)
Jonah: I think we are going negatives to positives. I think it only works with positive negative, positive positive.	Sharing (a generalization)
Ms. N: And try them if my two coordinates are not the same sign, you mean?	Questioning (asking for clarification)
Jonah: You change the negative, you just kind of do the opposite.	Sharing (a generalization)
Ms. N: Okay, cool, can be something to add to our rule.	Responding (affirming)
Riley: This one, like go, go ones that he's talking about adding. They start with the positive number. And when we, with this [(points to (-1, 1) and (-4, 1)], and it starts with negative number, you can subtract it from before, and equals three.	Responding (building)
Jonah: Yeah, that's what I mean by like negative, negative.	Responding (affirming)
Ms. N: Okay, so in general, what am I looking for? Absolute value is asking us for a, what do we say? What kind of measurement?	Questioning (asking for an answer)
Robin: Distance.	Sharing (an answer)
Ms. N: A distance. So in general, this is always going to be true. What am I looking for between the two points that aren't the same?	Questioning (asking for an answer)
Quinn: Positive number.	Sharing (an answer)
Ms. N: I'm looking for, the word you just said -	Questioning (asking for an answer)
Riley: (Interrupts) Distance.	Sharing (an answer)
Ms. N: I'm looking for the distance between them, right? So if I'm finding the distance, Jonah, between a positive number and a negative number, you're right, I am going to need to know their absolute value so that I can combine them. But if they're already on the same side of zero, I can literally just do what I can count one, two, I can just count the distance, right? Like I know from negative one to negative four. It's how far -	Telling
Jonah: (Interrupts) I think that only works when they are both at opposite sides.	Responding (building) Sharing (a generalization)
Ms. N: Yeah, I think that's true if they don't have the same sign, I like your strategy.	Responding (affirming)

The excerpt began with Jonah's initially incorrect generalization, that you add the absolute value of the x-coordinates for any two points. Through a series of transformations, Ms. N and the students built on one another's statements to develop a modified generalization, which was that if the two points are on the opposite side of the origin, the absolute values can be combined to determine the distance, but if they are on the same side of the origin, one can count the distance between them. Riley did propose a modification to Jonah's generalization, that one can subtract the absolute values for the pair of points that were both on the same side of the origin, the teacher did not take it up. In her interview, Ms. N shared that she did not do so because her students had not yet learned arithmetic with negative numbers. So, she instead highlighted that one could just count to determine the distance.

Note that all of the CSGs in each of the two excerpts were from the Interactional Moves category. The CSGs in this category are ones that lend themselves readily to teachers' and students' utterances in conversation, as well as particular task prompts or representation choices, such as Ms. N's organization of the three pairs of points in Figure 2. These Interactional Moves, however, occurred within the broader Instructional Routine of *multiple examples to form a rule*. Ms. N enacted a what was for her a common routine, that of sharing and discussing multiple cases of the same phenomenon, before then directing the students to consider what was the same across the examples in order to develop a general rule. Within this routine, she also engaged in a Structuring Action, structuring generalizing by drawing students' attention to sameness across the three ordered pairs. Within the Structuring Action and Instructional Routine, the Interactional Moves were the more immediate, localized moves made by both the teacher and the students that worked together to build up to the final generalization for determining the horizontal distance between two points.

Discussion

The three categories of CSGs enable attention to classroom interactions simultaneously at three different grain sizes. We found that the manner in which the Interactional Moves supported particular generalizations needed to be considered in light of the larger Structuring Actions and Instructional Routines in which they occurred. For instance, a specific move such as *sharing a generalization*, *boundary clarifying*, or *asking for an explanation* may or may not be effective in supporting generalizing depending on the immediate structure of interaction in which it takes place, as well as the larger structure of pedagogical actions and routines that form the sociomathematical milieu of the classroom. By considering the classroom environment to be a system of mutually interacting agents (Voigt, 1995), we have been able to identify simultaneous levels of support in order to better understand how generalization emerges in classroom contexts.

Similar to other studies attending to aspects of interaction in supporting generalizing (Ellis, 2011; Jurow, 2004), we found that the teacher, the students, the enacted tasks, the students' use of tools and artifacts, and the nature of representations worked in concert to support generalizing. Ms. N's representation of the pairs of points on the board worked together with her guiding remarks and the students' contributions to build up to the final generalization for determining horizontal distance. This illustrates the collective nature of generalizing, and the manner in which members of the classroom community can collaboratively build upon one another's ideas to introduce, reflect on, and refine generalizations.

Acknowledgments

The research reported in this paper was supported by the National Science Foundation (award no. 1920538). We would also like to thank Ben Sencindiver for his assistance with collecting and analyzing the data presented in this paper.

INVESTIGATING WHAT MAKES BEGINNING TEACHERS' ENACTMENT OF NUMBER TALKS MORE OR LESS AMBITIOUS

Number talks, a popular mathematics teaching routine in the United States, may offer supports for beginning teachers (BTs) to engage in ambitious instruction. BTs' enactments of number talks, however, are varied, and there are few empirical studies that explore how BTs' enactment of number talks could be more (or less) ambitious. This paper draws on classroom observation data from a large investigation of BTs' enactment of ambitious instruction in elementary mathematics across five teacher preparation programs. We analyzed 19 transcripts of number talks enacted by seven BTs to investigate what makes number talks more or less ambitious. Findings illustrate three patterns among number talks that were categorized as approaching ambitious using the M-Scan (Berry et al., 2013) instrument. Discussions and implications are offered in relation to mathematics teacher education and research.

Keywords: Elementary School Education, Instructional Activities and Practices, Teacher Educators

Beginning teachers (BTs) are expected to engage in ambitious mathematics instruction (Kazemi, Franke, and Lampert, 2009; Lampert et al., 2013) that is also equitable for all students (e.g., Jackson & Cobb, 2010). This kind of teaching is inherently complex. For example, it requires teachers to be responsive to their students relative to both mathematics content and pedagogical methods, while also attending to unique social management demands required for productive mathematical classroom discourse (Lampert, Beasly, Ghuousseini, Kazemi, & Franke, 2010).

Number talks, instructional routines in which students use mental mathematics to solve computational problems, offer one way for BTs to engage in ambitious and equitable instruction. Number talks create a participation structure that may support "students to take back the authority of their own reasoning" (Humphreys & Parker, 2015, p. 1). The *routinized* nature of number talks can offer strong support for BTs to engage in aspects of ambitious instruction as novices. Despite the growing popularity of number talks in elementary classrooms there is a need for more empirical evidence about their enactment (Matney, Lustgarten, & Nicholson, 2020). In our recent work (Authors, 2021a, 2021b, and 2021c), we observed variation in BTs' enacted number talks in both structure and equitable opportunities offered to students. We continue this work to explore the features of BTs' enactment of number talks to answer the research question: What makes BTs' number talks more or less ambitious?

Theoretical Framework

To frame BTs' enactment of number talks, we build from the perspective that *ambitious instruction* in mathematics consists of teaching practices that foster students' deep, conceptual understanding of content (Lampert et al., 2013). Rigor, a hallmark of ambitious instruction, is evident in teachers' selection of tasks, supports for students, and how they respond to what students think and do (Kazemi et al., 2009). Further, when teaching ambitiously, teachers focus students on intellectual processes that support them to tackle demanding tasks, pushing students to justify their approaches, and pressing them to elaborate on their explanations and to clarify their thinking. Since the number talk routine provides space for students to engage in these kinds of mathematical practices, we see enacting number talks as a support for BTs to engage in ambitious teaching practices.

Additionally, we draw on Cazden's (2001) perspective on classroom interaction, which is shaped by two dimensions (*sequential* and *selectional*) of teaching. The *sequential dimension* describes relatively stable, cultural structure and routines. In contrast, the *selectional* dimension describes how individuals navigate such structures and routines. The *selectional* dimension highlights teachers' agency within a set of (taken for granted-or-not) constraints. Similar to Ehrenfeld and Horn's (2020) utilization of these two dimensions to describe teachers' group work monitoring routines, we view number talk routines as shaped by both *sequential* and *selectional* dimensions of teaching. For example, Parker and Humphrey's (2018) description of the "Revised Number Talk Routine" (p. 40) highlights the *sequential* dimension inherent in number talks. They found a strong correlation between teachers' decision-making within the number talk routine and the quality of teachers' number talks. Similarly, we found that BTs followed a predictable structure of enacting consistent phases in their number talks, *introducing*, *collecting*, *idea sharing*, and *closing* (See Figure 1; Cavanna et al., 2021; Pak et al., 2021a; and Pak et al., 2021b). Additionally, we identified important variations with the *idea sharing* phase on this structure (Pak et al 2021a), which highlights the *selectional* dimension of NT routines. Specifically, we found that number talks that included particular types of segments during the idea sharing phase created more opportunities for multiple students to engage with mathematical ideas than were available in number talks with only simple strategy segments shared by a single student. In this study we further explore the *selectional* dimension to understand the implications of BTs choices on the ambitiousness of their lessons.

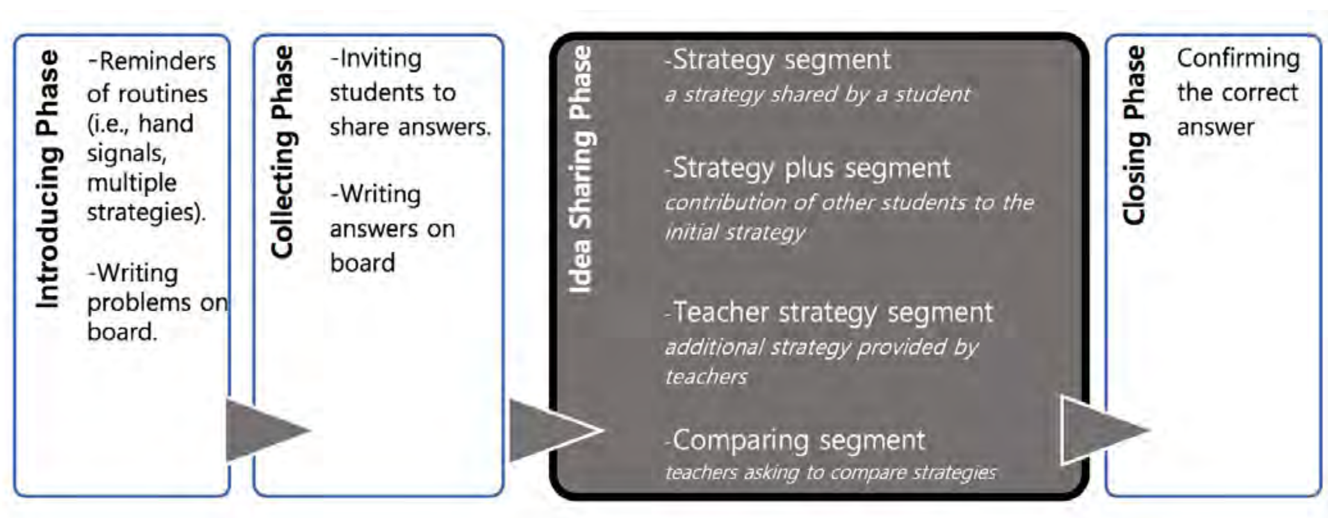

Figure 1: Number Talks Routine Phases

Methods

Context and Data Sources

Data for this study was gathered as part of a large research project that investigated BTs' enactment of instructional practices in elementary mathematics and English/language arts (ELA). Research project members video recorded BTs (n=69) three times per year as they taught mathematics and ELA. For this study, we draw on video data from a subset of 16 purposefully selected case-study participants. We reviewed 144 videos from these case-study participants (three mathematics lessons per year) over the course of three years. Of these, we identified 19 videos in which seven case-study teachers enacted Number Talks. The Number Talks occurred at the beginning of each lesson, with an average duration of ten minutes per number talk. These 19 number talk transcripts comprise the data for this investigation.

Data Analyses

As part of the larger project, all video recorded lessons were scored using the Mathematics Scan (M-Scan) instrument (Berry et al., 2013). This instrument offered an assessment of the ambitiousness of the mathematics instruction (Berry et al., 2010). Of the nine elements assessed by M-Scan, we focused on six categories of ambitious teaching: cognitive demand, problem solving, use of representations, mathematical discourse community, explanation and justification, and mathematical accuracy. These six dimensions capture key elements of ambitious mathematical instruction (Kazemi et al., 2009; Lampert et al., 2013). Scores on the M-Scan instrument range from 1 to 7, with scores of 6 or 7 considered to be demonstrating the most ambitious mathematical instruction. We considered mean scores across the six focal dimensions that were greater than 5 to be approaching ambitious instruction. Although the M-Scan scores were evaluated based on the full lesson and the number talks typically comprised less than that, we considered the instruction of the number talks portion as having a significant effect on the overall lesson score.

Our analyses of the number talk transcripts involved iterative stages of qualitative coding by the three authors of this study. First, to understand the *sequential* dimension of the number talks, we divided transcripts into phases (see Figure 1; Pak et al., 2021a). Next, we explored the *selectional* dimension of the number talks. We divided the *Idea Sharing* phase into segments, which were separated by the span in which teachers allow students to talk about a particular mathematical idea. We closely examined each segment in this phase because our prior works suggested that a systematic analysis of this *Idea Sharing* phase might show what made BTs' number talks more (or less) ambitious. The authors iteratively coded 19 transcripts, comparing individual codes until we reconciled all coding across the team. Table 1 outlines the segment types identified as a result of this process. We recognize the similarity of the *Strategy Plus* subcodes to well-known mathematical talk moves (e.g., Chapin, O'Connor, Anderson, 2009). In our presentation we expand on these points of convergence and divergence from existing literature.

Table 1. Codes to represent various teacher moves within Idea Sharing phase

Segment Types	Descriptions and subcodes	
Strategy	Asking students to volunteer talking about their strategies or calling on a specific student to explain a strategy to solve a problem.	
Strategy plus	Inviting, or calling on, students to share their ideas related to how they make sense of the initial strategy.	
	(1) Inviting	Directly inviting students to question the strategy sharer.

	(2) Interpreting	Asking another student to offer his/her own reasoning regarding how the initial strategy works.
	(3) (Dis)agreeing	(Dis)agreeing with follow-up (Not related to an error)
	(4) Detecting	Detecting error and may challenge the strategy sharer
	(5) Guiding	Generating the reasoning to draw attention to something specific in the strategy (e.g., funneling).
	(6) Repeating	Asking students to revoice what another student says
Teacher strategy	Initiating and providing additional strategies to solve the problem.	
	(1) Feeding a strategy	Making moves to push students to consider thinking in a certain way, but don't set up the problem in a way to use a certain strategy. (e.g., What if…Could I…?)
	(2) Do this strategy	Setting up the problem to be carried out a particular way.
	(3) Call and response	Walking a student (or the class in choral response) through a logical progression.
	(4) Guess my strategy	After asking students to guess, teachers explain what he/she did and ask students to unpack the reasoning.
Comparing Strategy	Asking students to compare similarities and differences between strategies.	

Lastly, in order to answer the question of what makes number talks more (or less) ambitious, we examined the segment types present across the set of 19 lessons and compared those to the M-Scan scores on those lessons. Specifically, we developed matrices that recorded the types and frequencies of segments within each number talk. We then looked for patterns across the lessons related to the M-Scan scores and patterns within those number talks.

Results

Our analyses of the number talk transcripts and M-Scan scores revealed six of 19 number talks as approaching ambitious mathematics instruction. Figure 2 lists these lessons and the mean scores of the M-Scan dimensions we utilized. Across this set of lessons, we identified three salient patterns that seem to be associated with approaching ambitious number talks. In the following sections we draw on excerpts from these six more ambitious lessons and compare to the other 16 less ambitious number talks to help us understand what makes some number talks more or less ambitious.

The first pattern we observed relates to the prevalence of *Strategy Plus* segment types across the more ambitious number talks. As shown in Figure 2, *Strategy Plus* segments appeared frequently across the *Idea Sharing* phase of the approaching ambitious number talks. Within the strategy plus segments, we also identified further variation across different teacher moves, including *Inviting, (Dis)agreeing*, *Interpreting*, *Guiding*, and *Detecting* (See Table 1). For example, Teacher B, in lesson Y1 M2, used both the *inviting* and *interpreting* moves in two adjacent *Strategy Plus* segments. Teacher B began the segment by inviting a student Jason to share an initial strategy. Jason responded to the invitation and explained his strategy for solving the addition problem 470 + 450. Next, the teacher *invited* the class to question Jason's work, saying "Does anyone have a question about that?". This question prompted two students to pose questions about the mathematics in Jason's strategy. Following this exchange, the teacher used an *interpreting* move to support one of the questioning students, Landon, to go further in unpacking Jason's initial strategy. The short excerpt below illustrates this *interpreting* move and the subsequent exchange.

> Landon: 450 plus 400 which is 850
> Teacher B: [writing on board] 850, okay.
> Landen: So, we're kind of back where we started up here a little bit? Right? Wait, why would we plus 30?
> Teacher B: We would plus 50, right? Why? Landen?
> Landen: Because you can benchmark.

This exchange from Teacher B is characteristic of the kinds of inviting and interpreting moves we observed in five of the six ambitious number talks. As illustrated in this exchange, BTs tended to use multiple *Strategy Plus* talk moves within these more ambitious lessons to move support multiple students to engage with the mathematical strategies being shared.

Lesson (Year, Obs)	M-Scan Means[2]	NT Idea Phase Segments
Teacher A (Y2 M1)	5.0	Strategy; Strategy Plus [Interpreting]; Strategy Plus [Detecting]; Strategy
Teacher B (Y1 M2)	5.3	Strategy; Strategy; Strategy; Strategy; Strategy; Strategy; Teacher Strategy [Do This Strategy]; Strategy Plus [Inviting]; Strategy Plus [Interpreting]; Teacher Strategy [Guess My Strategy]; Strategy; Strategy
Teacher B (Y1 M3)	5.2	Strategy; Strategy; Strategy Plus [Interpreting]; Strategy; Strategy; Teacher Strategy [Do This Strategy]; Strategy Plus [Inviting]; Strategy
Teacher C (Y2 M1)	5.2	Strategy Plus* [Guiding]; Strategy Plus* [(Dis)agreeing]; Strategy; Strategy Plus* [Interpreting]; Strategy Plus* [Detecting]
Teacher C (Y2 M2)	5.3	Strategy; Strategy Plus* [Detecting]
Teacher C (Y3 M2)	5.3	Teacher Strategy* [Do This Strategy]; Strategy Plus* [Inviting]; Strategy Plus* [Inviting]; Strategy Plus [Inviting]; Comparing

Note. * indicates the segment contained a mathematical error

Figure 2. Idea Sharing Phase Segments of Ambitious Number Talks

The second pattern we observed across this set of number talks was related to the ways BTs inserted their own strategies into number talk discussions. We call this kind of move *Teacher Strategy* segments. While not all examples of teacher strategy segments were associated with approaching ambitious instruction, we observed two subtypes of teacher strategy segments within the ambitious number talks: (1) *Do This Strategy* and (2) *Guess My Strategy.* The excerpt below illustrates how Teacher C set up a problem to be carried out in a specific way through an example of the *Do This Strategy* teacher move.

Teacher C: First of all, before we start sharing out strategies and agreeing and disagreeing with people. I'm wondering how we would put this into a bar diagram [pointing to diagram on board] because a bar diagram is a super important tool. Why is a bar diagram such an important tool? John, why is it an important tool?
John: Because you can use it to know parts and wholes.
Teacher C: Yeah, you can use it to understand your parts and your whole. And if you're going to add or you are going to —
Class/Teacher C: subtract.
Teacher C: And if this isn't a word problem, we know right away we are going to do what to solve this?
Class: subtract.

Following this excerpt, students worked the number talk routine, with many students utilizing bar models in their solutions. This excerpt shows how Teacher C intentionally encouraged students to use a bar model to solve a problem. Prior to solving the problem, however, Teacher C supported students to understand why a bar model might be helpful in solving this particular problem. We observed the *Do This Strategy* move in three number talks with approaching ambitious M-Scan scores (i.e., Teacher B (Y1 M2), Teacher B (Y1 M3), Teacher C (Y3 M2)).

In contrast, we observed a different teacher strategy, which we called, *Feeding Strategy*, only in number talks that were not ambitious according to their M-Scan scores. Due to space constraints, we did not present the less ambitious number talks from our dataset in Figure 2. We will expand upon the contrasting features of the more and less ambitious Number Talks in our presentation. To illustrate the differences between more and less ambitious teacher strategies, we offer an excerpt from Teacher D (Y2 M1), which includes a *Feeding Strategy*.

Teacher D: Did anybody use the distributive property, but you split it up in a different way? Or can you think of another way that would make sense to split it up? Ally?
Ally: I split up the 12 into 6 and 6. And did 6 times 3 and 6 times 3.
Teacher D: Yeah - So, if you split the 12 into 6 plus 6, then you have 6 times 3 plus 6 times 3. If you love your six facts. Maybe you don't know your 6 times 6. What's 6 times 3?
Class: 18.
Teacher D: 18 plus 18 is?

In this excerpt, Teacher D pressed students to think about how to solve the problem in a certain way (e.g., using the distributive property). This teacher, however, did not support students to reason about why this specific solution strategy might be helpful in this problem. We found it somewhat surprising that these *Feeding Strategy* appeared only in number talks that were not ambitious, while the *Do This Strategy*, another type of teacher strategy, appeared in ambitious number talks. We wonder if perhaps the nuances between the BTs setting students up with a possible solution strategy in advance, as was the case for the *Do This Strategy* move, offered more space for teachers to build from students' thinking than when BTs funneled students towards a particular strategy later in the number talk, as in the *Feeding Strategy* move. Further investigation is warranted.

The third and final pattern we observed relates to the role of mathematical errors in number talks. As noted in Figure 2, segments with an asterisk symbol (*) contain an error; there are three ambitious number talks in which students made mathematical errors. All three were facilitated by Teacher C. Across these number talks, we observed errors in both *Strategy Plus* segments and *Teacher Strategy* segments. Teacher C used a range of moves to respond to errors made by students, *Inviting, Guiding, (Dis)agreeing*, and *Interpreting.* Importantly, Teacher C demonstrated ambitious mathematics instruction in the ways she supported students to make sense of the mathematics related to the errors. For example, in Teacher C's (Y2 M1) lesson, many students shared incorrect answers to the subtraction problem 74–36. The excerpt below shows how Teacher C (Y2 M1) used a *Guiding* move to respond to these errors.

> Teacher C: So, it's already up here, alright, excellent, we have four different ideas, we have four different ways. What were we just doing when we were just thinking about that?
> James: Most of us were using that.
> Teacher C: Maybe we were using our algorithm. Who could walk me through what you did? [Many hands in the air] Who can walk me through it? Talk it up. Alex, what did you do?
> Alex: First, I did regrouping.
> Teacher C: Okay. How did you do that?

In this lesson, Teacher C received three different incorrect answers and one correct answer. The teacher guided the students to use "our algorithm" to solve the problem. The teacher asked Alex, one of the students who shared an incorrect answer, to walk the class through what he did to get the answer ("ideas"). This excerpt is characteristic of Teacher C's student-centered approach to handling students' incorrect answers.

Discussions and Conclusion

Our analyses revealed three patterns related to BTs' number talks being more ambitious, all of which related to teacher moves occurring within the *Idea Sharing* phase of the number talks routine. Specifically, we observed patterns related to the nature of *Strategy Plus* segments, *Teacher Strategy* segments*,* and the ways BTs responded to student errors. These findings offer potential insights for the field of mathematics teacher education as we seek to support BTs to engage in ambitious mathematics instruction.

First, these findings suggest that number talks offer a transportable container for BTs to engage in ambitious instructional practices early in their teaching career. At the same time, we found that only six of 19 number talk lessons could be considered examples of ambitious mathematics instruction. Therefore, we posit that the number talk routine itself– the *sequential* dimension– does not necessarily result in ambitious instruction. Instead, systemic analysis of BTs' number talks in terms of the *selectional* dimension (Cazden, 2001) offers insights into the role of teacher choice within the number talk container. It is within the *selectional* dimension that BTs exercised their instructional agency that created opportunities for the number talks to be characterized as more or less ambitious. This suggests that mathematics teacher educators must not only work with BTs to understand and use the overall number talk structure, or container, but also to consider the way certain segments are used within the *Idea Sharing* phase. This relates to our next point of discussion.

Second, these findings suggest that if we want BTs to engage in more ambitious number talks, then they need to move beyond strings of *strategy* segments, in which students simply share out one strategy after another. Instead, we offer that BTs need to integrate intentional talk moves (e.g., Chapin, O'Connor, Anderson, 2009; Kazemi & Hintz, 2014) to bring in multiple students into the conversation and shift towards *Strategy Plus* segments, as well as offer *Teacher*

Strategy segments. Such findings offer implications for mathematics teacher education. Specifically, mathematics teacher educators need to provide opportunities for BTs to learn to infuse *Strategy Plus* segments into their number talk lessons. Further research into the role that particular arrangements of talk moves play in the ambitiousness of number talks is warranted.

Third, our findings do not highlight *Comparing* segments as clearly tied to the ambitiousness of number talks. Building on prior literature, we anticipated that *Comparing* segments, which offer opportunities for students to build off of another's reasoning (e.g., Herbel-Eisenmann, Steele, Cirrillo, 2013; Wagganer, 2015) would be associated with ambitious number talks. Interestingly, we observed only one instance of a *comparing* segment, in Teacher C (Y3 M2). Since creating opportunities for students to build on one another's reasoning is a potentially difficult move, perhaps this is not so surprising given our dataset was lessons enacted by teachers within their first three years of teaching. At the same time, these findings may suggest that BTs could benefit from more opportunities to learn about moves to support students to compare mathematical reasoning. Such support could, in turn, contribute to more ambitious number talks.

Lastly, number talks are increasingly popular; and due to their portability and ease of use, they will likely continue to be a staple of mathematics classrooms. The elements highlighted in this study offer possibilities for enhancing the power of these flexible routines. Specifically, number talks that are more ambitious offer greater opportunities for engaging students in critical disciplinary practices of mathematics, such as the Standards for Mathematical Practice (NGA & CCSSO, 2010). At the same time, in number talks that are more ambitious, we see more space for equitable mathematical opportunities, as well. There is a need for further research that examines BTs enactment of number talks over time in order to understand how the ways students' mathematical identities develop and the ways number talks affect the nature of power structures within the mathematics classroom. Number talks that are both ambitious and equitable offer a route for teachers to provide meaningful opportunities for *all* students to engage in critical mathematical practices.

INSTRUCTORS' FACILITATION OF STUDENT PARTICIPATION IN ADVANCED MATHEMATICS LECTURES: A CASE STUDY OF TWO INSTRUCTORS

geisler_sebastian@web.de

Literature portrays advanced mathematics lecturing as a uniform teaching style, often criticized for offering minimal opportunities for student participation. In this paper we present results from a comparative case study of two instructors' facilitation of student participation in Real Analysis lectures. Analyzing fieldnotes from several observed lectures of each instructor, we found that the two instructors' facilitation of student participation during lectures consistently differed in (1) the participation structures were used, (2) the types of questions asked, and (3) how instruction responded to students' contributions. Our findings show that lecturing in advanced mathematics is not a uniform style and that active student participation in lectures is possible. We interpret the potential impact of observed differences on students' learning and experiences in terms of the Teaching for Robust Understanding (TRU) framework (Schoenfeld, 2018).

Keywords: Instructional Activities & Practices, Undergraduate Education, Classroom Discourse

The undergraduate math education literature tends to portray lecturing in advanced mathematics as a single teaching style, in which instructors engage in "chalk talk" (writing formal mathematics on the blackboard while providing oral commentary) and student participation is minimal (Artemeva & Fox, 2011; Lew, Fukawa-Connelly, Mejía-Ramos, & Weber, 2016; Paoletti et al., 2018). Here, we join other recent scholarship (e.g. Pinto, 2019; Viirman, 2015) in problematizing this homogenous picture of advanced mathematics lectures. We report on variability in two instructors' practices of facilitating student participation during Real Analysis lectures, discussing potential implications of each approach for student experience in terms of the Teaching for Robust Understanding (TRU) framework, which delineates five dimensions of classroom practice important for learning (Schoenfeld, 2018).

Active student participation leads to more robust learning outcomes than passive observation (Chi & Wylie, 2014), specifically in the context of tertiary STEM education (Freeman et al., 2014). Furthermore, agentic participation in classroom discourse provides students with opportunities to develop productive disciplinary dispositions and identities (Gresalfi, Martin, Hand, & Greeno, 2009). Because of this and based on the shared assumption that lectures involve minimal student engagement, many mathematics education researchers argue against lecturing, and instead advocate for student centered teaching approaches such as Inquiry Based Learning (IBL: Laursen & Rasmussen, 2019). Yet others argue that it is neither realistic nor desirable to abandon lectures altogether (Sfard, 2014). Most advanced mathematics courses are still taught in a lecture format (Johnson, Keller, & Fukawa-Connelly, 2018), and mathematicians – many of whom claim that lectures are "the best way to teach" – are not likely to abandon lecturing in favor of radically different teaching approaches (Woods & Weber, 2020).

Instead of a complete overhaul of lecturing, several scholars suggest "tilting the classroom" (Alcock, 2018) – incorporating minimally invasive active-learning strategies into traditional lecturing (Woods & Weber, 2020). Suggestions include using participation routines such as Think-Pair-Share and classroom polls (Braun, Bremser, Duval, Lockwood, & White, 2019). However, there is little research on how implementation of such strategies actually looks like in the context of advanced mathematics lectures (Woods & Weber, 2020), and what such practices may be good *for*. Our paper begins to address this gap in that it provides an analysis of two distinct examples of how instructors facilitate active student participation during lectures and discusses the relative affordances of each for student experience and learning.

Participation in Classroom Practices and the TRU framework

We draw on sociocultural theories that conceptualize disciplinary knowledge as participation in disciplinary practices (Lave, 1996). Within this tradition, participation in classroom practices is seen as a central mechanism by which students both learn disciplinary content and develop disciplinary identities and dispositions (Cobb, Stephan, McClain, & Gravemeijer, 2001; Esmonde, 2009). Hence, an important aspect of teaching is how instructors organize classroom environments to support student participation, including the specific moves they make to invite and facilitate such participation. What matters is not just *that* students participate, but also *what* they get to participate in, and *how*; the nature of classroom practices shapes the kinds of content, skills, and dispositions students develop through their participation (Gresalfi et al., 2009).

The Teaching for Robust Understanding (TRU) framework is a synthesis of such research on aspects of classroom practice associated with robust learning outcomes (Schoenfeld, 2018). The framework delineates five dimensions – *(1) the content, (2) cognitive demand, (3) equitable access, (4) agency, ownership and identity, and (5) formative assessment* – meant to comprehensively characterize a classroom environment. *The content* captures the extent to which the enacted mathematics is coherent, connected and centered on important practices and ideas. *Cognitive demand* refers to the degree to which classroom activities provide opportunities for "productive struggle", hitting the sweet spot of accessibility and challenge. *Equitable access* refers to classroom practices that ensure that *all* students have opportunities for meaningful engagement with disciplinary activities. *Agency, Ownership, and Identity* refers to the extent to which students get to make significant choices, generate mathematical content themselves, and get positioned as mathematically competent by having their ideas built on in the classroom. *Formative assessment* refers to the extent to which student thinking – including productive beginnings and possible misunderstandings – is surfaced and responded to in instruction.

In this paper, we use TRU to organize our findings about instructors' practices of facilitating student participation in ways that directly connect them to central mechanisms of learning in classrooms. We focus on dimensions 2-5 of TRU, for which student participation is relevant. Our focal research question is: *how did the observed lecturers facilitate student participation, and what significance might these moves have for student learning and experience?*

Methods

Context & Data Collection

The data our project is grounded in are observational fieldnotes of Real Analysis lectures taught in a large research university in the western U.S. during Fall 2019. We observed three instructors teaching the same elective upper division undergraduate course in parallel during a period of 3 weeks in the first half of the semester. Due to space limitations, here we focus only on Dr. A and Dr. B. We observed eight 50-minute lectures taught by Dr. A and four 80-minute lectures taught by Dr. B (a total of 400 and 320 minutes, respectively). Each lecture-section was attended by approximately 30 students.

Each author took detailed fieldnotes using a note-taking instrument specifically designed for our analytic purposes. The top third of each page was used to document blackboard inscriptions verbatim. The bottom two-thirds were devoted to descriptions of participants' speech and actions. This section was further divided into two columns: the left column for general actions made by the instructor, the right column for events related to student participation. Board inscriptions and speech/action descriptions were linked to one another by number indexing, allowing us to reconstruct the sequential organization of each lecture, coordinate speech and inscriptions, and systematically document student participation – the analytic focus of this paper.

Data Analysis

Our analysis proceeded both inductively and deductively. Each author reviewed their own fieldnotes independently to identify participation facilitation routines. In subsequent analytic discussions, we consolidated our independent characterizations, and organized them into three aspects of facilitation practice: what participation-structures were used, what kinds of questions instructors asked, and how instructors responded to student contributions. Next, we took a deductive approach. We turned to the literature to learn about how these three aspects (participation structure, teacher questions, response to students) were defined in prior work. This process helped us refine and operationalize our initial analytic categories. With refined definitions, we returned to the data, and coded all instances of student participation in relation to these categories. What follows is an explanation of the analytic categories we used.

Participation structures are defined as "the organization of persons' reciprocal rights and obligations in social interaction" (Erickson & Mohatt, 1977, p. 139). Common classroom structures are: whole-class discussion, group work, and individual work. One can, however, further specify "persons' reciprocal rights and obligations" within each broad category. Thus, in addition to a general *participation structure* category, we looked at *initiation type*, where type refers to who has the right and obligation to respond to a particular initiation (some student, a specific student, all students), and *who participated* as a result (all or some students).

In the literature, teacher questions are typically coded for the kind of responses they require from students. While precise category-labels vary, most studies use a coding scheme that organizes question-types in an hierarchical progression, from low- to high-order questions (DeJarnette, Wilke, & Hord, 2020). We adopted a similar approach, and categorized instructors' mathematical questions broadly as either *low, medium or high level* in terms of the question's cognitive demand (e.g. definition recall vs. proof idea) and openness (a single correct answer vs. many possible answers). In addition to mathematical questions and tasks, we also coded instances of: non-mathematical questions, solicitations of questions from students (e.g. "do you have any questions?") and comprehension-monitoring questions (e.g. "does that make sense?").

Finally, to characterize responses to student contributions, we first noted the *extent* (in terms of length and complexity) of student contributions. We then noted whether instructors' initial *response to student contributions* was encouraging or evaluative, as well as the extent to which subsequent lecture-talk *builds on student ideas*. Finally, we noted whether response episodes involved a single exchange sequence (a student asks a question, the instructor answered) or several back-and-forth exchanges, as these are indicative of the extent to which classroom discourse is dialogic and ideas are co-constructed (Wells & Mejia Arauz, 2006).

The last step of our analysis involved connecting these observables to the dimensions of the TRU framework. The same behavioral indicator can be implicated in more than one TRU dimension. For example, a student's opportunity to explain their thinking in relation to a conceptually rich task involves *cognitive demand,* disciplinary *agency*, and constitutes a *formative assessment* opportunity for the teacher. Thus, for each dimension of TRU, we used the definition of the dimension to read across the coding described above and synthesized all aspects of instructors' facilitation of student participation that contribute to that dimension.

Findings & Discussion

The table below summarizes our findings. The two sections that follow provide detailed descriptions and examples of each instructor's facilitation practices, unpacking the codes and descriptions in the table. In the last findings section, we interpret the potential impact of identified practices in terms of the four selected TRU dimensions: *(2) cognitive demand, (3) equitable access, (4) agency, ownership and identity, and (5) formative assessment*.

Table 1: Facilitation of Student Participation - Dr. A and Dr. B

	Dr. A		Dr. B
Participation Structure	Whole-Class	Think-Pair-Share	Whole-Class
Initiation Type	Voluntary Q & A Poll	Pair: *"Discuss with your neighbor..."* Share: randon calling using name-cards	Voluntary Q & A Poll
Who participated?	A few students	All students	A few students
Types of Tasks	Math: low-level	Math: med-level	Math: low, med & high-level
Types of Questions	Open solicitation: *"What are your questions so far?"*	Open solicitation: *"X, what are your thoughts, ideas, and questions here?"*	Non-mathematical, Comprehension monitoring: *"Does that make sense?"*, Open solicitation: *"Any questions here?"*
Length of student contributions	Short and quick take-over		Some short & some extended
Instructor's response to student contributions	Encouraging (all contribution types): *"That's a great question!"*		Endorsing (correct answers): *"You got it!"* ; *"Perfect!"*
Lecture building on student ideas	Short		Some short & some extended
Extent of dialogue	Single exchange		Some single exchange some back-and-forth

Facilitation of Student Participation:

Dr. A. Dr. A utilized two distinct participation structures in his lectures: a traditional whole-class format and a participation structure known as "Think-Pair-Share" (Braun et al., 2019).

During whole-class (i.e., outside of Think-Pair-Share), Dr. A invited students to participate by asking questions addressed to all students, to which individual students could respond verbally on voluntary basis. Dr. A rarely asked "known-answer-questions" in the whole-class format. The vast majority of questions Dr. A posed were open solicitation questions such as "what do you notice?" or "what are your comments so far?". *Any* thematically relevant thoughts, comments or questions could count as a legitimate student response, and indeed, students utilized these open-solicitation prompts as invitations to ask questions and clarify confusions. Whenever Dr. A asked specifically mathematical question during whole-class, the question required only short responses from students. Several times during our observation period, Dr. A initiated polls; prompts involving several specified answer-options (e.g., "should this be $\leq$, $\geq$, or $=$?") on which *all* students were asked to vote, though often only a subset of them did. Occasionally, Dr. A initiated short IRE exchanges in the middle of an explanation (e.g. "what is $cos\ cos\ \pi/3?$"). The purpose seemed to be ensuring that all students are "on the same page".

Think-Pair-Share was a salient participation structure in Dr. A's class. Several times each lecture (at least 2-3 times), Dr. A introduced a short mathematical task and asked students to discuss it with their "neighbor." Students were seemingly used to this routine by the time of our observations; all seemed to work on the task and lively talk could be heard. Meanwhile, Dr. A left his front-of-the-room position, circulated among the desks, and stopped to talk with students (typically called-on by the students themselves). After a few minutes, Dr. A called the class back to a whole-class format and nominated a specific student to “share.” The choice of student to call on was done through a randomized selection mechanism: a stack of cards with students’ names. Students cooperated with the “cold-calling” approach, and to the extent evident from our observations, seemed to be comfortable with it. In the public “share” phase, Dr. A initiated student contributions with open-solicitation prompts such as “what are your thoughts, ideas, questions here?” The format implied that it was acceptable to “share” by stating a confusion, a hesitation or asking a question rather than providing a direct answer to the original task. Indeed, students often responded by asking a question and sometimes by saying “I don’t know”.

The tasks Dr. A used for pair activities incorporated an assortment of mathematical practices. To name a few examples, students were asked to: determine if an example satisfies a definition, complete a few steps in a proof, interpret a theorem-statement in terms of a diagram, and complete a proposition claim. One overarching characteristic of such tasks is that they are all at a medium-level in terms of task-openness and cognitive demand; they involve non-trivial mathematical engagement from the students, yet were structured and accessible. A similar approach to selecting classroom activities for Real Analysis lectures was articulated by Alcock (2018), where she described such activities as “short-and-snappy” and geared toward “conceptual understanding” rather than calculations (p. 24).

Whether in the whole-class format or the “share” phase of Think-Pair-Share, students’ verbal contributions in the public sphere of the classroom were short. In whole class, Dr. A’s initiations typically called-for short responses only. In the “share” part of pair-share, students sometimes began articulating what could potentially be a longer contribution, but in all of our observations, Dr. A quickly took over. The impression we had was that Dr. A took over to make the explanation clearer to the whole class and cut students’ own explanations short to “save time”. In general, there was a sense of fast pace in Dr. A’s class, both in terms of the speed of Dr. A’s “chalk-talk” and because of swift transitions between many planned activities.

Whenever a student asked a question or offered an idea, Dr. A responded encouragingly (e.g. “great question!”), with level of enthusiasm independent of the contribution’s sophistication or correctness. Whenever a student’s question generated new mathematical content, Dr. A took it up and responded to it (e.g., by answering the question). However, in all of our observations, such contributions never led to an extended whole-class discussion or significantly altered the lecture. Furthermore, they rarely involved a back-and-forth of ideas between Dr. A and the student, or other students. For example, once a student asked why two quantities are equal. Answering that question prompted Dr. A to write a sketch of a proof for “why it should be equal” on the board. Thus, the student’s question altered the course of the lecture slightly, and prompted Dr. A to generate new content, both verbally and in writing. However, the episode was short and neither the student who initiated the question nor other students made any follow-up contributions.

Dr B. Dr. B’s lecturing was “traditional” in that it was conducted through a whole-class participation structure, “chalk-talk” was a pervasive discourse genre, and student participation was organized primarily through voluntary question-answer exchanges with the instructor.

A salient feature of Dr. B’s lecturing was frequent use of short IRE sequences. This involved both low-level math tasks, such as simple recall, and tasks we considered to be medium-level, such as discerning proof-structure. A common routine in Dr. B’s class featuring low-level IRE sequences can be broadly described as scaffolded "chalk-talk". Dr. B often prompted students to verbalize the precise formulation of a definition, and then used students' responses to "dictate" her board writing. As a mathematical task, this routine is closed and involves low demand. Yet, given that verbalizing formal mathematical texts can be difficult for newcomers (Shepherd & van de Sande, 2014), such a scaffolded version of "chalk-talk" (in which the instructor does the "chalk", and a student does the "talk") could have important benefits. A medium-level IRE routine Dr. B often used was to engage students in discerning logical-structure. She prompted students to recognize assumptions, or givens, by asking questions such as "What else do I know?" or "What is my claim?". While such questions follow a relatively narrow path (a student responded, Dr. B endorsed it), discerning proof-structure is a non-trivial skill for students to learn in proof-based courses (Selden & Selden, 1995). Thus, we considered such tasks to be at a medium-level, as they required actions that went beyond recall and recitation.

Though less frequently, Dr. B also posed questions that can be considered high-level in terms of openness and cognitive demand. On several occasions, Dr. B invited students to suggest mathematical examples, contribute central steps in an argument, or generate proof ideas. Occasionally, Dr. B made use of classroom voting, or polls. This seemed to primarily function as a formative assessment mechanism, that is, as means for Dr. B to gauge whether all students are following and could discern the correct option. Dr. B also routinely asked short comprehension monitoring (e.g. "does that make sense?") and open-solicitation (e.g. "any questions?) questions. Students rarely volunteered verbal responses to such questions, though we presume that Dr. B read some non-verbal feedback from students. Notably, Dr. B also regularly asked questions engaging students in decisions pertaining to mathematical conventions such as notation (e.g. "what letter should I used?"), as well as non-mathematical questions (e.g. "what's that French word for combining two words together?"). Such questions invited broad student participation.

Students' mathematical contributions, whether as responses to Dr. B's initiations or initiated by the students themselves, varied in extent and complexity, ranging from single phrase responses to lengthy articulations of mathematical scenarios and ideas. Furthermore, extended student contributions were often situated within longer classroom episodes that involved substantial building on student ideas and several back-and-forth exchanges between students and Dr. B. The following vignette serves as an example of one such case:

> Dr. B introduced a definition for *limit points* of a set in a metric space and offered an illustrative context: R (the set of real numbers) as the metric space, the interval $S = [0,1]$ as a set under consideration, and the 1 as a possible *limit point* of $S = [0,1]$. Later, she wrote the following statement on the blackboard: $1 \in lim\ (S) \Leftrightarrow \exists (x_n)$ in S s.t. $x_n \to 1$ as $n \to \infty$, which can be read as: the number 1 is a limit of point S if and only if there exists a sequence of numbers all of which are within the interval $[0,1]$ such that this sequence approaches 1 at infinity. Referring to the sequence x_n, Dr. B asked students "What's an example?", and a student suggested the sequence $x_n = 1 - \frac{1}{n}$. Dr. B picked up and elaborated on this suggestion by writing several elements in this sequence, and indicating that each belongs to the interval S: $x_1 = 0 \in S$, $x_2 = \frac{1}{2} \in S$, $x_3 = \frac{2}{3} \in S$ $\ x_4 = \frac{3}{4} \in S \ldots x_n = 1 - \frac{1}{n} \in S$. The last equality refers to the general pattern: *any* element in the sequence x_n belongs to the interval $S = [0,1]$. She then turned to the class and asked, "how do we prove it?". Another student (not the same one that originally suggested the sequence), provided an elaborate answer

constituting steps of a proof. Dr. B picked-up and "re-voiced" the student's idea by producing a short proof-text mirroring the argument the student described verbally.

This episode illustrates several of the general trends mentioned above. High-level mathematical questions from Dr. B, while not the most frequent form of questions used in her class, prompted students to contribute ideas, both short (e.g. suggesting an example sequence "$x_n = 1 - \frac{1}{n}$") and extended (e.g. verbally describing a proof-argument). When ideas were suggested, Dr. B took them up by writing them on the board, and further elaborated and explained them. Dr. B often posed further questions in the context of an initial student-suggestion. In this case, the question "how do we prove it?" prompted another student's response. Such moves initiated extended episodes that featured back-and-forth exchanges between instructor and students, and at times, allowed students to build on one another's ideas.

Interpretation of instructors' facilitation of student participation using TRU

Cognitive Demand. In Dr. A's class, Pair-Share activities provided students with routine opportunities to engage in mathematical tasks. The tasks Dr. A used were at a consistent medium-level of demand; they involved non-trivial mathematical engagement such as interpreting a proposition statement, or completing steps in a proof, yet were concrete and accessible. In Dr. B's class, there was greater variability in terms of tasks' cognitive demand. Dr. B's questions ranged from basic recall and verbalization questions (e.g., dictate a definition), to medium-level proposition-structure tasks (e.g., "what is my claim?"), and up to open and cognitively demanding questions (e.g., "how do we prove this?"). Both approaches – Dr. A's keeping cognitive demand at a consistently moderate level, and Dr. B's varying demand level from low to high within a single lecture – provided "productive struggle" opportunities.

Equitable Access. Several of Dr. A's teaching routine supported *equitable access* to mathematical content and practices. His frequent use of the Pair-Share participation structure provided opportunities for *all* students to actively engage with non-trivial mathematical tasks. In addition, the open-format of the questions Dr. A posed ("what are your thoughts?"), and his explicitly affirmative responses ("that's a great question!"), reduced access barriers for students' verbal participation during whole class, since all types of contributions (whether questions, suggestions or articulated confusion) were framed as legitimate and valuable. In Dr. B's class, we identified few explicit mechanisms that supported equitable access to mathematical content. Dr. B asked questions frequently, and several students participated verbally, but this participation was not distributed equally and the experiences of students who did not participate verbally is difficult to gauge (though we do not assume silent students did not participate, see e.g. (O'Connor, Michaels, Chapin, & Harbaugh, 2017)). Dr. B's non-mathematical questions seemed to encourage broader participation. However, her closed-form mathematical questions were typically responded to by a single student (once a correct response was given, no further were needed). Most notably, extended discussions (as describe above) seemed to engage a select few.

Agency, Ownership, Identity (AOI). In Dr. A's class, it was not clear to what extent students had opportunities to see themselves and peers as creators of mathematics. The selected tasks supported students' engagement with important mathematical practices. However, given that they were relatively narrowly circumscribed, we might ask to what extent engagement with the tasks allowed students to exercise mathematical *agency* and take *ownership* of the content. For example, a fill-in the blank task to complete a proposition text engages students in important mathematics. However, does it make students feel *ownership* over the resulting mathematical text and ideas? Similar questions can be raised about students' participation in whole class too.

Given that students' verbal contributions in whole class were short and not significantly built upon, it is not clear to what extent participation in Dr. A's whole class discussions provided students with opportunities to feel *ownership* of the content, exercise mathematical *agency*, and be positioned as competent doers and creators of mathematics. In Dr. B's class, extended episodes provided participating students with ample opportunities to exercise *agency*, feel *ownership* of ideas and be recognized as mathematically competent. Yet, as described above, only a few students in Dr. B's class had this experience. Silent observers of extended dialogic interactions are afforded valuable learning opportunities (O'Connor et al., 2017). However, the impact on students' negotiated *identities* may be more problematic. As observers in Dr. B's class, we could "read" a mathematical hierarchy among students. In contrast, in Dr. A's class, we could not discern a similar pattern: it was not easy to tell who "the smart students" were.

Formative Assessment. Dr. A's practices afforded ample opportunities to surface and notice student thinking, at all levels of correctness and completion. When walking around during pair work, Dr. A could observe and respond to students' ideas. Also, Dr. A's explicit framing of all contribution types as legitimate through open solicitations and encouragement, ensured that students voiced confusions and partial understandings, not just confident correct answers. Dr. B's facilitation afforded less systematic surfacing of student ideas. Dr. B asked many questions, yet most were responded to by one student at a time, so a range and variety of student ideas were not easy to pick up on. Importantly, students rarely voiced incorrect ideas, and mistakes and confusions were not part of the whole-class discussion in Dr. B's class.

Conclusions

Our results indicate that the observed instructors used distinct approaches to facilitate student participation. Dr. A and Dr. B utilized different participation structures, posed different kinds of questions, and used contrasting approaches in responding to students' verbal contributions. Similarly to Pinto (2019) and Viirman (2015) we found that lecturing is not a uniform teaching style. This paper contribute to the field's understanding of the nuances of mathematics teaching practices at the university level (Speer, Smith, & Horvath, 2010). However, how widespread the observed facilitation moves are among mathematics instructors remains an open question.

By interpreting observed variations using the TRU framework (Schoenfeld, 2018), we further suggested that Dr. A's and Dr. B's approaches to facilitating student participation have different consequences for learning. Dr. A's frequent use of Pair-Share activities and non-evaluative questioning routines, afforded *all* students with consistently moderate level of cognitive demand and provided ample opportunities to surface and respond to partial understandings. Students could not hide in Dr. A's class; everyone's name was called-on at some point. Yet, no student "out-shined" others; identities of competence (Gresalfi et al., 2009) were not a salient aspect of the classroom stage. Content learning opportunities were distributed more equally, but we suspect classroom interactions may have not supported students in developing strong disciplinary identities. Dr. B's diverse questions provided students with a range of "productive struggle" opportunities and contributed to the enactment of multifaceted mathematical practice. Extended, student-centered episodes provided a few students with opportunities to generate and refine mathematical ideas on a public stage in ways that positioned them as mathematically competent. For observers, this was an "existence proof" that mathematics *can* be generated by a student, and thus constituted an important socio-mathematical norm (Yackel & Cobb, 1996). But, did all students emerge to see themselves as mathematically competent? We suspect not. The extent to which each approach to facilitating student participation (Dr. A's or Dr. B's) actually contributed to longer term outcomes for learning and identity remains an open question for future research. Coordinating such analyses with student assessment and interview data could be a productive direction for future research.

When debating the effectiveness of different teaching approaches, it is important to keep in mind there might not be a single "best" way. Here, we showed that distinct approaches to incorporate "minimally invasive" active learning in lectures are possible and may have different affordances in terms of learning and identity. Thus, negotiating our values and ultimate goals for advanced mathematics education is an important part of the conversation about what is "best".

EXPLORING TEACHERS' RESPONSIVENESS TO CHILDREN'S FRACTION THINKING AND RELATIONSHIPS TO FRACTION ACHIEVEMENT

Identifying components of teaching that make a difference in children's learning is an ongoing challenge in our field. Focusing on teaching that is responsive to children's fraction thinking, we decomposed responsiveness into the instructional practices of questioning to support and extend children's thinking, noticing children's thinking, and anticipating children's thinking. We worked with 49 teachers in grades 3–5 in multiyear professional development and assessed their expertise in each of the practices. We also assessed their students' fraction achievement at the beginning and end of the school year. Correlational analyses revealed significant moderate relationships among teachers' expertise in the three practices, and a multilevel regression analysis revealed significant positive relationships for both expertise in teacher questioning and years of professional development with children's fraction achievement.

Keywords: Instructional Activities and Practices, Professional Development

An ongoing challenge in mathematics education is identifying components of teaching that make a difference in children's learning (Hiebert & Grouws, 2007). We take up this challenge guided by a vision of teaching in which children's mathematical thinking is centered and teaching is responsive to that thinking. By *responsive to children's mathematical thinking,* we mean teaching that elicits children's ideas and takes up and builds on those ideas as an integral feature of instruction (Richards & Robertson, 2016). This kind of responsiveness involves the continuous adjustment of decisions during instruction about what to pursue and how to pursue it in response to children's ideas.

A small number of studies have documented that teachers' instructional practices related to responsiveness to children's mathematical thinking are linked to children's achievement. For example, Webb and colleagues (2014) found that the more teachers engaged children in each other's thinking during instruction, the higher children's achievement was on a story-problem assessment. Bishop (in press) found that the more teacher discourse reflected uptake of children's ideas, the higher the gains were in children's proportional reasoning. (See also Fennema et al., 1996; Howe et al., 2019; Ing et al., 2015; Saxe et al. 1999).

We contribute to this body of work by presenting findings from our analyses of relationships between teachers' responsiveness to children's fraction thinking, which we decomposed into three instructional practices, and children's fraction achievement. The three practices were selected as a focus of our study because we considered them foundational to teachers' expertise in responding in the moment to children's fraction thinking. They include teacher questioning to support and extend children's mathematical thinking (Jacobs & Ambrose, 2008; Jacobs & Empson, 2016), teacher noticing of children's mathematical thinking (Jacobs et al., 2010), and teacher anticipating of children's mathematical thinking (Smith & Stein, 2018). Throughout the paper for the sake of brevity, we refer to these practices in shorthand as questioning, noticing, and anticipating, with the qualification that each focuses on children's mathematical thinking. We recognize other important aspects of teachers' responsiveness, such as to children's cultural, social, and linguistic identities (Parsons et al., 2018) but do not address them here.

Data for our study were drawn from a professional development (PD) design project in which we enrolled three successive cohorts of teachers to participate in up to three years of professional development (Jacobs, Empson, Pynes, et al., 2019). The PD was designed to support the development of teachers' expertise in responsiveness to children's fraction thinking, informed by research on the instructional practices and on children's fraction thinking (Empson & Levi, 2011). Our goals in this study were to explore relationships among the three practices comprising this expertise and between this expertise and children's fraction achievement. We collected data at the end of the third year of the project, in which teachers were enrolled in either their first, second, or third year of PD, to capture variation in expertise in questioning, noticing, and anticipating. Assessments given near the beginning and end of the school year documented children's fraction achievement at each point. These data allowed us to answer two questions: *(1) Do the instructional practices of questioning, noticing, and anticipating children's fraction thinking relate to each other? (2) Does teachers' expertise in questioning, noticing, and anticipating children's fraction thinking relate to children's fraction achievement?*

Conceptual Framework

Our conceptualization of responsiveness to children's mathematical thinking is informed by a theoretical view of teaching that foregrounds the work of teaching and its decomposition into instructional practices that are complex enough to authentically represent teaching but simplified enough to be accessible to teachers who are developing expertise (Grossman et al., 2009; Hiebert & Morris, 2012). The work required to enact a vision of teaching as responsive to children's mathematical thinking has been increasingly parsed by researchers (Boerst et al., 2011; Jacobs & Spangler, 2017; Franke et al. 2009; Munson, 2019). Although researchers have identified a number of potential practices, we selected three based on their connections to teachers' capacity to be responsive to children's mathematical thinking in the moment.

The first practice, *questioning to support and extend children's mathematical thinking,* involves making children's thinking visible during instruction and responding to that thinking in ways that consider children's existing understandings (Fraivillig et al., 1999; Jacobs & Ambrose, 2008; Jacobs & Empson, 2016). We have conceptualized the essence of this questioning as embodied by a teacher in conversation with children to explore their thinking about a mathematics problem—often a story problem—by posing questions to elicit children's thinking and pressing children for explanations of specific parts of their problem-solving processes (Jacobs, Empson, Jessup, & Baker, 2019). In these conversations, a teacher may also question to ensure children are making sense of a problem, link children's representations to the story context (if one exists), encourage children to consider other strategies, connect children's thinking to mathematical notation, or pose a related problem linked to children's understandings. Questioning is customized with respect to children's thinking and can be enacted during instruction in both one-on-one conversations with children as well as in conversations with groups of children, such as during whole-class discussions of children's strategies.

The second practice, *noticing children's mathematical thinking,* involves attending to and making sense of children's thinking in the moment. We have previously conceptualized noticing as a set of nested skills that are temporally and conceptually linked, which include attending to the details of children's strategies, interpreting children's understandings reflected in those details, and deciding how to respond on the basis of those understandings (Jacobs et al., 2010). Noticing is an invisible practice, in that it occurs prior to a teacher's observable response. Thus, teacher noticing is foundational for teacher questioning because, without noticing, teachers would not be able to question in ways that were customized with respect to children's thinking.

The third practice, *anticipating children's mathematical thinking*, involves envisioning how children might engage in solving a problem. We draw on a conceptualization of anticipating as teachers' consideration of the array of strategies that children would be likely to use for a problem prior to posing that problem. Anticipating orients teachers to possible conversations with children during instruction and can inform selecting and adapting problems, interacting during circulating, and planning for and facilitating discussions (Simon, 1995; Stein et al., 2008). Thus, teacher anticipating prepares teachers to notice and question.

This set of practices has three qualities which we argue are useful for enhancing teacher learning in PD and beyond. First, the practices are organized around a specific focus to lend coherence to the set. In our study, this focus was responsiveness to children's fraction thinking. Second, the practices are accessible to teachers as they are beginning to learn but also offer room for growth. They were therefore usable in all three years of our PD. Third, the practices are generative with respect to teachers' continued learning in that as teachers enact the practices in their classrooms, they have opportunities to not only support children's thinking but also improve their understanding of children's thinking and use this understanding to further develop expertise in the practices. Based on earlier findings about the generative nature of practices used by teachers to engage with young children's mathematical thinking (Franke et al., 2001), we conjectured that our practices would create similar opportunities for the teachers who completed our PD and continued to use the practices. In selecting a set of practices, we drew inspiration from a well-known precedent in mathematics education: the "5 practices," which are focused on the expertise needed to facilitate whole-class discussions of children's solutions to cognitively demanding tasks, and were also designed to support teacher learning (Stein et al., 2008).

Methods

Participants

The study was situated in three demographically diverse neighboring districts in a state in the southern region of the United States. A total of 49 teachers and 876 children were included in the analysis. The teachers represented a subset of the 92 teachers who were participating in the larger PD design project and were selected because they were working as classroom teachers in an upper elementary grade (3–5), were available to have one of their mathematics lessons observed, and had at least a third of the children in their classes who completed both the fall and spring administrations of the fraction assessment. Data were collected during one school year, when teachers were at the end of their first ($N = 15$), second ($N = 20$), or third ($N = 14$) year of PD.

The 49 teachers (42 females, 7 males) ranged in teaching experience from 2–36 years, with a mean of 12.4 years. The mean number of children per class who completed the fraction assessment was 18 (72% of the class) and ranged from 8–27 (33%–96% of the class).

Professional Development

The PD in which teachers were participating at the time of data collection was focused on teachers' responsiveness to children's fraction thinking, conceptualized in terms of the three instructional practices described above combined with research-based frameworks of children's fraction thinking (Empson & Levi, 2011). It included over 150 hours of face-to-face workshops over three years. Workshop activities involved working with children, analyzing children's written work, and discussing videos of math instruction focused on classroom instruction, small group instruction, and one-on-one conversations with children. These experiences provided teachers with opportunities to reflect on their teaching, explore new practices, and collaborate with colleagues (Jacobs, Empson, Pynes, et al., 2019).

Teacher Assessments and Scoring

We assessed teachers' expertise in each of the practices separately. The questioning assessment was based on a lesson observation and the noticing and anticipating assessments were written assessments. The questioning data were independently scored by at least two researchers and all disagreements were resolved through discussion, a process described as a consensus method for reliability (Goldsmith et al., 2014). Noticing and anticipating data were blinded so that teacher identities were hidden, and all data were at least double-scored. Interrater reliability was 80% or higher and discrepancies were resolved through discussion.

Questioning assessment. We asked teachers to plan a lesson that included at least one Equal Sharing story problem with a fractional answer (e.g., 6 children sharing 10 pancakes equally), using whatever lesson format they would normally use for story problems. All lessons were videorecorded by a member of the research team using a camera that followed the teacher, to capture all mathematical conversations between the teacher and children and as many details as possible of children's mathematical thinking. After the lesson, teachers were interviewed about the lesson. We used the videorecorded observations, supplemented by the interviews, to determine the level of responsiveness in teacher questioning. All parts of the lesson that focused on fraction story problems were considered, including launch, circulating, and discussion phases.

Rather than consider the lesson representative of teachers' typical instruction, we considered it evidence of teachers' capacity for questioning to support and extend children's fraction thinking. To indicate the extent of evidence of expertise in questioning in the midst of instruction, we assigned a holistic score of 1 ($N = 8$), 2 ($N = 18$), 3 ($N = 15$), or 4 ($N = 8$) to each teacher, with 4 representing the most evidence of expertise. We developed our scoring using an iterative process, which started by adapting prior research on teachers' engagement with children's thinking (Franke et al., 2001) and incorporating findings from earlier research on questioning (e.g., Franke et al., 2015; Jacobs & Ambrose, 2008; Jacobs & Empson, 2016).

Broadly, our scores reflected a continuum. We were not looking for "perfect" questioning but rather evidence that questioning made room for children's existing understandings and building on those understandings. At the high end, teachers actively explored children's thinking. Their questioning was customized with respect to the details of children's thinking and persistent in eliciting the details of that thinking. If there was a group discussion, children's thinking and talking predominated. When children shared their thinking, teachers followed up to support and extend that thinking, and children were regularly given opportunities to describe their thinking and engage with the thinking of others. In short, there was room for children to work from their existing understandings, and teachers positioned children as having authority for sensemaking. At the low end, teachers tended to question to evaluate the correctness of children's thinking and often took over children's thinking, especially when children had incorrect responses. If there was a group discussion, the teacher's thinking and talking predominated and children were provided few opportunities, if any, to describe their thinking or engage with the thinking of other children. In short, there was little room in these lessons for children to develop their existing understandings, and teachers positioned themselves as the authority for sensemaking.

Noticing assessment. Building on our earlier work on professional noticing of children's mathematical thinking (Jacobs et al., 2010), we assessed teachers' expertise in noticing with a written assessment structured around three instructional scenarios linked to solving fraction story problems. The scenarios were conveyed by strategically selected artifacts (video or children's written work), and for each scenario, teachers were asked to notice children's thinking and respond, in writing, to four categories of prompts. These prompts were related to the component skills of noticing: (a) attending to children's strategy details (*Describe in detail what you think each child did in response to this problem.*), (b) interpreting children's understandings (*Explain what you learned about these children's understandings.*), (c) deciding how to respond via follow-up questions (*Describe some ways you might respond to this child's work on the problem and explain why.*), and deciding how to respond via next problems (*What problem or problems might you pose next? What is your rationale?*).

We scored teachers' responses for the extent to which we had evidence for their engagement with children's fraction thinking. We then conducted a latent class analysis on the scores to empirically identify groups of teachers who displayed similar patterns of responses across the noticing assessment. This analysis yielded a 3-profile solution that was ordered in terms of overall noticing expertise. We assigned the profiles a score of 1 ($N = 25$), 2 ($N = 33$), or 3 ($N = 14$) for use in our multilevel model, with 3 representing the highest level of expertise. At the high end, teachers showed consistently strong expertise across the noticing component skills. They centered children's thinking in all their responses and the details of children's strategies were consistently visible. At the low end, teachers showed consistently weak expertise across the noticing component skills. They provided fewer details in their strategy descriptions and those details played a smaller role in other responses. Further, teachers sometimes privileged their own strategies over children's strategies by describing how they would funnel the children's thinking toward the teachers' preferred strategies (Wood, 1998). (See Jacobs & Empson, 2021, this volume, for more information on the noticing assessment and analysis.)

Anticipating assessment. In contrast to questioning and noticing, the construct of teacher anticipating was exploratory in that we had little prior empirical research on which to base our assessment. We created a written assessment with two open-ended items that asked teachers to anticipate a range of valid strategies that elementary-grades children might use to solve two fraction story problems. One was a Partitive Division (Equal Sharing) problem and the other was a Measurement Division problem, although neither was labeled as such for the teachers.

We scored each item on a 0–4 scale, for a total maximum score of 8. Teachers' scores on the assessment ranged from 2–8, with a mean of 5.8 ($SD = 1.7$). At the high end of the scale, teachers anticipated a variety of distinct strategies that were consistent with typical strategies children have been documented to use, spanning multiple levels of understanding and showcasing variety within those levels. At the low end, teachers tended to anticipate a smaller number of strategies that showed less variety and were sometimes accompanied by strategies that were inconsistent with research findings about children's fraction thinking and its development.

Fraction Assessment for Children

We assessed children's fraction achievement with a written assessment teachers administered to their students in the early fall and late spring. Teachers were told to allot 45 minutes but encouraged to allow extra time for children who wanted it. The assessment consisted of 7 items—5 fraction story problems and 2 fraction comparisons (see Table 1 for sample story problems). All items were open response and children were simply instructed to solve each problem. The story problems were designed to assess children's understanding of fraction quantities and relationships in story situations, whereas the comparison problems were designed to assess children's understanding of ordering relationships without the support of a story situation. The assessment was developed using an evidence-centered design approach and included protocols to ensure content-related validity (Mislevy & Haertel, 2006).

There were two versions of the assessment—one for grade 3 and one for grades 4 and 5. The versions were parallel, with simpler numbers in the fraction story problems for grade 3. Due to the parallel nature of the assessments, they were treated as equivalent in the analyses. For all grades, the fall and spring forms of the assessment were identical.

Assessments were blinded for scoring. Scoring took place in teams of 3–5 researchers, who were trained on using a code book developed for the assessment. Total scores for the assessment ranged from 0–12, with the 5 fraction story problems each scored 0–2 and the two fraction comparisons each scored 0–1. When scoring the 5 story problems, we considered both the correctness of the children's answers and the validity of their strategies. When scoring the 2 fraction comparisons, we considered both the selection of the greatest number and children's rationales. Interrater reliability was at or above 80% for all items and the internal consistency of the assessment was adequate, as indicated by a Cronbach's alpha of .80. The grand mean of the 49 class means improved from fall ($M = 2.2$, $SD = 1.9$) to spring ($M = 5.8$, $SD = 1.9$), showing that learning did occur. The grand mean of 5.84 (out of 12) in the spring suggests that the assessment was challenging.

Table 1: Sample Story Problems from the Fraction Assessment for Children

Mathematical Focus	Grades 4/5 items (*Grade 3* number adjustments)
Equal Sharing	Mr. Lara gave 3 children 5 oranges to share so that each child got the same amount. If the children shared all of the oranges, how much orange did each child get? (*Grade 3:* 4 children, 9 oranges)
Multiplication	It takes 1/5 of a block of cheese to make a pizza. How much cheese do you need to make 17 pizzas? (*Grade 3:* 1/4 of a block of cheese, 6 pizzas)
Missing Addend	Allie has 1 6/8 sticks of butter. She needs a total of 5 1/8 sticks of butter to make cookies. How much more butter does Allie need so that she can make cookies? (*Grade 3:* 1 2/3 sticks of butter, 4 sticks of butter)

Findings

Research Question 1: *Do the instructional practices of questioning, noticing, and anticipating children's fraction thinking relate to each other?*

To explore the relationship among the instructional practices, we began by examining the three pairwise correlations, including the correlation between questioning and noticing (r (47) = .56), between questioning and anticipating (r (47) = .50), and between noticing and anticipating (r (47) = .54). All pairwise correlations were significant ($p < .05$) and of similar, moderate strength, suggesting that the practices are related, but distinct.

We were also interested in the relationships among the three practices when they were considered as a set. We therefore conducted a partial correlation analysis to identify the strength of the relationship between any two practices when all three were included but the effect of the third practice was removed. Again, all three partial correlations were significant ($p < .05$) and of moderate strength: .39 for questioning and noticing, controlling for anticipating; .29 for questioning and anticipating, controlling for noticing; and .36 for noticing and anticipating controlling for questioning. These findings suggest that the three practices together have interrelated features reflective of a coherent set of practices.

Research Question 2: ***Does teachers' expertise in questioning, noticing, and anticipating children's fraction thinking relate to children's fraction achievement?***

We conceptualized teachers' responsiveness to children's fraction thinking as the collection of our three practices—questioning, noticing, and anticipating children's fraction thinking. We were interested in the relationship between teachers' expertise in these practices, as captured by our three teacher assessments, and children's achievement. We used the children's spring scores on the fraction assessment as our measure of children's achievement and included children's fall scores on the identical assessment as a covariate. One-tailed tests were conducted because we hypothesized based on prior research that more questioning, noticing, and anticipating expertise should increase children's achievement (Carpenter et al., 1989; Jacobs et al., 2007).

We began by examining the three practices independently in unadjusted bivariate models. All three practices were significantly related to children's spring achievement ($p < .05$) and so were included in the multilevel model. We next constructed our multilevel model with the practices as independent variables, the children's spring achievement as the dependent variable, and the children's fall achievement as a covariate. The overall multilevel model (see Model 1 in Table 2) was significant (Wald χ^2 (4, $N = 876$) = 425.10, $p < .05$). Children's fall achievement was significantly related to their spring achievement, as expected. At the teacher level, questioning was the only practice that remained significantly related to children's spring achievement. Given that our PD was designed to help teachers develop expertise in the three practices, we were also interested in the relationship between the number of years of PD teachers had completed and children's fraction achievement. Further, we were interested in whether the relationship between teacher questioning and children's achievement would remain significant even when years of PD was included as a teacher-level variable. We therefore extended our multilevel model to include teachers' years of PD (see Model 2 in Table 2). As before, the overall model was significant (Wald χ^2 (5, $N = 876$) = 435.40, $p < .05$). In addition, the number of years of PD was significantly related to children's spring achievement, and again, teacher questioning remained significantly related to children's spring achievement.

Table 2: Models Relating Instructional Practices and Children's Spring Achievement

	Model 1		Model 2	
	Coefficient (*SE*)	*z*	Coefficient (*SE*)	*z*
Children's Fall Achievement	0.66 (0.03)	20.18*	0.66 (0.03)	20.26*
Teacher Questioning	2.59 (1.04)	2.50*	1.99 (1.02)	1.95*
Teacher Noticing	0.04 (0.37)	0.11	– 0.08 (0.35)	– 0.23
Teacher Anticipating	– 0.48 (1.15)	– 0.41	– 0.91 (1.11)	– 0.82
Years of PD			0.66 (0.29)	2.31*

*$p < .05$, one-tailed

In summary, increased expertise in teachers' questioning and increased years of PD were directly linked to children's higher achievement on the spring assessment, after adjusting for fall achievement. Expertise in teacher noticing and teacher anticipating were not significantly related to children's spring achievement after adjusting for fall achievement. However, as seen in the analyses for Research Question 1, expertise in these practices was significantly related to expertise in questioning. In other words, they appear to be necessary but not sufficient for teachers' questioning expertise and its direct link to children's achievement.

Discussion

Our first research question focused on investigating the relationships among teachers' expertise in three instructional practices representing responsiveness to children's fraction thinking. Our findings provide evidence that teachers' expertise in each practice is positively related to expertise in the others. We conjecture that these positive relationships may be due to the joint knowledge base on which the practices draw—namely, knowledge of children's thinking, which includes general knowledge of children's thinking and specific knowledge of individual children's thinking. However, each practice also captures a distinct piece of responsiveness, connected with how this knowledge is used in the work of teaching represented by each practice. For example, when teachers notice, they start with a specific instance of a child's thinking and connect it with what they know, but when teachers anticipate, they start with what they know and use it to generate possible instances of a child's thinking.

Our second research question focused on investigating relationships between teachers' expertise in instructional practices and children's fraction achievement. Our findings provide empirical support for the direct link between the two, and we add to a small but growing body of evidence of positive relationships between practices that are responsive to children's mathematical thinking and children's mathematics achievement (see, e.g., Bishop, in press; Webb et al., 2014). We highlight in particular the significant positive relationship in our final multilevel model between teacher questioning and children's achievement. Children in the classrooms of teachers with higher questioning scores tended to have higher fraction achievement, indicating their greater capacity to apply their understandings of fractional quantities and relationships to solve story problems and compare fractions. This finding provides evidence of the power of questioning to support and extend children's fraction thinking, which we conjecture resides in creating ongoing opportunities for children to articulate, consider, coordinate, and refine their fraction understandings in conversations with the teacher during instruction. We assessed teachers' capacity to create such opportunities and future research should directly assess the opportunities created over time in teachers' classrooms.

With this study, we identified three practices—questioning, noticing, and anticipating children's mathematical thinking—that comprise a set of related instructional practices for teaching that is responsive to children's thinking. We intentionally focused on a small number of practices because it offered a manageable way for teachers to engage with the complexity of responsiveness. Our findings suggest that teachers were indeed able to engage with this complexity. A focus on a manageable, but coherent, set of instructional practices defined by teachers' work with children's thinking thus offers a way to decompose teaching expertise so that it is accessible for teachers and can make a difference in children's learning.

We present an analysis of three 9th grade integrated mathematics lessons in which a group of teachers and researchers redesigned a sequence of lessons with the goal of engaging a linguistically diverse group of students in productive and powerful discussions (Herbel-Eisenmann et al. 2013). The three lessons were part of a design experiment. Two lessons were observed during regular school day instruction, and the other lesson was part of an after-school teaching experiment. Drawing on a sociocultural framework and methods of classroom discourse analysis (Cazden, 2001; Pierson, 2008), we analyze how the teachers in the three settings structured whole-class discourse to create opportunities for a multilingual group of students to participate in the discussion and to appropriate mathematical tools for thinking.

Keywords: Equity, Inclusion, and Diversity; Design Experiments; Algebra and Algebraic Thinking; Classroom Discourse

In this paper, we describe results from a design research effort in which a group of teachers and researchers redesigned a sequence of lessons with the goal of engaging ninth graders in academically productive whole-class discussions (Herbel-Eisenmann et al., 2013). The research was situated in a US school where nearly all students were from minoritized communities, most students were multilingual, and about 30% of students were designated as English Learners (ELs). Drawing on the Academic Literacy in Mathematics framework (Moschkovich, 2015), project-specific design principles (Zahner et al., 2021a, 2021b), and research on student learning of linear rates of change (Lobato & Ellis, 2010; Thompson, 1994), we created a sequence of lessons specifically designed to promote student participation in classroom discussions about linear rates of change. In the empirical results below, we show how, in comparison to student engagement before the design intervention, the redesigned lessons led to increased student participation and higher levels of cognitive work in whole class mathematical discussions.

Theoretical Framework & Prior Research

This study is rooted in a sociocultural perspective on learning, where mathematics learning is conceptualized as appropriating problem-solving tools and developing participation in valued mathematical practices, including mathematical discourse practices (Forman, 1996; Moschkovich, 2002). In alignment with this theoretical focus, our analyses focus on classroom discussions and patterns in teacher and student discourse. We also drew upon the Academic

Literacy in Mathematics (ALM) framework (Moschkovich, 2015) to create study-specific design principles (Figure 1). In the ALM framework, developing academic literacy in mathematics includes developing forms of mathematical *proficiency*, engaging in mathematical *practices*, and participating in mathematical *discourse*.

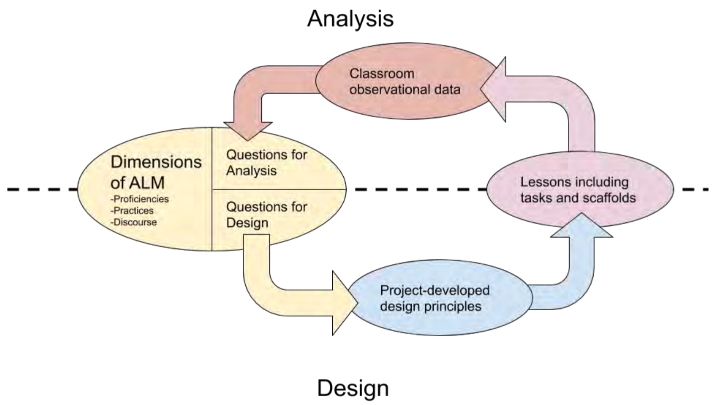

Figure 1: Overview of the Design Cycle. (Image credit Authors year, used with permission)

Multilingual students, including those learning the language of instruction, can learn critical mathematical concepts and reasoning practices through engaging in productive and powerful discussions (Chapin & O'Connor, 2012; Erath et al., 2018; Erath et al., 2021; Gutiérrez, 2002; Khisty & Chval, 2002; Moschkovich, 1999). Following Herbel-Eisenmann et al.'s (2013) definitions, *productive* discussions are those that lead students to appropriate mathematical tools for thinking (i.e., develop mathematical proficiencies and practices in the ALM framework). *Powerful* discussions are those that promote students' participation in and identification with mathematics (i.e., engage in the disciplinary discourse). One way to foster productive and powerful discussions is for students and teachers to engage in authentic dialogue focused on important mathematical concepts (e.g., O'Connor, 2001). Yet, most multilingual students who are classified as English Learners have very limited opportunities to engage in productive and powerful classroom discussions. Instead, these students are often tracked into low-level classes where they have little access to either rich content learning opportunities or the discourse of the discipline (Callahan, 2005; Kanno & Kangas, 2014). Thus, one critical question facing the field is how to transform patterns of classroom discourse in multilingual settings.

The default template for most classroom discussions is the triadic Initiation-Response-Evaluation (IRE) sequence (Cazden, 2001). Initiations are questions or statements. Responses occur after, and in response to, an initiation. Evaluations are moves that offer judgement–either explicit or implicit–on the response and end the IRE sequence (Cazden, 2001; Mehan, 1979). IRE-dominated instruction typically positions the teacher as the authority, thereby limiting students' opportunities to engage in productive and powerful discussions. In this project our goal was to transform patterns of discourse. Yet, we found that, while the ideal transformation of classroom talk may be to create dialogic discussions like the one in O'Connor (2001), achieving such transformation is challenging, possibly due to institutional constraints and the deeply ingrained patterns of discourse in school mathematics (Herbel-Eisenmann et al., 2010).

Short of a wholesale transformation, there are subtle ways to document transformations in classroom talk while still within the IRE framework. For example, it is possible to distinguish between evaluation and follow-up moves in the "third slot" of the IRE sequence (Wells, 1993).

Follow-up moves include asking students to expand on their reasoning, presenting new examples to build on their contributions, and asking for clarification (Pierson, 2008; Wells, 1993). While evaluation moves typically close a sequence, follow-up moves can extend the discussion. When students respond to a teacher's follow-up move, they often provide a justification or explain the reasoning behind their answer – two examples of disciplinary discourse practices (Moschkovich & Zahner, 2018).

Pierson's (2008) analysis of teacher and student talk in 13 seventh-grade mathematics classrooms offers an avenue for unpacking more and less productive uses of talk within the triadic IRE framework. Pierson (2008) developed two coding schemes: (a) one to capture the level of a teacher's *responsiveness*, the extent to which the teacher focused on student thinking, and (b) a second focused on the level of *intellectual work*, the kind of cognitive effort imposed on or requested from students within a teacher's move. Pierson found a positive relationship between more responsive teacher moves and higher levels of intellectual work in teacher talk with growth in students' mathematics achievement as measured by a curriculum-aligned assessment.

The constructs of intellectual work and responsiveness connect to this project's goal of promoting productive and powerful discussions. In a productive discussion, we would expect to see higher levels of intellectual work. In a powerful discussion, we would expect to see higher levels of responsiveness as teachers take up and build upon students' ideas. Thus, we adopted Pierson's (2008) coding schemes to explore whether our design efforts were effective in promoting powerful and productive talk in linguistically diverse classrooms.

In the analysis that follows, we address the following research question: To what extent did each lesson engage multilingual students in productive and powerful discussions? Specifically,

1. What were the levels of intellectual work and responsiveness in teacher moves?
2. What was the distribution and frequency of student participation in whole-class discussion?

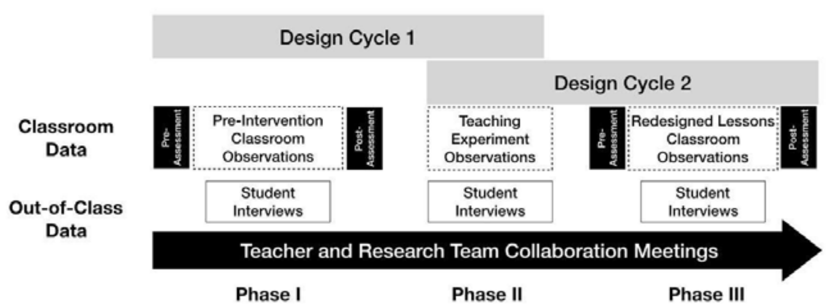

Figure 2. Design Cycles (Image credit Authors year, used with permission)

Methods

The overall framework for this research arose from design research (Cobb et al. 2003). While researchers have identified productive practices in multilingual classrooms (e.g., Chval & Chávez, 2012; Chval et al., 2021), these productive practices appear to be relatively rare in linguistically diverse mathematics classrooms (Callahan, 2005). Therefore, design research was

Olanoff, D., Johnson, K., & Spitzer, S. (2021). *Proceedings of the forty-third annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Philadelphia, PA.

chosen as a method for studying phenomena unlikely to arise without intervention (Cobb et al., 2003). The project included two design cycles spread across three academic years (Figure 2).

Setting

We present data from three lessons recorded in ninth grade Integrated Mathematics 1 (IM1) classes at City High, an urban high school located near the US-Mexico border serving linguistically diverse students. The school was chosen as a research site in order to situate this research in a setting that parallels the inequitable educational experiences of minoritized students in US schools, particularly students who are classified as English Learners (Gándara & Contreras, 2009). At City High, 77% of students were identified as Latinx, 12% Asian, 7% African American, and 4% other. About 89% of students were from low-income families. Thirty percent of all students at City High were classified as ELs. Three City High IM1 teachers joined our research group in redesigning a unit on linear rates of change for Design Cycles 1 and 2.

The Phase I data includes eight class meetings recorded during regular school hours. These lessons were taught by the students' regular teacher, Mr. S, who was certified to teach mathematics and who had taken teacher education coursework related to teaching ELs. Mr. S was bilingual in Spanish and English. He primarily spoke in English during class, and he talked to some students in Spanish during small group work. The Phase II data includes ten lessons taught after school in a Teaching Experiment (TE) setting. The TE lessons were designed by the teachers and researchers. A bilingual researcher with experience facilitating classroom discussions with linguistically diverse students taught the Phase II TE lessons while Mr. S and the other teachers and researchers served as observers. The Phase III data includes ten redesigned lessons taught by Mr. S during regular school hours. In the analysis presented below, we focus on one lesson from each phase, each chosen for analysis because they feature a pivotal concept in the design experiment unit—introducing average rate of change. All whole-class discussions and talk among one small group of students were transcribed. Further, students were invited to participate in the language of their choice across all three phases. This invitation was made explicit in Phase II. In Phases I and III, students could use the language of their choice, but this option was not emphasized. In this analysis, we narrow our focus to whole-class discussions.

Redesign

The design principles and illustrations of the redesigned lessons are presented in Authors (Zahner et al. 2021a, 2021b). In brief, the main foci of the redesign effort were developing student participation in productive and powerful discussions through (a) adopting a coherent mathematical focus across the unit and strategically using problem contexts, (b) designing a unit of lessons with intentionally integrated mathematical and language development goals, and (c) integrating language and discourse supports including technology and mathematical language routines (Zwiers, 2017) throughout the unit.

Analysis

To start our analysis, we coded the transcripts as whole-class and small group interactions, noting the time spent in each participation structure. We noted that in the Phase I lesson (Pre-intervention), 41 of 48 minutes (~85%) were whole-class interactions, 36 of 63 minutes (~57%) in Phase II (TE), and 46 of 77 minutes (~60%) in Phase III (Redesigned lesson). We then examined discourse patterns during these whole-class interactions, coding each teacher- and student-turn of talk as I, R, E, or F, allowing up to two codes per turn of talk since teachers often offer an evaluation and then initiate a new question in one turn.

Next, we used Pierson's (2008) responsiveness and intellectual work coding schemes for analyzing each teacher's talk during whole-class discussions. Pierson's (2008) responsiveness coding scheme categorized each teacher follow-up move (F) into one of four levels of responsiveness: Low, Medium, High I, or High II. The level of each follow-up was determined based on whether the move addressed a student's comment, whose idea (teacher's versus student's) was the focus, and whose reasoning (teacher's versus student's) was displayed. Pierson's (2008) coding scheme for intellectual work had four categories: Low Give, High Give, Low Demand, and High Demand. The two Give codes were for teacher moves in the third slot (E/F) of an IRE/F sequence of talk that provided information, whereas the two Demand codes were for teacher moves that requested information from the students. Teacher moves that both supplied and requested information were double-coded with a Give and a Demand category. The designations Low and High for Give and Demand codes depended on the type of information being supplied or requested in a teacher's move. Low was for basic information, whereas High was for more elaborate information intended to extend mathematical reasoning.

Consistent with Pierson's coding mechanism, we only coded talk with a math focus (e.g., we did not code segments of classroom management). We coded every instance of talk in the third slots (E/F) of the IRE/F sequences as either Low, Medium, High I or High II responsiveness. We expanded Pierson's intellectual work coding scheme to include both the first or third slots (I or E/F) of the IRE/F sequences as either Low Give, High Give, Low Demand, or High Demand, allowing for double-coding of single turns with both Demand and Give codes when applicable. We chose to include the first slot (I) of the sequence because we were not working with predetermined questions as the teachers were in Pierson's study. At each stage, coding was done by one researcher and then the research team met and reviewed the coding to discuss each code, consider questions, and reach consensus.

Results

Evaluation and Follow up Moves

During the Phase I lesson, Mr. S's most common move during the third slot of the IRE sequence was evaluation, occurring in 94% of coded moves. After noticing this trend, we made transforming the pattern of IRE discourse a target of our design efforts. Our aim was to encourage teachers of the Phase III lessons to use more follow-up moves, such as pressing for reasoning or asking students to elaborate on an idea (Chapin et al., 2009). This pattern of discourse was modeled during the Phase II TE lessons, during which 53% of the researcher's E/F moves were follow-ups. As indicated in Figure 3, this form of discourse appeared to be taken up by Mr. S in the Phase III lesson, where 36% of Mr. S's turns in the third slot of triadic IRE discourse were follow-up moves rather than evaluations.

The level of intellectual work coded in the teachers' talk was relatively consistent across Phase I, Phase II, and Phase III. In general, the majority of teacher moves (both Gives and Demands) were coded as Low. Many of the Low Demand turns were questions that had a known answer and that could be answered without offering an explanation or justification. The Low Give moves included providing information without explanation or justification. Figure 4 shows a summary of Intellectual Work across the three classrooms.

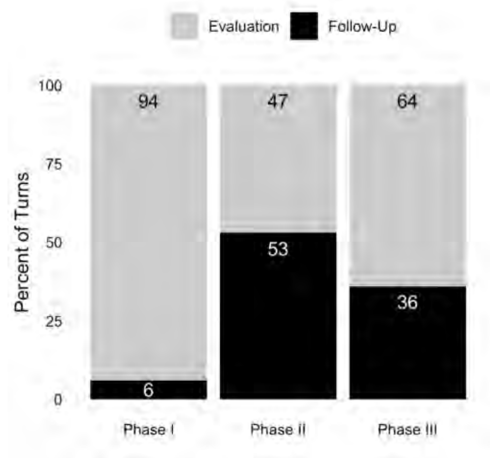

Figure 3. Percent of "third slot" turns that were evaluation or follow-up

Intellectual Work

Despite this consistency, there was one notable shift in the level of intellectual work in the Demand category. During the Phase I lesson, 14% of the teacher's questions were coded as High Demand. This increased to 29% in the Phase III lesson. Thus, while the overall proportion of High Demand turns in each lesson remained under 30%, the proportion of High Demand moves doubled from the Phase I to the Phase III lesson.

There was a complementary shift in the Give category. The proportion of High Give moves decreased from 13% in the Phase I lesson to only 4% in the Phase III lesson. One possible interpretation of this unexpected decrease can be attributed to the teacher using talk moves (Chapin et al., 2009) such as rebroadcasting student input rather than providing high-level explanations. Following the coding scheme, rebroadcasting moves were coded as Low Give. In a sense, Mr. S may have been trying to shift the authority to the students by not engaging in lecture, which decreased the level of Give moves.

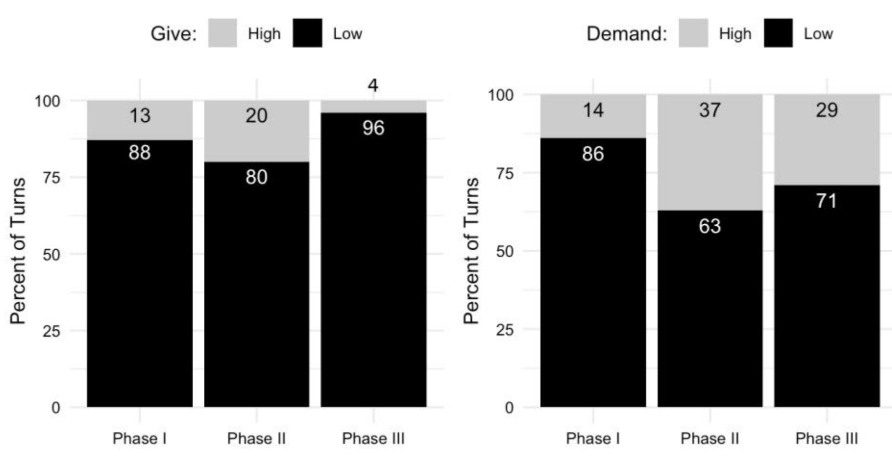

Figure 4. Intellectual Work (Give and Demand) across the three learning environments

Responsiveness

In parallel with the results for intellectual work, the coding for the level of responsiveness of the teachers' discourse showed two trends. First, across all three lessons, the majority of the teachers' talk was coded at a low level of responsiveness. Second, despite this trend, there was also a notable increase in the proportion of turns coded at the high level of responsiveness. Over half of Mr. S's talk in the Phase I and Phase III lessons were coded Low in responsiveness (see Figure 5). However, the proportion of teacher talk that was coded as high in responsiveness (combining the categories High I and High II) increased from 14% to 25%. With this increase, the pattern of responsiveness in the teacher's talk in the Phase III lesson was relatively similar to the pattern of discourse in the TE lesson.

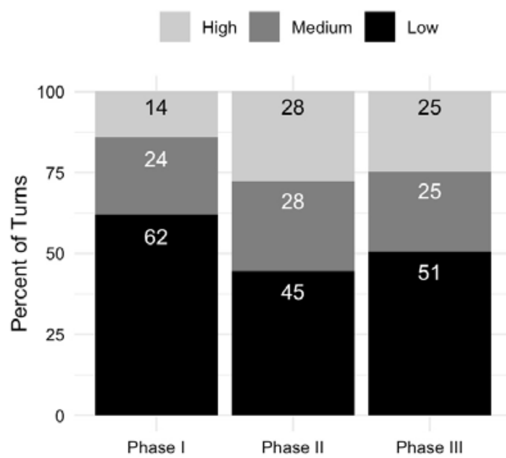

Figure 5. Coding Results for Responsiveness

Distribution and Frequency of Student Participation

Recall that powerful discussions are those which build students' identification with mathematics and broaden student participation (Herbel-Eisenmann et al., 2013). Thus, we were curious about who was contributing and how often in the whole-class discussions. Looking at the patterns of who talked, we were able to characterize the proportion of the talk by the teacher versus students in the whole-class setting. We were also able to identify how many unique students made a contribution to the whole-class discussion. Table 1 shows a total count of the number of coded teacher and student turns, the unique number of students who were called upon by name to contribute to the whole-class discourse, and the number of times each of the called upon students contributed to the whole-class talk.

Table 1. Patterns in Classroom Discussion Participation

	Phase I	Phase II	Phase III
Coded Turns	345	497	447
Students present	28	12	33
Number of unique student speakers called by name	7	12	10
Average turns per identified student	2.5	24	7.3
Number of choral responses	55	7	40
Unidentified student turns	109	0	89
Teacher turns	163	202	230

Looking across the two lessons recorded during regular school hours (Phase I and Phase III), we saw approximately the same proportion of students who were called upon to participate: seven out of 28 students (25%) in the Phase I lesson and 10 out of 33 (~30%) in Phase III. Yet, comparing these lessons, one striking trend was that the students who contributed spoke an average of 7.3 times in the Phase III lesson and only an average of 2.5 times in the Phase I lesson. Thus, for the students who were called on to participate, the average number of turns per student was higher in the Phase III lesson than in the Phase I lesson. As might be expected for the much smaller class in the Phase II TE, all 12 of the students who were present were called upon to contribute to the whole-class discourse, and students tended to have more frequent contributions.

In addition to the identified student turns in whole-class talk during the Phase III lesson, students also had multiple opportunities to talk during small group discussions: a substantially higher proportion (38%) of class time was devoted to group work (compared to only 15% in the Phase I lesson). Therefore, the counts of student turns presented in Table 1 underreport the amount of student talk in the Phase III lesson. Our analysis also revealed that during the designated small group times in the Phase I lesson, very little time was dedicated to group discussion and was actually used for individual seat work. Therefore the counts in Table 1 are more likely reflective of the total number of student turns in the Phase I lesson.

Discussion

The trends we identified in the levels of intellectual work in these three lessons lead to questions about what may explain the relatively frequent incidence of low give and low demand during Phases II and III. One possible explanation is that repeating, one of the talk moves from Chapin et al., (2009), was coded as a low level of intellectual work. Yet, we wondered if this coding accurately captured the effects of these moves. Alternatively, the teachers of these lessons used fewer High Give responses to provide space for the students to supply explanations and needed information to each other. In this respect, we consider this trend from decreasing High Give evaluations or follow-ups to increasing the number of High Demand evaluations or follow-ups as a signal of providing students with more mathematical authority. Finally, an additional alternative to consider is that, in our redesigned lessons, some evaluation and feedback was built into the Desmos activities we created for these lessons, which may have reduced the need for the teacher to voice these moves and be picked up in our analysis.

Considering teacher responsiveness to student thinking, we found that our Phase II and Phase III lesson designs helped the teachers increase the proportion of medium and high levels of responsiveness to student thinking. While we would like to have seen this improve even more, we found that change to classroom discourse in this setting has been gradual. Recall that each phase occurred in a different school year. The ability to document a change in teaching practice even after several months had passed since the TE intervention is noteworthy, and speaks to the potential of our redesigned lessons to support teachers in engaging multilingual students in mathematical discourse.

In our next analyses, we plan to look more closely at the small group interactions that take place both during designated group work segments and those side conversations that take place in small groups during the whole-class discussion. Our preliminary analyses indicate that much more mathematical discussion is happening student-to-student than one finds when focused on the whole-class discussions.

SEMANTICALLY LINKED SYNTACTIC LITERACY AFFORDANCES IN SECONDARY MATHEMATICS

Ethan P. Smith
University of Delaware
etsmith@udel.edu

This report details a literacy affordance framework for describing and connecting the ways in which teachers focus their students on the syntactic structures of reading, writing, speaking, and listening in mathematics. This framework is intended to serve as a critical access point for connecting and moving broader research in secondary mathematics teaching towards a sociolinguistic perspective. The framework is applied to a sample of teachers from two U.S. states to indicate ways in which these secondary mathematics teachers currently attend to such literacies in otherwise dialogically orientated lessons. Findings indicate the applicability of the framework as well as the opportunities and shortfalls in how such teachers currently attend to language in secondary mathematics.

Keywords: Classroom Discourse, Communication, Mathematical Representations, Instructional Activities and Practices

It is impossible to disentangle the use of language from the learning of mathematics. Reeves (1990) states, "language is the essential vehicle for transmitting and understanding mathematics in school, for turning experience into thinking and learning" (p. 213). Pimm (1987) goes further, declaring that mathematics *is* a language, and if mathematics is a language then the teaching of mathematics *is* the teaching of language. Research on how reading, writing, speaking, and listening relate to mathematics teaching in sequester is abundant (e.g., Österholm [2006] for reading; Resnick [1982] and Shield and Galbraith [1998] for writing; Chapin and O'Connor [2007] for speaking; Hintz and Tyson [2015] for listening) but, as Gutiérrez and colleagues (2010) explain, studies on how all four such modalities of language *intertwine* to mediate the teaching of mathematics are lacking. Research on multilingual or English learners in mathematics education has striven to promote a multimodal and resource-oriented perspective to the topic of teaching such students (see de Araujo et al., 2018), but broader research in mathematics education is fraught with culturally neutral (at best) or deficit-oriented (at worst) perspectives towards language (Moschkovich, 2010).

My aim with this study is to describe the opportunities which secondary teachers do (or do not) afford students to grapple with the multimodal, multisemiotic language of mathematics. The present study thus describes a literacy affordance framework which recognizes and connects the multimodal dimensions of language in mathematics teaching. Further, the study demonstrates the utility of this framework in the context of twelve secondary mathematics lessons. Specifically, this study seeks to answer the following questions:

1. In what ways do secondary mathematics teachers enact affordances addressing their students' use of syntactic structures to read, write, speak, and listen mathematically?"
2. In what ways do such teachers' instructional affordances semantically link the syntax of these different modes of language?

Texts, Literacy, and Literacies in Mathematics

One of the challenges in addressing the role of language in mathematics education is the limited definition of literacy within the field. For instance, Draper and Siebert (2010) describe how teachers may not recognize *reading a graph* or *writing an equation* as literacy practices if their conception of literacy is confined to only "fluency in reading and writing [with] print texts" (p. 23). Such restrained conceptualizations of literacy mask opportunities to recognize and study the use of language in mathematics education. This study addresses this concern by integrating consistent and inclusively defined definitions which are meant to better connect ideas of language, literacy, and mathematics.

At the core of this study are the ideas of *texts*, *literacy*, and *literacies*. Although traditional definitions of texts and literacy are limited to a focus on reading and writing printed text (Draper & Siebert, 2010), this work recognizes a more inclusive understanding of such terms. In the present study a *text* is considered any representational object which is intended by its creator to communicate a meaning (Draper & Siebert, 2010; Wells, 1990). Literacy, in turn, can be considered "the ability to negotiate (e.g., read, view, listen, taste, smell, critique) and create (e.g., write, produce, sing, act, speak) texts in discipline-appropriate ways" (Draper & Siebert, 2010, p. 30).

Literacies then are the multiple modes (or "meaning-making systems"; Kress, 2001, p. 11) of texts through which students must navigate during the learning process. These include both primarily receptive (reading and listening) and primarily expressive (speaking and writing) literacies (Aguirre & Bunch, 2012; Bloom, 1974; Draper & Siebert, 2004). Meaning can also be communicated in other ways such as gesture (Arzarello et al., 2009). However, because this study adopts the four primary language demands of reading, writing, speaking, and listening which students face in school mathematics (Aguirre & Bunch, 2012), such modalities fall beyond the focus of this study.

Syntactic Literacy Affordances

Given the current study's definition of texts as representational objects, and literacies as different modes of texts, literacies themselves can be considered representational systems. Goldin (2002) came to a similar conclusion in recognizing the development of representational systems in mathematics as akin to language learning. The current study adopts Goldin's conception of representational systems and flips the focus back to the realm of literacy in mathematics teaching. Of particular relevance is Goldin's (1998, 2002) recognition that representational systems have internal *syntactic* configurations as well as *semantic* relations with other representational systems.

Regarding the syntactic nature of representational systems, Goldin (1998) explains that "To know and be able to construct the configurations formed from characters, and to use the relationships among configurations established by higher-level structures, is one way of giving *meaning* to the characters and configurations in a representational system" (p. 144). Representational systems are not immaculately bestowed with meaning. Rather, understanding and using the syntax of the system fosters that meaning. In the present study this indicates the importance of affording students' opportunities to grasp the syntax of reading, writing, speaking, and listening.

Syntax is traditionally defined as "grammatical relationships among words in a sentence or the structural arrangement among sentences in a passage" (Vacca & Vacca, 2002, p. 381). Given this study's broader definition of text, syntax also refers to valid ways in which symbols or objects that hold mathematical meaning can be procedurally manipulated or configured (Bayaga

& Bossé, 2018; Goldin & Kaput, 1996; Kaput, 1987). A *syntactic literacy affordance* thus occurs when an instructional activity supports students with developing their understanding or use of syntactic structures within the representational systems of reading, writing, speaking, or listening. Specifically, corresponding definitions of such affordances within each relevant literacy are drawn from this overarching definition to form the crux of the literacy affordances framework:

- A **syntactic reading affordance** is when a teacher focuses students on interpreting the syntactic structures of *already-constructed written texts* (representational objects such as written language, graphs, tables, equations, charts, etc.). This instructional move emphasizes how attending to such structures helps to uncover mathematical meaning. Ambiguities of a construct*ed* written text are addressed.
- A **syntactic writing affordance** is when a teacher focuses students on the syntactic structures of *their own written texts*. This instructional move emphasizes how attending to such structures helps to communicate mathematical meaning. Ambiguities while construct*ing* written text are addressed.
- A **syntactic speaking affordance** is when a teacher focuses students on the syntactic structures of *their own spoken texts* (representational language such as explanations, justifications, clarifications, etc.). This instructional move emphasizes how attending to such structures helps to communicate mathematical meaning. Ambiguities while construct*ing* spoken texts are addressed.
- A **syntactic listening affordance** is when a teacher focuses students on interpreting the syntactic structures of *others' spoken texts* (representational language such as explanations, justifications, clarifications, etc.). This instructional move emphasizes how attending to such structures helps to uncover mathematical meaning. Ambiguities of a construct*ed* spoken text are addressed.

Semantically Linked Syntactic Literacy Affordances

Lingering beyond this focus on syntactic literacy affordances are the (previously noted) semantic aspects of representational systems. Indeed, the above definitions of syntactic literacy affordances, with their emphasis on addressing ambiguities within each literacy, are semantic in nature. It would make sense, for instance, for a mathematics teacher to help students *read* the syntax in a graph of a linear function by *speaking* with students about the representation.

This is intentional, as the literacy affordance framework does not describe the modalities used to enact all instruction (which certainly extends beyond the scope of reading, writing, speaking, and listening) but rather which syntax the teacher is *focusing student attention towards* in its relation to mathematical meaning. I fully recognize that teachers and students may be *using* semantic cues as well as syntactic structures within and across literacies throughout their instruction. This emphasis on literacy affordances shifts the conversation away from literacies as they arise with or without the teacher's intention to instead emphasize instructional aspects of literacy that are more directly within the teacher's control.

However, semantic aspects can still be considered through the literacy affordances framework. Kaput (1987) astutely describes the mathematical power in "applying the syntactical properties of a given symbol system's symbol scheme to a new field of reference" (p. 181). In other words, corresponding the syntax of one representational system onto that of a new representational system is "among the key ways that mathematics evolves, both historically and within individuals" (Kaput, 1987, pp. 180-181). This study's framework provides a window into how teachers might promote such correspondences from a literacy standpoint by identifying when teachers address the syntax of *multiple* literacies in relation to a single mathematical text. Such groupings of syntactic literacy affordances are thus considered *semantically linked*.

The Literacy Affordances Framework

When combined, the literacy affordances framework situates syntactic reading, writing, speaking, and listening affordances along similar dimensions as Aguirre and Bunch's (2012) visualization of language demands of reading, writing, speaking, and listening. However, this model stands apart in focusing on the teacher's role in attending to language rather than on the demands of the language itself. Given the importance of semantically linking such affordances, this aspect is centered on the representation of the framework, shown in Figure 1.

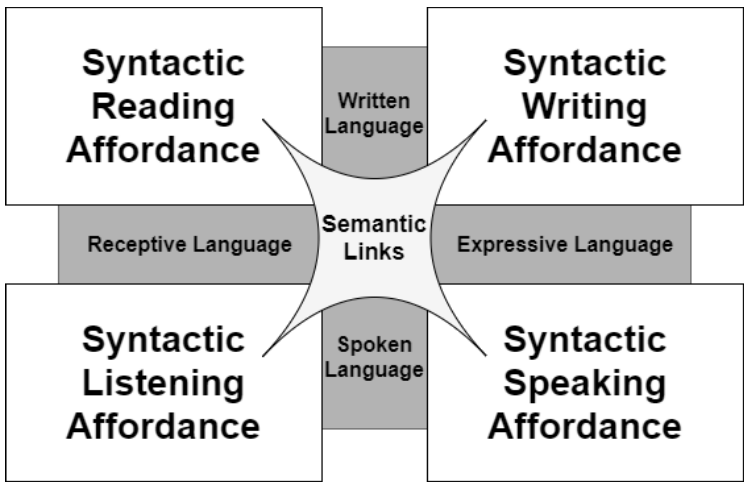

Figure 1: The literacy affordances framework adapted from Aguirre and Bunch (2012)

Methods

Research Setting and Participants

This study is based on recordings collected from 9 secondary mathematics teachers' lessons in two U.S. states. 6 of these teachers taught in a mid-Atlantic state and 3 in a southwestern state. 6 of these teachers identified as white while the remaining 3 teachers identified as Black, Hispanic, and white/Asian, respectively. These recordings were captured as part of the SMiLES project (Secondary Mathematics in-the-moment Longitudinal Engagement Study), which collected student survey data, classroom observations, and teacher and student interviews to understand the role of engagement in secondary mathematics classrooms.

These nine teachers were chosen for the present study because their instruction appeared highly dialogic. Three such qualities of dialogic instruction are the use of high-level tasks (Henningsen & Stein, 1997), opportunities for sharing multiple representations or strategies (e.g., graphs, tables, etc.), and student discourse (Munter et al., 2015). Each of these dialogic qualities had previously been captured in qualitative coding of the classroom videos as part of the SMiLES project (Jansen et al., 2021). High demand tasks were hypothesized to present more opportunities for reading comprehension, while sharing multiple representations and mathematical talk were conjectured to afford more opportunities for writing, speaking and listening. Thus, teachers who enacted dialogically focused instruction were hypothesized to be ideal candidates for this investigation.

The mean of these three qualities was taken for all 156 lessons analyzed for SMiLES and lessons with a mean greater than 2 (out of 3) and with no individual dialogic quality rating lower than 2 were selected for inclusion in this study. Additionally, for teachers who had more than two lessons that met these criteria, only the two lessons with the highest mean were selected so that any one teacher's instruction would not dominate the focus of the results. This left 12 lessons to analyze for the present study.

Classroom Observations

Observations were conducted during the 2018-2019 and 2019-2020 school year. The observed lesson episode for SMiLES was an activity which the teachers believed would be most engaging for students. When teachers would attempt to engage students in learning mathematics, it was hypothesized that they would be likely to also provide a greater number of opportunities for students to engage with or across different literacies. However, the absence of such literacy affordances in these activities would also be valuable, as such results would indicate that these teachers do not necessarily include literacy as part of their conceptions of engaging mathematics instruction. As such, the activities captured in these classroom recordings were well suited for the present study.

Unit of Analysis

Given this study's focus on syntactic literacy affordances – including those which are semantically linked – it was critical to define a unit of analysis that would capture affordances which genuinely correspond with one another and to not confuse these with semantically isolated affordances. For instance, enacting a syntactic reading affordance to support students in interpreting the features of a linear function represented in a graph and then later providing a syntactic writing affordance to support a student in revising a written function equation would not inherently link the two affordances. However, if both the reading and writing affordance attended to how the *slope* of the same function manifests (in the graph and in the equation), then these two affordances would be (from an instructional standpoint) semantically linked.

As such, this study delineated its unit of analysis not only by the overarching mathematical ideas that constitute an instructional task (i.e., Stein & Lane, 1996), but also what Gresalfi et al. (2009) refer to as the task *affordances*, which includes "the ways that mathematical knowledge got constructed – individually, in pairs, with the entire class, and with the teacher" as well as "the ways that the teacher engaged with students around the task as they completed it" (p. 56). The unit of analysis for this study can thus be considered a *textual affordance*, or an instructional moment where one or more texts are being used to communicate meaning about a particular mathematical idea in a particular social context.

Reliability of the Framework

To establish reliability for this study, the author met with two colleagues to test the unit of analysis and the types of syntactic literacy affordances. In the first round of checks, the author identified distinct textual affordances within a sample activity from SMiLES and asked the colleagues to replicate the procedure. Together, these two colleagues correctly identified 100% of the textual affordances that the author had previously identified.

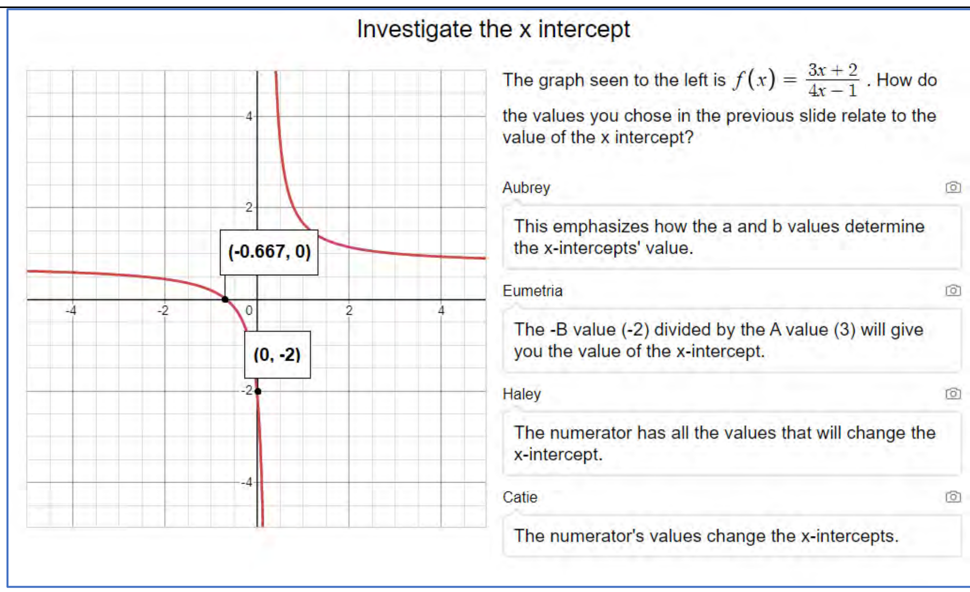
Examples of different syntactic literacy affordances (reading, writing, speaking, and listening) were then identified by the author from a sample observation recording and transcript, including examples where multiple, semantically linked syntactic literacy affordances were present. These same examples were sent to the two colleagues for them to replicate the process of identifying the type of syntactic literacy affordance. Interrater agreement from this process was approximately 85%, indicating a sufficiently reliable framework.

Results

The 12 analyzed observation recordings ranged in length from approximately 15 to 28 minutes. Every activity investigated included examples of syntactic literacy affordances. Fifty-two enactments of syntactic reading affordances and 44 enactments of syntactic writing affordances were found. Eleven enactments of syntactic speaking affordances were present in the analyzed activities as well as one syntactic listening affordance. In addition, 16 examples of semantically linked groups of affordances were also found, although 73 of the 108 syntactic literacy affordances were not linked. Although different amounts of literacy affordances would be expected given that the length of teacher-selected activities varied, these data show the prevalence of such affordances throughout such activities regardless of the length of the activity.

Use of Technology for Whole Group Writing Affordances

Syntactic writing affordances were intentionally defined as focusing students on their own constructed texts. As such, a teacher merely asking a student to describe a mathematical text whole group could not be considered a syntactic writing affordance since the syntax of the written text is not at play but rather the syntax of the student's spoken interpretation of that text. This could have potentially limited whole group syntactic writing affordances to instances where students construct (or reconstruct) their texts in a public space (e.g., a white board) or the teacher has the means to share individual work publicly (e.g., a document camera). For the latter option, the results showed that several teachers used virtual learning platforms (e.g., GeoGebra and Desmos) to enact whole group syntactic writing affordances.



Mrs. Hudson: So a and b were the coefficient of x and the constant term in the numerator. All right. And when you all started to analyze that, there were a couple of you are like -- I'm going to point out -- this one here, where it said, "the -B value, which is (-2), divided by the A value (3) will give you the value of that x-intercept." So, there were a couple of us -- we explained that -- or some of you all even said "if you set the [denominator] equal to 0, and solve for x." I saw some of that. So I'm glad that you all saw the patterns there, but at least you all saw that it is in the numerator and it is the values of the coefficient and the constant.

Figure 2: A whole group syntactic writing affordance

For example, Figure 2 shows how Mrs. Hudson (all names are pseudonyms) provided feedback on students' written explanations of how features of a rational function relate to the x-intercept. She contrasted some students who simply referenced "the numerator" against those who described the actual a and b values and the procedure of solving for x. She noted how these students "saw the pattern there, but at least you *all* saw that it [the values used to find the x-intercept] is in the numerator and it is the values of the coefficient and the constant." The ambiguities in some students' displayed writing, such as a response which stated "The numerator's values change the x-intercepts" were drawn out through this syntactic writing affordance.

Semantically Linked Syntactic Literacy Affordances

There were 16 examples of semantically linked literacy affordances in the data. Figure 3 shows an example from Mrs. Barnett's classroom, where she enacted a semantically linked syntactic speaking and listening affordance during a lesson about maximization with systems of inequalities. She posed a question to Jimmy about how it can be known that one combination (or solution) is "the best." She then engages in a revoicing talk move (Chapin & O'Connor, 2007), having other students respond to Jimmy's answer. She focuses students on *how* to effectively listen during this talk move ("the exercise here is, can we restate or rephrase what Jimmy just said? We need to listen carefully.") allowing both Jimmy and his peers to attend to the clarity of his spoken response. Her insistence that Jimmy must "tell me the math that supports that" with his justification further cements the syntactic speaking affordance within this exchange.

Mrs. Barnett:	I've written my question quite large here. You need to convince me that this is the very best combination. We've talked about the fact that, okay, everywhere within this region…is possible, but Jimmy told us that there are better combinations than others. Of course we want to carry the most passengers. But then how do I know?
Jimmy:	If you were to do all the other combinations, you would still find that with that combination of vans, you would not be able to carry as many senior citizens as the (0,5) combination, which would carry 75.
Mrs. Barnett:	Do you guys hear what Jimmy had to say? Can someone restate or rephrase what Jimmy just said? Say it one more time, Jimmy, because now the exercise here is, can we restate or rephrase what Jimmy just said? We need to listen carefully.
Jimmy:	There's no other way to get more than 75 people due to the budget. There are good combinations. (0,5) is the best combination because it gives you the most people that you can carry within the vans.
Mrs. Barnett:	Okay. Can someone restate or rephrase what Jimmy just said?
Michael:	Based on the money you have, you can't get any more 75 senior citizens to be taken in the vans.
Mrs. Barnett:	Jimmy, did Michael adequately rephrase what you said?
Jimmy:	I mean, yeah. It's kind of the main idea of that.
Mrs. Barnett:	There's no larger amount of passengers that can be carried. You're telling me that it's what, 75 people?
Jimmy:	Yes.
Mrs. Barnett:	Can you tell me the math that supports that?
Jimmy:	Five times 15, because each large van carries 15 passengers. If we purchased five large vans, five times 15 is 75.

Figure 3: Semantically Linked Syntactic Literacy Affordances

Nonexamples Syntactic Literacy Affordances

Many instructional moves fell short of focusing students on the syntactic structures of reading, writing, speaking, and listening mathematically. The key definitional piece of the literacy affordances framework that held back additional moves from being classified within it was the need for the move to *emphasize **how** attending to such structures helps to communicate mathematical meaning*. While the teachers in the study often alluded to the fact that different texts do communicate mathematical meaning, these conversations did not always describe how. Indeed, many such interactions between teachers and students could be described as funneling rather than focusing patterns (Wood, 1998). For example, one teacher (Ms. Ellis) asked a student "what direction would this graph open" for a quadratic function written in expanded form ($f[x] = ax^2+bx+c$). The student believed it would open down and when asked "How do you know?" they ambiguously said because it was negative. Ms. Ellis then responded with "What is a negative?" and realized that the student was referring to the c value. At this point Ms. Ellis told him that "c tells you the y-intercept letters. That is correct. What tells you the direction of the graph?" and proceeded to funnel the student towards recognizing that his a value, with the value of 1, would mean that the graph of the function would open upwards.

Although this paper does not stake any claims on the efficacy of this instructional move for supporting the student in matching equations of functions with their graphical representations, the lack of emphasis on the student's mathematical speaking syntax is apparent. Instead of focusing the student on the ambiguity of their one-word responses (e.g., "what do you mean by 'it's negative?' I'm not sure what you are referring to in the equation when you just say 'it.'") the teacher ignored the ambiguity of the spoken syntax (or at most implied its ambiguity by asking "What is a negative") and moved on without addressing how she interpreted it to be so.

Discussion

This study investigated how secondary mathematics teachers support student meaning-making by attending to and linking the syntactic structures involved in reading, writing, speaking, and listening to mathematical ideas. This first required the construction a literacy affordance framework which described – in corresponding terms – how teachers can attend to these four literacies. Such a framework on its own represents a critical step in drawing research on mathematics teaching towards a sociolinguistic perspective (Moschkovich, 2010) by providing a basis upon which to describe teachers' attention to the syntax of language.

This framework was validated and applied across a diverse set of secondary mathematics classrooms, providing an exploratory glimpse into the ways that teachers do (and do not) attend to and connect these literacies. Some findings indicate concerning trends. For instance, the limited findings of spoken language affordances could indicate that, despite the critical role of mathematical discourse and argumentation in mathematics reform movements (see CCSSI, 2010; NCTM, 2014), dialogic instruction (Munter, Stein, & Smith, 2015) is still limited in these classrooms.

However, the results also indicate that these teachers *are* attending to literacy, and that over 30% of the time these affordances semantically link multiple literacies in relation to a particular mathematical idea. The use of technology to attend to student writing in a whole-group setting is also notable. Such whole group opportunities could expose more students' writing to feedback and validation from the teacher and position such students as competent participants in mathematical discourse (Gresalfi et al., 2009).

If, as Pimm (1987) says, the teaching of mathematics is the teaching of language, then the opportunities which mathematics teachers afford for students to engage with literacy warrant the upmost attention. Language, as the core means of our ability to communicate mathematical meaning, dictates not only *what* mathematical meaning is elevated in the classroom but also *who* plays a part in constructing that meaning. Affording students opportunities to develop their language of mathematics is thus a critical piece of affording them the means to mathematical power.

DEVELOPMENT OF TEACHERS' PRESS FOR CONTEXTUALIZATION TO GROUND STUDENTS' UNDERSTANDING

Luke Reinke
UNC Charlotte
LReinke@uncc.edu

Michelle Stephan
UNC Charlotte
Michelle.Stephan@uncc.edu

We investigate the development of a teaching practice called pressing for contextualized operating, which is teacher questioning aimed at grounding students' mathematical activity to their understanding of the problem context. We found significant differences in two teachers' facilitation of class discussions after making the teachers aware of the learning opportunities that pressing for contextualized operating provides. The teachers demonstrated similar patterns in their development of their practice, both exhibiting a phase where contextual backing for mathematical activities were elicited through leading questions. We also provide descriptions of more student-centered approaches to contextual press that the teachers developed, as they experimented with the practice.

Keywords: classroom discourse, professional development, problem-based learning, instructional activities and practices

In response to reforms in math education, teachers and curriculum designers frequently aim to develop students' mathematical understanding by having them solve contextual problems (CPs). To realize the potential of teaching through problem solving, mathematics teachers press students to explore the conceptual meaning underlying their mathematical work (Kazemi & Stipek, 2001; Thompson et al. 1994). To elaborate the construct of conceptually-oriented teaching, Reinke et al. (under review) described *pressing for contextualized operating*, or teacher questioning aimed specifically at grounding students' use of representations to their understanding of the problem context. We extend this research by asking, how does teachers' press for contextualization develop after co-analyzing video of a teacher pressing for contextualized operating and transcripts of their own classroom discussions?

Theoretical framework

In contrast to traditional instruction, which positions CPs as opportunities to apply mathematics at the end of instructional sequences, Freudenthal (1973) advised that problem contexts should anchor students' mathematical development from the start of instruction when possible. Through progressive formalization (Freudenthal 1973, 1991), students' concrete, context-bound activities can slowly build toward formal reasoning with conventional representations. The goal is for students' formal reasoning to be grounded in their common sense understanding of real-world phenomena (Gravemeijer and Doorman, 1999).

Researchers demonstrate, though, that without proper support, students tend to solve problems in procedural ways that suspend, rather than rely on sense making (Verschaffel et al., 2000). Because of this, teachers must intentionally support students in using their everyday experience to make sense of problems and the mathematical activity used to solve these problems. Thompson et al. (1994) describe a conceptual orientation toward teaching, that pushes students to understand and work deeply within problem situations. Other researchers describe teachers' press for conceptual thinking (Doerr, 2006; Henningsen and Stein, 1997; Kazemi and Stipek, 2001). Elsewhere, we elaborated on these ideas to identify a particular type of press for conceptual thinking called *pressing for contextualized operating*, aimed at grounding students' calculations in their common sense understanding of the problem context (Reinke et al., under review). Such press is particularly important during discussions in which the reason for a calculation is difficult to explain in the abstract. When a meaningful context is used, it is often easier to understand why an operation is used by appealing to actions on realistic objects. As an example, we describe a teacher-facilitated discussion of solutions to a problem related to the teachers' fictional dream, wherein she discovered that (1) she could pacify invading aliens by feeding them candy bars and (2) one bar was sufficient for pacifying three aliens. Figure 1 shows a students' strategy for solving the problem "If one food bar feeds three aliens, how many food bars are needed to feed 39 aliens".

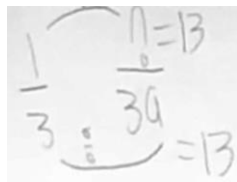

Figure 1: A students' strategy using formal proportional notation

We documented how the teacher, Ms. Kent, engaged in contextual press by asking students to explain the contextual meaning of dividing 39 by 3. She did so through a series of questions to focus students on the meaning of division in the aliens/candy bar context, including "why would he divide thirty-nine by three? and "why would we use division?" More importantly, the teacher was able to surface the idea that it makes sense to divide 39 aliens by 3 because they are grouping the 39 aliens into groups of 3.

The development of productive norms of discourse takes time, as teachers try new practices and respond to feedback from students and students adapt to expectations that may be different than they have experienced in the past (Hufferd-Ackles et al., 2004). As Staples (2008) points out, researchers and practitioners "need detailed accounts of the development of these communities for teachers who face the challenge of transforming their students' participation, and potentially their own as well" (p. 164-165). In this study, we seek to understand how two teachers' practice of press for contextual operating developed with support from university-based coaches.

Methods

To determine how teachers' press for contextualization developed over time, we observed two teachers teach the same unit over two consecutive years: a 7th grade ratio unit that uses contexts in its design. During the first year, we joined planning meetings to help the teachers anticipate student responses and plan for productive mathematical discussions (Smith and Stein, 2011; Stephan et al., 2016). Before observing during the second year, we met with the teachers specifically to share our findings related to press for contextualized operating. First, we described our finding that their beliefs about the benefits of teaching through contextual problem solving had evolved from a focus on engagement to a focus on how the contexts helped students better understand mathematical concepts (Reinke and Casto, 2020). Then, we contrasted the typical language around using contexts as "hooks" with an alternate analogy: contexts as anchors for understanding (Stephan et al., 2020). We then presented transcript excerpts from their classroom the previous year, including a case where students described their work with a ratio table but provided a justification that was not contextualized. In this case, students were shown a table relating the number of candy (Snickers) bars to the number of aliens:

Table 1: Ratio table relating the number of candy bars to number of aliens.

Snickers	1	2	3	4	5	6
Aliens	3	6	9	12	15	?

Teacher: Yes? So, what did you do to get 18? Green group? What did you do to get 18?
Student(s): Six times three.
Teacher: Six times three. That gave us 18? Why did we multiply by three?
Student(s): Because one times three equals three, two times three equals six, three times three equals nine, four times three equals 12, and five times three equals 15.

We collectively brainstormed what an appropriate contextualized backing would be. We also presented a video case where a teacher pressed for contextualized operating and students had difficulty providing that contextual backing. We discussed ways she supported students in making connections between their work with informal, pictorial solution strategies, long tables (as shown in Table 1) and formal proportion representations.

Following these coaching sessions, we then observed a number of lessons from both teachers as they taught the unit again. We were able to record four of the same lessons we had recorded in Ms. Kent's classroom the previous year and three of the same lessons that we had recorded in Mr. Jones' classroom. We transcribed the portions of the recordings that contained whole class discussions of students' strategies. We then coded the transcripts with an a priori coding scheme that had been developed during a previous study. Specifically, we coded each teacher turn for the presence of press for contextualized operating, press for a conceptual explanation (but not specifically contextualized operating), press for contextualized operating through leading questions, and instances where the teacher provided the contextualized backing for the mathematical activity. We coded the student turns for the presence of unprompted contextualized operating and contextualized operating prompted by the teacher.

Results

Across the two teachers, we found a similar pattern in the evolution of the manner in which they pressed for contextualized operating in the second year compared to the first year. We focus on one teacher here, due to limited space.

Year One

During the first year, Ms. Kent frequently engaged in conceptual press that had the potential to surface contextualized operating, but she regularly accepted explanations for operations with ratio tables and formal proportions that did not include contextual justification, (as in the excerpt above related to Table 1). The press through funneling described above (in figure 1) was one of two instances of press for contextual operating with preformal (ratio tables) or formal (proportions) representations in the dataset from 2018.

Year Two

After we made Ms. Kent aware of the construct of contextualized operating and brainstormed different ways to support students in providing contextualized operating, we observed Ms. Kent engaging in significant press for contextualized operating in a variety of ways: by referring to their initial pictorial strategies, by asking students to identify the contextual backing for mathematical activity in their small groups, and by consistently checking for understanding of the contextual meaning of their activity with ratio tables and formal proportional notation.

For example, in the second investigation, a student introduced a formal proportion as a way of describing whether 12 bars will be enough to feed 36 aliens and multiplied both the numerator and denominator of the original 1 bar: 3 alien ratio by 12. Ms. Kent asked "What is that 12?" referring to the multiplier. When students struggled to explain what multiplying by 12 meant in terms of the food bars and aliens, she highlighted a students' pictorial strategy and, after identifying where the various quantities showed up in the picture, she asked:

Kent: Why did we multiply by 12? What was that 12?
Student 3: scale factor
Kent: You're saying scale factor but what does that mean? Think about it. Talk it out with your group. Talk it out. What does that 12 mean? I saw it also on the top and bottom? Why? Where do we see that in the picture?

Throughout the initial lessons in the unit, Kent consistently pressed for the contextual meaning of additive build-up strategies using ratio tables and multiplying by a scale factor and the coefficient of proportionality. While engaging in this press, she frequently checked for understanding from multiple students.

Implications and Limitations

Comparing across the two cases, we found that, after making the two teachers aware of the construct of contextualized operating and brainstorming ways of supporting students to make connections between formal representations and informal, situation-specific strategies, both teachers exhibited a tendency to press for contextualized operating. We also note that both teachers progressed through similar stages as they developed the practice. As Ms. Kent and Mr. Jones first demonstrated an inclination to press for contextualized operating, they elicited this backing through a funneling pattern (Bauersfeld, 1988; Wood, 1998), or a series of leading questions, when students struggled to produce the intended backing. At the beginning of year 2, Ms. Kent demonstrated other forms of press, including connecting back to pictures and providing small group time to encourage students to identify contextual meanings for operating with ratio tables and proportions.

We hypothesize that the changes in practice were significant because the intervention was very specific, focused on a particular practice and a particular mathematical topic, using data from their own classroom. This likely helped support teachers in this unit, but also it remains to be seen how these practices transferred to other units. Furthermore, the teachers in the study knew that we were observing for the presence of press for contextualized operating during year two, so it is unclear the extent to which the observations we recorded were due to this observer effect. However, it is clear that making teachers aware of the possibility of press for contextualized operating supported them in developing the capacity for this practice, which is important for supporting students' meaning making through problem-solving, particularly early in instructional sequences when the contextual grounding of their operating is not yet established.

This study identifies characteristics of two "outstanding" elementary teachers of mathematics who were different in style and who taught in different settings. The intent is to determine what characteristics make these different teachers outstanding in hopes of helping preservice teachers improve their teaching of mathematics. Preliminary findings indicate that both teachers were (1) focused on children's learning of mathematics; (2) focused on the mathematical solution methods used by students; (3) believed that all of their students could learn mathematics; (4) were enthusiastic and dedicated to the profession of teaching; and (5) cared deeply about their students and emphasized the necessity of building relationships with them.

Keywords: Instructional Activities and Practices, Algebra and Algebraic Thinking, Elementary School Education, Professional Development, Preservice Teacher Education

Two teachers in the Conceptual Algebra Readiness for Everyone (CARE) Project for students in grades 3 to 8 distinguished themselves as "outstanding" elementary teachers of mathematics. Each teacher had different styles of teaching and they taught in different classroom settings. Both of the teachers in this study had CARE training, became CARE workshop trainers, and presented project work at national conferences. CARE is a curriculum development project for grades 3 to 8 in partnership with a high-needs school corporation (Feikes, Pratt, & Griffiths, 2012). CARE includes professional development for teachers around helping students develop conceptual algebra readiness and curriculum use. In interviews, both teachers described how CARE shaped their views of teaching mathematics. The goal of this study is to explore commonalities and differences in characteristics of these two teachers and discuss implications for teacher education.

Methodology

This study employs a multiple-case study design (Baxter & Jack, 2008; Merriam, 2009) with a thematic analysis approach. In our analysis, we identified emerging themes which we understood to be "an extended phrase or sentence that identifies what a unit of data is about and/or what it means" (Salda a, 2013, p. 175). Correspondingly, we grouped quotes from the interview transcripts to identify similarities, differences, and themes. The voices of the teachers are used to add understanding to outstanding teaching of mathematics. The two teachers were recruited to participate based on their work with CARE. They participated in structured interviews about their teaching practice and the recordings were transcribed. Additionally, the teachers were observed multiple times and one or two observed lessons were video-taped. This paper reports the analysis of the interviews, using the observations to support the analysis.

Theoretical Framework

A review of studies that deal with excellence in teaching mathematics helped identify some characteristics of outstanding teachers (Hinz, Walker, & Witter, 2019; Lim, Tang, & Tan, 2013). One of these characteristics is building rapport with students and making strong connections.

Building rapport and making connections includes caring about students and the students recognizing that the teacher cares. A second characteristic is focusing on conceptual understanding while recognizing the importance of procedural knowledge. Additional characteristics noted in the research included demonstrating enthusiasm, showing respect for students, being prepared for instruction, and striving to be a better teacher. The literature review produced few current studies that focus on outstanding teaching of mathematics in the elementary school. A key premise of this paper is interpreting what has been learned by these two elementary teachers to help preservice teacher education.

Commonalities and Differences in Characteristics

The first teacher, Mr. Francis (pseudonym), taught for forty years in a Midwestern city with a population of 20,000. A majority of his teaching was in fourth grade. Mr. Francis taught in the school with the highest state standardized test scores in the district. The students in the school were predominantly middle class and White. The school had a 12% minority population and a free and reduced lunch rate of 24%. In recognition of his excellent teaching, Mr. Francis was the winner of the Presidential Awards for Excellence in Mathematics and Science Teaching.

The second teacher, Mr. Marker (pseudonym), taught in a Midwestern city with a population of 40,000. Mr. Marker taught several different primary grade-levels over fifteen years, most recently sixth grade. The school where he taught had a 55% minority population and a free and reduced lunch rate of 76%. Mr. Marker was also recognized as an excellent teacher as a finalist for the Presidential Awards for Excellence in Mathematics and Science Teaching.

Observations and interviews found that the teaching styles and personalities differed for each teacher. Mr. Francis was a composed and caring teacher, describing one of his classroom interactions as "… without being angry or loud." His students never misbehaved. Mr. Francis was very organized, as demonstrated by his calendar of academic standards to be addressed for the entire year. Mr. Marker was higher-energy and sarcastic. The students enjoyed their relationships with Mr. Marker, as evidenced by the number of students who came up to him before school to joke around and share stories. Observed math lessons were energetic and nonstop. Despite the high number of students that lived in poverty, Mr. Marker's sixth-grade students demonstrated success on the state standardized mathematics test, with all but one student earning a passing score.

Differences between the teachers help put their commonalities in starker contrast. Mr. Francis was a planner. When comparing himself to other teachers he noted, "I spend more time planning and creating my own curriculum, making sure I have all the standards outlined." In contrast, when Mr. Marker was asked to compare his planning to Mr. Francis he said, "I go more spontaneously in the classroom." Another difference between the two teachers was their level of confidence about their own mathematical ability. Mr. Francis described a lack of confidence in his mathematical ability. "By the time I got to high school I was not confident. … I did not feel like I was a great math student." His lack of confidence motivated him to make mathematics more meaningful for his students. In contrast, Mr. Marker was very confident in his mathematical ability. Referring to his high school math classes, he said, "At the time it was being taught, I could go the process of it and do the work fine."

Despite these differences, analysis of the interviews found characteristics that the teachers had in common. The first characteristic described by the teachers during the interviews was focusing on children's learning of mathematics. When asked what aspects of mathematics were personally interesting, Mr. Francis talked about children's learning. "It is interesting to see how children think and to see how they solve certain problems and to see how they develop from one stage to another in certain areas." When asked the same question, Mr. Marker also talked about children's learning of mathematics.

> It is trying to get kids to be problem solvers. It's the most challenging because it is so broad. You can find 5 or 6 approaches to solve any problem using computational strategies. … They do it a different way because they are smart enough, because they have built the skills.

In the mathematics education community, we categorize all the different types of mathematical and pedagogical knowledge, but these teachers did not make that distinction in the interviews. For them the interesting aspect of "mathematics" was how children learn mathematics.

The second common characteristic was that each teacher focused on the solution methods used by students when working on mathematics problems. During the interviews, both teachers mentioned that they encouraged the students to share a variety of solution methods. Mr. Francis said, "You wouldn't think it would be so diverse, to see the different types of thinking going on." He relished the enthusiasm students had when they explained their ways of thinking and noted that they especially enjoyed describing different ways to think about a problem. Mr. Marker said, "Some of the coolest moments in the classroom are when kids show different ways that they figured it out and they can't wait to express it. They do not want to be like anyone else."

The third common characteristic was the belief that all students could learn mathematics at a meaningful level. Mr. Marker regularly commented that all his high-poverty students could be successful in mathematics. Mr. Francis expressed similar sentiments about his middle-class students. Both teachers commented on the importance of the solution process and on the value of enabling students to develop their own mathematical thinking.

The fourth common characteristic from the interviews was that each teacher was enthusiastic and dedicated to the profession of teaching. Mr. Francis said "I love it when you see students getting something and you see them excited." Mr. Francis built his enthusiasm off of children's excitement of learning. Mr. Marker was also enthusiastic about teaching, he said, "I really care about [teaching]. I care about the kids being successful, I love to teach. I get excited about it every day, like every day is a fun day for me." These comments demonstrate their enthusiasm for and dedication to teaching.

The interviews and observations provided evidence of a fifth characteristic shared by the teachers; both teachers cared deeply about their students and emphasized the necessity of building relationships with them. This finding is consistent with prior research (Lim, Tang, & Tan, 2013). For example, Mr. Marker stated:

> Once you are able to build that relationship with the kids, once they know that you care about them and they can trust you, they will do anything for you in the classroom. … I think the kids have a good respect for us and we do for them. And that goes a long way in how you manage your classroom and build relationships with students.

When asked what made him an outstanding teacher Mr. Francis referred to his organizational ability and his relationship with children. "I think with the planning and wanting to know the whole child and caring about them and wanting to know their whole picture."

Discussion

The analysis of the data demonstrated that these outstanding teachers of mathematics focused on children's mathematical learning, focused on students' solution methods, believed that all of their students could learn mathematics, were enthusiastic and dedicated to the profession of teaching, and cared deeply about their students and emphasized the necessity of building relationships with them. These findings have implications for mathematics teacher education.

Research has shown that preservice teachers benefit from learning how students learn about mathematics (Feikes, Pratt, & Hough, 2006; Philipp, Thanheiser, & Clement, 2002). In preservice teacher education, we can emphasize the value of knowing children’s thinking and focusing on children’s solution methods to develop conceptual understanding and assessment. Both mathematical content and methods of teaching in the education of preservice teachers should foster a focus on students’ learning of mathematics.

In order to help preservice teachers focus on solution processes or take an inquiry approach in their teaching (Richardson & Liang, 2008), similar approaches should be modeled in college courses. Field experiences that focus on the process and not the product should be available for prospective teachers. Experiencing a focus on process in their college courses and in the field will help preservice teachers adopt this approach to teaching mathematics.

Mr. Francis supported students who were two or three grade levels behind. Mr. Marker taught in a high poverty school and in one year, 55 out of 56 students passed the state accountability test in mathematics. A point to emphasize with preservice teachers is that teachers can make a difference when their teaching embodies the idea that all students can learn mathematics.

As professionals participating in ongoing teacher education, these two teachers regularly participate in professional development. They were interested in what other teachers do and often tried to adapt their teaching based on conversations with other teachers. Preservice teacher education should encourage this type of professional collegiality. Similarly, instructors of preservice teachers need to model enthusiasm for the teaching profession and provide field experiences where prospective teachers see this in action.

Both teachers in this study described developing positive teacher-student relationships with their students. These relationships added to the learning of mathematics and promoted a safe learning environment. Preservice teachers need to learn about developing teacher-student relationships with students based on respect so that the students know they care about them.

Conclusion

This paper describes commonalities and differences in characteristics of two outstanding teachers of elementary mathematics. The teachers taught in different instructional settings, one was a planner and one was not, and one was very confident in his math abilities and the other had significant reservations. However, both teachers focused on children’s learning, the solution methods used by students, and all students being able to learn mathematics. Both teachers were enthusiastic about being teachers and dedicated to professional growth. They cared deeply about their students and building relationships with them. These characteristics have implications for higher education teacher education programs. Preservice teachers need experiences that help them consider student solution methods and student learning about mathematics. Teacher education programs should provide opportunities for collegial interactions around mathematics education and building enthusiasm for mathematics teaching.

Because the characteristics identified in this research are limited to the case study of two teachers, there are limitations to these findings. Interviewing additional outstanding teachers of mathematics and comparing findings to existing research (e.g., Hinz, Walker, & Witter, 2019) could provide additional insights, especially for the teaching of mathematics in the elementary school. Identifying key characteristics and incorporating them into teacher education programs can help advance the effectiveness of future teachers of mathematics. Additional research on how these characteristics can positively impact mathematics teacher education is also needed.

ELEMENTARY MATHEMATICS TEACHERS' FEEDBACK PRACTICES: A MULTIPLE CASE STUDY

Dr. Kristin Hartland
University of Alabama in Huntsville
Ksh0025@uah.edu

Feedback is essential for helping students move forward in their learning, and the beliefs teachers hold could potentially affect the way they provide information to their students. However, the ways in which teachers provide feedback during mathematics instruction and their own implicit beliefs are often overlooked as contributors to the various types of feedback they provide. The purpose of this study was to examine the ways in which elementary teachers provide feedback during mathematics instruction. The results of this study revealed that (1) although both participants ascribed to an incremental theory, they demonstrated varying commitments to providing self-level feedback, (2) one participant provided all three types of feedback within one classroom observation on multiple days, and (3) both participants provided little to no feedback directed at the process and self-regulation levels overall.

Keywords: Teacher Beliefs; Teacher Noticing; Instructional Activities and Practices; Communication

Introduction

Students develop mathematical problem-solving skills through interactions with teachers as well as other students (Jung, Diefes-Dux, Horvath, Rodgers, & Cardella, 2015; Slavin, 1996). Through these interactions students gradually increase their understanding of the content as well as their ability to solve problems (Jung et al., 2015). This information transferred between teachers and students, particularly through questions asked and informational responses, is known as feedback and can help advance students' mathematical knowledge towards a conceptual understanding of the mathematics (Brookhart, 2008; Hattie & Timperley, 2007; Slavin, 1996). Feedback is essential for helping students move forward in their learning (Brooks, Carroll, Gillies, & Hattie, 2019), and the beliefs teachers hold could potentially affect the way they provide information to their students (Rattan, Good, & Dweck, 2012). Thus, the purpose of this study was to examine how elementary mathematics teachers provide feedback. To this end, the research question was: In what ways do elementary teachers provide feedback during mathematics instruction?

Feedback

Feedback, defined as the information conveyed to learners about their actions (Hattie & Timperley, 2007; Shute, 2008), is intended to make a connection between what students understand and what is meant for them to understand (Sadler, 1989). This information educates students as to how they are doing relative to the learning goals of the lesson (Hattie & Timperley, 2007) and how they might modify their work to reach these goals (Jung et al., 2015). Based on numerous observations and analyses of hundreds of studies on feedback, Hattie and Timperley (2007) found that in order for feedback to be effective, it must answer three questions: "Where am I going?, How am I going?, and Where to next?" (Hattie & Timperley, 2007, p. 86). These questions correspond to the three types of feedback: feed up, feed back, and feed forward, respectively (see Figure 1). Additionally, Hattie and Timperley (2007) identified four feedback levels at which each type of feedback can be given. The levels are intended to help facilitators provide “specific feedback to individual learners dependent upon their learning needs” (Brooks et al., 2019, p. 19). The feedback model shown in **Error! Reference source not found.** displays t he four levels at which the feedback can operate, including feedback at the task, process, self-regulation, and self levels.

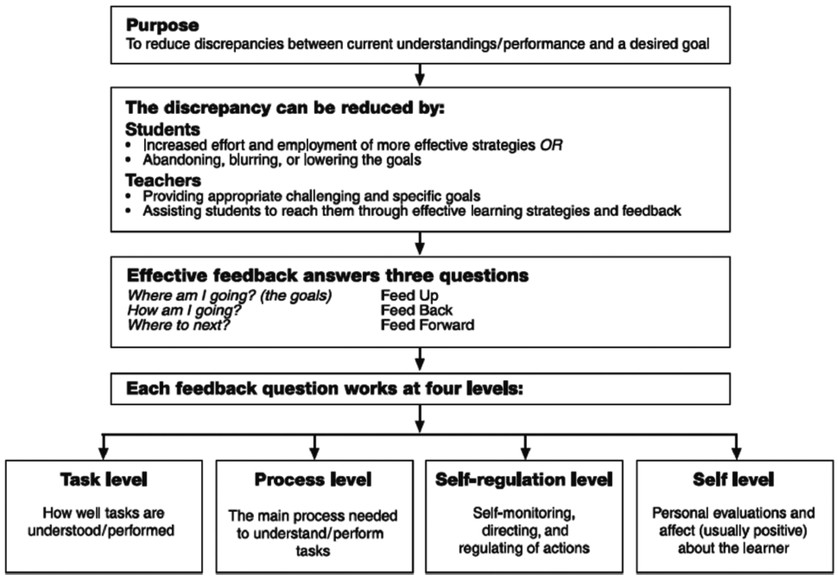

Figure 1: Model of Feedback to Enhance Learning. From Hattie, J., & Timperley, H.

Theoretical Framework

There were two theoretical frameworks that combined to form the conceptual framework for the study. Models of feedback and implicit theories were used as theoretical frameworks to understand the distinct teacher feedback practices in two elementary mathematics classrooms. Observed feedback was categorized according to Hattie and Timperley’s (2007) Model of Feedback to Enhance Learning including the types (i.e., feed up, feed back, and feed forward) and levels (i.e., task, process, self-regulation, and self) in which the feedback was directed. The second model, implicit theories (Dweck, Chiu, & Hong, 1995), was used to select the participants and served as a potential basis for understanding the individual differences that may contribute to the ways elementary mathematics teachers provide feedback.

Methodology

My initial intent was for the two participating teachers to offer contrasting conditions (i.e., one who held an incremental theory and one who held an entity theory); however, due to the unavoidable issues during the participant selection process, both of my participants ascribed to the same subgroup (i.e., an incremental theory). Continuing my study with two participants who ascribed to the same implicit theory was beneficial to see whether there were similarities in the feedback practices within the subgroup of elementary teachers who ascribe to an incremental theory. To this end, I used an exploratory multiple-case study with two elementary mathematics teachers within the same subgroup: one who ascribed to a strong incremental theory and one who ascribed to a weak incremental theory (Dweck et al., 1995).

Participants, Instruments, and Data Sources

The first participant was Ian Smith, an African American male in his late twenties, who ascribed to a strong incremental theory. The second participant was Ellie Jones, an African American female in her mid-forties, who ascribed to a weak incremental theory. I gathered data from multiple sources to fully describe each case: an implicit theories survey, observational protocol, audio recordings, video recordings, semi-structured interviews, and participant reflective journals. To select my participants, I administered all teachers at an urban elementary school (Byron Elementary, a pseudonym) a modified version of Dweck et al.'s (1995) Implicit Theories Measures. The modified Implicit Theories Survey contained an additional domain of mathematical ability (Willingham et al., in press). Once the two participants were selected based on their implicit theory, I conducted daily observations for approximately 11 days during their mathematics instruction. Following each daily observation, I interviewed the participants individually and all data were transcribed and coded for analysis based on the analytical framework of Hattie and Timperley's (2007) characterizations of feedback types and levels. I conducted a cross-case analysis of the two participants to determine any patterns, similarities, or differences across the cases (Yin, 2014).

Results and Discussion

I will organize the results and discussion of the data according to my three key findings. First, although both Ian and Ellie were identified as holding an incremental theory, there were varying commitments to providing self-level feedback during the observed mathematics instruction. Second, while both participants provided all three types of feedback (i.e., feed up, feed back, and feed forward) throughout the 11 days of classroom observations, Ian provided all three types of feedback within one classroom observation on multiple days. Last, feedback at the process and self-regulation levels are necessary for helping students to move towards the Goal of Mathematical Proficiency (NRC, 2001); however, the data showed that Ian and Ellie provided little to no feedback in these ways.

Self-Level Feedback

Although Ian and Ellie were classified as incremental theorists based on their overall average choices on the Implicit Theories Survey (Willingham et al., in press), they demonstrated varying commitments to providing self-level feedback (i.e., praise) during mathematics instruction. Ian, who ascribed to a strong incremental theory, provided self-level feedback directed at the person by praising students for their intelligence, bravery, confidence, and actions, and at the process by praising students for their thinking. He explained that by providing feedback in these ways, he wanted to instill self-confidence and a growth mindset in his students to build a safe and comfortable classroom community of learners. Ian's actions aligned with Hattie and Yates's (2014) idea that some praise could be valuable for establishing relationships within the classroom. These relationships are particularly essential for teachers who ascribe to an incremental theory for building a supportive learning community (Willingham, 2016).

Feedback Type

My second key finding was that although both participants provided all three types of feedback (i.e., feed up, feed back, and feed forward) throughout the 11 days of classroom observations, Ian provided all three types of feedback within one classroom observation on multiple days. This aligns with Hattie and Timperley's (2007) model of feedback to enhance learning where the authors described effective feedback as feedback which answers all three questions (i.e., Where am I going? How am I going? and Where to next?). Effective feedback provided in this way should help students move forward from their current understanding to their desired goal and increase student achievement overall (Hattie & Timperley, 2007). However, Hattie and Timperley (2007) also noted that the degree of effectiveness depended on the level at which effective feedback should be directed and described the specific details of effective feedback between the types and levels as "fuzzy" (p. 103).

It is important to note that although Ian answered all three questions on multiple days, Ellie had no instances where she answered all three questions (i.e., provided feed up, feed back, and feed forward) within one classroom observation. This result, however, only shows that Ellie did not provide effective feedback during the 11 classroom observations according to Hattie and Timperley's (2007) definition of effective feedback. An area of future research would be to closely examine the feedback practices, particularly the types and levels of feedback, of more mathematics teachers in their own classrooms and the impact on student learning as a result of the observed feedback to determine the effectiveness of providing feedback of various types and levels in a natural setting and the direct impact on student learning.

Feedback Level

The last key finding from my data showed that Ian and Ellie provided little to no feedback directed at the process and self-regulation levels overall. When breaking down how each participant provided feedback by level, the results showed that Ellie provided task-level feedback (63 instances) approximately twice as many times as she provided process (25 instances) and self-regulation (two instances) levels combined. Ian provided the most feedback at the task level (56 instances); however, he provided more feedback at the process level (36 instances) and self-regulation level feedback (33 instances) combined. The result that Ellie provided little feedback at the process and self-regulation levels is important given that students use feedback at these levels to build a deeper understanding and take more control of their learning (Hattie & Clarke, 2019; NRC, 2001). Although task-level feedback is the most common form of feedback and necessary in the mathematics classroom to build a strong surface-level understanding (Brooks et al., 2019; Hattie & Clarke, 2019), it is not sufficient for helping students move towards the Goal of Mathematical Proficiency (NRC, 2001).

The result that Ian provided more process-level and self-regulation level feedback is important as feedback directed at the process and self-regulation levels are essential for fostering independent students and helping students in moving forward with their thinking (Hattie & Clarke, 2019; Hattie & Timperley, 2007). In addition, self-regulation level feedback supports students in monitoring and assessing their own learning, and often leads to the detection of their own errors (Hattie & Timperley, 2007). Although feedback at the process and self-regulation levels are essential in the mathematics classroom for supporting students, teachers do not often recognize what "higher levels of feedback look like, and are, thus, unable to use them to enhance learning" (See, Gorard, & Siddiqui, 2016, p. 69). Thus, the results of my study suggest the need for preservice/in-service training to address the different types and levels of feedback in the mathematics classroom.

Conclusion

This study examined how two elementary mathematics teachers, both who ascribed to an incremental theory, provided feedback during mathematics instruction. Teacher feedback has been established as one of the most important influences on learning and student achievement (Hattie & Timperley, 2007; Hattie & Yates, 2014; Wisniewski, Zierer, & Hattie, 2020). However, the ways in which teachers provide feedback during mathematics instruction (Jung et al., 2015; Li et al., 2016) and their own implicit theories are often overlooked as contributors to the various types of feedback they provide (Rattan et al., 2012). Students must be given opportunities to engage with meaningful mathematics through effective feedback that supports their efforts in moving forward with their learning and understanding (Boaler, 2015).

shillman@svsu.edu

Although characteristics of discussions have been identified in the mathematics education research literature, pedagogy of MTEs' discussion practice is underexplored. Using a self-study methodology, we characterize three MTEs' pedagogy of discussion practice for teaching about teaching mathematics in methods courses. Data sources include recordings and transcripts of weekly critical friends' meetings, MTE facilitated discussions, and instructional artifacts. We identify commonalities in our pedagogy of discussion practice: anticipating PTs' thinking and layering instructional activities. We argue that scaffolding informs MTEs' discussion practice.

Keywords: Classroom Discourse, Preservice Teacher Education, Teacher Educators

Discussion is a core practice in mathematics teaching (Grossman et al., 2019). Although teaching about mathematics teaching involves engaging teachers in discussions (e.g., Steele, 2005), mathematics teacher educators' (MTE's) pedagogy that informs such discussions has received less research attention. We address this gap by describing pedagogy of practice and identifying scaffolding as a concept with potential to inform MTEs' pedagogy of discussion practice. Findings from qualitative self-study of MTEs' discussion practice are used to describe two processes: anticipating prospective teachers' (PTs') responses to discussion prompts and layering instructional activities. We argue that scaffolding (Bakker et al., 2015) is a pedagogy that informs MTEs' discussion practice in teaching about teaching.

Background and Literature

Pedagogy is a theory of teaching and learning such that together "they lead to growth in knowledge and understanding through meaningful practice" (Loughran, 2006, p. 2). Grossman et al. (2009) described three concepts teacher educators use to teach about practice: representations, approximations, and decomposition of teaching practices. These concepts are useful in the design and analysis of pedagogy in mathematics teacher education (e.g., Ghousseini & Herbst, 2016). Yet Grossman et al. (2009) caution that instructors mediate the "learning potential" (p. 2089) of representation or approximation of practice used in professional education through "planning, modeling, and feedback" (p. 2090). This caution raises questions about pedagogies that inform MTEs' practices. Thus, we explored MTEs' pedagogy of discussion practice guided by the research question: What is our pedagogy of discussion practice in mathematics methods?

Discussion is defined as an interaction in which people address "a question of common concern" (Dillon, 1994, p. 8) through an exchange of ideas (Alexander, 2019) and examination of differing views to share ideas or solve a problem (Kim & Wilkinson, 2019). Drawing from this definition we describe discussion as a talk strategy MTEs use to support PTs' development of concepts and perspectives on concepts relevant to mathematics teaching practice. Discussion is informed by teacher educators' use of "knowledge, theories, and understandings" (Pinnegar & Hamilton, 2009, p. 16) in practice to develop "knowledge from practice" (Pinnegar & Hamilton, 2009, p. 17) as a way of "knowing to" (p. 18) engage PTs in a given practice.

Scaffolding is a process teachers use to support students' concept development. Bakker et al. (2015) assert that scaffolding can inform instructor pedagogy, pedagogies which Grossman et al.

(2009) claim vary and may produce different outcomes. Smit et al. (2013) described whole class scaffolding as involving the characteristics of diagnosis of understanding, responsiveness to current understandings and needs, and fostering independence (Visnovska & Cobb, 2015). Whole class scaffolding is "layered, distributed and cumulative" (Smit et al., 2013, p. 829) suggesting that these characteristics may take place during and outside whole-class interactions.

MTEs draw from research on the role of PTs' mathematics experiences on their practices. PTs' experiences learning mathematics have been shown to inform their practice (Drake, 2006; Mewborn, 1999; Mewborn &Tyminski, 2006, Towers et al., 2017). As such, MTEs assume such experiences inform PTs' responses to discussion questions. MTEs' experiences facilitating mathematics discussions inform tacit knowledge of productive discussions (Munby & Russell, 1994) in mathematics methods. MTEs' facilitation of discussions of mathematics teaching and learning requires understanding that teachers' pedagogical claims draw from values and experience (Steele, 2005) unlike their mathematics claims.

MTE's discussion practice in mathematics methods is impacted by phenomenological factors (Dillon, 1994). Such factors are necessary but not sufficient conditions for discussions (Kastberg et al., 2020) that support concept development and perspective taking (Lischka et al., 2021). PTs need a sense of community and relevant common experiences as a foundation for discussion. MTEs' facilitation of discussions, including structuring discussion questions, facilitating the interpretation of the question, and constraining evidence PTs use to address the question, impacts the form (i.e., IRE, recitation, discussion) and content of the PTs' talk (Lischka et al., 2021).

Institutional Contexts and View of Learning that Informs Pedagogy

We teach in different institutional contexts including elementary and secondary mathematics methods, and a range of institutions from teaching-focused to research-intensive. Signe's study of discussion practice focused on opportunities for PTs to address the question: "How do children learn mathematics?" Alyson's discussion study was guided by the question: "How is effective feedback practice enacted?" Susan's study of discussion practice was guided by the question: "How does cognitive demand of tasks and knowledge of children's mathematical thinking inform planning instruction?" We draw from a constructivist epistemology in our pedagogy (Steffe & D'Ambrosio, 1995) of teaching about teaching to create and use models of PTs' knowledge of mathematics teaching that inform instructional decisions such as the development of discussion questions. We create models of our practice and identify "living contradictions" (Whitehead, 1989, p. 41) between the models and our practice.

Methodology and Methods

Self-study methodology as characterized by LaBoskey (2004), is a form of practitioner research (Borko et al., 2007) uniquely positioned to support inquiry into pedagogy of practice. Evidence of such pedagogy spans the dynamic experience of MTEs and artifacts from such experience. During Fall 2020, we engaged in weekly critical friend conversations in the form of analytical dialogues (Guilfoyle et al., 2004) focused on facilitating discussions in mathematics methods. Support for trustworthiness was attended to by including course artifacts from teaching. Within the methodology of self-study, we used three qualitative analytic methods: dialogic analysis (Guilfoyle et al., 2004), evidentiary maps, and descriptive coding (Saldana, 2016). Ongoing dialogic analysis of our discussion practice in Fall 2020 semester supported our process of "coming to know" that served as the basis for "action (in knowing, understanding, and doing)" (Guilfoyle et al., 2004, p. 1111). Ideas contributed in our weekly discussions were unpacked, analyzed and critiqued. Analysis of transcripts from seven meetings during Fall 2020, unearthed the development of "coming to know" that served as the basis for our action. We created evidentiary maps of the "structure of events" (Jordan & Henderson, 1995, p. 57) from courses relevant to our discussion practice using teaching artifacts. Evidence from artifacts were analyzed and critiqued regarding the extent to which they supported or contradicted initial findings from the dialogic analysis. Descriptive coding (Saldana, 2016) of transcripts from our dialogic conversations used the ways of knowing for discussion practice identified during the dialogic analysis. We looked for evidence of ways of knowing relevant to describing our pedagogy of discussion practice. Important in these methods is the movement from dialogue to course artifacts and back to dialogue. These three analytic methods created an evidentiary basis for findings common across three MTEs' discussion practice and related contexts.

Findings

We used two processes during Fall 2020 to inform our discussion practice: anticipating PTs' thinking and layering instructional activities. Shifts in one process resulted in shifts in the other. Examples from Signe's pedagogy of discussion practice are used to illustrate our findings.

Anticipating PTs' Thinking

Signe originally planned to have a whole-class discussion of the question "How do students learn mathematics?" around the middle of the term. We agreed that PTs' thinking about students' learning of mathematics influenced curricular decisions, yet we struggled during early conversations to anticipate how PTs might address this question:

> Signe: . . . we're trying to build this idea of knowing each other as teachers and what kinds of things we would do as teachers and where that comes from. . . . That's going to be a big question that I'm leading up to, . . . but I'm really nervous about sustaining it and facilitating the discussion without meddling in it. . . . so how do I make sense of my development of knowledge for teaching? Not me, but them. How are they aware of it?
>
> Alyson: So you are seeing these different perspectives that might come out from the [PTs]. . . Would it help you to sustain the discussion, if you thought through those different perspectives, and … what are the positive things of those different perspectives that you might draw out or probe more deeply? … it's like you're anticipating different directions that the discussion might go and being ok with different outcomes based on what they're bringing to the table. (Conversation 08-31-2020)

Our dialogue of anticipating PTs' responses to planned discussion questions illustrates this difficulty. Across the semester Signe created opportunities to support PTs' understandings of the word "learning." Such opportunities led to diagnosing PTs' responses to determine next steps in a cycle of anticipating and creating learning opportunities. Signe's evidentiary map illustrated a shift from the language of "conceptual knowledge" used in classes during the first few weeks of the course to "learning" used in a course assessment prompt at the end of the course. We continued to have conversations about how we were getting to know our students, anticipate their ideas about teaching mathematics, and how to provide learning opportunities that would support discussion. As a result of these conversations about anticipating PTs' ideas, our conversations revealed how initial target dates for discussions were shifted back again and again. The discussion Signe aimed for was moved from the middle of the term to the end of the semester and evolved from multiple layers of evidence. In her effort to support PTs' understanding of the terms "conceptual knowledge" and "procedural knowledge," Signe's intended discussions became dialogues and recitations. To have a discussion regarding conceptual knowledge Signe needed PTs to gain facility with the terms in the context of their student work. As our conversations continued, we realized that layering experience and learning over time helped us reconsider and expand the time frame of discussions we had planned.

Layering Instructional Activities and Situations

Instructional activities designed to gather evidence of PTs' ideas and experiences resulted in diagnosis of PTs' responses that informed anticipating PTs' understanding of key ideas relevant to our planned discussion questions. Focus was maintained or we designed and implemented new activities for PTs to build understanding. This cycle created layers of instructional activities. As we reflected on events toward the end of the semester, we gained clarity on the importance of the layers for supporting discussions, which served to reframe the timeframe of our discussions:

> Signe: So, going iteratively, over the course of the semester, shows me that those seemingly divergent points of view, actually are convergent in the way that many of them are talking about it. . . . hearing this discussion go on, incrementally over the course of the semester, has given me pause to say maybe they understand more about the nuance than I thought . . .
>
> Alyson: I think that is the thing I keep coming back to, is it's the idea of the experience. . . . So, if we're trying to force a discussion into one class period, are we really allowing them the opportunity to draw on their experience, particularly if we don't prime it ahead of time in some way? . . .
>
> Signe: . . . I think we understood intuitively not explicitly that it's going to take space and time, for the students to be ready to have a discussion.
>
> Alyson: We decided early on, there was work to be done before you could have a discussion. . . . But we still came into this semester saying, if I've done that prep work, then I can have this discussion. And it's this enclosed thing that happens within one class period. I feel like right now, we're not even saying that. (Conversation 11-10-2020)

A few weeks later, the conversation continued but with a focus on what the layers of opportunity were fostering in relation to the discussion question. Although our conversations over time shifted from talking about anticipating to talking about layering of instructional activities, the interactions between anticipating PTs' understanding and layering of activities was a cyclical process in which we engaged while pursuing our study of discussion practice.

Discussion

Study of our discussion practice unearthed two processes: anticipating PTs' thinking and layering instructional activities. These processes, identified as contributing to the integrative concept of scaffolding (Bakker et al., 2015), maintain the relationship between teaching and learning (Loughran, 2006) while informing our discussion practice. Thus, MTEs' pedagogy (Loughran, 2006) of discussion practice is informed by the concept of scaffolding and as such constitutes a key concept "for understanding pedagogies of practice in professional education" (Grossman et al., 2009, p. 2058). Each instructional activity resulted in diagnosis to anticipate PTs' sense-making of ideas foundational to the discussion. Layers of opportunity to learn were distributed over time and accumulated to support understanding of the discussion question and significance of that question. The layers of instructional activity are created by a cycle of instructional design initiated by the MTEs' needs to anticipate PTs' thinking, be responsive to PTs' thinking, and support PTs toward independence (e.g., Smit et al., 2013). This paper addresses in part how MTEs' pedagogy plays a key role in the "learning potential" (Grossman et al., 2009, p. 2089) of representations or approximations of practice used in professional practice by outlining how scaffolding informs MTEs' discussion practice.

FACTORS INFLUENCING THE INSTRUCTIONAL PLANNING OF SECONDARY STATISTICS TEACHERS

Taylor R. Harrison
Northwest Missouri State University
tharrison@nwmissouri.edu

An increasing number of secondary teachers are being asked to teach standalone statistics courses. In planning for these courses, teachers draw upon their beliefs and are influenced by the context in which they teach. In this collective case study, seven high school statistics teachers participated in a series of interviews and observations designed to assess their decision-making processes, the beliefs they draw upon to make these decisions, and influential contextual factors.

Keywords: Instructional Activities and Practices, Teacher Beliefs, Data Analysis and Statistics.

Recent technological advances and world events make it imperative that every student acquires a basic understanding of statistics (Wild et al., 2018). Often, statistics is integrated throughout other mathematical courses, but increasingly at the secondary level, it is taught as a separate course. With this rapid rise in the number of statistics courses being offered comes an increased need for teachers to teach these courses. However, inservice and preservice secondary teachers often feel unprepared and lack confidence to teach statistics (Banilower et al., 2018; Lovett & Lee, 2018). This paper examines the process by which secondary statistics teachers draw on their beliefs to make instructional decisions by addressing the following two research questions: *What beliefs do secondary teachers draw on when planning statistics instruction? What contextual factors impact whether secondary teachers' beliefs are put into practice?*

Theoretical Framework

Teachers' beliefs have a significant impact on the decisions they make in the classroom, but this relationship is often mediated by the context in which they teach. Teachers' beliefs regarding statistics and teaching statistics have been shown to be quite varied (Chick & Pierce, 2008; Lee et al., 2017; Umugiraneza et al., 2016), and many of these beliefs are at odds with recent recommendations and guidelines for teaching statistics (e.g., Bargagliotti et al., 2020). Schoenfeld (1998) proposes a model of *teaching-in-context*, in which teachers' instructional decision-making depends, in part, on a certain subset of their beliefs that are activated by the context in which they are teaching.

Previous studies (e.g., Zieffler et al, 2018) have shown a large variation in the content and setting of statistics courses being offered to secondary students in the United States. This study examines how teachers' beliefs may impact their teaching of statistics and which contextual factors may influence how and whether these beliefs are put into practice.

Methods

Data and Participants

Participants in this study consisted of a volunteer and convenience sample of seven secondary mathematics teachers who were currently teaching at least one section of a statistics course. The teachers taught in a variety of contexts, including a traditional public high school, selective private and public schools, a private religious school, and a charter school across five counties in a state in the southeastern United States. Participants' years of teaching experience ranged from 4 years to 16 years, with the participants having taught between 1 and 32 prior sections of statistics. Five of the teachers were teaching Advanced Placement (AP) Statistics.

As part of a larger study, each participant was observed for three consecutive lessons (one teacher was observed for two lessons). Prior to the first observation, each teacher participated in an interview designed to identify factors that influenced the teacher's statistics instruction and to identify their learning goals and planned activities for the upcoming lessons. After each observed lesson, an additional interview was conducted with the participant, which included questions asking the participant to discuss reasons behind observed practices that were not discussed in the prior interview and to discuss the planning of the next observed lesson, if any. Part of the post-observation interviews consisted of a stimulated recall (Calderhead, 1981), in which teachers were shown video recordings or were read a description of an instructional practice, and were asked to recall reasons behind decisions that were made. The seven pre-observation interviews and 20 post-observation interviews serve as the data corpus for this study.

Analysis of Data

Passages from the 27 interviews were assigned codes using the constant comparative method (Glaser, 1965; Kolb, 2012) indicating specific types of beliefs that teachers discussed. Passages were also coded to indicate when a teacher discussed their instructional plan for the lesson, the context in which they taught, or previous experiences.

To answer the research questions, passages were identified that contained one of the following combinations of codes: *instructional plans/beliefs*, *instructional plans/contexts*. For each such passage, a short summary was written that captured the essence of the relationship between the two constructs. Each of these summaries were then analyzed along with summaries from other passages containing the same pair of codes to identify common themes, first for each individual teacher and then across all teachers.

Findings

Five different areas of beliefs were identified that impacted teachers' statistics instruction. The three areas most pertinent to statistics will be discussed here: beliefs about learning, about statistics, and about technology. Influential contextual factors that were discovered include limited planning time, limited instructional time, the presence of external assessments, large class sizes, and others. What follows elaborates on these findings.

Influential Beliefs about Learning

For all participants, beliefs about how students learn impacted how participants structured their classroom, norms they established for interactions, as well as larger curricular structures and goals of a lesson. Beliefs about learning that impacted instruction included beliefs about the role of discourse in learning, about needed supports for learning, and about the types of activities that best supported students' learning.

All seven teachers valued student-student discourse, but teachers had varying beliefs about the value of teacher-student discourse that impacted their instruction. Four teachers consciously tried to limit the amount of teacher-student discourse in favor of student-student discourse. These teachers held beliefs similar to those of Mr. Dennis (all names are pseudonyms):

> It's through that conflict that they have--of reading the question, not understanding it, and asking their neighbor--that they start to really solidify their understanding, much more so than me just talking and doing it. And so I found that they can internalize the concepts at a

> much deeper rate, at a much faster rate, if they go through that productive struggle in their groups without me interjecting the answer.

Other teachers felt that teacher-student discourse was invaluable to student learning. These teachers typically had discussions with as many students or groups as possible, in order to assess their understanding and to help them progress in their thinking. Large class sizes and limited class time often made this difficult for these teachers.

All of the teachers in the study valued "hands-on" experiences for their students. They believed that when learning was situated in active experiences, it was more likely to lead to students retaining information and making connections in later units between old material and new. However, limited instructional time often impacted how often these activities were used and resulted in teachers modifying activities to take less time. For example, several teachers believed that having students collect their own data would help them build a deeper understanding and establish a personal connection with the data. However, a lack of instructional time, either for a single class period or over an entire course, often caused these teachers to omit or shorten student data collection. A lack of access to effective hands-on activities and a lack of planning time to search for such activities also caused some teachers to use less hands-on activities than they believed was ideal.

Influential Beliefs about Statistics

Only three of seven teachers regularly expressed that their beliefs about statistics impacted how they taught statistics. These teachers believed that statistics was different than mathematics and thus effective statistics instruction looked different than it did for mathematics. Teachers' belief about the importance of communication in statistics, rather than the following of procedures, impacted these three teachers' instruction, as expressed by Ms. Greene:

> I think just, like, algebraically working through problems is very different than manipulating data….There's not but so much stats you can do, there's a lot of stats that you have to talk about….I have stressed to my students that stats is not about following procedures. Procedures will only get you so far. Whereas a lot of, I think, algebra and calculus is, like, building procedures that you can then use to solve different problems. But statistics is a little bit different from that.

These beliefs resulted in Ms. Greene using less direct instruction than in her other mathematics courses. However, like other teachers, she also felt pressures to cover all the material that was on the AP exam, and felt direct instruction was often a quicker way to cover this material. Because of this as well as the fact that she teaches four different courses and has limited planning time, she sometimes falls back on direct instruction despite her beliefs.

Influential Beliefs about Technology

Four participants expressed concerns that certain types of technology, if not used carefully, could hinder students' learning of statistics. These teachers would sometimes include technology-free portions of a lesson to ensure students would have a better understanding of what the technology was doing once it was introduced. Some of these teachers regularly expressed that technology such as applets and simulations could better support students' learning than graphing calculators did. However, contextual factors often made teachers utilize graphing calculators more often than they may have otherwise. A lack of sufficient instructional time resulted in some teachers using graphing calculators for the sake of efficiency, despite believing that the use of calculators was not the most effective way for students to learn. For those teachers that taught AP statistics, the fact that graphing calculators were the only technology allowed on the AP exam caused some teachers to avoid or reduce the use of other technologies.

The other three teachers believed that technology allows students to focus less on calculations, and more on interpreting results and understanding underlying statistical concepts. For some of these teachers as well, limited available class time impacted how frequently students would use technology other than calculators. Some would make compromises in how technology was used for the sake of time. For example, Mr. Fahey and Ms. Greene would often manipulate data or perform simulations on their own computers and project it to the students, despite beliefs that having students work with the data themselves would likely serve their learning better.

Discussion

It is noteworthy that only three of seven teachers readily discussed how they approached the teaching of statistics different from mathematics. Teachers were not directly asked if they approached these subjects differently. However, for these three teachers, these differences emerged in their interviews rather frequently, while for the other four teachers, these differences were almost never mentioned. There are some key differences between statistics and other mathematical topics (Rossman et al., 2006) that are reflected in recommended guidelines for teaching statistics (e.g., Bargagliotti et al., 2020). Considering these differences is an important part of planning effective statistics instruction. Most participants reported receiving little to no instruction on teaching statistics during their preservice education. Introducing this instruction into preservice teacher education could help teachers recognize some of these differences and positively impact their teaching of statistics.

Regardless of whether beliefs about statistics were influencing teachers' instruction, many of the planning decisions teachers made are particularly meaningful in statistics classrooms. Soliciting two different solutions to a problem, for example, can play a very different role in a statistics course than it can in many other mathematics courses—the non-deterministic nature of statistics allows for two different solutions to both have merit, whereas in mathematics, one of two competing solutions is likely to be incorrect. Choosing contexts for problems that are relevant to students can have a larger impact in statistics, where context plays a more vital role in the problem-solving process (Cobb & Moore, 1997; delMas, 2004). Giving students the opportunity to engage in non-procedural tasks, though important in other mathematics courses, is crucial in statistics courses to allow students' statistical thinking to develop (Bargagliotti et al., 2020). As technology has a significant impact on statistical analyses that can be performed and on the learning that can result, the choice of which technology to include in the classroom is also an important one (Bargagliotti et al., 2020). These decisions are among the many that teachers of statistics must consider if they are to meet the learning needs of their students.

All seven participants had to continually grapple with contextual factors, ranging from limited planning time, large class sizes, short class periods, external assessments, and limited access to technology. Even though these teachers may have had the knowledge needed to effectively teach statistics under ideal circumstances, these factors often resulted in the teachers having to either compromise their beliefs or be inventive in the ways in which they dealt with these factors. However, preservice teachers are often tasked with lesson planning without regard to these contextual factors. They are often given weeks to plan a lesson, given access to technology that may not be accessible in many schools, and are given the freedom to choose their class length and characteristics of students. These utopian conditions unfortunately do not match the reality that these teachers will likely face in real classrooms. Making preservice teachers aware of contextual factors that they will have to contend with and giving preservice teachers practice planning in more realistic situations (e.g., an hour to plan a 50-minute lesson for a class of 25 students) can better equip these teachers with the skills they need to succeed in the classroom.

UNDERSTANDING SPECIFIC STRATEGY DETAILS TO SELECT STRATEGIES FOR WHOLE-CLASS DISCUSSIONS

Amy Hewitt
University of Illinois Springfield
Ahewi2@uis.edu

Whole-class discussions have become an integral part of mathematics lessons that focus on teaching that is responsive to students' thinking. Central to these discussions are the student strategies, thus it is beneficial to understand the criteria teachers consider when engaging in the practice of selecting strategies for discussions. In particular, understanding the specific strategy details for fraction story problems can make selecting strategies for whole-class discussions more purposeful. This study explored 3 teacher cases and 41 teachers participating in professional development activities who were engaged in the practice of selecting. Examination of the data revealed specific strategy detail categories which help characterize the practice of selecting strategies. This article illuminates the specific strategy details teachers can consider to make selecting strategies for whole-class discussions more purposeful.

This study is grounded in a type of high-quality instruction called *responsive teaching*, which encompasses three characterizing features identified by Richards and Robertson (2016): (a) attending to the substance of students' ideas, (b) recognizing the important connections within those ideas, and (c) taking up and pursuing those ideas. One way that teachers are able to learn about their students' reasoning in mathematics classrooms is by providing opportunities for students to articulate their mathematical ideas during whole-class discussions. In these discussions, teachers typically showcase some strategies and then facilitate a conversation by posing questions based on the mathematical ideas within and across strategies. Smith and Stein (2018) highlighted the complexity of orchestrating productive discussions in their seminal book that identifies five practices in which teachers must engage: (a) anticipating strategies, (b) monitoring strategies, (c) selecting strategies, (d) sequencing strategies, and (e) connecting strategies in whole-class discussions.

Despite the widespread appreciation of the five practices, I argue that there is limited specific guidance on purposefully selecting strategies based on the details for whole-class discussions. *Selecting* strategies refers to the practice in which teachers determine the pieces of student work to be shared in whole-class discussions. Given the importance of selecting strategies to orchestrate productive discussions and the limited information about how to specifically engage in this practice, this study was designed to illuminate teachers' criteria for purposefully selecting strategies based on specific strategy details in the context of fraction instruction in the upper elementary school grades.

Literature

The practice of selecting strategies for whole-class discussions is one of the five practices identified by Smith and Stein (2018) to orchestrate productive discussions. There have been some criteria identified by research to purposefully select strategies for discussions (Cirillo, 2013; Kazemi & Hintz, 2014; Kersaint, 2017; Meikle, 2016; Smith & Stein, 2018). These criteria have been general in nature and provided a starting point for teachers working to improve their selecting expertise. Hewitt (2020) built upon the information to create a framework for selecting strategies. The framework for selecting strategies for whole-class discussions identifies three main criteria (Hewitt, 2020) applicable in any content area. The three main criteria for selecting strategies include: (a) the mathematics of the strategy, (b) the author of the strategy, and (c) the class engagement with the strategy. Teachers can base their strategy selections for whole-class discussions on one or more of three main criteria. These criteria do not serve as a checklist, but rather provide different considerations for teachers when selecting strategies. This article builds on the specific strategy details, which are a sub-criteria of the mathematics of the strategy criteria, by exploring the following research question:

- *How do elementary school teachers, who are working toward being responsive to students' thinking, select strategies based on specific strategy details for fraction story problems for whole-class discussions?*

Methods

In this study, I collected and analyzed data from two data sets that come from a larger set of data, *Responsive Teaching in Elementary Mathematics*, in which teachers participated in three years of professional development (PD) focused on developing teachers' responsiveness to students' thinking. The first data set included six observations and 12 interviews about the practice of selecting strategies with three teachers (grades 3-5) who had demonstrated expertise in teaching that is responsive to students' thinking. The second data set included PD conversations of 41 grades 3-5 teachers as they collaboratively engaged in the practice of selecting strategies during workshop activities in year two or three of a PD. Data included four PD activities and included a total of 17 video-recorded conversations among small groups of teachers. My analyses involved a constant-comparative method (Glaser, 1965) to make sense of the data and identify the range of criteria teachers considered. I used descriptive coding (Miles et al., 2014) to capture the specific strategy detail teachers were discussing when selecting strategies. To be considered a code, teachers had to mention it more than once if it was an individual teacher or by more than one teacher. I then synthesized these criteria to create the categories based on specific strategy details for selecting strategies for whole-class discussions.

Findings

In selecting fraction strategies to share, teachers considered one or more of three main categories of specific strategy details: (a) final answer, (b) representation, and (c) use of quantities (Hewitt, 2020). Each of these detail categories includes multiple sub-categories, which were determined as a result of this study and will be described in the remainder of this article.

Teachers' Decision Making Linked to the Final Answer

Teachers considered the specific strategy detail of the final answer when selecting strategies to share during whole-class discussions. *Final answer* refers to the teachers' consideration of how the final answer was included in the strategy, including the correctness, the form, or the visibility in the strategy.

Teachers considered the *correctness of the final answer* when selecting strategies to share with the class to broaden assessment of problem solving. Specifically, the final answer was considered in conjunction with the validity of the strategy yielding multiple possibilities: correct answer with a valid strategy, correct answer with an invalid strategy, incorrect answer with a valid strategy, or incorrect answer with an invalid strategy. Because many teachers emphasize helping students reach correct answers, one might assume teachers would typically select strategies that have correct answers with valid strategies or incorrect answers with invalid strategies. The sub-category of correctness of the final answer underscores that there is more complexity to this decision making.

Teachers selected strategies based on the *form of the final answer* to showcase the different ways the answer can be written and still refer the same quantity. Answers could be written in word form, using fractions that are not combined, or using proper or improper fractions.

Teachers selected strategies based on the *visibility of the final answer in the strategy* to promote understanding of how an answer can be reached using a drawing-based strategy. When the symbolic notation used to identify the final answer is consistent with the drawing, students are supported in seeing how the final answer was reached. In contrast, at the end of a strategy, students sometimes transform the final answer into an equivalent fraction (e.g., a fraction in lowest terms) and this transformed answer may make it harder to see the connection between the drawing and the final answer.

Teachers' Decision Making Linked to the Representation

Another specific strategy detail category teachers considered when selecting strategies for whole-class discussions was the representation. *Representation* refers to how the student used drawing (i.e., pictures), symbolic notation, or words in solving the story problem. In particular, teachers considered the overall form of the representation, the use of word labels in the strategy, the extent of the representation, and the specific shapes used in the strategy.

Teachers selected strategies based on the *overall form of the representation* to highlight the variety of ways story situations could be represented. In particular, teachers distinguished three types of strategies: strategies based solely on drawing, strategies that relied exclusively on symbolic notation, and strategies that involved a mixture of drawing and symbolic notation. Drawing strategies refer to all of the fractional quantities being represented with a picture and no use of symbolic notation except for the answer. Symbolic-notation strategies refer to strategies in which the amounts are only represented numerically, and no drawings are used. Strategies that involved a mixture of drawing and symbolic notation refer to strategies that have a drawing representing part of the strategy, but other parts of the strategy or the fractional amounts are symbolically notated.

Teachers selected strategies based on the *use of word labels in the representation* to explicitly connect the story problem to the strategy. Teachers considered whether or not any labels existed as well as what types of labels. Labels typically identified problem quantities (e.g., children, pizza, etc.) or pieces of the story situation (e.g., amount needed, amount already have, etc.).

Teachers considered the *extent of the representation* to refer to the way students represented various problem quantities when they were selecting strategies for whole-class discussions. Each story problem involved multiple pieces (e.g., items to share, items to group, sharers, etc.), and teachers considered how these pieces were or were not represented in strategies. This criterion was important because when students initially start solving problems, they generally represent all of the problem quantities or at least all of the quantities that need to be manipulated (Empson & Levi, 2011).

Teachers selected strategies based on the *specific shapes used in the representation* to highlight the importance, or lack of importance, of the shape being used. Specifically, teachers considered whether rectangles, circles, or other shapes were used to represent the quantities in the story situation. Students typically start by matching shapes to the shapes of the objects described in the story problem (e.g. circles for pizza and pancakes, or rectangles for sticks of wood) and eventually move to using shapes that are easiest for them to draw and partition regardless of what those shapes are representing. Research has shown that the specific shape used does not reflect different levels of fraction understandings (Empson & Levi, 2011) but students may initially hesitate to move away from the real-world representations.

Teachers' Decision Making Linked to the Use of Quantities

The third specific strategy detail category teachers considered when selecting strategies for whole-class discussions was the use of the quantities to highlight the ways quantities were manipulated in the strategy. *Use of quantities*, refers to how the quantities were manipulated in the strategy. In particular, teachers considered equivalent quantities, benchmark quantities, and operations used on quantities. Additionally, teachers considered the fractional quantities students created, most often for equal sharing story problems.

Teachers selected strategies based on the inclusion of *equivalent quantities* to highlight important comparisons of fractions of different sizes or ways to combine fractional quantities of different sizes.

Teachers selected strategies based on the inclusion of *benchmarks quantities* (also called landmark numbers) to emphasize the power of using familiar amounts (e.g., one whole) when solving problems. Benchmarks play a role in strategies using a drawing, as well as those that relied exclusively on symbolic notation.

Teachers selected strategies based on the *operations used on quantities* so that they had the opportunity to connect students' reasoning to formal operations. Teachers also connected operations across strategies to help students make sense of the relationship between operations or to link use of formal operations to drawings.

Teachers selected strategies based on the *fractional quantities created* in equal sharing problems to give students familiarity with a variety of fractions (e.g., thirds, fourths, eighths, etc.). Teachers often posed story problems that would likely result in the use of different fractional quantities, and then, depending on the goal for the lesson, teachers would select strategies because certain fractional quantities were created. This consideration was most prevalent in equal sharing problems.

Teachers also selected strategies based on the inclusion of an explicit link between the number of sharers and number of partitions to highlight the power in considering this relationship in equal sharing problems. Sometimes the number of partitions corresponded to the number of sharers (e.g., using sixths with 6 sharers) and other times factors of the number of sharers were involved (e.g., using thirds with 6 sharers).

Conclusion

The specific strategy details described in this article illuminate what teachers might consider when purposefully selecting fraction strategies for whole-class discussions. These detail categories are not meant to be a checklist to be executed, but instead they are meant to give a sense of the range of what specific strategy details can inform the selection of strategies for whole-class discussions. The specific strategy detail categories provide benefits to both researchers and practitioners. For researchers, the specific strategy details elaborate on criteria already identified in the literature, while also incorporating new criteria. In particular, the specific strategy details elaborate on the selecting strategies framework (Hewitt, 2020) by providing more nuanced ways to think about selecting fraction strategies. For practitioners, the specific strategy details can inform teachers' decision making and help them become more purposeful when selecting strategies, thereby providing students with more opportunities to learn in whole-class discussions.

ILLUMINATING PURPOSES OF GROUP WORK THROUGH TEACHERS' LANGUAGE IN EVERYDAY MATHEMATICS LESSONS

Teachers have responded to NCTM's (2014) charge to enact student-centered pedagogy by having their students work together on mathematical problems in small groups. To investigate how teachers enact group work in everyday mathematics lessons, we analyzed 33 video recorded 4th-5th grade mathematics lessons using an inductive qualitative approach. Our preliminary findings report on 115 instances of group work across the lessons, revealing multiple simultaneous cognitive and social purposes of group work evident in teachers' language. We share a variety of examples from our data to illustrate the interaction between these purposes.

Keywords: Classroom Discourse, Elementary School Education, Instructional Activities and Practices

Many teachers have responded to the National Council of Teachers of Mathematics' (NCTM; 2014) charge to shift to more student-centered pedagogy by having their students work together on mathematical problems in groups (Featherstone et al., 2011). While researchers have documented productive conditions for cooperative small-group learning (Cohen, 1994), less is known about how teachers enact small group work in everyday mathematics lessons (Webb et al., 2019). Moreover, teachers' facilitation of small group work influences how students engage with each other's mathematical ideas (Yackel et al., 1991; Webb et al., 2006; Franke et al., 2015), students' dispositions toward mathematics (Jansen, 2012), as well as equitable participation (Cohen & Lotan, 2014; Featherstone et al., 2011). The goal of this study is to examine teachers' language as they initiated small group work to illustrate multiple simultaneous purposes of group work. Our research question is: What purposes of group work are conveyed by teachers' language?

Theoretical Perspectives

The perspective that learning and talking are inextricably linked underlies our work. Drawing from Vygotskian-inspired theories of learning (Sfard, 2015; Cazden, 2011), learners construct their own knowledge via language (both verbal and non-verbal) either internally or with others. Cognition (or thinking) cannot exist without communication, implying that communication is a necessary condition for thinking, and, in turn, learning. From this perspective, teaching and learning transpire through talk in the classroom (Mercer, 1995; Resnick et al., 2010; Michaels et al., 2008; Hufferd-Ackles et al., 2004). For our study, we are concerned with talk as it pertains to the immediate learning environment. Since we are interested in how talk influences classroom interactions, we operationalize teachers' language as *tools* (Michaels & O'Connor, 2015) for structuring classroom discourse. That is, teachers' utterances surrounding group work become tools that communicate explicit and implicit purposes for group work.

Methods

Data were collected from 2014 to 2016 as part of a larger project. Participants in the study were 33 4th and 5th grade teachers in one mid-sized urban school district in the Pacific Northwest with teaching experience ranging from 1 to 30+ years (averaging 15.3 years). One full mathematics lesson from each of the 33 teachers was analyzed. The 33 lessons were sampled based on variation of Mathematical Quality of Instruction (MQI; Hill, 2014) into three categories: high, medium, and low (4,5=high, 3=mid, 1,2=low). This data was selected because it represents variation in mathematical quality of instruction across one school district. Therefore, we anticipated that teachers' language surrounding group work would vary across these lessons.

Our first analytic phase consisted of creating transcripts from the group work portions of the video recorded lessons. The criteria identifying instances of group work were: 1) students were prompted by the teacher to work in groups or with partners and/or 2) there was evidence that students talked to each other in pairs or small groups. Two coders independently viewed each lesson and identified *group work segments* (unit of analysis); 115 such group work segments were identified across the lessons. Next, we created segment memos (Creswell & Poth, 2016), then iteratively read through the data and memos to develop initial codes related to cognitive purposes (drawing on cognitive demand; Stein & Smith, 1998) and social purposes of group work that began to emerge (see Tables 1 and 2). One researcher coded all 115 segments, and a second researcher served to challenge interpretations. Any disagreements were resolved through discussion.

Table 1: Cognitive Purposes for Group Work

Cognitive Purposes	Description	Percentage
Facts/Answers	Recall facts, or share/tell, compare, check answers.	16%
Procedures	Complete procedural problems or talk about procedures without connections (Stein & Smith, 1998).	17.9%
Sense-making	Make sense of mathematical words/language, symbols, procedures with connections (Stein & Smith, 1998), contexts, representations, and relationships.	38.4%
Problem-solving	Analyze strategies, solve mathematical problems, pose problems, compare solutions or strategies.	21.4%
Justify/Generalize Math Claims	Construct mathematical arguments to justify a claim or statement; generalize a pattern or use a counterexample to disprove a claim.	6.3%

Table 2: Social Purposes for Group Work

Social Purposes	Description	Percentage
Optional	No clear purpose or prompt to talk, students can choose to work individually or with others.	11.6%
Sharing	Talk (e.g., share, tell, explain) with no additional social purpose.	43.8%
Sharing and Listening	Get help from each other, share ideas while others listen without defined roles, or read/interpret ideas without further engagement.	15.2%
Sharing and Listening +	Share and listen with defined roles or read/interpret ideas with further engagement (e.g., agree or disagree, why, think of a question).	16.1%
Comparing/Connecting	Compare or make connections between each other's ideas or other students' ideas.	4.5%
Interdependent	Co-construct ideas (e.g., come to an agreement, persuade each other).	8.9%

Preliminary Results

Our research question aimed to identify purposes for group work evident in teachers' language. The data displayed in Figure 1 illustrates the interconnection between cognitive and social purposes across the 115 coded group work instances (data points are scattered for clarity). We share examples from the data that highlight different interactions between cognitive and social purposes.

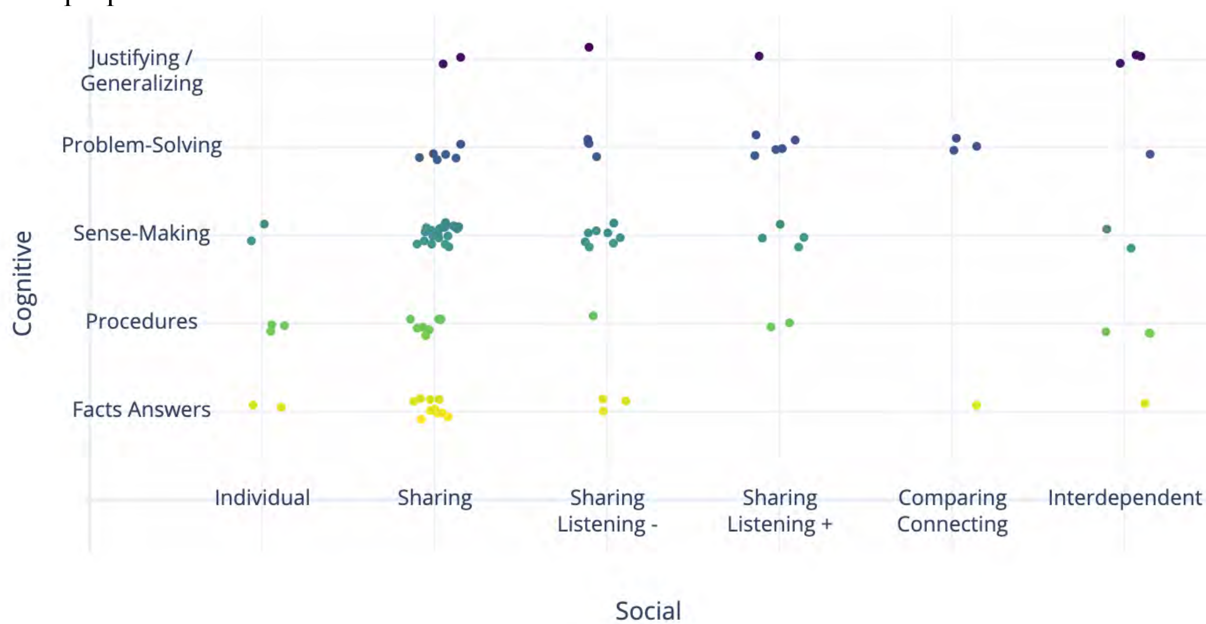

Figure 1. Interaction between Cognitive and Social Purposes of Group Work

Example 1: Sense-making and Optional Purposes

In a 4th grade lesson about modeling fraction multiplication problems with manipulatives, students sat together at table groups talking and exploring the manipulatives. The teacher addressed the whole class, “a nice thing to do might be to see if you can put them together from the largest fractions to the smallest … and then do you know what each fraction is worth.” Here the teacher’s language indicated that the cognitive purpose was to order the fraction pieces while exploring the size or value of the pieces (Sense-making). However, students could have done this individually or together since there was no explicit prompt to talk to each other (Optional).

Example 2: Sense-making and Sharing Purposes

At the beginning of a lesson, a teacher asked students to first solve the problem 4 divided by 1/4, then prompted, “Why would I be dividing and then all of a sudden, it's multiplying […] why would I do that? Does that even make sense? What do you think? […] turn to your partner and talk about it.” The teacher’s language suggested that the purpose of group work was to “turn” and “talk about” “why” a procedure makes sense moving beyond just sharing procedures to making sense of why a procedure works (Sense-making), but without additional social structure for how to talk about it with their partners (Sharing).

Example 3: Comparing/Connecting and Problem-solving Purposes

A 4^{th} grade teacher made two students’ work publicly available for the whole class. After providing individual time to study and think about the two students’ strategies, the teacher then initiated small group work: “Since some of you are on the floor and stuff with your elbow partner or in a small group of 3… talk about what you notice about the two works, about how they're similar and how they're different, go.” The language here is reminiscent of the Sharing social purpose (“talk about what you notice” with a partner), however the social purpose went beyond sharing *their own* strategies (Problem-solving) to comparing *two different* student strategies with someone else (Comparing/Connecting).

Example 4: Interdependent and Sense-making Purposes

During a lesson about solving equations, a teacher wrote 5 = 3 on the board, and asked students a warm-up question to learn about what they think an equal sign means: “So what does that equal sign *mean* when you see that? I would like you to turn to your color partner and see if you can decide– agree on a different definition for an equal sign.” The social purpose here was not just to share ideas, but to *agree on* a definition with their assigned partner (Interdependent), while the cognitive purpose was to come up with a definition for an equal sign – making sense of the meaning behind a common mathematical symbol (Sense-making).

Conclusion

Teachers’ enactment of small group work in everyday mathematics lesson has received little attention in the literature. The contribution of our preliminary analysis revealed multiple simultaneous cognitive and social purposes of group work evident in teachers’ language. We shared a variety of examples from our data to illustrate the interaction between these purposes. We argue that by making subtle purposes of small group work visible, the research community can better understand how teachers’ language shapes student-student interactions and impacts students’ opportunities to access and engage in mathematical discourse with their peers. This work provides further insight into the complexities of enacting group work to achieve simultaneous goals during mathematics lessons, and has the potential to inform existing teacher professional development programs focused on talk in the classroom (Michaels & O’Connor, 2015).

Teacher's why-question can press students toward justification, make sense of mathematical structure, and make students' thinking visible to others. However, the productivity of why-questions hinges on their underlying purpose. In this brief report, we illustrate our framework of underlying purpose of why-question by examining 152 why-questions from 49 classroom videos (grade 4th-8th). While a particular question can appear similar in content, the expected student responses ranged significantly and thus we argue for two implications. First, as researchers, coarsely defining question types by categories such as "why" may be insufficient to tie a teacher move to a particular functional purpose. Second, if we want why-questions to cue students to provide mathematical domain explanations (justifications), there is a need to better understand what classroom/discourse factors lead to productive why-question use.

Keywords: Classroom Discourse, Instructional Activities and Practices

The questions that a teacher poses to students can shape mathematics classrooms in terms of opportunities for students to reason mathematically (e.g., Boaler & Brodie, 2004; Franke, et al. 2009; Sahin & Kulm, 2008). One particularly powerful type of question is the why-question which is often associated with higher order questioning (Kawanaka, & Stigler, 1999) which can serve to press students towards justification (e.g., Conner, et al., 2014), make sense of important mathematical structures (e.g., Jones & Bush, 1996), and make students' thinking available for the teacher and other students (e.g., Sahin & Kulm, 2008). However, the productivity of such questions hinges on their underlying purpose. The same question, "Why?," can lead to a substantially different level of student engagement in varying classrooms.

In a larger project classifying teacher prompts (Melhuish, et al., 2020), we discovered that why-questions were particularly anomalous when compared to other moves that can be productive in engaging students in rich mathematical discourse and reasoning. When we created profiles of various types of classes via a cluster analysis of teaching moves, we found that "why" questions did not serve as a marker differentiating classes that were more focused on mathematical reasoning from classrooms where the teacher did the majority of the mathematical work (Author, year). In fact, the "generic why" prompt was the most prevalent of any of our codes and spanned the majority of the lessons in the project. As a result, we conjectured that why-questions were likely serving substantially different roles for different teachers.

In this paper, we share an analysis of the why-questions found in a corpus of 64 video-taped mathematics lessons spanning grades 4-8. For each instance, we considered the nature of the why prompt, conjectured an instructional purpose, and considered how the students responded to the request. As a result of this analysis, we developed a framework to classify the mathematical why's of instruction. We share this framework and discuss the implications for instruction.

Problematizing Why-Questions

The mathematics classroom reflects a community of a teacher and students where norms shape the overall activity (e.g., Cobb, 2002). And so, we argue there is a need to go beyond categorizing teacher questions based on linguistic form, but to situate their meaning in the larger classroom domain and likely functional outcome. This is especially true for "why-questions" which have often been differentiated from other types of requests because of their context-sensitivity (Cox, 2019). We define a why-question as "some proposition *P* along with the request that *P* be explained" (Temple, 1988, p. 141). Often these questions will be of the form "Why *P*?" such as "Why did you add five to the nine?"; however, such a request for explanation could be asked with an implicit why such as, "How come you added five to the nine?" Thus, why-questions can be operationalized as any prompt for an explanation that could be formulated into a "Why *P*?" question without changing the intended meaning.

Why Questions are Context-Dependent

Temple (1998) elaborated that the "assumption that lies behind the [why-question] seems to combine a *motive* for asking the question in this way with an *expectation* about the sort of answer that is likely to be given" (p 150). The motive may not be immediately apparent as why-questions are particularly context-sensitive (Cox, 2019; van Fraassen; 1980) relating to both contrast (why this and not that) and domain sensitivity (what is an acceptable explanation in the relevant domain). Take the example from above. Depending on contrast, this question could be implicitly asking why "five" was added (rather than another number) or why the numbers were "added" (rather than another operation). Further, why-questions are domain dependent where adequate explanation depends on the relevant domain. While all of the why-questions in this project are in the context of a mathematics classroom, it is quite likely that the domain of explanation could vary based on norms (such as a procedure or conceptual focus).

Why-Questions as Implicit Requests for a Mathematical Justification

In mathematics education literature, why-questions are often treated as serving a particular motive: requesting a justification or proof which we call a *domain explanation.* A proof or justification can be thought of as a mathematical argument for why a particular mathematical claim is true using accepted premises, structures, and modes of argument (Stylianides, 2007). If we consider tools focused on teaching, we find "why" often plays this role explicitly or implicitly such as in EQUIP where teacher questions are categorized as *why*, *how*, *what*, or *other* (Reinholz & Shah, 2019) or Conner et al.'s (2014) collective argumentation framework where the questions: "Why?" or "Why doesn't that work?" are used to exemplify a request for a justification. Similarly, educators like Jones and Bush (1996) illustrate that why-questions are fundamentally linked to exploring mathematical structure. However, we conjecture that why-questions may not always be linked to the expectation of a mathematical domain explanation.

Why Questions are Not Always Requests for a Domain Explanation

While some philosophical (Sandborg, 1998) and empirical attempts (Stacey & Vincent, 2008) have been made to operationalize explanation in the domain of mathematics, they tend to stem from mathematician communities or mathematical text. Such explorations are likely to idealize mathematical explanation in ways that do not fully account for the types of explanations requested during conversation in a K-12 classroom. The literature about why-questions outside of the classroom point to a number of ways they are used in conversation including: serving the role of critiquing (Bolden & Robinson, 2011), rhetorical (Larrivée & Levillain, 2019), requesting a fact or process (Faye, 1999), or requesting an opinion (Mishra, & Jain, 2014). Further, the work on mathematical domain explanations (Sandborg, 1998; Stacey & Vincent, 2008) focus on mathematical claims rather than why a student did a particular thing, a second-person perspective (Roessler, 2014) likely to exist in a classroom. Such why-questions in mathematics classrooms could reflect legal (why are we allowed to do that?) and strategic (why did you make that choice?) decisions (Chazan & Sandow, 2010).

The Project and Analyzing Why-Questions

In this report, we share an analysis of the why-questions teachers ask in mathematics lessons. Our data corpus includes 64 lessons (49 which had why-questions) from distinct teachers spanning two school districts in the United States. In district 1, a midsized urban district in the Pacific Northwest, we selected a stratified random sample of 33 4th and 5th grade lessons based on their Mathematical Quality of Instruction (Hill, 2014) score. In the second district in the Southwest, a large urban district, we included 31 middle school (5th-8th grade) mathematics. For each video, two coders identified any instance of a "generic why" – that is a why question coming from the teacher-to-student(s). The coders met and reconciled any differences. From this process, we identified a set of 152 instances of why-questions. For each why-question, a member of the research team wrote a memo containing context leading up to the why, a transcript of the why-question, and the student response. From the first twenty videos, two researchers took notes describing the evidenced purpose of the why-questions eventually leading to a framework including a number of dimensions: type of why (why, why not, why or why not; strategic, legal, peer-evaluation, or claim), conjectured expected student response (elaborated below), focal mathematical object, and who introduced the mathematical object (teacher, student, peer, class). The initial framework and categories were tested and refined based on the remaining data.

The Why of the Whys in the Mathematics Classroom

An overview of expected student responses can be found in Table 1. Notice that of the why-question, 55% aligned with an expected response in the mathematical domain—evidencing that why-questions do often serve the motive implicitly assigned to them of seeking a mathematical justification. However, 45% of the why-questions did not appear to seek mathematical-explanations reflecting substantial variation.

Table 1: Expected Student Responses

Non-Explanation (32%)		Non-Domain Explanation (13%)		Domain Explanation (Justification) (55%)			
No response (Rhetorical)	3%	Explain the process of arriving at an answer or step	6%	Argue for representational or numerical equivalence	9%	Argue that a mathematical claim (propositional) is true or false	8%
Correct an error or mistake	13 %	Explain a strategic choice or efficiency of approach	3%	Argue that an instantiation meets a definition	14 %	Argue for the Reasonableness of an Answer	3%
Refer to a rule/fact	16 %	Explain a linguistic or task context choice/feature	4%	Argue that a strategy is appropriate conceptually	15 %	Critique or debate a peer's contribution	7%

Table 2 illustrates several examples to contextualize some of these variations. The first example illustrates a why-question whose purpose aligns with students generating a mathematical explanation (justification) -- which is consistent with the implicit treatment of why questions in the literature. In the second example, we see a teacher asking students to provide a fact that makes a procedural option invalid (a legal request). In the third example, the why-question does not seem to be requesting an explanation but rather is serving the purpose to notify the student of a mistake.

Table 2: Illustrative Examples

Description and context	Interpretation
The teacher asked whether each piece of a given shape is equal to 1/4 and students said, "No." So, the teacher said, "why not?" It was followed by the student's explanation, "because they are not even, these don't make a square."	**Type:** why not & claim **Expected response:** argue an instantiation meets a definition **Focal object:** concept
During whole class discussion, the teacher asked whether they can add 5/7 and 2/3 and students said "No." So, the teacher asked, "why not?" A student answered, "because they don't have the same denominator."	**Type:** why not & legal **Expected response:** refer to a rule/fact **Focal object:** procedure
Students are working in small groups on a problem involving elephants eating 150lbs per day, determining how much they eat in April. The teacher asks one of the groups, "So why did you divide these two numbers?" The student then attempts to explain their process, to which the teacher responds, "Are you sure you want to divide, though?"	**Type:** why & strategic **Expected Response:** correct a mistake **Focal object:** strategy to solve a problem

Discussion

In this brief report, we share our analysis of why-questions spanning a diverse set of mathematics classrooms. We found that the context-sensitivity of why-questions is apparent in the mathematics classroom discourse. While a particular question can appear similar in form, the expected student responses ranged significantly. With these results in mind, we argue for a few implications. First, as researchers, coarsely defining question types by categories such as "why" may be insufficient to tie a teacher-move to a particular purpose. Second, if we want why-questions to lead to students providing mathematical domain explanations (justifications), there is a need to better understand the necessary components for a why-question to be productive. Finally, the ambiguity of why-question can also lead to situations where students interpret why-questions as different from the teacher's intent. Such mismatches could lead to student responses being assessed as incorrect or incomplete (on exams or in conversation). As educators, we should be attentive to the very valid alternative way students can understand these types of questions, which this data suggests has its roots in how teachers likely vary in their intentions while using the same linguistic form.

MATHEMATICAL AUTHORITY IN AUTHORING, ANIMATING, & ASSESSING MATHEMATICAL IDEAS

Jessica Pierson Bishop	Michael D. Hicks	Christina Koehne
Texas State University	Texas State University	SUNY New Paltz
jbishop01@txstate.edu	mh1653@txstate.edu	koehnec@newpaltz.edu

In this paper, we describe how mathematical authority is enacted in middle-grades mathematics classrooms where authority, for us, is dynamic, negotiated, and discursively enacted. To operationalize authority, we considered (a) the mathematical activity for which one was claiming authority, and (b) the holder of authority (who deferred to whom for a given activity). We accounted for three broad categories of mathematical activity: Authorship, Animation (oral and written communication), and Assessment of mathematical ideas. The results shared here provide an overall characterization of mathematical authority for the classrooms in our study.

Keywords: Classroom Discourse, Communication

How often do students see themselves as a mathematical authority in their classroom? Are students positioned as important contributors to the mathematics under investigation? How regularly do students assess the correctness or validity of mathematical ideas? We view these kinds of activities as important indicators of mathematical authority in a classroom. Moreover, we contend that it is necessary and productive for students to have mathematical authority.

Classroom environments in which students have opportunities for increased mathematical authority are not only difficult to create and maintain, but they also produce new challenges. For example, Stein, Engle, Smith, & Hughes (2008) identified the importance of balancing student authority and disciplinary accountability when facilitating student-driven discussions. Students should have authority to solve problems in ways that make sense to them and be positioned as mathematical authorities within their classroom community. But students' work also needs to be accountable to the discipline and consistent with accepted knowledge and practices of the larger field. This tension looms large as teachers and students navigate new responsibilities in contexts with shared authority. And, yet, too often students are not given these opportunities. Much of the way we organize and structure classrooms (Pimm, 1987) as well as the words we use positions students with little authority (Drew & Heritage, 1992; Herbel-Eisenmann & Wagner, 2010; Wagner & Herbel-Eisenmann, 2009). But it is possible to create classrooms in which students have mathematical authority (Cobb et al., 2009; Gerson & Bateman, 2010; Langer-Osuna et al., 2020; Wilson & Lloyd, 2000). And a growing body of literature suggests that when students have authority to engage in problem-solving and sense making, they develop deeper understanding of concepts (Boaler, 2002; Wilson & Lloyd, 2000), more productive identities and dispositions toward mathematics (Bishop, 2012; Boaler & Greeno, 2000; Cobb et al., 2009; Gresalfi et al, 2009;), and may become more responsible, empowered, independent learners (Wilson & Lloyd, 2000). Thus, in this paper, we consider how mathematical authority is enacted in middle-grades mathematics classrooms, with an eye toward students' mathematical authority.

Review of the Literature on Authority in Mathematics Education

Scholars use various conceptualizations to study authority in mathematics classrooms. The primary conceptions we draw from are: (1) authority as a relation between groups or individuals, (2) authority as an opportunity to make a choice, and (3) authority as discursive, each of which we discuss below. Benne (1970) defined authority as a triadic relationship between a bearer of authority, their subject (i.e., someone in need of guidance or direction willing to defer to the bearer), and the field (context in which the subjects operate and in which determinations of competence are made). Authority, unlike power, involves a decision for one to acquiesce to another in service of a common purpose. Pace and Hemmings (2007) frame authority as relational, socially constructed, mutable, and dependent on contextual factors. These relational conceptions of authority highlight its dynamic, negotiated, malleable, and social nature. Some scholars do not focus on relationships per se, but instead foreground the idea of opportunities for choice as a core component of authority. For example, Cobb, Gresalfi and Hodge (2009) defined authority as "the degree to which students are given opportunities to be involved in decision making about the interpretation of tasks, the reasonableness of solution methods, and the legitimacy of solutions." (p. 44) While a relationship between individuals may be inferred in this definition, the focus of Cobb et al.'s definition is on characterizing authority by looking at what students are allowed to do with respect to the mathematics in the classroom (see also Gresalfi et al., 2009). And still other research demonstrates how authority is discursively constituted. For example, there is a growing body of work that uses positioning theory to highlight certain types of discursive moves (such as invitations for students to consider and respond to a peer's idea and directing a peer's problem solving) that position students as a mathematical authority or competent (Bishop, 2012; Engle, et al., 2014; Langer-Osuna, 2016; Turner et al., 2013). Others focus on the structural organization of classroom discourse and relate observed discursive patterns to authority. For example, Herbel-Eisenmann, Wagner, and Cortes (2010) used the construct of a lexical bundle to identify repeated phrases (e.g., "I want you to") that structured authority relations in classroom settings by, for instance, obligating students to engage in particular mathematical activities (see also Herbel-Eisenmann & Wagner, 2010).

Our operationalization of authority draws from all three of these conceptualizations. We define *authority* as a dynamic and negotiated relationship between people (or groups or organizations) where one party defers to another within a mathematical situation. We account for the source (or bearer) of authority by focusing on who makes decisions about what is permissible or allowable during various mathematical activities and how those activities are discursively constituted moment to moment. The research questions guiding our work were: (1) In what ways and by whom is mathematical authority enacted during whole-class interactions within and across multiple middle grades classrooms? (2) What patterns and variations in authority relations exists across classrooms in our study?

Methods

Participants, Data, & Analytic Framework

This study is part of a larger research program investigating mathematics discourse in middle-grades classrooms. The participants are eleven grades 5-7 classrooms across four US states. Data was comprised of video recordings and transcripts of at least four lessons on algebraic reasoning in each classroom for a total of 57 algebra lessons. The unit of analysis for our coding was a segment. We define a segment as a series of turns of talk with a common focus (e.g., activity or strategy) and a consistent form of participation (whole-class, independent work, etc.). Boundary markers for segments were indicated by changes in a problem, task, or topic often indicated by changes in intonation, resources, physical orientation, or linguistic markers. To analyze authority relations, we considered the activities in which students *collectively*, as a group, had the authority to engage, during a given segment. Thus, our analysis focused only on whole-class interactions around a bounded activity. To operationalize authority, we considered (a) the mathematical activity for which one was claiming authority, and (b) the holder of authority (who deferred to whom for a given activity). We accounted for three broad categories of mathematical activity: Authorship, Animation, and Assessment of mathematical ideas which are defined in Table 1. In our analytic framework, the categories of Author and Animator are consistent with Goffman's (1981) forms of participation, though we created separate subcategories for oral (speaking) and written (scribing) animation.

Table 1: Authority Relations AAA Coding Categories

Category	Description
Author	**Who generated the main mathematical idea that was the focus of the segment.** Identifies the source of the mathematics that was taken up by the class.
Animator[1]	*Speak*: **Who orally communicated the mathematics.** Identifies who verbally (and publicly) uttered the mathematical ideas in the segment. Speaking includes asking probing questions, clarifying, or adding on to a previously-stated idea. These contributions, on their own, are not sufficient for authorship.
	Scribe: **Who publicly contributed to the mathematics through written or gestural communication.** Identifies who was responsible for public inscriptions or gestures such as inscribing math content using a document camera, or pointing to written work while standing at the board.
Assessor	**Who explicitly judged or validated the mathematics under consideration.** Assessments could take multiple forms: expressing an opinion or conclusion about information; determining the value or quality of a mathematical object or process; and expressing disagreement or agreement. We did not include implied evaluations (i.e., echoing a correct answer, repeating a question) as assessments.

For each segment we assigned a code for *who* enacted authority for each of the four mathematical activities described in Table 1. Mathematical authority for Authorship, Animate Speaking, Animate Scribing, and Assessment might lie with the Teacher, Student(s), Both, or None (i.e., did not occur). Codes for Authorship, Animate Speaking, and Animate Scribing were assigned *holistically* by looking across the entire segment and assigning a single code that best characterized the overall discourse in terms of who authored and animated the mathematical ideas. We did not code Assessment holistically; instead, we aggregated individual assessments within a segment by identifying every assessment in a segment and who made it. We assigned codes of None, Teacher, Student, and Both when, respectively, no assessments were present, only teachers assessed, only students assessed, or both teachers and students assessed. Examples of the Authority Relations AAA (read 'triple A') Framework are presented in the Results.

Results

The main result of this study is the development of the Authority Relations AAA Framework. The example and coding explanation in Figure 1 below illustrate how we used the AAA Framework to account for mathematical authority across the activities of authorship, animation, and assessment. Further, this example illustrates how students and teachers can work together to productively share mathematical authority within a bounded mathematical activity.

Figure 1: Illustrating Mathematical Authority with the AAA Framework

Illustrative Segment: Which is larger, *x* or -7?	**Coding: Both-Both-Teacher-Student**
Students in Teacher L's classroom were working on a series of comparison tasks to determine which algebraic expression was larger or if they had enough information to determine. Here, the students were comparing *x* and -7. *Anuj:* So I think it has to be *x*. [For problem 9, *x* and -7] *Student 1:* No. *T:* Why? *Anuj:* … Because um, because um, um *x* is a positive number. *Student 2:* How do you know? *Anuj:* Wait, that's where I'm kind of getting confused. … *T:* So it didn't, what does *x* mean? What's a variable mean Anuj? We could replace the *x* with? *Anuj:* Any number but I didn't [trails off]. *T:* So you guys were asking him why do you know? Why'd you ask him that? *Hays:* Because he doesn't know what number *x* is. *T:* Okay so you're saying *x* could be what? *Multiple Students:* Be a negative or a positive. Or a fraction. Anything. … *Anuj:* But wait. I thought if they replace a negative number they have to put something like a negative *x*. Right? *T:* Well if we go back to looking at this [Points to expression -*x* on board from previous problem]. This is the part that we're just replacing [circles *x* in expression -*x*] is this. This [points to *x*] is where the number is. *Student 3:* Then it could be a negative. *Anuj:* Yeah but if it was a negative number, then uh, I'm just kind of confused. Because then if it was a negative number I thought they have to put a negative *x*. *T:* So look right here. So here's your *x* [points to *x* in the expression -*x*]. And you're saying if it's a negative number, if it's a negative five. Do you see how these we just took this *x* and we said okay we're just going to make it a negative five [gestures to – (-5) already written on board]. But we still have to keep this negative in front [points to negative sign on -*x* and negative sign to left of (-5) in expression – (-5)] . And that's how we end up with that negative, negative. … *Anuj:* Well in that case it's a mystery. … Because uh, there's a negative seven, but then you don't know what *x* is. *T:* So if *x* were a negative number what would happen? If *x* were a negative three, which one would be larger? *Anuj:* It would be negative three. *T:* If *x* were a negative seven which one would be larger? *Goldie:* They're equal. *T:* What if *x* were a negative ten? *Anuj:* Then it would be negative seven.	**Author:** Anuj and other students share their understanding of the problem as they consider whether the sign of the variable determines its domain (i.e., is it valid to consider $x < 0$ for the expression *x*) and reason about the conditions under which *x* is greater, equal, and less than -7. The teacher demonstrates how to substitute values for *x* and selects three cases of $x = -3$, $x = -7$, and $x = -10$ for Anuj to compare to 7. Thus, in this segment **Both** the teacher and students had authority for authorship. **Animator (Speaking): Both** the teacher and students had authority to verbally present mathematical ideas. **Animator (Scribing):** The teacher is directing the students' attention by gesturing to written board work. Thus, the **teacher** had authority for scribing. **Assessor:** Student 1's disagreement ("No") and Anuj's statement of confusion ("I'm just kind of confused") are explicit **student** assessments. There are no explicit teacher assessments in this segment.

After developing the AAA framework, we also used this analytic tool to explore trends across the classrooms in our study and generated authority profiles to describe important differences in those classrooms. Though we do not have space to discuss these findings here, we found, in general, that teachers were more likely to share authority for authorship of ideas, but maintain authority for scribing and assessing. In closing, we hope this framework can provide a lens for teachers, teacher educators, and researchers to reflect on the ways teachers and students enact mathematical authority.

Note

[1] The codes of Author and Animator differentiate the roles of generating the mathematics under consideration and communicating the mathematics. In many cases the Author and Animator coincided, but not always. For example, if a teacher revoiced a student strategy, the student was the Author and the teacher the Animator.

EXAMINING THE RELATIONSHIP BETWEEN AMBITIOUS INSTRUCTION AND CULTURALLY RESPONSIVE TEACHING IN ELEMENTARY MATHEMATICS

Casedy A. Thomas
The University of Alabama
cathomas14@ua.edu

Mathematics education research has yet to reach a consensus on what ambitious instruction looks like in practice with historically marginalized learners. This mixed methods study examines the relationship between ambitious instruction and culturally responsive teaching (CRT) in elementary mathematics classrooms. The first phase of this study incorporated a multi-case study to understand how three teachers who have been certified in CRT by professional development opportunities within their district are implementing CRT. In the second phase of the study, a quantitative observation measure was used to examine the standards-based mathematics teaching practices of the three teachers. The findings suggest that effective mathematics teaching practices are foundational to implementation of CRT and examine dimensions of ambitious instruction that support CRT in practice.

Keywords: Culturally Relevant Pedagogy, Elementary School Education, Equity, Inclusion, and Diversity, Instructional Activities and Practices

Purpose & Frameworks

The construct of ambitious instruction is well supported in the literature on teaching (Franke, Kazemi, & Battey, 2007; Grossman, Cohen, Ronfeldt, & Brown, 2014; Lampert, Boerst, & Graziani, 2011; Thompson, Windschitl, & Braaten, 2013). Ambitious instruction is broadly defined as a set of teaching practices that foster students' deep conceptual understanding of standards-based mathematics concepts (Newman & Associates, 1996). However, Smith et al. (2017) claim that "ambitious mathematics teaching must [also] be equitable" and responsive (p. 5). Although there are numerous practitioner resources on equitable teaching practices for all learners, there continues to be a lack of research on the prevalence and practice of ambitious instruction with historically marginalized learners (Gutierrez, 2013). Therefore, mathematics education research has yet to reach a consensus regarding what ambitious mathematics instruction looks like in practice with historically marginalized learners. Combined with heightened awareness of social injustices, this lack of a strong research base has revived researchers' commitment to critical pedagogies.

While the theoretical framework for CRT has informed the educational community for some time, scholars (e.g., Hammond, 2015) continue to discuss the challenges of how to operationalize CRT. Mathematics education has produced limited research examining the teaching practices of culturally responsive teachers in preK-12 (Thomas & Berry, 2019). Bonner (2014) offers three reasons for why this might be the case, including: the majority of the works are specific to one population such as African American learners (e.g., Ladson-Billings, 1994); there is a broad focus on content and practice, making it non-mathematics-specific (e.g., Gay, 2010); and, the works remain largely theoretical (e.g., Greer et al., 2009).

The purpose of this study is to examine the relationship between CRT and ambitious instruction through the lens of standards-based instruction in elementary mathematics. A mixed methods comparative case study design (Creswell & Clark, 2018) has been used in which qualitative and quantitative data were collected concurrently and analyzed in phases. Qualitative data were collected to analyze the CRT of the three participating teachers and quantitative data were collected to examine dimensions of ambitious mathematics instruction.

Theoretical Framework

Gay (2010) introduced a CRT framework for "using the cultural knowledge, prior experiences, frames of reference, and performance styles of ethnically diverse students to make learning encounters more relevant to and effective for them." (p. 31). Gay (2010) defines CRT as being: validating and affirming, comprehensive, multidimensional, empowering, transformative, and emancipatory. While Ladson-Billings' (1994) framework of culturally relevant pedagogy (CRP) differs in some ways from the CRT, Gay (2010) stated, "Although called by many different names, including *culturally relevant*, … and *responsive*, the ideas about why it is important to make classroom instruction more consistent with cultural orientations of ethnically diverse students, and how it can be done, are virtually identical" (p. 31). Thus, both CRT and CRP influence the work being done in the focal district in this study. Furthermore, the district draws upon the work of Hammond's (2015) *Ready for Rigor Framework* in which she claims to make explicit, "the natural intersection between so called brain-based-learning and CRT" (p. 4).

Conceptual Framework

Ambitious pedagogies are often used interchangeably with *standards-based teaching practices* (e.g., Lampert et al., 2010). *Standards-based* refers to teaching practices that provide learners with opportunities to engage in mathematical practices or behaviors as outlined in the National Council of Teachers of Mathematics (NCTM, 2000) process standards that focus on problem solving, reasoning and proof, communication, connections, and representation (Walkowiak et al., 2018). Such teaching practices also capture more recent standards (e.g., mathematical modeling and argumentation) in the U.S. released by the National Governors Association Center for Best Practices and Council of Chief State School Officers (2010; Walkowiak et al., 2018). These standards focus on teaching practices that support conceptual understanding. Numerous observation measures have been developed to measure for standards-based mathematics teaching practices including Mathematics-Scan (M-Scan) (Berry et al., 2017).

Research Question

1. How do three elementary teachers, who have been certified in CRT, implement mathematics teaching practices? How does the mathematics instruction support CRT?
2. What are the Mathematics-Scan scores of the three teachers' elementary mathematics lessons? How is the instruction similar or different across the cases?
3. What is the relationship between ambitious instruction and CRT in these elementary mathematics classrooms?

Methods

This mixed-methods study draws on observations and interviews from three teachers in Wayne (all names and locations are pseudonyms) school district in the South East. The school district is large, serving 14,000 elementary students. The district is known for its diverse student population, and for the past four years has been offering teachers CRT certification. All three teachers were part of the 2019 cohort to receive CRT certification.

Participants

The three teachers in this multi-case study are Sophia, Ava, and Chris. Sophia is a pre-kindergarten teacher at River Elementary. She is a Black woman in her mid-30s, and she has been teaching for six years. There were 18 students in her classroom including: 11 Latinx, 5

African American, and two students of Middle Eastern descent. Ava is a third-grade mathematics teacher in a second and third-grade multiage classroom at River Elementary. She is a Black woman in her late-20s who has been teaching for five years. Ava described the students in her class by saying that nine students are Black, one is White, two are multi-racial, one is Asian, and seven are Latinx. Chris is a fourth-grade teacher at Willow Elementary in a Spanish immersion program. He is a White, Jewish man in his late-40s who has been teaching for 11 years. Chris had 20 students, 13 of whom are Latinx and seven are White.

Data Collection

In the first phase of the study, I conducted a semi-structured interview with each of the participants to understand how they perceived their CRT in mathematics. The interview was followed by a questionnaire about each of the participant's cultural reference points (Hammond, 2018). Next, I spent approximately 20 hours in each of the classrooms conducting observations. Data were collected using double-column field notes and all of the lessons were video-recorded. Additionally, the teachers completed journal prompts for each of the observations. Following observations, I conducted a second-round of semi-structured interviews. The second phase of the study involved going back through the recorded video footage to score 32 mathematics lessons using the observation measure M-Scan.

Analytical Strategies

In Phase 1, the information gathered from the mapping of cultural reference points questionnaire (Hammond, 2015) served as preliminary data and led toward the development of other methods. Teacher journal reflections were re-read and compared to data from the corresponding classroom observations to examine each teacher's awareness. Both rounds of semi-structured interviews were recorded and transcribed to allow for member checking. I transferred all fieldnotes into write-ups and wrote analytic memos intermittently to document emerging themes and inferences from transcripts, write-ups, journal reflections. Dedoose was used to support the coding process, using a combination of inductive and deductive coding (Corbin & Strauss, 2015). I compared confirming and disconfirming evidence and continued to adjust the findings until all of the evidence was accounted for.

In Phase 2, I used M-Scan to analyze observation data. M-Scan represents a schema of instruction used to observe teacher' implementation of standards-based teaching practices. The instrument is used in research that focuses on ambitious mathematics instruction because it captures differences between teaching for conceptual understanding and teaching for acquisition of procedural knowledge (Berry et al., 2017). M-Scan has nine dimensions that measure teaching practices in four domains: task selection and enactment, use of representations, the use of mathematical discourse, and lesson coherence. See Berry et al. (2017) for a conceptual model and definitions of each domain and dimension, and Walkowiak et al. (2014) for the measure's validity and score reliability. When using the scoring rubric, the dimensions are each coded on a scale of 1 to 7 with descriptors of low (1-2), medium (3-5), and high (6-7).

In Phase 3 of data analysis, strategies (Creswell & Clark, 2018) were used to merge the two sets of results, such that cases were compared based upon the criteria outlined and results were integrated. In Phase 4, interpretations were made based upon the merged results.

Results

In addressing the first research question, it became evident that the teachers' conceptions of CRT were highly influenced by the work of Hammond's (2015) *Ready for Rigor* framework. However, some practices of CRT exemplified across the three cases are more thoroughly captured in other literature (e.g., Gay, 2010; Ladson-Billings, 1994). The findings for CRT focus on *Quadrant 1: Awareness* (recognizing cultural reference points and reflecting upon teaching practices), *Quadrant 2: Learning Partnerships* (partnerships with families, partnerships with learners, care, and high expectations), *Quadrant 3: Community of Learners* (classroom environment, cultural competency, and power), and *Quadrant 4: Information Processing* (growth mindset, relevance, mathematical representations, and mathematical discourse). The quadrants are oriented to mathematically model the coordinate plane and the ways in which the teachers went about building CRT at the beginning of the school year. However, after the initial phase (of consecutive order), this model is viewed as a continuous cycle without particular attention to order and the quadrants are not mutually exclusive. *Gaining knowledge* has been placed at the center of this model or at the origin of the quadrants. Lastly, within each quadrant, there are nested circles such that the first indicator (in parentheses above) represents the outer circle and each succeeding indicator is nested within the previous.

Initial data from M-Scan scoring revealed similarities and differences across the cases. For example, all three teachers have consistently scored in the medium-high (5) range on use of mathematical representations and mathematical discourse and for encouraging multiple strategies for problem solving. Furthermore, while the cognitive demand of the tasks were often low-medium (3), the teachers' enactment of such tasks were most often medium-high (5). An exemplar of differences identified across cases relates to the teachers' scores for connections and applications of mathematical tasks. In general, these scores were fairly low which certainly speaks to opportunities for improvement in making the mathematics more relevant, but Chris' scores were higher in this dimension across the lessons than those of Sophia and Ava.

When making comparisons across the two data sets, conclusions can be drawn about the relationship between CRT and ambitious instruction with these three teachers. The teachers were all engaging in elements of both ambitious instruction and of CRT, but at times in their lessons, vital elements were missing from each. For instance, in ambitious instruction, the teachers were engaging in strong use of mathematical representation and of mathematical discourse but all struggled with connecting and applying the mathematical tasks to their students' lived experiences. This parallels the teachers' use of CRT in which they were implementing strategies that drew upon students' funds of knowledge to help students process information while neglecting to realize that the mathematical tasks were rarely culturally relevant. On the other hand, the presence of dimensions of ambitious instruction seem to relate to tenets of CRT. For example, the teachers' scores in mathematical accuracy speak to their mathematics content knowledge and their comfort with giving students choice and power in their learning.

Discussion & Significance

In mathematics education, there is still uncertainty regarding how to operationalize CRT (e.g., Bonner, 2014) and other pedagogies focusing upon equity and social justice, indicating that more work is needed in this space (Thomas & Berry, 2019). Researchers in mathematics education continue to wrestle with the relationship between ambitious instruction and CRT. When mathematics education researchers focus upon issues of equity, they are often met with criticism surrounding the lack of emphasis on the mathematics content (Foote & Bartell, 2011). Yet work that focuses on content often neglects to address learners' funds of knowledge and cultural backgrounds. This work looks at both CRT and ambitious instruction, bridging the divide. The finding that teachers' strengths and weaknesses across CRT and ambitious instruction are parallel has profound implications for how we think of these two constructs.

dearaujoz@missouri.edu

In March 2020, the COVID-19 pandemic drastically impacted schooling across the United States. Many schools closed rapidly giving teachers little time to prepare. In May 2020, as part of an ongoing study on Algebra instruction, we interviewed teachers to understand how their instruction changed as a result of the switch to emergency remote teaching. Using a framework of practical rationality, we consider the breach of norms due to the COVID-19 pandemic, a natural breaching experiment, in examining three teachers' instructional responses during that time. Our findings suggest that while teachers often cited similar norms being breached, their responses to those breaches and the reasons behind those responses varied.

Keywords: Instructional Activities and Practices; Online and Distance Education; Middle School Education; High School Education

Introduction and Background

When the COVID-19 pandemic began to impact the United States in March 2020, schools rapidly transitioned to remote instruction. For many schools, this enormous shift to schooling occurred with little time to prepare. We describe instruction during this time as *emergency remote teaching* (ERT) (Hodges et al., 2020). ERT differs from typical online instruction in that it is temporary, rapidly deployed, and, in contrast to instruction designed to be online from the start, shifts in-person instruction to remote delivery (Hodges et al., 2020). Though there have been other recent crises that have impacted schooling in the United States (e.g., wildfires, hurricanes), the scope of COVID-19 has been unprecedented in terms of reach and duration.

Despite its recency, there have been studies on teachers' actions during the pandemic. Horn and McGugan (2020) studied secondary mathematics teachers' transition to ERT. They found that the teachers encountered obstacles surrounding time management, centering student thinking, and maintaining student relationships. They also suggested strategies for supporting teachers in these areas. Whittle et al. (2020) also examined the shift to ERT. Working with teachers and instructional designers, researchers documented challenges in moving to ERT. In doing so, they developed a framework that included eight dimensions related to the design of ERT environments: (1) critical learning goals, (2) pedagogy and the student social role, (3) ratio of teacher to students, (4) social role of the instructor, (5) building agency, (6) communication methods, (7) assessments, and (8) feedback. In the present study, we too examine teachers' move to ERT and focus specifically on the rationales for their instructional decisions.

The notion of practical rationality (Herbst 2010; Herbst & Chazan, 2011) has been used to describe the way that teachers justify instructional actions. Herbst and Chazan (2011) explained that teachers' actions, "are not mere expressions of their free will and personal resources; rather their actions also attest to adaptations to conditions and constraints in which they work" (p. 407). Webel and Platt (2015) used the construct of practical rationality to understand conflicts between teachers' goals and professed obligations and discussed the ways that disciplinary obligations impacted two teachers' decision-making. In these ways, practical rationality can be used as a means of studying changes in teacher practice.

The COVID-19 pandemic acted as a natural breaching experiment (Herbst, 2010), whereby classroom norms were suddenly violated, and teachers were required to adjust their instruction. Under practical rationality, when a norm is breached, teachers can use one of three *repair strategies* that "not only confirm the existence of that norm, but also elaborate on the role that the norm plays in the situation" (Herbst, 2010, p. 52). In response to this breach of norms, teachers can engage in actions that allow them to reject, repair, or accept the situation (Herbst & Chazan, 2011). Rejecting norms would imply a teacher chooses to continue classroom instruction as though the norms had not been breached. In contrast, teachers who accept the breach in norms will align their instruction with the new condition. Finally, teachers might opt to repair the situation by offering a "softer version of rejection" (Herbst & Chazan, 2011, p. 438) whereby teachers approach the breach with a repair strategy that indicates acknowledgment of the breach but adhere closely to teaching practices prior to the breach. In deciding upon a response to the breach of norms, teachers might draw from four categories of obligations: *individual* (individual learners' needs)*, institutional* (policies and practices related to the profession of teaching)*, interpersonal* (social interactions of the classroom)*, and disciplinary* (mathematical principles and practices) (Herbst & Chazan, 2011; Shultz et al., 2019).

Past studies that drew on practical rationality have mainly focused on how teachers would respond to predetermined scenarios. Little is known about how teachers respond to rapid, radical environmental changes in their classrooms. In this study, we seek to understand such an instance in answering the following research question: In the abrupt move to ERT due to the COVID-19 pandemic, what norms were breached, and how did the teachers respond?

Method

This study is part of a larger study examining teachers' instruction in algebra. During the final year of the larger study, the teachers were forced to move to ERT. Prior to that shift, we had observed the teachers' instruction 3 times throughout the 2019-2020 school year. We interviewed 11 teachers in Spring 2020 to understand how their instruction changed. For the present study, we focus on 3 of those participants: Ms. B, Ms. N, and Mr. J. We purposefully selected these participants because they varied in their instructional approaches (Table 1).

Table 1: Participant Information

Teacher	Grade	Location	Original Teaching Mode
Ms. B	8th	Suburb	Flipped
Ms. N	9th	Suburb	Non-flipped
Mr. J	9th	Rural Fringe	Individually Paced

The main data source for the present study is a semi-structured, video-recorded interview. Each interview lasted between 30-60 minutes. The interview aimed to understand the teachers' transition to ERT, and the questions centered on how the transition occurred and what their current instructional practices entailed. We also included the teachers' pre-ERT classroom observation and survey data as secondary data sources.

We first transcribed the video data verbatim. The authors then independently read through Ms. B's transcript to summarize the norms that were breached, her response to the breach, and the obligations on which she drew in determining that response. We met as a team to discuss our initial summaries. This meeting resulted in our development of a coding scheme that we used to consistently identify the breaches, responses to the breaches, and changes to instruction. Our resultant scheme required us to first identify instances in which the teacher explicitly described a breach of norm, then we identified the teacher's response to that breach, and we then classified the obligation the teacher drew on in deciding their response (Table 2). Lastly, we independently re-coded Ms. B's data to establish the reliability of the scheme, and then two authors coded the remaining two teachers' data independently and met to confirm the results.

Table 2: Coding Excerpt from Ms. B

Norm	Breach	Response to Breach	Obligation
Teachers deliver new content to students regularly.	Principal told teachers to only teach one topic per week.	*Reject:* Ms. B continued to teach new content.	*Individual:* "I just didn't think it was fair to teach them one topic per week when I knew that they were the accelerated or advanced students."

Findings

We found four norms that were breached across all three teachers in their move to ERT: 1) students complete assigned work, 2) teachers deliver new content to students regularly, 3) teachers consistently meet with students, and 4) teachers assign grades. Due to the brief nature of this report, we present our findings related to the first two norms and the teachers' responses to their breaches in the following sections.

Students Complete Assigned Work

"But just a handful [of students], for whatever reason, like haven't done anything." (Mr. J)

In discussing their move to ERT, the teachers consistently mentioned a significant decline in students' completion of assignments, suggesting a breach of a previous classroom norm. In discussing the reason for this breach, Mr. J and Ms. N cited their district's "hold harmless" policy that prevented teachers from assigning new grades that would lower students' overall course grades. Given that the teachers described grades as motivation for students to complete their work, the teachers perceived the inability to assign grades as a loss of a key incentive for students. In addition, because there were no set, compulsory class meeting times, the teachers had limited connections or space to motivate students to work on the assignments.

To encourage students to complete classwork, the teachers tried different strategies in seeking to repair the breach. Ms. N and Mr. J offered one-on-one virtual meetings with individual students either by appointment or dedicated virtual office hours. Ms. B and Ms. N set more flexible assignment deadlines as they understood students may have had difficulty completing the work on time due to the situations at home. In addition, all three teachers sought to consistently communicate students' progress with them and their families. In enacting these repair strategies, the teachers described individual students' needs in learning mathematics during ERT, thus evidencing their adherence to individual obligations.

Teachers Deliver New Content to Students Regularly

"I tried to reassure them that this was not something that I was going to throw brand new units out to them and expect them to be able to gain the knowledge and be assessed on that content on their own." (Ms. N)

In contrast to their instruction pre-ERT, the teachers discussed being constrained in their ability to move forward in the curriculum during ERT. Ms. N and Mr. J discussed a school policy that explicitly limited the amount of new content they were permitted to deliver to students during ERT. Ms. N's administration encouraged teachers to review prior content rather than move forward in the curriculum. Thus, rather than introducing new content, she provided her students with review materials to complete practice on topics they had already learned.

The three teachers responded to their new content policy to varying extents and drew on different obligations to justify their instructional decisions. Ms. N accepted the school's policy of not moving forward in the curriculum, suggesting adherence to institutional obligations.

> We basically took the sections in a [prior] unit and took the big ideas and put them together in basically very similar to what we would do for a "note section." Practice problems, but a lot more visuals for them. (Ms. N)

As she followed her school's new policy, she also discussed her obligation to individual students' needs by creating the review materials similar to what they previously did before the pandemic so the students would feel less anxious after they moved to the online setting.

Mr. J taught in an individually paced program in which students could move ahead through algebra and into the next course at their own pace. However, after the move to ERT, he was told only to allow students to finish their current coursework in algebra, but not permit them to move to the next course. As he already took out some sections (e.g., a project on sequences and series) due to either its difficulty or hard to manage in a virtual setting, he accepted this school's policy. He said, "I feel like you can't guarantee that they're learning the proper way" In adhering to the administration's policy, these teachers evidenced adherence to their institutional obligations.

Unlike the other two teachers, Ms. B rejected her administration's edict that she introduce no more than one new topic per week. She said that she did so because she did not feel it was fair to teach her 8th graders one topic per week since they are "advanced students." In making this decision she drew on her obligation to individual students' needs.

Conclusion and Discussion

We found that although teachers perceived many of the same norms being breached, they often responded differently to the breach and/or used different justifications for their actions. Most often, teachers cited individual and institutional obligations. We rarely saw teachers cite disciplinary obligations as a factor in their decision-making. This finding is in keeping with the obstacles that remained most salient to teachers in Horn and McGugan (2020), but different from the professional obligations that the teachers used differ from the obligations that teachers used for justifying their actions in changing teachers' teaching practices (Webel & Platt, 2015) or in dealing with students' mathematical contributions in whole class discourses (Herbst, 2010). This could be because, in the context of an ERT environment, the teachers not only respected their school's regulative decisions but also attended most to student needs when they addressed the breached norms. Additionally, "during COVID-19, participants experienced a focus on the method of delivering instruction rather than the learning goals" (Whittle et al., 2020, p. 315), which could have impacted the obligations teachers drew on when making decisions. In future research, it will be important to build from what we know about ERTs and how we can improve and synchronize directives from administrators regarding these changes to instruction.

The purpose of this case study is to understand how one teacher supports generalizing in her classroom by examining her beliefs about generalization and how to support generalizing in classrooms. We found that the teacher held numerous beliefs about generalization and these beliefs influenced her beliefs about how to support generalizing in the classroom. Moreover, we found that her beliefs about generalization and how to support generalizing formed a system of beliefs that were consistently evidenced in her classroom instruction. Practical implications of the findings, particularly for mathematics teacher educators, are discussed.

Keywords: Teachers' Beliefs, Instructional Practice, Generalizations

Generalization is an important aspect of learning mathematics; researchers have argued that the development of generalizations is essential to all mathematical activity (Becker & Rivera, 2006; Pierce, 1902). Researchers have investigated different types of generalizations students make (e.g., Ellis, 2007; Radford, 2006; 2008), the mental activities required to generalize (e.g., Amit & Neria, 2008; Becker & Rivera, 2006), and the types of instructional activities that support generalizing (e.g., Doerfler, 2008; Steele & Johanning, 2004). Still, studies investigating what teachers do to foster generalizations in the classroom are scant (Mata-Pereira & da Ponte, 2017) and the field lacks research that considers the *teacher's* perception of generalizations. Because understanding teachers' beliefs is an integral part of fostering substantive, lasting change to their practice (Pajares, 1992), the purpose of this case study is to examine one teacher's beliefs about generalization and how to support generalizing in classrooms as well as how these beliefs relate to her instructional practice.

Theoretical Framework and Literature Review

Generalization and How They Are Developed

Researchers investigating how instruction can foster generalization have identified a number of specific recommendations. These include techniques such as showing variation across tasks (Mason, 1996), emphasizing similarity across tasks (Radford, 2008), and ordering the structure of tasks in a progressive sequence (Ellis, 2011). Other recommendations address pedagogical moves (e.g. Amit & Neria, 2008, Koellner et al., 2008), yet research investigating teachers' efforts to foster generalizing at the classroom level is limited. Overall, however, recognizing, elucidating, and encouraging appropriate generalizations remains challenging for teachers (Callejo & Zapatera, 2017). Given these challenges, it is critical to identify teachers' perceptions of generalization and their beliefs about how to teach for generalization, in order to better support their ability to foster generalizing in the classroom.

Defining A Belief

For the purposes of this study, we use the definition provided by Rokeach (1968), who defined a belief as “any simple proposition, conscious or unconscious, inferred from what a person says or does, capable of being preceded by the phrase, ‘I believe that…’” (p. 113) and added that “all beliefs are predispositions to action” (p. 113). Another construct that was influential to this study is that of a belief system. Green (1971) proposed a theory of how beliefs are held in a system, and described three characteristics of a belief system. First, individuals hold beliefs in a manner that is logical and consistent to them. The second characteristic is that beliefs can be held with varying psychological strength. Thirdly, beliefs can be held in clusters and these clusters may be isolated from other clusters.

Mathematics Teachers’ Beliefs Research

The types of beliefs mathematics education researchers have most commonly investigated can be grouped into three categories: beliefs about *mathematics*, *teaching mathematics*, and *learning mathematics* (e.g. Conner et al., 2011; Thompson, 1984). Of the three categories, beliefs about mathematics may be most influential, as some researchers (e.g. Cross, 2009; Thompson, 1984) have argued that these beliefs influence a teacher’s beliefs about both learning and teaching mathematics. Regarding the consistency of teachers’ beliefs, a number of researchers have found teachers’ beliefs to be consistent with their practice (e.g. Conner & Singletary, 2021; Cross Francis, 2015). Yet, others have claimed inconsistency between the beliefs teachers hold and their practice (e.g. Raymond, 1997). Consistent with our definition of beliefs, we agree with Leatham (2006) and Philipp (2007) who claimed that researchers should not assume that a teacher holds beliefs that are inconsistent.

Although there is extensive research on teachers’ beliefs, investigations into what teachers believe about generalization and how to support generalizing in the classroom are scarce. Due to our view that beliefs have profound influence on one’s actions, we believe investigations into teachers’ beliefs about generalizations can yield novel insights into their instructional practices and can aid educators as they help teachers support generalizing in classrooms.

Methods

The present study was a case study (Merriam, 1998) of one teacher’s beliefs about generalizations and how to support generalizing in the classroom. Ms. N, the participating teacher, was a third-year teacher who taught sixth-grade mathematics. We conducted four classroom observations during one week of instruction and recorded each observation with two cameras. For the observations, Ms. N chose lessons in which students explored various properties of ordered pairs in the coordinate plane and how to choose appropriate axes scales.

Because we believe a teacher’s beliefs must be inferred from both their words and actions, we also conducted two interviews with Ms. N after the observations. The first interview was semi-structured and provided opportunities for Ms. N to discuss her beliefs about mathematics, generalizations, and how she supported generalizing in her classroom. The second interview was a videoclip interview (Speer, 2005). Two clips which Ms. N chose from one of the observations formed the basis of the interview. Both interviews were video recorded and transcribed.

The data from each observation was transcribed. We began data analysis by coding the two interviews with the broad codes of *generalization* and *classroom supports for generalizing* (CSG). We then determined emergent themes within each code and created subcodes according to these themes (Strauss & Corbin, 1998). With the new subcodes, we then analyzed Ms. N's classroom data and determined if there were any themes not captured with the current codes. After analyzing the observation data and revising our codes, we re-coded the interview data, looking for evidence for the existing codes and asking if new codes needed to be included. Once no new codes emerged from this iterative process, we began to write narratives for what Ms. N believed about generalizations and how to support generalizations in the classroom.

Results

In the following sections we discuss Ms. N's beliefs about generalization and her beliefs about supporting generalizing with examples of how she enacted those beliefs in her instruction.

Beliefs About Generalizations and How They Are Developed

The beliefs we inferred Ms. N held about generalization form a subset of her beliefs about mathematics. We identified two primary beliefs and three derivative beliefs (Green, 1971) Ms. N held about generalization. One of her primary beliefs about generalization was that a *generalization is an always true statement*. On multiple occasions she described a generalization as something that will always be true. The transcript below captures Ms. N's response when asked to contrast a generalization with a strategy. We underscore that Ms. N described generalization as the "one true thing" that she wanted students to walk away having developed.

Interviewer:	Why was this a strategy and not necessarily a generalization?
Ms. N:	Because…when I think of a generalization, I'm thinking of…one truth.
Interviewer:	Say that again, you cut up a little bit.
Ms. N:	Sorry, I'm thinking of, like, there's one truth. Like, there is one true thing that I want them to get. That's the generalization in my mind.

One of Ms. N's derivative beliefs was that *a theory is an idea that is not yet a generalization*. She described a theory as an idea that is either untested or true in some cases, but not in others. In one instance, Ms. N described a student's initial idea as a theory because it was based off one example and "it was true for that example". Implied in the way Ms. N described the student's theory was that it worked in some cases but not all cases. Ms. N also described theories as being untested. After being asked when a theory becomes a generalization, Ms. N responded by saying "Yeah. When…have you seen enough different types that you always trust it?"

Another belief Ms. N held that appeared to be derivative to her belief about generalizations was that *generalizations are tested theories*. In one instance from her classroom Ms. N claimed that she knew one student's initial theory "wasn't always true". However, after testing his theory and engaging in a discussion about the theory, the student modified his statement so that it was true for all cases. Ms. N claimed it was important for the student to refine his theory into "a more accurate statement that he could cling to." In this instance the student was able to develop a generalization as his theory went through a process of refinement.

Another notable and primary belief Ms. N held about the development of generalizations was that generalizations are actively developed rather than passively received. Throughout both interviews, Ms. N continually described generalizations as something her students would "discover", "develop", and "notice".

Beliefs About How To Support Generalizations In The Classroom

Ms. N believed it was important to engage students in examples that were "easy" and accessible for all students. The purpose of the easy examples was for students to "clearly *see* that it (the pattern she wanted students to notice) works". For instance, in a lesson in which students were to determine when two points were reflected across the x- or y-axis, Ms. N began the lesson by placing a red dart on the front board, then had a student place a yellow dart where the point would be if reflected across the y-axis. After discussing the coordinates of these two points and writing them on the board, Ms. N repeated this sequence for a second pair of reflected points. Rather than writing the two ordered pairs on the board and telling students that one point is the reflected image of the other, students were able to see this and presumably trust it to be true.

As alluded to in the previous paragraph, Ms. N believed it was important to leverage these easy examples to lead students to notice and discuss relationships that emerged from the initial examples. She did this by asking students a focusing question highlighting certain relationships. Ms. N also seemed to indicate that the relationships students noticed and discussed from the initial examples were not yet generalizations, but theories. Hence, Ms. N believed that accessible examples could be leveraged in a way that students could notice patterns and develop theories which then could be cultivated into generalizations.

After noticing and discussing the patterns, or theories, that emerged from the initial examples, Ms. N believed that engaging in additional examples helped students refine or reinforce their theories. For instance, after discussing the relationships between the coordinates of a point with the coordinates of its reflection, Ms. N gave additional examples for students to work in small groups. Ms. N claimed such examples were important because if "(you) do practice with them, and then they can do it independently on their own, they've like, got it (the intended generalization)".

Ms. N's System of Beliefs

Together, Ms. N's beliefs about generalization and how to support generalizing in the classroom form a system of beliefs (Green, 1971) that appear to be internally consistent and consistent with her practice. Specifically, we infer her beliefs that generalizations are developed through refining or reinforcing a theory to be consistent with and related to her beliefs about what constitutes a generalization and a theory.

Ms. N's beliefs about generalizations and how they are developed also appear to influence her beliefs regarding how to support generalizing in the classroom. Her beliefs about refining or revising theories to develop generalizations appear to influence her beliefs that students need to engage in easy, accessible examples first, then discuss patterns salient across those examples, then do additional examples so that students develop the intended generalization. As described in the previous section, Ms. N's beliefs about how to support generalizing in the classroom seem to be consistent with her instructional practice, and these beliefs also appear to be consistent with her beliefs about generalizations and their development.

Discussion

This study reveals one teacher's beliefs about generalization and how to support generalizing in the classroom and how those beliefs relate to her instructional practice. Most notable is that her primary belief that a generalization is "an always true statement" appears to heavily influence her beliefs concerning how generalizations develop and, as an extension, how to support students' in generalizing in the classroom. As we continue to work with teachers, in our own on-going project, their beliefs about generalization and how they are developed have been a paramount consideration in our interactions with each teacher. Moreover, the teachers' beliefs about generalization have been critical as we plan professional development aimed to co-construct a vision of productive generalizing in classrooms and generate instructional strategies that foster this type generalizing.

SUPPORTING IMPROVEMENT EFFORTS IN TERTIARY INSTRUCTION: THE CASE OF CHARLES AS A BRICOLEUR

Amy Been Bennett
University of Nebraska-Lincoln
abennett14@unl.edu

The French anthropological notion of bricolage has been used as a research framework to describe various phenomena, but rarely to describe teaching mathematics. In this study, one college mathematics instructor, Charles, positions himself as an expert when lecturing, but acts as a bricoleur, or do-it-yourself craftsperson, when teaching via active learning. The case of Charles illustrates the obstacles that many experienced lecturers encounter as they attempt to transition to evidence-based instructional practices and reframes the efforts of teachers as bricoleurs with an anti-deficit perspective. This paper provides implications for tertiary institutions wanting to support instructors who wish to improve their pedagogy.

Keywords: Instructional Activities and Practices, Undergraduate Education, Precalculus

Levi-Strauss' (1974) notion of *bricolage* concerns the manipulations and resources used to engage in scientific sense-making. Bricolage could be defined colloquially as "do-it-yourself crafting" and refers to the intellectual and hands-on work of "crafts-people who creatively use materials left over from other projects to construct new artifacts" (Rogers, 2012, p. 1); in other words, these are creative, versatile workers who often use indirect means to accomplish a task.

Hatton's (1989) positioning of teachers as *bricoleurs*, or colloquially, "professional do-it-yourself" people (p. 75), provides a lens to view the efforts of teachers as they work toward multiple objectives with a fixed pool of resources. Toward humanizing the work of college mathematics instructors and supporting their pedagogical efforts, I present an interpretation of Hatton's (1988) established framework that aligns with anti-deficit discourses (Adiredja, 2019) and celebrates their productive struggles toward improving tertiary instruction.

Conceptual Framework

Internationally, institutions and instructors are moving toward active learning approaches to teach mathematics (AAU, 2017; CBMS, 2016) due to evidence that it is more effective than traditional lecture approaches (e.g., Freeman et al., 2014); however, lecture remains the norm (Stains et al., 2018), and the feasibility of implementing interactive strategies is often challenged by faculty and instructors (Le et al., 2018; Michael, 2007).

The lack of research about the *practice* of teaching (Rasmussen & Wawro, 2017; Speer et al., 2010), specifically those who teach via active learning (Bennett, 2020), leads to limited research-based support for instructors who are beginning to shift toward evidence-based teaching practices. Furthermore, institutional factors such as the physical learning space can influence pedagogy (e.g., Haines & Maurice-Takerei, 2019), and instructor self-efficacy to lecture in traditional spaces does not always translate to implementing innovative norms, such as groupwork, in collaborative spaces (McDavid et al., 2018).

Instructors make pedagogical decisions based on demands imposed on them by external stakeholders and structures. The actions of teachers can be understood via the practical rationality of mathematics teaching framework (Herbst & Chazan, 2003, 2012), which describes the *practice* of teaching, and thus shifts the unit of analysis to the external factors and justification sources that influence instruction, rather than internal factors of the instructor.

In this paper, the data were analyzed through the lens of practical rationality (Herbst & Chazan, 2012); however, the case of Charles as an instructor journeying toward an active learning approach is structured and presented via the tenets of teachers' work as bricolage (Hatton, 1988). Similar to other frameworks that describe teachers' pedagogical decisions and justifications, the positioning of teachers as *bricoleurs* is a way to examine the factors that influence, support, and constrain their work. Hatton (1989) restructured the tenets of bricolage to draw parallels between the work of teachers and that of bricoleurs. The six main characteristics are: conservatism, limited creativity, *ad hoc*-ism, teacher's use of theory, indirect means, and repertoire enlargement. Here, I briefly explain three of these characteristics.

The notion of *limited creativity* acknowledges that teachers' responses to many (often contradictory) obligations and goals can be restricted by external factors, such as content coverage in a curriculum or a lack of time and resources to demonstrate complete, unhindered creativity. A key parallel between teachers and bricoleurs is the *ad hoc* nature of their work (Hatton, 1989). The necessary improvisation of teaching highlights the versatility and competence of teachers to tackle situational challenges; namely, they use ad hoc-ism to make in-the-moment decisions and solve problems. Teachers' *use of theory* plays a key role in their pedagogy and "intellectual bricolage" (Hatton, 1989, p. 80), referring to how they order, justify, and explain their decisions. Similar to the bricoleur, teachers are expected to borrow knowledge from other disciplines and interpret it to fit their situation.

Here, I reiterate that the purpose of framing an instructor (Charles) as a bricoleur is to humanize his efforts and experiences as an instructional faculty member shifting toward a completely new teaching approach with the fixed pool of resources available to him.

Methods

This study took place at a large, public, research-oriented university in the U.S. that had recently created collaborative learning spaces as part of an initiative to improve undergraduate STEM teaching (AAU, 2017). This paper focuses on one non-tenure-track, instructional faculty member, Charles, in the Mathematics Department. Charles had over 40 years of experience teaching mathematics at the tertiary level, mostly at community colleges, and he had recently started teaching at this university. During the semester of data collection, Charles taught one section of College Algebra in a collaborative learning space with adaptive furniture and one section of Pre-Calculus in a traditional classroom with individual desks in rows (see Table 1).

Table 1. Information about Charles and His Courses

Course	Classroom	Class Size	Experience
College Algebra	Collaborative Space	72	Over 40 years of experience teaching college-level math
Pre-Calculus	Traditional Classroom	35	

The data presented here are part of a larger qualitative study. In this study, I observed Charles' teaching six times, three times for each class, using the Observation Protocol for Active Learning tool (Frey et al., 2016), which was validated for recording teacher and student actions in undergraduate STEM courses that utilize an active learning approach. I also took qualitative field notes during observations and immediately followed up some observed lessons with a debriefing conversation, which resembled an informal interview (Hatch, 2002) and helped to clarify my interpretations of Charles' actions during class. Toward the middle and the end of the semester, I conducted two semi-structured, in-depth interviews with Charles, which were guided by instructional situations from the observed lessons.

For data analysis, I coded qualitative interviews, lesson debriefs, and field notes using a combination of data-driven and theory-driven coding methods (Gibbs, 2007; Saldaña, 2016). I organized these data into teaching-related themes and goals as a single case study to describe Charles' pedagogy and experiences with active learning during this semester (Maxwell, 2012; Stake, 2006). Later, I realized that the central themes in Charles's case aligned with Hatton's (1988) theorizing of teachers' work as *bricolage* and restructured the case to present Charles' initial experiences of and experiments with active learning through the lens of a *bricoleur*.

Findings

Here, I describe Charles' experience (the successes and struggles) with active learning via the tenets of teachers as bricoleurs. Due to space constraints, I present only two of the six tenets.

Limited Creativity

Soon after arriving to the university mathematics department, after years of lecturing in community college settings, Charles was encouraged and inspired by colleagues to teach via an active learning approach. Charles taught College Algebra in a flexible learning space, with desks on wheels intended for both individual and group work. When this space was filled with the 72 students enrolled in Charles's section, it became a "swirling mass of chairs" and was challenging for Charles to maneuver between groups. Even though the "chaotic" arrangement of furniture in this space caused participation issues, Charles still preferred a collaborative-type room to promote active learning. He thought his Pre-Calculus students, currently in a traditional classroom, would be "more comfortable" in a collaborative space, admitting, "I like it when they have tables. If we had tables everywhere, that would be helpful, but I really don't mind."

Charles acknowledged that he could do more groupwork and even adapt how he structured collaborative activities if he only had different resources, such as a collaborative classroom with tables. His ideas for shifting instruction strategies in his Pre-Calculus class was limited by the lack of practical furniture. However, he was willing to work with what he was given.

During an interview, I asked Charles if he reflected on his own instructors for inspiration or guidance for teaching via active learning. He said that he had had "none" and that "working together [during class] was not an option in any environment" when he was a mathematics student. He agreed that he was trying to do something that he had never seen before – to create an image of a teacher that he had never experienced. He seemed to have a realization during our conversation: "Yeah, how do I do [collaborative learning]? I've never seen it before!" His lack of a role model or consistent mentor for shifting his teaching approach led to limited creativity in visualizing a collaborative learning environment for his classes.

Teacher's Use of Theory

Even after 40 years of teaching mathematics at the college level, Charles called himself a "novice" with respect to active learning. He acknowledged that many of the collaborative activities he tried in the classroom were "experiments," and later realized that having students work in groups sporadically is different from taking an active learning approach to teaching:

> I've done some group stuff in my class, but this is a different thing I'm finding out. …It's not just, 'I'm going to do a group activity every now and then.' This is a whole model of a

> pedagogical technique that we can use in the classroom that might be more effective. So I'm in the learning stage. …I feel like I don't really know what I'm doing.

This uncertainty led to a persistent theme in our conversations: his desire to understand the learning theories in education and psychology research. He admitted, "A big part of my anxiety about [teaching via active learning] is I'm not a psychologist." He felt that facilitating groups and letting students work on problems on their own required a deep understanding of how students learn. Lacking this knowledge, he experienced "anxiety" about teaching via active learning.

To better understand the mathematics education research, Charles initially sought out mentors at his university. He spoke about reading research articles written by his mentors to learn about collaborative learning techniques. Charles also read the Instructional Practices guide published by the Mathematical Association of America (Abell, 2018), hoping it would help him understand how students best learn mathematics and thus, how to teach effectively.

Charles was concerned about making groups work effectively, not simply ensuring that groups stay on task but also that they cooperate, participate equitably, and learn the mathematical concepts. At the end of the semester, Charles reflected on his educational background:

> There's so much psychology involved, and college teachers aren't necessarily trained in psychological aspects of teaching. …I've just pretty much modified whatever I started with over the years. I didn't really have any formal teacher training. And I guess now I'm kind of realizing, I might want to try to look into some formal aspects of how [teaching] works.

After a semester of modifying active learning strategies to align with a teaching approach he used for decades, he realized that a "formal" teacher education would be the next step in understanding how to implement the best teaching practices. Charles consistently demonstrated his thoughtfulness and dedication to improving his pedagogy by trying to understand the theory behind new teaching practices before implementing them.

Discussion and Conclusion

The case of Charles describes the ongoing journey of an experienced lecturer attempting to shift to an active learning approach to teaching introductory-level college mathematics. Positioning Charles as a bricoleur highlights the resourcefulness of his practices (*ad hoc-ism* and *indirect means*) and his dedication to improving his teaching regardless of the obstacles he encountered (*use of theory* and *repertoire enlargement*). Although Charles initially reached out to mentors and thoughtfully reflected on improving his pedagogy, he viewed the wide gap between understanding theory and using it in practice as very daunting without "formal" support structures. In other words, a key contributor to his *conservatism* and *limited creativity* could be the lack of formal support structures available to him. Charles' accomplishments during just a single semester can be celebrated, but it is also important to acknowledge his struggles in order to understand how they can be mitigated for other tertiary-level instructors.

Finally, I emphasize that the case of Charles illustrates an anti-deficit interpretation and re-presentation of Hatton's (1988) framing of teachers as bricoleurs. Recognizing the skill that bricoleurs bring to their craft, I argue that for an instructor who is completely changing their teaching approach, exhibiting the adaptability and resourcefulness of the bricoleur is commendable, given the many obligations and institutional constraints they must navigate (Bennett, 2020; Mesa et al., 2019). Charles made substantial progress toward an active learning approach within one academic year and planned for future improvements. He was working toward becoming an expert craftsman in active learning, rather than a bricoleur, striving to learn the theory and demonstrate unlimited creativity. But acting as a bricoleur was a critical part of his pedagogical journey, as it likely is for many tertiary-level instructors, who typically do not have formal teaching preparation (Laursen, 2019). In research, anti-deficit framings of teachers should be explored, elaborated, and utilized across all levels. As a field, we can study and promote institutional policies and sustainable systems that minimize the tensions in teaching obligations and support improvement efforts in tertiary instruction.

Digital simulations have become an increasingly popular approach to practice-based teacher education. In this paper we report on a professional learning intervention where we used digital clinical simulations to help mathematics teachers' fluency in facilitating both small group and whole group discussions. Further we discuss implications of digital clinical simulations as a tool that can help mathematics educators develop, practice, and further support their teaching.

Keywords: Equity, Inclusion, and Diversity, Professional Development

Purpose of Study

Imagine a classroom is split into small groups and one of the students raises their hand to have the teacher address a mathematical dispute. The students share their answers and rather than elicit more information about their different understandings, methods, and perspectives, the teacher smiles and only invites the student with the correct answer to elaborate on their response. Just as other researchers, we view classroom interactions as powerful sites of learning for educators (Hiebert et al. 1997; Mellone, Jakobsen & Ribeiro, 2015). These interactions illustrate the nuanced relationship between power, identity, and participation in mathematical discussions. These interactions send powerful messages about what and who is valued in mathematics, and how students orient themselves to these messages is consequential for how students see themselves as mathematics doers. Teachers need to be mindful not to position students or their ideas as outsiders to the mathematical conversation (Amit & Fried, 2005).

In light of the complexities of orchestrating inclusive math discussions, practice-based teacher education (Grossman et al., 2009) presents an opportunity for mathematics teachers to develop sensibilities toward facilitating inclusive mathematical discussion. Through iterative cycles of practice, whether it be modeling (e.g., McDonald et al., 2013), rehearsals of "approximations" of practice (Grossman et al., 2009; Lampert et al., 2013), or video recording (e.g., Ball, 2013; Schoenfield, 2017), educators have the opportunity to deconstruct their actions in teaching and try new skills and routines in low stakes settings, while receiving feedback and support (Grossman et al., 2009). Increasingly, digital simulations have become a popular approach to practice-based teacher education (Driver, Zimmer & Murphy, 2018; Cohen, Wong, Krishnamachari, & Berlin 2020) as they provide the opportunity to distill the complex task of ambitious teaching into smaller, distinct, manageable approximations (Grossman et. al, 2009). As a community, educators and researchers collectively reflect on teachers' moves in a low-stakes setting i.e. before stepping foot in front of a classroom full of students (Dieker Hynes, Hughes, & Straub, 2017; Thompson et al., 2019).

In this study, we investigated the effectiveness of our efforts to help teachers 1) choose to include a range of student perspectives in their discussions and 2) to see these contributions not solely as errors to be rectified, but as sources of mathematical thinking to be valued and explored. We used a digital clinical simulation called *Teacher Moments*, in our 2019-2020 fellowship program supporting 19 in-service math teachers in grades 3 through 9. The platform engaged participants in vignettes representative of a teachers' classroom experience and then called on participants to respond, "in the moment" (Thompson et al., 2019). The simulations required participants to check-in with three simulated small groups and then discuss how they would lead a whole group discussion. In the small group interactions, participants were presented with student work and scripted student responses. The three simulated groups displayed four distinct approaches or attempts to solve the task. One group presented an *incomplete student response* (e.g., students who had difficulty solving the problem and stated they needed help); another group presented an *unconventional student response* (e.g., students used guess and check to correctly solve the problem); and the last group presented both, a *sophisticated student response* (e.g., correct algebraic equation) and an *incorrect student response with a misconception,* a designed mathematical dispute for the teacher to settle. At the close of each of these interactions, participants were purposefully asked the open question "how would you respond to this group" to capture a wide range of participants' responses (see Figure 1 for selected interactions in the scenario. The full scenario can be played https://teacher-moments-production.herokuapp.com/run/fb24f9ea87/slide/0) After checking in with all three groups participants had to decide which group they would call on to start the ensuing class discussion and why.

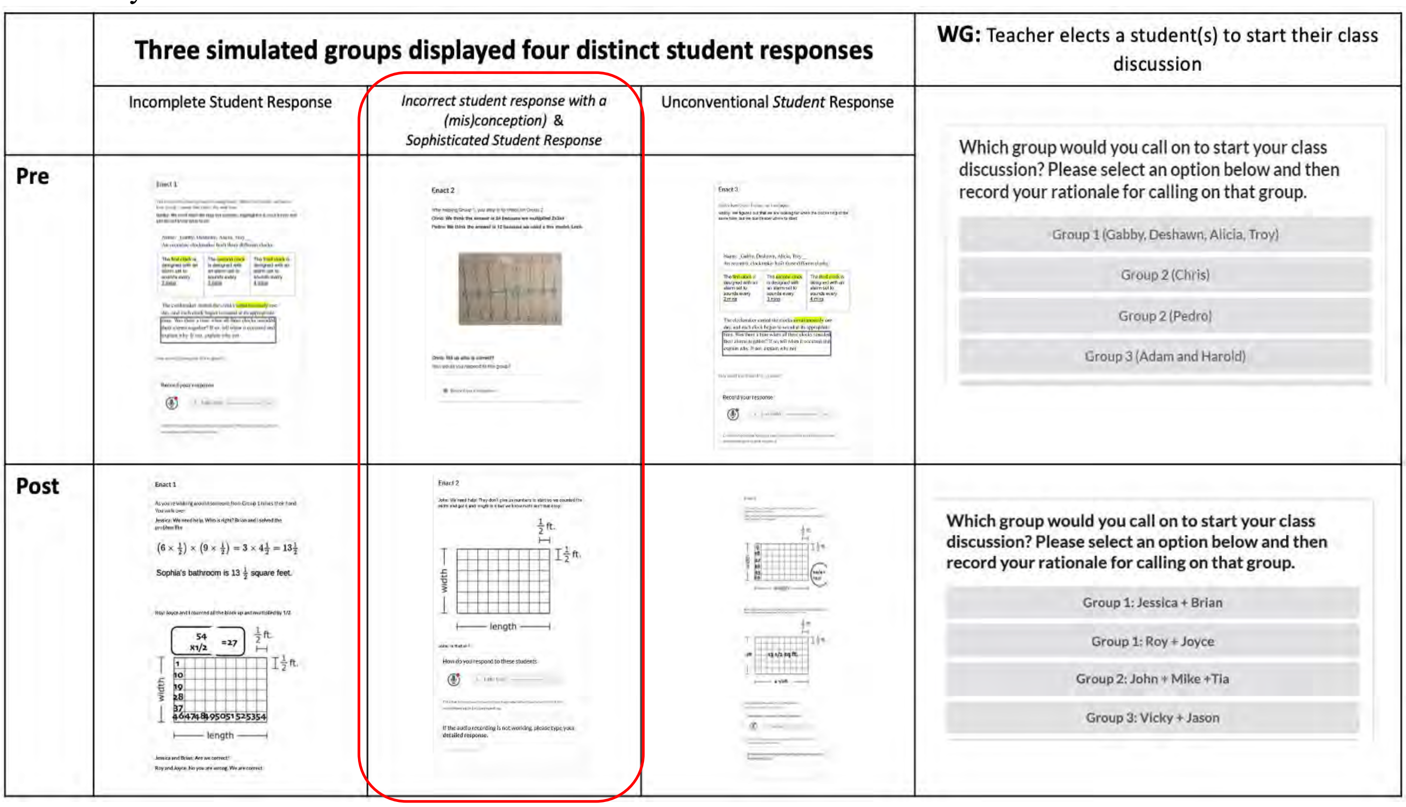

Figure 1: Teacher Moments Simulation Design

We address two research questions to understand what teachers learned and how their simulated behavior changed during this process: 1) In the post-test simulation, did teachers include diverse perspectives while initiating small group discussions, and did they recognize the potential value of contributors without correct, efficient answers? 2) In the post-test simulation, did teachers similarly include diverse perspectives and recognize their potential value while initiating whole group discussions?

Methods

As part of the research design teachers engaged in a pre-test simulation administered in February 2020, in which participants' responses and selection choices were recorded. Participants then engaged in monthly professional development workshops (two four-hour in person sessions, four 90-minute virtual sessions), where participants explored excerpts and readings geared towards the affirmation, validation and incorporation of multiple students in math discussion. Teachers engaged in simulation play that required them to rehearse and reflect on their instructional moves as well as debrief various sample responses in the Teacher Moments platform. In June 2020 participants then completed a post-test simulation, which had a parallel structure to the pre-test simulation.

Data analysis

Data analysis began with a systematic review of all participants' responses from the pre-test simulation's small and whole group discussion (Miles & Huberman, 1994). Researchers individually listened to participants' responses paying close attention to whether the teacher provides space for students with misconceptions to share their approach and/or explain their thinking. Researchers also listened to how students with misconceptions were treated and positioned; were they viewed from a deficit lens? Researchers then used the constant comparison method (Strauss & Corbin, 1998) to systematically examine all participants' responses in small and whole group discussion respectively. Discrepancies in coding were settled by another trained member of the research team. Data from the post-test simulation was handled in a similar manner. Further data from participants' pre-test simulation and post-test simulation were analyzed separately at first and then together to examine any changes in teacher responses.

Results

Small Group Discussion

Due to interruptions from COVID and data collection issues with the technology, fourteen teachers completed the pre-test simulation, and nine completed the post-test simulation. Overall, in the small group task of the simulation, participants chose more inclusive starting points for conversation following the intervention. Participants were more attuned to including all students. In Table 1, we show Teacher 14's small group response in the pre-test and post-test simulations as representative of a teacher whose views on including a range of student voices in discussion changed following the intervention.

Table 1: Teacher 14 SMG Simulation Response

Participant	Pre-Test Simulation	Post-Test Pre-Test Simulation
Teacher 14	"Okay, Chris, so you multiplied 2x3x4, and Pedro, to summarize, you made this drawing and found that it was 12.	Okay, so I see Jessica and Brian have one answer, Roy and Joyce have another, different answer. First, I'd like to hear

	Pedro, do you want to explain to Chris how you thought to do this, why you decided to do it this way?”	Jessica and Brian walk through their process so I could understand. I think I see what you did, but I'd like to hear from you, how you did it, and Roy and Joyce, I'd like you to then walk me through your process to see what you did, and then we'll go from there.

During the pre-test simulation, Teacher 14 elects to only invite the correct student (Pedro) into the conversation to voice their opinion, ignoring other ideas and possible contributions. Additionally, Teacher 14’s response illustrates how positions are verbally constructed in classroom interaction. Her response suggests one student (Pedro) can provide a meaningful mathematics experience for the other (Chris) but disregards what Chris’s conception adds to the conversation. The roles that were assigned within this interaction left little to no room for Chris to be a contributor in this interaction. While probably not intentional, this interaction could leave others not involved to feel excluded and discouraged from the learning process. Though this interaction may seem subtle and insignificant to teachers, students may have a different perspective.

During the parallel interaction in the post-test simulation, Teacher 14 now addresses the small group interaction by providing the opportunity for both students to further explain their thinking. In this remark, we first notice that Teacher 14 is oriented to understanding students’ processes and creates space for both students to share their ideas. Secondly, she does not give directive authority to any student. She uses questions to continue to engage all students as sense-makers and provide space for both students to continue exploring the problem rather than evaluating and designating one student(s) to lead the mathematical experience.

Whole Group Discussion

In contrast to the small group discussion simulation task where we saw participants adopt new strategies to facilitate more inclusive discussions, we saw very little change from pre- to -post in the whole group discussion task. Even when participants did invite non-correct perspectives into the discussion, simulated students were not positioned as sense makers or contributors. For instance, Teacher 11 elected to start the WG discussion with the *incorrect student response with a misconception*. In describing her approach to introducing this incorrect response, she states,

> I will show a drawing on the board of the length of 1/2 foot and 1 foot) Are these two measures the same? Is 1/2 foot the same as 1 foot? So, the length of 9 of 1 foot each, the same as 9 of 1/2 foot each? And the width of 6 of 1 foot each, the same as 6 of 1/2 foot each? So then, do you think this group's answer makes sense?

This response is focused on remediating their initial conception rather than encouraging students to think more deeply or identify strains of thinking that might be useful in other contexts. She publicly positioned the student as not knowing and took the mathematical authority way, funneling the student to a particular understanding. Students are guided on a directive path of information gathering to the answer, steering them further away from their own idea. This brief interaction is focused on accuracy of procedures and answers and is not situated to be a discussion but rather a list of commands ending with what could be considered a rhetorical question.

Discussion

Digital clinical simulations hold great promise for helping teacher educators both support and measure changes in teacher's practice. We found evidence that after our professional development workshops, participants espoused more inclusive discussion practices. Qualitative evidence showed that participants changed their simulated behavior when facilitating small group discussions: more teachers invited students to share their ideas regardless of correctness and/or efficiency and teachers included these perspectives for evaluating and consideration, not just for remediation. We did not, however, find any evidence that teachers substantially changed their practices in facilitating whole group discussion. In the final task of the simulation, our participants continued to choose to primarily feature students with correct, efficient answers. Why might that be? One possibility is that teachers agreed with our instruction that emphasized inclusiveness in small group discussions but did not believe that these principles should be applied to whole group discussion. Another possibility is that teachers continue to feel the pressure of the larger system that evaluates their effectiveness by student test scores, supporting a desire to simply tell students how to solve problems and have discussions about answers instead of ideas. A third possibility is that teachers did not know how to facilitate whole group discussion that start with diverse students' conceptions, though we saw evidence that participants knew how to do so with small groups. Though teachers may have agreed with our inclusive principles and knew how to employ strategies to initiate a discussion with diverse perspectives, they may have had concerns about sustaining such a discussion. While research recommends teachers frame their discussions around student-created strategies and suggest engaging in open discussions as a way for deeper mathematical understandings (Hiebert et al. 1997), this is no easy task as it requires teachers to have content knowledge and/or pedagogical content knowledge expertise. In a real classroom setting, this might be expected—teachers might legitimately fear that they might not be able to navigate a whole group discussion from an unfamiliar starting point to a collective class understanding that advances mathematical goals. In a simulated setting, however, we anticipated that the very low-stakes of the situation would allow participants to take pedagogical risks, and try new strategies with the confidence that no real student learning will be harmed.

More research is needed to understand whether any of these possibilities are manifested in our particular participants or in future participants, or if other alternative explanations better explain our mixed results.

COMPARING MOTIVATIONS FOR FLIPPED INSTRUCTION TO DATA ON FLIPPED IMPLEMENTATIONS IN ALGEBRA

Flipped instruction, where videos are assigned for students to watch as homework in lieu of problem sets, has been implemented by an increasing number of mathematics teachers. Their reasons for flipping range from a desire to have less time spent in class on lectures and more time on collaboration (and greater engagement) to a hope that videos increase completion rates for homework compared to problem sets. This study examines the extent to which those reasons for flipping instruction are reflected in observation data from 22 flipped and 25 non-flipped Algebra 1 classes. Flipped classes were found to have less lecture time in class but the increased student work time was not necessarily collaborative. During student work time engagement levels were higher in flipped classes than non-flipped classes but the reverse was true during whole-class discourse. Homework completion rates were not significantly different.

Motivations for Flipped Instruction

The reliance on video lectures during the COVID-19 pandemic has highlighted a pre-existing trend which is the use of videos as homework in flipped mathematics lessons (Zainuddin et al., 2019). Although flipped instruction is defined by the presence of video or multimedia homework, reducing the need for content delivery during in-class time, it is not a unified instructional model. Many varieties of flipped implementation have been documented (e.g., de Araujo et al., 2017a; Muir, 2019). There are also a variety of reasons that teachers or school leaders have for choosing to flip instruction. One primary reason may be that they have seen reports of flipped instruction having positive outcomes with regard to student achievement (e.g., Amstelveen, 2019; Bhagat, Chang, & Chang, 2016; Overmyer, 2015). But other studies have found mixed results (e.g., DeSantis et al., 2015; Lo & Hew, 2017), which perhaps is to be expected given the variety of implementations just mentioned.

Beyond achievement, there are other reasons educators have for flipping instruction that potentially address phenomena that undergird not only achievement but also other important outcomes like identity, agency, and attitude. These reasons below, documented by de Araujo and colleagues (2017b) and also our own surveys and interviews with teachers implementing flipped instruction, are not exhaustive but do constitute the focus of the present brief report:

- Flipping will **increase the amount of in-class time available for students to work on problems or exercises**, which can lead to more support from the teacher, more collaboration with peers, or possibly more opportunities to engage in cognitively-demanding tasks;

- Flipping will **increase student engagement** throughout the in-class portion of the lesson by reducing the time the teacher spends lecturing in class;
- Flipping will **increase homework completion** because it is easier to watch a finite-length video than it is to solve a set of problems (where there is a risk of getting stuck or struggling for an inordinate amount of time); and
- Flipping will **provide an accessible version of the lesson material** via the video recording rather than a live lecture and students can refer to the video as needed.

Our guiding question was: To what extent do these reasons for flipping instruction materialize in implementations of flipped instruction? We explored this question using observation data from a large-scale study of 47 Algebra 1 classes from a diverse set of school districts.

Conceptual Framework

The framework (Figure 1) of this study draws upon curriculum enactment theories (e.g., Remillard & Heck, 2014; Stein, Grover, & Henningsen, 1996), observation instruments (e.g., Walkowiak et al., 2014), and advice from experts in different fields (e.g., educational technology, mathematics education). The framework's scope is a lesson and it distinguishes between structural features of the at-home and in-class portions while also attending broadly to the activity formats (Otten et al., 2018). For the purposes of this brief report, we focus on the time spent in various in-class formats (whole-class, group work, independent work), behavioral engagement within those formats, homework types and homework completion rates, and, for flipped classes specifically, the involvement of videos during the whole-class discourse and the rate of video use during group or independent work time in class.

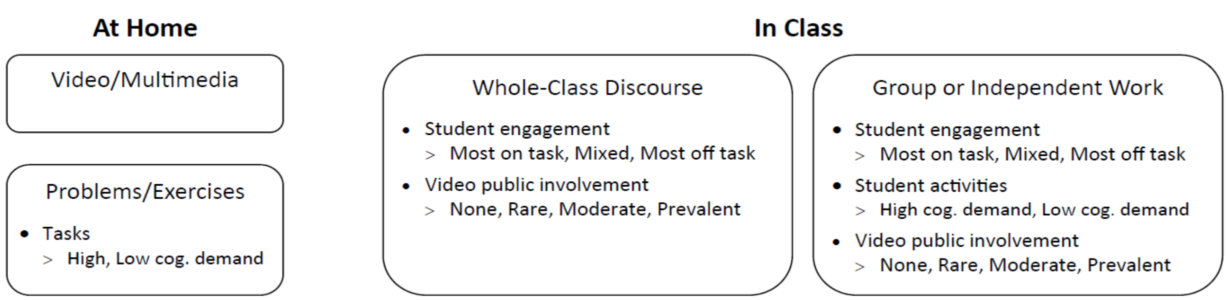

Figure 1: Simplified Flipped Mathematics Lesson Framework (Otten et al., 2018)

Method

Setting and Participants

Data were collected from 541 Algebra 1 students and their teachers. There were 22 flipped (338 students) and 25 non-flipped classes (203 students). The teachers who flipped chose to do so on their own and the project was observational in nature (no intervention). Most students were in the 9th grade but many were in 8th grade and a few were in 7th or 10th grade. The classes were located in 20 different districts ranging from rural to urban. The 34 participating teachers (some taught multiple classes in the data set) were varied in their background and experience.

Data Collection and Analysis

The primary data source for this study was field notes from lesson observations. Each class was observed three times throughout the school year with two observers for at least the first two observations. If reliability was high and a clear lesson pattern had been established, then in some cases a single coder conducted the third lesson observation. Field notes were coded using a protocol based on the Flipped Mathematics Lesson Framework (Otten et al., 2018). In particular, discourse formats were recorded to the nearest minute, behavioral engagement was coded on a 3-point scale from "most students off task most of the time" to "most students on task most of the time", and video involvement (in the flipped classes) was coded on a 3-point scale from rare to prevalent use of homework video in class and also a 4th code option of no video use. The three lesson observations for each class were discussed and condensed into a lesson profile.

A teacher survey and a student survey were also administered to gather information about their perspectives on the algebra instruction, attitudes toward the class, and, importantly for the present study, students' self report of homework completion and their perceptions of peers' homework completion (to attempt to account for desirability bias in the self-report data). A pre- and post-test containing measures of procedural understanding and conceptual understanding was also administered but not reported in this article. To answer our research questions, we conducted a series of Analysis of Variance (ANOVAs) to examine whether there were statistically-significant differences between flipped and non-flipped classes.

Findings and Brief Discussion

More Class Time was Used for Student Work in Flipped Lessons than Non-Flipped Lessons

Aligning with some teachers' motivation for flipping, there were statistically-significant differences in the use of class time. Flipped lessons had significantly more time allotted to student work compared to non-flipped lessons, but this difference came in the form of more independent work time, not more group work time. Non-flipped classes spent 3.4% of class time in group work (SD=12%) and flipped classes spent 4.6% of class time in group work (SD=12%); this difference was not statistically significant ($p=0.731$). With regard to independent work time, non-flipped classes spent 31% of time in that format (SD=17%) and flipped classes spent 64% of time (SD=31%) in independent work, which is statistically-significantly greater ($p<0.001$).

A purported advantage of flipped instruction is that the extra work time can be used to enact cognitively-demanding tasks. Not enough lessons involved group work for us to compute meaning statistics on that activity format, but for the independent work time, non-flipped classes had 5.0% of tasks that were cognitively demanding tasks (SD=6.9%) and this was not significantly different ($p=0.661$) from the 4.2% of cognitively-demanding tasks in flipped classes during independent work time (SD=5.5%). So although flipped lessons incorporated more independent work, the cognitive demand of the tasks in our data set was not different.

Was the independent work time nevertheless worthwhile? Our pre/post-test analysis does suggest a positive correlation between independent work time and the learning measures. But for the present report, we instead look to the engagement levels, which was another motivation for flipped instruction and which relates to independent work time because teachers have expressed that having students solve problems is more active than listening to a lecture during class.

Student Engagement was Not Different Between Flipped and Non-Flipped Lessons

Looking first at engagement levels during whole-class discourse, it averaged 3.0/3.0 in the flipped lessons (SD=0) and 2.84/3.0 in the non-flipped lessons (SD=0.37), which was not a statistically-significant difference ($p=0.068$). Recall that whole-class discourse was briefer in flipped lessons which may explain why it maintained high levels of on-task behavior. In the non-whole-class discourse (group work and independent work), engagement in flipped lessons averaged 2.55/3.0 (SD=0.50) and in non-flipped lessons averaged 2.64/3.0 (SD=0.49), which was not a statistically-significant difference (p=0.291). Conversely to the whole-class discourse, the non-whole-class discourse was briefer in non-flipped classes than in flipped classes. Overall, although lessons had slightly higher engagement levels in the activity formats that were relatively brief (whole-class discourse in flipped lessons and work time in non-flipped lessons), these differences were neither meaningful nor significant. What may be more meaningful is not the behavioral engagement as coded here but rather the nature of the activity format itself, that is, students engaged in solving problems or completing exercises versus listening or discussing.

Homework Completion was Reported Similarly for Flipped and Non-Flipped Lessons

Homework completion rates were calculated for non-flipped classes as the percentage of students who reported usually or always finishing the homework. The mean homework completion rate was 0.90 (SD=0.14). Video watching completion rates were calculated for flipped classes as the percentage of students who reported usually or always watching the assigned videos. The mean video watching rate was 0.83 (SD=0.22). This difference in completion rates was not statistically significant (p=0.182). We also asked students whether their peers completed the homework. The mean peer homework completion rate was 0.44 (SD=0.28) in non-flipped classes. The mean peer video watching rate was 0.35 (SD=0.25) in flipped classes. Again, this difference was not statistically significant (p=0.252). As with engagement, the benefit (if any) of flipped instruction may not be the rate of homework completion but rather the type of activity done outside of class: completing exercises or receiving content delivery.

Videos were Accessible to Students but Not Often Accessed During the Flipped Lessons

A motivation for flipping was the accessibility of videos and for this feature we looked only at the flipped classes. Of the 22 flipped classes, 12 consistently had both a video associated with the lesson and a whole-class discourse segment within the lesson. For these 12 classes, the video involvement level on the 0–3 scale was 0.92 (SD=0.95) which means that, on average, the homework video was briefly referenced in class but not shown or discussed substantially. With regard to non-whole-class discourse, during which students might pull up the video on a computer or phone while they are working, 19 flipped classes had videos and non-whole-class discourse and the video involvement level was 1.63 (SD=1.26), which means that, on average, a few students might access the video but not usually a majority of students. The standard deviation indicates that in several of the flipped classes, no students accessed the videos in class.

In survey responses, teachers reported appreciation for videos being accessible to absent students and for content review, but we do not have data of students' delayed video access behaviors. Future research may investigate how students rewatch lecture videos compared to students in non-flipped classes who review lecture notes or ask the teacher to reteach material.

Conclusion

Many existing studies of flipped instruction use student achievement as the measuring stick (e.g., Ichinose & Clinkenbeard, 2017), but in this study we compared implementations of flipped instruction to some of the primary motivations that teachers have for flipping instruction in the first place. Is this instructional model providing the learning opportunities and taking advantage of the affordances as intended? Note that we were not comparing a teacher's flipped instruction to their own instruction prior to flipping, but rather to other non-flipped teachers in the same or similar school contexts. The broad reach and the variation in our data set, however, still make the comparison meaningful.

We found that flipping did provide substantially more time in class for student work but that this time was not necessarily used for more student collaboration or more cognitively-demanding tasks. We found that student reports of homework completion were not higher than those in non-flipped classes but the videos do provide options with regard to accessibility and rewatching prior lectures. These results imply that additional support (new curriculum materials, strategies for collaborative practices, guidance for video creation and access) may be required for teachers to take full advantage of the affordances of flipped instruction to meet their intended goals.

ANALYSIS OF TEACHER ACTIONS TO PROMOTE GENERALIZING

Allyson Hallman-Thrasher | Susanne Strachota | Jennifer Thompson
Ohio University | Tufts University | Ohio University
hallman@ohio.edu | susanne.strachota@tufts.edu | jh859394@ohio.edu

This study analyzes the instruction of one teacher in two classroom episodes. We analyzed the teacher's instruction using a framework for whole-class discourse and a framework for identifying activity that supports generalizing. Across both episodes when priming and particularly generalizing-promoting activity increased, students' generalizing activity also increased. An increase in the number and quality of questions and student contributions occurred with more student generalizations. Similarly, the responsibility for questioning and thinking shifted from teacher to student as more students responded to requests for justification. Future research should identify productive small group practices to support generalization.

Keywords: Algebra and Algebraic Thinking, Preservice Teacher Education, Discourse

Algebraic thinking appears as early as Kindergarten in the Common Core State Standards (National Governors Association Center for Best Practices and Council of Chief State School Officers, 2010) and is often linked to the development of critical thinking and problem-solving skills (Schoenfeld, 1995). We focus on the algebraic practice of generalizing, the situated activity of "lifting" and communicating reasoning to a level where the focus is no longer on a particular instance, but rather on patterns and relationships of those particular instances (Kaput, 1999, p. 137). Algebraic thinking involves reasoning with generalizations--constructing generalizations and justifying and applying them (Blanton et al., 2011; Cooper & Warren, 2011; Kieran, 2007; Kieran et al., 2016; Mason, 1996). We consider how instruction can support students in engaging in the mental activity that leads to generalizing about functional relationships represented in a pattern task. Prior research has mapped out how students develop functional thinking (e.g., Stephens et al., 2017), but we do not have a clear understanding of general ways to support students in engaging in generalizing about functions. By examining the actions of one preservice teacher as she worked to support students' generalizations of a visual pattern, we have identified features of teacher actions and classroom activity that support students in generalizing.

Conceptual Framework

Central to fostering algebra learning is understanding how to support students in generalizing, thus we conducted our analysis using a framework (viz., Strachota, 2020) built on a teaching experiment (Ellis, 2011) that identified seven types of generalizing-promoting actions. The framework (Strachota, 2020) used here was designed to identify students' generalizing and the activity that supported them in developing those generalizations, which is described as *generalizing-promoting activity*, the moves and interactions that promote generalizing, and *priming activity*, the moves and interactions that typically prepare students to engage in a later generalizing-promoting activity (see Table 1 for a description of priming activities and Strachota (2020) for descriptions of generalizing promoting). Understanding the context of generalizing is needed to support students in developing and refining generalizations. Ellis (2011) argues that generalizing is tied to a specific socio-mathematical context through which people construct generalizations. Generalizing is demonstrated through an individual's activity and discourse (Ellis, 2011; Kaput, 1999), so we use the Math-Talk framework (Hufferd-

Ackles et al., 2004) to capture how students and teachers use discourse to support mathematics learning. We focused on questioning and mathematical explanations to capture the back and forth of teacher-student interactions to see how teachers' questions drew students' attention and explanations towards aspects of the mathematics that may have contributed to their generalizing.

Table 1: Priming Activities

Priming Activities	
Naming a phenomenon, clarifying critical terms, reviewing critical tools	Offering a common way to reference a phenomenon or emphasizing the meaning of a critical term or tool.
Constructing or encouraging constructing searchable and relatable situations	Creating or identifying situations or objects that can be used for searching or relating. Situations that can be used for searching or relating involve particular instances or objects that students can identify as similar in some way.
Constructing extendable situations	Identifying situations or objects that can be used for extending. Extending involves applying a phenomenon to a larger range of cases than that from which it originated.

Methods

Ms. Patton was enrolled in a one-year master's program for individuals with STEM degrees and was in the first semester of a year-long placement in an Algebra II classroom. She planned, taught, and reflected on her video data from two episodes of teaching a pattern task with grades 9-10 students as an assignment for her mathematics teaching methods course. Data included planning documents, video recordings, and reflections of Ms. Patton's teaching episodes of the pattern task. With her mentor and supervisor, Ms. Patton co-reflected on her teaching, and then retaught the same task. She then analyzed the video of her teaching using several frameworks, described in the data analysis section, to determine the effectiveness her promoting students' generalizations. In our analysis, we coded the video data in 15-second segments by noting: the types of interaction; who was directing the activity; questioning and mathematical explaining (Hallman-Thrasher, 2017; Huffered-Ackles et al., 2004); and instances of priming activity (PA), generalizing-promoting activity (GPA), or generalizing activity (GA). Each instance of generalizing was coded when it initially occurred only even though a single instance may have spanned multiple segments. Interrater reliability was established by all members of the research team reviewing and coding all video data and transcripts. Disagreements were discussed until consensus was reached (Syed & Nelson, 2015). The quantity, density, and distribution of codes across a lesson helped us determine the relationship between PA and GPA to GA, and connections among generalizing and math-talk.

Results

We compare two episodes of Ms. Patton teaching the same lesson. In the first generalizations were more sparse than in the second. We focus on what different activities occurred during these episodes and how those activities may have been linked to or contributed to students' generalizations. Hereafter, we refer to the generalization sparse class as Episode 1 and the generalization dense class as Episode 2. We highlight Episode 2 because Ms. Patton presents a positive example, especially for a novice, that is worthy of investigation. Overall, Ms. Patton used more instances of priming activity (PA) and generalizing-promoting activity (GPA) and, as noted, had more generalizing activity in Episode 2 (Table 2). While this finding validates prior work (e.g., Strachota, 2020), we also identified patterns in the ways the practices were used. Moreover, while the difference between six and ten generalizations may seem insignificant, we highlight that these kinds of sophisticated statements are fairly rare and result from intentional instruction and students engaging in highly complex cognitive mental activity. Across both episodes, we observed that when priming and particularly generalizing-promoting activity increased students' generalizing activity also increased. In Episode 2, there were repeated instances of GPA-PA, PA-GPA, or PA-GPA-GPA, before a generalization occurred. Further once student generalizations were made, they were often closely followed by additional generalizations. Repeated instances of GPA and PA were nearly always necessary to produce GA. For example, Ms. Patton asked students to share expressions to represent the fourth image in Figure 1. Ms. Patton elicited several examples of expressions and represented them on the board, which was one way she constructed relatable situations (PA). Once students provided an example she followed up with a GPA, such as encouraging justification or encouraging relating. In one instance when she encouraged relating and in turn justification, she asked the student to explain how their expression was represented in the fourth image. In response, one student explained "(you) have two 4 by 4 perfect squares." When Ms. Patton helped the student clarify the student concluded, "(they) have two 4 by 4 squares, plus 2." In response Ms. Patton encouraged reflection (GPA) by asking, "How would you represent that algebraically?" The student who described seeing two 4 by 4 squares said, "It would be $2 \times 4 \times 6 + 2$."

Table 2: Summary of Priming, Generalizing-Promoting, and Generalizing Activities

	Teaching Episode 1*			**Teaching Episode 2****		
	Instances	% of Episode	% of Discussion	Instances	% of Episode	% of Discussion
PA	9	5%	9%	11	7%	9%
GPA	17	10%	17%	27	18%	21%
GA	6 St, 2 Tr	5%	8%	10 St, 2 Tr	8%	9%

*Note episode 1 was 43 minutes, 26 of which were discussion. **Episode 2 was 38 minutes, 32 of which were discussion.

We share this excerpt to show how Ms. Patton set students up for situations that could be built on in a way that supported generalizing. It succinctly illustrates the generative nature of priming, generalizing-promoting, and generalizing activity.

Ms. P: What about another one? **(PA)**
Jen: 2s and 4s.
Ms. P: Where's that at? **(GPA)**
Jen: Huh? I mean split in to 32 with 2s and 4s.
Ms. P: How would you do that? So you're talking about like this 32 [points to 8 by 4 rectangle]? **(GPA)**
Jetta: Yes.
Ms. P: What do you mean by 2s and 4s? Like how would you split the picture? **(GPA)**
Jen: Columns of twos.
Addie: $2 \times 4^2 + 2$

Ms. P: How would you show that in the picture? **(GPA)**
Addie: Just have two 4 by 4 perfect squares.
Ms. P: So you have two 4 by 4s, plus 2. Lets go back to what you were just saying Jen.
Jen: Yeah. Would it be rows of two and columns of four?
Ms. P: So how would you represent that algebraically? **(GPA)**
Addie: It would be $2 \times 4 \times 6 + 2$.

The quality of students' contributions, including when students explain their ideas to each other, and the quality of teachers' questions seemed to play a critical role. We noted an increase in instances and quality of teacher questioning and eliciting students' ideas (Table 3) that we identified using the modified Math Talk rubric (Author, 2017). Within the rubric, lower levels are associated with teacher-generated and answered questions (levels 0 and 0.5), whereas the higher levels are associated with richer justifications that are prompted by the teacher (levels 1 and 1.5). As the levels increase, the responsibility of generating questions shifts towards the students, in turn student-to-student dialogue increases (level 2 and above).

In Episode 2, when students' generalizing increased, there was a shift of responsibility for questioning and thinking from teacher to student. The number of questions and student contributions of thinking increased as did the quality of those interactions (Table 3). The number of questions Ms. Patton posed doubled in the second episode and Ms. Patton used more follow-up questions that pressed students to justify their ideas (level 1.5). Similarly, there were more than double the instances of eliciting student contributions in the second episode and those instances involved a greater number of students sharing their thinking (level 1) and responding to follow-up requests for justification (level 1.5 and 2). The increase in frequency and quality of questions and explanations provided opportunities for generalizing in the second episode. The increase in the quality of student contributions and teacher moves to facilitate those contributions made student thinking and ideas more visible to the class so that ideas with the potential to be generalized were public to the work of the class.

Table 3: Instances of Questioning and Explaining for each Level of the Math Talk Rubric

	Teaching Episode 1		**Teaching Episode 2**	
	Questioning	Explaining	Questioning	Explaining
Level 0	6	8	9	11
Level 0.5	6	0	9	6
Level 1	4	1	7	30
Level 1.5	18	6	43	15
Level 2	0	4	4	13
Level 2.5	1	0	0	0

Conclusion

Within the complex task of teaching, this study provides more evidence that intentionality leads to better outcomes for students, specifically in supporting students in developing mathematical generalizations. We argue that teachers should be purposeful in the questions they ask and the structure of interactions. Our study highlights that small pedagogical moves can have a big impact, and we illustrate some of those moves in practice. Future research should aim to better understand supporting teachers in implementing those practices.

This 5-year mathematics professional development project involves 27 elementary teachers being prepared and supported as Elementary Mathematics Specialists (EMSs) through completion of a university's K-5 Mathematics and Teacher Supporting & Coaching Endorsement programs, as well as participation in Professional Learning Communities and individual mentoring. Across the project, data are gathered to examine changes in mathematical content knowledge, instructional and coaching practices, beliefs, and teacher leader skills of the EMSs. Described here are Year 1 data from the participants, who have been identified as successful, experienced teachers, focusing on specific aspects of teacher effectiveness. The findings illuminate their classroom instructional practices, including those that are learner-centered and equitable, along with their early histories as learners of mathematics.

Keywords: Instructional Activities and Practices; Teacher Knowledge; Teacher Beliefs; Equity, Inclusion, and Diversity

Purpose of the Study

This study's context is a 5-year mathematics professional development project involving 27 elementary teachers who are prepared and supported as Elementary Mathematics Specialists (EMSs). They complete a university's K-5 Mathematics and Teacher Supporting & Coaching Endorsement programs and participate in Professional Learning Communities and individual mentoring. Across the 5 years, data are collected to examine how the intentional and continuous project components affect the mathematical content knowledge, instructional and coaching practices, beliefs, and teacher leader skills of the EMSs. Described here are specific data collected in Year 1, with these questions guiding the inquiry:

- To what extent do experienced, successful elementary teachers implement instructional practices that foster standards-based learning environments in mathematics?
- What are the relationships between these instructional practices and their mathematics content knowledge and beliefs?
- What are their early histories with mathematics as learners?
- What are their views on equitable mathematics instruction and their own enactment of equitable teaching practices in mathematics?

Perspectives

Teachers should implement effective and equitable instructional practices in mathematics (NCTM, 2014) that support *standards-based learning environments* (SBLEs). They should use instructional tasks with high levels of cognitive demand that support students' reasoning and problem solving, and facilitate productive discussions that elicit student ideas, attend and respond to student thinking as it unfolds during a lesson, and use that thinking to guide instructional decisions. These practices place children's thinking and learning at the center of classroom activity and instructional decision-making, leaning heavily on developed teacher identity and agency, and provide fruitful opportunities for students to develop positive identities as mathematics doers and learners (Aguirre, Mayfield-Ingram, & Martin, 2013). Teachers must navigate many constraints when it comes to implementation of these learner-centered practices, including those that are contextual and their own divergent past experiences as a learner of mathematics (Bartell, Cho, Drake, Petchauer, & Richmond, 2019).

Teachers' content knowledge and beliefs are also related to their support for children-centered learning environments. Teachers require deep and broad knowledge of mathematics to be effective in their teaching (Hill, 2010), including *specialized content knowledge* characterized as "mathematical knowledge needed to perform the recurrent tasks of teaching mathematics to students" (Ball, Hoover Thames, & Phelps, 2008, p. 399). This depth of understanding equips teachers to navigate children's mathematical thinking during instruction, including misconceptions, and the continuous decision-making processes required for responsiveness to this thinking. Also, teacher beliefs shape classroom instruction. Two important teacher beliefs constructs include pedagogical beliefs (i.e., beliefs about teaching and learning) and teaching efficacy beliefs (i.e., beliefs about capabilities to teach effectively and influence student learning).

Methodology

The design of this study includes a descriptive, holistic singular-case approach (Yin, 2014). The case is experienced elementary teachers who have been identified as effective teachers of mathematics and teacher leaders; all were employed in one urban-situated school district and teaching in high-need schools with diverse student populations. Multiple sources of data, both quantitative and qualitative in nature, were collected to form the descriptive findings. Participants were 27 elementary teachers in a large, urban school district in the southeastern USA. Their schools (n=22) served 91% students of color and 69% students eligible for the free/reduced lunch program. The participants identified as 24 females and 3 males and 70% teachers of color. They are a highly educated group, with 100% having a master's degree and 33% holding an educational specialist degree; further, they are experienced teachers, on average having 10.5 years of teaching experience. Teaching positions vary widely and include: three kindergarten, one first grade, two second grade, five third grade, one fourth grade, seven fifth grade, four STEM/Math Specials, one English to Speakers of Other Languages, one Special Education, one Early Intervention Program, one Accelerated Content, and two Dual Language Immersion.

The teachers had recently been selected to participate in a federally-funded, 5-year professional development project focused on developing EMSs. EMSs are generally considered to be teachers, teacher leaders, or coaches with the expertise to support effective elementary mathematics instruction and student learning (Association of Mathematics Teacher Educators, 2013). The project's recruitment efforts had concentrated on the highest need elementary schools in the district, as determined by free/reduced lunch program rates. The teachers were chosen based on criteria that identified them as successful, experienced teachers of mathematics and teacher leaders. Their application materials and interviews were reviewed for meritorious professional achievement, academic accomplishment, knowledge of mathematics, commitment to teaching mathematics, and evidence of/desire for teacher leadership. These criteria, plus consideration of race/ethnicity, gender, grade level, and school site with the aim of assuring participation of underrepresented groups and diverse school sites and grade levels, informed the selection of the 27 teachers in the project.

Quantitative data were collected from all participants via a classroom teaching practices observation protocol (i.e., Standards-Based Learning Environment Observation Protocol [SBLEOP], Tarr et al., 2008), *specialized content knowledge* assessment (i.e., Learning Mathematics for Teaching [LMT], Hill, Schilling, & Ball, 2004), background and practices survey, and two belief surveys (i.e., Mathematics Beliefs Instrument [MBI], Peterson, Fennema, Carpenter, & Loef, 1989, as modified by the CGI Project; Mathematics Teaching Efficacy Beliefs Instrument [MTEBI], Enochs, Smith, & Huinker, 2000). Qualitative data were gathered through individual interviews of all 27 participants, as well as three focus group interviews with nine participants in each group. The interview protocol includes questions related to their histories with mathematics and their mathematics instructional practices, particularly equitable mathematics instruction. Data were collected using virtual means at the start of the professional development project. This collection occurred during the COVID-19 health pandemic, and all teachers were providing instruction via different hybrid models with a mix of face-to-face and virtual delivery. Both descriptive and inferential statistics were used for analysis of the quantitative data. Relationships between scores from the different instruments were analyzed using Pearson Correlation. Analysis of the qualitative data involved constant comparative methods (Lincoln & Guba, 1985).

Results

Table 1 displays data from the SBLEOP used to assess the extent to which participants enacted learner-centered SBLEs during their classroom observations. The SBLEOP evaluates specific classroom events on a scale of 1-3, with higher scores indicating more alignment with a SBLE. For example, across the SBLEOP rubric criteria a score of 2 indicates partial evidence of a classroom event (e.g., “students had *some* opportunity”, “the teacher *sometimes* encouraged students to orally explain how they arrived at an answer”, and “different perspectives or strategies were *occasionally* elicited from students”). Shown are the mean scores on eight classroom events, or dimensions of facilitating a SBLE, and the overall mean score across classroom events. Lesson structures were somewhat consistent across all observations per school district guidelines, with teachers beginning with an activation activity, followed by a whole group mini-lesson and gradual release model, and ending with small group instruction based on ability grouping.

With an overall mean score of 1.5, the participants’ implementation of SBLEs was less than partially evident. Teachers were rated the highest on the *Mathematical Connections* indicator, suggesting that they were observed making some connections among mathematical topics during the lesson, though those connections were not typically discussed in detail. *Conceptual Understanding* (i.e., how the lesson fostered the development of conceptual understanding) was the next highest rated indicator. Both of these mean scores, though comparatively higher than other events, still fall below a 2. Teachers scored the lowest on the indicators *Making Conjectures* (i.e., observed opportunities for students to make conjectures about mathematical ideas) and *Reflecting on Reasonableness*, suggesting that teachers were rarely asking students whether their answers were reasonable and when students gave incorrect responses, another student was asked to provide a correct answer.

Table 1. Means on the SBLEOP

Classroom Event	**Mean Score (1-3)**
Making Conjectures	1.3
Fostering Conceptual Understanding	1.7
Making Mathematical Connections	1.9
Connections with Daily Lives	1.6
Students Explaining Strategies	1.6
Valuing Multiple Perspectives	1.4
Using Student Statements	1.4
Students Reflecting on Reasonableness	1.2
All Classroom Events	1.5

The analysis of the quantitative data reveals several other key findings. Notably, the extent of teachers' implementation of SBLEs was related to the depth of their content knowledge and strength of their pedagogical beliefs, as the correlational analysis shows a significant positive relationship between scores on the SBLEOP and both the LMT and MBI. When it comes to content knowledge (LMT), the participants' understandings of number and operations were the strongest compared to the two other content areas measured (i.e., algebra and geometry). All three of the subscales evidence considerable variability in scores. Further, when considering beliefs about the teaching and learning of mathematics (MBI), they were largely uncertain about cognitively-oriented pedagogy. And, while they were confident in their capabilities to teach mathematics effectively (MTEBI), they were less confident that this effective teaching would influence student learning in positive ways.

The analysis of the individual and focus group interview data provides insights into the participants' histories with mathematics and how their early experiences as a learner shape their instructional practices. They also described views on equitable mathematics instruction and specific practices they use with their students to support access and equity. Participants expressed a variety of firsthand experiences involving marginalization as mathematics learners and doers, sometimes as early as kindergarten, and how those early occurrences shaped their mathematical teacher identity and trajectory. Participants recalled experiencing inequities, though they recognized not having that language or awareness at the time, and how finding that language and awareness in adulthood as teachers has impacted their practices and relationships with their students. Participants are committed to providing equitable instruction, and the interview data show a range of enactment of those equitable practices with a consistent focus on learning new and better ways to teach mathematics equitably.

Discussion

The quantitative findings give us a distinct picture of these participants, who have been identified as successful, experienced teachers, at the very beginning of a lengthy, rigorous professional development project. The details and nuances of this picture are provided by the interview data, telling a story of themselves historically as mathematics doers and learners, and how those impact their practices, especially in addressing issues of equity and agency. The project's continual data collection and analyses across 5 years provide a unique and exciting opportunity to follow the trajectory of the participants as teacher leaders in high-need schools serving student populations rich in diversity.

PATTERNS OF REASONING: WARRANTS IN ELEMENTARY MATHEMATICS AND CODING ARGUMENTS

Argumentation is widely used in teaching mathematics, but little research has been done on argumentation in teaching integrated mathematics and coding. As part of a larger study investigating collective argumentation in teaching mathematics, science, and coding, we classified the warrants given by elementary age students who were engaged in argumentation in mathematics and coding. Three major categories – calculation, visual, and unformalized knowledge – accounted for the majority of warrants given. Further analysis revealed differences in types of warrants when the primary focus of the argument was coding versus when the primary focus of the argument was mathematics. Our results suggest that expecting students to provide reasons for modifying their code, similar to what is expected in mathematics arguments, helps move them away from a trial-and-error to a more structured approach to coding.

Background

Reasoning in Mathematics and Coding

Reasoning is important in the teaching and learning of mathematics. Research suggests students should develop an understanding of mathematics beyond a collection of facts and procedures (Cuoco et al., 1996; Goldenberg, 1996; Kilpatrick et al., 2001). Building on this research, national policy documents in the United States have highlighted the importance of reasoning in K-12 mathematics (National Council of Teachers of Mathematics [NCTM], 2000; National Governors Association Center for Best Practices and Council of Chief State School Officers, 2010). Together, these policy documents suggest K-12 mathematics instruction should enable students to recognize the importance of reasoning in mathematics, make and explore mathematical conjectures, construct and critique mathematical arguments, and use various types of reasoning and proof.

Although coding/computer science/programming is a relatively new area of instruction, the K-12 Computer Science Framework ("K-12 Computer Science," 2016) recognizes communication as one of the seven core practices. This practice requires students to describe and justify their processes and solutions, promoting a more structured approach to coding rather than the trial-and-error approach commonly used by novice programmers (Lye & Koh, 2014; see recommendation by Fessakis et al., 2013). Thus, reasoning and the ability to communicate rationales are valued in both coding and mathematics.

Collective Argumentation in Mathematics and Coding

One lens that provides insight into the reasoning practices of students and teachers is that of collective argumentation. We define collective argumentation as teachers and students working together to establish or reject claims. There are multiple examples in the mathematics education literature of teachers facilitating collective argumentation to support student learning, reasoning, and sense making (e.g., Forman et al., 1998; Krummheuer, 1995, 2007; Yackel, 2002).

Although argumentation has not been widely used in teaching and learning coding, the larger project from which this study originates proposed that teaching coding through argumentation has several benefits, including (1) constructing and critiquing arguments provides a more structured approach to coding than trial-and-error and (2) teaching coding through argumentation allows teachers to use methods they already use in teaching mathematics, thus making it more likely for them to teach coding in conjunction with mathematics. One of the goals of the larger project was to provide teachers with strategies to help improve students' abilities to construct and critique arguments. The present study builds on the collective argumentation literature by focusing on one component, the warrant, of Toulmin's (1958/2003) model for argumentation.

Conceptual Framework

In mathematics education research, argumentation is often studied using Toulmin's (1958/2003) structure of an argument which includes data, claims, warrants, qualifiers, rebuttals, and backings. Toulmin argued that although what is accepted as valid for each component is discipline dependent, the structure of arguments is the same across disciplines. This structure can be expanded to include sub-arguments and the contributor(s) of each component (see Conner, 2008). Although entire arguments can provide insights into the reasoning that occurs in classrooms, warrants can provide a clearer understanding of what students and teachers use and accept as rationales. According to Toulmin (1958/2003), a warrant in argumentation serves as a bridge that explains how a person got from the data to a claim. The types of warrants provided during collective argumentation can illuminate the ideas on which teachers and students base their reasoning. Existing research classifies warrants in multiple ways (Conner, 2012; Inglis et al., 2007; Nardi et al., 2011). In this study, we adapted and expanded Conner's (2012) framework for analyzing warrants. The initial framework identified 29 types of warrants that were collapsed into ten major categories.

Methods

The larger study from which these data were analyzed included two phases of data collection with 32 elementary school teachers. During the first phase, teachers participated in a semester-long professional development course that included block-based coding content across multiple platforms and discussions about using collective argumentation across multiple disciplines. In the second phase, ten teachers were selected for classroom observations and coaching sessions. This paper is focused on analysis of video recordings of classroom observations. Participating teachers selected the topics for the observed lessons, focusing on integrating multiple disciplines and using argumentation during their teaching. Videos of classroom observations were reviewed and episodes of argumentation were identified via identifying main claims and associated argument components. Episodes of argumentation from each teacher's class were selected for analysis through a random sampling process, diagrammed by pairs of researchers using Conner's (2008) modified diagram structure, and then compared until consensus was reached. A total of 222 arguments were diagrammed across ten participants. We labeled the primary and secondary focus of each argument as mathematics, coding, science, literature, or social studies. For this study, we analyzed 108 warrants from 35 arguments with a primary focus of mathematics (secondary focus coding) and a primary focus of coding (secondary focus mathematics) from four teachers' classrooms. We inserted all of the information from each argument into a spreadsheet, noting whether the warrant was implicit or explicit. Implicit warrants were identified when a warrant was not explicitly stated or written but seemed to be understood by at least part of the group. We categorized the types of warrants provided by students and teachers according to the framework developed by Conner (2012). However, due to the context of our data – mathematics and coding arguments in elementary classrooms – we made adaptations to this framework, which was originally developed from high school algebra and geometry arguments. Using this adapted framework, we examined the types of explicit and implicit warrants contributed by students and teachers to make sense of the kinds of reasoning that were evident in mathematics and coding contexts. Analysis of these data is ongoing.

Results

In our initial analysis, we identified 21 different types of warrants with 15 of these having been identified in Conner's (2012) initial framework and six being newly identified from our data. By examining our data using Conner's framework as a starting point, we collapsed the 21 types of warrants into 11 major categories (Table 1).

Table 1: Relative Frequencies and Types of Warrants

Categories	Types of Warrants	Coding Focus	Math Focus	Total
Authority	External Authority, Given, Mathematical Convention	2 (7.4%)	1 (1.2%)	3 (2.8%)
Given	Given	0 (0.0%)	1 (1.2%)	1 (0.9%)
Interpretation	Interpretation of Problem*, Interpretation of Written Code*	4 (14.8%)	0 (0.0%)	4 (3.7%)
Method	Procedure-General	2 (7.4%)	4 (4.9%)	6 (5.6%)
Patterns	Patterning, Pattern Noticing	1 (3.7%)	4 (4.9%)	5 (4.6%)
Preference	Personal Preference*	0 (0.0%)	3 (3.7%)	3 (2.8%)
Visual	Appearance, Observation*, Observation with Quantification*, Visualization	8 (29.6%)	14 (17.3%)	22 (20.4%)
Calculation	Procedure-Calculation	0 (0.0%)	29 (35.8%)	29 (26.9%)
Unformalized knowledge	Informal Understanding, Number Sense, Previous Experience	5 (18.5%)	19 (23.5%)	24 (22.2%)
Knowledge	Definition, Prior Knowledge	3 (11.1%)	0 (0.0%)	3 (2.8%)
Reasoning	Interpretation of Definition, Calculation-Why*	2 (7.4%)	6 (7.4%)	8 (7.4%)
Total		27	81	108

An asterisk (*) indicates a newly identified type of warrant.

We first examined all of the warrants aggregated across both foci: mathematics and coding. Of the 108 warrants, approximately 70% of the warrants were classified into one of three categories: *calculation*, *unformalized knowledge*, or *reasoning*. More than a quarter (26.9%) of all warrants analyzed were classified as *calculation*; these were warrants in which a student or teacher provided a mathematical process or set of steps that produced a solution to a specific problem. For example, a student offered the warrant "Because 6 x 4 = 24" to justify the claim that a square with side length 6 would have a perimeter of 24. It is unsurprising that the largest category of warrants was *calculation* because each of these arguments included mathematical operations familiar to elementary students. Warrants classified as *unformalized knowledge* made up the second largest category (22.2%). For example, when investigating the relationship between time and distance, one student explained, "When I go to the gas station, it's really close to my house so [I] have a shorter time to go. But when I go to [the grocery store], it's like in the city, it takes a way longer time because it's more farther." The large proportion of these warrants that were *unformalized knowledge* suggests that students reasoned intuitively or based on ideas that had not yet been formalized in class. The third largest group of warrants (20.4%) were classified as *visual*, as students based their reasoning on physical representations they could see. For instance, when justifying why the robot needed to travel a longer distance along one side of a rectangle that was taped on the tile floor, a student offered, "This side looks longer. This [side] is 4 squares width and then this [side] has 3 squares width."

Although the remaining categories made up only 30% of the warrants, there are interesting things to note in this smaller group. Warrants were classified as *reasoning* when a student or teacher provided evidence for a claim based on the *interpretation of a definition* or when they provided a rationale for performing a calculation (*calculation-why*). Even though this category makes up a small percentage of all warrants analyzed (7.4%), the idea that one should give a reason for a calculation was evident in these elementary classrooms. In addition, the category of warrants that were based on some *external authority* made up one of the smallest percentages overall (2.8%), indicating that students were not relying heavily on what the teacher said when providing evidence for claims.

When we examined the warrants according to their primary focus, we found that almost 30% of the warrants in coding-focused arguments were classified as *visual*, compared to only 17.6% of warrants in mathematics-focused arguments. The higher proportion of *visual* warrants in coding-focused arguments could be due to students working with robots that students could observe carrying out their written code. For example, the reasoning students provided for their claim "we halved one second" to adjust how far the robot should travel was "one second got us two times too far." This warrant was classified as *observation with quantification* because students noticed the robot traveled too far and they used mathematical ideas ("two times") to describe what they observed.

Although more than a third (35.8%) of warrants provided in mathematics-focused arguments were *calculation,* none of the warrants provided in coding-focused arguments involved only calculation. Warrants involving a calculation in coding-focused arguments included a reason for doing the calculation (*calculation-why*). When students were attempting to code a robot to go a certain distance, they often related it to a previously established distance and time: "Because the length is doubled and 12 inches is doubled so I should double the delay." When focused on coding, it is reasonable that students include justifications related to the task in their warrants.

Discussion

Understanding the patterns of reasoning from these elementary mathematics and coding arguments provides insight into what teachers and students accept as appropriate justifications. Although some research exists on what types of warrants are acceptable in mathematics classrooms, little is known about what is considered valid reasoning in coding-focused arguments. Understanding reasoning patterns in coding contexts can help us support teachers in engaging students in argumentation in learning coding. Additionally, none of arguments in this analysis showed students used a trial-and-error approach to coding, which is commonly used by novice coders (see Lye & Koh, 2014). This is likely because the teachers insisted that students provide reasons for modifying their code, promoting a more structured approach to coding. This gives us reason to believe that argumentation is a promising approach for teaching students to code. And, the coding context, with expectations of argumentation, provided a way to access students' reasons for their calculations.

In this case study, we report how a ninth-grade mathematics teacher's beliefs about her students and knowledge influenced her decisions and actions. We first illustrate how the teacher retrospectively interpreted her response to an unexpected incident in the classroom as a mistake mediated by her beliefs about the students' abilities (i.e., "let's just focus on the basics"). Then, we illustrate how the teacher's response to that moment played a role in enabling her to leverage meaningful mathematical discussion. Results showed that, although the teacher was aware of different conceptualizations of slope, she wanted to promote a particular meaning of slope (i.e., slope as a formula) in the moment guided by her mathematical knowledge for teaching slope and beliefs about her students' mathematical knowledge.

Keywords: Algebra and Algebraic Thinking, Mathematical Knowledge for Teaching, Teacher Beliefs

Researchers have long argued that a teacher's belief system and mathematical knowledge for teaching have significant influence on instructional practice and student learning (e.g., Ball, Thames, & Phelps, 2008; Campbell et al., 2014; Wilkins, 2008). Moreover, teachers' beliefs about their students play a key role in designing and implementing instruction (Skott, 2001; Sztjan, 2003). In this paper, we illustrate the role that one teacher's beliefs about her students' ability and mathematical knowledge played in influencing her teaching decisions and actions.

Literature Review and Theoretical Framework

Teachers' Beliefs about Students

The types of beliefs typically investigated in the field fall into three categories: beliefs about mathematics, about teaching mathematics, or about learning mathematics (e.g., Conner et al., 2011; Liljedahl, 2009; Thompson, 1984). Of these three types, beliefs about mathematics are particularly important, given their potential to profoundly influence teachers' beliefs about teaching and learning mathematics (Cross, 2009). A number of researchers have also studied more specific or nuanced teacher beliefs. For instance, Skott (2001) investigated how one teacher's beliefs influenced his interactions with student groups, finding that the teacher's beliefs about raising students' self-confidence influenced how he interacted with different groups in different ways. Similarly, Sztjan (2003) studied two teachers' enactment of recommendations for change in mathematics teaching and found that they implemented these recommendations differently as a consequence of how each teacher perceived students who came from different socioeconomic backgrounds. The teachers' practices were ultimately mediated by their "value-laden visions of students, of parents, and of society" (Sztjan, 2003, p. 70). Together, these studies suggest that mathematics teachers may hold beliefs about their students that may not fit neatly into the categories of mathematics, teaching mathematics, and learning mathematics, and that these beliefs can have great influence on their practice.

Teachers' Meanings for Slope

Researchers (e.g., Byerley &Thompson, 2017; Stump, 2001; Nagle & Moore-Russo, 2013) have characterized a variety of teachers' meanings for slope including, but not limited to, (i) slope as an index of the steepness of a line, (ii) slope as a procedure, and (iii) slope as a ratio. *Slope-as-steepness* involves conceiving a line as a physical object and making perceptual associations between its steepness and a particular numerical value. For example, when considering the graphs of two lines, that person might conclude the slopes are necessarily the same if they have the same steepness visually despite being graphed in coordinate systems with different scales. *Slope-as-procedure* involves either the idea of "rise over run" (i.e., slope as a direction on how to move up and over on a Cartesian coordinate plane) or the slope formula (i.e., vertical change/horizontal change). Stump (2001) and Byerley and Thompson (2017) showed that most teachers' meanings of slope include the slope formula. In our study, we focus on a teacher who intended to promote an understanding of slope in terms of formula and prevent the slope-as-steepness meaning.

Methods

The present study is an investigative and descriptive case study (Merriam, 1998; Yin, 2003;) of Ms. R's beliefs about her students and the knowledge influencing her instruction. Ms. R was a sixth-year high-school algebra teacher. We conducted classroom observations in her ninth-grade algebra class, where we observed a four-day unit on equations and inequalities. We recorded all classroom sessions using two video cameras, one focused on the teacher and one focused on a focus group of three to four students, capturing the entirety of their engagement including conversations, gestures, and written work. We also conducted two interviews with Ms. R after the observations. The first interview was semi-structured (Roulston, 2010), and its goal was to discuss Ms. R's beliefs about mathematics and how she supported student learning. The second interview was a videoclip interview (Speer, 2005), and its goal was to further explore Ms. R's beliefs. Prior to the videoclip interview, we asked Ms. R to watch her lesson on Systems of Equations and Inequalities, choose clips where she thought there was evidence that her students had developed a generalization, and describe the generalizations in each clip. Ms. R chose clips depicting students' engagement in the pet sitter task, where they were asked to represent a situation both algebraically and graphically (Figure 1). In this task, Ms. R also provided students with two pieces of graph paper to represent the solution set for each constraint.

Carlos and Clarita have been worried about space and start-up costs for their pet sitters business, but they realize they also have a limit on the amount of time they have for taking care of animals they board. To keep things fair, they have agreed on the following time constraints.

<u>Feeding Time:</u> Cats will require 12 minutes to eat per day. Dogs will require 20 minutes to eat per day. Carlos can spend up to 8 hours each day to feed the animals.

<u>Playing Time:</u> Cats need 16 minutes each day to be brushed. Dogs will need 20 minutes each day playing with the ball. Clarita can spend up to 8 hours to play with the animals.

Write inequalities for each of these additional time constraints. Shade the solution set for each constraint on **separate** coordinate grids.

Figure 1: The pet sitter task.

Including a multi-phased qualitative process, we analyzed both transcripts and video recordings from the interview. In the first pass, we coded each interview using an open and axial coding approach (Strauss & Corbin, 1998) to identify and characterize the teacher's beliefs about students as she reflected on the video clips that she chose. In this paper, we report a portion of the interview data in which Ms. R reflected on her actions facilitating the discussions of the graphical representation of the solution set for the feeding time constraint.

Results

In this section, we report on how Ms. R's beliefs and knowledge influenced her actions. We begin by illustrating how an unexpected incident happened and how Ms. R responded to it.

Unexpected moment. Recall that there were no explicit directions in the task regarding the axis orientation. While the students worked in their small groups, Ethan asked Ms. R if they should assume that the number of cats should be represented on the vertical axis of the coordinate plane. Ms. R responded, "Yeah, I guess we should make that a general thing with everybody," and she asked the whole class "Alright, just so we're all staying consistent. What do you guys want to be your *y*-axis? Let's just all keep it consistent." After Ms. R noticed that the students had different opinions regarding axis orientation, she said to the whole class, "Actually, let's just see who comes up with what. I think that'll be better. …That'll be cool to see." In the second interview, we played the short video clip from the classroom data in order to get Ms. R's insights into the decision that she made. She began stating, "Oh Lord! [sighs]. That is an exact example of a moment like I don't know what I want to do, so let's just bring both ways [laughs]." She further explained that her student teachers had taught a similar version of the task the day before, and she could not remember what they had done in terms of the axis orientation. Therefore, she did not want to ask the students to graph in a certain way that might be different from what they had done the day before.

As the lesson progressed, Ms. R viewed this decision to let her students choose the axes orientation as a mistake. As she rotated from one group to another in the class, she said "Man, I wish I had never said anything about y'all's axes." In the interview, she added that, except for a couple of students, most of her students would find the lack of direction difficult. Although Ms. R considered the idea of graphing the same relationship in two differently oriented axes to be an important discussion, she believed that this was too advanced or difficult for many of the students in an on-level class to understand. We infer that Ms. R's regret about letting the students choose the axes' orientation was a consequence of her beliefs about her students' abilities.

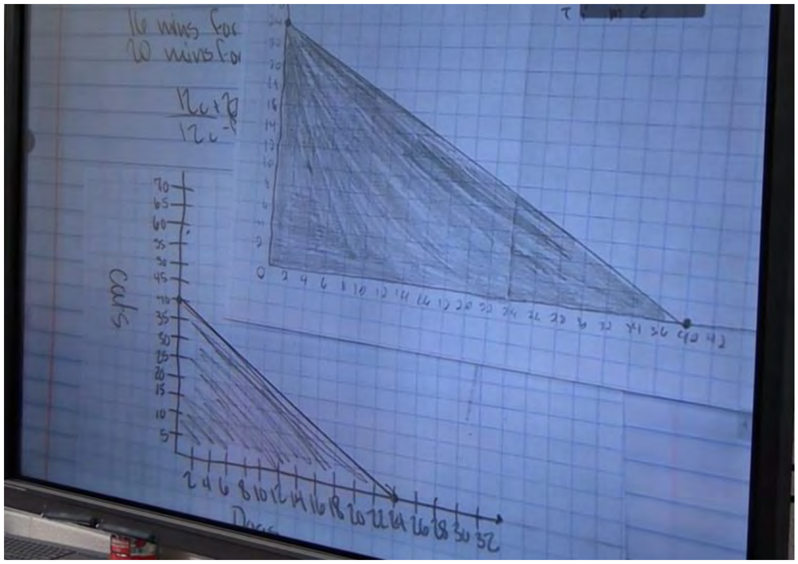

Figure 2: Two differently oriented graphs for the feeding time.

Pivoting at this unexpected moment. Although Ms. R regretted letting the students do what they wanted, she still capitalized on this moment by bringing two students' graphs to the whole class, each graph with a different orientation (see Figure 2). She put the two graphs under the document camera, saying, "I thought it was interesting, um, how you guys graphed. So, the cats and the dogs, the axes were different and similar."

Ms. R asked the whole class, "Alright, so do you guys see the difference between these two graphs?" Several students responded that the dogs and cats were "flip-flopped" on the axes of the coordinate plane. Then, Ms. R asked, "What about key features wise? You guys notice anything?" There were different opinions regarding the slopes as the students began answering "same slope," and "different slopes." The teacher then drew the students' attention to the fact that "they [both graphs] represent the feeding time … the one has cats as a y-axis, one has dogs as a y-axis," and asked "So, would the slopes be the same or different?" After students discussed "the rise and run would be like switched," most of the students concluded that the slopes were different, in fact, they were "flip-flopped" meaning that two slopes were reciprocal.

In the second interview, we played a short video clip depicting Ms. R's move to bring the two graphs to the whole class. We asked Ms. R what would be "cool to see" about the two different orientations, and why she chose to show these two graphs to the whole class. Ms. R stated that she wanted to get the students to discuss about the slopes being the same or not, and to realize that the slopes were reciprocal. She believed that this can be done if the students use a procedure (i.e., apply the slope formula) that they learned to a new situation. For her, if the students are not able to extend the use of this procedure to a new problem (i.e., the other graph), they might think the slopes are the same. Relatedly, Ms. R spoke about "a common misconception" regarding the shape of the graphs, which is that if "both of them are decreasing, and they look about the same amount of spread," then the slopes are the same. Ms. R thought that showing different orientations could help "to show that oh, we are just looking at how this vertical distances is changing over this horizontal distances is changing." We infer that Ms. R wanted to create an opportunity for her students to calculate the slope for the two different axes orientations, compare the slopes, and in turn, make sense why the slopes were reciprocal.

Discussion

In this paper, we illustrated that a teacher's beliefs about students and mathematical knowledge for teaching can operate together to guide her actions and decisions in the classroom. We showed that the teacher's beliefs about students made her regret her move in the moment. That is, she perceived herself making a mistake by letting her students choose the axis orientation in their graphing activity. However, her mathematical knowledge for teaching came into play and supported her decision to bring the two different oriented graphs to the board. Ms. R then was able to turn her mistake into an opportunity for her students to develop a particular meaning of slope. We interpret that Ms. R's mathematical knowledge for teaching slope productively informed her ways of designing her instruction in the moment and responding to the students in her classroom. It was this knowledge that allowed her to become *pedagogically powerful* (Diamond, 2020).

This study examined how implementing mathematical language routines affected multilingual learners in Math 1 classrooms engaged in productive struggle. We used the theoretical framework of productive struggle to investigate two co-taught special education Math 1 classes, qualitatively analyzing video data from one student in each class. We noted a difference in students' productive struggle between lessons taught prior to the introduction of the mathematical language routines and lessons in which teachers implemented the mathematical language routines. This study illustrates how teachers participating in professional development promoted more frequent and deeper productive struggle in lessons utilizing mathematical language routines.

Keywords: Problem Solving, High School Education, Instructional Activities and Practice

The population of multilingual learners in U.S. schools is increasing (NCES, 2020). Across the United States, it is expected that multilingual learners will make up one-quarter of the total number of students in K-12 settings by 2025 (National Education Association, 2005). In addressing this trend in relation to mathematics classrooms, this study used a "studio days" model of professional learning (Von Esch & Kavanagh, 2018) to introduce teachers to mathematical language routines that could engage multilingual learners in rich mathematics content (Zwiers et al., 2017). We examined the differences in teachers' instructional practices, and more critically, the difference in multilingual learners' mathematical processes during observed lessons from these professional learning cycles. This study sought to answer the following research question: How did implementing mathematical language routines affect how multilingual learners in Math 1 classrooms engaged in productive struggle?

Theoretical Framework

This study is framed by the construct of productive struggle**.** We draw our definition of *productive struggle* from Hiebert and Grouws (2007) and Grandberg's (2016) work around this concept. Hiebert and Grouws described productive struggle as the intellectual efforts that students expend to make sense of mathematical concepts. This sense-making includes making connections between facts, between concepts and procedures, and most importantly, assimilating new information with prior knowledge (Granberg, 2016; Hiebert & Grouws, 2007). Specifically, productive struggle occurs when present comprehension is insufficient, and students engage in cognitive processes that restructure prior knowledge and construct new knowledge in relation to what is already known. Granberg (2016) further situated productive struggle in the learning of mathematics with understanding. In addition to student struggle, student interactions with teacher responses can alter the possible outcomes of the student struggle (Warshauer, 2015). Teachers play an important part in supporting the students' productive struggle (Smith et al., 2017). This study utilizes Granberg's (2016) definition for *productive struggle*, considering viewing activities that afforded students' deeper insight or that were needed to solve (all or parts of) a given problem as *productive*.

Methods

Our study was situated in one school district in Central California that included a substantial number of multilingual learners. Teachers engaged in a two-year professional development program organized around mathematics "studio days" (Von Esch & Kavanagh, 2018) for multilingual learners, in which teachers developed and studied a single lesson focused on one mathematical language routine and one mathematics language principle during each cycle. The findings of this paper come from the first studio day cycle of the larger study.

Participants

Nine mathematics teachers from three high schools participated in this study. Of the nine teacher participants, five were female and four were male. Seven were White/Caucasian, one was Latinx, and one was Asian American. One teacher was bilingual (Polish), and the rest were monolingual English-speakers. Four of these nine served as focal teachers.

For this study, the research team then chose to focus on two of the classrooms featuring focal teachers – Ms. Frasca's and Ms. Parker's– due to similarities in the classroom environments. Both classes utilized an inclusive co-teacher model with a special education teacher (Rimpola, 2014). We used data from two students' cameras, Chris, from Ms. Frasca's class, and Jorge, from Ms. Parker's class.

Chris and Jorge were each chosen due to the similarities of their demographics and availability of data. Each student was designated as an "English learner" (we use the state designation here rather than multilingual learner). Additionally, each student was designated as a special education student. Both Chris and Jorge also volunteered to wear the "student cameras" during the lessons, allowing for an intimate look at their processes during the observed lessons.

Professional Development Cycle

The data in this study were situated in a professional development cycle. Using Von Esch and Kavanagh's (2017) professional development model of studio days, we created a cycle of three professional development meetings for our participants. The studio day cycle of interest paired the mathematical language routine "Three Reads" (Kelemanik et al., 2016), which provides students access to rich text, with the principle *disciplinary language demands and supports* (Aguirre & Bunch, 2012).

Mathematical language routines support students to engage productively with content, providing them with tools that they can grow familiar with and return to regularly when engaging in cognitively demanding mathematics work (Kelemanik et al., 2016). Mathematical language routines are effective instructional practices when working with multilingual learners, due to the simultaneous foci of developing mathematics skills and language use in mathematics classroom (Zwiers et al., 2017). Utilizing the mathematical language routine, Three Reads, students become familiar with reading mathematical text for three different purposes – to understand the context, interpret the task, and identify information requisite for completing the task (Kelemanik et al., 2016).

The professional development cycles were guided by five key principles of reform-based instructional practices for multilingual learners in mathematics classrooms (Roberts & Bianchini, 2019). These principles grounded our work with teachers and framed the conversations with teacher participants about the teaching and learning of mathematics for multilingual learners. The fourth principle, *identifying disciplinary language demands and supports for multilingual learners* (Aguirre & Bunch, 2012; Lyon et al., 2016), focuses on language demands typical for critical thinking in mathematics and the challenges and supports teachers utilize in facilitating mathematics language use.

Data Collection

The research team observed the teachers four times across the study – once before beginning the professional development, twice on studio days, and once more after the first studio day cycle. We use student data for this data: video cameras in the form of eyeglass frames (Estapa et al., 2016), referred to as "student cameras" in this study, to capture audio and video data of the teacher's instructional practices. This study utilizes data from the first studio day cycle – the initial observation prior to professional development, in which no mathematical language routines were utilized, and the first studio day, which incorporated the Three Reads routine.

Data Analysis

The research team coded instances in which students engaged in struggles and activities that afforded them deeper insight needed to solve (all or parts of) a given problem (Granberg, 2016). The research team identified all such instances; for each, we reconciled whether or not it was an example of *productive struggle*; and we discussed whether the instance showed *productive*, *low-level productive*, or *unproductive struggle* (Warshauer, 2015).

Findings

Our findings noted a difference in productive struggle between lessons taught prior to the introduction of the mathematical language routines and lessons in which teachers implemented mathematical language routines.

Initial Observation

In Ms. Frasca and Ms. Lacrosse's Math I classroom, they taught transformations primarily utilizing direct instruction during our initial observation. One teacher lectured in the front of the room, while the other teacher circulated through the class and modeled participation by asking clarifying questions and encouraging students to participate (they swapped these roles interchangeably). Throughout the lesson, Chris engaged with the mathematics using a task-oriented focus, meaning that he recorded responses verbatim to his notes, but there was no evidence that he worked toward a conceptual understanding. Chris' interactions with his peers and teachers did not prompt additional insights for Chris, but rather, led to Chris' completion of the class tasks, meaning the data collection lacked evidence of any productive struggle

Ms. Parker and Mr. Neuman's initial lesson focused on linear relationships. Their instructional sequence and task was also more task-oriented than conceptual. Jorge worked throughout the lesson, fixing responses once he identified them as incorrect, such as when he restarted a task during class after graphing a line incorrectly. However, Jorge appeared to be more focused on completing the task than on increasing his conceptual understanding of linear relationships, as he showed frustration by crumpling his paper and restarting his work after making a graphing mistake—indicating unproductive struggle, because while he eventually corrected his mistake and completed the assigned task, Jorge failed to communicate his understanding verbally or in writing.

Studio Day Observation

Ms. Frasca and Ms. Lacrosse designed a lesson utilizing the Three Reads mathematics language routine to introduce a lesson on polynomials involving an algebra tiles task for their studio day lesson. Students engaged in the Three Reads routine prior to collaborating with peers and teachers in the classroom to represent the area of a specified rectangle. Similar to the initial observation, direct instruction proceeded the routine and collaborative opportunity; however, in this studio day lesson, a different peer interaction occurred. Chris and his group engaged with the task and discussed the various configurations available with the algebra tiles. The group struggled with the task, but Chris engaged authentically with the manipulatives. A teacher present for the observation prompted the group to follow Chris in his exploration. Chris and his peers showed evidence of *productive struggle*, as their conceptual understanding of area was recorded through the representation of the algebra tiles and the resulting equation for the rectangle's area was recorded on the worksheet.

Ms. Parker and Mr. Neuman's studio day lesson attended to parallel and perpendicular lines, while utilizing the Three Reads routine. Unlike the lesson observed in Ms. Frasca and Ms. Lacrosse's class, evidence of productive struggle was seen during the implementation of the mathematical language routine, as opposed to after the fact. Jorge began to show evidence of conceptual understanding of linear relationships during the second read of the routine, in which he interpreted the purpose or task in the problem as he worked at his own pace through the routine. He stopped the task after graphing one line, appearing to struggle with graphing a second line that was supposed to be parallel and transformed five units higher. After hearing the discussion of a teacher with another student, clearly audible in the student camera, Jorge then completed the task. When prompted on his worksheet, "What is the relationship between $y = \frac{3}{5}x - 4$ and its image?", Jorge wrote, "They have the same slope they look parallel." This showed evidence of *low-level productive struggle*, as he advanced his understanding of linear relationships, but did not clearly grasp an understanding of parallel lines.

Discussion and Conclusions

We found lessons involving the mathematical language routines engaged the two multilingual learners followed in this study in more opportunities for productive struggle. In both initial classroom observations, students did not appear to engage in advancing their conceptual understanding of the mathematics content. However, lessons utilizing mathematical language routines appeared to engage students in productive struggle in two ways. First, teachers provided more opportunities for students to engage in productive struggle. Second, through the use of mathematical language routines, teachers facilitated spaces in their Math I classrooms to allow for deeper exploration and understanding of the mathematics content, and ultimately, to lead to productive struggle among their students. This study provides evidence of another avenue by which researchers and practitioners may utilize professional development to improve instructional practice and student learning in mathematics classrooms for multilingual learners.

How does the design of lessons impact the types of questions teachers and students ask during enacted high school mathematics lessons? In this study, we present data suggesting that lessons designed with the mathematical story framework in order to elicit a specific aesthetic response ("MCLEs") have a positive influence on the types of teacher and student questions asked during the lesson. Our findings suggest that when teachers plan and enact lessons with the mathematical story framework, teachers and students are more likely to ask questions that explore mathematical relationships and focus on meaning-making. In addition, teachers are less likely to ask short recall or procedural questions in MCLEs. These findings point to the role of lesson design in the quality of questions asked by teachers and students.

Keywords: classroom discourse, mathematics curriculum, aesthetic, mathematical story.

There is a broad consensus that the quality of the questions asked in mathematics classrooms influence student learning as it can constrain or broaden learning opportunities (Doyle, 1983; Chapin, O'Connor, & Anderson, 2009; Smith & Stein, 2011; Sullivan & Clarke, 1991). Despite this importance, there is evidence that mathematically rich questioning in high school mathematics lessons is rare (e.g., Boaler & Brodie, 2004; Hiebert & Wearne, 1993).

Responses to this challenge have been two-fold. First, one approach is to provide professional learning opportunities for teachers to learn more about productive mathematical discourse (e.g., Breyfogle & Herbel-Eisenmann, 2004; Chapin et al., 2009). A second approach has focused attention on incorporating teacher questioning as a part of designing lessons with high cognitive demand tasks (e.g., Smith & Stein, 2011) since such tasks provide potential opportunities for questions that involve meaningful mathematical connections and reasoning.

In this study, we describe how the mathematical questions posed by teachers and students in enacted lessons shifted through a third approach, namely, by having teachers design mathematically captivating learning experiences ("MCLEs") using the mathematical story framework (Dietiker, 2013, 2015). What is novel about this approach is that the professional learning and lesson design, which focused on how the ideas unfolded across a lesson as a form of narrative, included no attention toward the types of questions that would be asked during the lesson. This study is a part of a larger research project where lessons that students identified as highly interesting on a post-lesson survey were compared with those described by the same students as low interest in order to identify the characteristics of lessons that students find captivating. Since captivating mathematical stories should, in theory, provide opportunities for curiosity and questioning, the current study compares the types of questions asked during MCLEs and non-MCLEs. We report the ways in which this approach shifted the mathematical questions of both teachers and students, asking *How are the questions asked during MCLE* *enactments the same or different than those posed during non-MCLE enactments?* We end with a discussion on how this lesson design approach likely led to these improvements.

Theoretical Framework

This study interprets a sequence of mathematical events (e.g., tasks, discussions) that occur across a lesson as a *mathematical story* (Dietiker, 2015). Similar to literary stories, mathematical stories can differ in ways the content unfolds throughout the story and impacts the experiences of the audience (i.e., a student experiencing the lesson). Through the release and withholding of information, a mathematical story dynamically shifts a reader's recognition of what they know and enables them to recognize what they do not yet know. This shift in tension can compel a reader to wonder how the story will progress and end. For example, a mathematical story can provide a hint of a future revelation, thereby supporting the formulation and pursuit of questions (e.g., "Can leading coefficients of a polynomial help to identify its roots? How?"), similar to how a reader of a literary story might wonder how the story will advance. Although the MCLEs in this study were designed using the mathematical story framework, the non-MCLEs can also be interpreted for how the content unfolds in ways to inspire inquiry (or not).

Methods

The data for this study includes transcripts of lessons that were designed and taught during the 2018-2019 school year. Immediately after each lesson, students individually rated their interest in the lesson. The analysis of this survey data enabled the identification of lessons for each teacher that students described as most (and least) interesting. The six lessons with the highest interest measures were MCLEs, and the six lessons with the lowest interest measures were all non-MCLEs. These 12 lessons were taught by six experienced teachers with a minimum of four years of experience, and who taught in three high schools in New England with different curricula and demographic settings. The lessons were designed by teachers, with researchers, and represent a range of mathematical topics for both honors and non-honors courses spanning from Integrated Math 1 to calculus. To support the teachers' designing process of MCLE lessons, the teachers attended a two-week professional development during the summer of 2018 to learn about the mathematical story framework and begin the design process.

Data Analysis

Each of these lessons was transcribed and later coded for the mathematical plot by a team of researchers. The team identified the mathematical questions that were raised, explicitly or implicitly, by teachers and students throughout the lesson. Any questions that were non-mathematical, such as "Can you show it under the document camera?", were not included. We also did not formulate questions that clearly involved content from earlier grades, as we interpreted these as "checking answers" (e.g., "Is 18 times 3 is 54?"). Also, repeated questions were not counted as additional questions in this study. After identifying all the questions, we identified the acts during which each question was open and unanswered.

Then, each of the three researchers independently coded each question raised in the mathematical plots for its mathematical qualities. To distinguish the types of questions, we adapted Boaler and Brodie's (2004) categories of questions. We began with including six categories, namely *gathering information: procedural and factual* (GIPF), *inserting terminology* (IT), *exploring mathematical meanings and/or relationships* (EMMR), *probing for an explanation of thinking* (PET), *linking and applying* (LA), *extending thinking* (ET). We excluded three categories because either these categories are non-mathematical and thus not part of the mathematical story (in the case of *establishing context)* or they could be merged with other categories (in the case of *generating discussion* and *orienting and focusing*).

This coding framework was used to distinguish the qualities of the questions raised explicitly or implicitly by teachers and students. An important distinction of our coding scheme is that we coded questions based on how they were taken up and addressed within the story arcs as opposed to deciding the intent of the question independent of how the question was answered. Based on our initial analysis of questions in non-MCLEs and MCLEs lessons, we added two new categories: struggling with recently learned procedure and facts (SIPF) and problem-solving without known procedures (PSWP). SIPFs also are recall type questions; however, unlike GIPFs, students do not provide quick responses but instead struggle to recall the recently learned facts and perform the procedures. PSWPs a range of problems; both novel (unfamiliar to students) and challenging (perhaps familiar, but students choose to reason their way through the problem instead of applying a familiar procedure).

After questions were coded, the researchers met to resolve differences and to find consensus. To learn whether MCLEs have different proportions of each type of question when compared to non-MCLEs, we conducted a paired samples t-test for each teacher (pairing their MCLE and non-MCLE). Significance was determined when $p < 0.05$.

Findings

Overall, there were 417 teacher questions and 176 student questions in the 12 lessons, out of which 182 teacher and 99 student questions were from six non-MCLEs and 235 teacher and 77 student questions were from six MCLEs. On average, MCLEs have 30% more teacher questions in comparison to the non-MCLEs. In contrast, students asked approximately 27% more questions in non-MCLEs in comparison to MCLEs. However, the numbers of teacher and student questions were not significantly different between these two types of lessons. Note that we found only one *extended thinking* question across all the lessons. It was asked by a student in an MCLE lesson. Because of the lack of this type of question this category was excluded from further analysis. Following are our findings on the shifts of teacher and student questioning when comparing MCLEs to non-MCLEs.

Shifts in Types of Teacher Questions

The data (Table 3) show a stark difference for the types of questions that emerged in lessons that were MCLEs, as compared to those that were non-MCLEs. Overall, in MCLEs lessons, approximately one-fourth of the teachers' questions were for encouraging students to explore the mathematical meaning and reasoning (EMMR) in comparison to their non-MCLEs with only 1.6% of such questions. In fact, only two teachers asked either one or two EMMR questions in their non-MCLEs. These preliminary findings suggest that teachers tend to ask significantly more EMMR questions in their MCLEs (M=23.8, SD=10.4), which encourage students to explore underlying mathematical meaning and relationships, as compared to their non-MCLEs (M=1.3, SD=2.1) lessons (t (5) =5.6, p=0.003). On the other hand, in non-MCLEs, teachers tend to ask twice as many recall questions (i.e., GIPF and SIPF types) (M= 27.6, SD=12.5), which is significantly different as compared to their MCLEs (M= 56.6, SD=18.9) lessons (t (5) = -3.5, p=0.018).

Our data also suggests that teachers probe students to explain their thinking more often in their MCLEs (M= 18.6, SD=16.2) as compared to their non-MCLEs (M=6.4, SD=5.2), though this difference is not statistically significant (t (5) =1.97, p=0.11). The "problem solving with logic and unspecified procedures" (PSWP) type of questions were slightly higher in non-MCLEs

(M=35.6, SD=19.2) in comparison to MCLEs (M=29.6, SD=15.7). However, there was no significant difference between MCLEs and non-MCLEs for this question type, (*t* (5) = - 6.8, *p*=0.53), as both types of lessons have questions that require problem-solving where students felt challenged and used multiple strategies (e.g., logic, guess and check).

Table 3. Proportions of Student and Teacher Questions in MCLEs and non-MCLEs

	Teacher Questions		Student Question	
	MCLE mean (SD)	non-MCLE mean (SD)	MCLE mean (SD)	non-MCLE mean (SD)
No. of questions/ lesson	39.2 (5)	30.3(8.5)	12.8 (7.3)	16.5 (6.8))
EMMR	23.8 (10.4) *	1.3 (2.1)	25.8 (24.1) *	0.06 (1.6)
GIPF	27.2 (12.7) *	50.7 (16)	19.4 (13.5)	38.9 (17.8)
SIPF	0.4 (0.97) *	5.9 (5.8)	6.2 (13.4)	11.6 (18)
PET	18.7 (16.2)	6.4 (5.2)	18.5 (14.1)	23.5 (15.8)
PSWP	29.6 (15.7)	35.6 (19.2)	23.4 (14.4)	22.4 (14.8)
IT	0.38 (0.9)	0.0 (0.0)	6.7 (10.3)	3.02 (5.7)

Note: *Reflects a statistically significant difference (alpha < .05)

Shifts in Types of Student Questions

Similar to teachers, students also asked a higher proportion of exploring the mathematical meaning and reasoning (EMMR) questions in MCLEs (M=25.8, SD =24.1) in comparison to non-MCLE lessons (M=0.06, SD=1.6), and this difference was significant (*t* (5) =2.6, *p*=0.048). In contrast, the proportion of student recall questions (GIPF and SIPF, combined) in non-MCLEs (M=50.6, SD=31) was nearly twice that of MCLEs (M=25.6, SD=19.5). However, this difference was not significant (*t* (5) = - 1.8, *p*=0.14).

Discussion

We are encouraged to find that when teachers design lessons as MCLEs, it also results in a richer and wider variety of teacher and student questions during enacted lessons. This unexpected benefit of designing lessons with the mathematical story framework raises new questions for mathematics teacher education; namely, rather than training teachers what types of questions to ask during instruction, might it be better to prepare teachers to design lessons that encourage student curiosity and inquiry? We suspect that the teachers' intentional focus on how and when to enable certain mathematical ideas to emerge throughout a lesson in order to spur student curiosity and inquiry in MCLEs likely supported both teachers and students asking a rich and wide variety of questions.

Across all our lessons, we note the lack of *linking and applying* and *extended thinking type* questions in both types of lessons. This finding is supported by other studies (e.g., Kosko, Rougee & Herbst, 2014) where secondary school teachers did not include these types of questions in their planned lessons. One possibility is that the data of this study did not include any consecutive lessons, so therefore these question types did not appear in these lessons. The reason for non-significant differences in question types, such as teachers' *probing* questions, was likely due to the limited number of lessons in our study. Future research is needed to better understand the impact of designing lessons using a mathematical story framework on teacher and student questioning during enacted lessons.

SPIN-UPS: HOW TEACHERS SCAFFOLD GROUPWORK WITH WHOLE CLASS PROMPTS AND THE MESSAGES THEY CONTAIN

Erika David Parr
Middle Tennessee State University
eparr@mtsu.edu

Elizabeth B. Dyer
Middle Tennessee State University
edyer@mtsu.edu

Teachers often employ groupwork to actively engage students in mathematical activity. While groups work, teachers may support groups in a number of ways. We extend the metaphor of a "launch" to define a "spin-up" as an instance in which teachers scaffold groupwork with whole class prompting. We examined an AP Calculus AB classroom in which the teacher often used spin-ups for a variety of purposes to support groupwork. We describe our findings from analyzing the occurrence of each spin-up during the lesson, the content of each spin-up instance, and the messaging around each spin-up. These findings help highlight the complex decision-making involved in supporting students' more autonomous work in the classroom.

Keywords: Classroom Discourse, High School Education, Instructional Activities and Practices

As educators seek to involve students in mathematical activity, groupwork has become increasingly important for both researchers and educators (Cohen & Lotan, 2014; Dunleavy, 2015; NCTM, 2018). The groupwork format shifts the responsibility of problem-solving and confirming solutions from the teacher to students. Using groupwork in the classroom creates opportunities for the unpredictable, often requiring teachers to improvise how they build on students' thinking or give feedback to groups. To begin to account for the pedagogical judgments that teachers use and their impacts, researchers have documented the ways in which teachers monitor and decide to intervene in individual groups (Ehrenfeld & Horn, 2020) as well as students' uptake of such scaffolds (van de Pol et al., 2019). Yet, teachers may also choose to provide scaffolds to the entire class, rather than an individual group, during groupwork time.

We refer to such scaffolding as a *spin-up.* We build on the metaphor of a rocket *launch* (Jackson et al., 2012) to describe teachers' work to initiate an activity, and extend this notion to a *spin-up* which stabilizes rockets while in flight to describe teachers' support to stabilize groupwork. This notion of a *spin-up* builds on the practice of monitoring (Stein et al., 2008). Rather than monitor for students' ideas to build on in a discussion to follow groupwork, *spin-ups* are used to support and sustain the continued activity of groups. A spin-up may not only consist of additional content information, it may also convey messages to students about how knowledge is built and their role in that process.

In this brief research report, we describe the preliminary findings from our investigation of one teacher's use of spin-ups and its impact on her class, by answering the following questions: (1) When do spin-ups occur in class during groupwork? (2) What is the content and purpose of each spin-up offered? (3) What messages are conveyed via the teacher's framing of the spin-up?

Theoretical Framing

We consider classroom learning to be a *situated interactional activity* among students and teachers and the content. Effective teaching that centers students is highly improvisational, context-dependent, and responsive to activities that happen within the classroom (Robertson et al., 2017). Especially in the enactment of groupwork, in which students take on a central role, outcomes may be unpredictable. Yet, patterns still exist in these interactions that emerge as routines, which we can characterize and investigate (Horn & Little, 2010).

Within this framing of classroom interaction, we adopt a lens of framing and messaging (Scherr & Hammer, 2009; Russ, 2018) to characterize teachers' use of spin-ups as whole-class scaffolds to support groupwork. Framing and messaging are one dimension of teachers' behavior that impacts student-teacher interaction by communicating to students their roles in the learning process and notions about the content itself. This communication is not direct, but embedded in the routine moves of the teacher and interactional routines the students and teacher negotiate together (Kelly, 2020). Literature on framing and messaging does not attempt to make inferences about teachers' judgements or purposes for enacting instructional moves. Instead, the theoretical lens of framing and messaging recognizes the ways that meaning about "what is happening here?" are socially constructed within classroom interactions among the teacher and students.

Methods

Using a grounded approach (Corbin & Strauss, 2014), we analyzed video and audio recordings of one lesson from an AP Calculus AB teacher, Barbara, from the 2014-2015 academic year. Barbara taught in a racially diverse, high-performing, suburban school. In this school, teachers were beginning to consider access and representation of students who had historically not taken advanced mathematics classes, which Barbara discussed in reference to her AB Calculus students. These data come from a larger study (Dyer, 2016), which investigated 10 high school mathematics teachers aiming to become more attentive and responsive to student thinking in their teaching. The lesson video was captured with several cameras placed around the classroom, and audio recorders placed at the center of desks that were grouped together in the room, and included all five groups of students in the classroom. The content of the lesson was the use of integration to calculate volumes of solids of revolution. Specifically, the students were given a warm-up task, which they worked for the first 15 minutes of the lesson. Then, the students worked on a related task, which was given as "team practice," described in Table 1.

Table 1: Groupwork Tasks Used in Lesson

	Class Time	Task
Warm-up Task	~00:30-15:00	1. Make a sketch of the region bounded by y=2x+4, y=4, and x=5. 2. Rotate this region around the line, y=4. What shape have you formed? What is the formula you learned in Geometry to find its volume? 3. Use the formula from #2 to calculate the volume of this solid. 4. Use calculus to find this same volume.
Team Practice	~16:00-42:00	Find the volume for each solid of revolution described below: 1. Region created by y-axis, x-axis, y=sin(x)+1 and x=3pi/2, revolved around x-axis (three more solids of revolution are given)

We first used *Datavyu* software to code the activity formats used in the lesson according to the codes: launch, content discussion, groupwork, and other for unstructured time. Portions of the lesson were coded as content discussion when the teacher addressed the class as a whole regarding content, for a duration longer than twenty seconds. From our analysis, a notion of spin-up emerged as we attempted to classify the teacher's interaction with the class as students worked in groups. We classified an instance of teacher intervention as a spin-up when she offered a supporting statement, question, or direction to the class as a whole, meant to sustain the activity of students in groups. We then coded instances of spin-ups by marking the beginning of the spin-up. Through a process of open and axial coding (Corbin & Strauss, 2014) to analyze the content of the spin-ups, we developed definitions of six types of spin-ups. Finally, we began a preliminary analysis of messages embedded in the framing of each spin-up according to three dimensions: epistemic, social, and disciplinary framing. Throughout this process, we listened to the audio recordings of each group the teacher interacted with before and after each spin-up to better contextualize the spin-up, alongside the videos.

Results

We identified 12 instances of spin-ups in the calculus lesson that we analyzed. The time series in Figure 1 shows the occurrence of each spin-up as a blue asterisk overlayed on the varied types of activity formats used in the lesson. The official lesson ran for approximately 42 minutes of the video recording, and three different activity formats were used in the lesson: launches (l), content discussions (cd), and groupwork (g). Unstructured time at the end of the lesson was coded as other (o). The density and spacing of the spin-ups in the lesson provide more insight into how the teacher made use of them. Nine of the twelve spin-ups occurred in the first fifteen minutes of the lesson, when students worked on the warm-up task and were given in closer proximity the earlier in the lesson they occurred. Furthermore, the first six spin-ups occurred in very close proximity to each other, within a four-minute window, shown in portion of the time series magnified in Figure 1. Only three of the spin-ups were given in the portion of the lesson when students worked the team practice tasks. Additionally, four of the spin-ups led to content discussions, shown in green on the time series, which also became increasingly spread apart as the lesson progressed.

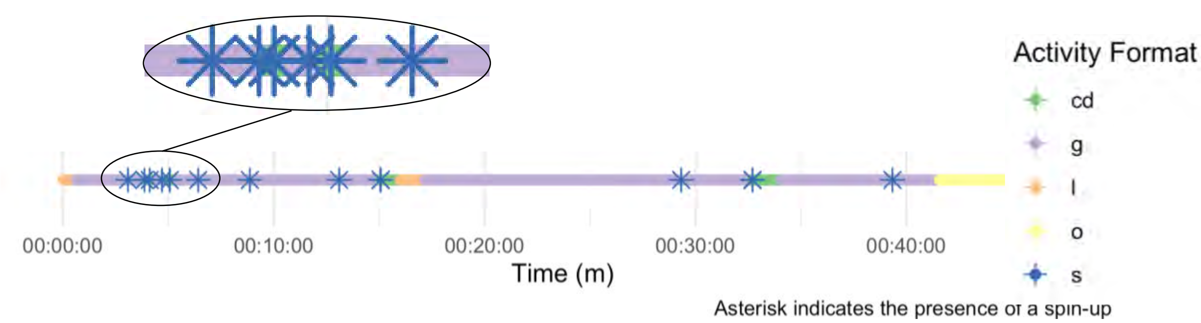

Figure 1: Time Series of Lesson's Activity Formats and Instances of Spin-ups

To better understand the messaging contained in the spin-ups, we first analyzed the content of each spin-up Barbara offered. We developed codes to classify the spin-ups according to their content and purpose and found six distinct purposes to the spin-ups, shown in Table 2. These purposes are: restating a question, referencing previous work, offering a method to check a solution, giving a directive, asking for a status check, and offering content information. We note that a single spin-up may be classified as multiple types, as it may contain multiple statements with distinct purposes given in the same talk turn of the teacher. The six distinct types of spin-ups center students, support students' group activity, and frame mathematics in strategic ways through the messages they contain. Analyzing the content and type of spin-up through a framing lens revealed three categories of messages: (1) framing students as epistemic authorities, (2) framing learning as social, and (3) framing the discipline as coherent and cohesive.

Table 2: Six Types of Spin-Ups Identified in this Lesson

	Spin-Up Type	Definition	Example (Instance #)	Instances
1	Restate a Question	The teacher restates a question asked by a student	Restating a question that a student asked the teacher in his group: “I don’t know, *is* the radius $2x+4$?” (#1)	1, 2, 5
2	Reference Previous Work	The teacher references previous work as guidance	“Isn’t that the one Megan asked us yesterday?” (#3)	3, 6
3	Offer Method to Check Solution	The teacher suggests a method for students to check their solution	“So [number] 4 is you get the integral…you should get an answer that matches the one you know from Geometry” (#7)	7, 8
4	Give Directive	The teacher directs students to do a specific step of the task	“Do me a favor, make a little 10-second sketch of the revolution…” (#4)	4, 7, 8, 12
5	Status Check	The teacher asks about or provides expectation of student progress through tasks	“What’s the consensus on the radius?... So, make sure you have someone in your team can convince why the radius is $2x$” (#6)	6, 9, 10
6	Offer Content Information	The teacher provides mathematical information	“What’s 2x+4 measuring? The height to the axis, right? …The 2x+4 is this height” (#5)	5, 11

The messaging in spin-up types 1-4 frame students as owners of their mathematical activity, communicating to students that they are central to the knowledge-building process. Restating a question (type 1) to the whole class amplifies an individual student’s thinking, and gives groups the chance to hear others’ thoughts beyond those of their own group. Referencing previous work (type 2), offering a method to check a solution (type 3), and giving a directive (type 4) all serve to give students a path forward without directly giving content knowledge. Some spin-ups contained messages that framed learning as social. For instance, in Spin-up 6, Barbara asked students to make sure someone in their team could convince them why the radius was $2x$. The message embedded in this spin-up is that students can and ought to rely on each other for knowledge building. Finally, some spin-ups framed the discipline of mathematics in a particular way. For instance, by referencing previous work, Barbara sent the message that the current content (volumes of solids) was directly related to other topics and tasks (area between curves), framing mathematics as cohesive and coherent.

Discussion

The findings of this study further characterize how teachers orchestrate group work and whole class activity. With the use of spin-ups, Barbara supported her class with various scaffolds to advance groups’ activity while also signaling about students’ roles in learning, supporting each other, and mathematics as a discipline to the class as a whole. Future work in this study will follow each groups’ activity throughout the lesson, note instances in which a teacher scaffolds a group without using a spin-up (not speaking to whole class), the content and messaging of these scaffolds, and what precedes each intervention type for any discernable patterns. More broadly, future research into the messaging of spin-ups in mathematics classrooms may analyze connections between such messaging and larger discourses and ideologies, such as those researchers have identified in other settings (Louie, 2018; Louie et al., 2021; Philip et al., 2018).

A FRAMEWORK FOR ANALYZING THE USE OF LANGUAGE IN UNDERGRADUATE MATHEMATICS

Ernesto D. Calleros
San Diego State University
ernestocalleros@gmail.com

Keywords: Classroom Discourse; Undergraduate Education; Equity, Inclusion, and Diversity

While there is a common notion that mathematics is a universal language, on closer examination we find that doing mathematics also involves engaging in mathematical practices that require sophisticated uses of language (Moschkovich, 2002). For instance, the authors of the Common Core State Standards for Mathematics state that students should "communicate precisely with others… using clear definitions in discussion" (NGACBP & CCSSO, 2010, p. 7). The issues related to language and mathematics have received less attention at the undergraduate level, though some research has considered the linguistic demand of undergraduate mathematics (Barton et al., 2005; Cornu, 1981; Kaplan, Fisher, & Rogness, 2009; Lavy & Mashiach-Eizenberg, 2009; Parker, 2011; Tall, 1993). Yet, much of this work focuses on "language as a problem" rather than as a resource (Planas, 2018; Ruiz, 1984). These observations warrant a careful analysis of the ways teachers and students use language in undergraduate mathematics classes. To pave the way for this analysis, this poster develops a conceptual framework of language use in undergraduate mathematics.

Drawing primarily on a situated sociocultural theory of learning (Moschkovich, 2015), the proposed framework is organized based on the use of several language components (and their relationships). I briefly elaborate on four such components: lexical ambiguity, students' linguistic resources, multiple-semiotic systems, and mathematical practices. *Lexical ambiguity* highlights that certain words may share the same form but have different (and sometimes even conflicting) meanings within and outside mathematics, whereas other words may have two or more different but related meanings (e.g., Kaplan, Fisher, & Rogness, 2009). For example, I have seen linear algebra students use everyday meanings of dependence (e.g., reliance on something or someone) to make sense of linear dependence as a relationship. Related to this component is the use of *students' linguistic resources*: Not only is it important to build on the students' everyday understandings in the language of instruction (e.g., English in most US undergraduate mathematics classrooms), but also on their understanding in their additional language(s) (Erath et al., 2021). *Multiple semiotic systems* is the use of three interrelated mathematical language systems (natural language, visual displays, and symbol system), each with different affordances and limitations (O'Halloran, 2000). For example, when teaching linear independence in linear algebra, a teacher might describe a linearly independent set of vectors in terms of a world problem context as well as using a graph or a vector equation. By doing this, the teacher could engage students in connecting multiple representations -- one important *mathematical practice.*

For researchers, this framework could function as an organizing tool for analyzing uses of language and refining a theory on language use. It could also be used to design professional development or student support workshops that promote intentional and strategic language use. This could increase multilingual students' access to mathematics and ultimately promote equity.

HOW LANGUAGE SWITCHING FACILITATES FOLDING BACK TO COLLECT

Sitaniselao Stan Manu
University of the Fraser Valley
Stan.Manu@ufv.ca

My ongoing interest in researching the role of 'language switching' – described by Baker (1993) as the way bilingual individuals alternate between two languages, whether in words, phrases or sentences[1] – dates back to my mathematics and bilingual upbringing in Tonga, a small island country in the South Pacific. This study focuses on Tongan bilingual teachers in a mathematics classroom setting and explores the connection between their use of *language switching* and *folding back to collect* – a form of 'thickening' students' mathematical understanding by recalling, accessing and collecting their prior or existing knowledge. The contention here is that if interventions for the purpose of folding back ought to be intentional, explicit or stimulating, then language switching could be a powerful way to invoke or facilitate folding back to collect in bilingual situations. This study further articulates an adaptation into the bilingual domain of the theoretical foundation, the Pirie-Kieren or P-K Theory (1994), which has been presented and discussed previously at a number of PME meetings (Martin, 2008).

Folding back, a central key construct of the P-K Theory, occurs when a learner is faced with a challenge, one that is not immediately solvable, and he or she is prompted to return to an inner mode of understanding in order to reconstruct, and to extend his or her currently inadequate inner-layer understanding (Pirie & Martin, 2000). In a classroom situation, teacher interventions are sometimes required to stimulate the process of re-collection and especially important in its ability to *invoke* folding back to collect by *facilitating* a learner's awareness of what he or she already knows and the recognition of the need to fold back and collect a relevant piece of information whenever he or she is confronted with a mathematical obstacle (Martin, 2008). If and when this process is initiated or engaged through language switching within a bilingual setting, the choice of which language is more accessible or appropriate becomes quite potentially significant to the 'thickening' effect of one's mathematical understanding (Manu, 2005).

This study is based on video recordings, followed up with interviews, of two experienced bilingual mathematics teachers within one high school in Tonga during the second half of the 2019. Two excerpts were highlighted to explicate some of the ways in which Tongan-type bilingual teachers use language switching to facilitate students in *folding back to collect* from prior knowledge or from existing understanding. The first shows the role of a teacher in choosing her first or native language and also the 'thickening' effect of folding back that engaged the students to return to a more specific and local understanding at an inner layer in order to support and extend their understanding at the outer layer. The second illustrates how a teacher and her students both used *substitution* and *borrowing* of equivalent and non-equivalent mathematical words as forms of language switching to facilitate their existing or prior knowledge.

In short, this study finds that when the instructional transition moves from one language to another, the continued learning relies upon *what the students already know*, including their knowledge of, and proficiency in, both languages. This inner layer knowing is significant and easily receptive whenever 'collecting' is initiated or called upon. It supports both the use of the students' first language and the view that effective instruction involves identifying clues that can help students draw upon both their entire linguistic repertoire and their *primitive knowing*.

Note

[1] Manu (2020) discusses further the flip-flop nature of 'language switching' and its relation to *translanguaging*.

THE EVOLUTION OF ROUTINE TASKS IN THE COLLECTIVE

Geneviève Barabé
Université du Québec à Montréal
Barabe.Genevieve@courrier.uqam.ca

Keywords: Problem solving, problem-based learning, instructional activities and practices

Which fraction is represented by this drawing? Can you believe that this task led to a deep mathematical investigation of about fifty minutes in a Grade 6 classroom (Proulx & al., 2019)? While it is recognized that teachers play an important role regarding the students' mathematical activity, numerous research on problem-solving has focussed on what could be "good problems" for the mathematics classroom (Hoshino & al., 2016; English & Gainsburg, 2015). However, some experiences that I had shown myself that routine tasks have the potential to become good problems through the mathematical interactions in the classroom. Could the notion of "good problems" be more complex than what it appears at a first glance? Could it be broadened? Does the problem in itself play such an important role? These concerns can find echo in Beghetto's work (2017) on lesson unplanning, and in Mason's (2019) work where he states that "it is not the task that is rich, but whether the task is used richly" (p. 146).

In this regard, in this poster presentation, I propose a theoretical framework to study the evolution of routine tasks through the mathematical activity of the classroom. This framework is built from enaction theory (e.g., Maturana & Varela, 1992), a biological cognition theory, and from works being conducted in the "teaching of mathematics *via* problem-solving" area of research (e.g., Borasi, 1996; Lampert, 2001). A particularity of the proposed framework is to consider the classroom as a collective entity, a collectivity, who bring forth a mathematical activity together; meaning that the classroom is the unit of study. The framework allows to study the nature of the evolution of the task through the mathematical practices that are put forth to solve it. The nature of the evolution of the task is also characterized as implicit or explicit: the implicit evolution referring to the evolution of the task through the steps being posed to solve it, and the explicit evolution to new mathematical (sub)tasks that emerge from the collective mathematical activity and on which the collectivity tries to solve. In this poster presentation, examples are given to illustrate the proposed framework that studies the evolution of routine tasks in the collective mathematical activity that takes place.

Keywords: Systemic Change; Equity, Inclusion, and Diversity; Instructional Activities and Practices

In a systematic review of the literature, we find that the concept of ambitious mathematics teaching (AMT) has evolved over the past two decades. This poster summarizes this evolution and considers implications for teacher educators and researchers. Early descriptions of AMT (which did not use the term ambitious as it is used currently) focused on aligning teaching and learning in school mathematics with disciplinary practices (Lampert, 1990).Teachers facilitate student engagement in problem solving activity and discussion. This "ambitious" vision was contrasted with "traditional" math classes. The disciplinary practice vision of AMT permeates standards documents and associated guidance (NCTM, 2014), and some recent research equates standards-aligned teaching and AMT (e.g., Coburn et al., 2012; Litke, 2020).

Since the introduction of AMT into the research lexicon, mathematics educators have investigated how to make this vision a reality in multiple settings with a diverse array of teachers. Currently, several related constructs appear in the literature alongside AMT, including classroom discourse, tasks, teacher noticing, and equity. Classroom discourse is connected to AMT because student engagement in disciplinary practices often requires a teacher to skillfully solicit verbal and/or written contributions by students (Chapin et al., 2009; Hufferd-Ackles et al., 2004). Using instructional tasks with higher levels of cognitive demand can support student engagement in classes characterized by AMT (Boston & Candela, 2018; Tekkumru-Kisa et al., 2020). But, in order to facilitate discussions of such high cognitive demand tasks, teachers must notice (Jacobs et al., 2010) and build on student ideas (e.g., van Es et al., 2017). Finally, equity has grown as a central area of focus in the body of research concerned with AMT. Early conceptualizations of equity in research on AMT focused on the extent to which discipline aligned learning was available to "all students" (Lampert & Graziani, 2009) or in schools serving students from minoritized communities (Boaler & Staples, 2008; Jackson & Cobb, 2010). More recently, mathematics educators have focused on articulating how a more specific equity stance toward minoritized students (e.g. building on students' funds of knowledge) is integral to learning to engage in AMT (Kinser-Traut & Turner, 2020).

For teacher educators, one implication of this shift is that while the original vision for and definition of AMT remains viable, the field is expanding this concept to address multiple overlapping concerns that arise in teacher education including (equity, teacher development, and supporting a shared vision across contexts). For mathematics education researchers, the evolving definition of AMT implies we should be careful to specify what aspects of AMT are the focus of each investigation and how the definition matches prior research and each study's conceptual framework.

Keywords: Classroom Discourse; High School Education; Instructional Activities and Practices; Problem-Based Learning

There has been a push towards increasing student-centered learning within mathematics classrooms (NCTM, 2000; 2014; NGA & CCSSO, 2010), which has been shown to improve both mathematics achievement and overall attitudes (Zarkaria et al., 2010). Student presentations of their mathematical work allow teachers to build on student thinking to optimize learning for the class as a whole. The presentation of student work can sometimes give rise to errors. Rather than these instances being avoided or dismissed, presentations of incomplete or incorrect student work can be opportunities for pivotal teaching moments (Stockero & van Zoest, 2013; van Zoest et al., 2017). When teachers discuss and build upon incomplete or incorrect student work, they may do so in a variety of ways. Previous studies have documented how teachers may build on incorrect student thinking (van Zoest et al., 2017) and authority relations among teachers and students during class presentations (Byun et al., 2020). In this study, we detail how teachers and students interact when incorrect mathematics is presented to better understand this particular aspect of teaching practice. Our study investigates the question: How do students and teachers interact when students present incorrect or incomplete mathematics in secondary classrooms?

To answer this question, we analyzed video of nine 100-minute lessons that contained student presentations, three each from three secondary mathematics classrooms. With the use of *Datavyu* software, we first coded the various activity formats used within these lessons to identify instances of student presentations. We closely analyzed these specific episodes to capture the variety in student-teacher interactions when incorrect mathematics was presented. Through a process of open and axial coding (Corbin & Strauss, 2014), we analyzed relevant aspects of student-teacher interactions within these episodes.

We found three distinct ways in which the teachers brought other students into the conversation. These other students advanced the presentation in different ways. One way involved the teacher restating other students' comments or questions to include them in the discussion. A second way that teachers involved other students was to ask the class follow-up questions in order to fill in the gaps throughout the presentations. In the third way, teachers invited other students to help the presenter, even allowing the presenter to choose which student supported them.

A REVIEW OF A FUNCTION-BASED APPROACH TO ALGEBRA AT THE SECONDARY SCHOOL LEVEL

Sheree Sharpe
University of New Hampshire
sheree.sharpe@unh.edu

Keywords: Algebra, Secondary School Education, Systematic Review

The purpose of this study is to conduct a systematic review of the empirical studies that explore a function-based approach to algebra at the secondary school level. The author reports on the various ways this approach has been implemented: the types of teaching experiments used, the types of technology used, and the study's outcome. As reported in the *Common Core State Standards for Mathematics* and by the U.S. Department of Education, school algebra is foundational to mathematics in grades K to 12 (NGA & CCSSO, 2010; U.S. Department of Education, 2008). All students should have the opportunity to be successful in school mathematics (NCTM, 2000), and consequentially be successful at school algebra. Thorpe (1990) argues that "functions should form the backbone of a first course in algebra" (p. 17). A function-based approach to algebra is defined as "an approach that assumes the function to be a central concept around which school algebra curriculum can be meaningfully organized" (Yerushalmy, 2000, p. 125).

Methods

A systematic review provides a means to aggregate, interpret, explain, or integrate related existing research on a topic over a period to describe the trends in that topic (Xiao & Watson, 2017). In this study, a systematic review was conducted to examine each included study's teaching experiment, use of technology, and outcome to investigate for secondary students under what conditions a function-based approach to algebra was implemented. The data collection occurred in two steps: screening and inclusion (which includes searching the literature) and coding of studies. The inclusion criteria for this systematic review were as follows: only empirical studies: (i) with primary student data; (ii) explore the use of functions to teach algebra; (iii) the unit of analysis is students in grades 6 to 12; and (iv) reported in English.

Discussion

The studies in this analysis varied across the type of publication, the decade of publication, the vicinity where the study was implemented, the research approach, the methods for data collection, the grade level, the sample size, and the algebra level. This systematic review showed that technology, that is, some type of graphing tool, seems to play an important role for successfully introducing a function-based approach to algebra with secondary school students. Also, the outcomes seem to indicate that a function-based approach to algebra has been effective in developing secondary students' understanding of variables, functions, problem solving strategies, use of multiple representation, and algebra, across the years. Therefore, given the difficulties students experience when transitioning from learning arithmetic to learning algebra (Sharpe, 2019), a function-based approach to algebra instruction may improve the educational foundation students need for the transition to learning algebra.

Public records of student contributions are a common resource mathematics teachers use to make student thinking accessible in whole class discussions. Studies have implicitly addressed the use of public records in whole class discussions, such as to scaffold students' engagement with each other's ideas (e.g., Webb et al., 2014), but the detailed nature of how teachers use public records is largely unknown. Our research on whole class discussions that leverage student thinking (Van Zoest et al., 2016) surfaced the ways teachers regularly used public records throughout such discussions. In our work, we consider public records of student mathematical thinking to be physical and visual representations of student mathematics that are accessible to all participants within a classroom. This poster will present findings from our analysis of 12 secondary teachers' *explicit referencing* of public records. Our analysis focused on how referencing helped teachers to build on student thinking throughout whole class discussions.

Explicit referencing is a teacher's physical or verbal actions or combination of actions that draws attention to the public record or a portion of the public record. Physical actions include gestures towards specific or general parts of the public record; verbal actions include words that draw attention to the public record in some way (e.g., naming student thinking, using locator words). Early in the discussions, explicit referencing is needed to make a student contribution an object so that there is no ambiguity regarding the contribution as a discussion develops around it. Additionally, explicit referencing can focus and engage the class with specific mathematical ideas of the student's contribution. As discussions continue, explicit references to additions or edits of the public record help the class to identify and coordinate the mathematical ideas emerging in the conversation.

ELEMENTARY PRESERVICE TEACHERS INTEGRATING MULTICULTURAL LITERATURE TO DESIGN CULTURALLY RELEVANT MATHEMATICAL TASKS

Alesia Mickle Moldavan
Fordham University
amoldavan@fordham.edu

Dittika Gupta
Midwestern State University
dittika.gupta@msutexas.edu

Keywords: Preservice Teacher Education, Instructional Activities and Practices, Culturally Relevant Pedagogy

Teaching with a commitment to culturally relevant pedagogy recognizes the need for preservice teachers (PTs) to have structured learning opportunities to explore culture in the context of mathematics pedagogy and content. For PTs to engage in such practice, PTs must have mathematics methods courses that enable them to learn about and build on the cultural assets and identities that students bring to the classroom (Association of Mathematics Teacher Educators, 2017; Ladson-Billings, 1995). One way to recognize culture in mathematical studies is by integrating multicultural children's literature to make connections between mathematics and students' cultural experiences (Mendoza & Reese, 2001). Research suggests that such texts can be essential resources to situate story problems and encourage reflection in terms of mathematical identity, cultural competence, and critical consciousness (Chappell & Thompson, 2000; Harding et al., 2017; Iwai, 2013; Leonard et al., 2014; Moldavan, 2020). Motivated by the need to further explore how PTs might work with multicultural literature in a digital context, the researchers designed an instructional activity during a mathematics methods course to get PTs working with such texts in conjunction with mathematical tasks. In this study, we examine the following research question: What are elementary PTs' experiences integrating multicultural literature with mathematical concepts to design culturally relevant mathematical tasks?

Research Design

We used a qualitative case study design conducted in an online elementary mathematics methods course. The PTs engaged in an instructional activity facilitated by the researchers that modeled culturally relevant mathematical tasks using multicultural literature to teach mathematical concepts. Following the activity, the PTs worked in groups to design similar tasks using multicultural texts of their choosing. Accompanying the tasks, the PTs submitted reflections on how the tasks used the texts to portray cultural awareness and elicit culturally relevant mathematical thinking. Data also included survey responses comparing the PTs' experiences integrating such texts into their tasks before and after their participation in the instructional activity. The collected tasks, anecdotal notes, reflections, and survey responses were analyzed using open coding to discern emerging themes (Grbich, 2013; Saldaña, 2016).

Summary of Findings

We report on the PTs' experiences using multicultural literature to make connections to mathematical concepts for purposes of designing culturally relevant mathematical tasks. We note two themes that emerged from the data. The first theme addresses the PTs' growth in awareness of and confidence in using multicultural texts to explore mathematical concepts. The PTs described how various texts were used to create a cultural context that prompted reflection and appreciation for cultural diversity. The second theme looks at how the tasks elicited culturally relevant mathematical thinking with targeted concepts (e.g., multiplication, geometry, patterns). Recommendations are made for how others can build on this work in mathematics education.

INSTRUCTORS' MODIFICATIONS OF ANALYSIS PROOFS INTO PEDAGOGICAL PROOFS

David Varner
Central Michigan University
varne1d@cmich.edu

Katrina Piatek-Jimenez
Central Michigan University
k.p.j@cmich.edu

Keywords: Reasoning and Proof, Undergraduate Education, Advanced Mathematical Thinking

Despite the fact that mathematical proofs are central to the field of mathematics, proofs are difficult for many undergraduate students to understand (Almeida, 2000; CadwalladerOlsker, 2011; Hanna, 1990; Hersh, 1993; Mills, 2011; Weber & Mejia-Ramos, 2014). Given the significant role that proofs play in the field of mathematics, we believe that it is critical to investigate ways to improve the teaching and learning of mathematical proof at the undergraduate level. The work described in this paper is part of a larger study and focuses on how mathematics professors modify proofs in order to make them more understandable to undergraduate students.

Using the framework of communities of practice (Lave & Wenger, 1991; Wenger, 1998), we view mathematicians as forming their own community of practice, and through participation in community activities, mathematicians reify ideas and experiences into physical artifacts such as textbooks, journal articles, lecture notes, and solutions to problems. Proofs are the most prolific of these objects, being used in nearly every mathematical task that a mathematician performs. Mathematics students are peripheral members of the community, similar to apprentices, who are given small tasks that simulate parts of the practice within the community. When reading a proof in a textbook or written by a professor, students can see the way a mathematician thinks about the task of proving a theorem, and thus learn more about theorems and proofs, in general.

Since students spend a significant amount of time reading proofs, it is important to study how those proofs are modified for presentation to students. A prior study (Lai et al., 2012) asked several instructors to modify two proofs to improve student understanding and then invited 110 mathematicians to provide feedback on the original and modified proofs. Lai and colleagues found that the mathematics community agreed that the changes the professors made to the proofs should improve student understanding of those proofs. One goal of our study is to better understand how instructors modify textbook proofs in real analysis to make them clearer to undergraduate students. While similar to the work of Lai et al. (2012), our study has significant differences in environment and context.

For this portion of the study, four proofs were selected from undergraduate analysis textbooks. These proofs were then given to three mathematics faculty members at a given university in the Midwest, who were asked to modify the proofs over the course of a week to make them more understandable to students. These modified proofs were coded based on the codes developed in Lai et al. (2012). Then, each faculty participant engaged in a 90-minute interview. These interviews were recorded, transcribed, and coded inductively using an open coding method (Corbin & Strauss, 2014).

Thorough results will be discussed during the presentation. However, initial findings suggest that faculty participants chose to add significant portions to the proofs, often turning proofs that were originally 5 lines into a page-long proof. The most common addition to the proofs was to follow symbol-heavy sentences with a colloquial English explanation. It was also common to add sentences that draw the readers' attention to the goals of small parts of the proofs, such as explicitly stating that they were proving the injective or surjective part of a bijective theorem.

IMPLICATIONS OF THE UNSTANDARDIZED NATURE OF STANDARDS-BASED GRADING IN MIDDLE SCHOOL MATHEMATICS CLASSROOMS

Michelle King
Western Colorado University
MMKing@western.edu

Keywords: Instructional Activities and Practices, Standards

In recent years, there has been movement towards implementing an alternative to traditional grading practices called standards-based grading (e.g., Vatterott, 2015). Critics of traditional grading practices claimed that such practices focus too much attention on rote memorization and procedural skills (Gentile & Lalley, 2003). In contrast, advocates of standards-based grading argued argue that grades are determined "by the complexity of tasks and the level of mastery of higher-level thinking skills that students can attain" (Vatterott, 2015, p. 28).

Research Design

Currently, there is a lack of qualitative research focused on implementation of standards-based grading (Brodersen & Randel, 2017). Using a multicase study design (Stake, 2006), this research study sought to fill this gap by focusing on implementation of standards-based grading practices within middle school mathematics classrooms. Data collection consisted of a combination of interviews and classroom observations. The data were analyzed at the both the case and cross-case levels for themes related to the purpose of this study. Peer examination and member checking where among the strategies used to ensure increased trustworthiness and rigor.

Results and Discussion

Mx. Brown claimed they did not receive "much formal training" and, instead, graded by using their "mental calibration for assigning the scores.". Mx. Johnson "love[d]" standards-based grading. They believed that the practice helped them better target student strengths and weaknesses with respect to students' understanding. They had a general perception of what each score, on a four-point scale, meant; however, the requirements for a score depended on the specific competency they were measuring. Mx. Williams perceived the district rubric as a "loose" description of each level on a four-point scale and there was "no expectation" that teachers use the rubric when determining students' grades. According to Mx. Miller, the overarching purpose of standards-based grading was "to give more specific feedback to students and parents about specific skills on what, where students are proficient or not." When assigning standards-based grades, they considered the whole body of evidence related to a student's work focused on a single learning target based on a one-time-only summative assessment.

While all four teachers used a four-point grading scale to evaluate and grade students, the teachers differed on how they (a) defined and interpreted that grading scale, (b) supported and allowed students to improve their grade, and (c) communicated and calculated the students' grades. These differences greatly influenced to type of mathematical learning opportunities they provided to their students. Furthermore, the discrepancy in grading reduces the possibility of determining the mathematical understanding the students' hold. The evidence suggested the need for improved standards documentation, resource development, and professional development both at the preservice and inservice levels to better achieve the recommendations of the standards-based grading literature.

MAKING 'TALK' A (NON)MATHEMATICAL ACTIVITY

Abhinav Ghosh
Harvard University
abhinavghosh@g.harvard.edu

Jon R. Star
Harvard University
jon_star@gse.harvard.edu

Keywords: Classroom Discourse. Affect, Emotion, Beliefs, and Attitudes. Teacher Beliefs

Utilizing classroom talk and discussion-intensive pedagogies are seen as essential to 'reform-oriented' mathematics instruction (Staples, 2007; Walshaw & Anthony, 2008). However, teachers often struggle to engage and support student participation while facilitating mathematical discussions (O'Connor et al., 2017), despite spontaneous inclinations of many students to casually converse with peers about non-mathematical topics. In this research project, we explore the complex intersection between mathematical talk and classroom norms. Specifically, we seek to understand the following research question – how do teacher messages about norms and behavior complicate student perceptions of talk as a mathematical activity?

We use the distinction between social and sociomathematical norms to animate our argument. While the former involve generally acceptable forms of activity in the classroom, the latter are more specific to mathematical aspects of student activity (Yackel and Cobb, 1996; Yackel et al., 1991). Yackel and Cobb note that students develop their personal perspectives based on the continuous negotiation of these norms with the teacher. Put differently, the kinds of actions permitted in the mathematics classroom influence what students consider as acceptable mathematical activity (Wagner & Herbel-Eisenmann, 2008).

Methodological Notes

We observed video recordings of over 20 mathematics lessons in Algebra I courses from a large high school in Northeastern United States as part of a larger project that investigated teachers' use of discussion in their mathematics teaching (Durkin et al., in press). For this study, we selected three classroom scenes to be presented as vignettes, having analyzed them using a line-by-line coding of their transcripts.

Findings and Implications

In our vignettes, teachers convey discipline-related social norms that prohibit talking in the classroom (Vignette 1), permit talking only if it is relevant to mathematical problem solving (Vignette 2), or permit talking only if supervised by the teacher (Vignette 3). At the same time, the students show a spontaneous tendency to socially interact with each. Though the students are encouraged to talk to each other due to the discussion-oriented nature of these classrooms, the 'talk' is permitted to be only about mathematical topics, and additionally, only under teacher supervision. These scenarios show how teachers create boundaries between mathematical and 'non-mathematical' talk - rendering the former as a special *kind* of talk that is unrelated to the latter. However, this distinction is complicated for students, and we speculate whether the fuzziness of these boundaries makes it difficult for students to switch between these two *kinds* of talk in various situations. As a result, students might possibly begin seeing their spontaneous inclination to converse as a non-mathematical activity – which might subsequently influence their motivations to instinctively participate in mathematical discussions. We call for further explorations of how teachers distinguish mathematical and non-mathematical talk, how students perceive social norms in talk-centered mathematics classrooms, and how the facilitation of mathematical discussions conflict with teacher beliefs about discipline and order.

USING PROCESS MINING TO ANALYZE TEACHER-STUDENT INTERACTION

Kathleen Melhuish
Texas State University
melhuish@txstate.du

Christina Koehne
SUNY New Paltz
koehnec@newpaltz.edu

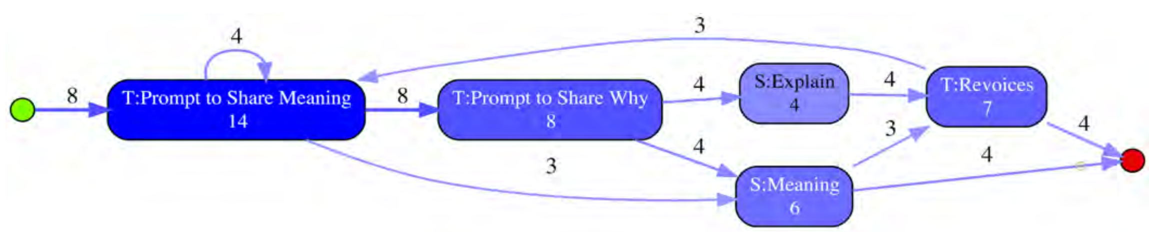
Brittney Ellis
Portland State University
bme3@pdx.edu

Keywords: Research Methods, Classroom Discourse

Prevalent mathematics classroom observation tools do not currently capture "interactive nature of leading discussions—the timing of teaching moves is not always considered, and teacher actions and student actions are often coded separately so that teaching moves are not always linked with specific student responses" (Jacobs & Spangler, 2017, p. 784). In this poster, we share some of our exploratory work adapting process mining (Van der Aalst, 2012) into the educational context to address this need.

Underlying our project is the assumption that the classroom is a social system where the learning of mathematics depends on interactions between teacher, students, and content. The data analyzed in this report stems from a larger project analyzing student-teacher activity in the mathematics classroom (Melhuish, et al., 2020). We analyzed lessons from 31 middle school teachers from a large, urban school district in the Southwest United States. Each lesson was coded for: *teacher moves* that can serve to engender students in rich mathematics and *student contributions* reflecting standards-based mathematical practices (National Governors Association Center for Best Practices) along with corresponding time stamps to create an *event log*.

Educational process mining (EPM) "uses log data gathered specifically from educational environments in order to discover, analyze, and provide a visual representation of the complete educational process" (Bogarín, et al., 2018, p.1). The techniques involve analyzing logs of events (*activities*, *timestamp,* and other information such as actor or resource) to capture the most frequent events and paths. See Figure 1 for an example of a process (along with frequencies) mined from our data.



In this poster, we will share several common processes and illustrate how this research methodology has the potential to provide unique insights into classroom discourse analysis by unearthing processes beyond the traditional Initiate-Respond-Evaluate/Feedback patterns (Cazden, 2001).

IN-SERVICE TEACHERS' PERCEPTIONS ABOUT VIRTUAL COLLABORATION IN MATHEMATICS CLASSROOMS: CHALLENGES AND POSSIBILITIES

K-12 instruction took a drastic turn during the global pandemic in early 2020. As the pandemic continued, questions arose about the affordances and constraints of virtual mathematics instruction (Carius, 2020; Iuvinale, 2020; Khirwadkar et al., 2020; Mulenga & Marbán, 2020; Reimers et al., 2020) on how to provide continued instruction and maintain best teaching practices in a virtual environment. We aimed to learn about mathematics teachers' experiences planning for, designing and implementing lesson plans to allow student collaboration. Our research question is: *How can in-service mathematics teachers be supported to foster virtual collaboration in their mathematics classrooms?*

To answer the research question, we used a teacher engagement, challenge, & opportunities for learning framework (Rahman, 2018). The framework allows for analysis of teachers' learning opportunities emerging from challenges they face while planning, implementing, collaborating and reflecting about their teaching practice. In this study, two middle school and one high school teacher from a professional learning community worked together on a Desmos activity focusing on transformations and then prepared a shared document that explained their thinking. Data consisted of (a) video recording(s) of the teachers' engagement with online mathematics collaboration and their reflections on their experience especially describing the challenges they would face, (b) their lesson plans for implementing this activity, and (c) one teacher's reflection on actual implementation of their lesson. We used open coding (Strauss & Corbin, 1998) to analyze the data to learn about the teachers' experience.

The teachers first developed group norms and communicated that these norms were different for them (as compared to students), because they were adults; they had their cameras on and so used hand gestures to communicate. During the task itself, the high school teacher took the lead in explaining their understanding of the task and all three teachers worked together in developing the final document. In terms of connecting their collaborative experience to their own classrooms and their students, the teachers expressed several possibilities as well as perceived challenges: the benefits of a collaborative space to encourage student communication, the importance of helping students develop group norms or assigning roles to help them collaborate, the ability to monitor student work simultaneously, the challenge of not being able to send students to breakout rooms due to district policies, providing explicit directions to the students, and assisting students with technology tasks like taking a screenshot.

A real challenge emerged when one teacher designed and implemented a lesson in their classroom. The students did not have their cameras on (as per district policies teachers are not allowed to ask the students to turn their cameras on) and the teacher could not see student reactions and get a sense of any challenges they were experiencing. Findings show there are possible benefits for virtual collaboration as implemented in K-12 classrooms. More research is needed to learn about perceived and experienced teacher challenges to design effective tasks.

In examining interactions in an online environment, we utilize Moore's (1989) framework in which he outlined three types of interactions. In his work, he purports that to determine appropriate levels of interactions for effective learning, it is first important to be able to classify the types of interactions taking place in distance learning environments. He identified three interaction types: learner-content, learner-instructor, and learner-learner. We add to that, the work of Hillman et al. (1994), who added a fourth interaction, learner-interface.

We received a single video from each of 19 high school mathematics teachers with between six and 34 years of experience, representing seven different school districts. Three levels of coding were applied to the analysis of each video. First, the type of interaction was identified (learner-content, learner-instructor, learner-learner, learner-interface). Then the activity (level 2) within that interaction was coded. Finally, it was noted if technology was used during the activity. The researchers, who are the authors of this paper, met to view a video together, clarify the unit of analysis, and define each of the codes. A unit of analysis was considered a level 2 interaction type. When there was a change in the activity type, that was treated as a new unit to code. A video was coded together and then six videos were assigned to pairs of researchers to determine inter-rater reliability. Agreement on units of analysis was determined (87.1%) and agreement on codes on the units that were in common was calculated (86.7%). Once inter-rater reliability was established, the remainder of the videos were coded by one researcher.

In their online teaching, mathematics teachers are overwhelmingly utilizing learner-instructor interactions (75.97%), which are predominately expository. Of the learning-instructor interactions, 52.14% are expository and 29.91% are explanatory. Overall, 23.38% of the interactions were learners engaging with mathematics content. The majority of the learner-content interactions were students solving a problem (58.33% of learner-content interactions). Instances of problem-solving were observed across all learning types: hybrid classes (n=5), pre-recorded videos (n=10), and synchronous classes (n=6). In addition, we found evidence that teachers provided a few opportunities for their students to conjecture (n=8), confirm their answers (n=4), predict (n=2), and interpret their solutions (n=1). We found no learner-learner interactions of any type across the videos of our 19 participants.

The teachers were facilitating high school mathematics classes across different modalities of online teaching. Seven of the 19 videos were prerecorded (36%) included students in a hybrid setting or synchronous classroom. While there was a high percentage of learner-instructor interactions there were no learner-to-learner interactions observed across all videos. In hybrid and synchronous settings where learners were present with the instructor, typical interaction occurred between the teacher and the students. Could this be because of Covid-19 which requires social distancing among in-person students? Although, we noticed it also when students were remote. We may want to provide additional professional development to teachers, particularly those teaching online, about ways they can engage students in conversations with each other to support mathematics learning.

SUPPORTING THE CONSTRUCTION OF VARIABLES IN AN INVERSE FUNCTION CONTEXT THROUGH TARGETED QUESTIONS

Keywords: Algebra and Algebraic Thinking, High School Education, Instructional Activities and Practices

While international and U.S. mathematics standards expect secondary students to develop connected meanings of inverse functions (Bergeron & Alcantara, 2015), previous research has found post-secondary students, pre-service teachers, and practicing teachers often struggle to construct these productive meanings (Brown & Reynolds, 2007; Engelke, Oehrtman, & Carlson, 2005; Even, 1992; Lucus, 2005; Paoletti, et. al, 2017; Vidakovic, 1996). In three implementations of a problem-based lesson on inverse functions, we observed the teacher place value on asking students to consider "any value" when learning about inverse functions. After previously solving for a team's fee based on its number of players, students are asked to find the number of players on a team based on its fee. While the students are given a table of values to work with, the teacher asks them to consider "any receipt," "because there might be more receipts than [they] … have" in the table. The teacher continued to ask for a method that works for "any value" throughout the lesson. We connected this idea to the notion of conceptualizing quantities as variables (e.g., Thompson & Carlson, 2017). We present what we have learned about how teachers can support the construction of variables in an inverse function context.

We designed the problem-based lesson in collaboration with a teacher from a large midwestern public high school (Stevens et al., 2020). We then recorded and qualitatively coded three lesson implementations (Corbin & Strauss, 2008). We coded for inverse function conceptions based on the findings of Stevens et al. (2020), and problem statements and questions based on the teacher moves identified by Milewski and Strickland (2020) and our own observations. Next, we created a table that matches the questions and restatements of the problem launch used to get students to consider "any value" with the inverse conceptions expressed by the student the teacher is speaking with. From the results of this table, we believe the teacher selectively asked these questions to students he viewed as holding inadequately generalizable inverse conceptions. We see this as a potential strategy for supporting students to construct the conception of variables in an inverse function context. To learn how teachers view this way of launching an exploration of inverse function, we designed three ways of launching the problem (solving for an unknown value, generalized number, variable). We then asked eight teachers to discuss the alternative launches and to depict the remainder of classroom discussions started with each alternative. Teachers preferred the "any value" generalizable number framing employed by the lesson we studied, citing, for example, the benefit of allowing students "to experiment with concrete scenarios before … discussion of the abstract" concept of inverse.

MATHEMATICS VOCABULARY PRACTICES IN EARLY CHILDHOOD CLASSROOMS

Minnah J. Sabree
minnah.sabree@protonmail.com

Keywords: Instructional Activities and Practices, Early Childhood Education

Mathematics vocabulary plays a key role in the learning and understanding of mathematics concepts and is a critical component of communicating mathematical thinking (Monroe & Panchyshyn, 1995; National Council of Teachers of Mathematics [NCTM], 2000; Olander & Ehmer, 1971). Learning mathematics vocabulary, however, can be challenging. In addition to technical vocabulary with precise meanings (e.g., polynomial), mathematics consists of words from everyday language that have different meanings in mathematical contexts (e.g., plane), as well as symbols (e.g., +) (Capps & Pickreign, 1993; Raiker, 2002; Schell 1982). The majority of research studies on mathematics vocabulary instruction focused on the teaching of general academic vocabulary in the upper grades (Fisher, Blachowicz, & Watts-Taffe, 2011; Scott, Jamieson-Noel, & Asselin, 2003). This study investigated the extent to which mathematics vocabulary instruction occurred in early childhood (Grades K-2) classrooms and the instructional practices teachers utilized. The following research questions were examined: 1) *How is mathematics vocabulary taught to young children during mathematics instruction?* 2) *How often does mathematics vocabulary instruction occur and how many words are taught?*

An observational research design was used to investigate how three teachers from an urban independent school in the northeastern United States taught mathematics vocabulary to their students during mathematics lessons in a summer school program. Each teacher was observed during seven mathematics lessons for the entirety of each lesson, for a total of 21 observations. The lessons were audio recorded, and for each, I also completed an observation protocol, which was utilized to take field notes and dictation of the teachers' vocabulary instruction. Transcripts of the audio recordings as well as the observation protocols were analyzed using a general inductive approach (Cresswell, 2012; Thomas, 2003).

The findings of this study revealed that the three teachers taught 486 mathematics vocabulary words during their mathematics instruction with students during 1,254 episodes of vocabulary instruction. This indicates that some words were taught repeatedly, providing students with multiple exposures to a number of the words. Across the episodes of instruction, the teachers employed three categories of instructional practices, which were explanations, visuals, and demonstrations, which represent forms of direct instruction methods advocated for the teaching of academic vocabulary, including mathematics vocabulary (Flevares & Perry, 2001; Good & Grouws, 1979; Stahl & Fairbanks, 1986; van Oers, 2013). All three teachers employed multiple instructional practices during some episodes of vocabulary instruction.

Absent from the teachers' repertoire of instructional practices were strategies particularly supported for young children's conceptual understanding and building mathematics language, such as utilizing rich discussions and children's literature (Hong, 1996; Schiro, 1996). Teachers can purposefully plan discussions for particular mathematics concepts and the related vocabulary, providing students with explicit vocabulary instruction as they explain the meanings of targeted words, and encourage the use of precise terminology in interactive and meaningful contexts (Carrison & Muir, 2013; Hassinger-Das, Jordan, & Dyson, 2015).

TEACHER CANDIDATES' TEACHING FOR CONCEPTUAL UNDERSTANDING THROUGH THE LENS OF REPRESENTATIONS

Emily C. Elrod
North Carolina State University
ekelrod@ncsu.edu

Keywords: Mathematical Representations; Preservice Teacher Education; Assessment

It has been agreed that conceptual understanding is a key tenet of current mathematics education reform efforts for both prospective and practicing teachers (AMTE, 2017; National Council of Teachers of Mathematics [NCTM], 2014). Utilizing multiple representations within instruction can help develop rich mathematical understandings and flexibility with mathematical structures (Dreher et al., 2016; Stylianou & Silver, 2004). While these practices are certainly supported by recent reform efforts (AMTE, 2017; NCTM, 2000, 2014), the enactment of teaching for conceptual understanding and for flexibility when dealing with representations is not an easy feat, especially for novice teachers (Eisenhart et al., 1993; Lampert et al., 2013).

The purpose of this embedded multiple case study was to investigate the following research question: During mathematics instruction, how do teacher candidates (TCs) implement and reflect on the inclusion of multiple representations in ways that support conceptual understanding? This study's conceptual framework was situated around qualities of teaching mathematics for conceptual understanding (Hiebert & Grouws, 2007; Jansen et al., 2017). The TCs in this study were selected from a stratified random sample of completed edTPA portfolios of recent graduates from elementary and secondary mathematics teacher preparation programs (TPPs) at a large university in the southeastern United States. These TPPs maintain preparing teachers to teach mathematics for conceptual understanding as a key tenet of their program design and delivery.

Document analysis was completed on edTPA artifacts, including written commentary responses, lesson plans, instructional materials, student work samples, and transcripts of video recorded teaching segments. The commentary responses provide evidence regarding TCs' reflection of representation inclusion and conceptual understanding. Through the lens of the study's conceptual framework, data were analyzed utilizing *a priori* coding, along with open coding for recurrent themes. Codes such as explicit connections between symbolic and visual representations, student to student talk, and probing questions were included within the *a priori* codes.

Data analysis suggest that TCs are planning for the inclusion of multiple representations in ways that support conceptual understanding, such as questioning and explicit connections; however, these are not always realized during lesson implementation. Additionally, assessments captured in the edTPA artifacts include opportunities for students to engage with multiple representations and explanations of solution strategies. Cross-case analysis provides evidence to understand how the elementary and secondary cases incorporate representations in ways that support conceptual development. Data support that TCs were able to harness qualities of teaching mathematics for conceptual understanding during a snapshot of their student teaching placement. This study adds to the scholarship around how practices learned within TPPs are realized within TCs' classrooms during student teaching. Much of the current literature is situated around a single grade band (e.g., Jansen et al., 2017; Yang, 2012), thus examining any relationships between TCs from various grade level programs has the potential to inform TPPs' practices.

A TEACHER'S STRUGGLES TO TEACH CONDITIONAL PROBABILITY FOR UNDERSTANDING: THE CASE OF MR. KANTOR

José N. Contreras
Ball State University
jncontrerasf@bsu.edu

Teachers' knowledge is considered as one of the most important factors that influences teachers' instructional decisions and their long-life journey of learning to teach (Da Ponte & Chapman, 2006; Franke, Kazemi & Battey, 2007).

In a previous research study, Borko et al. (1992) examined from several perspectives a classroom lesson in which a student teacher failed to provide a conceptual explanation for the standard division-of-fractions algorithm. While the student teacher believed that good teaching involves making mathematical meaningful to students by explaining the reasons behind the procedures, the researchers concluded that those beliefs were difficult to achieve in practice because the student teacher lacked strong content and pedagogical content knowledge about division of fractions.

In the present study, I examined the pedagogical events (explanations, representations, and questions) that a middle school mathematics teacher, Mr. Kantor, provided when teaching the concept of conditional probability to eight graders. The main sources of data were videotaped lessons supplemented with questionnaires, open and semistructured interviews, and written documents.

The analysis of the teaching episode revealed that Mr. Kantor struggled to help his students understand why $P(A \cap B) = P(A) \times P(B \text{ given } A)$. However, unlike the student teacher in Borko et al.'s study, Mr. Kantor's difficulties were unrelated to his mathematical and pedagogical content knowledge. His explanation for the topic of conditional probability was conceptually based, indicating that his content knowledge was strong. This finding suggests that other factors, such as the intrinsic difficulty of a topic and students' cognitions about the topic, play an important role in the success of teachers' explanations.

Palabras clave: Modelización matemática; Probabilidad; Bachillerato

Este trabajo es un primer acercamiento para responder la pregunta: ¿Cómo justifican estudiantes de bachillerato la probabilidad de un evento en una actividad de modelización? Observamos que la modelización matemática en educación ha ganado relevancia a nivel internacional y que se ha enfocado en áreas como cálculo, geometría, estadística y álgebra, con poca atención a otras áreas tales como probabilidad (Preciado Babb et al., en prensa).

Aquí presentamos algunos resultados preliminares del análisis de las justificaciones que dieron estudiantes de bachillerato sobre el resultado más probable de la suma de los puntos que se obtendría al lanzar dos dados en el contexto de modelización matemática.

Este trabajo se enmarca en la perspectiva *educativa* de la modelización matemática (Kaiser & Sriraman, 2006), en la cual el objetivo es enseñar un contenido específico, en este caso una introducción a la probabilidad con el uso de un simulador (Batanero, 2003, Koparan, 2021). Blum y Leiß (2006) describieron la modelización mediante un ciclo en el que se parte de un fenómeno para construir un modelo matemático que permita su estudio. Un paso importante en el ciclo es la validación del modelo, incluyendo modificaciones si fueran necesarias.

En este estudio participaron cuatro grupos de 50 estudiantes cada uno. Los alumnos usaron un simulador para obtener resultados del lanzamiento de dados en muestras de al menos 30 lanzamientos. Después de representar sus resultados con gráficas de frecuencia, se les pidió a los estudiantes que indicaran cuál sería el resultado más probable y que justificaran su respuesta. Un diagnóstico previo a la actividad mostró que solo un 8% de los estudiantes tenía conocimiento de la actividad y sus posibles resultados. Los datos se recabaron de forma individual por medio de un formulario de Google y a través de un archivo que enviaron de su trabajo por equipo.

Al revisar las justificaciones de los estudiantes notamos que, si bien usaron distintas representaciones, estas se podían clasificar en argumentos teóricos o experimentales (Gómez et al., 2013). Es importante mencionar que, hasta el momento de esta actividad, no se había abordado en la clase la probabilidad teórica.

Los resultados indicaron que la mayoría de los estudiantes (más del 60%) respondió utilizando cálculos de probabilidad teórica, sin considerar los resultados del simulador, aproximadamente el 11% tiró los dados varias veces o revisó los resultados del equipo, casi 20% contestó conforme al número de tiradas (25, 100 y 1500) en el juego y un 3% decidió continuar usando el simulador hasta obtener una muestra más grande.

El hecho de que la mayoría de los estudiantes justificaron sus respuestas con argumentos teóricos sugiere que le asignan mayor importancia al modelo matemático sin considerar la validación del este, como sugiere el ciclo de modelización propuesto por Blum y Leiß (2006).

Keywords: Mathematical modelling; Probability; High school

This study is an initial approach to answer the question: How do high school students justify the probability of an event in a modelling activity? We have noticed that mathematical modelling in education has increased relevance internationally and has focused subjects such as calculus, geometry, statistics and algebra, with less attention to other subjects such as probability (Preciado Babb et al., in press).

Here, we present preliminary results from the analysis of high school students' justifications on the most probable outcome for the sum of the numbers obtained by throwing two dice in the context of mathematical modelling.

This work is framed within the *educational* perspective on mathematical modelling (Kaiser & Sriraman, 2006), in which the goal is to teach a specific content, in this case an introduction to probability with the use of a simulator (Batanero, 2003, Koparan, 2021). Blum y Leiß (2006) described modelling through a cycle that begins with a phenomenon to build a mathematical model for its study. An important step in the cycle is the validation of the model, including modifications, if they were required.

Four groups of 50 students, each, participated in this study. Students used a simulator to obtain the results of throwing the dice with a sample of 30 throws. After representing the results in a frequency graph, students were asked to indicate which would be most probable outcome, justifying their answers. A prior diagnostic to this task showed that only 8% of the students had prior experience with this activity and its possible outcomes. Data were collected individually using a Google form and through the files with the work they did as a team.

After reviewing students' justifications, we noticed that while they used different representations, their justifications could be classified in theoretical and empirical arguments (Gómez et al., 2013). It is worth mentioning that by the time students engaged in the task, theoretical probability was not introduced yet to the course.

Results showed that most of the students (more tan 60%) answered using calculations for the theoretical probability, without considering the results from the simulator, 11% of the students, approximately, throwed the dice several times or reviewed the results of the team, almost 20% answered based on the number of throws (25, 100 and 1500) in the game and 3% decided to continue using the simulator until they obtained a larger sample.

The fact that most of the students justified their answers with theoretical arguments suggests that they gave more relevance to the mathematical model, without considering its validation, as suggested by the modelling cycle proposed by Blum y Leiß (2006).

"WHAT GOT FLIPPED?": A TEACHER'S USE OF CONTRASTING CONCEPTIONS TO SUPPORT STUDENTS' DEVELOPMENT OF INVERSE FUNCTIONS

Irma E. Stevens

istevens@umich.edu

Patricio Herbst
University of Michigan
pgherbst@umich.edu

Keywords: Algebra and Algebraic Thinking, Mathematical Representations, Teacher Noticing

This study builds on literature on teacher noticing (e.g., Sherin et al., 2011) and management of the complexity in teaching (e.g., Lampert, 2001). In attending to the complexity of a lesson, teachers may elect not to attend to different conceptions among students. Yet, doing so can be instrumental to achieving instructional goals that might be more difficult to reach by following on single approaches. In this study, we focus on how a teacher might support students with differing conceptions of inverse function in discussing ideas central to an instructional goal.

We started by identifying different student conceptions These conceptions were created by considering prior research on students' conceptions of inverse (e.g., Paoletti, 2020; Paoletti et al., 2017; Stevens et al., 2020; Teuscher et al., 2018; Vidakovic, 1996) and then refining descriptions by representation by analyzing student work (Strauss & Corbin, 1998). In this report, we focus on two meanings students could have when representing an inverse function on a graph: switch-graph and undo-graph. In switch-graph, students switch the independent and dependent variables while keeping the same variable labels; they anticipate that one graph can represent both directions of a relationship. In undo-graph, students think about an undoing process; after representing one direction of the relationship with a graph, they create a new graph to represent the inverse relationship by switching the coordinate values and their corresponding labels.

We used these conceptions to code video of a teacher using a contextualized problem-based lesson in a high school algebra class in the midwestern U.S. In this poster, we focus on one instance in which the teacher was talking with two students who were working on the graph of the inverse relationship during small group time. We identified these students as having two different conceptions for inverse- an undo-graph and a switch-graph. Rather than telling the students how to reconcile their differences in order to produce a graph with conventional inverse notation, the teacher asked the following questions: "Why are they different?", "Which one do we want or does it not matter?", and, "So what got flipped?". In asking these questions and listening to the students' responses, the students had the opportunity to exchange around the different ways they were representing their inverse relationship, explicitly discussing matters of the labeling, independent/dependent quantities, and axes orientation in their representations.

We conclude by noting that the features that the teacher decided to have the two students attend to were directly related to topics that moved the students closer to the instructional goal of the lesson. For example, the focus was on variable roles rather than discrepancies in scale on axes. We argue that this illustration of a teachers' interaction with students with different conceptions opens up a way for us as researchers to attend more to the conception-specific ways in which teachers can promote productive ways for students with differing conceptions to learn and build their own mathematical understandings.

REFLEXIONES ACERCA DE LAS IDEAS MATEMÁTICAS EN EL PROCESO DE DISEÑO

REFLECTIONS ON THE MATHEMATICAL IDEAS IN THE DESIGN PROCESS

Mike Saldaña Guerrero
Cinvestav
mike.saldana@cinvestav.mx

Palabras clave: Educación primaria, Experimentos de diseño, STEM/STEAM integrado, Conocimiento del profesorado

Perspectiva teórica

La educación integrada STEM postula que al abordar las disciplinas STEM de una manera conectada pueden hacer que las materias sean más relevantes para los estudiantes y profesores, y se pueda aumentar el interés y los logros en el aprendizaje (National Rearch Council, 2014). Por otro lado se sustenta que el proceso de diseño puede ser una actividad central al implementar actividades STEM debido a que "el proceso de dise mplia y refuerza la forma de pensar en los problemas y ofrece herramientas que pueden ayudar a los estudiantes a ampliar de forma creativa su pensamiento" (NCTM y NCTM, s/f, p. 3).

Para esta investigación se llevó a cabo un taller de diseño con estudiantes para profesor de nivel primaria. Se adoptaron algunas actividades que sugieren Benenson y Neujahr (2002), otras se diseñaron en función del interés de la investigación. Para organizar y analizar los resultados de las actividades de diseño y responder a las preguntas de investigación, se retoman las categorías que integran la estructura de la reflexión en acción (Schön, 1983; 1987).

El diseño y las preguntas de investigación

El diseño de la investigación fue de corte cualitativo, con enfoque fenomenológico. El propósito de la investigación fue distinguir la forma en la que los profesores resolvían los problemas que les planteaba el diseño y las ideas matemáticas que ponían en obra. Las preguntas fueron ¿Cómo resuelven los profesores el problema de diseño de objetos del entorno en un escenario STEM? ¿Qué tipo de reflexiones tienen lugar en los profesores acerca de los conceptos matemáticos que utilizan para resolver el problema de diseño de objetos de su entorno?

Técnicas de recolección y análisis de datos. En la fase de diseño de las actividades del taller se crearon formatos para recuperar información, los formatos incluían cuadros de doble entrada, preguntas, espacio para hacer operaciones, etc. También se usaron técnicas cualitativas: diario de campo, observación participante, charlas informales. Las herramientas con las que se hizo el análisis de la información fueron el registro ampliado (Bertely, 2000), la construcción de categorías y la triangulación (Woods, 1978), la escritura de memos (Corbin y Strauss, 2015).

Resumen de los hallazgos. Se encontró que al enfrentar el diseño de un objeto, los profesores recurrieron al repertorio de conocimientos que poseen, no sólo ideas matemáticas, lo hicieron en un ambiente de colaboración, de discusión de sus ideas y de negociación para seleccionar la propuesta de diseño a cumplir en el prototipo. Las ideas matemáticas que utilizaron inicialmente para plantear un cambio en el diseño estaban asociadas a las características físicas, se referían a un cambio en el ta "al doble" "aumentar los espacios" " ande", pero en las siguientes fases del diseño se involucraban en reflexiones sobre conceptos y operaciones abstractas: proporcionalidad, regla de tres, escala 1:2, si $\frac{36.5}{x} = \frac{1}{2}$.

REFLECTIONS ON THE MATHEMATICAL IDEAS IN THE DESIGN PROCESS

REFLEXIONES ACERCA DE LAS IDEAS MATEMÁTICAS EN EL PROCESO DE DISEÑO

Mike Saldaña Guerrero
Cinvestav
mike.saldana@cinvestav.mx

Keywords: Elementary School Education, Design Experiments, Integrated STEM/STEAM, Teacher Knowledge

Theoretical perspective

Integrated STEM education postulates that approaching STEM disciplines in a connected way can make the subjects more relevant to students and teachers, and can increase interest and learning achievement (National Research Council, 2014). On the other hand, it is argued that the design process can be a central activity when implementing STEM activities because "the design process broadens and strengthens problem thinking and provides tools that can help students creatively extend their thinking" (NCTM and NCTM, n/d, p. 3).

For this research, a design workshop was conducted with students for elementary level teacher. Some activities suggested by Benenson and Neujahr (2002) were adopted, others were designed according to the research interest. To organize and analyze the results of the design activities and answer the research questions, the categories that integrate the structure of reflection in action (Schön, 1983; 1987) are taken up.

The research questions and design

The research design was qualitative, with a phenomenological approach. The purpose of the research was to distinguish the way in which teachers solved the problems posed by the design and the mathematical ideas they put into action. The questions were How do teachers solve the problem of designing objects of the environment in a STEM setting? What kind of reflections take place in teachers about the mathematical concepts they use to solve the problem of designing objects of their environment?

Data collections techniques and analysis. In the design phase of the workshop activities, formats were created to retrieve information; the formats included double-entry boxes, questions, space to do operations, etc. Qualitative techniques were also used: field diary, participant observation, informal talks. The tools with which the analysis of the information was done were the extended register (Bertely, 2000), the construction of categories and triangulation (Woods, 1978), the writing of memos (Corbin and Strauss, 2015).

Summary of findings. It was found that when facing the design of an object, teachers resorted to the repertoire of knowledge they possess, not only mathematical ideas, they did so in an environment of collaboration, discussion of their ideas and negotiation to select the design proposal to fulfill in the prototype. The mathematical ideas they initially used to propose a change in the design were associated with physical characteristics, they referred to a change in size: "double" "increase the spaces" "bigger", but in the following phases of the design they were involved in reflections on abstract concepts and operations: proportionality, rule of three, scale 1:2, if 36.5/x=1/2 .

This study aims to describe how preservice secondary mathematics teachers (PSMTs) reason about different function representations. The study focuses on two PSMTs' reasonings across static and dynamic representations of functions. Sfard's (2008) Theory of Commognition guided our analysis. Findings indicate that while static representations restrict attention given to covariation, dynamic representations support PSMTs' reasoning about covariation including making connections to how covariation is represented in static graphs.

Keywords: Mathematical representations, algebra and algebraic thinking, technology

The concept of function permeates all levels of mathematics and is a large focus of the high school curriculum. Central to the treatment of functions in high school is attention to characteristics of families of functions given their usefulness for mathematical modeling. This attention means that significant emphasis is placed on graphical representations of functions (i.e., static graphs on a Cartesian plane). Research has shown that when analyzing graphical representations of functions, students and teachers alike often attend to perceptual cues rather than the relationships between the variables the perceptual cues are representing (e.g., Moore & Thompson, 2015; Sinclair et al., 2009). The coordination of two quantities represented in a graph of a function and the ways they change in relation to each other is called *covariational reasoning* and has been identified as foundational for mathematical modeling as well as many calculus concepts (e.g., Carlson et al., 2002). Given the role that functions play in the high school curriculum, it is essential that preservice secondary mathematics teachers (PSMTs) develop covariational reasoning skills. Carlson et al. pointed to the potential of dynamic technologies to support those learning to apply covariational reasoning. Recent work with a particular dynamic representation of functions in one dimension, the dynagraph (Goldenberg et al., 1992), has pointed to its potential to elicit student reasoning about the ways in which independent and dependent variables vary and covary (e.g., Antonini et al., 2020; Sinclair et al., 2009). To that end, the purpose of this study was to examine the similarities and differences in the ways PSMTs reasoned about different representations of functions–static and dynamic.

Background Literature

Reasoning about Static Graphs

Static representations of functions include tables, lists of ordered pairs, equations, and graphs. There is evidence that students' limited experience with graphical representations constrains them from making meaningful connections among algebraic and graphical representations (Knuth, 2000). Static graphical representations also conceal the dynamic aspects of function, such as the rate of change and relative position, that are essential for forming a robust understanding of function (e.g., Antonini et al., 2020; Carlson, 1998; Confrey & Smith, 1995; Ng, 2016). Research has shown that when reasoning about static graphs, it is not unusual to pay attention to shape and perceptual cues rather than the ways the graph represents how the variables change together (e.g., Moore & Thompson, 2015; Oehrtman et al., 2008; Weber, 2012). Moore and Thompson (2015) have also shown that it is not uncommon for a graph to be interpreted as the function itself, rather than a representation of the function. They distinguished *static shape thinking* from *emergent shape thinking* and described static shape thinking as considering a graph as an object, reacting to perceptual cues and the perceived shape of the graph rather than perceiving a graph as a trace and a representation of covarying quantities. Students with emergent shape thinking interpret features of the graph as properties of covariation. Thompson and Carlson (2017) noted that covariational reasoning happens "most strongly when a person is strategizing how to keep track of quantities' values simultaneously" (p. 438). Thus, dynamic representations where one can act on one quantity and track the concurrent relationship with another quantity might support the development of covariational reasoning skills.

Reasoning about Dynamic Representations of Functions

Digital technology provides many affordances related to the ways in which one can interact with functions and their graphs (Drijvers, 2015). Such technologies allow for the use of tables, expressions, and graphs to be dynamically linked to animated motion (e.g., Johnson et al., 2020; Kaput Center, 2016). There is evidence that engaging in activities of these types can support the development of reasoning about varying quantities and the ways in which they are represented in graphs (e.g., Johnson et al., 2020). Another way of leveraging the dynamic affordances of digital technologies to represent function is to use parallel axes rather than perpendicular axes, typically referred to as a dynagraph. Goldenberg et al. (1992) introduced dynagraphs to draw attention to dynamic function behavior and to help students focus on the function by eliminating complex information shown in a Cartesian graph. Students can test their conjectures of the relationship between input and output by dragging the input and observing the resulting change in the output. With the movement of this interactive representation, identification of invariants and covariation become central to one's exploration. Antonini et al. (2020) described dynagraphs as dynamic interactive mediators because students can engage in discourse with a dynagraph, "asking" questions of the tool and engaging to receive an "answer". Research has shown that use of dynagraphs can support the teaching of functions (e.g., Antonini et al., 2020) and can foster covariational reasoning by eliciting attention to movement, time, and space (Lisarelli, 2017).

There is little research comparing student reasoning when engaging with static and dynamic representations of function (exceptions include Antonini et al., 2020; Ng, 2016, and Sinclair et al., 2009). Given the potential of dynagraphs to support the development of reasoning about variables both separately and together, it is of interest to compare the ways in which one would reason about static and dynamic representations of the same functions. Our aim is to describe how PSMTs reason about functions with different visual mediators (i.e., static and dynamic).

Theoretical Framework

Sfard's (2008) Theory of Commognition unites cognitive and communicational processes to explain student thinking as "an individualized version of interpersonal communication" (p. 81). For Sfard, communication is a back and forth (action/reaction) that includes all communication, including with oneself. From this perspective, Antonini et al. (2020) explained "doing mathematics means engaging in the type of communication defined as mathematics and learning means becoming able to access and express this discourse" (p. 4). So, to study students' learning, we must attend to the words, visual mediators, narratives, and routines that form their discourse.

Mathematical discourse is characterized by specific words that are used by experts in specific ways. In the context of this study, that might include words like function, quadratic, increasing, rate of change, domain, or it might include informal language that is clear enough for an expert to understand the mathematics one is referring to. Visual mediators are objects that can be seen and operated on in the communication process. In mathematics, visual mediators can include, but are not limited to, symbols and graphs. Visual mediators of this type are static in that they can be seen and operated on, but not interacted with. In contrast, Antonini et al. (2020) introduced a dynamic interactive visual mediator (referred to as a DIM) described as a mediator that is "both *dynamic* - they change over time - and *interactive* - they respond to a person's manipulations" (p. 5). A dynagraph is an example of a DIM. In this study, we attended to the ways students communicate with and about different types of visual mediators (i.e., static vs. DIM).

Context of the Study

Since our goal was to compare and contrast the ways in which PSMTs reasoned about static graphical representations of functions and dynamic interactive representations of functions, asking students to compare and contrast within each representation type met our needs. To this end, we decided to use the instructional routine of Which One Doesn't Belong (WODB) (Danielson, 2016). A typical WODB task includes four objects and students are simply asked, which one doesn't belong? The main characteristic of a WODB task is that all of the options within the task can be considered correct which shifts students' focus away from trying to obtain the "correct" answer to distinguishing attributes of the objects presented in each option. This study used two WODB tasks, one with four static graphs of functions – each from a different function family (referred to going forward as the static task) and one with four dynagraphs of the same four functions (going forward referred to as the dynamic task).

In the static task, PSMTs considered four graphs (Figure 1) of functions and were asked to decide WODB and why. Once the PSMTs explained their choice, they were then asked to explain why someone else might argue that each of the other remaining graphs does not belong.

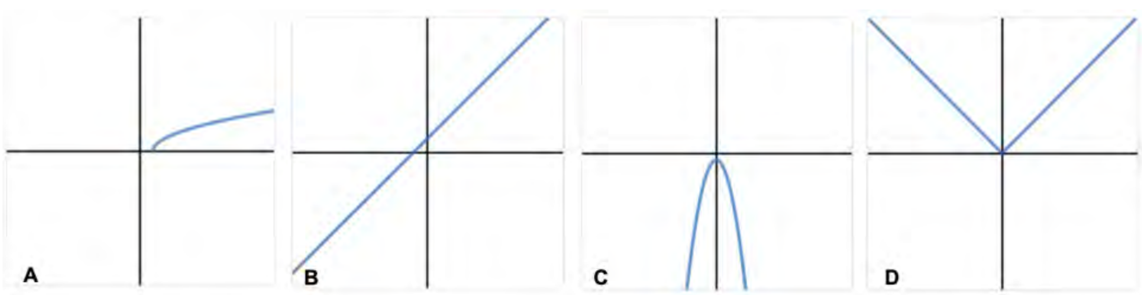

Figure 1: The static WODB task

In the dynamic task, the same four functions were presented (in a different order) but this time represented using dynagraphs (Note: PSMTs were not told they were the same). As a reminder, a dynagraph consists of two parallel number lines (function input on one, output on the other), and as the input is dragged, corresponding changes to the output will result (Figure 2). Just like the static task, PSMTs were asked to decide and explain WODB. Then they were asked why someone else might argue that each of the other remaining dynagraphs does not belong.

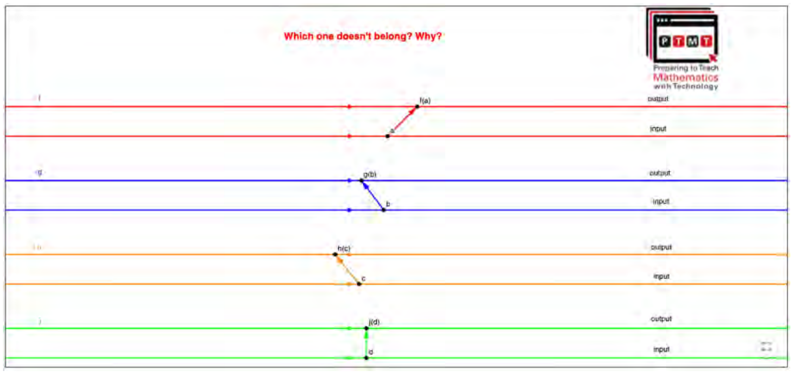

Figure 2: The dynamic WODB task–linear, square root, quadratic, and absolute value functions from top to bottom (https://www.geogebra.org/m/wjecnfev)

Methodology

This study was situated within the context of a larger study investigating how PSMTs reasoned across static and dynamic representations of function. Here we used a multiple case study design (Yin, 2017) to explore two cases, where each case was defined by the type of visual mediator (i.e., static and DIM) with which the students interacted. Our overarching research question was: What is the nature of students' discourse about function as they interact with different visual mediators (i.e., static and dynamic interactive mediators)?

The full study included 25 PSMTs attending six universities. Here we focus on two female participants; neither had experience with dynagraphs before. They were secondary mathematics education majors attending different universities. Both participants were enrolled in a math methods course, prior to student teaching, at the time of the study.

Video screen capture recordings of semi-structured interviews (Goldin, 2000) served as the main data source. One interview posed the static visual mediator first, and the second began with the DIM. Interviews were transcribed verbatim and uploaded in Atlas.ti to assist with coding.

Similar to Antonini et al. (2020), we used Sfard's (2008) Theory of Commognition to guide our analysis. We attended to words, discourses, and narratives to code the PSMTs' comparing and contrasting of the mediators presented in the tasks. In our consideration of the scholarly mathematical discourse (words), we were specifically interested in the characteristics of function that were elicited. We read the transcripts for the specific characteristics of function being described (e.g., domain, range, increasing, decreasing, maximum), created quotations for each chunk of transcript referring to a specific characteristic, and applied labels. A full list of these characteristics is included in the findings.

Next, we coded for the discourse about and with each mediator. To do so, all team members watched each video and reviewed the transcript to become familiar with each participant's discourse. This was followed by full team meetings to develop short codes describing the discourse using the protocol set forth by DeCuir-Gunby et al. (2011). We compared the data and emerging codes using a constant comparative method to create our final version of the codebook. From there two researchers coded each interview, and any discrepancies were discussed amongst them to come to a consensus. Finally, the researchers read the coded data again, condensing codes into categories and then identifying themes in the participants' narratives about the different types of mediators. These themes are presented in the findings section.

Findings

The PSMTs engaged with two different visual mediators, a set of four static Cartesian graphs and a set of four dynagraphs. Regardless of the order of engagement (i.e., static or DIM first), the characteristics of function they attended to when comparing and contrasting the functions in each activity were similar. The characteristics elicited included: differentiability, domain and range, function families, function vs. non-function, increasing and decreasing, independent and dependent variables, local and global extrema, rate of change, and symmetry. Representative examples from our data for the most commonly noted characteristics are shown in Table 1. The only characteristics not included in the communication with both mediators were function/non-function and symmetry. In both cases, these characteristics were mentioned by only one of the two PSMTs and on only one of the four functions being compared. The other seven characteristics were routinely included by both PSMTs in their discourse about both visual mediators. Given the similarities in the mathematical focus of their discourse related to both visual mediators, we next present findings related to the nature of the discourse related to the mathematical focus for each of the two visual mediators.

Table 1: Representative examples of discourse related to characteristics of functions

	Representative Examples	
	Static	DIM
Domain/Range	PSMT 1: "The domain [of A] is only from one to infinity."	PSMT 1: "The domain [of h(c)] is going to go on forever here."
Increasing/ Decreasing	PSMT 1: "[A's] just going to keep going up."	PSMT 2: "And *b*, I'm noticing that as you increase the input of *b*, more and more like the like *g(b)* increases less."
Rate of Change	PSMT 1: "The slope of the lines [of absolute value function] was one or negative one."	PSMT 2: "And it looks like so as *d* is approaching negative infinity *j(d)* increases at the same rate that *d* is decreasing."

Nature of Discourse with and about Static Visual Mediators

When engaging with the static version of the WODB task, the nature of the PSMTs' discourse was routinely focused on using formal mathematical language (though not always precisely) and what we referred to as "describing the image". Representative examples for each of these types of narratives are provided in Table 2.

As they compared and contrasted the four static graphs, the PSMTs consistently used the formal language to typically describe characteristics of functions – e.g., domain, range, increasing, decreasing, slope, concave up. For example, PSMT 2 described graph A using the term "restricted domain" (see row 1 of Table 2). This is to be expected given the years of experience they have of being asked to identify characteristics of functions based on their graphs. Of course, their discourse would include the words used by the mathematicians they have learned from over the years. However, the PSMTs did not always use these words in precise ways. For example, when trying to describe the non-constant rate of change of the function in graph C, PSMT 1 refers to it as "average rate of change" with uncertainty, as she knows it is not constant, but is not sure what to call it.

Table 2: Representative examples of discourse about the static visual mediators

Features of PSMTs' narratives	Representative Examples
Use of formal and precise mathematical language	PSMT 2: "[A's] the only one that has like a restricted domain. Because it like, it doesn't have any inputs, that work for the, they give, like a real value lower than one."
Use of formal and imprecise mathematical language	PSMT 1: "The slope [of D] from zero to infinity and the range is going to be positive one. But I wouldn't say it's that's not really an av- (pause) that's not really an average rate of change."
Describing the image	PSMT 1: "Well, [C's] concave down, it's opening down. ... [D's] the only one that goes through the origin. ... B's the only one that doesn't belong because it's the only one that touches all or touches three quadrants while the rest touch one or two." PSMT 2: "[C's] only one where it doesn't go above zero. It doesn't have an output above zero, right."

Whether their formal mathematical language was precise or not, the PSMTs consistently compared and contrasted the static graphs by describing the presented images as if they were pictures. For example, while PSMT 1 (see row 3 of Table 2) correctly described graph C as "concave down", the follow up phrase "it's opening down" reveals she is describing the image rather than the increasing and then decreasing rates of change that the term concavity is intended to describe. The routine of describing the image in the static graphs is consistent with what Moore and Thompson (2015) refer to as "static shape thinking" or "treating a graph as a piece of wire ... attending to perceptual cues and the perceptual shape of a graph" (p. 784). The attention to perceptual cues (e.g., "goes through the origin", "touches three quadrants") and shape (e.g., "doesn't go above zero") is evident in both examples presented in row 3 of Table 2.

Nature of Discourse with and about Dynamic Interactive Mediators

When engaging with the dynamic version of the WODB task, the nature of the PSMTs' discourse was routinely focused on describing relative direction, distance, and/or speed and connecting their noticing to imagined graphs of known functions. Representative examples for each of these routines are provided in Table 3.

The PSMTs interacted with each dynagraph by dragging the independent variable and examining the resulting reaction of the dependent variable. As they explored dynamically, they described the dynamic characteristics they noticed. Both PSMTs consistently noted the variables' relative direction and speed. For example, as PSMT 2 dragged *d* to the far left, she saw *j(d)* move to the right and stated, "as *d* is approaching negative infinity, *j(d)* increases". In addition, she noted that "*j(d)* is increasing constantly or very close to the same amount that *d* is". Relative distance and speed were also often discussed. For example, when describing her exploration of *g* alongside of *h*, PSMT 1 noted their relative speed but used distance to make sense of it, referring to the length of the connector between *c* and *h(c)* to describe that distance, she explains "so, the outputs, the *g(b)* aren't moving as fast as this one" and then describing *h* she said, "it's like the arrow from the inputs, the outputs, gets larger and larger and larger." The arrow getting "larger" corresponded to the increasing rate of change. In the PSMTs' discourse about the relative speed, direction, and distance, there is evidence of attending to not only how each of the input and output are varying, but also the ways in which they are covarying.

Table 3: Representative examples of discourse about the dynamic interactive mediators

Features of PSMTs' narratives	Representative Examples
Describing relative speed, direction, and/or distance	PSMT 1: "So the outputs, the *g(b)* aren't moving as fast as if like if I move this one [talking about *h*]. And I move it, it's like the arrow from the inputs, the outputs, gets larger and larger and larger. But here [talking about *g*] it does get larger. But it's like it takes a longer time for it to get as long, like cause see, like here I have to move *b* all the way to the right for it to get really long."
	PSMT 2: "It looks like *j(d)* is increasing constantly or very close to the same amount that *d* is and then when *d* is less than zero *j(d)* is increasing, oooh. And it looks like so as *d* is approaching negative infinity, *j(d)* increases at the same rate that *d* is decreasing. And so that reminds me of the absolute value function."
Imagining a Cartesian graphical representation of a known function	PSMT 2: "Because, so like, if I'm picturing, like, the function, like absolute value of *x* and to the right of zero, *d* would be, or to the right of zero, *x* and *f(x)* would be the same or *d* and *j(d)* would be the same. But then to the left of zero, as *d* approaches negative infinity *x* would approach or I feel like a mixing of other notation like as *x* approaches negative infinity, *f(x)* would approach infinity at the same rate. If that makes sense, like it's just the *x* function on both sides. But. Yeah."
	PSMT 1: "[h(c)'s] probably like (pause) a quadratic that is facing down or maybe even an absolute value, because if I move. The *x* values from negative to positive, the *y* values look like they're staying. (pause) They're kind of repeating themselves, the outputs are similar."

Another routine that emerged in the PSMTs' discourse was connecting the relationships they were observing among the variables with Cartesian graphs of function families with which they were familiar. They tended to describe images of static graphs of functions on Cartesian planes they envisioned as sharing characteristics with the dynamic representations they were investigating. For example, as PSMT 2 dragged *d* from the far right to the far left and noticed *j(d)* moving at a constant speed and the same direction until a certain point and continuing at a constant speed but moving the opposite direction she said, "like if I'm picturing, like, the function, like absolute value of *x* and to the right of zero, *d* would be, or to the right of zero, *x* and *f(x)* would be the same ... as *x* approaches negative infinity, *f(x)* would approach infinity at the same rate. If that makes sense, like it's just the *x* function on both sides." She is connecting what she is seeing in the dynagraph with a Cartesian graph that she is familiar with. PSMT 1's description is similar; she starts by connecting the relative direction of *d* and *j(d)* to "probably like (pause) a quadratic that is facing down", but then considers the constant relative distance and says "maybe even an absolute value ... *y* values look like they're staying. They're kind of repeating themselves". This routine of connecting the dynamic movement of the dynagraph representation to an imagined Cartesian graph of a known function is consistent with what Moore and Thompson (2015) referred to as emergent shape thinking, "understanding a graph *simultaneously* as what is made (a trace) and how it is made (covariation)" (p. 785). Here the PSMTs were imagining the one-dimensional trace as a two-dimensional trace and in doing so demonstrated their understanding of the ways in which the quantities were covarying.

Discussion and Conclusion

In this study, we investigated the similarities and differences in the ways PSMTs reasoned about static and dynamic representations of functions. Findings from this study suggest that static representations of function limit students' attention to covariation; this is consistent with prior research that showed students pay attention to shape and perceptual cues rather than the ways the graph represents how the variables change together (Moore & Thompson, 2015; Oehrtman et al., 2008; Weber, 2012). On the other hand, we found evidence of emergent shape thinking when students engaged with the DIM. They were imagining how their action would be represented in a static graph (a trace) which led them to reason covariationally. This attempt to make a connection raises a question: Do PSMTs not naturally tend to reason covariationally when presented with static representations in the first place or did the DIM support this connection making? Further research is needed to gain more insight to the reason behind this connection.

Results also suggest that different representations of function influenced PSMTs' use of mathematical language. The DIM seemed to disrupt PSMTs' reliance on formal mathematical language since they did not have a formal language to attach to the non-traditional function representations (i.e., dynagraphs). This is consistent with Ng's (2016) findings that students demonstrated increased reliance on verbs of motion and less reliance on formal mathematical language in the dynamic environment. In both representations, PSMTs described dynamic situations; however, they used dynamic language only with the DIM. It is possible that PSMTs had to think differently than they are used to, and thus did not have an expert's discourse at hand to describe what they observed. Whereas the familiarity of the static representation caused them to draw upon formal language (sometimes imprecisely), either because they are accustomed to doing so or because they felt it was expected. The fact that the DIM elicited more informal language may benefit the development of precise use of formal language. PSMTs tend to attend to dynamic features of the function as they are describing what they see. This will eventually evolve into formal mathematical language with the support of mathematics teacher educators.

Given the promise of the use of dynagraphs in supporting PSMTs' use of dynamic language and expressing emerging shape thinking, we plan to scale up the study with more PSMTs to determine if the patterns we saw here are consistent. In addition, we plan to consider how the use of DIMs might support the development of emergent shape thinking about static representations.

Preservice teachers (PSTs) often demonstrate difficulty learning to attend to content-specific student actions in-the-moment. However, machine learning algorithms applied to PSTs' viewing of 360 videos provides a potentially useful tool for teacher educators. In this paper, we describe the initial development of such a tool and the implications for its use.

Keywords: Teacher Noticing; Technology; Preservice Teacher Education.

"Effective teaching requires attending to students' mathematical thinking and reasoning during instruction" (AMTE, 2017, p. 16). These skillsets of attending, interpreting, and responding to students' mathematical reasoning encapsulate *professional teacher noticing* (Jacobs et al., 2010; van Es & Sherin, 2002). When observing mathematics classrooms or viewing video of such contexts, novice teachers often attend to the teacher's actions or describe students' non-mathematical activities, whereas more experienced teachers focus on a specific set of students and describe their mathematics in detail (Huang & Li, 2012; Jacobs et al., 2010). There is clear evidence that, with appropriate scaffolds, preservice teachers (PSTs) can progress to more specific, focused professional noticing (Schack et al., 2013; Teuscher et al., 2017), with mathematics teacher educators continuing to pursue improved techniques and technologies to facilitate such pedagogy. Typically, standard video has been used as the technological medium for facilitating professional noticing in mathematics methods courses (van Es et al., 2017). However, recent technological advances have made certain tools and mediums more commonly available. One such medium is 360 video, which is a version of virtual reality that records video omnidirectionally (see Figure 1). Specifically, PSTs viewing a 360 video can choose which direction to look in the recording, whereas standard videos (e.g., camcorders, Swivl cameras) select what is viewable a priori (Balzaretti et al., 2019; Kosko et al., 2021).

Evidence suggests that 360 video may facilitate PSTs' professional noticing, by creating a viewing context more representative of being in the classroom (Kosko et al., 2021; Roche & Rolland, 2020). Beyond this, 360 video allows for PSTs' choices of *where* they look in a classroom to be measured by recording their selected field of view (FOV). Extending the potential of this technological affordance, recent advances in machine learning, or artificial intelligence (A.I.), allow for examination of patterns in what PSTs focus in their recorded FOV. The purpose of this paper is to examine the efficacy of a machine learning algorithm in identifying the kind of mathematical actions that students engage within a video, and use of such a tool to examine PSTs' professional noticing. This paper reports on our initial efforts to align attending behaviors of PSTs (observed by teacher educators) with patterns recognizable from a machine learning algorithm.

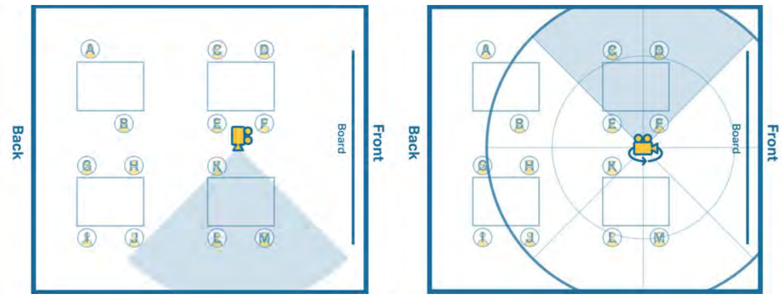

Figure 1: What is viewable from a standard video (left) vs. a 360 video (right).

Background Literature & Theoretical Perspectives

Attending as part of Professional Noticing

Professional noticing involves identifying key aspects in a pedagogical context, interpreting those aspects to one's professional knowledge and norms, and then applying this reasoning to decide how to engage next (van Es & Sherin, 2002). As noted by Scheiner (2016), scholars examining PSTs' act of identifying key aspects have often focused on PSTs' perceptions rather than examining the constructs of attention or awareness. However, "attention selects certain stimuli of a perceived scene for detailed analysis, while perception goes to build up a certain visual experience" (Scheiner, 2016, p. 231). Furthermore, attention involves coordination between various elements of one's professional knowledge and contextual resources. Studies including eye-tracking to examine professional noticing provide insight in how attending is actualized by teachers. Comparing 40 inservice and preservice teachers, van den Bogert (2014) found that more experienced teachers focused their gaze on more students but spent a majority of time attending to a smaller, select set of students in the video examined. By contrast, PSTs scanned the room for larger swaths of time and focused their gaze on relatively few students for any meaningful duration of time. Expanding upon such findings, Dessus et al. (2016) observed that more experienced teachers tend to identify a focal sub-group of students that allows them to attend to more specific, fine-grained events. By contrast, more novice teachers were observed to scan a wider range of events and students, thus limiting their ability to focus on more specific events. Studying this phenomenon using 360 video, Kosko et al. (2021) found that PSTs with less variance in where they attended also had more specific descriptions of children's mathematics. By focusing more attention on two front tables in the classroom, certain PSTs were able to describe more specific aspects of the lesson that occurred. Such findings resemble those of Dessus et al. (2016) and suggest there may be several ways to examine teachers' attending behavior.

As noted by various scholars, professional noticing in general, and attending in particular, are complex skills, but can be taught and learned (Jacobs et al., 2010; Schack et al., 2013). Key commonalities in many of these successful approaches include numerous interactions with videos of students engaging in mathematics, and a focus on giving "opportunities to recognize the power of attending to the subtle details in individual children's strategies" (Jacobs et al., 2010, p. 176). Analysis of such teacher education initiatives have yielded frameworks for specificity of teachers' articulated noticing. As noted by Barnhart and van Es (2015), teachers may initially describe classroom management events and/or focus on the teacher with little focus on students' content-specific actions. As teachers begin to attend to and interpret students' actions, they may describe them from a procedural perspective before eventually learning to describe them from a more conceptual view. Jacobs et al. (2010) provide one example of such progression noting that more conceptual-based attending involved specific descriptions of a student's decomposition of numbers by place value and use of benchmark numbers. By contrast, a more procedural attending included descriptions of the numbers the child wrote down and that they added them, but concepts of place-value were absent.

The preceding paragraphs describe how teachers' attending has been examined from data of where and how they look in a recorded scenario and the specificity of how they describe such events in written or spoken noticings. Different scholars have examined the overlap in these sources of data using 360 video (Ferdig & Kosko, 2020; Kosko et al., 2021), wearable cameras (Sherin et al., 2008), and through analysis of teacher discussions while viewing videos (Jacobs et al., 2010; Schack et al., 2013). Each approach has demonstrated capacity for facilitating teachers' professional noticing, but they are often time-intensive and become less practical when considering large cohorts of PSTs in a teacher education program. This limitation motivated the need for applying machine learning to the study of PSTs' attending, with a long-term hope of applying this technology in pragmatic contexts (i.e., mathematics methods courses). Before describing our use of machine learning, however, we provide a brief overview of this technology and our vision for applying it to study professional noticing.

Applying Machine Learning to Study Professional Noticing

Machine learning is an artificial intelligence (A.I.) subdomain that relies on the ability of a machine to learn from an external source and develop and refine its own algorithms and routines toward a given goal. This goal may descriptive (describing a phenomenon), predictive (predicting a phenomenon), or prescriptive (suggesting how a phenomenon should occur). This technology has been used in education in two different ways. First, it has become a STEM field itself to explore and investigate in primary education – particularly high school (e.g., Korkmaz & Correia, 2019; Mariescu-Istodor & Jormanainen, 2019). Second, it has been deployed for staging the so-called "precision education" to develop personalized instruction from individual academic performances (Luan & Tsai, 2021). Recently, there has been increasing attention on machine learning for teacher education, targeting instructional videos. For instance, Goldberg et al. (in press) validated a manual approach for guiding machine learning algorithms in evaluating videos of three university lessons. Specifically, videos of instruction were examined to code for recorded students' visual engagement in class. Nückles (2020) explored eye tracking and related machine learning processes in video professional development for teachers, claiming that more efforts based on computation are needed for understanding how educators deal with lesson recordings and their elements. In particular, Nückles (2020) questioned the relevance of some eye tracking and machine learning approaches to video analysis in teacher education as focusing too much on teachers' perceptions of on/off task student behavior. Instead, there is a need to address how such technologies may be used to facilitate PST education. In line with Nückles (2020) view, we argue that such tools can be used to provide PSTs feedback in how they attend within a classroom, and this feedback can be used to improve their practice. Yet, to reach this eventual application to teacher education, examination and piloting of machine learning must take place. Thus, the purpose of this paper is to examine the efficacy of a machine learning algorithm to examine PSTs' professional noticing.

Method

Participants & Data

Analysis in this paper focused on six PSTs' viewings of a 360 video focusing on 4th graders' solving fraction equivalence tasks (2 minutes, 49 seconds). Data represents a subsample of 70

PSTs who participated in a larger study. Specifically, the analysis presented here reports on the training process for the machine learning algorithm used to analyze PSTs' 360 video viewing experiences. All six participants were preparing to become elementary teachers in a Midwestern U.S. teacher education program. The program included two focused mathematics methods courses. A focus of the second methods course is fraction pedagogy, including several video-based assignments focused on improving PSTs' professional noticing of students' mathematics (two such videos focus on fractions). Participants included a junior enrolled in their first mathematics methods courses (Nate), three seniors enrolled in their second mathematics methods course (Lynn, Aubrey, & Brie), and two seniors completing student teaching (Anna & Nash).

PSTs participated in the study near the end of their Fall 2020 semester (after Lynn, Aubrey, & Brie had viewed prior videos on students' fractions). As part of a larger study, participants were asked to watch the 360 video focusing on 4th grade students solving a task to determine equivalent fractions. Within the video, students were initially asked to use pattern blocks to find how many red trapezoids covered the shaded region of given shape ($\frac{3}{4}$). Next, they were asked to use green triangles to find the equivalent fraction ($\frac{9}{12}$). Towards the end of the video, student I suggested the answer was $\frac{8}{12}$, to which student G disagreed. Following the teacher's press for student G to "prove it," G demonstrated that there were three triangles for every trapezoid.

Prior to watching the scenario, PSTs were prompted to take notes on any 'pivotal moments' regarding students' mathematics they noticed in the video. Following viewing the scenario, participants were asked to transcribe (type) their notes and then to select one moment to describe as the most important and explain why it was significant. Participants were also prompted to describe what should happen next in the lesson, but the preliminary nature of this analysis, we currently focus on PSTs' attending and interpretations in this paper. In addition to written noticings, participants' viewing sessions of the 360 videos were recorded to allow for analysis of where PSTs' turned their perspective in the 360 video, and what in the scenario they focused on at specific timepoints in the video.

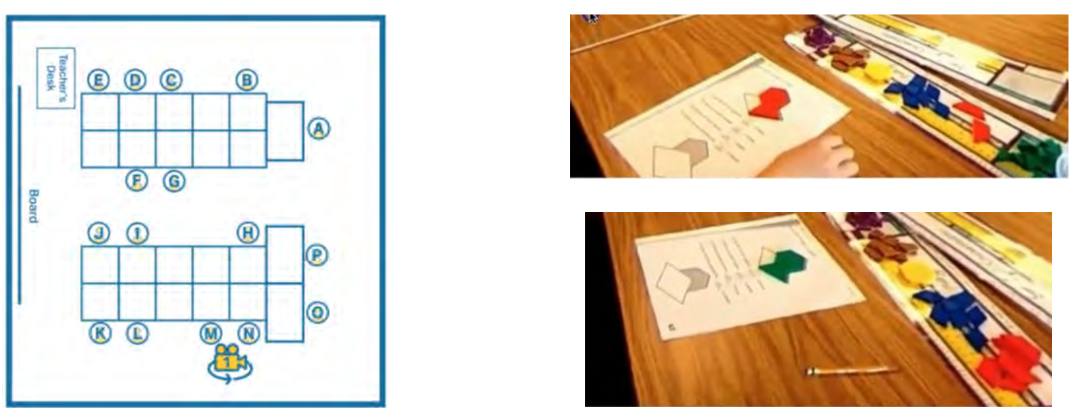

Figure 2: Classroom map with camera positioned between students M & N (left) and screenshots of student M's equivalent fractions (right).

Analysis & Findings

Machine learning in the context of video-based data involves identifying specified visual patterns and teaching the computer-based algorithm how to find the same visual patterns and provide feedback for when the A.I. provides false-positives or false-negatives. To facilitate this process in our current work, we incorporated an iterative analytic process. First, participants' screen recordings of their 360 video viewing experiences were collected from the Praxi platform. Next, body tracking was used to overlay digital "skeletons" of recorded students and teacher to identify their torso, orientation of their arms, and direction of where recorded individuals' heads were turned (see Figure 5). The first, third, and fifth authors then analyzed PSTs' screen recordings second-by-second to identify observable student actions present or absent from participants' viewings. Given prior evidence that suggests PSTs' written noticings are related to what and where they attend when watching 360 video (Ferdig & Kosko, 2020; Kosko et al., 2021), PSTs' written noticings were also examined as a way of ensuring that analyzed videos were more likely to include relevant patterns to train the A.I. The analysis and findings of each stage is provided in the sections that follow.

PSTs' written noticings. Analysis of PSTs' written noticing was conducted using Systemic Functional Linguistics (SFL) (Halliday & Matthiessen, 2014, Eggins, 2004). SFL is a methodology for examining how participants' use of grammar conveys meaning. In the present study, we examined PSTs' conveyed meaning through use of reference (i.e., PSTs' use of grammar to refer to grammatical objects). In particular, *reference chains* are formed by the repeated incorporation of references throughout a written text. As a referent continues to be used, the writer may provide additional information, thereby transforming, expanding, or clarifying the meaning of this referent. To analyze for reference chains, and how a referent's meaning was conveyed, the first and third author analyzed written text for PSTs' use of nominal groups and transitive processes. Figure 3 illustrates a snapshot of this process for two students, Nash and Anna. Nominal groups referring to pivotal moments are underlined, where a nominal group "is the part of the clause [that] contains nouns and the words that accompany nouns" (Eggins, 2004, p. 96). Each clause established by the user is separated by "//". Transitive processes, bolded in Figure 3, represents how the participants conveyed meaning for referent nominal groups.

Nash

Some pivotal moments I noticed were from
student M and N. //
When the teacher **asked** the questions about
what shapes to **fill** in their diagram and //
find the answer.
Some pivotal moments **were** when the
students **were** able to immediately **find** the
answer and // were eager to raise their hands.
Also, they quickly noticed the
teacher's "error" and //
wanted to address //
and // **fix it** because they **knew** the
answer.

Anna

There **were** a few pivotal moments in the video. //
One of the first ones **was** when the teacher has the
children define how many green triangles were needed to
fill the WHOLE shape. //
The student, I, was **given** the opportunity
to **think** and **respond** to both the questions //
how many to fill the whole and //
how many to fill the shaded. //
It is interesting that this student **responds** with a fraction,
8/12's. //
A key pivotal moment in the middle **is** also when the
other students announce they disagree with that answer. //
The teacher **says** there is a debate //
and challenges the student, G, to **prove** it.
G then goes to **show** //
how she **counted** the six in the top part and
then the three in the bottom part
to get 9/12's not 8/12's.

Figure 3: Example of written noticings of Nash and Anna.

Notable in Figure 3, Nash identifies the pivotal moments in the lesson as focusing on students finding an answer. The referents “what shapes to fill in their diagram” and “find the answer” both point toward this. Further, finding the answer is continuously referenced throughout the text. Towards the end, this manifests in a judgment of “the teacher’s error” and students fixing “it” (the answer) because they knew the correct “answer.” Similar to Nash, analysis of Brie and Aubrey’s reference chains also indicate a focus on students finding the answer. By contrast, Anna’s written noticing (see Figure 3) focuses more on fraction-based references. Initially, Anna references the pivotal moment as children “define how many green triangles…to fill the WHOLE shape.” This referent is clarified by the referents “fill the whole” and “fill the shaded” and then later with students’ responses of “8/12” and “9/12.” More than providing a math-specific referent, Anna’s response differs from Nash (and Brie & Aubrey) by the transitive processes used to convey the referents’ meaning. Nash continuously uses processes like **find**, **fix**, and **knew** “the answer” whereas Anna uses **think**, **respond**, **prove**, **show**, and **counted** to refer to the parts in relation to the whole. So, while Nash, Brie, and Aubrey’s reference chains focused on “the answer,” Anna, Nate and Lynn’s reference chains focused on children’s actions on and with fractions. Referencing Figure 3, We used these findings to help triangulate results of our preliminary video analysis and that of the A.I..

PSTs’ 360 video viewings. Following an analytic approach we have previously used (Kosko et al., 2021), the first, third, and fifth authors examined each participants’ screen recorded viewing second-by-second to identify which recorded students were in their field of view (see Figure 4). We then used findings from analysis of their written noticings to look for differences between PSTs’ viewing patterns. Figure 4 provides one example comparison between Anna, who attended to the mathematics, and Brie, who attended to students’ finding the answers (but no explicit reference to mathematics). Notably, between 44-88 seconds in the video, Anna tends to switch her field of view focusing on student M and students I and J, and these two sets of students are along the same line of sight from the camera perspective (see Figure 4). By contrast, Anna includes students M, J and I, H, and P in her field of view during the same timeframe. Notably, these students are not in the same line of sight but require the viewer to turn the camera perspective as much as 110 degrees from one moment to the next. At around 90 seconds in the video, Anna and Brie’s viewing patterns appear similar. This is when a class discussion begins regarding the task involving a fraction of $\frac{8}{12}$ or $\frac{9}{12}$. Thus, it appeared that any significant differences in viewing patterns were within the first 1.5 minutes of the video.

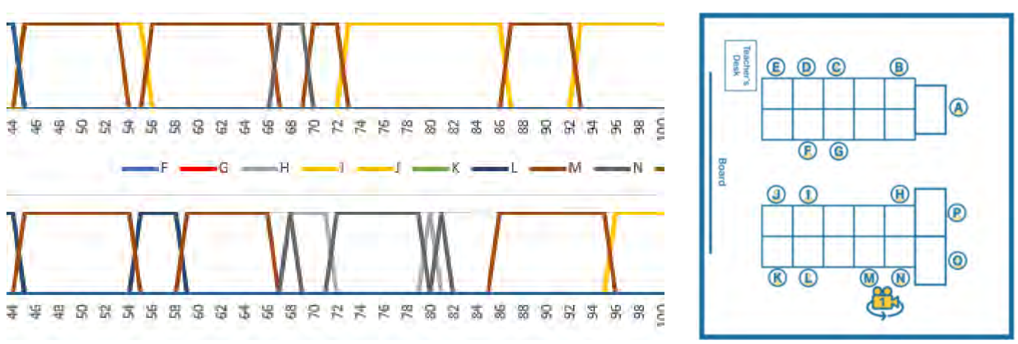

Figure 4: Anna (top) and Brie’s (bottom) student focus.

Next, videos were reexamined using the skeleton wireframes as a guide while focusing on specific intervals identified in the initial video analysis. Specifically, we used AlphaPose (Fang et al., 2017; Li et al., 2019; Xiu et al., 2018) to estimate skeleton points of students in the videos, and attached these wireframes to the video, with the goal of using a machine learning approach to analyze them. This allowed for several particular patterns to emerge from the data, but we discuss one such pattern for sake of space and focus. Common in screen recordings of PSTs like Anna was a focus on attending to students' working with the pattern block manipulatives. This was characterized by the skeleton wireframes when students' arms were both pointed inward and their head-gaze was directed downward (where their arms meet). Such instances were present across all screen recordings, but at varying frequencies. Figure 5 provides a comparative example of Nash and Anna's viewing patterns at two instances in the recorded scenario. At 38 seconds, Anna is focusing on student N's manipulation of green triangles onto the figure while Nash is adjusting his field of view from one end of the table to another (back-and-forth). At 50s, both PSTs are attending to student M, but Anna is also attending to students I and J (within the same line of sight). The first and fifth author coded for presence of these skeleton wireframes (K=0.87) and found that Anna attended to students' use of manipulatives for 51 seconds in the first 90 seconds of the video, while Nash did so for 28 seconds in the same interval (no such moments occurred after 90s in the video).

Figure 5: PSTs' attending captured, with wireframes overlain, at 38s (left) and 50s (right).

Initial machine learning results. Based on the initial analysis of participants' screen recordings and written noticing, a machine learning algorithm was developed to identify whether participants attended to students' manipulating fractions. We proposed three layers of a neural network model, which has an input layer, a hidden layer, and an output layer. We used categorical cross-entropy loss to update the parameters in the model, and trained the model for 20 epochs to achieve better performance. Developing and teaching a machine learning algorithm takes multiple iterations, and we report only on the initial run of the model. In training the algorithm, 42 skeleton wireframes were extracted from the sample videos and assessed in comparison to examples provided through the human-coded video analysis. To help train the algorithm further, an additional action was included (students raising their hand) to help the A.I. discern one action from another. The algorithm reached an accuracy of 75.86% in an initial training run (n=29) and then 69.23% on a test run (n=13) of the A.I. Results of the initial training and test run are positive and encouraging, but do call for the need for additional attending elements be included, and additional data be collected from participants' videos. Fortunately, our current dataset includes additional 360 video screen recordings of 70 PSTs, and there are several other attending elements (e.g., teacher within FOV, student(s) counting blocks on paper) that will be used to train the machine learning algorithm further. As additional attending elements are included, and more examples are extracted from participants' videos, the A.I. will improve in accuracy and provide a report comparable to human coders (but in a fraction of the time).

Discussion

Similar to prior findings examining more and less sophisticated noticing (Barnhart & van Es, 2015; Jacobs et al., 2010), we found that certain PSTs referenced children's mathematics-specific actions (Anna, Lynn, & Nate). By contrast, others focused on more general (not mathematics-specific) events. Nash, Brie, and Aubrey each attended to how and whether people in the recording found the correct answer. Interestingly, this focus on "the answer" infrequently referred to a numeric fraction. Corresponding to research on eye-tracking (Cortina et al., 2015; Dessus et al., 2016), analysis of PSTs' 360 viewing indicated participants with more sophisticated noticing (via writing) had more focused attention than their counterparts. For example, Anna's focus on three students within the same line of sight contrasted Brie's shifting from one length of the table to the other, and back (see Figure 4). This corresponds to Dessus et al.'s (2016) observation that more experienced teachers focused on subsets of students and examined more specifics, but more novice teachers scanned the room more frequently. However, findings here do not compare expert and novice teachers, but PSTs at similar levels of experience. Thus, findings presented here suggest that PSTs' embodied attending behavior may be due less to level of experience and more to some underlying professionalized knowledge.

This paper includes a diverse set of authors spanning mathematics education, computer science, and educational technology, with each area of expertise represented in the development and application of this new tool for teacher education. Thus, beyond the implications for our specific machine learning A.I., an additional implication is the benefit and need for cross-disciplinary collaboration. As mathematics educators seek to incorporate more 21st century technologies into teaching and teacher education, there is a critical need for such collaboration. This paper serves as an example of what such collaborative efforts can yield, as well as providing a description of how one such technology (machine learning) is developed in such contexts. Specifically, applied machine learning to PSTs' attending in 360 video. Findings are preliminary, but suggest that nuanced student actions relevant to pedagogical content-specific noticings can be detected by A.I. This is highly significant, since prior applications of machine learning have focused on more generic student behaviors (Luan & Tsi, 2021; Nückles, 2020). As the accuracy and breadth of our machine learning A.I. improves, it has potential not only for improving capacity for research of PSTs' professional noticing, but in providing timely feedback for PSTs in mathematics methods courses. Some of the attending element patterns detected with the A.I. described here can be applied to other videos (360 or standard), but such application is likely context specific and require additional training of the A.I. However, such additional validation of these machine learning algorithms will likely yield more robust tools for mathematics teacher educators and teacher education researchers.

THE INFORMAL COVARIATIONAL STATISTICAL REASONING: FOCUS ON THE NOTION OF AGGREGATE USING DIGITAL TECHNOLOGY

Cindy Nathalia Morgado Hernández
Center for Research and Advanced Studies (Cinvestav), Mexico
cindy.morgado@cinvestav.mx

Ernesto Sánchez Sánchez
Center for Research and Advanced Studies (Cinvestav), Mexico
esanchez@cinvestav.mx

We report the results of a study on informal covariate statistical reasoning conducted with 22 students (aged 16 and 18 years). We designed and implemented a task in a digital technology environment to introduce the line of best fit. The task design having elements that foresee misconceptions reported in the literature, and by focusing on four statistical ideas that we consider being central to the development of informal reasoning about the line of best fit. After having used the digital technology environment, students transitioned from viewing points of a scatterplot as individual points or fragmented into subsets to viewing the scatterplot as an aggregate from a mathematical mechanism that links them through the notion of distance from a point set to a right line.

Keywords: informal covariational reasoning, line of best fit, aggregate, digital technology

Introduction

In statistics, covariation is the variation of two statistical variables that take numerical values (Moritz, 2004).The values for each variable are obtained from the same observation unit and expressed as an ordered pair; observations compose a set of pairs called bivariate data. The graphical tool used to represent a bivariate data set in a plane is a scatterplot. The most used techniques to investigate statistical covariation are correlation and regression. Correlation quantifies the strength of the linear relationship between a pair of variables, while regression expresses the relationship as a mathematical model (linear equation).

The correlation and regression are statistical objects that express global properties of a data set, properties that do not belong to isolated points of the data set but all of them. An isolated individual data does not contain the properties that will emerge when a data is associated with other data, namely the data viewing as an *aggregate*. Stigler (2016) used the term aggregation to designate the first pillar of statistical wisdom. For him, aggregation is the mechanism by which can provide more information of a data set, there is a loss of information of the individual data for retaining global properties of the data set.

Statistical educators have mentioned the aggregate to highlight a recurrent phenomenon in the learning of statistical concepts. Hancock et al. (1992) were the first to raise the problem that in data analysis, students are prone to focus on the characteristics of individual data without making sense of the aggregate properties of a data set, such as the mean. Other authors have mentioned the same problem concerning the notion of distribution (Bakker & Gravemeijer, 2004), in group comparison (Ben-Zvi & Arcavi, 2001), and the concept of the sample (Saldanha & Thompson, 2002). The correlation and regression result from an aggregation process and require that a point could be conceived of as an aggregate.

With the availability of specialized statistical applications and software, opportunities open up in teaching for students to look at data sets as an aggregate; the possibility of multiple representations, dynamic trawling, real-time data updating, and performing tedious calculations are ideal to show how statistical summaries are related to the data set from which they originate (Biehler et al., 2013). This paper informs about a design research that use the online data analysis platform CODAP, and an applet designed in GeoGebra with the aim to promote the development of covariational reasoning in high school students; In particular, we are interested in observing if the design of the task and the use of the software allow students to begin to see the points of scatterplot as an aggregate or, more precisely, the process of finding the line of best fit as an aggregation process.

Background

Many researchers have been interested in the problems of the correlation and regression teaching and learning. The first studies were about the conceptions of university students, such as of Truran (1995), who was interested in the detection and characterization of the interpretations of university students about the correlation coefficient and the determination coefficient. Sánchez-Cobo et al. (2000) studied verbal, graphical, and numerical representations of correlation, and Sorto et al. (2011) studied students' conceptions of the line of best fit. At the pre-university school levels, there is the study by Watson and Moritz (2007) analyzed students' reasoning when making graphical representations about covariation, and Casey (2015, 2014) studies of students' conceptions of what the line of best fit is. Regarding high school students' conceptions, two studies related to the graphical representation of covariation stand out: the study by Watson and Moritz (1997) analyzed the graphical representation established by students about the covariation present in non-symbolic contexts, and the study of Estepa and Batanero (1996) established some conceptions of covariation in students when they judge the relationship of two variables based on scatterplots.

A current trend in statistical education is to conduct research that investigates the relationships between teaching design and progress in student learning. In this way, studies have begun in which the design of the intervention in the classroom is an important component highlighting technology as an element that can help students make more accurate covariation judgments (Batanero et al., 1998; Cobb et al., 2003; Inzunza, 2016). At the high school level, research that includes teaching intervention is still scarce and scattered; we found only three studies at this level, each paper covering one topic: covariation in big data contexts (Gil & Gibbs, 2016), scatterplots, and the line of best fit (Medina et al., 2019), visualization and trend in the data (Dierdorp et al., 2011).

Framework Conceptual

The following four subsections present the concepts we consider central for understanding the research from which this report was done. We defined the conceptual framework used here as a set of concepts that clarify the key aspects to be studied. We aligned this notion of the conceptual framework with the one presented by Miles and Huberman (1994, p.18).

Definition of Aggregate and Aggregation in Statistics

From examining how researchers use the term aggregate, we define it as a set of data belonging to a larger whole with global properties. An aggregation process comprises an object produced from an aggregate that highlights properties common to all data, properties that individual data does not have. Thus, the mean and the line of best fit result from an aggregation process. A condition for the mean of a data set or the line of best fit of a "cloud"[1] of points to be seen as representatives of their respective data sets is that we must conceive them as aggregates. This characterization tries to synthesize the comments of Hancock et al. (1992), Konold and

Higgins (2002), Bakker and Gravemeijer (2004), Casey (2015), and Stigler (2016). From an educational perspective, the question arises: How does a student come to conceive that a data set is an aggregate? We hypothesize that there are two sources: context and mathematics. We can perceive that all the data belong to a phenomenon or associate them with a causal relationship. Here, we see the data within a context that unifies them. Also, we can perceive the data as part of an aggregate if it belongs to a set linked by a mathematical property, for example, even numbers in a set of numbers, cloud points aligned in a bivariate data set, etc. In both cases, the totality transcends the given set such that we can imagine the existence of other data that could be added to the given set.

Beliefs, Conceptions and Difficulties about Covariation

The literature reports that students do not separate their previous beliefs for observing and evaluating the behavior of two quantitative variables, and they do not include the word variation in their vocabulary (Moritz, 2004). Also, the previous concepts of a linear function in mathematics can interfere in their ability to make sense of determining the line of best fit (Casey & Nagle, 2016). Estepa and Batanero (1996) established some conceptions in the students when they evaluate the covariation and the line of best fit. Deterministic conception when students considered the relationship between the variables from a functional point of view (a line that passes through all the points), they expect a correspondence where each value of the dependent variable correspond to another value of the independent variable when this is not the case, consider that there is no dependence between the variables, local conception when they use only a part of the data and they generalize conclusions to the entire data set. Casey (2015, 2014) establishes the following strategies for students to draw the line of best fit: draw a line that divides the data points so that half of the points are at the top of the line and half are below the line, draw the line through the midpoints of different cloud groups. In addition, in the students may emerge the concept of "closeness" between the line and the point cloud but there is a lack of understanding of other elements such as the error that corresponds to the sum of the squares of the vertical distances between the observed and predicted values.

Informal Covariational Statistical Reasoning

Reasoning refers to the processes of obtaining and verifying propositions (conclusions) based on evidence or established knowledge or assumptions. Reasoning can take many forms, ranging from informal argumentation to deductive demonstration (National Council of Teachers of Mathematics, 2009, p.5). Informal statistical reasoning is related to data, samples, chance, inference, and relationships between statistical variables. Informal statistical reasoning about covariation is related to bivariate data sets and relationships between statistical variables. In the present research, the purpose is to develop students' informal statistical reasoning about the line of best fit. For this purpose, we define informal notions of linear (instead of quadratic) distance and line of best fit, which does not coincide with the formal concepts but is not inconsistent with them and has the advantage of being closer to students' intuitions.

The Influence of Digital Technology on Reasoning about Statistical Covariation

Research suggests that technology can help students make more accurate covariation judgments (Batanero et al., 1998; Cobb et al., 2003; Inzunza, 2016). Technology plays a very important role in statistics since it makes them visual, interactive and dynamic, allowing a focus more on concepts rather than algorithms and calculations, where interactivity and the quality of use of graphs allow conducting experimentations with data; this allows engaging students in productive activities (Biehler et al., 2013). Specifically, the topics of regression and correlation with the technology possess the following relevant features: 1) The possibility to form scatterplots and fit a regression line by visually showing the changing quadratic deviations of the line as it fits the cloud of points. 2) Obtain the numerical value of the correlation coefficient and determine the algebraic expression of the regression line. 3) Dragging points from the scatterplot and observing in real-time the effect of their location within the cloud on the strength (correlation coefficient) and direction (regression line) of the relationship, allowing one to see the interactions between the elements dragged and the statistical measures. 4) Linking multiple representations to discover and observe patterns and trends in data simultaneously from different perspectives (the graph, the summary measures, the regression line). In the present study, we show how with the help of technology, students can conceive of the line of best fit as the result of an aggregation process.

Methodology

The study participants were 22 high school students around the age of 17 who had not studied the topics related to correlation and linear regression. The application of the task took place in a computer classroom during a two-hour class session. The author of the present work carried out the implementation of the task. The data obtained were the worksheets developed by pairs of students.

We follow the principles of the design experiment of Cobb & McClain (2004) for the design and implementation of the task: the *use of technology*, we used *CODAP* and *GeoGebra* software because their features allow designing elements that we consider relevant for students to observe and interact with. For the *classroom discourse*, the teacher oversaw, monitoring, coordinating, and making sense the interaction between the students and between students and the technological tool. The *structure of the task* in the classroom is collaborative work students had the opportunity to explore solutions, compare them with those of their peers, and clarify them in a group meeting. To establish the *central statistical ideas*, we analyzed the difficulties and conceptions reported in the literature to promote elements of the task that anticipate the difficulties and students' conceptions. Also, we reviewed the content stipulated by the NCTM (2000, p.327-328) for the study of bivariate data (correlation and regression) in the last school level of high school and the bivariate data unit of the program of the College of Sciences and Humanities of the UNAM, Mexico.

The task starts from the graphical view in GeoGebra, where the data in Table 1 are displayed. The data correspond to the measure in fat gain (in kilograms) and change in energy use (in calories) from other "non-exercise activity" (NEA) (restlessness, daily life, and the like) of 12 young adults who overfed for eight weeks. We suggest that the teacher conduct a discussion asking whether changes in restlessness and other non-exercise activities explain weight gain in overeaters, guiding students to study the relationship between the variables on pencil and paper, followed by making the scatter plot in *CODAP* and leading them to describe the behavior of the point cloud (intensity and direction).

Table 1: Measures of Change in NEA and Fat Gain in the 12 Young Adults

NEA change (cal)	-94	-57	-29	135	143	245	355	486	535	571	620	690
Fat Gain (kg)	4.2	3	3.7	2.7	3.2	2.4	1.3	1.6	2.2	1	2.3	1.1

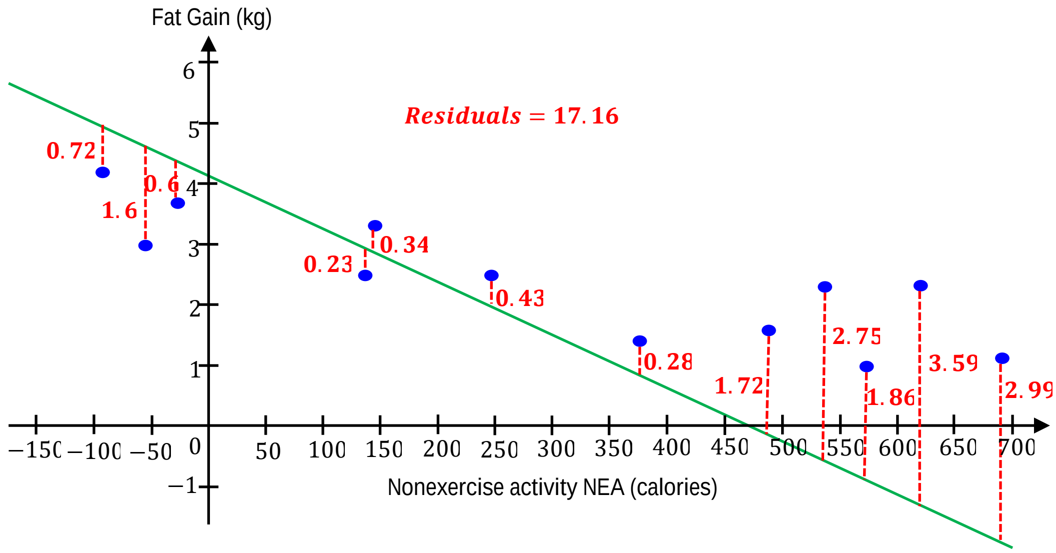

Figure 1: Screenshot of the Graphical View of the Task in GeoGebra

The *central statistical ideas* related to the line of best fit are present in the elements that make up the task and are:

1. The possible line always depends on all points in the scatterplot, i.e., all points influence the determination of how close or far away a line is.

The graphical view of GeoGebra shows a line that is movable by holding the click anywhere on it this line moves in different ways as desired, varying its slope or varying its point of intersection with the axis. The intrinsic characteristic of the movable line of being connected to the points (data in Table 1) focuses on the idea of conceiving a point cloud as an *aggregate*, i.e., all points in the cloud influence the determination of the best fit line.

2. Given a cloud of points and a line, we define the error of a pair of points (called residual) as the absolute value of the difference between the ordinate of the point and the ordinate of the projection of the point on the line of fit.

For each dashed segment in the graphical view, we show the numerical value called residual that corresponds to the difference between the ordinate of each data and the ordinate of the point that belongs to the moving line. What happens to the value of each residual if you move the line near or far from the point cloud? We intend to focus on the statistical idea of error, seen as a distance between a moving line point and a cloud point (datum).

3. Adding all the residuals, we obtain the measure (residuals) of closeness or remoteness between the cloud of points and the moving line.

In the file, there is a value called residuals. The teacher should mention that the residuals correspond to the sum of all residuals, and we calculate them by adding the absolute values of the difference between the points of the cloud and the possible points of the movable line. The objective is to provide a notion of distance from a line to a point cloud, and with this, to define a measure of the closeness of the line to the point cloud; this distance is the sum of all residuals. The student will explore how the distance from the line to a cloud changes by freely moving the line and observing the corresponding distance value. We suggest asking the students: Where do you think you should place the line so that the value of the residuals is the minimum? Can you be sure that the location you consider is unique, yes, or no? why?

4. The line that best fits the data is the one where the sum of residuals is minimal.

With the idea of defining the line that best fits the data as the one where the errors (residuals) or vertical distances are the smallest possible in some average sense in general, we suggest that the teacher indicate how to determine the line of best fit that GeoGebra yields and ask Is the way you placed the movable line the same as the line yielded by GeoGebra, yes, or no? How do they differ? What do you think is the criterion that GeoGebra uses to determine the line of best fit? We use a notion of linear distance and not quadratic distance because the former is more intuitive for the students., however, it seems clear to us that, understanding the idea with linear distance, it can be easily generalized considering the quadratic distance, arguing the reason for the advantages of this one.

Findings & Discussion

The analysis of the students' responses in judging the relationship between the variables shown in the problem situation together with the table of values without the use of technology provides the following reasoning as a result:

The *functional covariation* strategy comprises searching for and isolating bivariate data that adhere to a mathematical model, i.e., they focus their attention on the points they locate on a line. Students whose solutions fall into this category divide the data set into two parts, those that correspond to a linear model and those that do not. So their description of the data refers only to the subset of data that corresponds to the model and ignores those that are left out, and based on the data they selected, they describe the general trend, but their statements, often coinciding with the trend of the entire cloud, state, for example: "the more fat you consume, the more calories you increase", "the less you change in calories through movement, the less fat you will decrease". They also involve in their description's characteristics of the context of the problem*:* "fat increases because it remains encapsulated", "the less activity you do, the more fat", "the fats remain in the body". Their beliefs may influence their choice of the point cloud data set other than following the criterion that they lie on a straight line.

When students focus their attention on what happens in the passage from one point to the next within the values table, they present the strategy of *randomness.* They tracked the differences between successive points as they review the points from left to right, and they do not notice any predictable patterns. Sometimes, the difference is positive or negative, and the size varies. Thus, they conclude: "the fat increases or decreases depending on how many calories are burned in ANE", "if the calories decrease or increase depending on the ANE, the fat will also increase or decrease", "the calories that are burned will increase the kg or calories that are burned will decrease the kg", the students who follow this strategy, it is evident that there is no correlation since it is not possible to know if from one value to another value fat levels will go up or down. In both strategies, they visualize the data by paying attention to their individual or partial characteristics, and not as a whole. Thus, the analysis according to the first strategy consists of separating the data into two, in the second, of going through them one by one and seeing if and by how much they increase or decrease. When they use the CODAP platform to enter the table of values and make the scatter diagram and again to judge the relationship between the variables, the *inverse covariation* arises, which globally describes the behavior of the cloud, for example: “when increasing calories there is more fat-burning”, “the more change in ANE, the less fat increase there is”, “when the change in ANE is greater, the increase in fat is less”, “the more increase in ANE, the more fat loss there is. The less increase in ANE, the less fat loss”, the *context of the problem* also influences, for example: “the fat does not increase because, although you do not exercise if you keep moving”, “the increase in fat depends on the amount of ANE that is carried out daily”. Without using technology, students focus their attention on the variation from point to point (Randomness: fat sometimes increases and sometimes decreases), while that using the technology influences to make a description of the general trend the cloud, ignoring particular fluctuations (*inverse covariation:* fat values decrease as ANE values increase).

We see that treating the situation with the help of technology and the use of some of its possibilities influences students to abandon their tendency to highlight in their description of the cloud to a set of individual points that they compare with each other, to highlight a global property which becomes evident when you have an aggregate view of the set of data. In addition, with and without technology, the description that they did of the relationship between variables is influenced by the contextual content of the problem. Students do not see the data as simply numbers, but numbers with a context, which for Moore (1990) is what it implies to establish the statistical association.

Regarding the analysis of the students' responses when asked to establish the line of best fit to the data using the GeoGebra applet, the following reasoning emerged:

In many student responses when using technology, the intuition of the *closeness* of the set of points to a line is revealed; for example: "that the blue points were closer to each other to the line", "I think it is the line that passes near all the points and does not join them, so each one has a certain distance". This intuitive idea becomes operative with a notion of *distance* from a line to a set of points. The software allows to calculate the residuals, that is, the differences of the ordinates of each pair of points with the same abscissa, one belonging to the cloud and the other on the line. Each residual can be viewed as a distance from the point of the cloud to the line (for the present purpose it does not affect the fact that strictly the distance from a point to a line is defined as the distance of the segment that passes through the point perpendicular to the line) and the sum of residuals as the total distance of all residuals from the cloud to the line. As this sum can be seen in the software and is updated in real-time as the line moves, the students manipulate and see a real function determined by the point cloud and whose independent variable is the lines in the plane; then for them, the line that minimizes the function is the line closest to the points, that is, the one with the best fit. The following expressions of the students indicate some of their ideas in this regard: “the less distance there is between the points and the line, the remainder will change”, “the further the line of adjustment of the points in the table is in the graph is greater the value of residuals since there is a greater distance", " when the line is better centered, the level of residuals is lower, that is, it passes centering in the middle of the points.

One condition for viewing a set of data as an aggregate is to imagine a rational mechanism that unites them all into a totality that represents them, even if individual information is lost. When students choose a subset on a line from the point cloud, they consider the subset as an aggregate but ignore and discard some data; they do not see the cloud as an aggregate. The process of looking for the line closest to the point cloud with a notion of distance shows that each one of the points contributes to determining said line. This fact is significant because the literature has highlighted that one problem for students to understand the statistical notions of centers, variation, data comparison, and data distribution, is that they see the budding data set as an added (Bakker & Gravemeijer, 2004; Konold & Higgins, 2002; Roseth et al., 2008). Also, the context is an important factor to see a data set as an aggregate since in this case, it is the existence of a *causal mechanism* (the term is from Zimmerman, 2007) that suggests that all the data are related, in our case, that ANE and fat accumulation are part of a causal process.

Conclusions

A necessary condition for understanding the topics of regression and correlation is conceiving a set of bivariate data as an aggregate. However, students do not reach this conception spontaneously and probably not with traditional methods as they have been taught the topics at the high school level. There are two levels in which it is convenient to analyze the appearance and development of a set of points as an aggregate: the mathematical level and the contextual level. At the mathematical level, technological resources allow students to move from seeing a cloud of points as individual points or fragmented into subsets to seeing it as an aggregate based on a mathematical mechanism that links them with the notion of distance from a cloud to a straight line. At the context level, it is the existence of a causal mechanism that helps to imagine a unity in the data set. It would remain to work on the sources of variability for students to explain why the data differ from the probable causal model.

Note

[1] We use the term "cloud" of points or simply "cloud" to refer to bivariate data represented in the scatterplot.

DYNAMIC SPATIAL DIAGRAMS AND SOLID GEOMETRIC FIGURES

Camden Bock

camden.bock@maine.edu

Justin Dimmel
The University of Maine
justin.dimmel@maine.edu

This paper reports on a study of learners' use of immersive spatial diagrams to make arguments about three-dimensional geometric figures. Immersive spatial diagrams allow learners to use the movement of their bodies to control their point of view, while immersed in three-dimensional digital renderings. We present analysis of two pairs of pre-service elementary teachers' argumentation about the shearing of pyramids, using the ck¢-enriched Toulmin Model of Argumentation (Pedemonte & Balacheff, 2016) to link the affordances of immersive spatial diagrams to the learners' mathematical reasoning. We share how one pair of learners took points of view bending beside and standing within the pyramid to describe how the space inside is transformed without reference to one- or two-dimensional components of the representation.

Keywords: Measurement, Technology, Geometry and Spatial Reasoning

Diagrammatic Representations of Three-Dimensional Figures

Three-dimensional geometric figures are often represented with diagrams on two-dimensional canvases in school geometry (Clements et al., 2017; Dimmel & Herbst, 2015; Dorko & Speer, 2015, 2013; Duval, 2006; Pittalis & Christou, 2010; Stevens et al., 2015), mediated through projection or cross-section. These frozen perspectives split learners' attention between spatially navigating the diagram and attending to the features of the mathematical figure. While 3D dynamic geometry software (*e.g.*, Cabri3D) allows learners to make visual observations from many points of view (Mithalal & Balacheff, 2019), these points of view are often controlled by two-dimensional (*e.g.,* touch, mouse) or keystroke-based input systems. Learners have difficulty working with two-dimensional representations of three-dimensional figures without spatial observation of the 3D shape (Pittalis & Christou, 2010).

Further, it is often impracticable to change the perspective *while* continuously manipulating the figure. Continuous manipulations of a diagram are important because they support learners' reasoning in school geometry. The continuous manipulation of dragging can support learners noticing the spatial properties of the diagram that are mathematically necessary (Clements, 2003; Laborde, 2005) and dragging can also allow for geometric transformations to be represented as "continuous and temporal" processes (Ng & Sinclair, 2015, p. 85). Observations of two-dimensional representations of three-dimensional figures may focus learners' struggles on navigation and manipulation of the diagram rather than on discerning which spatial properties of the diagram are incidental or mathematically necessary.

Physical spatial inscriptions (*e.g.*, 3D pens) are one alternative to two-dimensional renderings of three-dimensional figures. Using physical materials (*e.g.,* extruded plastics), diagrams can take up space and be manipulated by the learners' grasp (Ng & Sinclair, 2018). Further, learners can vary their point of view as they might with any other physical object – by walking, turning and bending their body and turning their head. However, physical spatial inscriptions have material constraints and are not generally able to be manipulated continuously with nonrigid transformations.

Immersive spatial diagrams are digitally rendered diagrams that share the learners' spatial environment, like physical spatial inscriptions, but also offer the digitally rendered flexibility of

3D dynamic geometry software (Bock & Dimmel, 2020; Dimmel et al., 2020). Immersive spatial diagrams can be rendered using various consumer-ready devices: virtual-reality head-mounted-displays (*e.g.,* HTC Vive, Oculus Rift*),* augmented-reality head-mounted-displays (*e.g.,* Microsoft Hololens*),* and mixed-reality head-mounted-displays (*e.g.,* Varjo XR-3). These diagrams bring learners into a world where space-occupying objects can have the dynamic properties of digital renderings or bring those dynamic spatial objects onto the learners' physical world. Immersive spatial diagrams offer learners an opportunity to explore the properties of spatial representations governed by mathematical laws rather than the laws of physics.

By combining embodied control over point of view, continuous transformations, and a three-dimensional visual experience of the diagram, immersive spatial diagrams offer learners new modes of interactions with representations of three-dimensional figures. In this study, we explored how learners interacted with an immersive spatial diagram — a dynamic, digital, three-dimensional representation of a pyramid bound between parallel planes, focused on the affordances that allow learners to use their body to access multiple points of view. We asked: How do the points of view that learners take while immersed in a spatial diagram shape their argumentation about geometric transformations?

Theoretical Framework: ck¢-enriched Toulmin Model of Argumentation

We used the conception-knowing-concept (ck¢) enriched Toulmin model of argumentation (Pedemonte & Balacheff, 2016) to analyze the arguments that learners constructed while using an immersive spatial diagram. The ck¢-enriched Toulmin model of argumentation situates Balacheff & Gaudin's (2010) conception-knowing-concept models' rich description of learners' reasoning about a mathematical context within the Toulmin (1958) model's transformation of observed data into a claim through inference. The ck¢ model describes mathematical conceptions in terms of observable components of the interactions between learners and their environment (Balacheff & Gaudin, 2002, 2010; DeJarnette, 2018; Herbst, 2005; Mithalal & Balacheff, 2019). We chose this model to highlight how the points of view available to learners, as a constraint on their observations used for data in their argument, shaped their claims and inferences with a rich mathematical characterization. Components of the (ck¢) enriched Toulmin model are explained in greater detail with application to spatial diagrams in Bock and Dimmel (2020).

Mathematical Context: Shearing of Pyramids

The mathematical context for the study was the *shearing* of a pyramid between parallel planes. In plane figures, a transformation is a shearing transformation if a figure can be bound between parallel lines such that the lengths of the parallel cross-sections of the figure are preserved by the transformation (Ng & Sinclair, 2015). Shearing can be extended as a volume-preserving transformation of 3-dimensional figures bound between parallel planes. Consider a pyramid whose apex is bound to a plane parallel to its base (Figure 1: *ABCDE*).

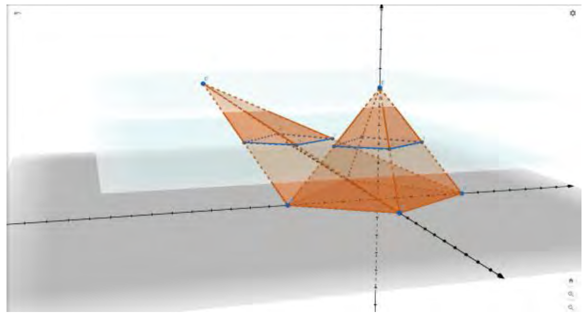

Figure 1: Pyramid *ABCDE* is sheared to form Pyramid *ABCDE'*

Any non-empty intersection of a pyramid and a plane parallel to its base is either the apex of the pyramid or a dilated copy of the base of the pyramid. In the case of a dilated copy of the base (Figure 1: *FGHI*), this cross-section is translated as the apex of the pyramid moves along a plane parallel to its base (Figure 1: *F'G'H'I'*). Then the area of the cross-section and the volume of the pyramid are preserved under the shearing transformation.

Figure 1 illustrates some difficulties with visual observations of three-dimensional geometric transformations mediated through a two-dimensional canvas. It is not immediately obvious if the cross-sections of the pyramid are (at least approximately) congruent. While a diagram, on its own, is not sufficient to prove geometric relationships, accurate diagrams are powerful heuristics that can suggest what relationships one ought to try to prove (Larkin & Simon, 1987). However, the two-dimensional diagram of a pyramid is caught in a conflict between seeing and knowing (Parzysz, 1988): perspectives that allow the pyramid to be *seen* as a figure that occupies space distort the polygonal cross-sections of the pyramid. As a result, it is difficult to show how the cross-section is transformed while showing how the cross-section relates to the volume of the pyramid.

Design of the Virtual Environment

We designed a virtual environment (Bock et al., 2020) where learners could explore the shearing of a pyramid with an immersive spatial diagram (Figure 2A). Learners could use pinch, drag and throw gestures to manipulate the apex of the pyramid, which was bound within a plane parallel to its base (Figure 2B). An open-palm gesture, parallel to the pyramid's base controlled the position of a cross-secting plane (Figure 2C). Instead of offering numeric representations of measure, a cube with volume equal to the volume of the pyramid and a square with area equal to the surface area of the pyramid could be loaded into the environment (Figure 2D). Finally, the participants had previously explored an analogous case of a triangle bound to parallel lines (described in Bock & Dimmel, 2020), which was also available for reference.

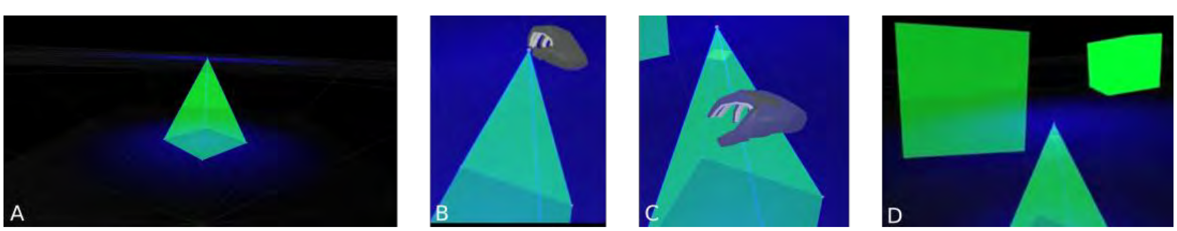

Figure 2: The Virtual Environment

Pedagogical Rationale

The environment was designed to provide immersed participants with direct embodied control over their point of view; it featured a gesture-based interface that allowed immersed participants to move the apex of the pyramid and investigate its cross-sections. By excluding numeric measures, we hoped to discourage learners from using routine empirical calculations (*e.g.,* calculating the area of the base as the square of the length of the sides, calculating the volume as the product of the area of the base and the height) to reason about the effects of the shearing transformation on the pyramid. We hypothesized that learners would instead make arguments using the congruence of stacks of cross-secting planes to make sense of the shearing of the pyramid – either as units of area, or as approximations to small units of volume.

Methods

This study used a case-study methodology (Yin, 2012), where a set of arguments made using a diagram was the unit for a case. We analyzed a set of arguments constructed by pre-service elementary teachers using an immersive spatial diagram at a public university in the United States. Participants worked collaboratively with asymmetric roles. One participant was immersed in the environment, via a head-mounted display, the other participant, who was not immersed in the virtual environment, viewed a real-time projected video of the immersed participants' interactions on a television screen. Though the learners' views of and roles in the environment were different, collaborative interactions have been analyzed in other settings with similar immersed and non-immersed roles where the non-immersed learner's view was mediated through a two-dimensional projection (Price et al., 2020, p. 216). We considered their co-constructed arguments as the unit of analysis.

Participants

Below, we analyze the argumentation of two pairs of participants. All four participants identified as female. The first pair of participants were a junior and senior pre-service elementary teacher with concentrations in mathematics and art, respectively. The second pair of participants were two first-year pre-service elementary teachers without selected concentrations. Each participant is referred to using a pseudonym.

We archived the participants' experiences using first person composite, mixed-reality composite (BluePrint Reality, 2017; Sheftel & Williams, 2019), and third-person physical views as well as a microphone for recording dialog between participants and interviewers (see Bock & Dimmel, 2020, p. 13). The mixed-reality view blends together the virtual with the actual, offering an observer's perspective on how the immersed participant navigated the immersive environment. We used these video records to identify episodes where participants made geometric arguments about the effects of shearing on the measures of the pyramid. We then used these episodes to construct ck¢-enriched Toulmin models of each argument.

Example of Analysis

We analyzed three arguments from two pairs of participants using the ck¢-enriched Toulmin model of argumentation. We report here on one excerpt of one of those analyses, as a means of illustrating how we applied the ck¢-enriched Toulmin Model. Each of the components of the ck¢-enriched Toulmin models are developed from the video records and transcriptions. Figure 3 shows an enriched Toulmin model for an argument made by Emily and Olivia.

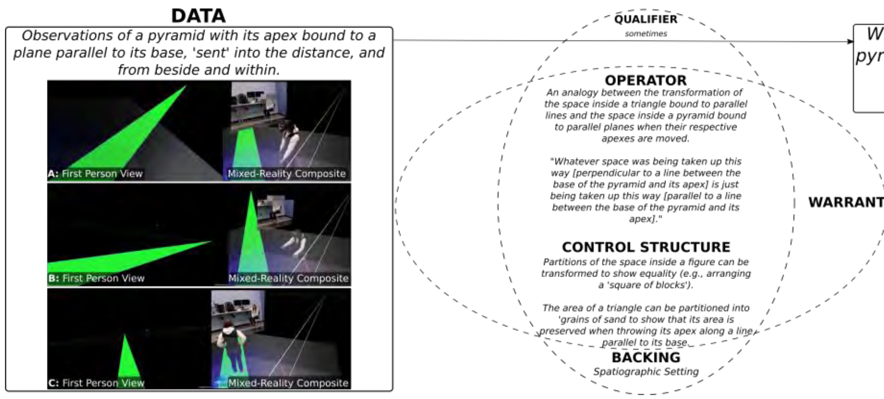

Figure 3. Model of Emily and Olivia's Second Argument

This excerpt explains the *data* element of the model in Figure 3, beginning after Emily and Olivia had experimented with manipulating the pyramid but had not begun developing an argument. Emily "sent" the apex of the pyramid into the distance by pinching, grasping and throwing the vertex. Emily waved goodbye as the apex was thrown along a line in a plane parallel to the pyramid's base.

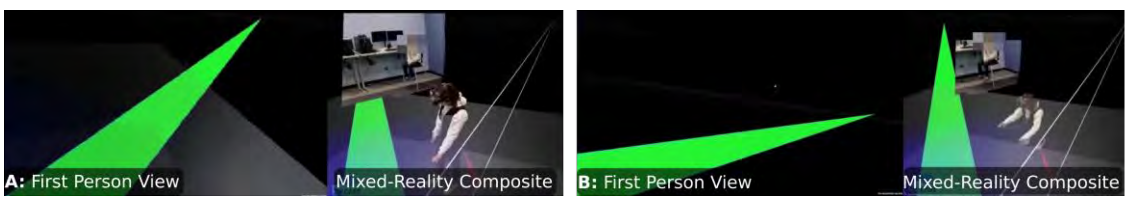

Figure 4: Emily's Points of View

As the apex continued to move away, Emily remarked that the pyramid "looks like its getting bigger" while her gaze looked along the length of the pyramid's nearest face (Figure 4A). Emily then walked beside the pyramid (Figure 4B), bent down, and remarked that "if you look at it...then it's getting so thin?". While in that position, Emily explained "whatever space was being taken up this way...it's just being taken up this way [gesturing along the length of the pyramid's face]." In this excerpt, Emily describes two visual observations: the pyramid "looks like it's getting bigger" and "if you look at it...then it's getting so thin." Emily's explanation of how the space inside the pyramid is being "taken up" showed that these observations serve as *data* (feedback from the virtual environment) to be transformed into their *claim* about the pyramid (see Figure 3).

Results

For each argument, a ck¢-enriched Toulmin model of argumentation was developed; these models are presented below and are accompanied by brief narratives. In our analysis, we were interested in how the feedback from the learner's environment – the *data* – shaped the mathematically rich descriptions of their conceptions in the *operator* and *control structure*. The data component of the model informs how the participants' interactions with the environment might have shaped their argumentation. The operator and control structure help to understand whether the learners used their interactions with the diagram to understand the shearing transformation differently then they might in other contexts.

A Point of View Within the Spatial Diagram: Emily and Olivia's Arguments

Emily and Olivia made two arguments about the shearing of a pyramid. In their first argument Emily and Olivia claimed that when you "send" or throw the apex of the pyramid into the distance within its plane, its volume will be conserved. Emily wore the head-mounted-display, while Olivia observed a mixed-reality third-person view on a large television screen and took three points of view within the virtual environment – standing beside the pyramid and dragging the apex of the pyramid locally (Figure 3A), bending down alongside the pyramid after the apex had been thrown (Figure 3B), and standing with her legs intersecting the pyramid (Figure 3C). While standing inside the pyramid, Emily remarked "this kind of looks like a road, I feel like Dorothy... I wish I could see my legs and see them being chopped off by the planes [faces of the pyramid]." Emily and Olivia used these observations from these three points of view to develop an argument that explained how it would be plausible that the space inside the pyramid is redistributed by the shearing transform such that the volume is conserved.

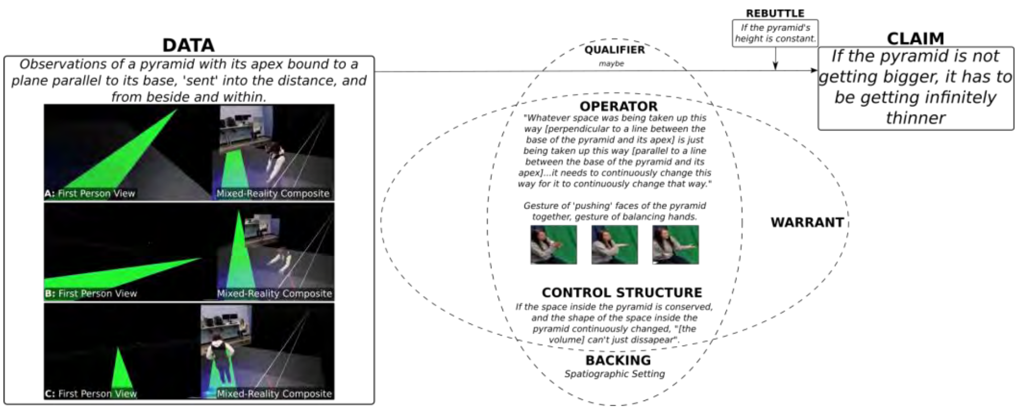

Figure 5. Model of Emily and Olivia's First Argument

After Emily and Olivia constructed this argument, the interviewers prompted: "is there anything else about the pyramid?... is there anything else about the pyramid changing?" Emily noted that the "length" [altitude] of the sides is becoming "super, super long... this looks infinitely long." While not infinite, the apex of the pyramid continued to move indefinitely into the distance. The interviewers prompted "so are you saying that a pyramid with infinitely long sides [faces] can have a finite volume?" Emily and Olivia then constructed another argument (Figure 5) to describe how the space inside the pyramid would need to change if the pyramid's volume is constant. Olivia described how "it would have to also get infinitely thin [as it is sheared], if it's not flattening out then I don't know where the space inside would like go," repeating gesture where she had her palms facing together and then pushed her palms together while tilting horizontally (Figure 5A). In this argument, Emily and Olivia reframed the warrant and control to be in terms of continuous and temporal transformations – describing how the pyramid is "flattening out", "getting infinitely thinner", and would need to "continuously change this way for it to continuously change that way". Emily and Olivia added a rebuttal that the height of the pyramid must be constant, however it was not clear why they attended to this measure.

Points of View from Above and Beside the Diagram: Abigail and Madison's Arguments

Abigail and Madison made an argument about the unbounded shearing of a pyramid where the only points they used were above and beside the pyramid. Abigail and Madison's argument included an argument about the area and perimeter preserving properties of shearing on a triangle to conclude that the volume and surface area of the pyramid would be analogously preserved under shearing (Figure 6). Abigail and Madison used a set of visual observations of the measures of the angles of the vertices at the base of the triangle and their line segments (Figure 6B) and visual observations of the behavior of the faces of the pyramid (Figure 6A) as they sheared each of the figures. While Abigail and Madison's warrant would not be understood to support their claim in a school mathematics context, the ck¢-enriched Toulmin model situates their conception within the feedback – or data – from their environment. During these observations, Abigail and Madison did not 'send' the triangle or the pyramid, so they did not have disconfirming feedback for their conclusions.

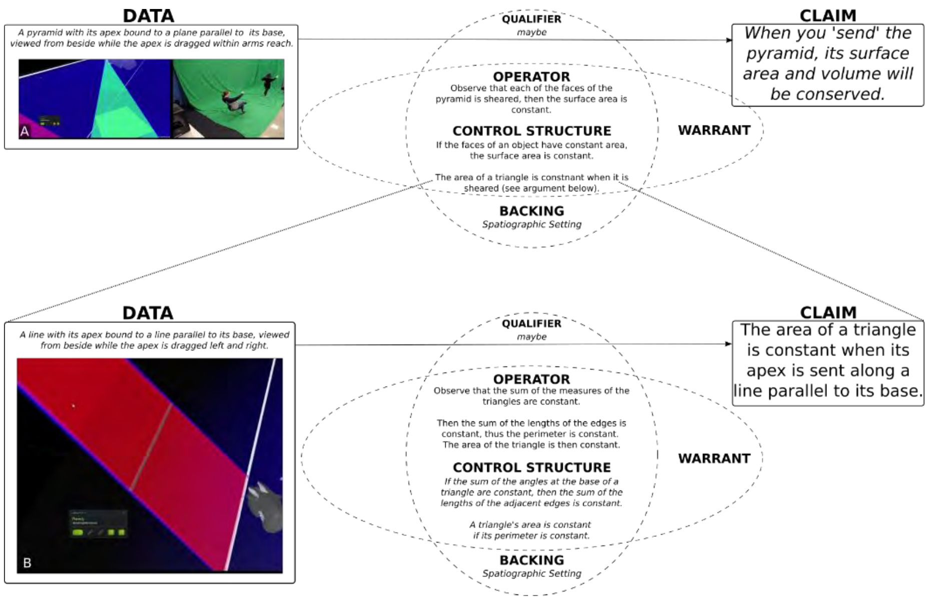

Figure 6. Model of Abigail and Madison's Argument

Discussion

In a school mathematics setting, the arguments developed by each pair of participants might feel incomplete – their arguments would need to be refined to be a rigorous explanation of the properties of the shearing transformation. With the lens of the ck¢-enriched Toulmin model we can look past a superficial evaluation of correctness to understand how the affordances of immersive spatial diagrams and the environment design supported their arguments, and the contexts where these diagrams might be useful in a less exploratory pedagogical setting.

Points of View

Both pairs of participants used their control over the point of view in the environment in ways that would be impracticable to replicate outside of immersive spatial diagrams: they used gestures to manipulate diagrammatic representations of pyramids and triangles while walking, bending, and turning their heads to make visual observations. Emily and Olivia took two points of view that would be difficult to replicate with two-dimensional diagrams: bending down beside and standing inside the pyramid. Emily took these points of view in order to share visual observations with Olivia and the interviewers as they constructed their argument. While we anticipated that participants might put their heads inside the pyramid, we did not anticipate the use of these points of view in the environment design. In contrast, Abigail and Madison engaged with the diagram using each of the novel affordances of immersive spatial diagrams but their visual observations of the triangle and pyramid are practicable to recreate with a two-dimensional dynamic representation of the figures.

Dimensionality

Emily and Olivia's argument had another unique feature – they described the continuous transformations of the space inside the pyramid and the triangle without describing lower-dimensional quantities. The points of view Emily shared beside and within the pyramid and Emily and Olivia's description of cross-sections of the pyramid through Emily's legs suggest that immersive spatial diagrams offer learners an opportunity to engage with three-dimensional mathematical figures without reconstruction from two-dimensional or one-dimensional elements. In contrast, Abigail and Madison's argument might have been better supported by the environment if measurement tools for angles, lengths and areas were available in the environment. Measurement of the triangle's angles or segments might have suggested that they do not correlate as Abigail and Madison suspected; measure of the faces of the pyramids might have suggested a changing surface area as the pyramid was sheared. This is a constraint of the environment design – not of immersive spatial diagrams – but also a feature that is easily accessible in many traditional dynamic geometric environments.

Existing research on immersive spatial diagrams has focused on representing mathematical figures with numeric representations of length and symbolic representations of area and volume (Lai et al., 2016), rigid transformations of static shapes (Gecu-Parmaksiz & Delialioglu, 2019), and gesture-based construction (Dimmel & Bock, 2017). This study was designed to explore how learners used points of view with immersive spatial diagrams to reason – and struggle with – the properties of continuous geometric transformations of three-dimensional figures. The results of this study explore two cases where learners investigated the shearing of three-dimensional figures, an extension of research on how learners reason about the shearing in plane geometry (Bock & Dimmel, 2020; Ng & Sinclair, 2015). In one case, the pair of participants identified mathematically relevant spatial invariants (volume of the pyramid, height of the pyramid) and described how these properties might relate to the shape of the pyramid for the spatial invariants to be plausible. However, the participants' argument did not relate properties of the figure to explain why the shearing transformation *necessarily* preserves volume. This is consistent with expectations from learners use of two-dimensional dynamic geometry environments, where dragging affordances have been linked to identification of spatial invariants (Clements, 2003). This process of "learning [to] identif[y] of visually relevant spatiographic invariants attached to geometrical invariants" is an important to the learning of geometry, alongside deductive reasoning from theoretical statements (Laborde, 2005, p. 177).

Conclusion

Emily and Olivia struggled productively to describe continuous transformations of volume without reducing to lower-dimensional elements, confidently reasoning from visual observations. This addresses a key constraint of two-dimensional representations of three-dimensional geometrical objects — that the figures must be analyzed through reconstruction from lower-dimensional components of the representation (Mithalal & Balacheff, 2019). Further research is needed to explore how spatial diagrams can be designed for learners to *see* or attend to one-, two-, or three-dimensional elements of figures, analogous to diagrammatic representations of two-dimensional figures (Duval, 2006, p. 116). Finally, there is an opportunity to explore how learners' analysis of three-dimensional figures without reconstruction from one- and two-dimensional elements might be designed into geometric construction environments and where this might best support learners' reasoning in school geometry.

We report the design of an analog technology, what we refer to as a SunRule, that uses sunlight to model multiplication. Physical models that explore multiplication are fixtures in elementary mathematics classrooms. Our interest in physical models of multiplication was driven by an overarching design problem: How could a physical tool realize a continuous model of multiplication? That is, how could we represent continuous, variable quantities with physical things? We identify specific challenges the SunRule was designed to solve. We explain the mathematical underpinnings of the device and report a teaching experiment during which pre-service teachers explored the device in small, socially-distanced groups. We consider how explorations with the SunRule create opportunities for mathematically rich instructional activities that are also essentially connected to being outside.

Keywords: Technology, Measurement, Geometry and Spatial Reasoning, Design Experiments.

Introduction

Sunlight provides an abundant, renewable, accessible source of naturally occurring parallel lines. It is the rare example of a mathematical contextualization with which nearly all children are familiar. Despite its familiarity and universality, sunlight plays almost no part in K-12 mathematics classrooms. Furthermore, while sunlight is among the closest physical realizations to the Euclidean ideal for parallel lines, there is scant research about how K-12 students might use sunlight and the real-world parallel rays it provides to engage in mathematical activities. But in the shadow of the global pandemic, when so much of schooling has moved to screens, there is an urgent need for outdoor, socially-distance-able activities that have robust mathematical designs – i.e., designs where mathematical concepts are intrinsic to the activity. To respond to this need, we report the design of an analog technology, what we refer to as a *SunRule*, that uses sunlight to model multiplication. We explain the mathematical underpinnings of the device and report an initial teaching experiment where pre-service teachers explored the device in groups. We consider how investigating multiplication with the *SunRule* can challenge familiar notions of contextualized mathematics.

Background & Design Problem

The sun shadows phenomenon

Sunlight and what has been described as the *sun shadows phenomenon* was used as a tool by Garuti and Boero (1992) to investigate geometric proportionality as a physical phenomenon with 11 and 12 year olds. This study offered promise that embedding problem situations in a context in which directly experiencing the geometrical-physical aspect is paramount may move students from an additive model to a multiplicative one. Building on this early success, the Genoa Group

(Boero, Garuti, & Mariotti, 1996a; Douek, 1999) used the overarching approach of examining heights of objects and the lengths of the shadows they cast to pursue a wide range of research questions within the sun shadows field-of-experience (Boero, 1989). Topics included argumentation, conjecture, proof construction, and angle concepts, among others. They all shared the structure of teaching experiments that capitalized on shadows cast by the sun (either imagined or observed and recorded experimentally) to explore problem situations in different dynamical ways (Boero, Garuti & Mariotti, 1996b). Students produced, through open problem solving situations, meaningful conjectures from a space geometry point of view. Douek (1999) also demonstrated the link between context-related arguments, mathematical modelling, and conceptualization of geometric ideas. The present study extends this work to use geometric proportionality of shadows cast by the parallel rays of the sun (Decamp & Hosson, 2012) to generate products of real numbers.

Models of multiplication

Various physical and visual aids are used to model multiplication in elementary classrooms (Kosko, 2019). There are discrete models that involve arranging things, such as playing chips, into equal-sized groups. For example, the problem (2)(3) could be represented as two groups of three things each or else three groups of two things each. Discrete models frame multiplication as a kind of repeated addition, and this is one of the most widely-used models to conceptually define multiplication (Hurst, 2015; Vest, 1985). But discrete models are harder to physically realize with fractions and decimals. Visual models that use area to represent multiplication are an alternative. For example, the numbers to be multiplied could be arranged as the length and width of a rectangle, and the area of the rectangle would be the product (Reys et al, 2014; National Governors Association 2010, 25). An advantage of this continuous model is that it applies to any of the kinds of numbers children encounter in school (Kosko, 2019). A drawback is that it models unidimensional numbers—that is, single points on a number line—as areas, thereby misrepresenting products as two-dimensional (McLoughlin & Droujkova, 2013).
Physical models are pedagogically compelling because they can create diverse avenues for exploration and learning (Clements, 2000; Domino, 2010). Our interest in physical models of multiplication has been driven by an overarching design problem: How could a physical, manipulable tool realize a continuous model of multiplication? That is, how could we represent continuous, variable quantities with physical things?

Design Framework

Diagrammatic multiplication

Our answer to this question was inspired by a geometric interpretation of multiplication that is predicated on the following observation:

> the hypotenuse of the right triangle determined by an object and its shadow must be parallel to the hypotenuse of any other object and its shadow. Hence, knowing the shadow of one object (we call this object the unit) gives us a way to deduce the shadow of any other object. (McLoughlin & Droujkova, 2013, p. 2)

From this observation, McLoughlin and Droujkova (2013) developed a diagrammatic definition that models multiplication as *continuous directed scaling*—*i.e.*, the length of one segment is a positive or negative multiplier that stretches the length of another segment in the positive or negative direction (Dimmel & Pandiscio, 2020). We initially realized this geometric definition of multiplication in a dynamic diagram that had draggable points (see Figure 1).

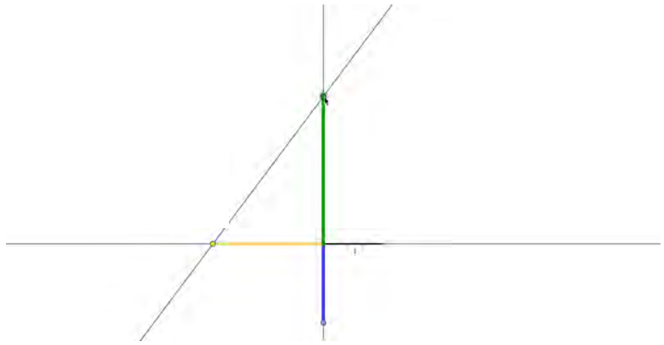

Figure 1. A dynamic diagram that realizes a geometric definition of multiplication. The yellow and blue points can be dragged along their respective axes to increase or decrease the lengths of the yellow and blue segments. The line that intersects the vertical axis determines the product of these lengths, which is represented by the green point.

In these diagrams, the "parallel to the hypotenuse" condition described above was satisfied by constructing a parallel line whose point of intersection with the *y*-axis would specify the product. The dynamic diagram we developed allowed students to use continuous transformations to explore ranges of products, such as products for pairs of numbers that are between 0 and 1 (Thompson & Saldanha, 2003). Because physical models for exploring arithmetic are common in elementary mathematics classrooms (e.g., Base Ten blocks, Cuisenaire rods, Pattern Blocks, Unifix cubes, chips and counters), we sought to design a physical embodiment of the multiplication diagram.

The variable altitude and variable length design problems

The keystone of the geometric definition of multiplication is parallel lines. Fortunately, sunlight offers a readily available, renewable, and abundant supply of naturally occurring parallel rays. The problem with using the sun as the source for parallel lines is that, at any time, the sun appears in one (and only one) position in the sky, and this position determines the proportion between an object's height and the length of its shadow (Douek, 1999). Thus, to multiply numbers in general requires control over the position of the sun. We refer to this as the *variable altitude* design problem.

Of course the sun cannot be moved, but there is nevertheless a solution to the variable altitude problem: We can change the *apparent* altitude of the sun by varying the angle of inclination of a surface onto which shadows are cast. By increasing the angle of inclination of a surface (i.e., the *shadow plane*), we decrease the lengths of any shadows falling upon it; by decreasing the angle of inclination, we increase the lengths of those shadows. Thus, by varying angles of inclination, it is possible to control the apparent altitude of the sun from 90 degrees (directly overhead, no shadow) to 0 degrees (sun on the horizon, undefined/infinite shadow).

The inclined plane provides control over the multiplier in a multiplication product – by varying the angle of inclination of a shadow plane, it is possible to stretch or shrink the length of the shadow of whatever object has been determined to be the multiplicative unit. What remains is a means to vary the multiplicand. This requires some method for increasing/decreasing length. We refer to this as the *variable length* design problem. The historical solution to this problem was the *slide rule,* an arithmetic aid that reigned from the 17^{th} century until it was abandoned for electronic calculators in the 1970s (Cajori, 1909; Tympas, 2017, 7-8). We adapted the sliding action of a slide rule, though not its logarithmic scales, to solve the variable length design problem.

Figure 2 shows a prototype of a device that embodies solutions to the *variable length* and *variable altitude* design problems. We refer to this device as a *SunRule*. It is not, strictly speaking, a combination of a sundial and slide rule; however the name is apt because it combines essential elements of each device (e.g., gnomons[1], adjustable scales) in novel ways.

Figure 2. A *SunRule* consists of a ruled board (shadow plane) and rods that are orthogonal to the ruled board. By changing the angle of the shadow plane, one changes the length of the shadow of the shorter rod, which serves as the multiplicative unit. The height of the longer gnomon represents the multiplicand. The device works because rays from the sun are parallel.

Method

Our initial plan was to analyze how pairs of elementary mathematics teacher candidates explored the *SunRule*. That plan is on hold until it becomes safe for pairs of students to interact in close proximity. In an effort to persevere through the challenge of data collection during the pandemic, we developed a handheld version of a *SunRule* that could be constructed from common household items (Figure 3). Thus, multiple devices could be built, which allowed students to interact at safe distances.

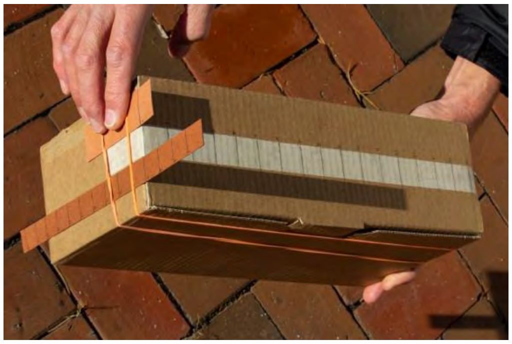

Figure 3. A handhels *SunRule*, constructed by elementary teacher candidates. The *SunRule* shows that (3)(4) = 12. Photo by Meg Pandiscio (2020).

In Figure 3, there is a longer gnomon (bottom) and a shorter gnomon (top). The shorter gnomon functions as a unit length. The unit length and the factor by which its shadow is stretched define a multiplier; in this case, that multiplier is (3), since the device has been inclined so that the length of the unit shadow extends (3) units. The height of the longer gnomon can be adjusted by sliding it up or down; the height of this gnomon specifies the multiplicand, which in this case is (4). The product is (12), shown here by the length of the shadow of the adjustable gnomon.

We report here an initial teaching activity where elementary teacher candidates built *SunRules* and used them to explore multiplication. We frame the initial teaching activity as a teaching experiment (Steffe & Thompson, 2000), where the second author was in the role of researcher-teacher. The purpose of the experiment was to generate hypotheses about how interacting with a *SunRule* creates opportunities for pre-service teachers to explore multiplication conceptually.

Context

During Fall, 2020, the second author taught an elementary mathematics methods course that convened in a hybrid in-person/online format. To comply with limits on indoor gatherings, the in-person students were split across two, five-student sections of the course that met on different days. The *SunRule* activity was planned as a two-class lesson that would allow elementary mathematics teacher candidates to explore a physical model of multiplication. For the first part of the activity, students worked with the second author to build *SunRules*. For the second part of the activity, students explored the *SunRules* outside, in small groups, while wearing masks and maintaining social distance. Both in-person sections of the course completed the first part of the activity. Students were told that the device had something to do with mathematics and that it needed to be used outside, on a sunny day. Figure 4 shows a selection of student-constructed *SunRules*.

Figure 4. *SunRules* constructed by elementary mathematics teacher candidates. Photo by Meg Pandiscio (2020).

Data collection

For the second part of the activity, five students from one section of the course[2] explored the *SunRules* in groups of two and three. The students within each group maintained social distancing throughout the activity, and the groups were separated by approximately twenty feet. Fixed video cameras recorded the activity of each group. The second author moved back and forth between the groups to facilitate their explorations of the device, following a semi-structured protocol. The protocol was designed to provide gradually more directed guidance to the groups of students. An example of a minimally directed question is, “What does the tool do?” An example of a more directed question is, “What are the ways that the lengths of the shadows of the gnomons could be varied?" The second author posed questions from the protocol to each group, as needed, to keep the students from getting stuck and spur them toward investigations of its mathematical opportunities. Below, we describe two episodes that capture how students explored and interacted with the *SunRule*. Episodes were identified by reviewing the video records of the teaching experiment and looking for instances where the tile of the shadow plane or the height of the gnomon was adjusted.

Episode 1: Sara's initial encounter with the *SunRule*

One group consisted of two students, Zak and Sara[3]. The second author launched the exploration activity for them by asking, "Any idea what this box does?" Sara replied, "Not yet", though as she said this, she had positioned the *SunRule* so that it was aligned with the azimuth of the sun, which caused the shadows of the gnomons to fall in parallel along its ruled surface (Figure 5).

Figure 5. While Sara declares that she does not know what the device does, she has oriented the device the way that it was designed to be oriented.

In this instance, Sara has guessed – in the technical sense of Wobbrock et al (2005) – how to interact with the device. She may not know what it does, but she already knows how it must be positioned in order to do it. Her next moves were to change the angle of inclination of the device. She tilted the device toward and then away from the sun, which caused the shadows of the gnomons to shorten and then lengthen (Figures 6, 7). As she varied the angle of inclination, she and Zak speculated that the device indicated a relationship between the sun and the shadows.

Figure 6. Sara inclines the device more toward the sun, which increases the sun's apparent altitude and causes the shadows of the gnomons to shorten.

Figure 7. Sara inclines the device less toward the sun, which decreases the sun's apparent altitude and causes the shadows of the gnomons to lengthen.

Sara noted the significance of the angle of inclination to the length of the shadows, "It really depends on how you hold it, like, if you tilt it towards (*sic*) the sun, then the shadows become very short, if you tilt it away from the sun the shadows get a lot longer." These initial interactions that varied the lengths of the shadows by changing the angle of inclination are the core of the mathematical design of the *SunRule*. This feature was salient for Sara almost immediately and suggests that the grounding predicate for the geometric definition of multiplication (block quote, above) is a natural and potentially powerful embodiment for a continuous scaling conception of multiplication.

Episode 2: Modeling division with the *SunRule*

After 10 minutes of open-ended exploration, both groups had zeroed in on the idea of the shadows varying in a constant ratio as the angle of inclination of the device was increased or decreased. As neither group had connected their observations about ratio to the operation of multiplication, the second author assembled the groups in a socially-distanced semicircle. He summarized the ratio ideas each group had discussed, and then stated that a mathematical operation the device could model is multiplication. Sara then demonstrated how the device could be used to show that (2)(3) = 6. The second author adjourned the groups to their respective places and asked them to continue exploring how the device could be used to model products.

In their discussion of multiplication, Zak and Sara realized that the device could also be used to represent division. Zak demonstrated this idea, which he attributed to Sara, by showing how the multiplication problem (5)(2) = 10 could be interpreted as the division problem (10)/(5) = 2 (Figure 8).

Figure 8. Zak positions the *SunRule* to show the quotient that (10)/(5) = 2.

To multiply with the *SunRule*, the angle of tilt varies the length of the shadow of the unit gnomon. This increase/decrease in the length of the unit shadow amounts to a scale factor that is applied to the length of the shadow of the other gnomon. To complete the product, one sets the height of the longer gnomon equal to the number that is being multiplied. The shadow of this gnomon is the answer. Zak and Sara realized that to represent division with the *SunRule* would require reversing this process; or, as Zak said: “there is an inverse relationship between multiplication and division.”

To use the *SunRule* to divide two numbers, set the height of the adjustable gnomon to be the divisor. Then, vary the angle of inclination of the *SunRule* so that the length of the adjustable gnomon’s shadow is the number that is being divided. The quotient will then be given by the length of the unit gnomon’s shadow. Sara made the connection to division within moments of demonstrating how the device represented multiplication. She and Zak conjectured that division should be possible to represent with the device and then worked out how that was possible. Zak demonstrated this, while narrating his *SunRule* manipulations. Zak pointed to the long shadow and said “10 divided by 5” and then pointed to the adjustable gnomon. He then said “equals 2” as he pointed to the shadow cast by the unit gnomon. He further noted that “2 is then the answer and it's the short shadow.” Sara and Zak's explorations of the connection between multiplication and division underscore the rich pedagogical opportunities of the SunRule.

Discussion and Reflections

The teaching experiment reported here documented pre-service teachers’ initial encounters with a physical device for modeling multiplication through continuous movements – e.g., tilting the device more or less, sliding the gnomon up or down. The movements made by Sara to vary the angle of inclination of the shadow plane and Sara and Zak’s linking of multiplication to division offer preliminary indications that the device worked as it was designed to work. Zak’s and Sara’s explorations of the *SunRule* suggested that it can be used to explore how multiplication and division are conceptually linked; we plan to develop and explore this hypothesis in follow up teaching experiments.

The *SunRule’s* connection to the real world is immediate, rather than applied or abstracted. The *SunRule* doesn’t apply mathematics to explain the world, rather, it uses an affordance of the world (sunlight) to model a mathematical operation (multiplication). Simultaneously, it shares a mathematically valid and robust representation of multiplication that is often missing in elementary school classrooms—that of multiplication as continuous scaling (Dimmel & Pandiscio, 2020; Kosko, 2019). By using a feature of the world to build a robust mathematical model, the *SunRule* represents an inversion of what is typically encountered in authentic/contextualized/real world mathematics.

The COVID-19 pandemic has triggered a reconsideration of how we gather. For schools, this has meant adapting instruction to remote, hybrid, or outdoor modalities, among other innovations, some of which will (hopefully) endure even when it is safe again to gather indoors. The *SunRule* provides a concrete material context for doing a mathematical activity outside—not simply for the sake of being outside, but because being outside is essential to use the device to do mathematical work. It provides a variable, tangible device for modeling families of multiplication problems and probing their mathematical structure. Beyond arithmetical utility, activities with the *SunRule* could pull students away from screens and create opportunities for students and teachers to reflect on how the geometry of sunlight is integrated with its design. These would be enviable outcomes at any time, and they are especially urgent in the face of the disruptions to teaching and learning brought on by the pandemic.

Notes

[1] This is the name for the part of a sundial that casts a shadow.
[2] The other section's opportunity was precluded by inclement weather.
[3] All names pseudonyms.

Acknowledgments

The research reported in this study was supported by grants from the Spencer Foundation and the NSF (award number 1822800) to the first author. The views expressed in this report are the author's and do not necessarily reflect the views of the Spencer Foundation or the NSF.
An expanded version of this research report was published in the July (2021) issue of the *Journal of Mathematics Education, Teachers College* (Dimmel, Pandiscio, & Bock, 2021).
The authors thank Adam Godet, of Godet Woodworking, for building prototypes of the *SunRule*.

RESOLUCIÓN DE PROBLEMAS VERBALES CON GEOGEBRA: UNA FUENTE DE POSIBILIDADES EN EL ESTUDIO DE RELACIONES

WORD PROBLEM SOLVING WITH GEOGEBRA: A SOURCE OF POSSIBILITIES IN THE STUDY OF RELATIONSHIPS

Adrián Gómez-Arciga
Cinvestav-IPN
agomeza@cinvestav.mx

El propósito de este estudio fue analizar cómo influye en las formas de razonamiento de estudiantes de bachillerato el uso sistemático de GeoGebra cuando lo incorporan en la resolución de problemas verbales. El estudio se realizó con un grupo de 20 estudiantes que cursaba la materia de Matemáticas I. Los resultados muestran que los estudiantes se apropiaron de recursos del sistema de geometría dinámica (GeoGebra) que, al utilizarlos de forma sistemática, les permitió implementar estrategias para representar geométricamente los conceptos involucrados en los problemas, explorar y analizar relaciones entre los elementos de los modelos dinámicos construidos y hallar las soluciones. Así, gracias a la exploración y análisis de relaciones, fue posible discutir con los estudiantes conceptos como: razón, dominio, lugar geométrico, variación.

Palabras clave: Resolución de Problemas, Problemas Verbales, Tecnología Digital, Álgebra

Introducción

El Covid-19 ha provocado un cambio sustantivo en el uso de tecnologías para el ámbito educativo. Se ha producido una rápida difusión de estas para mitigar las problematicas provocadas por el confinamiento. En particular, en lo que a Educación Matemática se refiere, el uso de tecnologías digitales está en un estatus marginal, pues su implementanción siempre va por detrás de la velocidad de la evolución digital, incluso antes de las modificaciones forzadas por la pandemia Covid-19, y a pesar de que es una necesidad en el siglo XXI para la enseñanza de las matemáticas (Cevikbas & Kaiser, 2020). Por ello, es importante que los profesores conozcan y utilicen estratégicamente diversas tecnologías, para que todos los estudiantes tengan las mismas oportunidades y posibilidades de acceder a las matemáticas (National Council of Teachers of Mathematics, 2011).

Implementar tecnología digital en las clases de matemáticas puede ayudar a aminorar los aspectos técnicos del álgebra que surgen cuando se resuelven problemas (Arcavi et al., 2017). Esto permite a los estudiantes enfocarse en desarrollar recursos y estrategias que sean útiles para describir relaciones y resolver problemas que involucren la construcción y uso de relaciones funcionales, que son objetivos principales en el estudio del álgebra porque favorecen la comprensión conceptual de los procesos algebraicos (Kieran, 2020). En este sentido, es válido reflexionar si debieran modificarse tanto el contendido como la forma en que se imparte álgebra; es decir, cuestionarse si hoy en día son adecuados los temas que se enseñan en álgebra y la manera en que se enseñan (Thomas, 2017).

Un hilo conductor en el estudio del álgebra es la resolución de problemas verbales, que van desde la educación básica hasta la superior (Amado et al., 2019). A través de estos, se espera que los estudiantes experimenten, articulen y debatan diferentes acercamientos a la solución que promuevan el análisis y comprensión de los conceptos e ideas principales del álgebra. De hecho, una propuesta bien recibida entre los investigadores y profesores para enfrentarse a estos problemas ha sido desarrollar los episodios y etapas del marco de resolución de problemas (Blum y Niss, 1991; Verschaffel et al., 2000), porque favorece el uso de estrategias y el trabajo colaborativo en los estudiantes.

No obstante, se han realizado investigaciones sobre propuestas de enseñanza que incluyen el uso de tecnología en la resolución de problemas verbales para conocer el impacto que tienen en los estudiantes. Por ejemplo, Amado et al. (2019) presentaron resultados de un estudio donde, además de trabajar bajo el marco de la resolución de problemas, utilizaron hojas de cálculo con el objetivo de observar cómo sus herramientas pueden ayudar a estudiantes de secundaria (entre 13 y 14 años) a representar y resolver problemas verbales y a introducirlos a métodos algebraicos formales. Ellos encontraron que, aunque los estudiantes todavía no aprendían a usar representaciones algebraicas (sistemas de ecuaciones de dos o más incógnitas) para resolver los problemas verbales, la hoja de cálculo no solo les ayudó a resolverlos, sino también a que interpretaran la solución como un valor que satisface un conjunto de condiciones que están asociadas a las ecuaciones.

En este contexto, el uso de un sistema de geometría dinámica (SGD) puede ser clave para el desarrollo del pensamiento algebraico y funcional en la resolución de problemas verbales, porque permite representarlos, explorarlos y resolverlos desde un enfoque geométrico. Bozkurt y Uygan (2020) explican que los SGD permiten a los estudiantes manipular objetos geométricos y explorar relaciones entre ellos. Además, identifican el arrastre como una estrategia eficaz de estos sistemas, que es el resultado de mover elementos de las configuraciones dinámicas sin cambiar sus relaciones geométricas subyacentes. Finalmente, reconocen su potencial didáctico, y la importancia de no usarlos de forma convencional, como sistemas de softwares estáticos.

Aunque se han hecho estudios que involucran el uso de la tecnología digital en la resolución de problemas verbales, todavía falta más evidencia que refleje una forma eficiente y adecuada de su implementación (Verschaffel et al., 2020). Entonces, con el objetivo de aportar más evidencias a esta discusión, se planteó la siguiente pregunta que guio la investigación: ¿Qué tipo de razonamientos construyen y exhiben estudiantes del nivel medio superior cuando resuelven problemas verbales con el uso de un sistema de geometría dinámica (GeoGebra) bajo el enfoque de resolución de problemas?

Marco Conceptual

Arcavi et al. (2017) identifican cinco puntos que son claves en la enseñanza del Álgebra. El primero está relacionado con enseñar álgebra a través de situaciones o problemas contextualizados, que tomen en cuenta las experiencias y conocimientos preliminares de los estudiantes. El segundo es fomentar prácticas que sean productivas: orientadas hacia actividades o tareas que requieran habilidades del pensamiento de mayor orden, como la búsqueda de diferentes formas de resolverlas, evaluación de la efectividad de los procedimientos, participación en las discusiones de clase, y reflexionar sobre los métodos o acercamientos mostrados. El tercero es reconciliar a los procedimientos de rutina con el entendimiento, porque, a pesar de que hay una amplia discusión de si se oponen o complementan, se necesitan ambos para potenciar el pensamiento algebraico. El cuarto es ver los errores de los estudiantes como una oportunidad para comprender de dónde o por qué surgen y, así, prevenir que sigan ocurriendo. Y el quinto punto es buscar formas de hacer accesible e involucrar a los estudiantes en pruebas o argumentos matemáticos, aun si estas se perciben abstractas y formales para ellos.

Por otra parte, Kieran (2020) identifica tres tipos de actividades en el estudio del álgebra que son esenciales para el desarrollo del pensamiento algebraico: (a) interpretación y representación algebraica de situaciones, propiedades, patrones y relaciones; (b) manipulación simbólica que permita el desarrollo de habilidades y aspectos conceptuales e; (c) implementación del álgebra como una herramienta para modelar situaciones, justificar y probar, hacer predicciones y conjeturas, buscar relaciones y resolver problemas. De cierta manera, estas acciones están comprendidas en los puntos que se mencionaron anteriormente.

Ahora, respecto al uso de tecnología digital, Santos-Trigo (2019) ha identificado que, cuando se involucra el uso de un SGD en la resolución de problemas, hay cuatro tipos de tareas que se pueden llevar a cabo, las cuales se caracterizan por las representaciones, estrategias y formas de razonamiento que surgen en los procesos de solución: (a) enfocarse en las figuras. Son tareas que utilizan un SGD para reconstruir las figuras que están descritas en los enunciados de los problemas o que aparecen como una imagen que acompaña al enunciado. Su valor está en la necesidad de identificar los elementos que componen a las figuras y explorar las formas en las que se relacionan; (b) tareas de investigación. Transforman problemas rutinarios, como los que se encuentran en los libros de texto, en una serie de actividades de investigación y reflexión matemática; (c) tareas de variación. En estas, interesa representar y analizar problemas que involucren fenómenos de variación mediante un modelo gráfico sin tener que recurrir a un modelo algebraico; (d) configuraciones dinámicas. El objetivo es formular problemas a partir de configuraciones dinámicas y buscar argumentos que validen las relaciones matemáticas encontradas.

Estas tareas no solo aportan información a la resolución de los problemas, sino también ayudan a comprender cómo se relacionan los datos y conceptos involucrados. Además, pueden realizarse de manera simultanea cuando se resuelve un problema. Por ejemplo, en los problemas verbales los estudiantes podrían concentrarse en *tareas de variación*, ya que la mayoría describen situaciones que involucran fenómenos de variación, sin embargo, también podrían dirigir su atención a tareas de *construcción de figuras* cuando el contexto de los problemas sea además geométrico.

Considerando este contexto, es importante un marco que permita planear, organizar y analizar las formas en que los estudiantes resuelven los problemas con el uso de tecnología digital. En este sentido, Santos-Trigo y Camacho-Machín (2013), basados en el marco de resolución de problemas propuesto por Schoenfeld (1985) y en el método de Polya (1945) para resolver problemas, articulan un marco que engloba la resolución de problemas y el uso de tecnología digital. Este consta de cuatro fases que se caracterizan por el tipo de preguntas que se plantean en cada una: (1) comprensión del problema. ¿Cómo representar la situación descrita en el problema en términos de las herramientas digitales disponibles?; (2) exploración. ¿Qué estrategias pueden implementarse con las herramientas digitales disponibles que permitan explorar las formas en que se relacionan los datos explícitos e implícitos del problema?; (3) búsqueda de distintos acercamientos a la solución. A partir de las exploraciones realizadas en la segunda fase, ¿cómo pueden aprovecharse para obtener la solución?; (4) integración y reflexiones. ¿Cuáles fueron las ideas principales durante el proceso? Y ¿qué aportó el uso de la tecnología digital a la resolución del problema?

Con base en estas ideas pueden evaluarse y caracterizarse las formas de razonamiento que exhiben los estudiantes durante la resolución de los problemas verbales con el uso de un sistema de geometría dinámica.

Metodología

Esta investigación es cualitativa, mediante la observación e interacción controlada se caracterizaron las formas de razonamiento que exhibieron los estudianes en el desarrollo de las tareas. Se seleccionó un grupo de Matemáticas I de nivel medio superior, el cual estaba conformado por 20 estudiantes (entre 15 y 17 años), y se trabajó con este por 24 sesiones, donde cada sesión tenía una duración de dos horas.

Para el desarrollo de las sesiones se dispuso de 11 iPads con la aplicación de GeoGebra instalada (10 para los estudiantes y una para el investigador) y un proyector. Debido al número limitado de iPads, se formaron equipos de dos estudiantes y se asignó un iPad a cada uno. La dinámica que se siguió durante la implementación de los problemas, después de haber utilizado las primeras cuatro sesiones para introducirlos al SGD, fue utilizar una o dos sesiones para que los equipos los representaran, exploraran, resolvieran y, después, discutieran sus resultados con todo el grupo mediante el proyector.

Para que los estudiantes pudieran resolver los problemas con el uso del SGD, se propuso el siguiente esquema (Figura 1):

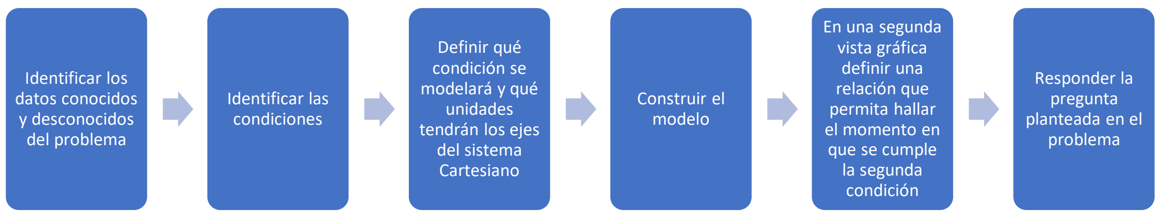

Figura 1: Esquema para resolver problemas verbales con el uso de GeoGebra.

Y para que pudieran representar algebraicamente la solución geométrica hallada con el SGD, se propuso el siguiente esquema (Figura 2):

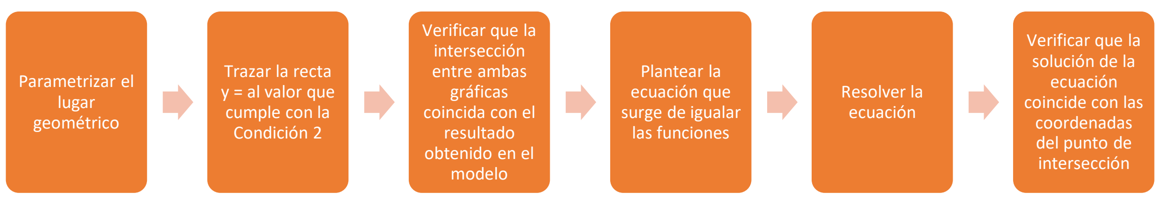

Figura 2: Esquema para algebrizar la representanción geométrica.

Los esquemas se constuyeron con base en los elementos del marco conceptual, y surgieron en respuesta a resultados obtenidos en investigaciones previas (Gómez-Arciga et al., 2018; Gómez-Arciga & Reyes-Martínez, 2019).

Para la selección de los problemas se hizo una lista donde se categoraizaron por su contexto, se trabajaron en las sesiones de un seminario de resolución de problemas, y se identificaron los más apropiados para alcanzar los objetivos del estudio. En los resultados se reportan los desarrollos que mostraron diferentes equipos en la resolución de dos problemas verbales.

Los datos se recolectaron a través de archivos de GeoGebra, videograbaciones y notas de campo. Estas últimas se utilizaron para destacar algunas ideas que, en un primer momento, se consideraron importantes en el desarrollo de las sesiones. Así, al momento de revisar las videograbaciones, se analizaron secciones específicas que ya se habían detectado en clase.

Resultados

En cada problema de esta sección se muestran dos acercamientos a la solución. Estos fueron desarrollados por diferentes equipos.

Problema 1: El perímetro de un triángulo isósceles es de 48 cm. Si el lado diferente equivale a 2/3 de la medida de los lados iguales, ¿cuál es la medida de los lados del triángulo?

La idea inicial del primer acercamiento fue construir una familia de triángulos isósceles con perímetro de 48 cm. Para lograrlo, trazaron lo siguiente (Figura 3): un segmento AB en el eje horizontal, con A en el origen y B un punto móvil; una circunferencia centrada en A y con radio AB; una circunferencia centrada en B con radio $r = 48 - 2f$, donde f era la longitud del segmento AB; y el triángulo ABD, donde D era una de las intersecciones entre las circunferencias. Así, el triángulo ABD cumplía la condición de ser isósceles con $AB = AD$ y tener perímetro de 48 cm.

Cuando el equipo utilizó la prueba del arrastre para mostrar que su modelo era robusto, observó que el triángulo solo existía si B se movía en el intervalo abierto (12, 24), lo cual derivó en una discusión con todo el grupo sobre el dominio del problema y la relación que guardaban los lados del triángulo para que pudiera construirse.

Luego, definieron el punto $\mathrm{E} = \left(a, \frac{2}{3}b - a\right)$ que relacionaba al lado desigual con la diferencia de las dos terceras partes de uno de los lados iguales y el desigual (a era la longitud del segmento BD, y b, la longitud del segmento AD), con el objetivo de encontrar las dimensiones del triángulo que cumpliera con la condición restante del problema. La solución la hallarían cuando al mover B la ordenada de E fuera cero, que gráficamente significó hallar la intersección del lugar geométrico descrito por E y el eje horizontal (Figura 4).

Finalmente, el equipo intentó, pero sin éxito, parametrizar el lugar geométrico para obtener la solución algebraica.

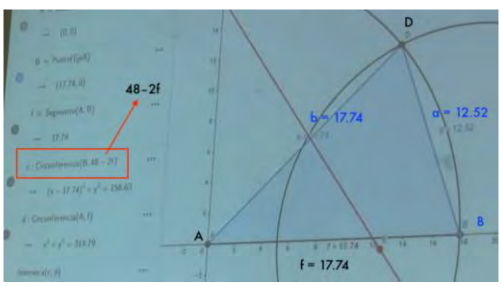

Figura 3: Construcción de la familia de triángulos isósceles con perímetro de 48 cm.

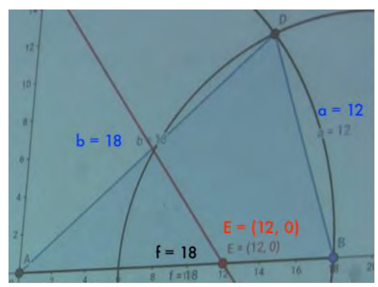

Figura 4: Dimensiones del triángulo que cumple con las condiciones del problema.

El segundo acercamiento, mostrado por otro equipo, consistió en modelar la relación entre uno de los lados iguales y el diferente (no construye el triángulo). Para ello, trazó un segmento AB, con A en el origen y B un punto móvil sobre el eje horizontal, y un segmento AC, donde C fue el punto de intersección entre el eje vertical y la circunferencia con centro en A y radio $r = \frac{2}{3}f$ (f era la longitud del segmento AB) (Figura 5). Con estos trazos, el equipo aseguró que la longitud del segmento AC fuera *2/3* de la longitud del segmento AB para cualquier posición del punto B. Entonces, la longitud del segmento AC se asoció a la medida del lado diferente del triángulo, y la longitud del segmento AB, a la medida de uno de los lados iguales.

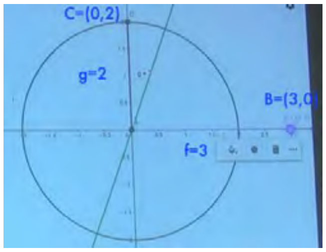

Figura 5: Modelo del segundo acercamiento.

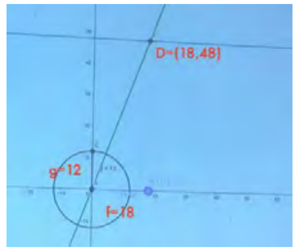

Figura 6: Solución gráfica.

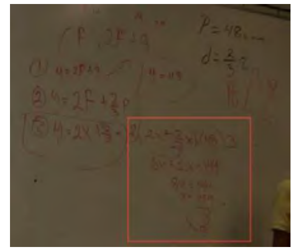

Figura 7: Solución algebraica.

A partir del modelo, definió el punto $D = (f, 2f + g)$ que relacionaba la medida de uno de los lados iguales del triángulo con su perímetro. La solución la obtuvo cuando la ordenada del punto *D* fue 48, porque cumplió con las condiciones descritas en el enunciado. En la Figura 6 se observa que cuando la medida de los lados iguales es 18 *cm* y la del diferente es 12 *cm*, el perímetro es de 48 *cm*, y que la solución gráfica se halla en la intersección del lugar geométrico descrito por *D* y la recta $y = 48$.

La parametrización y solución algebraica fue desarrollada adecuadamente por el equipo. En la Figura 7 puede observarse que planteó la ecuación $2x + \frac{2}{3}x = 48$, que fue resultado de igualar la función que surge de parametrizar el lugar geométrico y la función constante (*y = 48*), y la resolvió correctamente.

Problema 2: En cierta competencia de atletismo el corredor *A* se encuentra a 30 metros adelante del corredor *B*. El corredor *A* lleva una velocidad constante de 7 *km/h* y el corredor *B* lleva una velocidad constante de 8 *km/h*. Si los dos salen al mismo tiempo, ¿después de cuántos metros el corredor *B* alcanzará al corredor *A*?

El primer equipo que mostró su acercamiento seleccionó las unidades del eje horizontal como segundos (tiempo), y las del eje vertical, como *m/s* (velocidad). Eligió las unidades de los ejes de esta forma porque el problema pedía hallar una distancia en metros. En consecuencia, el equipo hizo las conversiones de las unidades de las velocidades de los corredores: la velocidad del corredor *A* fue de $1.9\overline{4}$ *m/s*, y la de *B*, de $2.\overline{2}$ *m/s*.

De este modo, como la distancia es el resultado del producto del tiempo y la velocidad, el equipo representó las distancias recorridas por los corredores mediante áreas de rectángulos: en la Figura 8 la longitud del segmento *AB* (*f = 2*) representó el tiempo, en segundos, transcurrido de cada corredor; las longitudes de los segmentos *AD* y *AC*, las velocidades de los corredores *A* y *B*, respectivamente; y las áreas de los rectángulos *ABED* (*c2 = 3.88*) y *ABFC* (*c1 = 4.4*), los metros recorridos por los corredores *A* y *B*, respectivamente. Así, la Figura 8 muestra el valor numérico de la distancia recorrida de cada corredor en dos segundos.

El equipo analizó, mediante el lugar geométrico que describía el punto $G = \left(c1, \frac{c2+30}{c1}\right)$, para qué distancia c1 se cumplía que $\frac{c2+30}{c1} = 1$ (Figura 9); dicho de otra forma, analizó, a través de una razón, qué distancia recorrió el corredor *B* para alcanzar al corredor *A* (quien, en el mismo tiempo que B, ha recorrido $c2 + 30$ metros).

En la Figura 9 se observa que, a los 253 metros, aproximadamente, el corredor *B* alcanzó al corredor A, ya que es la intersección entre el lugar geométrico y la recta $y = 1$. A partir de este resultado se preguntó al equipo sobre el significado de la razón cuando era menor o mayor a 1: el equipo identificó que cuando la razón era menor a 1, significaba que el corredor *B* había rebasado al corredor *A*; en caso contrario, *A* mantenía el primer lugar.

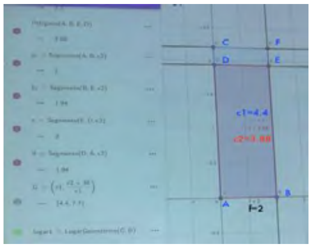

Figura 8: Modelo del primer acercamiento del problema 2.

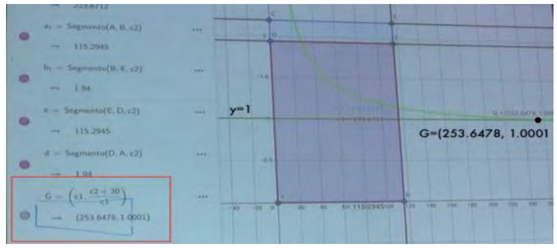

Figura 9: Exploración de la relación que hay entre las distancias recorridas por los corredores.

Figura 10: Solución gráfica robusta.

Al momento de parametrizar y resolver algebraicamente el problema, hallaron que la solución era 240 metros, lo que evidenció el margen de error provocado por no robustecer el lugar geométrico cuando lo intersectaron con la recta $y = 1$. Una vez corregida esa imprecisión en el modelo, observaron también que transcurrieron 108 segundos para que el corredor *B* alcanzara al corredor *A* (Figura 10).

Otro equipo, en su acercamiento, representó a las velocidades de los corredores como pendientes de rectas (Figura 11). Para ello, asignó al eje horizontal unidades de hora, y al eje vertical, unidades de kilómetro. Entonces, para construir las rectas con pendientes de 7 y 8 unidades (*km/h*), definió los puntos *B* y *C* sobre el eje vertical en 7 y 8, el punto *D* sobre el eje horizontal en 1, trazó perpendiculares a los ejes pasando por estos puntos, y con las intersecciones entre estas (puntos *E* y *F*), trazó la recta *AF* con pendiente 7 y la recta *AE* con pendiente 8.

Para representar el resto de los datos, el equipo ubicó un punto móvil sobre el eje horizontal (punto *G*), trazó una perpendicular al mismo eje pasando por este punto, marcó las intersecciones de esta con las rectas (puntos *H* e *I*) y, mediante perpendiculares al eje vertical que pasaban por los puntos *H* e *I*, marcaron las intersecciones de estas con el eje vertical (puntos *J* y *K*) (Figura 12). Así, el segmento *AG* representó el tiempo transcurrido (en horas) de la competencia, y el segmento *JK* o segmento a la distancia (en kilómetros) entre los corredores en el tiempo *AG* (pues *AK* era la distancia recorrida por el primer corredor, y *AJ*, la distancia recorrida por el segundo).

De esta forma, el equipo definió el punto $L = (AG,\ a)$ que relacionaba el tiempo transcurrido en la competencia con la distancia entre los corredores (Figura 12); y cuando su ordenada fue 0.03 (30 metros), obtuvo la distancia que recorrió el corredor *B* para alcanzar al corredor *A* en la longitud del segmento *AJ* (o en la ordenada del punto *J = (0, 0.24)*). Aunque el equipo identificó que la solución geométrica estaba en la intersección del lugar geométrico de *L* y la recta $y = 0.03$, no desarrolló el acercamiento algebraico.

Discusión de los resultados y conclusiones

En los procesos de solución de los problemas, se observó que los equipos realizaron distintas actividades: seleccionaron unidades para los ejes, identificaron el dominio, determinaron elementos fijos y móviles para los modelos, graficaron y analizaron relaciones, buscaron soluciones geométricas y algebraicas. Estas fueron resultado de implementar los esquemas que se les propusieron para trabajar con GeoGebra.

En el problema 1, el primer equipo mostró un acercamiento donde se enfocó en construir la familia de triángulos de 48 *cm.* de perímetro para después analizar la relación entre sus lados. Es decir, se centró en dos tareas: (1) construir la figura y (2) analizar la variación de sus elementos para llegar a la solución sin necesidad de utilizar ecuaciones algebraicas. El recurso clave de la primera tarea fue el uso de circunferencias para trasladar medidas, y la estrategia para hallarlas fue analizar su comportamiento o relación a través del lugar geométrico (que dependía del movimiento ordenado del punto B) que corresponde al desarrollo de la segunda tarea. De este proceso se dio la posibilidad de discutir sobre el dominio del problema y de determinarlo, ya que no es común prestarle atención a este concepto cuando se resuelven este tipo de problemas.

En el caso del segundo equipo, llevó a cabo una tarea de variación sin construir la figura. La relación que exploró y analizó fue la del comportamiento del perímetro del triángulo cuando variaban las longitudes de sus lados, las cuales conservaban una relación de proporcionalidad. De esta manera, pudo representar y resolver algebraicamente el problema.

Para el segundo problema, en los dos acercamientos mostrados, a diferencia de los anteriores, se fijaron los mismos datos en los modelos (las velocidades) y se analizaron las relaciones en función del tiempo. Sin embargo, las representaciones de los datos y las formas de explorar y resolver el problema fueron distintas.

El lugar geométrico que exhibió el primer equipo fue el resultado de analizar cómo cambia la razón de las distancias recorridas por los corredores respecto al tiempo. En cambio, el segundo equipo analizó cómo se relaciona la diferencia entre las distancias recorridas por los corredores con el tiempo. El acercamiento algebraico de este problema solo lo desarrolló el primer equipo.

En general, el uso sistemático de GeoGebra permitió resolver los problemas de distintas formas y visualizar el tipo de relaciones que hay entre los datos. Además, aunque no todos pudieron resolver los problemas algebraicamente, valoran este resultado como una prueba que sustenta su solución gráfica. De hecho, si se presta atención a los acercamientos de los equipos que no mostraron una solución algebraica, puede notarse que sus modelos son más elaborados que los otros. Por lo tanto, parametrizarlos es más difícil.

Así, las formas de razonamiento que exhibieron los estudiantes durante este proceso se caracterizaron por:

- Interpretar los conceptos de un problema en términos de sus propiedades y atributos geométricos (en términos de la herramienta).
- Cuantificar los elementos del modelo.
- Identificar el dominio del problema.
- Definir una relación que permitirá hallar la solución en una infinidad de casos.
- Determinar la solución en términos del modelo.

A pesar de que el uso sistemático de un sistema de geometría dinámica promueve el estudio de relaciones entre los conceptos involucrados en los problemas verbales, sigue habiendo dificultades para conectar estas representaciones geométricas con las representaciones

algebraicas. No obstante, trabajar bajo este enfoque parece ofrecer una serie de posibilidades para el desarrollo del pensamiento algebraico y funcional.

The purpose of this study was to analyze how the systematic use of GeoGebra influences the ways of reasoning of high school students when they incorporate it in the resolution of word problems. The study was carried out with a group of 20 students who were studying Mathematics I. The results show that the students appropriated resources from the dynamic geometry system (GeoGebra) which, when used systematically, allowed them to implement strategies to represent geometrically the concepts involved in the problems, explore and analyze relationships between the elements of the dynamic models built and find the solutions. Thus, thanks to the exploration and analysis of relationships, it was possible to discuss with the students' concepts such as: ratio, domain, locus, variation.

Introduction

Covid-19 has caused a substantive change in the use of technologies for education. There has been a rapid dissemination of these to mitigate the problems caused by confinement. As far as Mathematics Education is concerned, the use of digital technologies is in a marginal status, since their implementation always lags the speed of digital evolution, even before the modifications forced by the Covid-19 pandemic, and even though it is a necessity in the 21st century for the teaching of mathematics (Cevikbas & Kaiser, 2020). Therefore, it is important that teachers know and strategically use various technologies, so that all students have the same opportunities and possibilities to access mathematics (National Council of Teachers of Mathematics, 2011).

Implementing digital technology in math classes can help lessen the technical aspects of algebra that arise when solving problems (Arcavi et al., 2017). This allows students to focus on developing resources and strategies that are useful for describing relationships and solving problems involving the construction and use of functional relationships, which are main objectives in the study of algebra because they favor the conceptual understanding of algebraic processes (Kieran, 2020). In this sense, it is valid to reflect on whether both the content and the way in which algebra is taught should be modified; In other words, questioning whether the topics taught in algebra and the way they are taught are adequate today (Thomas, 2017).

A common thread in the study of algebra is the resolution of word problems, ranging from basic to higher education (Amado et al., 2019). Through these, students are expected to experiment, articulate, and debate different approaches to the solution that promote the analysis and understanding of the main concepts and ideas of algebra. In fact, a well-received proposal among researchers and teachers to deal with these problems has been to develop the episodes and stages of the problem-solving framework (Blum and Niss, 1991; Verschaffel et al., 2000), because it favors the use of strategies and collaborative work in students.

However, research has been carried out on teaching proposals that include the use of technology in solving word problems to find out the impact they have on students. For example, Amado et al. (2019) presented results of a study where, in addition to working under the framework of problem solving, they used spreadsheets with the aim of observing how their tools can help high school students (between 13 and 14 years old) to represent and solve word problems and introduce them to formal algebraic methods. They found that, although the students had not yet learned to use algebraic representations (systems of equations of two or more unknowns) to solve word problems, the spreadsheet not only helped them to solve them, but also to interpret the solution as a value that satisfies a set of conditions that are associated with the equations.

In this context, the use of a dynamic geometry system (DGS) can be key for the development of algebraic and functional thinking in solving word problems, because it allows representing, exploring, and solving them from a geometric approach. Bozkurt and Uygan (2020) explain that DGS allow students to manipulate geometric objects and explore relationships between them. In addition, they identify drag as an effective strategy of these systems, which is the result of moving elements of the dynamic configurations without changing their underlying geometric relationships. Finally, they recognize their didactic potential, and the importance of not using them in a conventional way, as static software systems.

Although there have been studies that involve the use of digital technology in the resolution of verbal problems, there is still more evidence that reflects an efficient and adequate way of implementation (Verschaffel et al., 2020). So, with the aim of providing more evidence to this discussion, the following question was posed that guided the investigation: What type of reasoning do students at high school construct and exhibit when they solve word problems with the use of a dynamic geometry system (GeoGebra) under the problem-solving approach?

Conceptual Framework

Arcavi et al. (2017) identify five points that are key in teaching Algebra. The first is related to teaching algebra through contextualized situations or problems that consider the preliminary experiences and knowledge of the students. The second is to encourage practices that are productive: oriented towards activities or tasks that require higher-order thinking skills, such as finding different ways to solve them, evaluating the effectiveness of procedures, participating in class discussions, and reflecting on the methods or approaches shown. The third is to reconcile routine procedures with understanding, because although there is extensive discussion of whether they oppose or complement each other, both are needed to enhance algebraic thinking. The fourth is to see student mistakes as an opportunity to understand where or why they arise and thus prevent further occurrence. And the fifth point is to look for ways to make accessible and involve students in mathematical proofs or arguments, even if they seem abstract and formal to them.

On the other hand, Kieran (2020) identifies three types of activities in the study of algebra that are essential for the development of algebraic thinking: (a) interpretation and algebraic representation of situations, properties, patterns and relationships; (b) symbolic manipulation that allows the development of skills and conceptual aspects and; (c) implementation of algebra as a tool to model situations, justify and prove, make predictions and conjectures, look for relationships, and solve problems.

Now, regarding the use of digital technology, Santos-Trigo (2019) has identified that, when the use of an SGD is involved in solving problems, there are four types of tasks that can be carried out, which are characterized by the representations, strategies and forms of reasoning that arise in the solution processes: (a) focus on the figures. They are tasks that use an DGS to reconstruct the figures that are described in the problem statements or that appear as an image that accompanies the statement. Its value is in the need to identify the elements that make up the figures and explore the ways in which they are related; (b) research tasks. They transform routine problems, such as those found in textbooks, into a series of mathematical research and reflection activities; (c) variation tasks. In these, it is interesting to represent and analyze problems that involve variation phenomena by means of a graphic model without having to resort to an algebraic model; (d) dynamic configurations. The objective is to formulate problems from dynamic configurations and look for arguments that validate the mathematical relationships found.

These tasks not only provide information to solve problems, but also help to understand how the data and concepts involved are related. In addition, they can be done simultaneously when a problem is solved. For example, in word problems, students could focus on variation tasks, since most describe situations that involve variation phenomena, however, they could also direct their attention to *figure construction* tasks when the context of the problems is also geometric.

Considering this context, a framework that allows planning, organizing, and analyzing the ways in which students solve problems with the use of digital technology is important. In this sense, Santos-Trigo and Camacho-Machín (2013), based on the problem-solving framework proposed by Schoenfeld (1985) and on Polya's (1945) method to solve problems, articulate a framework that encompasses problem solving and the use of digital technology. This consists of four phases that are characterized by the type of questions that are posed in each one: (1) understanding the problem. How to represent the situation described in the problem in terms of the digital tools available?; (2) exploration. What strategies can be implemented with the available digital tools that allow us to explore the ways in which the explicit and implicit data of the problem are related?; (3) search for different approaches to the solution. From the explorations carried out in the second phase, how can they be used to obtain the solution?; (4) integration and reflections. What were the main ideas during the process? And what did the use of digital technology contribute to solving the problem?

Based on these ideas, the forms of reasoning that students exhibit during the resolution of word problems can be evaluated and characterized with the use of a dynamic geometry system.

Methodology

This research is qualitative, through observation and controlled interaction, the forms of reasoning exhibited by the students in the development of the tasks were characterized. A group of Mathematics I of high school was selected, which was made up of 20 students (between 15 and 17 years old), and it was worked with this for 24 sessions, where each session lasted two hours.

For the development of the sessions, there were 11 iPads with the GeoGebra application installed (10 for the students and one for the researcher) and a projector. Due to the limited number of iPads, teams of two students were formed and an iPad was assigned to each. The dynamic that was followed during the implementation of the problems, after having used the first four sessions to introduce them to the DGS, was to use one or two sessions for the teams to represent them, explore, solve and, later, discuss their results with everything the group using the projector.

So that student could solve problems with the use of the DGS, the following scheme was proposed (Figure 1):

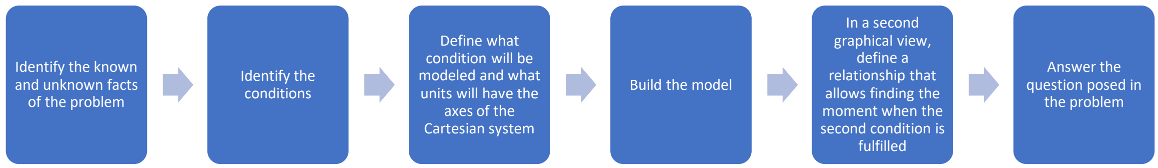

Figure 1: Scheme to solve word problems with the use of GeoGebra.

And so that they could represent algebraically the geometric solution found with the DGS, the following scheme was proposed (Figure 2):

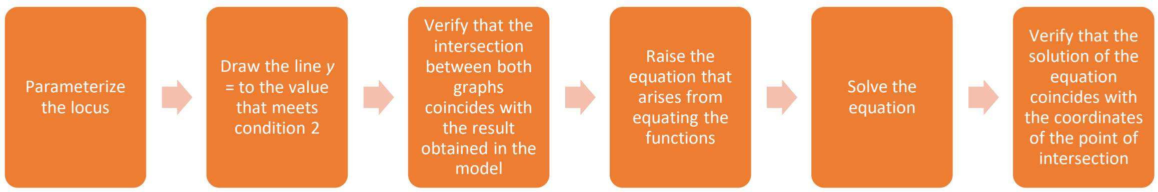

Figure 2: Scheme to algebrize the geometric representation.

The schemes were built based on the elements of the conceptual framework and emerged in response to results obtained in previous research (Gómez-Arciga et al., 2018; Gómez-Arciga & Reyes-Martínez, 2019).

For the selection of the problems, a list was made where they were categorized by their context, the sessions of a problem-solving seminar were worked on, and the most appropriate ones were identified to achieve the objectives of the study. In the results, the developments shown by different teams in solving two word problems are reported.

Data was collected through GeoGebra files, video recordings, and field notes. The latter were used to highlight some ideas that, at first, were considered important in the development of the sessions. Thus, when reviewing the video recordings, specific sections that had already been detected in class were analyzed.

Results

Two approaches to the solution are shown for each problem in this section. These were developed by different teams.

Problem 1: The perimeter of an isosceles triangle is 48 cm. If the different side is 2/3 the measure of the equal sides, what is the measure of the sides of the triangle?

The initial idea of the first approach was to construct a family of isosceles triangles with a perimeter of 48 cm. To achieve this, they drew the following (Figure 3): a segment AB on the horizontal axis, with A at the origin and B a moving point; a circle centered at A and with radius AB; a circle centered at B with radius $r = 48 - 2f$, where f was the length of segment AB; and the triangle ABD, where D was one of the intersections between the circles. Thus, the triangle ABD fulfilled the condition of being isosceles with $AB = AD$ and having a perimeter of 48 cm.

When the team used the drag test to show that their model was robust, they observed that the triangle only existed if B moved in the open interval (12, 24), which led to a discussion with the whole group about the domain of the problem and the relationship between the sides of the triangle so that it could be built.

Then, they defined the point E $= \left(a, \frac{2}{3}b - a\right)$ that related the unequal side to the difference of two thirds of one of the equal sides and the unequal one (a was the length of segment *BD*, and b, length of segment *AD*), to find the dimensions of the triangle that meets the remaining condition of the problem. The solution would be found when moving *B,* the ordinate of *E* was zero, which graphically meant finding the intersection of the locus described by *E* and the horizontal axis (Figure 4).

Finally, the team tried, but without success, to parameterize the locus to obtain the algebraic solution.

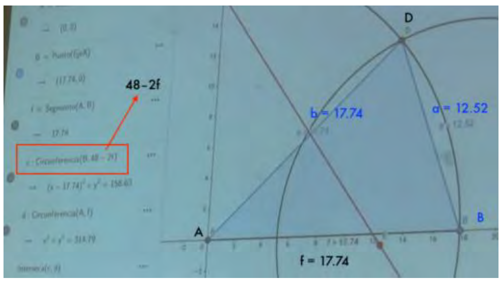

Figure 3: Construction of the family of isosceles triangles with perimeter of 48 *cm*.

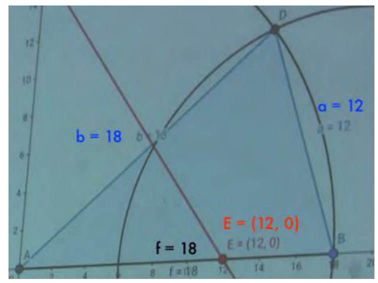

Figure 4: Dimensions of the triangle that meets the conditions of the problem.

The second approach, shown by another team, consisted of modeling the relationship between one of the equal and the different sides (it does not construct the triangle). To do this, the team drew a segment *AB*, with *A* at the origin and *B* a mobile point on the horizontal axis, and a segment *AC*, where *C* was the point of intersection between the vertical axis and the circumference with center at *A* and radius $r = \frac{2}{3}f$ (f was the length of segment *AB*) (Figure 5). With these traces, the team ensured that the length of segment *AC* was *2/3* of the length of segment *AB* for any position of point *B*. Then, the length of segment *AC* was associated with the measurement of the different side of the triangle, and the length of segment *AB*, measured by one of the equal sides.

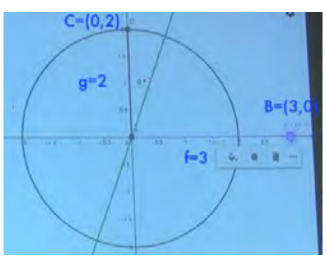

Figure 5: Model of the second approach.

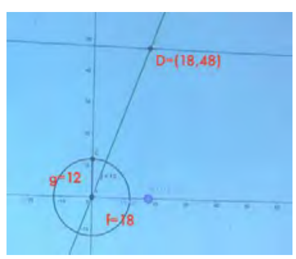

Figure 6: Graphical solution

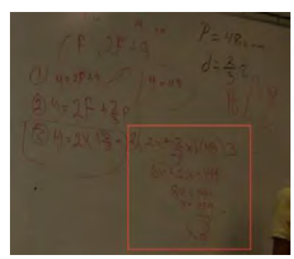

Figure 7: Algebraic solution.

Using the model, the team defined the point $D = (f, 2f + g)$ that related the measure of one of the equal sides of the triangle to its perimeter. The solution was obtained when the ordinate of point *D* was 48, because it met the conditions described in the statement. In Figure 6 it is observed that when the measure of the equal sides is 18 *cm* and that of the different one is 12 *cm*, the perimeter is 48 *cm*, and that the graphical solution is found at the intersection of the locus described by *D* and the line $y = 48$.

The parameterization and algebraic solution were adequately developed by the team. In Figure 7 the team raised the equation $2x + \frac{2}{3}x = 48$, which was the result of equating the function that arises from parameterizing the locus and the constant function (*y = 48*) and solved it correctly.

Problem 2: In a certain athletics competition, runner *A* is 30 meters ahead of runner *B*. Runner *A* has a constant speed of 7 *km/h* and runner *B* has a constant speed of 8 *km/h*. If they both start at the same time, after how many meters will runner *B* catch up with runner *A*?

The first team to show their approach selected the units on the horizontal axis as seconds (time), and those on the vertical axis as *m/s* (velocity). The team chose the units of the axes this way because the problem asked to find a distance in meters. Consequently, the team converted the units of the runners' speeds: runner *A's* speed was $1.9\overline{4}$ *m/s*, and *B's* was $2.\overline{2}$ *m/s*.

In this way, since distance is the result of the product of time and speed, the team represented the distances traveled by the runners using areas of rectangles: in Figure 8 the length of segment *AB* (*f = 2*) represented time, in seconds, elapsed from each runner; the lengths of segments *AD* and *AC*, the speeds of runners *A* and *B*, respectively; and the areas of the rectangles *ABED* (*c2 = 3.88*) and *ABFC* (*c1 = 4.4*), the meters covered by runners *A* and *B*, respectively. Thus, Figure 8 shows the numerical value of the distance covered by each runner in two seconds.

The team analyzed, using the locus described by the point $G = \left(c1, \frac{c2+30}{c1}\right)$, for what distance *c1* it was true that $\frac{c2+30}{c1} = 1$ (Figure 9); In other words, the team analyzed, through a ratio, how far runner *B* traveled to reach runner *A* (who, in the same time as B, has traveled $c2 + 30$ meters).

In Figure 9 it is observed that, at approximately 253 meters, runner *B* reached runner *A*, since it is the intersection between the locus and the line $y = 1$. Based on this result, the team was asked about the meaning of the ratio when it was less than or greater than 1: the team identified that when the ratio was less than 1, it meant that runner *B* had passed runner *A*; otherwise, *A* held first place.

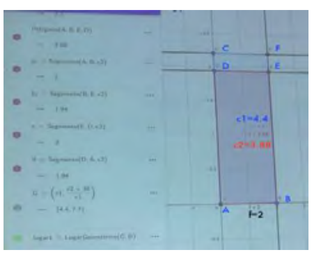

Figure 8: Model of the first approach of problem 2.

Figure 9: Exploration of the relationship between the distances covered by the runners.

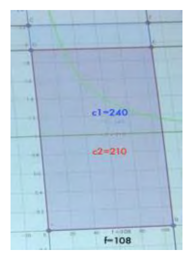

Figure 10: Robust graphical solution.

At the time of parametrizing and algebraically solving the problem, they found that the solution was 240 meters, which evidenced the margin of error caused by not strengthening the locus when they intersected it with the line $y = 1$. Once this imprecision in the model was corrected, they also observed that 108 seconds elapsed for runner *B* to reach runner *A* (Figure 10).

Another team, in its approach, represented the speeds of the runners as slopes of straights (Figure 11). To do this, he assigned units of hours to the horizontal axis and kilometer units to

Olanoff, D., Johnson, K., & Spitzer, S. (2021). *Proceedings of the forty-third annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Philadelphia, PA.

the vertical axis. So, to construct the lines with slopes of 7 and 8 units (*km/h*), the team defined points *B* and *C* on the vertical axis at 7 and 8, point *D* on the horizontal axis at 1, plotted perpendicular to the axes passing through these points, and with the intersections between them (points E and F), the team drew the line *AF* with slope 7 and the line *AE* with slope 8.

To represent the rest of the data, the team located a mobile point on the horizontal axis (point *G*), drew a perpendicular to the same axis passing through this point, marked the intersections of this with the lines (points *H* and *I*) and, using perpendicular to the vertical axis that passed through points *H* and *I*, they marked their intersections with the vertical axis (points *J* and *K*) (Figure 12). Thus, the AG segment represented the elapsed time (in hours) of the competition, and the *JK* segment or a segment the distance (in kilometers) between the runners in AG time (AK was the distance traveled by the first runner, and AJ, the distance traveled by the second).

In this way, the team defined the point $L = (AG,\ a)$ that related the time spent in the competition with the distance between the runners (Figure 12); and when its ordinate was 0.03 (30 meters), it obtained the distance traveled by runner B to reach runner A in the length of segment *AJ* (or in the ordinate of point $J = (0,\ 0.24)$). Although the team identified that the geometric solution was at the intersection of the L locus and the line $y = 0.03$, they did not develop the algebraic approach.

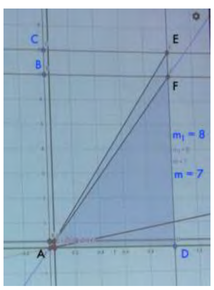

Figure 11: Speeds represented as slopes.

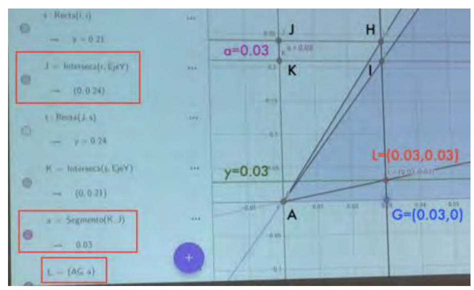

Figure 12: Geometric solution based on the slopes model.

Discussion of the results and conclusions

In the problem-solving processes, it was observed that the teams carried out different activities: they selected units for the axes, identified the domain, determined fixed and mobile elements for the models, plotted and analyzed relationships, and searched for geometric and algebraic solutions. These were the result of implementing the schemes that were proposed to them to work with GeoGebra.

In problem 1, the first team showed an approach where they focused on building the family of triangles with 48 *cm* perimeter and then analyzing the relationship between their sides. That is, he focused on two tasks: (1) constructing the figure and (2) analyzing the variation of its elements to arrive at the solution without using algebraic equations. The key resource of the first task was the use of circles to transfer measurements, and the strategy to find them was to analyze their behavior or relationship through the locus (which depended on the ordered movement of point *B*) that corresponds to the development of the second task. This process gave the possibility of discussing the domain of the problem and determining it, since it is not common to pay attention to this concept when solving this type of problem.

In the case of the second team, they carried out a variation task without building the figure. The relationship that the team explored and analyzed was that of the behavior of the perimeter of the triangle when the lengths of its sides varied, which conserved a proportional relationship. In this way, the team was able to represent and solve the problem algebraically.

For the second problem, in the two approaches shown, unlike the previous ones, the same data were set in the models (the speeds) and the relationships as a function of time were analyzed. However, the representations of the data and the ways to explore and solve the problem were different.

The locus exhibited by the first team was the result of analyzing how the ratio of the distances covered by the runners changes with respect to time. Instead, the second team looked at how the difference between the distances covered by the runners is related to time. The algebraic approach to this problem was only developed by the first team.

In general, the systematic use of GeoGebra allowed solving the problems in different ways and visualizing the type of relationships between the data. Furthermore, although not all of them were able to solve the problems algebraically, they value this result as a proof that supports their graphical solution. In fact, if you pay attention to the approaches of the teams that did not show an algebraic solution, their models are more elaborate than the others. Therefore, parameterizing them is more difficult.

Thus, the forms of reasoning that students exhibited during this process were characterized by:

- Interpret the concepts of a problem in terms of its geometric properties and attributes (in terms of the tool).
- Quantify the elements of the model.
- Identify the problem domain.
- Define a relationship that will allow finding the solution in an infinity of cases.
- Determine the solution in terms of the model.

Although the systematic use of a dynamic geometry system promotes the study of relationships between the concepts involved in word problems, there are still difficulties in connecting these geometric representations with algebraic representations. However, working under this approach seems to offer a series of possibilities for the development of algebraic and functional thinking.

THE RELATIONSHIP BETWEEN CONFIDENCE, ACCURACY, AND DECISION MAKING IN A CALCULUS SKILLS REVIEW PROGRAM

Carla van de Sande
Arizona State University
carla.vandesande@asu.edu

Jana Elle Vandenberg
Arizona State University
jevanden@asu.edu

Just like physical skills, cognitive skills grow rusty over time unless they are regularly used and practiced so academic breaks can have negative consequences on student learning and success. The Keeping in School Shape (KiSS) program is an engaging, innovative, and cost-effective intervention that harnesses the benefits of retrieval practice by using technology to help students maintain proficiency over breaks from school by delivering a daily review problem via text message or email. A growth mindset is promoted through feedback messages encouraging students to try again if they get a problem wrong and to take on a challenge problem if they get a problem correct. This paper reports on the relationship between confidence, accuracy, and decision making during the implementation of the KiSS Program at a large university during winter break for students enrolled in an engineering introductory Calculus course sequence.

Keywords: Calculus, Metacognition, Technology, Undergraduate Education

Introduction and Theoretical Framing

Many Science, Technology, Engineering, and Mathematics (STEM) topics require proficiency in previously learned skills and concepts. Introductory STEM course sequences mimic this structure so that foundation courses feed into subsequent closely-related courses. Students finish the foundation course with skills and confidence that are critical to their success in the target course. However, this growth erodes in the time between the courses, especially if there is a prolonged gap in academic engagement such as a lengthy academic break (e.g., summer slide) (Cooper et al., 1996), or if the way students absorbed the information was not conducive to retention (e.g., stress-induced intentional forgetting) (Ramirez et al. 2017). In order to address this loss of proficiency, many faculty, departments, and institutions of higher education would like to see students engage with course content outside of class and during academic breaks. Regrettably, this is not likely to happen spontaneously, so the issue is how to reach students and prompt them, in a non-threatening way, to regularly review things that they have learned and need to maintain for future learning. One way of doing this is to deliver review opportunities, along with encouragement to confront deficiencies and meet potential, in a location that students are unlikely to miss, namely on their mobile phones or via email.

This paper discusses the implementation of an engaging, innovative and cost-effective program that uses technology to help students maintain proficiency over breaks from school, while also promoting a growth mindset (van de Sande, 2019a, 2019b). Theoretically, the Keeping in School Shape (KiSS) program draws on the well-documented benefits of regular retrieval practice, namely recalling previously material as an effective way of maintaining cognitive performance (Butler et al., 2014; Roediger & Butler, 2011; Rohrer & Pashler, 2007). The KiSS Program embodies retrieval practice by sending students a multiple-choice mathematics question daily via text messaging or email. The problems are chosen specifically to be skills that are requisite for success in the mathematics course following the break from school.

Retrieval practice delivered daily is also consistent with the growth mindset metaphor of the brain as a muscle that grows stronger with exercise (Yeager et al., 2019). Many students approach their studies convinced that intelligence is fixed, so those who have to put forth effort lack natural talent and the ability to succeed (Boaler 2010, 2013; Dweck, 2006). This failure to believe that, through effort, the brain can grow stronger negatively affects achievement (Boaler, 2013), especially for more underrepresented groups (Aronson et al., 2002; Blackwell et al, 2007). When students engage in retrieval practice by testing themselves regularly to see if they can perform a previously learned skill or concept, they are essentially flexing and toning their "brain muscle" and keeping it from atrophying with disuse. The design of the KiSS Program further promotes a growth mindset by including features such as hints, the option to attempt more challenging problems, and feedback messages that praise and encourage effort so that students have opportunities to see mistakes and difficult problems as profitable opportunities to engage in productive struggle.

Mindset not only plays a role in broad measures of math achievement and but can also influence how students behave in a specific problem-solving context (Shen, Miele, & Vasilyeva, 2016). Students with a fixed mindset are less likely to persevere in a challenging math task than students with a growth mindset, and also have lower confidence in their ability to do math after being confronted with challenging problems. Given that what counts as challenging is a subjective judgment, we use technology to explore the relationship between student confidence in the ability to perform a task and subsequent navigation through a review activity.

Methods

The KiSS program was designed to encourage students to regularly connect with their studies and to gauge their ability to perform previously learned material over break by providing easily accessible review opportunities for requisite skills. At the same time, the configuration of technology allowed us to unobtrusively collect information on confidence, accuracy, and decision making as students engaged with the review activities.

Context

Each problem in the KiSS program was designed as an independent Qualtrics (https://www.qualtrics.com/) survey since Qualtrics allows surveys to be distributed as sms messages or emails. Figure 1 shows a schematic of how the daily problem link was pushed to students' phones as a text message or sent to their email addresses. Clicking on the link took students directly to the daily question survey. Before attempting the daily review problem, students were first asked to use a 5-point scale (ranging from "not at all" to "Super Duper") to show how confident they were that they could answer it correctly. Informal rating labels and accompanying emojis were used in an effort to make this self-assessment less threatening.

After that, as shown in Figure 2 which depicts a flowchart of the regular daily agenda, students responded to the question by selecting one of the answer options, which opened up a sequence of possible paths and opportunities. On certain days of the week, the agenda included additional paths (not shown here): On Tuesdays (aka "2's-days"), students could choose to do an additional problem and on Sundays (aka "Trivia Days") students could choose to do the daily calculus problem followed by a calculus trivia question or just respond to the trivia question. Figure 3 depicts the opportunities for engagement that stem from getting the daily problem incorrect, namely getting a hint and trying again (encouraged), seeing the solution, or exiting. Students who got the daily problem correct had the option of trying a related more challenging problem (encouraged), seeing the solution, or exiting. Whether they got the daily review problem incorrect or correct, students were prompted with messaging to adopt a growth mindset by persisting ("Let's rethink this!") or pushing themselves ("Let's push ourselves!").

Participants

This paper reports on select results from an implementation of the KiSS Program at a large university in the Southwest for students who were enrolled in an introductory Calculus course sequence for engineers. The program was designed for students who had successfully completed the first course of the sequence and were planning on taking the second course in the upcoming spring semester. At the end of the fall semester, students who were enrolled in the second course in the following spring semester were invited to participate in the KiSS Program over winter break via email notifications and posts by instructors on course websites. Students who responded by texting a self-selected code name were enrolled in the program and received a problem daily (with the exception of holidays) for each of the 33 days of break. 357 students signed up to participate in the KiSS Program, and 307 of these opened at least one of the 33 problems.

Data Collection

On any given day of the program, students could choose whether or not to respond to the daily problem and could also exit the daily problem at any stage (e.g., after rating their confidence but before answering the problem). The following data was logged for each participant who opened the daily problem: time and duration of participation, confidence rating (for the daily problem), answer choice, and problem path (e.g., whether or not they accessed the hint, viewed the solution, or opted for a more challenging problem). Answer choice and resource use was also logged for any second attempts at the daily problem following hint use, as well as for any challenge problem attempts. In an effort to engage students in the KiSS Program as a fun review tool (rather than as a research study), demographic data was not collected prior to participation. Data from entrance and exit surveys, along with more in-depth interviews on program experience are discussed elsewhere (author2 and author 1, 2021).

Results

In this paper, we report on how student confidence relates to performance and engagement in the program on a daily basis. In particular, we look at relationships between confidence and accuracy, and how confidence in the ability to solve the daily problem plays out in the decisions students make for navigating through the review activity.

Confidence Ratings

Figure 4 shows the percentage of confidence ratings of each level (n=5273). Students were generally very confident in their ability to be able to solve the daily problem, with 73% of the ratings being either "somewhat" or "super duper!" Although self-selection in KiSS Program participation may play something of a role, this skew towards higher levels of confidence is also not surprising since all of the daily problems were a review of fundamental skills learned in or prior to the course that students had just successfully completed (Calculus 1).

Confidence Phrases and Emojis	not at all! 	not very 	meh 	somewhat 	super duper! 
Percentage	5%	8%	14%	26%	47%

Figure 4: Percentage of confidence ratings of each level

Confidence and Accuracy

After rating their confidence, students were presented with the daily multiple-choice problem. Figure 5 shows the relationship between accuracy and level of confidence. As can be seen, there was a positive relationship between accuracy and confidence. In addition, although there were very few times when a student did not respond to the problem after having rated their confidence, these were all instances in which the student had low or very low confidence in their ability to solve the problem, even just by selecting an option from five possible answers.

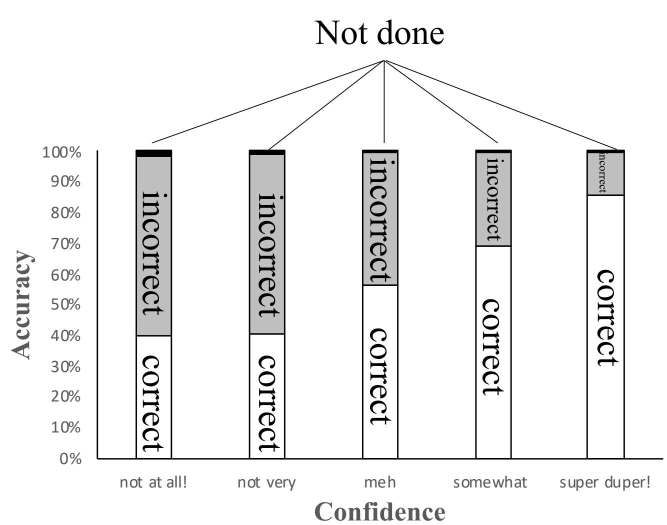

Figure 5: Accuracy of First Attempt on Daily Problem by Confidence (n=5273)

Accuracy and Path

After rating their confidence on their ability to solve the daily problem, students could take various paths through the daily review depending on their accuracy. Students who got the problem correct could choose to do a related challenge problem, view the solution to the daily problem, or simply exit for the day. Students who got the problem incorrect could choose to view a hint and retry the problem, view the solution, or exit. As can be seen in Figure 6 (left), for students who got the initial daily problem correct, confidence was related to the likelihood of engaging in a challenge problem afterwards. Students who were more confident in their ability to solve the initial problem were more likely to opt for a more challenging problem. Students who got the initial problem wrong (right), however, tended to choose to retry a problem, regardless of their confidence. Figure 6 also shows that exiting was more prevalent for students after getting the initial problem correct rather than incorrect, and that, in general, higher versus lower confidence was more characteristic of exiting the program for the day.

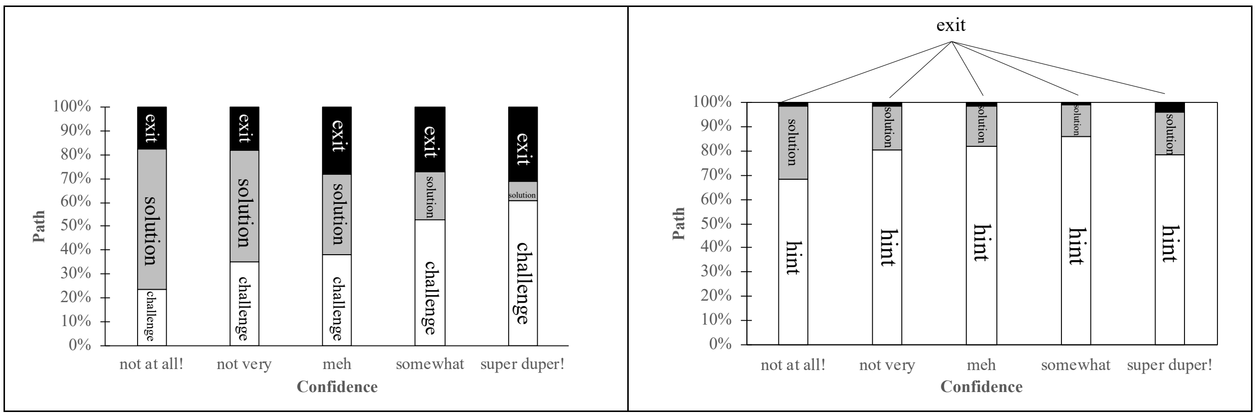

Figure 6: Path Taken by Students Who Got the Daily Problem Correct (left: n=3757) and Incorrect (right: n=1487)

Accuracy Following Challenge and Second Attempt

Depending on whether or not a student got the initial daily problem correct, they had the option to do a challenge problem or view a hint and retry the problem. Figure 7 depicts the relationship between confidence in being able to solve the initial problem and accuracy of the challenge problem (left) and accuracy of the second attempt of the initial problem (right). As seen in Figure 7 (left), confidence in being able to solve the initial problem was positively related to accuracy on the related challenge problem. However, for students who got the initial problem incorrect and then tried it a second time, the hints were helpful regardless of confidence (Figure 7, right). In addition, very few students changed their mind and exited for the day after choosing to view a challenge problem or a hint. However, these instances tended to occur more for students with low confidence who indicated that they wished to try a challenge problem after correctly solving the daily problem.

Path Following Second Attempt

Students who got the initial daily problem incorrect and chose to view a hint then had a second chance to attempt the problem. Whether or not they got the problem correct on this second attempt, students could choose to view the solution or exit for the day. As shown in Figure 8 (left), initial confidence was negatively related to viewing the solution for students who got the problem correct on their second attempt. More confidence initially, even though they got

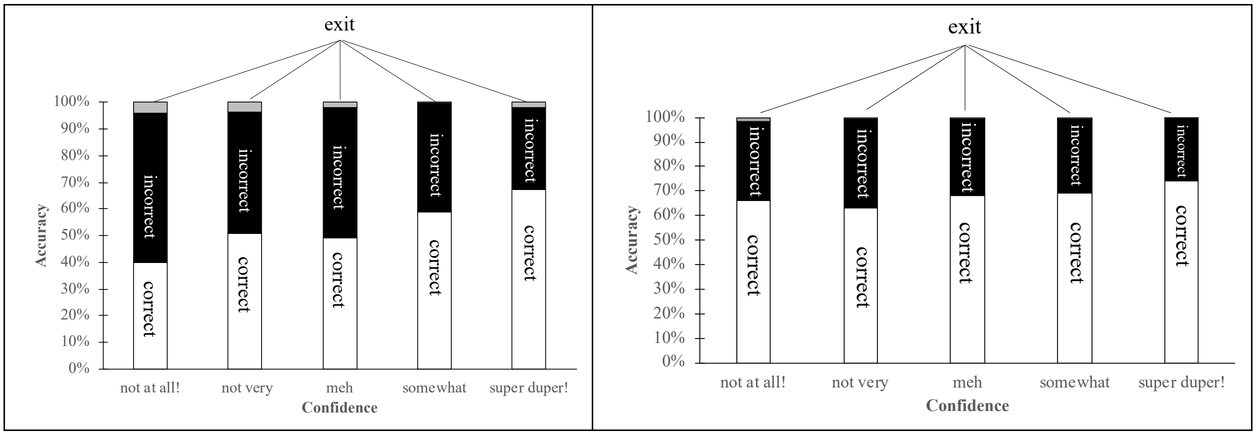

Figure 7: Accuracy on Challenge (left: n=2028) and Second Attempt of Daily Problem (right: n=1202) by Initial Confidence

the problem incorrect on the first attempt, was more associated with exiting, rather than viewing the solution, whereas less confidence initially was more associated with viewing the solution, even though the second attempt at solving the problem was successful. However, students who got the problem incorrect on their second attempt, regardless of their initial level of confidence, almost always chose to view the solution before exiting. As on the first attempt at the problem (Figure 6), exiting was much more characteristic of students after a successful versus an unsuccessful second attempt.

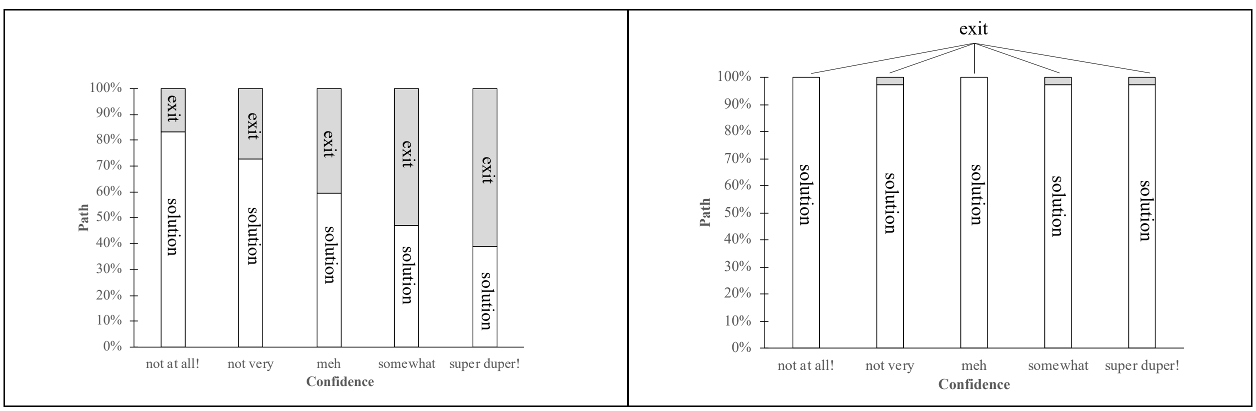

Figure 8: Path Taken by Students Who Got the Second Attempt of the Daily Problem Correct (left: n=827) and Incorrect (right: n=367) by Initial Confidence

Path Following Challenge

Students who got the initial daily problem correct could elect to do a second related challenge problem. Whether or not they got this more challenging problem correct, students could choose to view the solution or exit for the day. As seen in Figure 9 (left) initial confidence was negatively related to viewing the solution for students who got the challenge problem correct to some extent. Students who were unsure of their ability to solve the initial problem were more likely to look at the solution after getting both the initial and the challenge problem correct. This tendency was much more marked for students who got the challenge problem incorrect. Students who lacked confidence in their ability to solve the initial problem and then were unable to correctly solve the challenge problem almost always viewed the challenge problem solution. As on the first and second attempts at the problem (Figure 6 and 8), exiting was more characteristic of students after a successful versus an unsuccessful attempt.

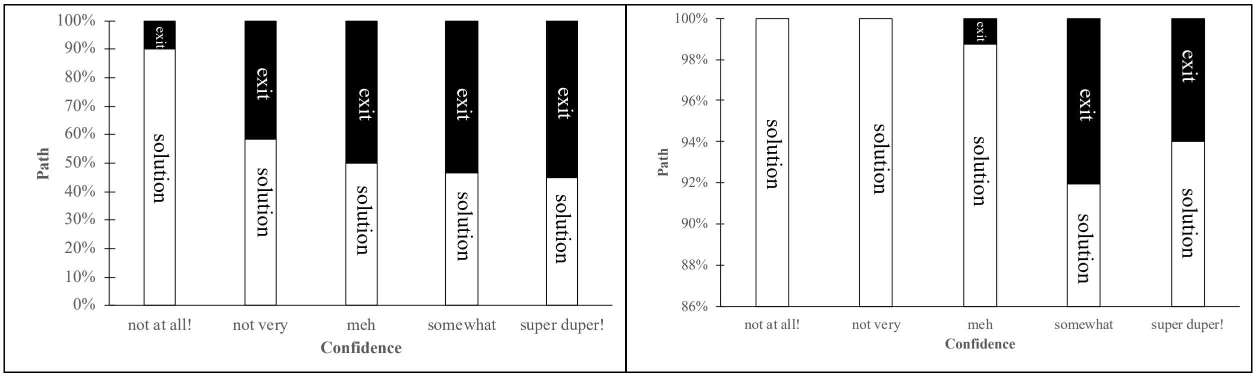

Figure 9: Path Taken by Students Who Got the Challenge Problem Correct (left: n=1243) and Incorrect (right: n=723) by Confidence on Daily Problem

Discussion

The KiSS Program illustrates the use of technology to engage students in productive struggle outside of the classroom during academic breaks. Since most students would otherwise not be testing themselves daily, the amount of voluntary participation is quite promising and could presumably be increased with more sophisticated and targeted marketing efforts. Also, the low exit rates after opening and engaging with the daily review activities indicate that the KiSS Program is successful at capturing student interest. The KiSS program therefore addresses the challenge of getting students to participate in beneficial regular retrieval practice (Kallookaran & Robra-Bissantz, 2017), even during breaks from formal instruction.

Implementing the KiSS Program and collecting judgments of learning (Rhodes, 2016) allowed us to explore metacognitive monitoring or metacomprehension (Dunlosky & Lipko, 2007) in an authentic setting. In particular, we were able to trace the relationship between confidence in the ability to solve a review problem and accuracy on that problem, as well as on a related more challenging problem. This use of technology also gave us insight into the role confidence plays on help seeking, although it did not provide a detailed account of how students used the various program resources.

Reaching students, especially those that are vulnerable, and helping them feel connected to their instructors and to their studies in a normal and predictable fashion is especially critical in light of unexpected disruptions, such as the recent pandemic, when students are overcome with feelings of alienation, uncertainty, and anxiety (Dziech, 2020). Therefore, the study of how technology can be used to deliver regular review opportunities outside of class, while simultaneously framing a positive mindset, is particularly timely and warrants attention and exploration. The tracing of the relationship between confidence, accuracy, and decision making in the KiSS Program sets the stage for future work to investigate the ways in which students use review program resources, how particular classes of problems affect student confidence, and how we can design popular and accessible review programs to build confidence and help students realize their full potential as they prepare for their future studies and careers.

We present a typology for characterizing online student-facing mathematics platforms that examines how they position students as learners, exemplified by 9 commonly used platforms. We identify three types of student learning experiences: instruction and practice, practice and support, and conceptual games and activities, and describe each one in terms of the relationships among instructional guidance, student agency, and the mathematical rigor of tasks. We find that within and across categories, there is substantial variation in cognitive demand and student agency, offering implications for further research, school decision makers and platform designers.

Keywords: elementary school education, instructional activities and practices, technology, curriculum.

Introduction

Increasingly, teachers and school systems in the U.S. are using a range of digital resources and tools to supplement regular mathematics instruction (Choppin, et al., 2014; Kauffman, et al., 2020). In this paper, we look closely at one type of resource that we call *online student-facing platforms* (OSFPs). These platforms represent an array of software programs, such as Dreambox, IXL, or Zearn, that have what Choppin et al. (2014) refer to as "individual learning designs." We present an analysis of 9 commonly used mathematics OSFPs and propose a typology for characterizing the nature of the learning experiences they offer elementary students.

Our interest in OSFPs has arisen out of evidence that students in the U.S. are using them in increasing numbers and as a substantial portion of their weekly mathematics learning. In our own interview study of elementary teachers' use of curriculum resources (Remillard et al., under review), 9 out of the 10 teachers in the U.S. reported assigning OSFPs at least once/week. In 3 cases, students used them 3 to 5 hours a week during dedicated periods and 5 teachers reported that OSFP use was dictated by school policy. These platforms can be understood as an often overlooked, but significant, component of mathematics learning. From this perspective, our analysis aims to consider the types of mathematics learning experiences available to students in OSFPs in U.S. elementary schools.

In order to achieve this goal, we draw on frameworks typically used to examine classroom instruction and features of digital resources. While research on digital tools often separates out components, we consider how components work together to frame comprehensive student learning experiences. Building on analyses of similar platforms in Choppin et al. (2014), Kay and Kwak (2018), and Cayton-Hodges et al. (2015), we consider how these platforms frame and structure teaching and learning interactions.

Our study contributes to what is known about OSFPs in a number of ways. First, by analyzing them using a teaching and learning framework, we suggest that students' experiences with supplemental tools matter for their mathematics learning. We do not assume that OSFPs should function in the same way or accomplish the same goals as classroom instruction, and we understand them to be supplemental in nature and useful for particular instructional goals. Nevertheless, given the increasingly extensive use of these platforms, understanding their affordances and constraints is important for teachers and researchers when considering their impact on students. Second, OSFPs are often thought of as similar in design and approach. By making visible the mathematical and pedagogical positions of some of the most commonly used OSFPs, our analysis demonstrates the diversity of these resources.

Background and Theoretical Framing

Our theoretical approach integrates frameworks that inform research and practice in mathematics teaching and learning with research on design components of digital learning tools that impact students' mathematical learning opportunities.

Summaries of research on mathematics teaching and learning speak to four critical domains of importance: a) mathematics content, b) types of learning experiences, c) learners' dispositions, and d) the role of teacher. There is general agreement that ideal *mathematics content* should be rigorous, meaning it should integrate procedural knowledge with conceptual understanding and opportunities for application of knowledge to familiar and novel contexts (NRC, 2001; Stein, et al., 1996). Recall of facts and fluency with procedures are both necessary but are only useful when connected with meaningful applications. We also know that *student learning* is increased when students are actively involved in tasks that require them to think through problems, make decisions on how to solve them, monitor their progress, and struggle with mathematical tasks (Hiebert and Grouws, 2007). These types of problem-solving experiences support students in developing *productive dispositions*, which include how students see themselves as mathematics learners in terms of identity, mindset, and agency (Boaler, 2016; Jackson, 2009; NRC, 2001). Research on the *role of the teacher* in supporting students' learning of rigorous mathematics through active engagement and fostering the development of productive dispositions is extensive. Several important themes stand out: Teachers play a critical role in scaffolding student learning, not by reducing task rigor, but by ensuring that all students can access the task (Jackson et al., 2013) and responding to students' needs during productive struggle. Some distinguish between "just-in-case" support, which provides all students with guidance prior to students engaging with problems, and "just-in-time" support which provides targeted guidance to particular students when they need it, allowing more opportunity for productive struggle (Dixon, 2020). This type of effective scaffolding is informed by knowledge of student understanding produced by ongoing, short-cycle formative assessment (Black & Wiliam, 1998; Copur-Gencturk & Rodrigues, 2020). By continuously monitoring students' understanding of a problem, teachers have the opportunity to provide scaffolds to students as necessary.

Research on the affordances of digital tools is still under development, and few studies have examined technological tools with an eye toward how they might contribute to mathematics education (Kay & Kwak, 2018). No studies focus exclusively on what we are calling OSFPs, instead classifying them as one type of broader collection of digital apps or tools. We build our analysis, in part, on a small set of studies that attend to the learning experience supported by these platforms or other digital mathematics apps, but do so in substantially different ways.

Clayton-Hodges, Feng, and Pan (2015) developed a framework for analyzing and assessing mathematics apps, which proposed four dimensions: a) quality of mathematical content (mathematical accuracy and richness), b) feedback and scaffolding, c) richness of interactions (modes of interaction and item types), and d) scoring and adaptability. To a large extent, Choppin and colleagues' (2014) analysis of digital curriculum programs hones in on the "richness of interactions" category. They focus on how learners interact with the platforms and found that they generally engage learners in one or more of three distinct types of activities: a) view video presentations, b) practice procedures that have been demonstrated, and c) manipulate representations to solve problems. Kay and Kwak (2018) offer the dimension of purpose as an additional category. Based on a review of research on mathematics apps, they found five different purposes: instructive, practice, constructive, productive, and game-based. They also offer a list of eight characteristics around which the apps they examined tended to vary, many of which overlap with or add detail to Clayton-Hodges et al's (2015) dimensions: types of learning valued, quality of the content addressed, clarity of learning goals, usability, engagement, adaptability to differing levels, mode of feedback, and opportunities for collaboration. Each of these classification systems contributed to the development of our analytical framework. Because we were interested in the learning experience offered by the OSFPs, we selected dimensions from these frameworks that most aligned with research on the nature of mathematics teaching and learning. These are described in the following section.

Design and Methods

The data for this study come from an analysis of student-facing mathematics platforms that are frequently used in the United States. We constrained our selection to platforms that students use by logging on and working individually as a supplement to primary mathematics instruction. We began with the OSFPs identified by teachers in a related study on teachers' use of digital resources (Remillard et al., under review). We then added platforms based on reports of OSFPs most commonly used by teachers in the United States (Kauffman, et al., 2020) and our own awareness of available platforms with unique features. After completing the first phase of analysis, we searched for additional OSFPs to test the viability of our emergent typology. In this paper, we report on a reduced subset of 9 platforms that exemplify the range and variation of each category.

To begin our analysis of each OSFP, we immersed ourselves in the student experience. Through completing multiple tasks and exploring the learning pathways of the platforms, we became familiar with the program organization, types of tasks, instructional supports, and responses to correct and incorrect student entries. We also read and watched instructional and promotional materials for teachers and reviewed teacher resources to understand the intended purposes of the platform features. Although the platforms included a number of teacher-facing features, we restricted our analysis to student-facing components, given our aim of understanding the student learning experience. From this phase of analysis, we wrote detailed memos that summarized the characteristics and features of each OSFP and outlined the overall nature of mathematics teaching and learning available in each platform.

Based on our initial exploration of the platforms, we developed a set of categories that roughly aligned platform features with constructs from the literature on mathematics teaching and learning and incorporated key dimensions included in analyses on platforms and apps. These are summarized in Table 1. The majority of categories were emergent, developed through successive rounds of description, comparison, and refinement. The levels of cognitive demand, introduced by Stein et al. (1996) and widely used in subsequent studies, were the only *a priori* categories applied.

Table 1: Categories and descriptions for OSFP analysis

Constructs	Platform Features	Categories
Mathematical Rigor	Cognitive demand (Stein et al., 1996)	Memorization (Mem); procedures without connections (PWOC); procedures with connections (PWC); doing mathematics (DM)
	Types of tasks	Examples: Replicating procedures, problem solving, creating models, test-like questions, conceptual activities, mathematical games
Instructional Guidance features	Instructional supports	How direct instruction is provided through videos or interactive lessons
	Responsive supports	How just-in-time supports are provided through feedback, hints, corrections, and optional instruction
	Learning pathway	How student's pathway through tasks is determined (type of adaptive tools)
Student agency/dispositions	Student decision making	How students monitor/guide their own work; availability of student choice

Many platforms we analyzed included a range of features, multiple task types, and several modes of interaction, making categorization challenging. For the purpose of this study, we focused on the most prominent features and approaches related to critical domains of teaching and learning mathematics, discussed earlier, in each OSFP. Many platforms included some timed practice of computation facts, which varied little across platforms and are not considered here. In addition, platforms used a range of gamification or engagement strategies (e.g., points, badges, characters, music, avatars, non-mathematical games), which we did not include in our analysis.

By analyzing the platforms using emergent categories and short descriptions, we were able to explore patterns in the combinations of features across different platforms. When grouped according to these patterns, we observed the potential for different learning experiences for students. We identified three primary types of *student learning experiences* offered by the platforms: Instruction and Practice, Practice and Support, and Conceptual Games and Activities. These categories overlap with and add depth to analytical frameworks from Choppin et al. (2014), Clayton-Hodges et al. (2015), and Kay and Kwak (2018).

Findings

We organize our findings around the three types of student learning experiences that emerged from our analysis. As illustrated by Table 2, the instructional guidance, student agency, and mathematical rigor of platforms intertwine to shape a distinct student experience. Within each type, we found variation across the subcomponents, which we illustrate through several exemplar platforms.

Table 2. Description of three OSFP types with exemplar platforms.

Student Learning Experience Categories	Nature of Interaction	Student Agency	Task Types with Levels of Cognitive Demand (Stein et al. 1996)
Instruction and Practice (Dreambox, iReady, Zearn)	Videos, sometimes with interactive tasks, followed by practice with identical tasks with hints or explanations	Minimal	Replicating procedures to create visual models and/or solve test-like word problems Mem, PWC
Practice and Support (IXL, Khan Academy, Prodigy, Study Island)	Practice tasks with hints or explanations; support may be corrective or conceptual	Choose type and amount of support	Test-like questions. Mem, PWOC, PWC
Conceptual Games and Activities (Beast Academy, Math Playground)	Concept-building mathematical games and activities; guided lessons or self-discovery of increasingly complex concepts.	Choose problem solving approach	Students solve game-like or progressively complex challenges Mem, PWC, DM

Instruction and Practice

Our first OSFP type, *instruction and practice,* demonstrates concepts or skills through direct or guided instruction and then has students replicate them through highly similar procedural tasks with little student agency. Within this type, we found several variations. Dreambox and iReady follow a gradual release approach to instructional guidance (I Do-We Do-You Do), where students first watch a demonstration, then participate in filling out incremental, predetermined steps, and then practice the same steps on their own. Zearn's approach is more guided, using interactive videos, during which the student is frequently asked to answer questions, interpret models, or demonstrate understanding along a conceptual pathway before they practice independently.

In terms of mathematical rigor, all 3 platforms employ visual models to connect procedures to underlying concepts (PWC tasks). iReady also includes mathematical games that allow students to apply their learning in a game context, for example by adding weights (negative) or balloons (positive) to a submarine to move it along a vertical number line and pass through a goal. Dreambox, however, uses a didactic approach of demonstrating each activity twice with a focus on completing steps. which reduces the rigor level, despite the use of interactive visual models.

We found student agency in these platforms to be minimal or superficial, as they require students to move through all lesson components in order. For example, in Zearn, video lessons start playing automatically, but students can skip through explanations of the steps, and in Dreambox students can select the topic of the next task while still proceeding down the same lesson path. Several of these platforms offer individualized learning paths based on initial diagnostics, though we found that in Dreambox students are often forced to practice many tasks at the same level despite having repeated correct answers. Zearn has no adaptivity; all students complete the same tasks in the same order.

Overall, the approach of *instruction and practice* OSFPs reflects a perspective that learning involves replicating procedures correctly in repeated practice, with iReady and Zearn at the more conceptual end of the spectrum, as students are introduced to conceptual models, and Dreambox at the more procedural end, with students using visual models in a rote manner. These OSFPs use a just-in-case model and appear to position students as passive learners, who may view mathematics as a set of steps to memorize.

Practice and Support

OSFPs that we describe as *practice and support* have students begin by directly practicing tasks and receiving instructional support only when they choose it or demonstrate need through incorrect responses. Students may access written/visual or video instruction at any time, encouraging them to select the level of support that they need. There is still substantial variation among platforms in this type, shaped by how the mathematical rigor of tasks and related instructional guidance work in tandem to modulate the level of student agency.

In *practice and support* platforms, tasks are formatted like test questions, including multiple choice, multi-select, fill-in-the-blank, drop-down, and interpreting or creating visual models. This range of task type, which includes word problems and visual models, reflects those commonly used in online assessments and textbooks in the U.S. We found that *practice and support* platforms vary in both the cognitive demand of tasks (procedural or conceptual) and the nature of instructional guidance (corrective or conceptual), often in tandem. At one end of the spectrum, Study Island provides tasks, videos, and explanations that focus on completing rote procedures without conceptual understanding (PWOC). The accompanying student feedback is corrective, providing a generic description of the solution strategy and then the correct answer. At the other end, IXL and Khan Academy use more complex tasks, based on visual models and alternative algorithms to develop conceptual understanding (PWC). Students are supported by conceptual feedback in the form of optional, stepped-out hints, explanations, and conceptually-focused video lessons. Khan Academy gives students a menu of support options and also uses a point system to encourage them to try solving first on their own. Prodigy lies in the middle, with more rigorous test-like questions, but the hints provide a small amount of supporting information or indicate the early steps of a solving strategy, and it only provides corrective feedback.

Practice and support platforms offer a higher level of student agency than *instruction and practice* platforms because they allow students to determine when and how to seek instructional guidance. Yet there is still a substantial range in student agency among *practice and support* platforms, depending on both the task complexity, the kinds of support offered, and students' level of choice in accessing the supports.

Overall, the components of *practice and support* OSFPs work together to suggest a model of learning in which students are encouraged to try solving problems independently and seek or be given help if they need it. This design positions students as active learners when practicing or figuring out a range of problem types and, in some platforms, gives them the opportunity to self-monitor their understanding. While IXL and Khan Academy offer somewhat more cognitively complex tasks and supports than Prodigy, all three use an underlying just-in-time model that begins with student practice.

Conceptual Games and Activities

OSFPs that we categorize as *conceptual games and activities* invite students to make sense of tasks and experiment with problem solving strategies. Many of these tasks offer minimal or no language introducing the problem or its objectives, inviting students to explore.

These platforms offer two types of tasks: problem progressions and logic games. Problem progressions start with a simple problem that requires only basic computation or memorization to solve and then provide increasingly more complex problems that organically lead to multi-step or algebraic thinking. For example, one Math Playground progression begins by showing two identical candies with a total cost of 6¢, which students drag to the 3¢ jar. The task quickly progresses to involve multi-step algebraic thinking to find the cost of an unknown candy when a 24¢ candy and two identical unknowns together cost 52¢, all without any instructions or demonstrations (doing mathematics; DM).

Math logic puzzles and games rely on an understanding of procedures but encourage conceptual thinking (PWC). Beast Academy and Math Playground both contain logic games where a limited set of numbers must be arranged to produce correct sums/products along horizontal, vertical, or diagonal lines, supporting flexible number sense. Additionally, some of the operational automaticity games in Math Playground support flexible number sense, for example by having students select different pairs of bubbles that have a sum of 8. (These flexible automaticity games are also available in iReady).

The instructional guidance features differ in our two exemplars. In Math Playground, feedback is minimal and corrective (e.g., a beep indicating a wrong answer), with no hints, explanations, or instruction. However, the responsive support is also unlimited; students can make endless attempts using different strategies until they find the correct solution. Beast Academy, meanwhile, provides instructional support that is more similar to a *practice and support* platform, where students may seek help at any time by clicking on a video or an illustrated lesson, and students are shown correct answers with brief explanations after two attempts.

Overall, the *conceptual games and activities* OSFPs suggest a view that students learn through solving increasingly complex tasks, using their own strategies, with minimal or no instruction. While Beast Academy provides a higher level of instructional guidance than Math Playground, the creative and rigorous tasks in both platforms position students to have agency in determining their own solution paths.

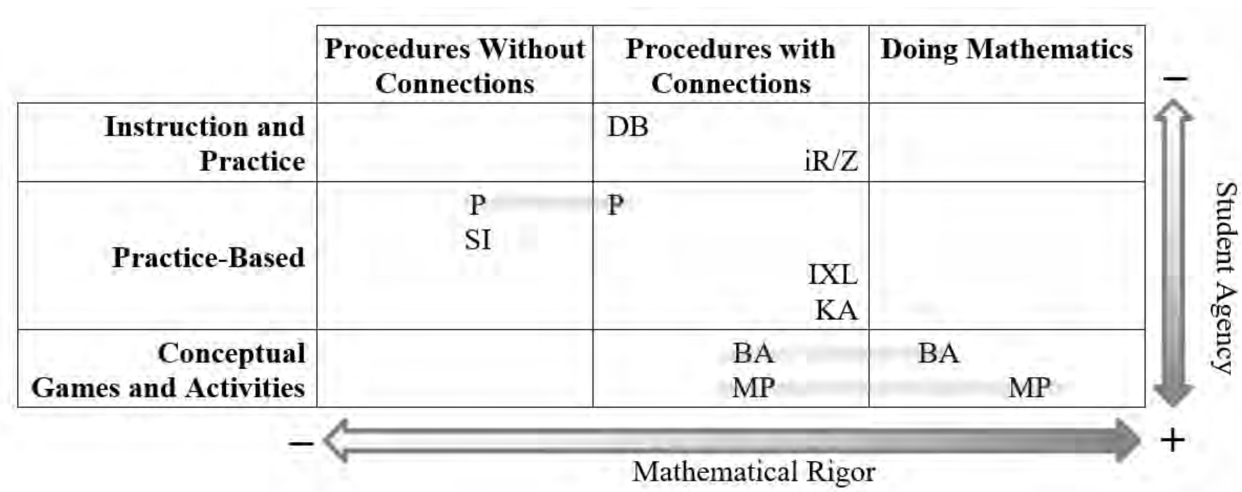
Discussion and Significance

Given the prominent use of OSFPs in U.S. classrooms, one aim of our study was to understand and make visible the types of learning experiences available to students when using these platforms. Though OSFPs are often overlooked as supplements to a core curriculum, the hours students spend with them has the potential to substantially shape their ideas about the nature of mathematics and themselves—whether they see themselves as active or passive learners, and whether mathematics involves replicating procedures, understanding them, or creatively solving problems (Boaler, 2015; Skemp, 1978).

Our typology offers a framework for analyzing OSFPs beyond the 9 that we showcase here, supporting researchers and school decision makers in understanding the affordances of these resources. While building on prior work that compared platform components and features (Cayton-Hodges, et al., 2015; Choppin, et al., 2014; Kay & Kwak, 2018), our analysis takes a more integrated approach. By putting components and analytical categories for conceptualizing mathematics teaching and learning in relation to one another, our framework offers a fuller picture of how platforms create mathematics learning experiences.

In particular, our approach illustrates the utility of our three analytical categories for examining OSFPs, instructional guidance, mathematical rigor, and student agency, while also highlighting how they work in relation to one another to shape a particular learning experience. There are substantial differences, for example, in the overall design of the three types we identified in how they position the nature of mathematics and students' roles. Moreover, we found that differences in how these components are combined leads to further variation, with the potential for substantially different students' experiences.

We have attempted to capture the way variation in mathematical rigor and student agency interact in our nine exemplar platforms in Figure 1. Moving horizontally, the platforms increase in mathematical rigor from left to right. Gray bars indicate platforms with tasks at two levels of cognitive demand. For example, Prodigy (P) contains tasks at both the PWOC and PWC levels. Student agency is placed along the vertical axis, increasing from top to bottom. Each platform is placed in relation to both continua and shown within our analytical types. In addition to showing how the platforms we analyzed differed, the figure demonstrates how the different categories influence the overall learning experience.



Key: DB = Dreambox, iR = iReady, Z = Zearn, P = Prodigy, SI = Study Island, KA = Khan Academy, BA = Beast Academy, MP = Math Playground. Gray bars indicate platforms with tasks at two levels of cognitive demand.

Figure 1: Relationship between student agency and mathematical rigor across and within each OSFP category.

Finally, we argue that the use of student agency as an analytical lens when examining digital platforms draws attention to important and unexamined aspects of OSFPs. Student agency differs qualitatively across the types of platforms and is supported by different features. In *practice and support* platforms, students are encouraged to monitor and manage their work on tasks, getting support only when they need it. In *conceptual games and activities* platforms, students can develop agency through sense making and directing their own approach to problem solving. Both types of agency can support students to develop productive dispositions and mindsets related to mathematics learning (Boaler, 2016). *Instruction and practice* platforms, on the other hand, provide limited attention to this consequential aspect of students' mathematical identity development, though Zearn suggests that this can be increased through interactive lessons where students complete some steps before they are modeled. We recommend that increasing opportunities for the development of student agency would be a fruitful path for designers of OSFPs to pursue.

The main goal of this study is to compare the relationships between the reading ability of prospective teachers and secondary school students measuring the average reading time per word as a proxy of the complexity of mathematical problem statements. Besides that, we study students' performance in word problems where the problem statement involves the fraction acting as an operator and the reconstruction of the whole. The results show that the proposal to express reading ability through a scale adapted to the distribution of the studied population through quartiles and interquartile range is consistent with the results obtained in the existing literature. In addition, due to the greater reading ability of prospective teachers, their success in solving problems is greater compared to secondary school students.

Keywords: reading, problem-solving, prospective teachers, students

Introduction

Reading skills are a basic tool for text comprehension and academic performance in the Primary stage (Alegría, 2006; Sweet & Snow, 2003). There are reading skills related to decoding processes, while other skills involve understanding processes themselves. As reading skills are automated, the understanding process also is developed, since cognitive resources are released that can be dedicated to understanding. However, reading does not necessarily ensure comprehension (Oakhill & Cain, 2007a, 2007b; Oakhill, Cain & Bryant, 2003). Although, there are studies, such as that of Sanz et al. (2020) who showed that the average reading time per word used when reading and solving the statement of a word problem allows predicting performance in solving the problem posed.

In this context, in the area of mathematics, there is an interaction between the processes of understanding the verbal statement and mathematical knowledge, so that reading comprehension plays an important role (Kintsch & Greeno, 1985). Different studies (De Corte and Verschaffel, 1991; Hegarty, Mayer and Monk, 1995) demonstrate the relationship between difficulty in correctly representing problem statements and mathematical performance.

But not only the student body deserves to be studied, authors such as Waller (2012) or Olfos et al. (2014) determined that teachers' knowledge is significantly associated with student performance.

Research purpose

In this context, we follow a methodology where the users' reading time is considered as a measure of the complexity of a word problem, with the particularity that given there are two actors in the teaching-learning process, we consider secondary students and prospective teachers as our study population.

Thus, the specific goals in this work are:

1. To design a proposal to compare the complexity of the statement of a word problem measured through the reading ability of prospective teachers and secondary students.
2. To verify the proposal designed to compare the complexity of word problem statements in the two populations considered.

Methodology

The process to measure the complexity of a word problem and classify the reading ability of a user

Following Sanz et al. (2020), the global complexity of the statement will be measured as the average reading time per word of the propositions that make up the statement.

Regarding the reading ability of a user when reading word problems (Eq.1), it will be calculated as the average of the time spent by the student in each proposition (t_{ijs}) for the words (w_{ij}) read.

$$rh_s = \frac{\sum_{i=1}^{k}\sum_{j=1}^{p_i} t_{ijs}}{\sum_{i=1}^{k}\sum_{j=1}^{p_i} w_{ij}}, \qquad (1)$$

where s corresponds to the student, p_i the number of propositions of each task, k is the number of tasks.

In this study, we design a proposal to be able to compare the complexity of a word problem statement in the two study populations selected characterized by integrands having different reading skills.

Following the methodology of PIRLS (2017), in which the level of school performance is expressed on a scale, in the present work, reading ability is adapted to a scale based on the distribution of the population studied. To do this, interquartile ranges are used to evaluate the dispersion of the distribution and determine four reading abilities levels or intervals (Table 1). It should be noted that values above the advanced or low level will be considered outliers and will not be analyzed.

Table 1: Reading ability levels. * o minimum ** o maximum

Reading ability level	Range
Advanced	[Q_1-1.5·R.I.C*, Q_1[
High	[Q_1, Q_2[
Intermediate	[Q_2, Q_3[
Low	[Q_3, Q_3+1.5·R.I.C**]

Technological environment

To obtain the reading time in each proposal, a technological environment named R&L will be used to design research experiments on reading comprehension in text and image-related learning tasks (Sanz et al., 2020). Experiments in R&L can include enriched texts with a list of questions and answers. A number of configuration settings are available, such as the possibility of accessing the statement at any time or only under certain conditions, the effect of alternatively hiding and showing parts of texts by clicking on them.

Covering parts of the text (including multiple choice answers) makes them remain hidden and can only be made visible by clicking on them. This allows obtaining a record of the time that the user spends reading said hidden parts.

Experiment design

We conducted a quantitative descriptive study with a sample of 113 participants (62 women) who belong to two populations of the educational system. In particular: a) 43 prospective primary school teachers (35 women), with an average age of 21.78 ± 1.44 years; and b) 43 male students and 27 female secondary students aged between 15 and 16 years.

First, we analyze the differences based on the participant's profile (Figure 1), obtaining that there are statistically significant differences at a 5% level of significance (TM = 58.520; p-value <0.0001).

In this context, Table 2 shows the levels of reading ability for each group population.

Table 2: Reading ability levels (seconds) secomdary students and prospective teachers

Reading ability level	Secondary students	Level	Prospective teachers	Level
Advanced	[1.424, 4.738[	A_4	[0.822, 2.708[	D_4
High	[4.738, 6.909[	A_3	[2.708, 3.321[	D_3
Intermediate	[6.909, 9.244 [	A_2	[3.321, 4.098 [	D_2
Low	[9.244, 14.846]	A_1	[4.098, 5.790]	D_1

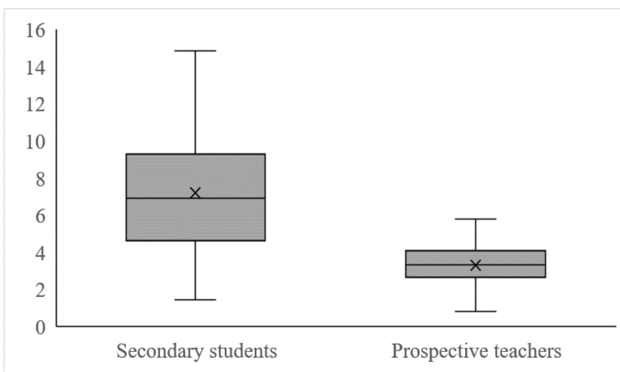

Figure 1: Reading ability classified by study population

Participants were asked to solve the following word problems:

P1. We have thirty candies. Two-thirds of them are strawberry flavored. How many strawberry candies do we have?;

P2. I have one-half of a pizza. Two-thirds of it is pepperoni. What fraction of the pizza is pepperoni?;

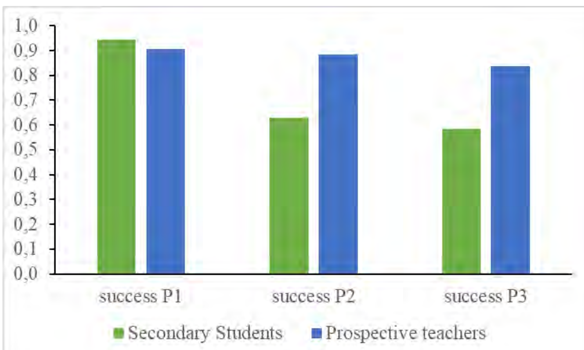
P3. In a fitness club, five-sixths of the 600 members do gymnastics, two-fifths of the rest do swimming. How many members do swimming?

Results and Discussion

Results show that the distributions of secondary students and prospective teachers performance, measured through the success rate when solving problems, are the same (Figure

2a). Thus, if the complexity of a word problem were determined from the probability of success, it could be said that P (success P1)> P (success P2)> P (success P3), which would indicate that P1 would be simpler than P2 and this in turn, simpler than P3. When evaluating the average time per word used when reading the problems statements (Figure 2b), it is observed that the data distributions coincide in both populations, and, in addition, the results match with the probabilities of success (Figure 2a), but they area inversely related. That is, the higher the success rate on a problem, the less time spent on solving the problem. These results are in line with the ones of Ivars & Fernández (2015) that conclude that the success rate can measure the complexity of a problem; so, then reading time can be used as a good proxy. Likewise, given the same distributions, in secondary students as in prospective teachers, the teachers must be studied to determine the difficulties of the students (Waller, 2012; Olfos et al., 2014).

a)



b)

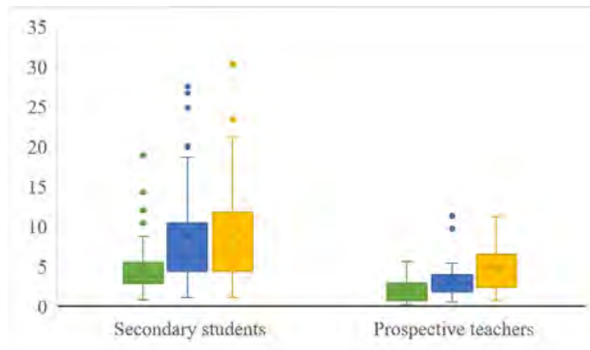


Figure 2: Results of the global statement in both populations a) Success of resolution measured as the probability of success; b) Success of resolution measured as reading time per word.

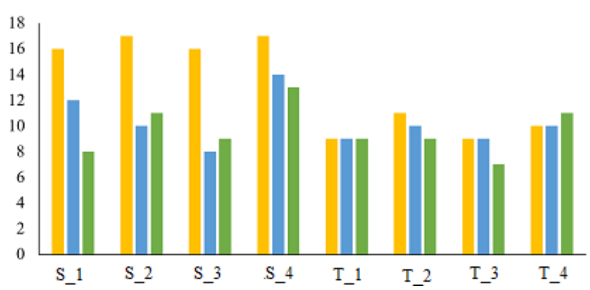
On the other hand, analogous results are obtained with the same analysis but taking into account the levels of reading ability for each population considered (Figure 3). Furthermore, it can be observed that at the advanced level (A_4 and D_4) the number of students who correctly solve the problems is greater. These results indicate that reading, and in particular reading level, is related to student's performance (De Corte & Verschaffel, 1991; Hegarty, Mayer & Monk, 1995; Alegría, 2006; Sweet & Snow, 2003).

a)



b)

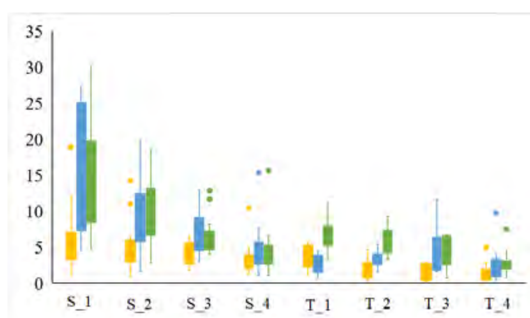


Figure 3: Results of the global statement in both populations a) Number of participants who have been correct; b) Resolution success, reading time per word per population.

Conclusion

This work opens a line of research on the use of technological environments and data analytics to determine the complexities of word problems, measuring the level of understanding of each of the statements through reading time and dealing with the mathematical concepts that they make it more difficult to solve. Likewise, it allows determining the user's reading ability.

The next steps include the design of a longitudinal study by age of the students that analyzes the evolution of the concepts and the possible blockages that may occur. Future work will also help define an index that allows you to create statements with pre-set complexities by weighting the propositions in the statement, according to their level as established in Sanz et al. (2020).

This research report presents the results of The Bessie Coleman Project (BCP), which was named for the first African-American and Native woman to receive a pilot's license. Urban and rural students from historically-excluded backgrounds (i.e., Black, Latinx, Indigenous, and female) were recruited to participate in the BCP. Computer modeling, 3D printing, flight simulation, and drones were used as interventions to enhance students' computational thinking (CT) skills and STEM efficacy. Project staff and facilitators implemented the project in Pennsylvania, Colorado, and Wyoming in Year 2. This research report describes the results of the Year 2 BCP study before the COVID-19 pause, specifically as they relate to student identity and to broadening underrepresented students' participation in STEM.

Keywords: Computational Thinking, Computing and Coding, Technology

Wing (2006) describes Computational Thinking (CT) as a "problem-solving approach that draws on concepts fundamental to computer science by 'reformulating a seemingly difficult problem into the one we know how to solve, perhaps by reduction, embedding, transformation, or simulation'"(p. 33). Thus, CT is a process that includes formulating problems, algorithmic thinking, generalization, and learning transfer (Barr et al., 2011; Repenning, 2012). Yet, CT is not just for computer scientists; children are able to engage in algorithmic thinking approaches similar to those posited in mathematics to carry out the problem-solving process (Sengupta et al., 2013). This study was conducted to expose historically and contemporarily excluded children to CT through computer modeling, flight simulation, and drones in order to broaden their participation in STEM.

Theoretical Framework

The theoretical frameworks that support this study is Critical Race Theory (CRT) and Tribal Critical Race Theory (TribalCrit). CRT began as a form of legal scholarship that examined how the law intersects with race showing the limitations of meritocracy and affirmative action policies (Anderson, 2019; Bell, 1987; Crenshaw, 1988). TribalCrit, an offshoot of CRT, provides a framework to support Indigenous values, culture, and identity (Brayboy, 2005). A common thread in both theories is naming and resisting the root causes of systemic racism. The main tenet of CRT is that racism is endemic to society such that "whiteness as an explicit cultural product [takes] on a life of its own" (Apple 2003, p. 113) to normalize practices in schools and society that privilege whites and marginalize people of color. In contrast, the main tenet of TribalCrit is that colonization is endemic to society, which is evident by government policies that subjugated Indigenous peoples and attempted to assimilate them into Western culture (Brayboy, 2005, p. 429). In response, both CRT and TribalCrit draw on counternarratives to dispel myths about their culture and ways of knowing while also asserting self-determination, self-identification, sovereignty and autonomy (Brayboy, 2005; Duncan, 2005). Research takes on new meaning when examined through the lens of historically-excluded children, especially when decolonized research principles are used to empower them to tell their own stories. These children's voices are critical to conducting research that broadens their participation in STEM.

The Bessie Coleman Project: Purpose and Objectives

The Bessie Coleman Project (BCP), named for the first Black and Native American woman to earn a pilot's license, was developed to engage students of color in computer modeling, 3D printing, and coding experiences. The primary objective of the BCP was to provide meaningful technology-based learning experiences to enhance students' CT while also using culture and place to make connections to their backgrounds. A second objective was to produce counternarratives about the STEM participation of Black, Latinx, and/or Indigenous students. Teachers, facilitators, and guest speakers with STEM expertise—some of whom were from the same background as the students—were recruited to deliver the content. The teachers participated in 15-18 hours of professional development where they learned how to code in Tinkercad and Sculptris. They also learned how to use flight simulation and operate drones prior to implementing the BCP with students. The research questions that guided data collection during the second year of the three-year study were as follows:

1. In what ways did emerging technological tools (i.e., computer modeling, 3D printing, flight simulation, and/or drones) influence participating students' CT and self-efficacy in STEM?
2. What impact, if any, did the technological tools and STEM professionals have on students' STEM content learning and STEM interest?

Methods

Mixed methods were used to collect data in the BCP. Quantitative measures included a survey instrument that consisted of four subscales. Qualitative measures consisted of field notes, focus group interviews, and journal logs (Creswell, 1998). In Year 2, the Computational Thinking Self-Efficacy (CompTSE) scale (Coenraad et al., 2020) was developed, field-tested, and added as a subscale to the survey instrument. This scale provided insight about students' computational thinking abilities and is useful in discerning how exposure to the interventions influenced students' interest in STEM.

Sample

Fourteen instructors and 85 students participated in the Year 2 study. Table 1 shows student demographics in the analytic sample by type of implementation. The BCP was implemented after school in three public schools in Philadelphia, Pennsylvania, in spring 2019. In addition to the curriculum intervention, Philadelphia students took a day trip to the National Air & Space Museum in Washington, D.C., and interacted with a guest speaker from NASA Goddard who was a solar scientist. Weeklong summer camps were held in June 2019 at a Boys & Girls Club in Denver, Colorado, and in July 2019 at two school sites in Wyoming—one in Riverton and the other on the Wind River Indian Reservation (WRIR). Guest speakers in Denver included Capt. Ed Dwight, the first Black astronaut candidate. Students in Denver also had a field trip to the

Wings Over the Rockies Museum. Students in Riverton visited the Wyoming Dinosaur Center in Thermopolis where they participated in a fossil dig. Arapaho students took a day trip to Beaver Rim to learn about buffalo jumps and to fly drones.

Data Sources and Data Analyses

A survey instrument that measured student efficacy in computing, science, and technology (Ketelhut, 2010) was administered to students at the beginning and near the end of the intervention. All of the subscales on the survey instrument were reliable (i.e., Cronbach $\alpha \geq 0.80$). Qualitative data sources included transcripts of student focus group interviews and journal logs, which were analyzed for themes and patterns using the constant comparative method (Strauss & Corbin, 1990).

Results

Computer modeling, flight simulation, and drones provided students with applications that allowed them to develop new knowledge and understanding of complex systems. Pre-post surveys were analyzed using paired *t*-tests (see Table 2). Results show a significant decrease on science self-efficacy (SciSE) ($t[40]= -2.744$ [$p = 0.009$]) in Philadelphia and no change on three other subscales. There were significant increases on computing self-efficacy (CSE) ($t[16]= -3.058$ [$p = 0.008$]) with medium effect and CompTSE ($t[16]= -2.463$ [$p = 0.026$]) with small effect at the Denver Boys & Girls Club. Results also revealed significant increases on five subscales in the Wyoming summer camps. These results should be interpreted with caution given the small sample sizes in some settings and lack of control groups.

Qualitative data also reveal important findings about student learning, STEM participation, and STEM professionals. Comments made by focus group students in Philadelphia and Denver and excerpts from Arapaho students' journal logs are presented below:

> *I liked all the 3-D printer. I liked that. I liked how we could design it and make whatever we want with it and also learn how to measure it and make sure that it's like a certain size or length.* Black male, age 12 (Philadelphia)

> *I'm not trying to offend him [NASA scientist], but I feel like we should get like, umm…. He's great. I'm not complaining, but I feel like we should get like a Black woman [speaker] because…like for us…I feel like we should get a Black woman because we need that….* Black female, age 11 (Philadelphia)

> *Tinkercad was really fun, and interesting but really hard. You have to know what to do and how to do it. Say you're trying to make a circle but only have a square. You can use a hole around the square by pulling it. We thought of a company, [and] modeled something we wanted to sculpt. Then we did Tinkercad and reimagined our thing then printed our idea.* Black Female, age 13 (Denver)

> *[Black astronauts] went through tough things, and you have to be a really smart person to get there. Like Black people couldn't fly and now they can.* Black male, age 12 (Denver)

> *Today, I learned drones can follow people, and I seen a drone video with…on a skateboard. He falls, but he's okay I think. Drones can fly themselves home when they are about to die..* Arapaho male, age 14 (WRIR)

> *I had fun recording the river, then everyone seeing it. So I learned that the drones can go in a perfect circle by just pressing a button.* Arapaho female, age 15 (WRIR)

Discussion

The BCP was successful in broadening STEM participation among Black, Latinx, and Indigenous students and females. In terms of quantitative results, Philadelphia students and predominantly Black children at the Denver Boys & Girls Club made significant gains on CSE and CompTSE, and Arapaho students made significant gains on technology interest and use (TIU) and CompTSE. Qualitative data revealed students enjoyed computer modeling, 3D printing, and flying drones. One student mentioned learning about measurement and another described how to make shapes in 3D. The latter is an example of CT: "*Say you're trying to make a circle but only have a square. You can use a hole around the square by pulling it.*" Moreover, an Indigenous student used a drone to track everyday activities like skateboarding. Implicit in their excerpts is the freedom to engage in tasks that were of interest to them: "*I liked how we could design it and make whatever we want; We thought of a company, [and] modeled something we wanted to sculpt; I had fun recording the river*." Furthermore, some students expressed opinions about the guest speakers: "*[Black astronauts] went through tough things; I feel like we should get like a Black woman [speaker]….*" These excerpts reveal the importance of students' seeing STEM role models who share the same gender/racial identity (Lane & Id-Deen, 2020). Although the guest speakers could have been more diverse, they helped students to learn STEM content and also understand that resilience was needed to persevere in STEM. While the BCP focused on out-of-school contexts, online modules [www.bessieproject.com] were developed during the COVID-19 pandemic that were piloted during the school day in Tennessee and Wyoming (Leonard et al., 2022). The results of the Year 3 project are forthcoming.

Table 1: Analytic Sample by Race, Ethnicity and Gender (Year 2)

THE EFFECTS OF INSTRUCTORS AND STUDENT ACTIVITY IN LEARNING FROM INSTRUCTIONAL CALCULUS VIDEOS

Aaron Weinberg

Michael Tallman
Oklahoma State University
michael.tallman@okstate.edu

We report the results of an investigation into the factors that affect students' learning from calculus instructional videos. We designed 32 sets of videos and assessed students' learning with pre- and post-video questions. We examined how students' engagement and self-identified ways of interacting with the videos connected to their learning. Our results indicate that there is a complicated relationship between the student, curriculum, instructional practices, and the video content, and that the effectiveness of instructional videos may be contextualized by both instructional practices and the extent to which the understandings supported in the videos are compatible with the meanings promoted during instruction.

Keywords: Online and Distance Education, Calculus

In recent years, "flipped" classrooms and massive open online courses have been promoted as effective ways to support students' active learning (e.g., Schroeder, McGiveny-Burelle, & Xue, 2015) and to deliver instruction remotely. Although there is increased interest in using these techniques and a growing body of research literature on student learning in flipped classrooms (e.g., Maxson & Szaniszlo, 2015), there is still minimal data to support claims of their efficacy.

With a few exceptions (e.g., Weinberg, Martin, Thomas, & Tallman, 2018; Weinberg & Thomas, 2018), there have been virtually no studies that have investigated how students utilize and learn from out-of-class video resources. Other research (e.g., Deslauriers, Schelew, & Wiemann, 2011) has largely been based on an implicit empiricist epistemology (Simon, 2013), assuming that exposure to out-of-class resources is sufficient to promote students' learning.

The dearth of empirical data on students' use of and learning from out-of-class resources suggests that it is imperative to investigate how mathematics students engage with and learn from instructional videos. In this report, we investigate the characteristics of students' and instructors' use of calculus video lessons that affect student learning outcomes.

Theoretical Framework and Research Questions

Both our instructional videos and research design were informed by Mayer's (2014) cognitive theory of multimedia learning. From this perspective, students are active participants in the process of learning from a multimedia presentation: they actively attend to, select, and organize information presented in the multimedia and integrate it into coherent mental representations. Thus, students' learning is influenced by the ways they engage in the video-watching process, their mental actions while they watch, and their prior knowledge and ways of thinking about the subject matter. Instructors can also play a role in the students' learning by supporting their development of particular knowledge structures and asking students to interact with the instructional media in particular ways.

Based on our theoretical perspective, we explored the following research questions:

1. Do differences between groups of students and different instructors influence how much students learn from watching instructional calculus videos?

2. How does student engagement with the videos affect their learning?
3. Do the instructors and the ways students report being asked to interact with the videos have an effect on student learning?

Methods

Materials

We created 56 instructional videos for 30 topics commonly taught in first-semester calculus. The videos were designed using Mayer's (2020) 12 principles of multimedia learning. We created pre- and post-video questions for each video set grounded in Tallman et al.'s (2021) theoretical principles of calculus assessment design. For each video set, we created a website that included a set of 2-4 multiple-choice pre-video questions, instructional videos, and post-video questions. The students were not informed whether their answers to the pre-video questions were correct but were informed of the correctness of their answers to the post-video questions and provided with unlimited opportunities to revise answers. The website collected information about when they paused or skipped while watching a video.

At the end of the semester, students were asked to complete a survey to report demographics such as gender, race, and major; indicate the mathematics classes they had previously completed; and report the ways their instructor asked them to interact with the videos (such as telling students which concepts they should learn from the video or giving credit for watching the videos). The overall response rate to this survey was approximately 32%.

Participants

In addition to one of the PI institutions (a large public university where all calculus instructors participated), fifteen instructors from fourteen institutions participated; these institutions ranged from regional liberal arts colleges to large public research institutions, located in eleven states and one international location. Data collection occurred during the fall 2019 and spring 2020 semesters; eight instructors participated during both semesters. Each instructor selected one or more video sets to assign and invited their students to participate in the study.

In addition to students who did not give consent, we excluded instances where less than 25% of an instructor's students completed a particular video set. We inferred that these responses were from students who were completing a set voluntarily rather than as part of an assignment, and might not be representative of their class as a whole. Overall, 1,166 students participated.

Data Analysis

We measured whether students' solutions on the pre-video questions were correct. For the multiple-choice post-video questions, we measured whether students' solutions were correct on their first attempt or, for the free-response questions, whether their solutions were correct by their second attempt. We used a modified version of normalized change (Marx & Cummings, 2007) to measure students' gains from pre- to post-video:

$$c = \begin{cases} \dfrac{post - pre}{100 - pre} & post > pre \\ drop & post = pre = 100 \\ 0 & post = pre \neq 100 \\ \dfrac{post - pre}{pre} & post < pre \end{cases}$$

We counted the number of times each student paused or skipped backward in each video; we called these instances "revisits." We computed the average rate of revisits for each student and each set of videos by dividing the total number of revisits the student made for a set of videos by the total length (in minutes) of the videos in the set.

Results

Overall Learning

Overall, the students demonstrated a mean normalized change of 7.77% (SD=59.21%). Thus, there was a considerable amount of variation in the students' learning. When we investigated learning on the separate video sets, we found that there was a significant effect of the particular video set on mean normalized change (F(29, 16818)=82.27, $p < 2 \times 10^{-16}$).

Student Characteristics and Learning

Student Engagement with the Videos. We first investigated whether the ways students interacted with the videos was associated with learning. We hypothesized that a "revisit"—an instance where a student either paused or skipped backward in the video—reflected the students' active engagement with the video content. Overall, only 19.9% of the student-video set pairs had a non-zero rate of revisits per minute, with a mean of 0.373 (SD=0.373). After excluding outliers, a simple linear regression to predict the normalized change based on the revisits per minute had non-zero slope (F(1,16086)=11.45, p=0.00717), but this was not practically significant, with b=0.031384 (t(16086)=3.384, p=0.00717). Thus, the students' engagement with the videos does not appear to predict their normalized change in a practically significant way.

Instructor Relationship with Student Learning. We investigated whether different instructors were associated with different levels of student learning. For the fall 2019 semester, a two-factor ANOVA using instructor and video set as factors within each semester showed a significant effect of instructor on normalized change (F(20, 8294)=2.351, p=0.0006) as well as a significant interaction between instructor and video set (F(344, 8294)=1.298, p=0.000225). In the spring 2020 semester, there was a significant effect of instructor on normalized change (F(14, 7817)=2.807, p=0.000337) but the interaction between instructor and video set was not statistically significant (F(300, 7817)=1.077, p=0.175556).

The Role of Curriculum. One of the participating institutions in our study included multiple sections of calculus each semester in which the content and pacing in the classes were centrally coordinated. We repeated the previous analysis at this institution and found that, in the fall 2019 semester, there was neither a significant effect of instructor on normalized change (F(8, 3181)=0.797, p=0.605) nor a significant interaction between instructor and video set (F(153, 3181)=1.046, p=0.338). Similarly, in the spring 2020 semester, there were neither a significant effect of instructor on normalized change (F(6, 2342)=2.094, p=0.051) nor a significant interaction between instructor and video set (F(148, 2342)=0.869, p=0.867). However, there was still variation between instructors. To investigate this, we transformed each instructor's mean normalized change on each video into a standardized score. Table 2 shows these scores, and demonstrates that some sets had consistently higher or lower scores across instructors, while there was considerable variation for other sets.

Table 2. Standardized scores for instructors by video set at the multiple-section institution.

	Instructor								
Video Set	A	B	C	D	E	F	G	H	I
Approximating Instantaneous Rates of Change	-0.17	-0.51	-1.03	-0.32		-0.38	-0.86	-1.02	-0.30

Product Rule	0.29	-0.41	-0.21	-0.29	-0.24	-0.41	0.44	-0.48	0.40
Quotient Rule	0.52	0.36	0.80	0.11	-0.39	0.43	0.86	-0.03	0.50

The Role of Instructor Interventions. We examined the total number of types of practices each student reported and compared the sum with their mean normalized change for each video set. We calculated a simple linear regression for the mean normalized change based on the sum of the total number of types of practices each student reported. The regression equation was not significant ($F(1, 8314)=1.535$, $p=0.2154$), with an R^2 of 0.00006431, and the result also was not practically significant, with $b=0.002708$ ($t(8314)=1.239$, $p=0.215$). However, when we repeated this analysis at the institution with multiple coordinated sections, the regression equation was moderately significant ($F(1, 1530)=5.816$, $p=0.016$) with an R^2 of 0.003136 although there was little practical significance, with $b=0.013574$ ($t(1530)=2.412$, $p=0.016$).

Discussion

The results of our study suggest that it is difficult to predict how much students learn from watching instructional videos and to discern how various ways students engage with video lessons influences their learning. In general, the students in this study demonstrated positive, yet modest learning from the videos, with a considerable amount of variation.

The fact that the students watched the videos and answered the pre- and post-video questions outside of their regular class meetings suggests that the in-class instruction should not have an effect on their learning. However, there was considerable variation from instructor to instructor and a significant interaction between the instructor and video set. These results highlight the complex relationship between how the instructor incorporates the videos into their pedagogy, the curriculum, and how effectively students use the videos to learn.

It would seem likely that the ways students interact with the videos would influence their learning. However, student engagement—measured by the rate at which they “revisited” the video—did not predict their learning.

The relative consistency of students’ performance at the institution with multiple coordinated sections of calculus suggests that curriculum—and its enactment— might play a role in what students learned from the videos. Additionally, the variability of instructor effectiveness by video set suggests that the effectiveness of mathematics video lessons is possibly contextualized by the extent to which the understandings supported in the videos are compatible with the meanings promoted during instruction and developed through various types of formative assessment. We hypothesize that aligning various forms of curriculum and assessment with the content of the videos would support students’ learning. However, even at this institution the students did not consistently achieve positive mean normalized change scores, and there was still variation in the relative effectiveness of the videos from instructor to instructor.

We conjecture that the key to effective learning from the instructional videos lies in the ways the instructors incorporate the videos into their pedagogy. Although we didn’t see a significant relationship between the number of practices students reported their instructors using, there were significant limitations to these data. In particular, the low response rate suggests the possibility of nonresponse bias, and our data don’t reveal the ways in which each instructor might have implemented the various types of practices, or how frequently or consistently—or on which video sets—the instructor implemented these practices.

Taken together, these results suggest that more research is needed to understand ways in which videos can be effectively incorporated into instruction. In particular, researchers need to create detailed descriptions of the ways instructors incorporate the videos into their classes and how their students enact these instructional practices, and investigate how this activity interacts with the content of the videos to support student learning.

ESTIMATING CLIMATE CHANGE NUMBERS: HOW TOLERANCE FOR ERROR CAN SUPPORT SCIENCE LEARNING

Ian Thacker
Univ. of Texas, San Antonio
ian.thacker@utsa.edu

Rachel Broadway

Informal Systems
shon.feder@gmail.com

Texts presenting novel statistics can shift learners' attitudes and conceptions about controversial science topics. Research suggests that such science learning can be supported by bolstering targeted mathematical reasoning skills, though these benefits were found to be strongest among people with mid/high prior knowledge. Our project aimed to build on this research by identifying specific skills that might have contributed to such learning. We conducted ten think-aloud interviews with undergraduate and graduate students as they estimated climate change data before being shown the scientifically accepted value. Findings highlight that students with higher prior knowledge tended to have a higher tolerance for error in their calculations, a willingness to make casual "back-of-the-envelope" calculations, and often interpreted quantitative feedback in terms of its scientific meaning rather than in terms of a measure of performance.

Keywords: conceptual change; integrated STEM; numerical estimation; science education

Misconceptions about controversial science topics are widespread. For example, as of September 2020, 43% of adults in the USA incorrectly believe that human activities are not the primary cause of climate change (Marlon et al., 2020). Misconceptions about climate change are held even among individuals who believe that climate change is real (Thacker & Sinatra, 2019). Fortunately, there are several approaches that exist to shift climate change misconceptions, and one approach that shows promise makes use of pertinent statistical information.

Numerical data (e.g., statistics) found in the news can be a catalyst for changing minds about science topics. For example, prompting people to estimate just a handful of statistics about climate change and then presenting them with the actual value can shift their attitudes, beliefs, and misconceptions to be more aligned with scientists (Ranney & Clark, 2016). The evidence further suggests that the impact of such an intervention can be enhanced by bolstering targeted numerical estimation skills that support the processing and interpretation of numbers, and that such impacts are moderated by motivational and affective factors (Thacker, 2020). However, findings from this research showed that the benefits of mathematical instruction were strongest among individuals in the middle/upper range of prior climate change knowledge.

This project aimed to address this gap by examining the role of prior knowledge more closely and to identify specific skills among medium-high learners that support the learning that occurs when people engage with climate change data. Specifically, we compliment Thacker's (2020) prior quantitative research on this topic using data from ten think-aloud interviews with undergraduate and graduate students as they estimated climate change numbers before being shown the true value and identified specific skills that supported subsequent learning. First, we summarize relevant theory.

Theoretical Framework

Conceptual Change

The Plausibility Judgments for Conceptual Change model posits that novel information can incite conceptual change because it prompts learners to appraise or reappraise the plausibility of their existing beliefs (Lombardi, et al., 2016). This model predicts that when people encounter novel information such as novel climate change data, they first process the data for validity (e.g., Richter & Maier, 2017) and then make a judgment of the plausibility of the conception supported by the new information. Plausibility judgments can be either implicit or explicit, and the extent to which an individual explicitly evaluates the plausibility of a conception depends, in part, on their motivation, emotion, and views about knowledge. More explicit evaluations of plausibility lead to an increased potential for conceptual change. In sum, Lombardi et al.'s (2016) model predicts that the extent to which people engage with and learn from numerical data is influenced by their motivation, emotion, and their ability to process and interpret numbers.

Numerical Estimation

One way that learners process and interpret numbers is by estimating whether they seem reasonable (e.g., Reys & Reys, 2004). Research on *measurement estimation* concerns the explicit estimation of real-world measures (Bright, 1976; Dowker, 2005; Sowder & Wheeler, 1989) and is useful for understanding factors that help people judge whether real-world quantities are reasonable. Findings suggest that peoples' estimation accuracy and judgments of reasonableness improve when they use measurement estimation strategies, such a tolerance for error (Shimizu & Ishida, 1994) and use of the benchmark strategy—the use of given standards and facts that can be applied by the learner through mental iteration and proportional reasoning to better estimate and judge the plausibility of real-world quantities (Brown & Siegler, 2001; Joram et al., 1998). For example, a person's estimate of the number of jellybeans in a container is likely to be more accurate, and they will be a better judge of the reasonableness of other peoples' guesses if they are first told the number of jellybeans in a different container. Measurement estimation strategies may therefore support people's comprehension and evaluation of given real-world quantities.

Attitudes and Knowledge

Attitudes are another factor that may influence learning from climate change data. Attitudes can be thought of as the valenced (e.g., positive or negative) evaluation of an object, person, or event and are expressed as behaviors, affects, and beliefs (Eagly & Chaiken, 1993). According to Sinatra & Seyranian (2016), knowledge and attitudes are related and can be thought of as adhering to a 2x2 axis. Knowledge can either be consistent or inconsistent with scientifically accepted views and can be either positively or negatively valenced, yielding four categories of attitude and knowledge, each representing a different approach that a person might take to learning climate change. Briefly, these four combinations are *pro-justified* (favorable attitude and accurate knowledge), *pro-unjustified* (favorable attitude and inaccurate knowledge), *con-justified* (negative attitude and accurate knowledge), and *con-unjustified* (negative attitude and inaccurate knowledge; Sinatra & Seyranian, 2016). This study, in particular, concentrates on differences between justified and unjustified learners (i.e., higher and lower prior knowledge).

Building on this theoretical framework, we contend that numerical estimation is an essential mathematical skill that helps individuals evaluate and learn from scientific data. Further, such learning can be magnified when people hold attitudes that enable receptivity and deep engagement with new evidence. As such, the purpose of this research was to develop a learning intervention that leverages these ideas and to also explore specific pre-existing skills and knowledge that benefit learners when they engage with climate change data. Therefore, our research question is: *What prior skills and knowledge support the learning that occurs when people engage with an intervention that exposes them to novel statistics?*

Methods

The Estimation Game

To build upon an existing learning intervention (Thacker, 2020), we used a design-based research (DBR) approach to guide the development of an online estimation game. As is characteristic of design-based research, the design, implementation, and revision of the intervention occurred over several iterations (Anderson & Shattuck, 2012). Though design iteration cycles are still underway, the current product of this research is an online, open-source number estimation game with a built-in numerical estimation strategy intervention that can be easily shared with practitioners and the general public online (http://143.110.210.183/).

In the intervention, people are asked to estimate climate change numbers before being shown the true value. The estimation process is thought to elicit relevant background knowledge that is restructured when incorporating the true value (e.g., Ranney & Clark, 2016; Rinne et al., 2006). Half of these prompts also include a "hint," (or benchmark value, Brown & Siegler, 2001; Joram et al., 1998) that can be mathematically manipulated to better estimate the unknown value.

The estimation game can also be modified by the researcher to present participants with instruction on numerical estimation strategies prior to estimating values. This instruction consists of a short text that encourages participants to draw from their background knowledge and think mathematically when estimating numbers. Specifically, it emphasizes the use of benchmark values by rounding and rescaling them based on one's expectations. This is followed by a worked example and a check for understanding (see Thacker, 2020 for more detail). Half of our participants received this modification.

Participants and Procedure

We conducted ten audio and video recorded "think-aloud" interviews (Desimone & Le Floch, 2004) with graduate and undergraduate students as they interacted with the estimation game. Students attended a large Hispanic serving institution in the Southern USA and identified as Female (90%), Hispanic/Latino (50%), White (30%), Black (10%), and mixed-race (10%).

While "thinking aloud," these students (a) completed a pretest of prior knowledge (Lombardi et al., 2013) and climate change attitudes (Lombardi et al., 2012), (b) engaged with the estimation game, with half of the participants receiving the modification that included math instruction, and then (c) completed a post-test identical to the pretest.

Analysis. Survey data was used to identify individuals with high/low prior knowledge and positive/negative climate change attitudes. Recordings were transcribed and open-coded by two independent coders for varying dimensions of student thinking (Corbin & Strauss, 2004), with special emphasis on examining strategies used by students when estimating climate change numbers among individuals with high and low prior knowledge.

Findings

Survey Results

Results revealed that, at pretest, all participants believed that climate change is real. All ten participants rated the statement, "climate change exists and is caused by humans" as plausible, ranging from 6 (somewhat plausible) to 10 (highly plausible; M = 8.02 out of 10). Yet, despite these generally positive attitudes, about half of participants held misconceptions (e.g., 50% of students disagreed that the "average sea level is increasing"). Pretest knowledge scores averaged at 65% correct. Climate change knowledge improved at posttest (94% correct); no participants disagreed that the "average sea level is increasing" at posttest.

All participants held attitudes that were consistent with scientists, yet many held conceptions that were not. As such, we divided our qualitative analyses into categories of students with positive attitudes but low and high knowledge at pretest (pro-unjustified and pro-justified, respectively). Participants were coded as having low knowledge if they scored below the median (those who scored 57% correct or less) on the knowledge pretest. Based on this criteria, six participants were coded as "Pro-Justified" while four were coded as "Pro-Unjustified."

Qualitative Results: Pro-Justified vs Pro-Unjustified Learners

All students made use of background knowledge and most used mathematical operations to modify given information to better estimate unknown information. However, what distinguished those in the high prior knowledge group from those in the low prior knowledge group was their tolerance for error implicit in the calculations (see also Reys et al., 1982; Shimizu & Ishida, 1994). Another important difference was that these students interpreted quantitative feedback in terms of its scientific meaning (e.g., "Wow, that number is different than what I expected") rather than as a reflection of their performance (e.g., "Wow, I got the answer wrong").

To exemplify these codes, we present an excerpt from an interview with a female preservice teacher and undergraduate student who was identified as "pro-justified" and completed the modified version of the intervention. After completing the survey pretest, the participant was thinking aloud when she read the instructions to an item, "Of 195 countries in the world how many are committed to climate action." then noted that she was "gonna round down to 194." When prompted by the researcher to explain why, she said,

> I [rounded to] 194 because [halving] 195 will result in a point five calculation and there's not really half a country, so I just rounded down because, you know, down is less... Half of 194 is 97, but I'm going to put 42 countries because it's less than half of 195. [*She then enters 42 and clicks to show the scientifically accepted answer, revealing that 175 of 195 countries are committed to climate action.*] No! I mean, yes! But no, I mean yes! So that's more than half. That's significantly more than half. Wow, that genuinely surprises me a lot, I did not know that. I really thought that a lot of the countries were not committed to climate action, this is a good statistic. I'm happy with this. I mean, I'm sad that I'm wrong, but I'm happy that I'm wrong at the same time.

This excerpt illustrates the flexible approach to working with imperfect calculations that were characteristic of pro-justified participants. Notably, this student drew from her expectation that the world is not very supportive of climate action and performed a few casual "back of the envelope" computations using the given number (i.e., rounding to an even number to ease halving, and then going much lower again). These casual arithmetic manipulations seemed to support students in making meaning of the numbers. When shown the true value, this student noted that, though she was not particularly happy to learn that her estimate was inaccurate, the meaning of the scientifically accepted value was most salient. In contrast, students categorized as pro-unjustified were generally less willing to manipulate given numbers and attended more to the accuracy of their estimate when compared with the meaning associated with the true value.

Conclusion

We sought to explore what prior skills and knowledge support the learning that occurs from an intervention that involves numerical estimation of climate change data. We found that students with higher prior knowledge were more tolerant of error, willing to make informal calculations, and make meaning of feedback compared with individuals with lower prior knowledge. Instructors who wish to support science learning through casual estimates of real-world quantities might assure students that, when estimating, it is okay to tolerate some error in computations. They may also provide feedback that de-emphasizes performance outcomes and highlights meaning. Future research stemming from this project will more closely examine mathematical reasoning that supports the interpretation of scientific meaning and investigate how learners with negative climate change attitudes interact with the intervention.

The purpose of this study was to investigate undergraduate students' interactions with diagrams while they were solving dynamic geometry-based proof tasks. Some of the tasks included a diagram while others did not. The participants in this case study included two senior college students, enrolled in an undergraduate geometry course at a public university. Differences in the way students interacted with the diagrams in each of these settings are described.

Keywords: Reasoning and Proof, Technology, Undergraduate Education, Mathematical Representations

Introduction and Related Literature

Mathematics education researchers have been investigating how individuals interact with diagrams for more than three decades (Chen & Herbst, 2013; Dimmel & Herbst, 2015; Duval, 1995; Fischbein, 1993; Gonzalez & Herbst, 2009; Herbst, 2004). Because dynamic geometry software (DGS) provides tools such as dragging and measuring we were interested in better understanding how students reason about geometry proof tasks with DGS. There is a large body of research on students' approaches to proof, with and without technology (e.g., Laborde, 2000; Sinclair & Robutti, 2012; Stylianides & Stylianides, 2009) and diagrams play an important role. Students' interactions with dynamic diagrams has been discussed in several research studies (Gonzalez & Herbst, 2009; Hollebrands, 2007; Mariotti, 2000), but there is limited research that compares how the presence of a diagram impacts students' reasoning. The purpose of our study was to investigate students' interaction with diagrams while they were solving dynamic geometry-based proof tasks in diagram-given and diagram-free settings.

Conceptual Framework

Two important theories (Duval, 1995; Fischbein, 1993) have been used to understand students' interactions with diagrams in mathematics education research. Based on Duval's (1995) theory, Herbst (2004) suggested a framework that includes four modes of students' interaction: empirical, representational, descriptive, and generative. Within the empirical mode of interaction, the student has a proximal, physical relationship with the diagram and uses measurements to make conjectures. In contrast, within the representational mode of interaction, the student maintains distal physical experiences with the diagram and student's conjectures stem from the definitions and properties (Gonzalez & Herbst, 2009; Herbst, 2004). In the descriptive mode, the student sets up a distal relationship with a diagram and makes conjectures based on visual perception through anticipating symbols (Gonzalez & Herbst, 2009). Contrary to the descriptive mode, the generative mode is often used to make hypotheses and build reasoned conjectures. In this mode, students make modifications to the original diagram to support their work. Gonzalez and Herbst (2009) proposed a fifth mode called the functional mode. They describe how students relate inputs and outputs when they use the dragging feature of dynamic geometry software. Within this mode, the combination of dragging and measuring provides students opportunities to explore relationships. Students may also check invariants when making changes to the diagram by dragging and may set up the same relation in several diagrams to compare and contrast them. In our study, we investigated undergraduate students' interaction with diagrams while they were solving dynamic geometry-based proof tasks. Some of the tasks included a diagram while others did not. Within these different settings, we examined whether students' modes of interaction with diagrams varies in diagram free and diagram given settings.

Context and Methods

The participants in this study included two senior college students, enrolled in an undergraduate geometry course at a public university. The first participant, Valerie (all names are pseudonyms), was a data science and statistics major and the second participant, Kate, was majoring in mathematics and mathematics education. Kate was more familiar with dynamic geometry programs and she was facile using the tools and features. Valerie had limited experiences working with dynamic geometry programs. Kate had taken a course on teaching mathematics with technology while Valerie had not.

To collect data, one Zoom interview was conducted with each participant using five tasks. Some of the tasks included a diagram while others did not. We asked students to work on their self-constructed diagrams while they were solving diagram free versions. These tasks are the proof tasks (see diagram given versions in Figure 1) which includes corresponding angles and a transversal (Task 1), the sum of the angles of a triangle (Task 2), the isosceles triangle (Task 3), the congruency between two triangles (Task 4) and a segment on a right triangle (Task 5).

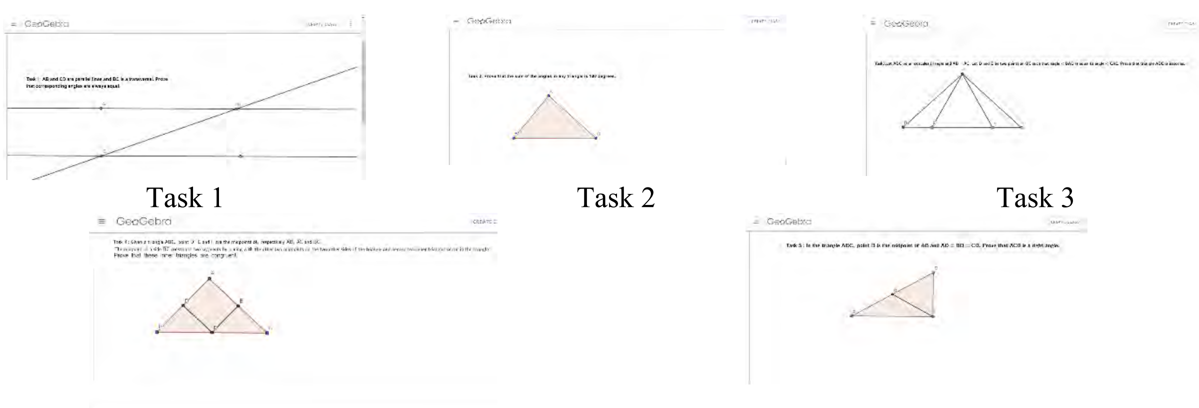

Figure 1: Screenshots of the Tasks presented in Geogebra Environment

During the interviews, we recorded participants' shared screens and voices. Aligned with the aim of this study, we presented half of the tasks with a diagram included and the others without. We analyzed the data in two cycles. In the first cycle, we focused on the students' main approach to characterize their thinking. In the second cycle, we coded participants' approach in terms of how they interacted with diagrams in each task. In order to explain the participants' approach of interaction with diagrams, the extended framework of Herbst (2004) (see updated version in Gonzales & Herbst, 2009) guided our analysis. After coding all instances, we determined how the answers varied according to the diagram given or diagram free versions of the tasks.

Results

The results showed that half of the instances were empirical, one instance was representational, two instances were functional and one instance was generative (Table 1). In just one instance, the student had a transitional process that is her interaction with diagrams started as descriptive in the beginning; however, it then converted to representational. When we investigated diagram given instances, most of them were empirical, only one was representational and one instance was generative. When compared to diagram given instances, the modes of interactions with diagrams in the diagram-free instances varied more. There were two functional instances and two empirical instances observed. Additionally, the transitional instance was seen while proving diagram-free tasks.

Table 1: Students' modes of interaction with diagrams in diagram given and diagram-free proof tasks.

	Diagram given	Diagram-free
Task 1	Representational (Valerie)	Functional (Kate)
Task 2	Empirical (Kate)	Empirical (Valerie)
Task 3	Empirical (Valerie)	Descriptive/Representational (Kate)
Task 4	Generative (Kate)	Empirical(Valerie)
Task 5	Empirical (Valerie)	Functional (Kate)

The most common mode of interaction with diagrams was the empirical mode. We had five instances of the empirical mode of interaction with diagrams among ten instances. Four of these five instances were Valerie's approach to the proof tasks. Whether or not the task is presented in a diagram given or diagram free setting she approaches proof tasks with empirical mode of interaction. In addition one empirical instance was shown in Kate's approach diagram given version of Task 2. In the second task, students were asked to prove that the sum of the angles in any triangle was 180 degrees. This task was presented to Kate as a diagram given and to Valerie as diagram free. In this task, the students' ways of interaction with diagrams were empirical no matter whether the diagram is given on the task or not. Kate measured the angles (a complementary angle of the angle ABC and two other interior angles) and she-used the calculator of her phone to calculate the interior angle (angle ABC). When she noticed the sum was 180, she verified her conjecture via *drag test* to convince herself or the researchers. In her diagram free setting, Valerie started to construct three different diagrams such as isosceles, scalene and right triangles (Figure 2a). She constructed a right triangle and claimed that the sum of the angles of any triangle is 180 because of the sum of the angles of the right triangle. Afterwards when the researchers asked her if her claim was valid in every case, she started to demonstrate again by constructing new three different triangles (Figure 2b). In this instance Valerie used dragging but her dominated approach was based on measurements, that is why the researchers defined her approach as empirical. While Kate's solving approach on diagram given context was familiar however Valerie's approach in the diagram-free setting was unique and not presented as the textbooks or high school geometry classes.

Discussion

The results of our study revealed that participants' approaches to proof in diagram given settings were generally based on drawing and measurements instead of justifying with axioms and theorems or reasoned conjectures. Based on the dominant mode of interaction with diagrams in diagram given settings, we deduced that these provided participants an environment that they were familiar from high school or undergraduate geometry classes. Even though Herbst (2004) noted that the empirical interactions with diagrams commonly occur before high school (Herbst, 2004), their approach to proof tasks may be influenced by their prior knowledge.

Based on the participants' experiences in the diagram free setting, the tasks provided participants in an open-ended context, which they may not have experienced in their courses before. Thus, before participants made conjectures on diagram free tasks, they constructed their diagrams based on the information they obtained from how they imagine the diagram implied and how they argue on this diagram. Their approach in the diagram-free instances were unique and varied unexpectedly. Surprisingly, there is one instance where the participant shifted her approach while she interacted with the diagram. Similar changes in the individuals' approach to proof in congruence based proof tasks have been observed in the study of Author et al. (in press).

Unfortunately, in some instances, diagram free tasks given to students may result in the construction of false diagrams and thus they may make conjectures based on spurious information. Also, the diagram they constructed in the diagram-free tasks may be overly constrained. When students are introduced with diagram-given tasks, their approaches are more typical of textbook approaches and they are more likely to reach the correct solution.

Variance and Invariance are essential to the development of advanced spatial perception and understanding of geometric objects. In this paper, we present an initial framework for analysis of teachers' experiences in a dynamic geometry environment from two perspectives – continuous variation and set of examples. We synthesized relevant literature followed by an empirical study of 122 descriptions of six teachers' experiences with variance and invariance tasks. As a result, we developed an analytic framework to describe how generating examples versus experiencing continuous variation might look like in a dynamic environment. We also found cases when we struggled to characterize an experience under a specific perspective and concluded that these perspectives might not be as far apart as the literature seems to suggest. Possible implications for designing opportunities to teacher education and future research directions are discussed.

Keywords: Geometry and Spatial Thinking; Continuous Variation; Set of Examples; Technology

Purpose and Background

Variance and invariance are two powerful mathematical ideas essential to the development of advanced spatial perception and understanding of figures, shapes, and objects (Battista, 2008; Baccaglini-Frank, Mariotti, & Antonini 2009; Leung, 2008; Sinclair, Pimm, & Skelin, 2012). Such understanding is critical for the learning and teaching of mathematics at all levels (Driscoll et al., 2007; Sinclair et al., 2012). Teachers should have robust understandings of variance and invariance (Sinclair et al. 2012; Stroup 2005), but more research is necessary in this domain.

The literature suggests a distinction between two views of draggable objects in a Dynamic Geometry Environment (DGE). In the first view – a *Set of Examples (SOE)* - draggable objects can be perceived as generating numerous examples of the object (Battista 2008; Marrades & Gutierrez, 2000; Laborde 1993). In the second view - *Continuous Variation of an object (CV)* - a person can understand draggable objects as "interesting, manipulable, visual-mechanical objects that have movement constraints" (Battista, 2008, p. 349). In the current work, we set two main goals: (a) to outline and describe a set of operationalized characteristics (framework) for analyzing teachers' experiences with draggable objects based on both perspectives CV and SOE; and (b) to provide examples of how this framework was used to analyze six high school mathematics teachers' interactions with draggable objects.

Theoretical Framework

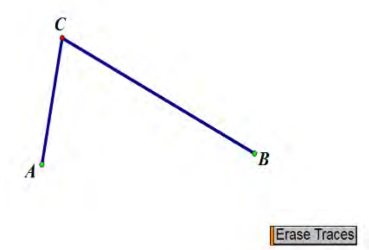
When we refer to invariance in this paper, we denote to certain geometrical properties that remain unaltered when a transformation on the object is applied (e.g., Baccaglini-Frank et al. 2009; Yerushalmy, Chazan, & Gordon 1993). Table 1 presents a summary of the differences and similarities between the two perspectives of draggable objects based on the literature we reviewed. The literature might not suggest an exhaustive list of characteristics, and it seems that some of these characteristics are described insufficiently. For instance, Battista (2008) and Laborde (1998) assert that under continuous variation the object is manipulable, but we are yet to find an explicit explanation of what 'manipulable object' means.

Table 1: Continuous variation of an object versus a set of examples

Continuous variation of an object (CV)	A set of examples perspective (SOE)
• Visual-mechanical objects (Battista, 2008) • The object has constrained movement (Battista 2008, Laborde, 1993) • Manipulable (Battista, 2008; Laborde, 1998) • It is possible to conceptualize and analyze invariant properties under continuous movement of the figure (Laborde, 1993) • Theoretical Geometry Objects that model the theoretical field and can be handle in a physical sense (Laborde, 1998) • Interesting (Battista, 2008)	• The figure is an example of something (a concept or a relationship) (Battista 2008; Marrades & Gutierrez, 2000) • Properties are derived from a set of examples (Battista 2008; Laborde, 1993) • Properties and relationships are abstracted and conceptualized from a set of examples (Battista, 2008; Laborde, 1993) • Transformation can give access to wide range of examples (Laborde, 1993; Marrades & Gutierrez, 2000)

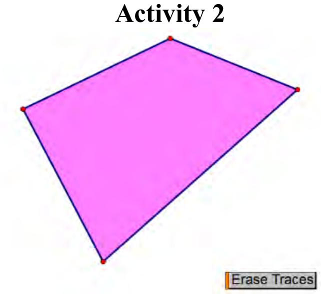
Data Sources and Methods

Activity 1



Participants could manipulate a draggable point (point C) connected to two fixed points A and B. Based on Leung's (2003) idea. Point C could be dragged to any location on the screen, and it leaves a colored trace when it is dragged. *Construction: Drawing three points, setting A and B to be fixed points, and constructing segments AC and BC.*

Activity 2



Participants were able to manipulate a dynamic polygon, by dragging one or more vertices. The vertices could be dragged to any location on the screen, and they leave a colored trace when dragged. It was possible to drag the vertices simultaneously. *Construction: Drawing four points and constructing the segments connecting adjacent points.*

Figure 1: A sample of two activities used in the study.

The Data came from a set of two 45-minutes video recorded task-based interviews with six high school mathematics teachers: Four females - Amanda, Lisa, Diana and Susan; and two males - Andy and Mark (pseudonyms). Each interview focused on a set of four activities that were designed using the Sketchpad® Explorer (Jackiw, 1991) to have teachers interact with draggable geometric objects to explore variance and invariance. Figure 1 presents two of these activities. All interviews were videotaped and transcribed verbatim. Each activity had two parts: In Part 1 (*Noticing*), participants were asked to describe what they notice when they drag one or more points in the space; and in Part II (*Maintaining*), participants were asked to think about ways to drag one or more points in a way that maintains an invariant property. All draggable aspects left a colored trace when dragged.

The analysis included two cycles of coding. In the first, we used *descriptive coding* (Miles, Huberman, & Saldaña, 2014) to look at what participants said (verbally) and did (through actions). In the second cycle, we coded characteristics related to the two perspectives as they have emerged from the literature and from our refinement process as described below. Lastly, we used a *pattern coding* method (Miles et al., 2014) to look for major themes and patterns.

Results

Operationalizing Characteristics of a Set of Examples and Continuous Variation

We found a set of six operationalized characteristics of the two perspectives. Three emerged from the literature. *Generating one or more examples* (SOE) indicates if participant generated one or more examples. *Maintaining dragging* (MD) indicates if the movement was constrained to keep an aspect as an invariance property. MD was also used to describe the movement. *Continuous movement* (CM) denotes to instances where participants moved an object continuously or explicitly described such a movement (e.g., saying "continue moving" / "if I drag this without stopping"). We added a characteristic of *Visual object* (VO) to see if descriptions might refer to objects that were not presented on the screen. Additionally, we noticed that participants, who seemed to experience continuous variation, described the object as one object that can have different formations / instantiations. Thus, we called this *One Object – Different Formations* (DF) and considered this as an indicator for CV. We also noticed that participants sometimes attempted to generalize, so we added this as *Links to Generalization* (LG) characteristic. The literature suggested some other characteristics, but we noticed that our participants used them too often and they seemed to be trivial, so we eliminated them from our scheme (e.g., describing the object as representing something – a concept or idea).

Using the Characteristics in Analyzing Teachers' Interactions with Draggable Objects

In analyzing 122 descriptions, we found 114 descriptions in which participants generated examples and/or described the object under continuous variation. We categorized them as follows: (a) cases in which one perspective was presented (108), (b) cases of ambiguity (6), and (c) cases of uncertainty (8). We distinguished cases of *ambiguity* - where we had the sense that both perspectives occurred at the same time versus *uncertainty* - where we were being careful in saying that we were not clear about how to characterize the description. To keep this paper within the word limit, we present results related only to descriptions of SOE and CV (excluding cases of ambiguity or uncertainty).

(a) (b) (c)

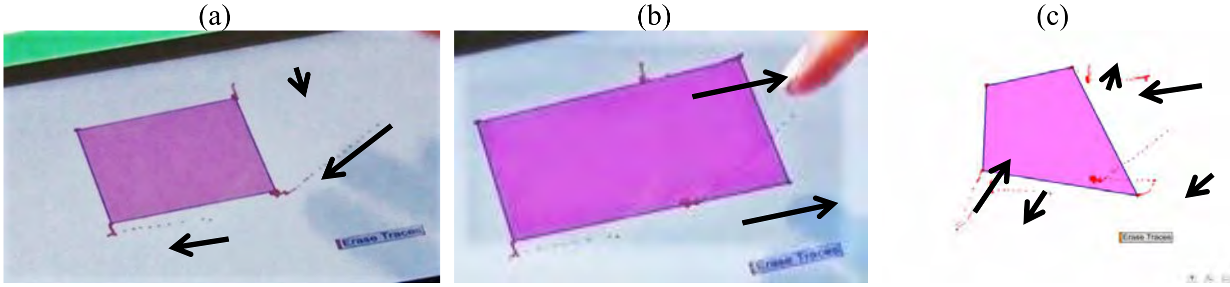


Figure 2: Diana's (a) square, (b) rectangle, and (c) kite

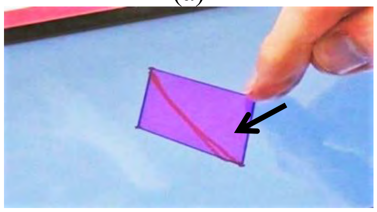
A set of examples. In Part 1 of Activity 2, when Diana was asked to drag one or more points and describe what she noticed, she said: "I have a quadrilateral …I could create, shapes that are quadrilaterals… I could create a square… a rectangle… I could create a kite… I could create any quadrilateral shapes that I wanted" [Figure 2]. Diana's description can be coded as generating examples of a square, a rectangle, and a kite (SOE). We did not have an indication that Diana referred to the figures as one object with different formations. Her dragging action was not maintaining dragging and the movement was not continuous. The object was visual (VO) and it seems that she tried to generalize that as long as we have a figure that is quadrilateral and it is possible to "move all four points", then it is possible to create "any quadrilateral shapes" (LG).

(a) (b)



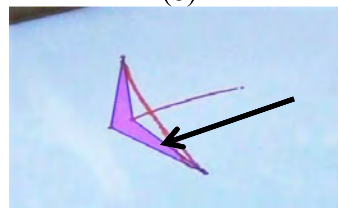


Figure 3: Mark showing, by dragging the right vertex from right to left, (a) when the polygon is still convex, (b) and when it is not convex anymore

Continuous variation. In Activity 2 Part 1, Mark shared a description suggesting an object under continuous variation to discuss when the figure is a convex polygon and when it is not:

Mark: Let me, um, draw this line very quickly [dragged the bottom vertex vertically to create a diagonal]... Right now the polygon is convex [Figure 3a]. I'm going to drag this point here in this direction [emphasized dragging the left vertex horizontally left]. If I drag it sufficiently... far enough, the polygon will no longer be convex...

Interviewer: What do you mean by far enough?

Mark: Far enough, far enough means crossing this line [pointed to the diagonal]. If this point [the right point] crosses this line [pointed to the diagonal] that I've made, it will no longer be convex. [While dragging the point horizontally left - Figure 3b] So, still convex, still convex, but then, once I cross it [stopped after passing the diagonal], no longer convex.

Mark enacted a continuous movement (CM) and constrained it horizontally as evidenced by his dragging action and his gestures (MD). His description of the polygon as being "still convex, still convex, but then… no longer convex" suggesting an object as one polygon that stays convex until it changes to have a different formation which is no longer convex (DF). Mark's description also contained a link to generalization in the sense of taking a convex polygon and maintaining it convex as long as one of its vertices is dragged horizontally but does not cross the diagonal (LG).

Discussion and Conclusions

Related to our first goal, our suggested analytic framework has implications for both research and teacher education. Future endeavor to unpack teachers' understandings of and interactions with draggable objects in the context of DGE and invariance is crucial for working toward designing learning opportunities for teacher education programs. Our framework highlights some important characteristics when interacting with draggable objects from both perspectives (SOE and CV) that are worth further consideration if one were to explore the affordances of generating examples and experiencing continuous variation in the context of DGE and invariance. For instance, we found that continuous movement can appear in descriptions related to both perspectives and it is not clear what is the role of such a movement under each perspective.

Our framework, which is drawn on the DGE literature (e.g., Battista, 2008; Laborde, 1998; Marrades & Gutierrez, 2000), looked at the perspectives of continuous variation and a set of examples as two distinct perspectives. Relevant to our second goal, we found it sometimes hard to characterize descriptions accordingly to this distinction. In every activity we coded cases of ambiguity or uncertainty, with the latest as being more dominant. This struggle suggests that it may not be a clear distinction between CV and SOE. This finding has important implications to the way the notion of draggable objects is described in the literature and how we might interpret and analyze individuals' interactions with objects in DGE. Future research should focus on examining other theoretical perspectives that might explain cases of ambiguity and uncertainty.

We investigated preservice mathematics teachers' engagement in virtual collaboration on geometry tasks. In online synchronous classroom environments, PSTs collectively explored four different transformations on Desmos applets and created written descriptions and exemplary figures to describe the mathematics behind each transformation. We analyzed video recordings of the online group discussion and identified emerging group actions mediated by technology, which demonstrated social and mathematical aspects of collaboration. The design features of the task (e.g., setting group norms, co-constructing deliverables) and the technological features of the virtual workspace (e.g., dynamic geometry, shared screen, shared presentation) fostered students exchanging ideas and engaging in sense-making. Limitations of the task design and the virtual environment will be discussed for future improvement.

Keywords: Technology, Online and Distance Education, Geometry and Spatial Reasoning, Preservice Teacher Education

There has been an increase in calls for effective instructional practices to facilitate student engagement in online learning environments (Carius, 2020; Iuvinale, 2020). While online instruction has become more prevalent for a variety of reasons, the COVID-19 pandemic hastened this. Given the importance of collaboration for learning, there is a need for more empirical research in mathematics education that investigates students' experience with and how to foster collaboration in virtual synchronous online environments.

This study aims to investigate how students engage in virtual collaboration for mathematics learning in an online synchronous classroom environment. We employed the design-based research methods (The Design-Based Research Collective, 2013) characterized by an iterative cycle of design, implementation, reflection, and refinement of task design to promote virtual collaboration in an online synchronous learning environment. In addition, this cyclic process involves analyzing how students socially and mathematically engage in collaborative workspace mediated by technology, which in turn, contributes to the building a theory of Virtual Collaboration for Mathematics Learning (VCML). This study serves as a pilot study of the initial task design and the first phase of the entire design-based research project with the following research question: *How can tasks be designed to foster collaboration using virtual learning tools in geometry?* We designed a Desmos task and implemented it in three mathematics and mathematics education courses for secondary mathematics pre-service teachers (PSTs). We analyzed students' online group work and identified emerging collaborative practices that demonstrated students' exchange of ideas, as constructions of shared-understanding. We discuss the features of task design that led to effective student collaboration.

Background Literature & Theoretical Perspective

Research on collaboration practices specific to geometry and technology exist (e.g., Alqahtani & Powell, 2017; Sthal, 2016). For example, Sthal (2016) explored Computer-

Supported Collaborative Learning (CSCL) with an emphasis on group-cognition (or shared-understanding) practices, contrasted from individual learning from cooperation. A longitudinal study of a small group learning online collaborative dynamic geometry identified the adoption of about 60 group practices under various categories emerged: on collaboration, technology, subject matter (mathematics), and discourse.

As a theoretical perspective, we used "mediated action" (Wertsch, 1994), a sociocultural approach that deals with the connections between human actions within context while considering the action and the setting as distinct but related. Here mediated action plays an important role in understanding sociocultural phenomena. As Wertsch explains, "Mediated action must be understood as involving an irreducible tension between the mediational means provided by the sociocultural setting, on the one hand, and the unique, contextualized use of these means in carrying out particular concrete actions, on the other" (p. 202). We use mediated action to explore students' engagement with the virtual task and how it produces opportunities for their learning. The mediating tool is the virtual task that influences how they interact with each other and with mathematics. We used mediated action to investigate the user-tool relation where users are the students and tool is the task in a virtual workspace. We used interaction between students and the virtual task as the basic unit of analysis, i.e., the actions taken by the students during the virtual task.

Methods

Setting & Participants

This research was conducted at three institutions: one Southern and two Mid-Atlantic public universities. Participants were all undergraduate students: undergraduate mathematics students enrolled in a geometry course, secondary mathematics pre-service teachers in a geometry course, and secondary mathematics pre-service teachers in a mathematics teaching methods course.

Task Design, Data Collection, & Analysis

We designed an activity that could be implemented in all three settings, with modifications as per course goals and students' needs in each course. The activity included two components: (1) a Desmos applet about geometric transformations and (2) a group product, in Google slides. The first goal of the activity was for students to learn how to engage in virtual collaboration, such as taking turns when speaking, being supportive, taking responsibility for the assigned work, etc. The second goal of the activity was different for each instructor based on their own classrooms. For example, the researcher teaching the methods course framed the activity as a mathematics teaching tool, whereas the researchers teaching the content courses used these to frame geometrical transformations. After the participants had experienced virtual collaboration they reflected on their experience and discussed its implications for teaching mathematics in their own future classrooms.

Prior to beginning the Desmos task, the students were asked to develop group norms. The Desmos task focused on the concept of transformations; students were asked to make sense of how they worked via kaleidoscopes as a context. The students first worked individually and then shared their initial thoughts with their teams. The teams were then asked to formally describe how the kaleidoscopes dynamically create transformational figures and provide pictures that best represent their description in Google slides.

Data collection included video recordings of group discussion and their submitted group documents sharing their findings. We conducted open coding (Strauss & Corbin, 1998) to identify emerging group actions: student-student verbal or non-verbal communications that may involve one or more aspects of virtual collaboration (e.g., use of technology). We then applied secondary-level open coding that fell into one of three dimensions: social (people), mathematical (content), and technological (tool). This open coding was not to isolate and distinguish episodes from others but rather to mark empirical evidence of students' virtual collaboration. The initial and secondary-level open coding were intended to highlight what made this episode interesting analytically with respect to virtual collaboration. Through this, we can identify emergent themes across those episodes for the nature of students' participation in collaboration and areas of improvement in the task design, enactment, or virtual environment.

Results

To illustrate our analysis, we describe one pivotal episode of collaboration. This episode was chosen based on the open-coding detailed above, for having all three of social, mathematical, and technological dimensions. It took place in one of the secondary geometry content courses. We draw out key features of the task that led to collaboration.

Tom, Val and Josh worked together as a group to understand how a kaleidoscope (transformations) worked. Real-time collaboration both in Desmos and shared slides were crucial: Students first individually and then together explored a Desmos applet. Then, in shared Google Slides, they had to paste a screenshot of their own drawing that best illustrated the transformation's workings and write a verbal description of the transformation.

First, the dynamic geometry environment of Desmos coupled with screen sharing allowed for real-time testing of conjectures. For example, Josh asked Tom to draw lines on the shared screen: "What happens if you draw a line...from $x = 0$ to down below?" Tom drew this with his mouse in Desmos so that the entire group could see it on his shared screen, as Josh gave more concrete instructions on how to draw what he was thinking. Upon seeing how the real-time drawing affected the mathematical space, Josh affirmed, "That's what I thought would happen." He had asked to test out a conjecture with the group and the dynamic geometry environment allowed him to visually verify that his predictions were accurate.

Second, the task component of selecting the best representation led to student justification for their choices. In deciding which drawing to select, Josh provided a rationale for why the group-generated representation was best: "I like it. I couldn't figure out if it [the transformation] was quadrants or not so this shows it much better than mine does." In needing to choose a representation, students justified their choice of one over another by referring back to the mathematics and how certain features best illustrated that.

Third, the existence of a "deliverable" led to students checking with each other and asking for reassurance. In the shared slides, Val began to type the description but seeked the group's thoughts and help by asking, "What do you guys think?" Later when Val finished typing, he again asked the group what they thought of his description. Tom provided reassurance by affirming the description, and Val then asked if Tom could pull up the Desmos app so he could see the picture. He explained a line of thinking he had considered adding to the description:

Val: I was thinking about it, maybe we should talk about how if we do cross quadrants, we'll be in a different quadrant. But it doesn't really matter because we could always just argue that that black line you drew was just on top of that quadrant and it duplicated to all the others equally.

Tom: If it's in the top right corner of quadrant one then it'll be in the top right corner of all the other three quadrants.

Val: Ok, that makes sense.

Val again was unsure, but this time voiced his thought aloud. In looking at the picture and sharing his thoughts out loud with the group, Val now felt satisfied about the description.

Discussion

Our results indicate that certain features of the task allowed the students to effectively collaborate in the virtual space: tools such as a dynamic geometry environment and screen sharing and task design features such as selecting a best representation and formally producing a group written product. For example, asking the students to present a final document as a group motivated the students to find the best possible phrasing to describe the working of the geometric transformations. This included students discussing what precise terminology to use (their use of "quadrants"). In addition, asking the students to first work individually and then share their thoughts in a group gave students time to think through the mathematics and come to the group with questions to ask and ideas to share.

When designing the task, some student experiences we had anticipated, while others emerged that were a surprise to us. We will incorporate these into future iterations of this task design. For example, we asked teams to develop group norms prior to starting the tasks; some groups did, and others did not. However, during collaboration these norms seemed to emerge organically, such as providing support when a team member was not confident about their work, allowing space for quieter group members to speak up, answering a group member's questions, etc. Not all groups developed or practiced the same norms leading to a diversity in observed collaboration.

Here technology acted as a mediator between students as they tried to make sense of the math and develop a group document together to submit. For example, the shared screen allowed students to easily look at the same mathematical environment at the same time; in person, it would be difficult for multiple students to see the same computer screen due to physical space. Students could also see what the presenter was sharing clearly at any given time, as opposed to how in real life, one may not be able to see a shared paper. Technology amplified their sharing.

Technology also served as a mediator for students' interactions with mathematics. For example, we asked students to first engage with Desmos individually and then bring their thoughts to the group for discussion. Here, technology aided their sense-making of how the kaleidoscopes worked. For example, students saw how the kaleidoscope replicated and transformed what they drew, including when they erased. This direct observation of cause and effect in real-time where students were in control aided their understanding of transformations.

While our analysis highlighted opportunities for student learning through collaboration in virtual space, there were also limitations to this approach. For example, there is vulnerability in showing individual work to a larger group and sharing it on a screen. Such limitations can be overcome by anticipating which moments of the task may feel most vulnerable and addressing them when designing the task. For example, encouraging the students to work in pairs using breakout rooms might allow them to feel comfortable when sharing their work with the larger group. In addition, students feeling comfortable sharing uncertainty with each other, asking for reassurance, and supporting each other are crucial for necessary.

As teachers we are the biggest mediators in our students' learning. Through mindful task design and implementation, limitations of a task can be overcome. For example, best practices for group norms can be modeled and encouraged. Norms to support students who are not confident in math or are worried about technology can be set. In our future work, we will develop framework(s) for how interaction occurs in virtual spaces specific to learning geometry.

When students with blindness and visual impairment (BVI) are confronted with inaccessible visual graphics in the geometry classroom, additional instructional supports are often provided through verbal descriptions of images, tactile and haptic representations, and/or kinetic movement. This preliminary study examined the language used by instructional experts to describe geometry images to students with and without access to a visual instructional image. Specifically, we investigated expert descriptions of geometry diagrams for 1) spatial information, 2) instructional concept information, and 3) overall description structure (e.g., length, vocabulary, image part/whole order/relationships). We found that experts used nearly twice as many words to describe diagrams in the no visual access condition. We consider the double-edged nature of this result for supporting BVI learners in classrooms and chart possibilities for future research.

Keywords: Students with Disabilities, Geometry & Spatial Reasoning, Mathematical Representations

Introduction

There are approximately 12 million people with blindness or visual impairment (BVI) in the U.S., including over 600,000 school-aged children ages 5-18 (Erikson, Lee, von Schrader, 2021). Their success in school mathematics is hampered by inadequate accessible learning technologies and curricular resources, because representations such as graphs, tables, and diagrams are generally only available in visual formats. However, the information in such visual representations can be communicated through other perhaps equally valuable sensory channels (e.g., language, sound, haptics, tactile) (Giudice, 2018; Abrahamson, Flood, Miele, & Siu, 2019). The study reported here is one segment of a larger project whose purpose is to design an interface that will allow students with visual impairments to perceive geometry diagrams through a combination of audio and tactile sensory modalities. We ask: How can geometry diagrams be apprehended through non-visual sensory modalities? As a first step toward investigating this question, we report a case study of how expert users of geometry diagrams used *natural language (NL)* (Herzog & Wazinski, 1994) to describe a core set of 2D images.

Theoretical Framework

We conceptualized geometry diagrams from a systemic functional linguistics (SFL) perspective (O'Halloran, 2005), within which diagrams are mathematical texts that use spatial (e.g., orientation, size, position) and graphical (e.g., strokes, congruence markings, labels) resources systemically to communicate mathematical concepts, properties, and relationships (Dimmel & Herbst, 2015). One technique for representing diagrams with non-visual modalities is through natural language descriptions. Natural language is a term used in psychology, linguistics, and computer science for the communication and representation of any language that has evolved naturally in humans through use and diffusion (Lyons, 1981). NL descriptions of 2D diagrams are used in studies of spatial reasoning and patterning development (Clements, 2004).

Methods

Protocol design

Instructional experts were presented a protocol that consisted of five horizontally oriented digital pictures, each representing a different geometric diagram. All the images were chosen to provide typical examples of geometry diagrams. The geometry diagram prompts are provided in Figure 1.

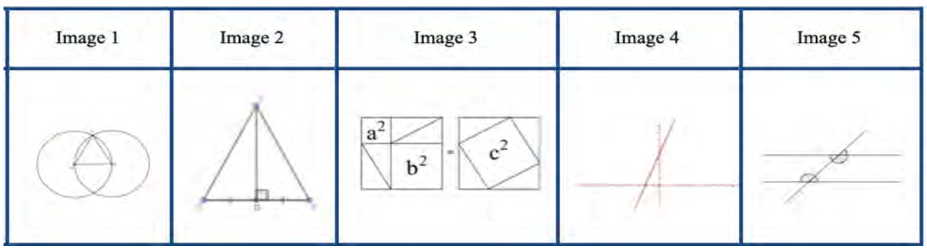

Figure 1: Diagrams used as prompts for expert NL descriptions

As a set, the diagrams were selected as realizations of a range of fundamental geometric relationships, including: *congruence* (images 1, 2, 3, and 5), *parallelism* (images 3 and 5), *perpendicularity* (images 2 and 3), *segment-angle relationships* (images 1and 2), and *incidence relationships* (each image). Images 1, 2, and 5 are examples of diagrams that might accompany typical proof problems (Herbst et al., 2009). Image 3 was selected as an example of a *proof without words,* and Image 4 was selected as a primitive example of a coordinate geometry diagram. The relationships described above are not exhaustive of the geometric concepts realized in the set of images, nor was the set of images intended to serve as a comprehensive set of primitive diagrams that would account for all possible diagrammatic variations. Rather, these images were selected because they entailed sufficient variation to provide a starting point for taking stock of how geometric concepts realized in diagrams could be described using natural language. Participants were given the following instructions and asked four questions for each of the diagrams used in the protocol:

> *Please briefly review the image and respond to the questions below for each image in the protocol. Record your responses to the questions for each image on a separate recording file.*

- How would you describe this image to a student in your class?
- How would you describe the image to a student who you are talking to over a phone or who was listening to a podcast, who cannot see the image?
- What are the most significant mathematical concepts, relationships, or features that need to be described in this image?
- How would you convey the mathematical concepts, relationships, or features to a student who you are talking to over the phone who cannot see the image or to someone listening to a podcast?

The question prompts specifically did not mention that the student who could not see the image had a vision impairment so as not to bias the expert into focusing on the student's disability, as opposed to the instructional concepts that should be explained to any student who could not directly see the image that was the focus of instruction.

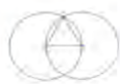
Participants, data, analysis

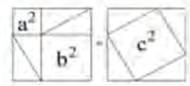
Four experienced mathematics teachers (university or secondary;1/F, 3/M; mean age: 45.8; mean years of experience: 12.3) completed the remotely administered study. Participants recorded their responses individually and at their convenience. The experts spent approximately 30 minutes to audio record their descriptions of 5 geometry diagrams. They were permitted to ask clarifying questions via email, if necessary, but none of the experts chose to stop the recording to ask follow-up questions.

The analysis of the description data used an NLP pipeline that included the processing of raw image descriptions and an annotation process based on techniques used in Cognitive Discourse Analysis (CODA) (Tenbrink, 2015). The annotation process coded specific elements of the image description such as the whole image description, the description of a specific part of the image, as well as identifying themes and relevant features in each *segment*, which was defined as "one coherent statement about a single item/space/topic." (Suwa & Tversky, 1997; Cialone, Tenbrink, & Spiers, 2017). An annotation review was then conducted segment by segment, counting the occurrences of each linguistic feature representing a specific annotation category. The relative frequencies were calculated for each image in relation to the overall number of words produced by each expert, the total number of words produced across experts, and the total identification of instructional or spatial concepts.

Results

80 raw image descriptions (4 experts x 5 diagrams x 4 description questions) were processed and analyzed for this case study. We present here the general language patterns found across expert descriptions based on several text-analysis metrics: Total number of words (n) and average number of words(M) across all expert descriptions for each image, variety of word types (unique) or range (R) of total words used by the experts, and average sentence length (M words per sentence) based on student visual access or non-visual access to each graphic. These aggregate descriptives are reported, by diagram (columns) and condition (rows), in Figure 2.

	Image 1	Image 2	Image 3	Image 4	Image 5
					




Visual Access	n= 293 words Unique =116 M= 73.25 R= 149 (18-167) M density = .73 M words per sentence = 21.4	n= 395 words Unique =138 M= 98.75 R= 101 (50-151) M density = .64 M words per sentence = 21.4	n= 1127 words Unique = 244 M= 108 R= 52 (77-129) M density = .39 M words per sentence = 23.8	n= 482 words Unique = 148 M= 120 R= 78 (87-165) M density = .53 M words per sentence = 14.27	n= 468 words Unique =155 M= 117 R= 103 (69-172) M density = .54 M words per sentence = 25.05
Non-Visual Access	n = 605 Unique = 189 M = 151.25 R= 188 (47-235) M density = .49 M words per sentence = 34.2	n = 560 Unique = 191 M = 186.66 R= 188 (63-328) M density = .55 M words per sentence = 25.8	n= 1880 words Unique = 342 M= 470 R= 511 (155-666) M density = .33 M words per sentence = 21.47	n= 412 words Unique = 170 M= 103 R= 23 (94-117) M density = 61.76 M words per sentence = 23.25	n= 1382 words Unique = 271 M= 345 R= 592(147-739) M density = 129.75 M words per sentence = 20.4

Figure 2: Summary statistics for expert description language use across the images.

Number of words in descriptions

The results reported in Figure 2 show that instructional experts used approximately two times the number of total words (n) in the non-visual access condition, including more unique words – i.e., words that were used only once in the description. This may suggest sighted instructional experts are using different description strategies (e.g., longer descriptions, a larger more diverse vocabulary set, etc.) for students without visual access to the image. This interpretation is consistent with the findings of a study using NL scene descriptions created by sighted participants for non-visual users (Doore, 2017).

Discussion

The primary findings from our analysis are that experts consistently used more words, sometimes as many as double, when describing diagrams for students without visual access to the diagram when compared to students with visual access to it. A critical question raised by these results is: *Do longer, more detailed natural language descriptions of diagrams result in more effective mental representations and conceptual comprehension for BVI students?* Future goals of this research include developing a controlled vocabulary to eventually generate automated descriptions for diagrams to be incorporated into a remote multimodal learning system that uses haptic, auditory, and NL supports for meeting the needs of BVI students in accessing diagrammatic information. The ultimate goal of the larger body of research is the development of a multimodal system that can act as an accessible personal learning environment (PLE) (Martindale & Dowdy, 2010) to support more BVI students to develop the academic skills and personal interests to enter the STEM professional pipeline as well as to increase their post-secondary attainment and employment success. This type of personal learning environment may someday provide a remotely- accessible, cloud-based system that will allow BVI students to direct their own learning.

Acknowledgments

The research reported here is supported by a *Cyberlearning for Work at the Human-Technology Frontier* grant (NSF solicitation 17-598) entitled "A Remote Multimodal Learning Environment to Increase Graphical Information Access for Blind and Visually Impaired Students (Award No: 1822800, PI: Giudice; CoPIs: Dimmel and Doore)". SUSTAINING COGNITIVE DEMAND WITH DESMOS TECHNOLOGY

Victoria Delaney
Stanford University
vdoch@stanford.edu

Gina Kinsey
Stanford University
gkinsey@stanford.edu

Teachers today are encouraged to incorporate digital technologies into mathematics instruction to build students' technological fluency and deepen mathematical understanding. However, the degree to which students' technology use sustains cognitive demand remains unclear. This study will contribute to the understanding of the complex relationship between technology and cognitive demand by providing a video analysis of an eighth grade mathematics teacher's task launch and the ensuing enactment by students. Our findings indicate that technology may raise cognitive demand in potentially transformative ways, although teacher actions and student familiarity with technology also play a role throughout enactment.

Keywords: Curriculum, Middle School Education, Technology

The acquisition of technological fluency, including strategic use of tools, continues to build momentum in classrooms. Unlike previous generations, there is considerable demand for teachers to instruct students with digital technologies that generate deep understanding of disciplinary concepts. Common Core Math Practice 5 states that children should select and use appropriate tools strategically, deepening their understanding of mathematical concepts (CCSSM). Yet despite general agreement toward incorporating these tools, there are few standardized practices that instruct teachers on how and when to use technologies for learning (Greenhow, Robelli, & Hughes, 2009). As a result, students may take up technology in different ways, which may impact cognitive demand. We ask: how does cognitive demand change throughout a task's enactment, and how do students use technology in relation to such changes?

Theoretical Framework

The dual foci of this study are fluctuations in cognitive demand during mathematics tasks and the use of digital technologies in relationship to demand. Stein and colleagues define a *mathematical task* as the arrangement of mathematics within the task combined with the resources provided to solve it. *Cognitive demand* refers to the cognitive processes required of students to navigate a task, identify key information, and activate prior knowledge that is useful for constructing solutions (Doyle, 1983). The current study focuses on a *high cognitive demand* task (Stein & Smith, 1998), which requires students to make conceptual connections, use multiple representations and solution strategies, and make conjectures. Cognitive demand is not a static construct; it is adapted from the task as written to the teacher's launch (Jackson et al., 2013), then negotiated by students and the teacher during the task enactment. Adaptations and negotiations have variable impacts on cognitive demand, and a key goal in this study is to examine changes in cognitive demand during the teacher's launch and student enactment.

Incorporation of digital technologies can alter mathematics tasks. This study focuses on Desmos, a technology which can automate graphing, give instantaneous feedback, and display multiple modes of representation (Sherman, 2014). The amalgamation of Desmos's features may alter the cognitive demand of the task and its outcome, which in turn may influence what math students learn and how they learn it. However, digital technology's potential to mediate task outcomes may be contingent on how teachers frame technologies to students and how students take up tools. This study proposes three classifications for examining students' technology use, adapted from Hughes's Technology as Transformation framework: students may use *technology as replacement* (using Desmos instead of a calculator), *technology as amplification* (using Desmos to do the same task faster), or *technology as potential transformation* (using Desmos to learn mathematics in new ways, potentially reshaping mathematical perspectives).

Methods

Context and Participant

This study is one component of a larger research-practice partnership (Coburn & Penuel, 2016) conducted between a large research university and Urban Unified School District (UUSD). Many students in UUSD are from non-dominant cultural and linguistic communities (UUSD, 2020). The district is committed to high-quality mathematics for all students, and developed a task-based curriculum for grades 6-8 that aligns with the Common Core State Standards for mathematics (Borko et al., 2017). To assist in implementing the new curriculum, UUSD identified and recruited teacher leaders (TLs) in each grade level to participate in professional development workshops with the intent of deeply understanding the new curriculum.

The subject of this study is Annie, a teacher, selected for her incorporation of Desmos into high demand tasks. Annie taught eighth grade mathematics at UUSD during the 2016 - 2017 school year at Pacific Middle School, and was involved in the research-practice partnership as a TL during the time of this study.

Task Selection

The Washing Machine Problem requires students to draw upon knowledge of linear equations and multiple representations to compare two scenarios of washer-dryer purchasing costs, or alternatively, using a laundromat (see Figure 1). This task meets the criteria for a *Doing Mathematics* by the Instructional Quality of Assessment (IQA) rubric (Boston & Wolf, 2006) as students solve a complex, real-world problem with potential for multiple solution strategies and representations. They must make conjectures about which washer-dryer combination is best without knowing additional details about the subject's life, justified with mathematical evidence. How students interpret assumptions impacts what washer-dryer combination they suggest, implying that a single, well-rehearsed, predictable solution is not present.

"Elena doesn't have a washing machine or dryer. She is considering buying one so that she doesn't have to go to the Laundromat. She wants to know if it makes sense financially to buy a washer and dryer. Each load of laundry at the Laundromat costs \$1.25 for the washing machine and \$1.50 for the dryer. A top-loading washer costs \$250, and each load costs \$0.26 for water and energy. A front-loading washer costs \$400, and each load costs \$0.09 for water and energy. A dryer costs \$300, and each load costs \$0.35 for energy. **What should Elena do? Give her some advice."**

Figure 1: The Washing Machine Problem (as written in UUSD's curriculum)

Data Sources and Analysis

Data for this project were obtained from video recordings of Annie's classroom while launching and enacting *The Washing Machine Problem*. Recordings contained the enactment of the task in groups of 4-5 students. All recordings were subject to additional screening for visual quality, audio quality, and completeness. Annie's launch was captured in a recording using a separate teacher camera and microphone. The research team then qualitatively analyzed the teacher launch and students' enactment to identify (1) changes in cognitive demand throughout the task, and (2) instances where Desmos was used by students to solve the task. The IQA was used to rate cognitive demand, and Hughes's framework was adapted for a student-facing stance where the researchers coded technology use as replacement, amplification, or potentially transformative. Recordings were broken into "conversation units": sequences of talk where students grappled with mathematical ideas. Throughout the analytic process, the research team used the IQA and stabilized technology codebook to rate and code independently, discuss ratings and codes during weekly meetings, and reach consensus.

Findings

Our first set of findings analyzes the teacher's launch and the resulting changes in cognitive demand from the task as written. We identify salient features that contribute to changes in cognitive demand and their hypothesized impact on students' enactment. The second set of findings focuses on three groups' enactment, changes in cognitive demand, and use of Desmos.

Teacher Launch

Annie announced students would solve a system of equations and give advice. She presented the task as a series of steps: (1) First, students would create three equations to model the two different washing machines and laundromat options, checking in with Annie once they finished. (2) Second, students would graph their equations in Desmos, framed as a step in the process of solving. (3) Finally, students would give advice for a washer-dryer combination.

We rated the cognitive demand of Annie's launch as a 2 on the IQA rubric, *Procedures without Connections.* Her launch focused on a sequence of procedures for students to follow during the task, including Desmos use framed as a procedure itself, which removed ambiguity and reduced opportunities for multiple solution strategies. Although Annie informed students to produce equation and visual representations, there was little question on how to do so. The focus of the launch seemed more suited toward completion of the task's sequence of steps than on high demand, non-algorithmic thinking.

Student Enactment: Aggregate Patterns in Cognitive Demand

The three student groups initiated enactment with low cognitive demand (level 2), then increased demand (levels 3-4) when they graphed, compared multiple representations, and gave a recommendation (see Table 1). When crafting the laundromat, top-loading, and front-loading equations, students tended toward low demand aspects of the task, and subsequentially, low demand explanations ("$1.25 is the slope, because it's 'per' load,"). Once students progressed to the graphing phase, Desmos afforded opportunities to instantaneously notice differences between equations, provide high demand explanations for those differences, and make conjectures grounded in the task's context. Students who reached cognitive demand level 4 observed that limited information about Elena's laundry habits prohibited them from making a single recommendation ("it really depends on how long she's going to use it."). In all groups, Annie monitored progress by asking open-ended questions (e.g., "what assumptions are you making?"), giving space for students to voice their thinking, and encouraging students to think beyond procedures. Despite a procedural launch, Annie appeared to have mediated cognitive demand by pressing students to consider the task's context and embedded assumptions.

Table 1: Students' Aggregate Cognitive Demand during Enactment

	Writing Three Equations		Desmos Graphing and Analysis	
Cognitive Demand	Minutes	Conversation Units	Minutes	Conversation Units
Level 1	0.0	0	0.3	4
Level 2	**15.0**	**54**	2.8	26
Level 3	13.0	37	6.7	26
Level 4	7.0	9	**15.4**	**44**

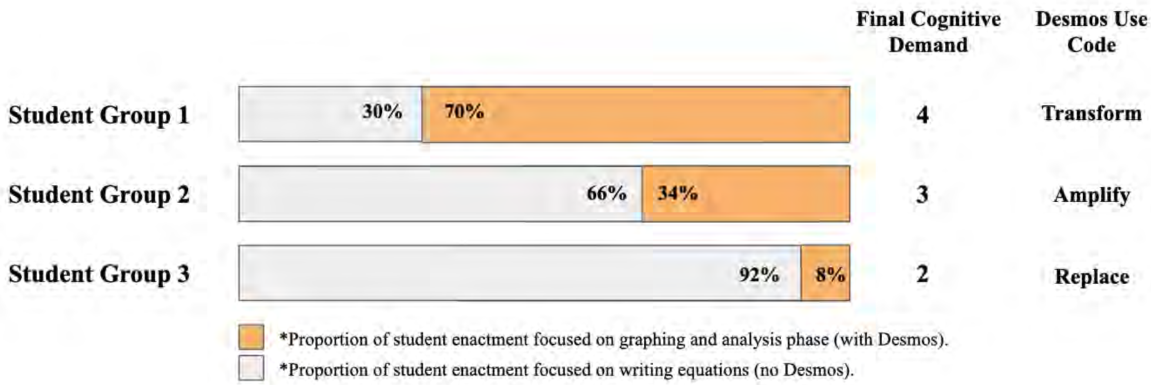

Figure 2: Cognitive Demand and Time Spent on Desmos

Student Enactment: Cognitive Demand and Desmos Use

Students who achieved higher cognitive demand used Desmos to amplify and transform the task's interpretive aspects at higher frequencies (see Figure 2). Student Group 1 graphed their linear models quickly and spent a majority of enactment discussing ambiguity and assumptions within the task. They expanded on the capacities of their laptop by searching, "*How long does a washing machine last, on average?*" into their internet browser, potentially transforming views of mathematics by triangulating multiple pieces of evidence to give a nuanced justification Student Group 2, who struggled for approximately six minutes signing into Desmos, eventually used the platform's scroll, zoom, and click features to identify points of intersection, compare rates of change, and move toward a recommendation. They made up for lost time by making use of Desmos's features, which amplified their analysis of the models. Student Group 3 spent most of enactment creating the equations, and only 8% of their time was spent constructing a graph. It took substantially longer than the other groups to input their equations, and by the time they finished, Annie called the class back to attention. We coded this group's Desmos use as replacement, as they procured a graph with a computer, but did nothing else with it thereafter.

Discussion and Conclusion

Annie's procedure-focused launch did not hamper all students' abilities to make rich mathematical meaning during enactment. Her strategic use of questioning, student voice, and press for justification from students helped two out of three groups construct equations more efficiently, which in turn, allowed them to make use of Desmos's affordances and raise demand. When Desmos was used as amplification or in potentially transformative ways, students gave more complex recommendations for which washer and dryer should be purchased, and why.

Our work suggests a synergistic relationship between the features of digital technologies, the demands of the task, and teacher actions when examining student outcomes. Desmos may have been well-suited to raise cognitive demand in this particular task because of its ability to produce multiple equations instantaneously, which shifted students' focus from graphing by hand to analyzing models and centering mathematical discussion. Simultaneously, Annie supported enactment by drawing students' attention to high demand aspects of the task during small-group interactions. Future research should further explore and build upon the relationship between cognitive demand, digital technology, and teachers' actions, taking into account different tasks, instructional tradeoffs with technology (e.g., the time teachers expend to familiarize students with new tools), and levels of teacher expertise when enacting curricula with technology.

POSITIVE CHANGE IN MATHEMATICS TEACHER EDUCATORS' MIGRATION TO EMERGENCY REMOTE TEACHING DURING COVID-19

Shannon O. Driskell
University of Dayton
sdriskell1@udayton.edu

Rachel A. Harrington
Western Oregon University
harringtonr@wou.edu

Ann M. Wheeler
Texas Woman's University
awheeler2@twu.edu

Steve Rhine
Pacific University
steverhine@pacificu.edu

Our consortium of four universities conducted survey research with mathematics teacher educators (MTEs) regarding their transition to online teaching during COVID-19. This research focuses on positive change in instruction that was identified by respondents in spring 2020. Results shared focus on general technology tools and mathematical technology tools for students' learning that were initiated by MTEs during the migration to online teaching. The data indicate MTEs altered the style of their teaching in response to the online environment, and some are likely to retain practices initiated during the emergency remote transition. The research has implications for MTEs who teach online, as well as those who are interested in incorporating more technological tools into their face-to-face instruction.

Keywords: Technology, Online and Distance Education, Instructional Activities and Practices

The unfolding response to the COVID-19 mandate to teach remotely provided a unique, one-time opportunity for groundbreaking research to study how crisis-induced changes to instruction influence faculty's teaching experience. The transition to online instruction necessitated by the COVID-19 pandemic created significant uncertainty for the nation's educators, including mathematics teacher educators (MTEs), many of whom had not previously taught online. This survey research examined MTEs' perceptions of the challenge of rapidly transitioning their teaching to emergency remote teaching, and how it impacted the quality of instruction they delivered during the COVID-19 pandemic. Data was analyzed using the technological pedagogical content knowledge ([TPACK]; Mishra & Koehler, 2006; Niess, 2005) framework to identify patterns of effective responses to the transition. These data will also facilitate the development of empirically informed policies to aid teacher education programs in navigating this current pandemic and reduce the disruption of such transitions in the future. This work will contribute fundamental knowledge on MTEs' adaptability—in the face of an urgent need—to deliver courses differently, and on improving teacher education programs by emphasizing effective ways to develop affective experiences while introducing effective technology tools for remote instruction. Furthermore, this work could help shape the design of professional development opportunities that promote adoption of research-based pedagogies and instructional technologies. The research question is: How did mathematics teacher educators change their instruction for migration to online instruction during COVID-19, and how did they perceive the value of that change?

Literature Review

Online learning is a well-discussed field in the past decade. Numerous articles and books communicate how to provide an optimal student-centered environment in synchronous online learning platforms (e.g., Flores Fahara & Lozano Castro, 2015; Goodman, 2019; Seifert, 2019). However, "there is virtually no representation of discipline specific programs for preparing college faculty to teach online" (Goodman, 2019, p. 1203). AbuZayyad-Nuseibeh (2017) examined the University of South Florida faculty's perceptions of their transition to online instruction and found that faculty were overwhelmed with the time and effort to transition, yet they designed more creative assessments and experienced increased active learning. Chiasson et al. (2015) also researched faculty's transition to online instruction using both a survey and interviews. Results indicated that faculty increased their confidence and believed they became better instructors in their face-to-face courses as a result of online teaching.

In the past year, various research studies have been conducted about how COVID-19 has changed the way we currently teach. These studies range from rethinking preservice teachers' clinical practice (Parker et al., 2020; Pike et al., 2020) to learning new ways of teaching with different digital applications, such as Twitter (Carey et al., 2020), Google forms (Khan & Jawaid, 2020), and Flipgrid (Goddard, 2020; Oliver et al., 2020). Others, such as Rapanta et al. (2020), shared ways to observe student work patterns in online learning environments.

The TPACK framework (Mishra & Koehler, 2006; Niess, 2005) guided our coding of qualitative data. TPACK extends Shulman's (1986) pedagogical content knowledge (PCK) to include the additional domain of technology, thus introducing technological content knowledge (TCK), technological pedagogical knowledge (TPK), and TPACK. This integrated knowledge of TPACK draws upon teachers' understanding of how to effectively use technology to teach mathematics.

Methods

The purpose of the survey was to gather information about MTEs' experiences with migrating their in-person classes to online classes due to COVID-19. The survey was specifically for MTEs' mathematics education or mathematics content classes that support a teacher education program for undergraduate and/or graduate students. The target population of this survey was a convenience sample of approximately 940 Association of Mathematics Teacher Educators members. The Mathematics Teacher Educators' Migration to Online Teaching in Response to COVID-19 survey was designed for this research and administered online (Nesbary, 2000). The survey consisted of 14 Likert and short-answer questions about migrating in-person classes to online classes, plus nine demographics questions. Survey topics included identification of new tools adopted for instruction; professional development participated in; benefits of online instruction over face-to-face instruction; challenges or affordances for equitable practices; as well as experiences with creating a community among students, engaging students, using general technology tools, using mathematics technology tools, and using formative and summative assessments.

To establish content validity, the survey was piloted with four MTEs and one instructional technology expert. The survey was refined and piloted with three new MTEs and one survey construction expert. Feedback from the second pilot was implemented, and the final survey was sent to AMTE members at the end of May 2020. One week after the initial email, a follow-up email was sent to ensure a high response rate.

Results

Altogether, 218 AMTE members responded to the survey. Nine of the responses were eliminated because the participants were not teaching mathematics education or mathematics content classes in spring 2020. Participants' data were collected anonymously; therefore, information is unavailable regarding which AMTE members did or did not complete the survey.

MTEs' experiences with teaching online or hybrid courses prior to COVID-19 were low. Of the 167 MTEs that responded to this question, 63 had zero experience with these modalities of teaching, while 65 had taught one to five classes, 21 had taught six to 10 classes, 7 had taught 11 to 15 classes, and 11 had taught 21 or more classes with these teaching modalities. Before spring 2020, participants were teaching 100% in-person (n = 147, 70%), no synchronous online classes (n = 196, 94%), no asynchronous classes (n = 165, 79%), and no blended classes (n = 190, 91%). Post-COVID-19, all MTEs were teaching fully online, 68% (n = 143) had some synchronous teaching, 68% (n = 143) had some asynchronous teaching, and 11% (n = 23) had some blended teaching. Therefore, spring 2020 was a shift from mostly in-person teaching—where online instruction was typically asynchronous—to all-remote instruction.

One survey question invited MTEs to share the extent of change in engaging students in learning, creating a community among students, using general technology tools, using mathematical technology tools, changing instruction to meet diverse learner needs and ensuring equitable access to content, etc. (see Table 1). MTEs used a five-point Likert scale to identify this change from *not at all* to *completely*. They also shared whether this change was positive, neutral, or negative. When combining the number of responses for *a lot* and *completely*, the opportunities for students to teach and to learn from their own teaching and the teaching of others was ranked as the most negative change. The two changes that received more positive responses than negative were general technology tools for students' learning and mathematical technology tools for students' learning.

Table 1: Extent of Change

To what extent did you change:	Not at all	Somewhat	Moderately	A lot	Completely	Blank		Positive	Neutral	Negative	Blank
the opportunities for students to teach and to learn from their own teaching and the teaching of others?	12	17	33	60	51	36		17	32	97	63
how you engaged students in learning?	4	31	38	79	22	35		20	65	64	60
the assignments/tasks/formative assessments of the course?	7	36	40	70	20	36		30	61	58	60

To better understand the long-term implications of these changes, MTEs were asked to share some examples of how their experience with online instruction due to COVID-19 will influence their future instruction, either online or in person. Responses indicated that, while many changes were forced by the swift transition to remote teaching, participants could identify instructional changes that would persist after remote instruction ended (TPACK). Participant 143 shared,

> I also believe that I will be more intentional about structuring whole class discussion so all students have an opportunity to participate. With using collaborative interactive Google slides, we all have access to a permanent record of each person's thinking. I would love to continue this practice with my future instruction, both online and in-person instruction.

The use of specific tools was also found in the qualitative responses data. Participants described a wide range of tool use in their new teaching context. These tools included: digital manipulatives (TPACK), physical manipulatives (PCK), digital tools for instruction (TPK), and virtual meeting tools (TPK). The data indicate that tool use was a value-added activity. Participant 1 commented, "I got to learn about new ways to engage students online synchronously and some of those had benefits over my traditional teaching face-to-face."

Implications for Teacher Education Research

Our initial goal was to capture the experiences and stories of MTEs during the unprecedented pedagogical shifts that happened in spring 2020. As we analyzed the data, we wondered, "What relevance do these stories have on the future of mathematics teacher education?" It is hopeful that spring 2020 and the reality of remote-only teaching will eventually become little more than a memory. However, the authors believe that the move toward increased dependence on remote teaching strategies and tools is inevitable, and teacher education programs need to accommodate this change while considering TPACK.

It does not appear that instruction at all levels, K–12 and higher education, will go back to the pre-COVID-19-pandemic normal. Instruction is trending toward online teaching and taking advantage of digital tools—to support even in-person teaching. There is comfort in the fact that not all of this change was perceived as negative. In fact, many participants saw the shift toward new pedagogical strategies and tool uses (TPACK) as a positive that they anticipate will continue. The data in this study are revealing ways to improve and capitalize on the lessons learned from the transition to emergency remote teaching. This survey provides a more global perspective, beyond our own individual stories. A sound message from this survey data is a sense of solidarity, a focus on positive takeaways, and persevering through challenges that MTEs can learn and grow from, through their personal experiences during this historical shift to emergency remote teaching.

HOW MIDDLE YEARS STUDENTS WITH MATHEMATICS LEARNING DISABILITIES BOOTSTRAP THEIR USE OF TECHNOLOGY

Alayne Armstrong
University of Regina
alayne.armstrong@uregina.ca

Grounded in a learner's perspective, this case study investigates the bootstrapping resources that middle years students with mathematics learning disabilities draw on in using their personal electronic devices to support their mathematical learning. Semi-structured interviews were conducted with 14 participants in two provinces in Western Canada. Using Bereiter's categories of bootstrapping resources, the participants' reported uses of technology are discussed. Early findings suggest that participants' bootstrapping behaviors are influenced by the practices and attitudes of those around them, including teachers, family, peers, and even people they observe online.

Keywords: mathematics learning disabilities, technology, middle years, bootstrapping

Working from the learner's perspective, this paper reports the early findings of a case study exploring how middle years students with mathematics learning disabilities (MLD) learned to use, and adapt their use of, personal electronic devices to support their work in mathematics. In an earlier exploratory study (Armstrong & Gutica, 2020), post-secondary students with MLD described using technology in ways that include the following: accessing content of texts and other information sources; capturing information offered in lectures; checking accuracy of calculations; and performing algorithms so they can focus instead on mathematical concepts. Most had picked up these strategies on their own through a process of "bootstrapping." My research questions were: 1) how do middle years students with MLD use their personal electronic devices to support themselves in school mathematics and 2) how did they learn to do so? While for postsecondary students bootstrapping is often an independent, solo endeavor, my results suggest that for middle years students bootstrapping is very much grounded in their communities, influenced by the actions and attitudes of those around them.

Literature Review

Students with MLD have learning needs that may cause them to rely more heavily on digital devices for academic support than other students do. MLD has still not been adequately defined in the mathematics education literature (Lewis & Fisher, 2016) with ongoing debates about what the disability may involve, and how much the diagnosis overlaps with "math difficulties." As a number of brain processes feed into performing mathematics, including language processing, visual/spatial awareness, and working memory (Furlong et al., 2015; Willcut et al., 2013), in this paper I work from the premise that MLD can manifest themselves in a variety of ways, including difficulties with reading math texts, working with numbers, spatial reasoning, problem solving, as well as performing other mathematical tasks. It has been estimated that anywhere from 3-8% of school-age students have MLD (Brennan, 2009; Geary, 2004).

Effective strategic use of technology in teaching and learning math enables teachers and students to use digital tools in "thoughtfully designed ways" to "enhance how students and educators learn, experience, communicate and do math" (NCTM, 2015). This has the potential to let students off-load routine tasks, such as repetitive calculations, so they can focus on understanding mathematical concepts (Kaput, 1992); provide immediate feedback; offer dynamic tools that enable students to perform interactive tasks; and encourage the presentation of mathematical concepts using a variety of formats (Suh et al., 2008). Thus, technology has been recommended for teaching mathematics to students with MLD (Bouck & Flanagan, 2009).

In recent years, personal electronic technologies – electronic computer devices which are easily portable and that are used to store, display, process and transmit data (a definition adapted from Ayres et al., 2016) – have become an indispensable part of everyday life. With regular and long term access to this technology, many K-12 students have become fluent and confident in its use (Trouche & Drijvers, 2010). While some people do receive formal training in using electronic devices and applications through work or school, many of us just learn as we go, a kind of "pulling yourself up by your own bootstraps" method where you are building on your own resources to improve your situation. Bereiter (1985) suggests there are four potential resources for bootstrapping. 1) Imitation involves following a model or a mentor in learning how to use a device or software. For example, students may engage in a mathematics activity using Geogebra based on how their teacher demonstrate using the software's controls. 2) Learning support systems aim to mimic aspects of a teaching situation by scaffolding the learner's experience through offering questions with increasing levels of challenge and providing quick feedback. For instance, students may play an online math game to improve their mathematics skills. 3) Chance plus selection, or happy accidents, occur in a situation where the user performs a particular action for one reason but then discovers that it helps them do something else as well. 4) Finally, piggybacking occurs when someone uses a feature in technology for something other than what it was originally intended to do. For example, a student might use a coloured transparent plastic overlay over printed texts to improve readability and realize they can apply the same principle for screen texts by implementing a coloured background.

Bereiter suggests that people are more likely to bootstrap when they are familiar enough with a task or situation that they have mental energy left to try to improve how they are doing the task, or to explore other options or goals related to that task. In a survey of 760 middle years students, grades 6-8 (Harris Poll, 2015) 38% of middle years students considered themselves to be early adopters of technology, and 50% reported that they waited to see others try it and then tried it too. Of those whose schools either provided students with laptops/tablets to work with or had implemented a "Bring Your Own Device" (BYOD) policy, 55% considered themselves to be early adopters. This suggests that middle school students may have a comfort with technology that makes them more likely to engage in bootstrapping behaviors.

Methodology

My research is informed by the theoretical framework of enactivism as it applies to the relationship between students and technology (Li et al., 2010). Working from the premise that the systems of body, mind and environment are entangled with each other (Merleau-Ponty, 1962), enactivism suggests that learning emerges through the interactions between these systems: "cognition is effective action" (Maturana & Varela, 1987, p. 29). This points to a potential reciprocal relationship between the use of technology and cognition in the act of learning (Li et al., 2010). Enactivism has been described as an "essential tool" (Abrahamson et al., 2019) for reimagining the design of inclusive mathematics learning environments as well as theorizing how learning can occur. Rather than viewing technology as a prosthetic device for the disabled, compensating for whatever it is about their minds or bodies that is deemed to be lacking (Ayres et al., 2016), from an enactivist perspective, technology moves from being an external "add-on" to the disabled body to something that becomes embodied within the learning system in its potential to open up and extend the learner's bodily senses to new experiences and capabilities (Söffner, 2017). In this case study, I seek to investigate relationships between MLD and technology that might otherwise remain unnoticed (Yin, 2014).

To recruit participants, administrators and student services teachers in two school districts distributed information letters and consent forms to parents. All students who wished to participate in the study were interviewed by me at their schools, with 14 middle school students in total taking part (seven in grade 6, seven in grade 8; six girls and eight boys). All had been formally identified as having MLD by their student services teachers and had self-identified as being confident users of technology: they were potentially "information rich" (Patton, 1990, p. 169) with valuable insights about best technological practices for supporting their learning (Demouy et al., 2016). Semi-structured interviews included open-ended questions to elicit information about participants' technological practices and opinions (Swan et al., 2005), such as "Would you show me any technology you regularly use as part of your math schoolwork or homework? How does it help you?" and "What would you do if you needed more information about a math topic?" The interviews were 40 – 90 minutes in length and recorded by two video-cameras (offering a view of the device screen, and a view from the shoulders down of the participant to capture their gestures as they used the device). To ensure maximum participation and accessibility, I used a strengths-based approach in working with the students (Alper & Goggin, 2017). All participants were asked to bring with them the personal electronic devices that they used for their studies, so that they could demonstrate how they used them; students with learning disabilities sometimes struggle with language processing, so this enabled participants to show through doing/demonstrating/gesturing rather than having to rely on telling.

As this was an exploratory study, I used a process of constant comparative analysis (Glaser & Strauss, 1967). This analysis began with initial observations of the videos and reading of drafts of the interview transcripts by me and by two research assistants (experienced classroom teachers not associated with the schools in the study). Our individual summary notes were compared with each other to generate a further set of notes. These notes were continually refined through further reviewing of the videos and transcripts to determine emergent relationships and patterns. Two other research assistants completed an independent viewing of the transcripts and videos which offered alternate interpretations (Li, 2013). This helped to further foreground features about the participants' technological practices (Demouy et al., 2016; Kukulska-Hulme & de los Arcos, 2011) prompting a further and final round of categorization.

Findings and Discussion

As there are many learning issues that may feed into MLD, I wanted to hear from participants about any technology or strategies for using technology that they used to support themselves in learning mathematics. All the participants mentioned using at least one type of bootstrapping strategy, although some described using these strategies more than others did. Interestingly, none of the participants mentioned technology such as virtual manipulatives, online graphing calculators or dynamic geometry software.

Bootstrapping

Imitation. Participants often reported modeling their behavior on the ways the people around them used technology. For example, one participant knew she could research technologies to use because a previous teacher had done that kind of research for her. Others whose family members were active in trying out new technology reported engaging in similar activities themselves.

Modeling did not always result in more confident technological behavior, however. Although participants mentioned their teachers showing mathematics videos in class, only one participant reported looking up mathematics videos on her own to find out more information. A few participants regarded using internet resources with suspicion, voicing concerns that the mathematics online would be too confusing, too sophisticated, or it would not replicate the way their teacher wanted them to do the mathematics. However, some of these students also mentioned using videos to teach themselves other things (like new strategies for playing video games), so perhaps school mathematics was regarded as a special case. A couple of participants reported exploring technology independently, sometimes pushing against adult expectations. One student had hacked the coding of a school typing program to generate high typing speeds and had also sought answers to his mathematics questions from "experts" on Discord and Reddit.

Learning Systems. Participants reported being allowed to play mathematics games if they finished their seatwork early and felt these games could be helpful to build their mathematics skills if played regularly enough. Experiences with IXL were reported in detail by two students. One used it as his entire math program – he sat in the back of the classroom doing independent work with IXL while the rest of the class engaged in the regular lesson. He thought it was "doing something" for him although he wasn't sure what. Another student used IXL for extra practice and as a general resource, finding it useful, but sometimes was frustrated by the program because it only accepted specific answers and not mathematically equivalent ones.

Chance and Selection. A few participants mentioned "messing around" with technology in their free time, in particular finding ways to narrow their Google searches more effectively or using the Google feature "People also ask" to explore new but related topics. None mentioned any discovery that had any impact on how they used technology to learn mathematics.

Piggybacking. One participant was able to use his knowledge of Google searches as a work-around when he didn't understand the formula for surface area offered to him by IXL. Another participant had figured out how to use the colour feature in Excel to highlight data trends for a health class project and had also used coding to create a game about Pythagorean theorem for mathematics class. A few students reported using technology they had learned in other settings (often coding camps) such as Scratch, iMovie, and Mindcraft for school projects in non-math subject areas and had been teaching peers to do the same. Given that post-secondary students with MLD (Armstrong & Gutica, 2020) use online resources to supplement the content of their mathematics classes, it is likely that middle years students will realize they can do so as well.

Conclusions

Children with disabilities are "a marginalized and unheard group" and there are few studies that consider these students' views on assistive technology (Wright, Sheehy, Parsons, & Abbott, 2011, p. 5). "[A]n evidence-based understanding of students' technological experiences" (Kennedy et al., 2008) and insights is essential to improving classroom use of technology in order to develop pedagogical practices that more effectively support learning (Herrington et al., 2009; Kukulska-Hulme et al., 2011) and to improve student access and equity in mathematics. I am now investigating how the strategies of students with MLD for using technology to support themselves in mathematics emerge over time.

Keywords: professional development, undergraduate education, technology

NCTM (2015), AMTE (2017), and CBMS (2012) have all pointed to the importance of preparing secondary mathematics teachers [PSMTs] to teach using mathematical action technologies (e.g., CODAP, Desmos, GeoGebra). However, a recent nationwide survey of accredited PSMT preparation programs found that while most programs do integrate technology in at least one course for PSMTs, many do not include opportunities to engage with a variety of mathematical action technologies and two programs reported that they do not include technology at all. In addition, responses to open ended questions indicated that faculty expertise is one of the reasons mathematical action technologies are not used more widely (Authors et al., 2020). To address this issue a 6 day virtual workshop on teaching undergraduate courses for PSMTs with mathematical action technologies was conducted. The workshop provided opportunities for faculty who teach mathematics, statistics, and methods courses to learn about technologies that are appropriate for use in their courses and are commonly used in secondary schools. Participants were organized into Teaching Interest Groups with opportunities to collaborate on ways in which they would incorporate what they were learning into their instruction. An overarching goal was to support the development of faculty self-efficacy for using the technologies and self-efficacy for using the technologies in their instruction.

To study faculty self-efficacy we used a survey methodology (Groves et al., 2009). Seventy participants representing 52 universities across 31 states participated in the workshop. Participants each completed a pre- and post- self-efficacy survey regarding the technologies presented in the workshop sessions. Participants rated their comfort level in using the technologies for themselves as well as teaching with the indicated technologies. The 24 question survey used a 6 point likert scale - where 1 represented “not comfortable at all” and 6 represented “extremely comfortable.” A repeated measures ANOVA was performed to assess the difference in self-efficacy as rated on the pre- and post- surveys (Norman, 2010). Preliminary findings suggest that participants began the workshop with low self-efficacy for using and teaching with the newer technologies commonly used in secondary schools today, while some reported higher levels of self-efficacy (and experience with) older technologies (e.g., TI-84 graphing calculator). A full analysis will be presented along with implications for future faculty development related to preparing to teach using mathematics and statistics technologies.

SIMULACIONES DE REALIDAD MIXTA EN LA FORMACIÓN DE MAESTROS: ¿QUÉ CANTIDAD ES SUFICIENTE PARA QUE SEA EFECTIVO?

Jair J. Aguilar
The University of Texas RGV
jair.aguilar@utrgv.edu

El uso de simulaciones en la educación ha evolucionado de forma que ya se implementan herramientas para mejorar las habilidades de los maestros en formación (MF). Las simulaciones de realidad mixta (SRM) son tecnologías de simulación que sirven como plataforma para brindar a los MF oportunidades para desarrollar estrategias de enseñanza, en particular, aquellas relacionadas con cuestionar, evaluar y comprender el pensamiento de los estudiantes. Especialmente, para desarrollar acciones productivas en el aula de matemática [APAM] (Chapin, et al., 2009). En este estudio, mostramos los avances obtenidos en nuestra investigación en donde se examina la efectividad del uso de las SRMs para preparar maestros de primaria en formación (MPF), y como ésta sirve para desarrollar sus habilidades sobre el uso de APAMs. Así, se reponden las preguntas: ¿En qué medida la exposición de los MPFs a SRMs mejora su aprendizaje, uso, e implementación de los APAMs, en comparación con otros MPFs no expuestos a la simulaciones? (ii). ¿Puede el número de sesiones SRMs ser un factor determinante para el desarrollo del uso de APAM? Se adoptó un enfoque cualitativo (Mills & Birks, 2014) considerando un proceso de codificación deductivo (Miles et al., 2014). Participaron 40 MPF, divididos en 2 secciones, en un curso de métodos matemáticos, donde el 93% eran mujeres y el 6% hombres. Un grupo fue considerado el grupo control y el otro el experimental o de tratamiento (fue expuesto a SRMs). Todos los MPF recibieron la misma preparación en el salón de clases. El grupo experimental recibió adicionalmente tres sesiones de entre 6-10 min. de SRM. Los MPF debían realizar una entrevista clínica con un alumno de primaria utilizando ejercicios de matemática de instrucción guiada cognitivamente (Carpenter et al., 2014). De estas entrevistas se analizaron, compararon y contrastaron las transcripciones de las interacciones entre los MPF y los alumnos de primaria. Los MPF expuestos a las simulaciones mostraron implementar un 55% más de acciones productivas en el aula de matemática en comparación los MPF no expuesto a las SRM. También mostraron estar más abiertos a construir una buena relación con su estudiante de primaria, lo cual es importante cuando se busca involucrar a los estudiantes en un tema o discusiones. En una primera etapa de este estudio realizado por el Autor (2018), se siguió una metodología similar, con la diferencia de que el grupo experimental sólo fue expuesto a una sola SRM. Al comparar la primera etapa con la segunda que se presenta aquí (3 SRM) se pudo encontrar evidencia que el número de sesiones de SRM puede potencialmente influir en cómo los MPF, aprenden e implementan acciones productivas en el aula de matemáticas al realizar una entrevista clínica. Sin duda, el uso de SRM representa, como se muestra en esta propuesta, una alternativa para que durante los primeros años en los programas de formación de maestros, se puedan ofrecer experiencias que se acerquen lo más posible la práctica pedagógica en el salón de clases, sin tener que esperar hasta que los MPF se encuentres en los últimos anos donde realizan sus practicas profesionales como docentes.

MIXED-REALITY SIMULATION IN TEACHER PREPARATION: HOW MUCH IS ENOUGH?

Jair J. Aguilar
The University of Texas RGV
jair.aguilar@utrgv.edu

The use of simulation technologies in education has been evolving in recent years and has made it possible for the implementation of technological tools to enhance pre-service teachers' skills. Mixed-reality simulations (MRSs) are a simulation technology tool that serves as a platform to provide pre-service teachers opportunities to develop high-leverage practices, in particular, those related to questioning, assessing, and eliciting students' thinking. In particular, to develop productive mathematical talk moves [PMTM] (Chapin, et al., 2009). In this study we depict results of an on-going research that examines the effectiveness of using MRSs as an alternative preparation tool to develop pre-service elementary mathematics teachers'(PEMT) ability to elicit evidence of students' mathematical knowledge and understanding through the use of productive mathematical talk moves. To this end, we answer the following question: (i) To what extent do PEMTs exposure to MRSs enhance their use of PMTMs, in comparison to other PEMTs not exposed to the simulation; (ii). Does the numbers of MRSs exposure improve PEMTs use of PMTMs to question and elicit elementary student's thoughts? In this study we took a qualitative approach (Mills & Birks, 2014) considering a deductive coding process (Miles et al., 2014). Participants were 40 elementary pre-service mathematics—divided in 2 sections—teachers taking a mathematics methods course during Fall 2019 from which 93% were females and 6% males. The elementary pre-service mathematics teachers were required as part of the course, to conduct a clinical interview with an elementary student. To prepare the elementary pre-service mathematics teachers for the assignment, 20 participants were exposed to Mixed-Reality simulations. They experienced three sessions that lasted between 8 -12 minutes each. The other half were trained in class, and both groups practiced the implantation of mathematical activities from the cognitively guided instruction framework of Carpenter et al., (2014). After the interview, the elementary pre-service mathematics provided the transcripts of their interaction with the elementary students. The transcripts were coded and analyzed following an adapted version of the framework of PMTMs. In general, the PEMT exposed to the state-of-the-art technology, have 55% more moves than the students that did not. They were also more open to build rapport with their elementary student, which is important when looking to engage students in a topic or discussions (Starcher, 2011). In a previous similar study conducted by Aguilar &

Telese (2018), they were comparing elementary pre-service mathematics teachers exposed only to a single MRSs. Although the treatment group that were prepared using MRS showed a tendency of using more moves, not all the moves were productive. In comparing with the current study (see table 3), it can be notices that the number of MRS exposure can potentially influence hw pre-service teachers use and implement productive mathematical talk moves when conducting a clinical interview. It can be inferenced that these students will also use these pedagogical strategies once they start their educational journey. It can be noticed that the use of Mixed-Reality Simulations during the teacher preparation program provide the elementary pre-service teachers an opportunity to practice teaching skills. However, we found evidence that the number of simulation exposure also play a roll when looking to develop and enhance the pre-service mathematical teacher's skills when fostering to assess, elicit, and questions their students in a formative approach.

ELICITING KINDERGARTEN STUDENTS' MATHEMATICS WITH A CODING TOY: A PILOT STUDY ON DESIGN FEATURES

Joseph S. Kozlowski

vrlee@stanford.edu

Research is beginning to highlight the mathematics that young children demonstrate when using coding toys (e.g., Nam et al., 2019; Palmér, 2017; Shumway et al., 2021), yet little is known about how the design features of coding toys elicit children's mathematics. The purpose of this pilot study is to understand in what ways a coding toy affords mathematical ideas. The research question for this study is: *How do the design features of the Cubetto coding toy elicit kindergarten student's mathematics?*

Theoretical Framework

Research shows that mathematics-focused manipulatives (e.g., physical, virtual) afford mathematics learning (e.g., Bullock et al., 2017; Moyer-Packenham et al., 2019). Coding toys have blended characteristics of these other mathematics-focused manipulatives, so it could be hypothesized that design features of the coding toys also play an important role in how the toys support young children's mathematics. Design features in this study are the physical elements of the coding toy that offer some level of engagement to the user. Gibson's (1979) affordance theory frames our analysis of a coding toy's design features, their affordances, and the way they elicit or do not elicit kindergarten students' mathematics.

Methods

We conducted a constructivist group teaching experiment (Cobb & Steffe, 1983) with four small groups of 5-to-6-year-old students (15 total) programming the Cubetto coding toy to move to various points on a grid. Each group's 30-minute activity was video recorded (~120 minutes total) and qualitatively analyzed for ways Cubetto's design features elicited mathematics.

Results and Discussion

Literature suggests that children using digital mathematics games need to be aware of design features in order to take advantage of the potentially beneficial affordances of those features (Bullock et al., 2017; Moyer-Packenham et al., 2020). One finding of the current study was that students were unaware of the simultaneous linking features (e.g., blinking lights) because they were on a separate interface, which may have hindered students' access to the mathematics. The second important finding was that anthropomorphic design features (e.g., face on the side of the body) elicited spatial mathematical concepts. Implementing Cubetto activities, and specifically directing children's attention to the anthropomorphic features, may prove a valuable way to provide these spatial mathematical opportunities to young children. The final important finding was that the grid squares on Cubetto's mat elicited mathematical number concepts (e.g., counting on, verbal number use). This is important because it means that specific instructional strategies

Olanoff, D., Johnson, K., & Spitzer, S. (2021). *Proceedings of the forty-third annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Philadelphia, PA.

should account for this alignment between grid squares and number concepts. Implications for instruction include prompting children to attend to Cubetto's face when learning how to use spatial rotation codes, or prompting children to attend to the grid squares when learning to count Cubetto's linear movements.

Keywords: Technology; Preservice Teacher Education; Teacher Noticing; 360 Video

A key aspect of professional noticing includes attending to students' mathematics (Jacobs et al., 2010). Initially, preservice teachers (PSTs) may attend to non-mathematics specific aspects of a classroom before attending to children's procedures and then, eventually their conceptual reasoning (Barnhart & van Es, 2015). Use of 360 videos has been observed to increase the likelihood that PSTs will attend to more mathematics-specific student actions. This is due to an increased perceptual capacity, or the capacity of a representation to convey what is perceivable in a scenario (Kosko et al., in press). A 360 camera records a classroom omnidirectionally, allowing PSTs viewing the video to look in any direction. Moreover, several 360 cameras can be used in a single room to allow the viewer to move from one point in the recorded classroom to another; defined by Zolfaghari et al., 2020 as *multi-perspective 360 video*. Although multi-perspective 360 has tremendous potential for immersion and presence (Gandolfi et al., 2021), we have not located empirical research clarifying whether or how this may affect PSTs' professional noticing. Rather, most published research focuses on the use of a single camera. Given the dearth of research, we explored PSTs' viewing of and teacher noticing related to a six-camera multi-perspective 360 video. We examined 22 early childhood PSTs' viewing of a 4th grade class using pattern blocks to find an equivalent fraction to 3/4. Towards the end of the video, one student suggested 8/12 as an equivalent fraction, but a peer claimed it was 9/12. The teacher prompts the peer to "prove it" and a brief discussion ensues before the video ends. After viewing the video, PSTs' written noticings were solicited and coded. In our initial analysis, we examined whether PSTs attended to students' fraction reasoning. Although many PSTs attended to whether 8/12 or 9/12 was the correct answer, only 7 of 22 attended to students' part-whole reasoning of the fractions. Next, we examined the variance in how frequently PSTs switched their camera perspective using the unalikeability statistic. Unalikeability (U_2) is a nonparametric measure of variance, ranging from 0 to 1, for nominal variables (Kader & Perry, 2007). Participants scores ranged from 0 to 0.80 (Median=0.47). We then compared participants' U_2 statistics for whether they attended (or not) to students mathematical reasoning in their written noticing. Findings revealed no statistically significant difference (U=38.5, p=0.316). On average, PSTs used 2-3 camera perspectives, and there was no observable benefit to using a higher number of cameras. These findings suggest that multiple perspectives may be useful for some, but not all PSTs'.

Keywords: Technology, WeBWorK, GeoGebra, Attitudes, Undergraduate Education

Introduction and Conceptual Perspective

Most university mathematics courses use homework to provide practice for topics and to evaluate student learning. Recently, mathematics scholars began designing cost free, innovative math resources for homework assignments that use cutting edge technology, for example WeBWorK and GeoGebra, to enhance student learning in undergraduate mathematics (May, Segal, Piercey, & Chen, 2020; The WeBWorK Project, 2021; SUMMIT-P, 2016). WeBWorK is an open-source on-line homework application supported by the Mathematical Association of America. GeoGebra is a dynamic math program that brings together geometry, algebra, spreadsheets, graphing, statistics, and calculus into one platform. Research points to positive students' perceptions for using WeBWork (Roth, Ivanchenko, & Record, 2008; Hauk & Segalla, 2013) and GeoGebra (Attard and Holmes, 2020; Radović, Radojičić, Veljković, & Marić, 2018) to complete homework and classwork. In a recent pilot study conducted by the proposal's authors at a large midwestern university, we found positive student perceptions for newly designed math co-requisite courses (three-credit course and one-credit technology lab) for business majors. For the one-credit technology lab, we also found that the interface and syntax of GeoGebra and the means for submitting technology lab assignments were not user-friendly and created unnecessary, unintended obstacles to student learning. To rectify this problem, a large project is underway to revise the curriculum for the co-requisite courses and to develop an interface that embeds GeoGebra applets into students' technology lab assignments (NewT) delivered in WeBWorK for the one-credit technology lab for business majors.

Research Question and Design and Data Collection

The research question for this proposal is the following: Is there a difference in students' perceptions for the NewT and the existing technology lab assignments (ExisT). This research project is an extension of the previously mentioned pilot study and larger project that called for the revision of curriculum and development of new technology lab assignments for the one-credit technology lab. By spring 2022, five NewT will be created to compare to the remaining ExisT. Approximately 160 students will be invited to complete a student perceptions survey and interviews. To compare student perceptions for NewT and ExisT, a paired-samples t-test will be used at alpha 0.05, where 40 students will be needed to ensure generalizable results. Five randomly selected students will be chosen to participate in a 30-minute interview comparing NewT and ExisT to gain a deeper understanding of students' perceptions. By week 6 of spring 2022, students will respond to survey questions about the five completed ExistT. During week 14, another survey will be given to compare student perceptions for the remaining NewT.

Data Analysis and Summary of Findings

Preliminary results for curriculum revisions for the co-requisite courses are positive. A student recently stated, "I am learning more from the technology lab than the three-credit course." We anticipate positive student perceptions for the NewT when compared to the ExisT.

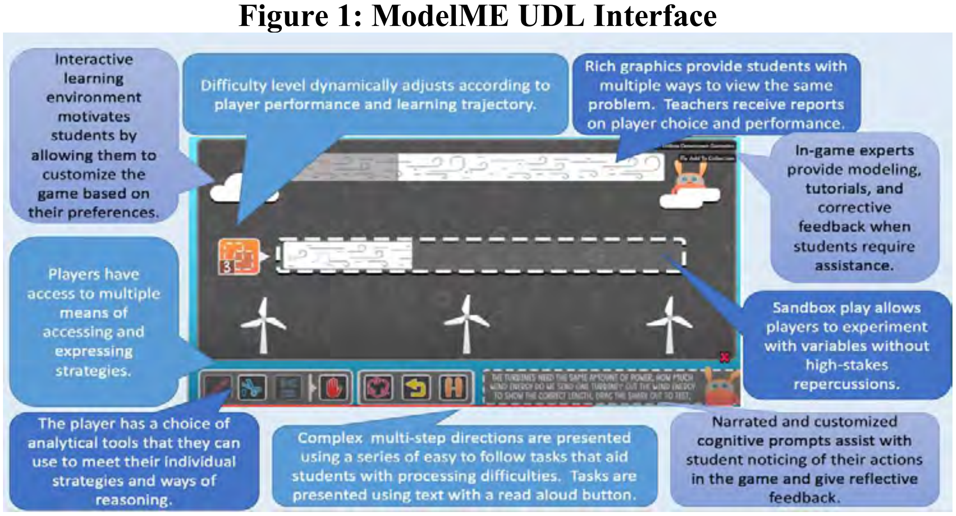
The 2017 National Assessment of Educational Progress highlights stagnant and declining performance in mathematics, foundational to STEM and ICT, in both 4th (17% proficient) and 8th (9% proficient) grades. At the same time, promoting diversity in the workforce is paramount for U.S. innovation in STEM and ICT fields. Individuals with disabilities are underutilized members of the STEM and ICT workforce. In this poster, we report on Model Mathematics Education (ModelME), a universally designed video game embedded into a student-centered Tier 2 (i.e., supplemental) mathematics curriculum.

Access, Advancement, and Power: Universal Design and Student Centered Instruction

Universal Design for Learning (UDL) addresses the need for students to access different tools to learn and express knowledge. Instruction is guided by three principles: (a) multiple means of engagement (i.e. considering how to engage students in multiple ways), (b) multiple means of representation (i.e. providing content in multiple formats), and (c) multiple means of action and expression (i.e. providing opportunities for students to demonstrate their understanding in multiple ways (see Figure 1).

Figure 1: ModelME UDL Interface



In session, we will demonstrate ModelME's use of student-centered design features and report on initial usability data with elementary school students.

INTRODUCING FUNCTION TO MIDDLE SCHOOL STUDENTS: A NOVEL REPRESENTATION

Michael S Meagher	Jennifer Lovett	Allison McCulloch
Brooklyn College - CUNY	Middle Tennessee State University	UNC Charlotte
mmeagher@brooklyn.cuny.edu	Jennifer.Lovett@mtsu.edu	amccul11@uncc.edu

Introduction

The purpose of this study is to examine the effect of a specially designed applet on middle school students' ability to develop an understanding of the concept of function as a relationship between inputs and outputs with some rules about the outputs.

The *Introduction to Function* task is a series of interactive applets compiled in a GeoGebra book that consists of seven pages and an accompanying worksheet. On the first two pages are two vending machines each of which consists of four buttons (Red Cola, Diet Blue, Silver Mist, and Green Dew). When a button is clicked it produces none, one, or more than one of the four different colored cans (red, blue, silver, and green), which may or may not correspond to the color of the button pressed (see Figure 1). The students are told that the first machine on each page is an example of something called a function, and the other is not a function, with their task being to identify what is the difference between the behaviour of the machines that makes one a function and the other not.

Participants

The *Introduction to Function* applet was used in fifteen seventh grade classrooms. These classrooms were across two different states (one Northeastern state and one Southeastern state) and five different teachers for a total of 138 students who engaged with the task. These students engaged with the applet towards the end of their seventh grade year and had not yet learned about the definition of function or function notation.

Results

Participants identified Machines correctly as follows: Machines E & F: 81.3%. Machines G & H: 95.8%. Machines I & J: 86.1%. Machines K & L: 80.7%. At a first level of analysis this shows that, broadly speaking, the pairs of students were able to correctly identify which machines were functions. In a qualitative analysis of the video recordings it was seen that the main challenge to correct identification of functions is the real-world context of a vending machine and the attendant challenge of accepting an output that doesn't match the input button in colour even when it does so consistently. Also, within this study, contrary to a well-known misconception, participants may be able to recognise a constant function as a function. Finally, it should be noted that the purpose of this activity was to set the scene for a class discussion of their definitions with the goal of arriving at a shared definition. The results of the study suggest that there is a good foundation for that discussion.

MIDDLE SCHOOL MATHEMATICS TEACHERS' COLLOQUIAL EVALUATIONS OF DIGITAL MATHEMATICS RESOURCES

Jamie Kautz
The Ohio State University
Kautz.8@osu.edu

Keywords: Digital Resources, Middle School, Professional Development

This study aims to explore the benchmarks used by middle school mathematics teachers to assess the quality of digital mathematics resources for use in their classrooms. Although calls have been made to districts, teachers, and teacher educators to be cognizant of the quality of digital resources, along with the intended learning and sequencing of their use (NCTM, 2016), little attention to how stakeholders should address such issues at the level of digital resources. While many evaluative tools (such as rubrics) exist, their goals and audience are varied. In an attempt to explore what contributes to the effective evaluation of digital resources as part of an integrated mathematics classroom, the following overarching research question *What guides middle-school mathematics teachers' colloquial evaluation (CE) of digital mathematics resources?* was explored.

A total of 33 mathematics teachers, a year-long professional development (PD) participants participated in the study, consisting of 4-5 math teachers and a building's mathematics coach from the same building —a strategy to further support a collaborative experience with coaching and professional support (Darling-Hammond et al., 2017). While many other digital resources were used during the PD, teachers' CEs on the following four digital resources were analyzed: Interpreting Stories and Graphs (PBS LearningMedia, 2012), Exploring Patterns: It's a Bit Nutty (Learn Alberta, 2003), On Your Mark (Mathalicious, 2015), Algebra Tiles (NCTM, 2015). A qualitative methods approach was used to analyze teachers' evaluations of assigned digital resources. The approach stems grounded theory, "in which the researcher derives a general, abstract theory of a process, action, or interaction grounded in the views of participants" (Creswell & Creswell, 2018, p. 14).

Upon analysis of the teachers' evaluations, thirty characteristics emerged from teachers comments and were grouped into seven larger criteria. Close to half of all CE comments were related to the *digital resource features* and *learning experience* criteria. The nature of teachers' comments confirmed their perception of the digital resource in the large majority of teacher CEs. The comparison of positively and negatively viewed digital resources may also bring to light another issue in identifying the underlying reasons that some resources fared better than others. That is, the variation in the frequency of the characteristics, criteria, dimension, or other construct-related coding mechanisms could be attributed, in part, to the digital mathematics resources that were used.

The lack of an appropriate evaluation tool with respect to being teacher-friendly are essential to supporting the successful implementation of digital mathematics resources into the middle-school, mathematics classroom. While digital content evaluation is key to determining the quality of a resource and making a choice with respect to implementation, teachers often rely on peers or a quick glance at a resource. This limited judgement of the quality of the resource coupled with evaluation tools that are too robust or difficult to use and the time it costs teachers, evaluation of digital resources takes a back seat to other factors that teachers focus on in preparation for their classes.

LEARNING MATHEMATICS WITH DYNAMIC REPRESENTATIONS: AN APPLICATION OF VARIATION THEORY

Claudine Margolis
University of Michigan
czmars@umich.edu

Keywords: Mathematical Representations, Technology

A general premise of school mathematics is that through engagement with some activity, students will learn. Planning activities that are likely to lead to the intended learning outcomes is a persistent problem of practice for educators at all levels. Variation theory (Marton, 2015) can be used to analyze the design of learning activities while keeping the learning goal at the center. Studies of mathematics learning have provided compelling evidence that dynamic representations (DRs), instantiated through digital media, can support students in developing rich conceptual understanding (Roschelle, et al., 2017). On the other hand, it is clear that simply including DRs in learning activities does not always create favorable conditions for student learning. In this poster, I seek to answer the question: *What does variation theory make visible about the learning opportunities provided by dynamic representations?*

As mathematics curricula are increasingly made available and implemented through digital platforms (Remillard & Reinke, 2017), students are being provided with more opportunities to learn through the use of dynamic representational tools. In 2020, Desmos published a middle school curriculum designed to "enhance the top-rated curriculum from Illustrative Mathematics and Open Up Resources" (Desmos, n.d.). By analyzing lessons from the Desmos middle school curriculum, which was specifically designed to leverage DRas, I investigate the role of DRs in making mathematics concepts available to students.

Dynamic representations create opportunities for students to "kinesthetically and intellectually interact with the designers' construction of [mathematical entities]" (Edwards, 1998, p. 74). This interaction occurs through a series of student-initiated actions followed by "interpretable feedback" (Edwards, 1998) which is automatically generated as a result of the way the DR has been designed and programmed. Discrepancies between what an activity designer intends for students to learn and what they actually learn can occur when students do not act on the DR in ways that bring about a necessary condition.

I apply Marton's (2015) variation framework to describe the learning activities that comprise a lesson in terms of variation or invariance of critical aspects of the object of learning. Marton's theory rests on the assumption that a necessary condition of learning is the ability to discern that which is to be learned, and that the ability to discern something relies on opportunities to experience variation and invariance across all relevant aspects of the object of learning. The critical aspects of an object of learning are the aspects of the mathematical content that need to be learned in order to meet the educational objective. Variation theory centers the mathematical learning goal(s) of a lesson and provides a framework for describing the learning activity as designed and as experienced by students in commensurable terms. In this study, I combine this curricular lens with an analysis of how students must interact with the DRs in order to make the critical aspects of the object of learning visible.

This poster will illustrate the application of variation theory to the analysis of lessons within a representationally rich curriculum. A preliminary finding is that due to the individualized and exploratory nature of DRs, students' interactions with representational tools have implications for whether or not they experience variation in critical aspects of the object of learning.

IDENTIFYING GRAPHICAL FORMS USED BY STUDENTS IN CREATING AND INTERPRETING GRAPHS

Jon-Marc G. Rodriguez
University of Iowa, United States
jon-marc-rodriguez@uiowa.edu

Steven R. Jones
Brigham Young University, United States
sjones@mathed.byu.edu

In this paper, we describe a framework for characterizing students' graphical reasoning, focusing on providing an empirically-based list of students' graphical resources. The graphical forms framework builds on the knowledge-in-pieces perspective of cognitive structure to describe the intuitive ideas, called "graphical forms", that are activated and used to interpret and construct graphs. In this study, we expand on the current knowledge base related to the specific graphical forms used by students. Based on data involving pairs of students interpreting and constructing graphs we present a list of empirically documented graphical forms and organize them according to similarity. We end with implications regarding graphical forms' utility in understanding how students construct graphical meanings and how instructors can support students in graphical reasoning.

Keywords: High School; University Math; Cognition; STEM/STEAM; Interdisciplinary studies

Interpreting and constructing graphs that model mathematical or physical contexts is a critical competency across disciplinary fields (Driver et al., 1996; National Council of Teachers of Mathematics, 2000; National Research Council, 2012). While much previous work has examined student difficulties and non-normative reasoning related to graphing (Beichner, 1994; Glazer, 2011; Leinhardt et al., 1990; McDermott et al., 1987; Shah & Hoeffner, 2001), more work is needed that leverages students' knowledge related to creating and interpreting graphs. A new framework has recently been developed that identifies specific types of knowledge resources called *graphical forms*, that permits a finer-grained examination of how students think or reason about graphs (Rodriguez et al., 2019b). The purpose of this paper is to extend the work on graphical forms by empirically documenting and organizing a large set of graphical forms that students used to create or interpret graphs. This work permits researchers greater clarity on the cognitive work involved in constructing and interpreting graphs, and helps instructors know what types of knowledge students can develop or use for productive graphical activity.

Brief Literature Review on Student Graphical Thinking

Past research on graphical thinking has documented students' difficulties (e.g., Beichner, 1994; McDermott et al., 1987), with the consensus being that students' ability to interpret graphs depends on interaction between students' prior knowledge and the nature and content of the graphing task (Glazer, 2011; Leinhardt et al., 1990; Shah & Hoeffner, 2001). Some work has emphasized the nature of assumptions and conventions associated with graphical interpretation (Moore et al., 2019), including work that described students' use of *intuitive rules* to interpret graphs (Eshach, 2014). According to Eshach (2014), students develop a set of *intuitive rules* that share a similar ontology to diSessa's (1993) *phenomenological primitives* (discussed in more detail later) in the sense that they are constructed based on experiences. However, *intuitive rules* are more broadly useful and are not specific to explaining a physical phenomenon. This approach to considering how students interpret graphs is insightful in the way it provides explanatory power for students' reasoning that moves beyond identification of misconceptions (Beichner, 1994; Elby, 2000; McDermott et al., 1987).

Much of the literature indicates the role context plays in students' ability to extract information from graphical representations. For example, students tend to perform better when presented with decontextualized graphs in comparison to analogous graphs involving chemistry or physics content (Bollen et al., 2016; Ivanjek et al., 2016; Planinic et al., 2012, 2013; Potgieter et al., 2008). To examine context-specific graphs, recent work by the first author and colleagues has focused on students' graphical reasoning in chemistry, specifically in the context of chemical kinetics (Rodriguez et al., 2018, 2019a, 2019b, 2019c, 2019d, 2020a), which is concerned with modeling the rate of chemical reactions. A limited number of knowledge resources, called graphical forms, have been discussed in these studies, including *steepness as rate*, *straight means constant*, and *curve means change.* In some cases, graphical forms such as *steepness as rate* seem to have a particularly strong cuing priority, which, in part, could be influenced by students' tendency to inappropriately force time onto expressions and graphical representations that do not include time as a variable (Bowen et al., 1999; delMas et al., 2005; Jones, 2017; Popova & Bretz, 2018; Rodriguez et al., 2019d, 2020a, 2020b). In this paper, we build on this work by presenting several graphical forms empirically observed in students' graphical reasoning.

Theoretical Perspective: Graphical Forms

Knowledge-in-Pieces & Symbolic Forms

The construct of graphical forms is rooted in the knowledge-in-pieces (KiP) paradigm, a cognitive model that characterizes the structure of knowledge and the mechanism associated with conceptual change (diSessa, 1993). The salient feature of the KiP view is the manifold ontology of cognitive structure, in which knowledge is conceptualized as a network of fine-grained cognitive units that are activated in concert because of perceptual cuing. These cognitive units, which we call *knowledge elements* and *resources* interchangeably (see also Hammer, 2000), may reflect a variety of types of knowledge, such as ideas related to concepts, epistemology, or ontology. Building within the KiP paradigm, Sherin (2001) introduced the "symbolic forms" framework to describe mathematical resources related to symbolic equations. According to Sherin (2001), this involves associating an idea (conceptual schema) to a pattern in an equation (symbol template). Based on the introductory physics (classical mechanics) context in which the symbolic forms framework was initially developed, the symbolic forms characterized by Sherin (2001) reflected ideas associated with algebraic manipulations such as combining terms, proportional reasoning, and the role of a coefficient in scaling or tuning an expression.

Graphical Forms

The graphical forms framework reflects a natural extension of symbolic forms, providing the language to further characterize students' mathematical resources. Like symbolic forms, reasoning involving graphical forms is characterized by focusing on a structural feature and subsequently associating an idea (Rodriguez et al., 2019b). Whereas the symbolic forms framework focuses on the ideas assigned to patterns in equations, the graphical forms framework augments this work by emphasizing the ideas assigned to patterns in a *graph*. Previously, the specific feature attended to in a representation has been framed as a *registration* (Lee & Sherin, 2006; Roschelle, 1991), which in the context of graphical reasoning can vary in size—an individual may attend to and associate an idea with the entire graph or a specific region of the graph (Rodriguez et al., 2019b).

Although these resources may be activated and applied in less useful contexts, it is important to acknowledge that students have these broadly useful cognitive tools for reasoning that have the potential to guide students in the sensemaking process. Therefore, consistent with the knowledge-in-pieces perspective, research and instruction should emphasize providing insight regarding how we can support students in productively using the resources they have, rather than focusing only on cataloging misconceptions (Cooper & Stowe, 2018). Students seem to commonly draw on graphical forms such as *steepness as rate*, which can result in sophisticated conclusions regarding physical processes. In the context of interpreting graphs, this often involves initially anchoring reasoning in mathematics by drawing inferences using graphical forms and subsequently assigning discipline-specific principles to explain the observed graphical shape (Bain et al., 2019; Rodriguez et al., 2019, 2019a, 2019b, 2019c). In the case of constructing graphs, the reverse is observed in which students consider the physical scenario and subsequently utilize graphical forms as part of the drawing process to create a graphical shape that aligns with the phenomena (Rodriguez et al., 2020a).

The goal of this study is to begin to develop an empirical library of graphical forms, mirroring the current list available for symbolic forms (Rodriguez et al., 2019b); necessitating a clear definition of what constitutes a graphical form. As part of this process, we drew on extant education research related to graphical reasoning and Sherin's (2001) description of symbolic forms to consider the implications for the graphical analog. First, we draw attention to the idea that symbolic forms focused more on meaning than conventions. Second, symbolic forms emphasized the information communicated by an equation, without drawing an explicit connection to what an equation fundamentally *is* in an ontological sense. Moreover, to narrow the scope of the framework we decided to define graphical forms as assigning meaning to the curve itself, as opposed to other aspects of a graph such as the axes and graph labels (Kosslyn, 1989). In summary, our definition of a graphical form was refined to consist of a specific aspect of the graphical curve itself (e.g., a *graphical pattern*) and an intuitive *conceptual schema* associated with that aspect. Thus, our definition excludes beliefs about the nature of the graph, knowledge elements associated with the axes, or general knowledge about functions.

Methods

This paper reports on one set of outcomes from a larger study on students' graphical activity in relation to real-world contexts. In the study, twelve students across two universities at the beginning of first-semester calculus were recruited to participate in two separate interviews that occurred within a one-week timespan. One interview focused on constructing graphs that model real-world situations and the other interview focused on interpreting graphs. For space constraints, we do not present all nine tasks here, but have provided in Figure 1 one graph construction and one graph interpretation prompt that we drawn on in the Results section. The students were interviewed in pairs, and are given the pseudonyms Anna and Aria, Berto and Blaine, Cindy and Caleb, Donato and Demyan, Ellie and Eric, and Fiona and Felicity.

(A) Graph Construction

A homeowner mows the lawn once a week on Wednesday afternoon for 4 weeks in a row. Then the mower breaks and he decides not to mow the lawn for the rest of the summer. Graph the height of the grass as a function of time throughout the summer.

(B) Graph Interpretation

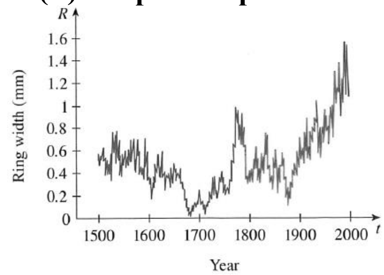

Figure 1: Prompts discussed in this paper.

Following transcription, initial data analysis involved dividing the interviews into bounded episodes based on content discussed to establish a codable unit (Campbell et al., 2013) and providing a narrative general overview of the student discussion within the episode (i.e., narrative coding) (Heisterkamp & Talanquer, 2015; Rodriguez et al., 2020b). Subsequently, we used a line-by-line analysis to analyze each statement within the episodes, focusing on the resources implied by what the student said—and did as they made the statement—also considering the context surrounding the statement, including nonverbal cues such as gestures. The process of identifying graphical resources involved a combination of deductive (previously identified graphical forms from the literature) and inductive analysis (identifying new graphical forms and other graphical resources). To refine our definition of graphical forms, we discussed together the various graphical resources we documented, which involved combining codes and creating new codes, some of which were determined to constitute graphical forms and others which were characterized more generally as "other" resources related to graphing.

Results and Discussion

We begin by providing examples of graphical forms observed in the data that have previously been identified in the extant literature. We then discuss new graphical forms identified and provide an overview list with the various graphical forms identified in the data.

Previously Identified Graphical Forms

Across the dataset various graphical forms were identified, some of which were previously discussed in the literature, such as *steepness as rate,* which involves students associating ideas about rate with the relative steepness of the graph (Rodriguez et al., 2018, 2019a, 2019b, 2019c, 2020a, 2020b). Given that this graphical form has been discussed in detail in previous work, we will not focus too much on it here, except to say that it was the one of the most frequent graphical form observed in the dataset, further building a case for its relatively high cuing priority, phenomenological basis, and its important role in graphical reasoning. For some of the previously identified graphical forms, as part of the process of developing a list, we also built on the prior descriptions, such as modifying *straight means constant* in favor of the more precise language *straight means constant rate*. This was to specify that students were focusing on *rate* as opposed to *values*. To illustrate this, one of the graph creation prompts involved a scenario related to modeling the height of grass over time (Figure 1A). When working through this prompt, Blaine and Berto initially drew the graph provided in Figure 2A, with Blaine describing the straight lines they drew as follows:

> **Blaine:** *So grass grows, um, it grows at a pretty constant rate, and you cut it every once, one or two weeks in the summer, at least where I live. Um, and then you would cut it.*

In this instance, Blaine's reasoning can be characterized as *straight means constant rate*, due to the emphasis on rate. Similar to *steepness as rate,* associations such as Blaine's above that drew a connection between straight lines and a constant rate were frequently observed in the dataset. Revisiting the distinction between specifying what is constant when describing a straight line, later in the interview Berto and Blaine drew a plateau as part of their graph (Figure 2B):

Interviewer: *... what do those horizontal flat points represent to you again?*
Blaine: *No growth.*

Here, Blaine is no longer referring to *rate* being constant, but rather the *height* of the grass being constant ("not growing"), indicated by the horizontal straight line (*horizontal as constant value*).

(A) Berto & Blaine **(B) Berto & Blaine**

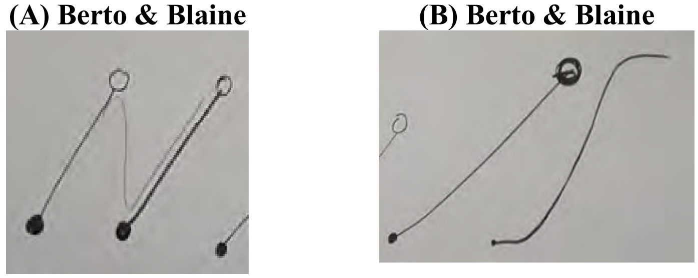

Figure 2: Two Types of "Straight": Linear-Straight as Constant Rate (A) and Horizontal-Straight as Constant Value (B).

New Graphical Forms

Although there is not space to provide student examples of all the new graphical forms identified, based on the contexts associated with the graphs provided, we discuss some of the graphical forms that emerged from the data that have not yet been discussed in the literature. For example, the nature of the grass prompt discussed previously (Figure 1A) resulted in students discussing ideas related to discontinuity, which we characterized using the graphical form *jump discontinuity means sudden*. Here, the graphical pattern of a jump/break in the graph was intuitively associated with a sudden event, such as when cutting the lawn results in a sudden decrease in height. As with other graphical forms, the name selected is intended to be descriptive for ease of communication and presentation. Another example of a new graphical form associated with the prompt in Figure 1A is *open/closed dot pair as existence*, as exemplified by Dontao and Demyan:

Demyan: *... I want to show that the height is like, this is something continual, like grass didn't like stop, uh, existing there [i.e., at the discontinuity] for like a very split microsecond while it was cut…*
Donato: *Yeah. I think that, in that case, you would do the like open circle here, closed circle there, but yeah, again, I don't think that happens-*
Demyan: *And if that is what, what, what counts, like if that makes it clear in mathematical terms that the grass is still around, it's just, you know, cut from the edge or from the bottom at three inches, then yeah, I'm down for that change.*

The graph drawn by the students did not initially have open and solid dots (only slanted lines), which bothered Demyan because it seemed to imply that the grass was no longer there because the graph was not connected (continuous). After discussing it with one another, they adopted the solid-open dot notation utilized by other students in the sample (Figure 2) to express the concept of existence at a particular point.

When analyzing student responses to the construction and interpretation prompts, we also noted graphical forms related to how features in the graph suggest realism or indicate the graph involves empirical data. For example, revisiting the grass prompt with Aria and Anna:

Interviewer: *And what does that mean that it's like a straight line segment and then a straight line segment, like as opposed to like a curve?...*
Anna: *Then we would assume it just grows at a constant rate over time, but I guess that's not true either. Cause there's a lot of factors that can affect the growing that isn't just time.*
Aria: *Yeah. Like bugs.*
Anna: *Yeah. But we're not looking at that. We're literally just looking at if grass grew in terms of time and not in terms of other things. So realistically that's probably not what it looks like. It probably is more gradual because of other factors.*

Here, the students above, as well as other students for multiple prompts, were hesitant to draw straight lines because that implies a direct linear relationship between the variables. We characterize this reasoning as *curves mean realistic*, in which students opted to draw curved lines to account for unknown factors and avoid making assumptions about the relationship between the variables. Moreover, this graphical form was complemented with *jagged means data*, which is related to *curves mean realistic* in the sense that a jagged graph with multiple sporadic increasing and decreasing regions is far from an "ideal" and "clean" linear plot. This idea was observed when students were asked to interpret the graph provided in Figure 1B:

Sally: *Well, it's varying changes [Figure 1B]. It's not I guess constant in a way.*
Samuel: *Yeah, it's not like a smooth function, it's staggered in a way, I guess.*
Interviewer: *What do you mean by staggered?*
Samuel: *It was drawn like, like that [draws a graph with rigid lines]. ... I feel like it's just data plotted on the graph.*
Sally: *Yeah, and it's more abrupt, I guess.*

For the students, the jagged nature of the graph indicates the plot involves empirical, collected data. Combined with *curves mean realistic*, *jagged means data* reflects a productive idea for thinking about the relationship between variables and what is expected when collecting data.

List of Empirically Identified Graphical Forms

Having discussed a few graphical forms in detail in the previous section, in this section, we now present the various graphical forms observed from our students as they created or interpreted graphs (Table 1). We have organized the graphical forms into "clusters" in terms of which forms deal with similar aspects of a graph, such as points or slopes.

Table 1: List of graphical forms, organized into clusters of related graphical aspects (e.g., patterns)

Graphical form	Graphical pattern	Conceptual schema
Point Cluster		
1. Point as instance		A single point on a curve is a single instance
2. Big dot as focal point		A large dot indicates a special instance or event
3. Connecting as transition		Connecting dots transitions from one instance/event to another
4. Open/closed dot pair as existence		The closed dot defines "exists", open dot defines "nonexistence"
Slopes Cluster		
1. Steepness as rate		The steepness of the graph indicates the rate of change
2. Straight means constant rate		A straight line indicates the rate is constant
3. Curve means changing rate		A curving graph indicates the rate is changing
Cardinal Direction Cluster		
1. Horizontal as constant value		Horizontal implies a constant ("*y*") value
2. Vertical as constant value		Vertical implies a constant ("*x*") value
3. Vertical as simultaneous		Vertical means simultaneous "*y*" values at one "*x*" value
4. Running along axis		The more parallel the graph is to one axis implies more change in that axis' variable
Global Trend Cluster		
1. Shape directionality		Up-right means increasing and down-right means decreasing
2. Wavy means variation		Lots of up/down implies a lot of variation
3. Plateau as levelling off		Plateauing means variable is "levelling off" to a stable value
4. Periodic means repeated		A periodic graph means a repeating situation
Smoothness Cluster		
1. Straight lines as idealized		Straight lines give rough approximation of graph segments
2. Curved means realistic		Curved graphs are more "realistic" for real-world quantities
3. Smoothness as strength of relationship		A smoother graph implies a stronger relationship between "*x*" and "*y*" (and vice versa)
4. Jagged implies data		A jagged graph implies it depicts real-world data
Two Graphs Cluster		

1. Intersection means same		Intersection means same values at that instant
2. Transformation as same		Shifting or stretching does not change the basic *x-y* relationship
Local Feature Cluster		
1. "U" as max/min		Top of a hill or bottom of a valley is a max or min
2. Jump discontinuity means sudden		Jump discontinuity implies a very sudden change
3. Cusp as event		A cusp implies an event occurred at that instance
Position Cluster		
1. Distance as value (horizontal or vertical)		The distance from an axis indicates the other variable's value
2. Displacement as difference (horizontal or vertical)		The displacement between points indicates the difference in values

Implications and Conclusion

Building on Sherin's (2001) work related to exploring how students use knowledge resources to reason about equations, our work has detailed many resources students used to reason about graphs. It is important to note that context likely plays an important role in the activation of these graphical forms (diSessa et al., 2016; Elby, 2000; Hammer et al., 2005). Thus, if students were provided different graphical shapes or alternative coordinate systems, we would likely observe additional graphical forms. In this way we do not claim Table 1 to be an exhaustive list of all graphical forms, but we do believe it represents many important forms. Further, additional types of graphing knowledge resources exist that do not fit the strict definition of graphical forms. For example, we also saw students use knowledge about the axes or functions in creating or interpreting graphs. Beliefs about the nature of graphs also were important resources the students drew on (see Hammer et al., 2005; Hammer & Elby, 2003 for more on belief resources). However, the point of this work is to better understand the conceptual schemas coupled with specific graphical patterns (such as steepness or points) that students used in both creating and interpreting graphs. Future work will unpack the additional resources we observed and how graphical forms and these other types of resources worked in concert when students created graphs or interpreted graphs.

Our work has important theoretical and pedagogical implications. Theoretically, we have extended the initial work on graphical forms (Rodriguez et al., 2018, 2019a, 2019b, 2019c, 2020a, 2020b) to an identification of a large set of graphical forms. Such identification allows researchers to see finer-grained aspects of student reasoning when creating or interpreting graphs. It can also help researchers code for these specific knowledge resources when studying students' graphical activity, or in examining how or when specific resources might be used. Pedagogically, our work is useful for instructors in identifying knowledge they may wish to help their students develop or to draw on during in-class graphical activity. It also helps instructors gain insight into the thinking their students might be doing in-the-moment as they interpret graphs or model a situation with a graph. Lastly, our results are important in demonstrating productive knowledge resources that students have and can use to create or interpret graphs. In other words, our work helps show what students can bring to problem-solving tasks in terms of graphical reasoning, rather than focusing on what they lack.

The purpose of this report is to present our process and results for establishing validity and reliability of an observation tool used to investigate teaching practices that high school mathematics teachers use to engage students. We developed our tool using established practices, such as reviewing literature to develop a framework for instruction and piloting the tool to design descriptive levels for rubrics. After validating externally by consulting experts, additional rubrics regarding teaching mathematics for equity were added to the tool. We conducted a reliability study of 149 episodes of classroom instruction (equivalent to 447 10-minute segments of instruction in all), two raters per episode, to investigate the nature of coding disagreements. Most disagreements occurred due to raters noticing different evidence rather than different interpretations of rubrics, which suggested the value of two raters and resolution meetings.

Keywords: Research Methods; Instructional Activities and Practices; High School Education; Affect, Emotion, Beliefs, and Attitudes

A range of observation tools exist to support the study of mathematics instruction that supports students' learning of mathematics (e.g., Bostic et al., 2019; Boston, 2012; Hill et al., 2012; Sawada et al., 2002; Walkowiak et al., 2014). These tools enable researchers to compare teaching practices, such as features of classroom discourse, that align with frameworks for quality instruction. Although these observation tools are well-established and validated, they focus primarily on behaviors that can explain students' learning, such as mathematical task enactment; they do not investigate how mathematics teaching influences students' engagement.

It is important to identify teaching practices that can motivate and engage students in mathematics classrooms, particularly in secondary grades. It has been well documented that students' mathematics engagement decreases over time as they move through levels of education into high school (e.g., Collie et al., 2019). Students' self-efficacy, enjoyment, and sense of the utility of mathematics tends to decrease as they move from elementary school into junior high (Wigfield et al., 1991); this trend continues through high school (Chouinard & Roy, 2008). However, students' motivation and engagement is socially situated and influenced by teachers' instructional practices in the moment (Anderson et al., 2004; Shernoff et al., 2017), so it is important to investigate teaching that supports engagement. The purpose of this paper is to describe the validity and reliability of the observation tool that we developed for the SMiLES project [Secondary Mathematics in-the-moment Longitudinal Engagement Study] to investigate how secondary mathematics teaching may impact students' engagement.

Potentially Engaging Mathematics Instructional Practices

For students to learn mathematics, they must be engaged. We conceptualize engagement in mathematics classrooms as a person's cognitive, affective, behavioral, or social investment in a pedagogically relevant object, such a mathematics task or lesson, as situated in the relationship between the self, the object of engagement, and others in the environment (Middleton, Jansen, & Goldin, 2017). In a study of almost 4,000 middle school and high school students in Western Pennsylvania, higher levels of cognitive, behavioral, emotional, and social engagement predicted students' course grades in mathematics (Wang et al., 2016). According to Greene (2015), it is well-established in prior research that motivation constructs such as students' self-efficacy support students' engagement in ways that lead to learning.

Instruction is likely to support students' engagement when teachers provide students with both *social support* for working together on content and *academic support* for accessing rigorous mathematical content (Shernoff et. al., 2016). Such support can take a variety of forms. *Academic support* may include opportunities for sense-making and reasoning (Stein et al., 1996); opportunities to make conceptual connections (Hiebert & Lefevre, 1986); pressing students to explain their thinking (Engle & Conant, 2002; Kazemi & Stipek, 2001); providing students with specific and detailed feedback (Stipek et al., 1998), opportunities to solve mathematics tasks in context (Koedinger & Nathan, 2004); or some combination of these. *Social support* may include motivational discourse with a focus on learning, positive affect, and encouragement of collaboration with peers (Turner et al., 2002); positioning students as competent (Cohen & Lotan, 1995; Gresalfi et al., 2009); accountability practices in the classroom (Horn, 2017); providing opportunities for student-to-student discourse in whole class discussions (Nathan & Knuth, 2003) or small groups (Fuentes, 2018) in ways that maintain mathematical quality; attention to students' lives outside of school (Yamauchi et al., 2005); or some combination of these teaching practices. Whether these supports can foster students' mathematical engagement remains at the level of conjecture, and an observation tool could explore this conjecture.

Development Process and Use of our Observation Tool

The SMiLES project's observation tool measures the extent to which potentially engaging teaching practices are present in a lesson. The tool does not establish whether instruction was engaging for students. Student engagement in observed lessons was assessed by an in-the-moment student survey using Experience Sampling Methodology (Jansen et al., 2019; Schiefele & Csikszentmihalyi, 1995).

The final version of the tool includes fifteen rubrics to assess eight dimensions of academic support and seven dimensions of social support. Rubrics designed for academic support measured students' opportunities for sense making and reasoning, connections between representations or strategies, pressing students to explain, contexts of tasks, mathematical correctness, mathematics language use, feedback, and students' opportunities for agency and autonomy. Social support rubrics assessed whole class discourse, small group discourse, status raising and positioning students as competent, motivational discourse, enthusiasm about mathematics, attention to students' lives, and accountability and high expectations. We defined each dimension with descriptive levels. Each dimension was scored on a four-point rubric with points (0-3) assigned to index each level: absence or the opposite of ideal enactment (0), weak level of enactment (1), moderate level of enactment (2), and strong level of enactment (3). Each rubric included a definition of the teaching practice, and we defined the observable indicators for each level of enactment. We share an example observation rubric below in Figure 1.

Social Support 6: Attention to Students' Lives

This rubric captures the degree to which the teacher attempts to connect with students' lives while teaching.

Strongly Present (3)	The teacher speaks about more than one example of cultural events or outside of school events during instruction OR talks with multiple students about aspects of their lives outside of school or mathematics class in ways that are *incorporated into instruction.*
Moderately Present (2)	The teacher speaks about one example of cultural events or outside of school events during instruction OR talks with one student about aspects of their lives outside of school or mathematics class in ways that are *incorporated into instruction.*
Minimally Present (1)	The teacher mentions cultural events, outside of school events, or other information personal to any students during class, but does not incorporate it into instruction.
Not Present (0)	The teacher does not mention/discuss anything personal to students during instruction.

Figure 1: Rubric for teachers' efforts to attend to students' lives

The SMiLES project's observation tool is designed to investigate potentially engaging teaching practices during an activity within a lesson. Before each classroom observation, we asked teachers to complete an online form in which they would nominate a potentially engaging activity that would take place within the lesson. Members of our research team video-recorded the entire class period, with a particular focus on these activities, which ranged from roughly 10 to 45 minutes with a median length of 30 minutes. These teacher-selected potentially engaging instructional activities lasted between 9 minutes and 40 seconds and 45 minutes and 40 seconds, with a median length of 29 minutes and 42 seconds.

We applied the observation tool rubrics to the video recorded activities in 10-minute segments. If the last segment was under three minutes, it was not rated. Each 10-minute segment in an episode was individually rated by two coders on the research team, who then met to resolve disagreements in scoring. Coders resolved disagreements in their segment ratings for each rubric by describing the observed behavior they used as evidence when scoring and how they interpreted that behavior within the framework of a rubric. Resolved scores for each segment were assigned. Episode scores were determined by averaging the resolved segment scores for each rubric.

To calibrate rating criteria and to address potential coding drift, all observation team members met at least once per academic semester to train for rating consistency with the observation tool and to resolve any outstanding questions that had arisen during the resolution procedures. Training involved all raters coding the same episode independently and meeting to resolve disagreements as a team. Orientation to the coding concepts also included reading and discussing relevant literature as a team (e.g., Middleton, Jansen, & Goldin, 2017).

Research questions. This report consists of two studies that respectively illustrate the validity and reliability processes used for the SMiLES project's observation tool. These studies answer two research questions:

1. Validity study: To what degree did the rubrics in the observation tool align with appropriate phenomena (instructional practices that promote mathematical engagement)?

2. Reliability study: To what extent did raters in our research team reach agreement when rating observation episodes? When there was initial disagreement, what explained lack of agreement?

Method: Participants and Context

The SMiLES project team collected classroom observation data from 29 secondary mathematics teachers' lessons in two U.S. states. Sixteen of these teachers taught in a mid-Atlantic state and 13 taught in a southwestern state. Twenty-one teachers were female and eight were male. The teachers also represented a variety of racial and ethnic backgrounds, with 22 teachers identifying as white, two identifying as Black, two identifying as Latinx, and one each identifying as Asian, Black/Hispanic, and White/Asian. The teachers worked with a diverse student population. In the Mid-Atlantic, the schools' demographics ranged from 12-34% low income, 25-60% white, 27-47% Black, and 6-21% Latinx. In the Southwest, the schools' demographics ranged from 76-94% low income, 1-6% white, 1-16% Black, and 77-96% Latinx. We targeted courses at the equivalent of on-grade level mathematics for ninth and tenth grade students, which included topics-based courses in the southwestern U.S. (Algebra I, Geometry) and integrated courses in the mid-Atlantic (Integrated Math [IM] 1, IM 2, IM 3). Each class period was observed two or three times during a course. A course was either one semester (if on block scheduling, such as schools in the mid-Atlantic) or a full academic year (southwest schools). The reliability study was conducted on a subset of these data.

Validity Study

Procedures

Characterizing teaching is a qualitative practice, and we conceptualize validity as multifaceted in qualitative work. Hayashi et al., (2019) present a variety of validity frameworks for qualitative work, including the following: *Descriptive validity* concerns the ability of the report of an event to faithfully record its important features. The interdependence of observations and the descriptions of those observations must be developed from theory. *Interpretive validity* concerns the ability of the tool to help the researcher construct the meaning of the events and the behaviors of the people engaged in those events. *Theoretical validity* refers to the consistency of the analytic coding and the theoretical argument that is constructed. It is thus concerned with the truth of the concepts and classifications developed in the analysis, and the ways in which the concepts and classifications interrelate in the abstraction of the event to the (nascent or developing) theory. *Validity generalization* refers to the ability of the method to be used in other situations, times, and places. For an instrument such ours, its descriptive and interpretive frameworks and its theoretical validity should be applicable in a new context.

Our first step toward internal conceptual validity was to operationalize the construct of engaging secondary mathematics instruction grounded in a theoretical frame from research literature (theoretical validity). This framework was developed by two researchers with expertise both in mathematics teaching and learning from mathematics education and motivation and engagement from educational psychology. For rubric development, we then translated the theoretical framework into descriptive rubric levels for each teaching practice. To internally examine construct validity in the rubrics, the entire research team (composed of graduate students and faculty with expertise in mathematics education or psychology) met multiple times to discuss whether and how these levels reflected the desired teaching practices and whether the descriptions were observable and amended accordingly.

We then piloted the tool by rating publicly available video from the TIMSS video study [http://www.timssvideo.com/] (descriptive validity). This pilot study involved all members of the research team rating the same two videos using the rubrics. The team met as a whole group to compare and contrast their ratings. Disagreements were discussed and the levels of enactment for each rubric were then specified further. A rubric to describe the nature of teacher feedback was added to reflect this teaching practice as a result of piloting.

To externally examine construct validity of the observation tool rubrics and individual rubric levels, we shared the observation tool with an expert panel, the SMiLES project's advisory board, which consisted of experts in educational psychology and mathematics education (interpretive and theoretical validity). All of the researchers in the advisory board had studied mathematics or science engagement in the context of learning environments, and they had all developed methods for studying teaching practices that support students' engagement. The results of the validity study reflected the team's learning from the expert panel.

Results

We initially generated twelve dimensions or rubrics based on our review of the research literature, and the expert review panel for our validity process led to three new rubrics. At the team's first advisory board meeting, three months into the three-year project, we shared the first draft of the observation codebook. The draft reflected a review of the literature, internal construct validity meetings, and revisions to the codebook after piloting it. Advisory board members then suggested additional rubrics that supported equity in mathematics teaching and learning.

As a result of external feedback, we revised the observation tool to reflect a broader conceptualization of equity in potentially engaging mathematics teaching (interpretive validity). In our initial rubrics, we approached equity primarily as access by writing rubrics that measured opportunities for students to experience sense making and reasoning, connections, tasks in context, and other aspects of high-quality mathematics instruction. We acknowledged that access is only one dimension of equity (Gutiérrez, 2002). Some of these rubrics were more closely aligned with supporting students' identities.

We added three rubrics related to promoting equity in mathematics teaching after feedback from our advisory board, resulting in 15 rubrics in all. We added a rubric about *attention to students' lives* in mathematics teaching (see Figure 1) (Yamauchi et al., 2005). Attention to students' lives could align with identities as students could begin to see themselves reflected in mathematics. We also added an *accountability* rubric to examine whether and how teachers held students to high expectations, acknowledging that high expectations are necessary but not sufficient to achieve equity (Lubienski, 2002). One final rubric was added after the pilot year of data analysis: *student enactments of agency and autonomy.* Our initial rubrics did not appear to capture the opportunities that students had to exhibit control over their own learning (Kosko, 2016). Opportunities to enact agency are chances for students to develop productive mathematics identities (Gresalfi et al., 2009).

Reliability Study

Data Sources

To investigate whether and how our rubrics could be applied consistently across raters, we conducted a reliability study of the analysis of 149 video-recorded episodes of teacher-selected potentially engaging activities. Each of these observation episodes was rated by two analysts. We dispersed resolution assignments to ensure that duplicate pairs of raters were minimized. Across the 11 raters who were on the team at any point from 2018-2020, 43 unique pairs of raters were assigned to resolve scores. The most resolutions shared by any single pairing was 19 episodes.

The resolution process began with both raters independently scoring each 10-minute segment of the observation video across each of the 15 rubrics in the observation tool. Every score was justified by documentation of evidence from the recorded observation, including timestamps. Raters then met to discuss any discrepancies in their initial ratings and to resolve the scores for each segment. This resulted in resolved scores for each rubric by segment, as well as episodic scores which were the average of resolved segment scores for each rubric. Every observation which was coded involved this resolution process; no episode was analyzed by a single rater.

During the final round of observation resolutions, raters also identified the nature of any initial disagreement in their individual scores to better understand the reliability of the observation tool. They identified whether any initial disagreement was the result of one rater noticing additional evidence in the video (resulting in a higher or lower score) or whether the initial disagreement was the result of conceptual differences between the raters with regards to the rubrics themselves (i.e., the same evidence was given different ratings).

Analysis Procedures

Following paired ratings, the Intraclass Correlation Coefficient (ICC) for each rubric was computed to examine the reliability of initial ratings *prior* to the resolution process. An excellent ICC, or a value greater than 0.9 (Portney & Watkins, 2000), could indicate that the resolution process was unnecessary (i.e., raters almost always agreed on the rubrics in their initial ratings). In contrast, a poor ICC of less than 0.5 (Portney & Watkins, 2000) suggests value in resolving.

The ICC used to determine reliability was a 2-way random effects model. Initial segment ratings were converted to a "low" and "high" score depending on how the two initial raters scored each rubric (low and high scores would be the same value when the initial scores were the same). In total 447 segments were analyzed for the ICC.

Table 1: Reliability Statistics (Absolute Agreement)

Academic Support Instruction Rubrics	Intraclass Correlation (Average Measures)	Social Support Instruction Rubrics	Intraclass Correlation (Average Measures)
AS1: Sense-making & reasoning	.618	SS1: Whole-class discourse	.809
AS2: Connections: representations & strategies	.602	SS2: Small-group discourse	.737
AS3: Pressing students to explain	.661	SS3: Status-raising / positioning students	.675
AS4: Context of tasks	.879	SS4: Motivational discourse	.581
AS5: Mathematical correctness	.378	SS5: Enthusiasm about mathematics	.524
AS6: Mathematical language precision	.548	SS6: Attention to students' lives	.476
AS7: Feedback	.530	SS7: Accountability & high expectations	.505
AS8: Agency and autonomy	.620		

Note: N = 447

The initial rubric scores held an ICC of between .378 and .879, with an average of .610 (Table 1). Two rubrics (*mathematical correctness* and *attention to students' lives*) had poor reliability (.378 and .476, respectively). The remaining rubrics had moderate reliability of between 0.5 and 0.75 except for AS4 (*context of tasks*) and SS1 (*whole-class discourse*) which had good reliability (.879 and .809, respectively). Recall that ICCs were calculated based on initial ratings, prior to resolution meetings.

The relatively low ICC values for the majority of the scales indicated a need for some process of resolution. This led to three important questions: 1) Was a resolution meeting necessary, wherein the source of discrepancy and its nature are discussed, when the mean of the raters' initial scores could suffice?; 2) In instances when raters' initial scores differed, what was the magnitude of the discrepancy?; and 3) Regarding the nature of disagreements, did disagreements reflect attention to different evidence or disagreements about interpreting the rubric?

To address the first question, the differences between the mean of raters' initial scores and the final resolution score were analyzed for instances when initial agreement was not achieved. While individual differences would be expected here, in the aggregate such differences would balance out if the resolution meetings held no consistent sway on the resolved score--i.e., if the discrepancy were random error. The second question was answered by looking at the magnitude of any initial disagreements - describing whether these disagreements were mostly of a single rubric point or whether they represented greater disagreement among raters.

To answer the third question, raters were asked to describe the nature of any initial disagreements with observations resolved in the Spring of 2020 onward. This resulted in such data for 70 different segments, or 1,050 resolved scores spread across the 15 rubrics. For each rubric in every segment where there was a disagreement, raters identified whether this resulted from individuals observing the same evidence and rating it differently or whether different raters identified different aspects of the same phenomenon resulting in different initial scores.

Results

The most frequent outcome for resolutions was an increase of 0.5 relative to the mean of the initial scores for each rubric. The exception to this was *mathematical correctness*, which most frequently dropped 0.5 points and *accountability and high expectations* which most frequently resolved to the initial mean. The most common difference in initial ratings was 1, which held true for every rubric in the observation tool. Together these results show that, when disagreements occurred, they tended to be minor and the resolution discussions tended to result in agreement on the higher score (e.g., initial scores of 1 and 2, with a mean of 1.5, would be expected to resolve to a 2).

Within the 1,050 resolution scores analyzed to understand the nature of such disagreements, 405 initial disagreements occurred. Among these, 60 (15%) occurred when raters observed the same evidence but still initially disagreed on their rating and 346 (85%) occurred when raters observed different evidence which influenced their initial scores. The fewest disagreements arose for *whole-class discourse* (8, with 0 for same evidence and 8 for different evidence) and the most arose for *connections with representations and strategies* (40, with 4 for same evidence and 36 for different evidence).

Discussion

Our process of establishing validity suggests that the SMiLES project's observation tool has potential for measuring mathematics instructional practices that are potentially engaging for secondary students. The rubrics align with prior research about engaging mathematics instruction, as suggested from both internal and external conceptual validity investigations. This tool offers a set of rubrics that differs from existing observational tools designed to investigate high quality mathematics instruction for supporting students' learning.

Our external validity study afforded an opportunity to reflect on mathematics teaching for equity in relation to mathematics engagement. Although access to high quality mathematics instruction is important for equitable teaching and learning, it is a limited conception of equity. We revised our observation tool to capture how teaching could potentially support development of students' identities to address another dimension of equity (Gutiérrez, 2002).

Regarding reliability, the moderate to good ICCs for all but two of the rubrics showed general agreement of raters prior to resolution meetings, but not to an extent that would justify removing the resolution meetings from the observation analysis process. When disagreements did arise, they were typically minor but still afforded valuable insight when resolving scores. In some cases (~15%) the coders had conceptual differences in understanding mutually observed evidence, but in most cases (~85%) one coder had captured additional evidence which strengthened the justification of the final, resolved score.

Such results support the original intention of the resolution meetings as a way to ensure that various manifestations of these instructional supports are actually captured from the data. The data was not just "double coded" and averaged by the research team, but rather every single rubric score was discussed and agreed upon. Conceptual differences were thus addressed continually as they arose in the data, and coders had opportunities to gauge the *sum* of their evidence before committing to a rating. Since resolved ratings trended higher than the mean of the initial ratings, this could indicate that these meetings uncovered more evidence of potentially engaging mathematical instructional practices than otherwise would have been revealed.

Reliability training and double coding are valuable tools for qualitative research, but they do not transform qualitative analysis into an automated endeavor. The SMiLES project's resolution process identified one way in which the human capital of a research team can be utilized to strengthen analysis and more reliably capture relevant findings. Through this approach, disagreements are not a source of alarm but rather an opportunity to strengthen the foundation of the work itself. Initial ratings are not immutable but rather subject to interpretation and revision. Through this process, the complex nature of these engaging mathematical instructional practices – and, in turn, the work of these educators endeavoring to make them a reality – is better recognized.

The SMiLES project's observation tool demonstrates promise for investigating the presence and quality of potentially engaging instructional practices. The process we used when enacting the process of double coding provided a powerful approach for assessing instruction thoroughly. Events in a classroom are complex, and our research team found it helpful to have more than one coder noticing events that could be relevant. With this tool and this analytic process, perhaps the field can go further to understand how mathematics teaching can engage secondary students.

A CONCEPTUAL SYNTHESIS ON APPROXIMATIONS OF PRACTICE

Approximations of practice create valuable opportunities for preservice teachers (PSTs) by engaging them in components of teaching. By reviewing the literature, this study explored PSTs' learning through approximations and the extent approximated practices preserve the complexity – or authenticity – of teaching. A review of 25 empirical studies related to approximations of mathematics teaching indicated that mathematics teacher educators are currently exploring an expansion of opportunities through approximations wherein PSTs could experience a higher degree of authenticity. The existing conceptualization of authenticity emphasizes the complexity of practices but overlooks how approximated practices prepare PSTs for their future teaching. An alternative definition is proposed for the emerging conceptualization of authenticity to highlight how PSTs' learning through approximations prepares them for their future teaching.

Keywords: Preservice teacher education, Instructional activities and practices, Approximations of practice, Authenticity

An effective mathematics teacher education program provides preservice teachers (PSTs) with opportunities to gain practice-based experiences and develop core pedagogical practices for teaching mathematics (Association of Mathematics Teacher Educators [AMTE], 2017). PSTs often gain such practice-based experiences by engaging in *approximations of practice* (referred to as "approximations"), which represent an opportunity for PSTs to engage in aspects of practice with additional support in order to develop their professional teaching skills such as leading classroom discussions, posing purposeful questions, developing lesson plans, etc. (Grossman et al., 2009; Schutz et al., 2018). Research has indicated these approximations are often simplified versions of actual classroom teaching because they: (a) are often enacted in teacher education settings, which cannot fully reflect social and cultural aspects of school contexts: (b) often include only some components of teaching, and (c) are usually enacted with scaffolding (Janssen et al., 2015; Tyminski et al., 2014). Thus, mathematics teacher educators have cautioned that approximations do not preserve the complexity of actual practices and are not necessarily authentic (Grossman et al., 2009). These conceptualizations suggest the following three dimensions in which to measure authenticity: context/setting of practice, nature of practices (e.g., decomposed practices vs. full practices), and scaffolding in practices. These three dimensions are utilized to explore the authenticity of approximations in this paper. While the literature has shown that approximations are valuable for PSTs' learning, the extent to which those approximations prepare PSTs for addressing the improvisational and interactional nature of teaching (Hunter et al., 2015) is still underexplored. Therefore, mathematics teacher education literature was synthesized to explore how approximations of practice create opportunities for developing PSTs' teaching skills and how teacher education programs conceptualize and practice authenticity during approximations. The following research questions guided this study:

1. What teaching practices have been used in approximations-based instructional activities?
2. What influences did approximations of practice have on PSTs' learning to develop their practices?

3. To what extent were the approximated practices authentic?

Perspectives

This study is grounded on the practice-based approaches to teacher education and the concept of authenticity in approximations. In recent decades, many mathematics teacher education programs have been designing and implementing instructional activities that provide PSTs with opportunities to engage in aspects of teaching practice (Ball & Cohen, 1999; Zeichner, 2012). Such instructional activities are usually referred to as approximations of practice (Grossman et al., 2009). The actual practices are assembled during approximations either by including only some aspects of practices and/or by providing PSTs with scaffolding; and thus, approximations usually have reduced complexity of teaching (Tyminski et al., 2014). Because of the reduced complexity, educators have stated limitations of the practice-based education and approximations (Zeichner, 2012). As such, simplified practices pose a risk of creating technicians who can only apply sets of routine skills but struggle to adapt them to the school context. To address these limitations, there is an ongoing discussion around how the authenticity in approximations should be conceptualized and practiced. Teacher educators primarily have two perspectives about when and how the complexity of practices should be adjusted during approximations. From one perspective, educators argued that it can be overwhelming for PSTs to begin their teaching with complex practices, necessitating a reduction of the complexity of teaching at the beginning phases of practices (e.g., Bannister et al., 2018; Klein & Taylor, 2017). Klein and Taylor (2017) mentioned that approximations should provide PSTs with opportunities to practice in a context that is different from the natural context as it has reduced complexity. Other educators have argued that simplified practices pose the risk of creating routinely inauthentic practices, and these practices might not be transferable to school contexts (e.g., Campbell & Elliott, 2015).

This discussion about complexity suggests that authenticity is related to the complexity of teaching. Educators have discussed the dimensions of authenticity in several ways. Grossman et al. (2009) proposed the approximations that (a) have less support (scaffolding), (b) are integrated (not decomposed), and (c) have a similar setting to actual classrooms are more authentic than the approximations which involve more support from educators and involve only some components of teaching. Campbell et al. (2020) mentioned that the location of approximations (university classrooms or school classrooms), students who participated in approximations (peers or students), and teacher educator's roles (providing scaffolding or not) would determine the degree of authenticity. Tyminski et al. (2014) and Janssen et al. (2015) also defined authenticity along the continuum of three dimensions: whether or not the practice is decomposed; what the contexts of practice are; and whether or not teachers provided with scaffolding. Based on these definitions, the following dimensions of authenticity are selected: decomposition of practice, setting/context of the practice, and scaffolding.

Decomposition of Practice

Decomposition of practice indicates breaking down the practice into small components to assist PSTs to learn those small portions of practice (Grossman et al., 2009). For example, PSTs may engage in responding to students' thinking, which is only one component of the practice of teacher noticing. In the studies related to approximations, educators often engage PSTs in some components of practices. For instance, Trent (2013) listed some components of teaching that PSTs engaged in: selecting tasks, organizing students for peer or group work, learning to provide feedback to students. One way to decompose the practice is to make small components of practices in a way that PSTs would be able to master practices on those modules (Grossman et al., 2009; Janssen et al., 2015). However, educators (e.g., Campbell & Elliott, 2015; Trent, 2013) have challenged PSTs might not automatically be able to recompose those decomposed practices into complex practices. Since teaching is both improvisational and interactional that is based on students' thinking (Hunter et al., 2015), how those decomposed practices prepare PSTs for teaching is still researchable. Therefore, how the current studies related to approximations are utilizing decomposition in their studies is a focus of this investigation.

Setting or Context of the Practice

The second dimension of approximations—settings— refers to the contexts where the practice is situated. Authenticity is associated not only with the decomposition of practice but also with the setting or context of practice (Campbell et al., 2020). McDonald et al. (2013) defined the school setting where teachers and/or PSTs have opportunities to engage in the full practice as authentic settings and the one where PSTs have restrictions to conduct activities are considered as controlled or designed settings. Since the university-level course setting (i.e., methods course) is different from the actual setting, approximations might lead to the divide between theory and practice (Grossman et al, 2009). Thus, teacher educators have been trying to replicate the social and cultural complexities of actual practices in the university-level setting through approximations (Codreanu et al., 2020). There are some efforts to include responsive teaching in approximations. For example, Campbell et al. (2020) included planted students' errors and asked PSTs to respond to those errors. In this study, how the literature related to approximations have negotiated the difference between university-course settings and actual classroom settings is explored; the factors that the approximation-based literature has highlighted to replicate the social and cultural complexities of the mathematics classrooms are explored.

Scaffolding

Scaffolding during approximations refers to supports that PSTs receive to improve their teaching practices. Since teachers often enact practices independently and do not receive feedback during teaching, the extent to which PSTs receive scaffolding differentiates the approximations from the actual teaching (Grossman et al., 2009). The feedback given to PSTs could impact what they focus on during approximations. Some approximations are more loosely constrained than others. When PSTs have options to choose and approximate the whole practice, it is a loosely constrained approximation (Kavanagh et al., 2020). This study explores several forms of scaffolding and their possible influences in PSTs' learning.

Methods

A conceptual synthesis method was employed to explore the primary concepts and discussions related to approximations (Petticrew & Roberts, 2008). First, inclusion and exclusion criteria were established to identify the literature, which was the data for the study. The literature was then analyzed through top-down and bottom-up interactive modes of analysis (Chi, 1997).

Data Source: Literature Search Procedures

Twenty-five articles were identified as involving approximations of practice with PSTs. The first round of the literature search involved Key Word Processes Search (Depaepe et al., 2013). Two key phrases of, "approximations of practice" and "math," were used to search the literature in Education Resources Information Centre (ERIC) and PsycInfo, which produced a total of 32 results. This number was narrowed down to 13 by eliminating dissertations, non-peer-reviewed journals, conference proceedings, and/or book chapters. Only empirical peer-reviewed journal articles were included in the study because the aim was to understand and analyze (a) how researchers have utilized approximations in teacher education programs, (b) what specific teaching skills PSTs developed by engaging in those approximations, and (c) what challenges are associated with the development of teaching skills. The second-round search involved a Journal Search Method. Articles were selected from *Journal of Mathematics Teacher Education* (JMTE), as it was the sixth most-cited journal in the field of mathematics education in 2017 (Williams & Leatham, 2017) and because it publishes empirical research around teacher education and teacher development. All published issues from the beginning of 2017 to 2020 were accessed to search the relevant articles from the journal. Using the inclusion and exclusion criteria described above, 12 articles were selected. The 25 articles can be found in the reference section of this paper.

Analysis of the Selected Literature

The interactive nature of the top-down and bottom-up approach (Chi, 1997) was utilized to code the articles; by considering one case as each article, teaching practices used in the study, teacher learning from approximations, and dimensions of authenticity were summarized. To answer the first and second research questions related to teaching practices involved in approximations and their influences on PSTs learning, a bottom up approach was utilized; the practices involved in approximations and major findings of each study were summarized. The three already identified dimensions of authenticity (a top-down approach) were used to answer the third research question of exploring authenticity in approximations. Once codes were identified collaboratively, researchers independently coded about 30% of the initially identified articles to calibrate initial coding at the beginning, including the identification of new codes, and any discrepancies between coding (i.e., a bottom-up approach). For example, "analyzing and reflecting on teaching" was a new code identified during independent coding, which was not in the initial sets of codes and was later added to the set of codes.

Findings and Discussions

This section is organized by research questions. Findings for the first, second, and third research questions are answered for the first, second, and third research questions, respectively.

Practices Used in Approximations-Based Instructional Activities

Research indicated the following five primary teaching practices used in the literature related to approximations: curriculum enactment (e.g., Earnest & Amador, 2019; Santagata & Yeh, 2014); eliciting, interpreting, and responding to student thinking (e.g., Bailey & Taylor, 2015; Webel & Conner, 2017); teacher professional noticing (e.g., Amador et al., 2016; McDuffie et al., 2014); organizing classroom discussions (e.g., Ghousseini & Herbst, 2016; Weston et al., 2018); and analyzing and reflecting on teaching (e.g., Auslander et al., 2020; Cooper et al., 2020; Kinser-Traut & Turner, 2018). In almost half of the research reports (13 out of 25 research studies), PSTs were engaged in two or more practices. In particular, the studies that explicitly focused on the teacher noticing and classroom discussion also included the practice of eliciting, interpreting, and responding to student thinking. In the noticing-related literature, researchers broadly assessed which aspects of classroom events (i.e., teacher actions vs. student actions) PSTs attended to and how they responded to those events, including how PSTs attended to and interpreted students' mathematical thinking. For example, Schack et al. (2013) explored the extent to which PSTs noticed students' equitable practices of mathematical learning, which included students' competencies related to mathematical thinking.

The literature indicated that in the approximations related to teacher noticing, PSTs often engaged in the components of noticing, including attending to, interpreting, and responding to student thinking. Some studies that focused primarily on leading classroom discussion involved the practice of eliciting, interpreting, and responding to student thinking. Ghousseini and Herbst (2016) focused on the practice of leading classroom discussions and included interpreting student thinking. Thus, the practice of eliciting, interpreting, and responding to student thinking was the most highlighted practice in the literature related to approximations. Another highlighted practice through approximations was analyzing and reflecting on teaching. PSTs analyzed their own and their peers' teaching to develop reflective practices. Reflective practices include teachers' ability to identify and analyze aspects of classroom actions (e.g., task posing) in which instruction is successful and other areas which they need improvement (Alsawaie & Alghazo, 2010). For example, PSTs reflected on teaching by analyzing classroom practices (Kinser-Traut & Turner, 2018) and by discussing their experiences of sequencing learning activities (Cooper et al., 2020).

Some studies did not explicitly emphasize specific practices; they focused broadly on curriculum enactment without highlighting one or more practices. In these studies, PSTs planned and taught lessons (or parts of lessons) either in a virtual classroom setting (e.g., video simulations; Amador et al., 2016) or in a real classroom setting. For example, in Earnest and Amador (2019), PSTs planned a lesson and enacted the first five minutes of their lessons through the given animation, indicating this approximation did not focus on only one teaching practice.

Types of approximations used to develop practices. Researchers from the identified articles primarily used two mediums of approximations: virtual mediums and role play. Virtual mediums often included enacting lessons using simulation tools (e.g., Earnest & Amador, 2019; Weston et al., 2018) and/or interacting with virtual student characters (Bannister et al., 2018; Webel & Conner, 2017). Role play involved rehearsals of one or more components of teaching, and PSTs rehearsed teaching either with their peers or during field teaching. For instance, in Tyminski et al. (2014), PSTs practiced teacher questioning with their peers in a teacher education classroom setting, while in Santagata and Yeh (2014), PSTs rehearsed teaching in a school setting. PSTs typically used role-playing or simulated classroom scenes to communicate what they noticed or to demonstrate their anticipated student responses with virtual mediums. Estapa et al. (2018) had PSTs use animated software to represent pivotal classroom moments that they noticed from a video lesson. PSTs also engaged in eliciting, interpreting, and responding to student thinking through both role-play and simulations. For instance, in Schack et al. (2013), PSTs interpreted and discussed diagnostic interviews as well as practiced diagnostic interviews (role play) to interpret and respond to student thinking. PSTs often engaged in leading classroom discussion through role-play with their peers. In Ghousseini and Herbst (2016), PSTs chose mathematical tasks that called for reasoning and communication, led classroom discussions in a constructed classroom dialogue, and practiced leading discussions during their field teaching.

PSTs' Learning Through Approximations

The literature revealed that approximations of practice afforded PSTs opportunities for understanding and enacting aspects of practices in a scenario simulating a classroom context. For instance, Campbell and Elliott (2015) mentioned that PSTs identified actual learning goals while role-playing leading classroom discussions. Earnest and Amador (2019) discussed that their approximated practices prepared PSTs for using the curriculum to design instructions; however, those practices could not prepare PSTs for how to select specific materials in their classes. PSTs conceptualized and applied some dimensions of equitable and responsive teaching after they engaged in approximations of responsive and equitable teaching. In responsive teaching, "teachers' instructional decisions about what to pursue and how to pursue are continuously adjusted during instruction in response to children's content-specific thinking" (Jacobs &

Empson, 2016, p. 185). For instance, in Bannister et al. (2018), PSTs began to focus on students' strengths rather than their deficit perspective as they engaged in approximated practices related to deficit thinking. Initially, PSTs highlighted students' mistakes and problems and defined those mistakes as problems, while PSTs began interpreting those mistakes as learning opportunities at the end. PSTs learned to attend to students' thinking and pose tasks to respond to student thinking from approximations (Estapa et al., 2018), suggesting that approximations contributed to cultivating PSTs' ability to develop responsive teaching.

Researchers claimed that approximations related to simulations also prepare PSTs for responsive teaching. PSTs often need to predict both teachers' and students' roles when creating classroom scenes using simulations (Amador, 2017; Schack et al., 2013). For instance, in Earnest and Amador (2019), PSTs created a classroom scene wherein they selected speech bubbles by anticipating students' responses to their questions, requiring them to predict and respond to student thinking. Similarly, in Amador et al. (2016), PSTs anticipated their students' responses and planned for how they would respond to those students. The findings from these research reports indicated that these virtual tools encouraged PSTs to anticipate and analyze students' thinking and specific responses, indicating that the approximations related to virtual simulations also prepared PSTs, to some extent, for responsive teaching (e.g., de Araujo et al., 2015).

These findings indicated that PSTs' learning through approximations was reported in terms of which practices PSTs developed at the end of approximations. Indeed, there was less attention to the extent PSTs are able to transfer the practices learned from approximations to their teaching. For instance, teacher educators have been exploring how PSTs develop noticing skills by comparing what PSTs notice at the beginning and at the end of approximations. Thus, there is a less attention in the literature on how PSTs possibly apply noticing skills in their future teaching. Since approximations have often different settings than the real practices, PSTs' learning at the end of approximations does not necessarily suggest they can improvise the learning in their actual teaching.

Degree of Authenticity in Approximations of Practices

The earlier defined dimensions (decomposition, setting, and scaffolding) were used to explore authenticity in approximations.

Decomposed vs. full practices. A review of the literature suggested the following three types of decompositions in approximations: (a) focused on only some components of a practice throughout the study, (b) began with a component of practice and gradually added more components, and (c) engaged PSTs in full practices without decomposition. The first category of studies focused on only some components of practice throughout practice enactment sessions. For instance, in Bannister et al. (2018), PSTs engaged in learning to notice students' strengths rather than their deficit thinking, which is a component of teacher professional noticing. The second category of studies decomposed a practice into small components by engaging PSTs in one component of practice at a time. For instance, in Estapa et al. (2018), PSTs engaged in a core practice of teacher noticing at the beginning by having PSTs practice only one component of teacher professional noticing, namely attending to classroom events. After a time, PSTs explained what they *attended to* and how they would *respond to* those events. The third category did not decompose practices; they provided PSTs with opportunities to engage in a full practice (e.g., teacher noticing) or in planning and enacting lessons. In Earnest and Amador (2019), PSTs planned and enacted a lesson using simulation technology.

As discussed, some studies provided opportunities for PSTs to engage in recomposed practices at the end of approximations. In the process of recomposition, several components of practices are combined together; thus, recomposed practices are more complex than decomposed practices (Janssen et al., 2015). Even though PSTs engaged in both decomposed and recomposed practices in some studies, they did not have opportunities to learn the ways to recompose practices. Thus, PSTs may not have learned skills of improvising decomposed practices during their teaching. Further, the literature does not suggest which kinds of decomposition is more beneficial in developing PSTs' teaching skills. Consequently, the decomposed practices without concrete ways of recomposition might pose a risk of creating a boundary between teacher education programs and school contexts because PSTs cannot experience the social and cultural complexities of school contexts (Grossman et al., 2009; Campbell & Elliot; 2015).

Less authentic vs. more authentic setting. As defined in the literature, a factor determining the degree of authenticity is the extent to which the context of an approximation is similar to a school classroom setting. The literature suggested that PSTs engaged in the practice of teaching in three different settings: simulated environments (e.g., Amador et al., 2016; Webel & Conner, 2017), teacher education classrooms (e.g., Lampert et al., 2013; McDuffie et al., 2014), and school classrooms (e.g., Santagata & Yeh, 2014; Schack et al., 2013). PSTs often enacted lessons either in a simulated environment or in their classrooms; PSTs considered their peers and/or virtual student characters as their students, suggesting that PSTs could not experience student interactions with the social and cultural complexities of classrooms through approximations.

Researchers (e.g., Janssen et al., 2015) identified simulated environments as less authentic than PSTs' classroom contexts. They claimed that simulated environments do not necessarily preserve the complexity of teaching as PSTs have limited opportunities to develop skills to make moment-to-moment decisions and to respond to their students in real-time while creating animated classroom scenes (e.g., de Araujo et al., 2015). The studies involving role play claimed that they preserved authenticity by engaging PSTs in tasks that were similar to tasks they would do in school settings. For instance, Tyminski et al. (2014) claimed that PSTs were asked to consider and write authentic students' problem-solving strategies. However, in both simulations and in role play, PSTs could not experience ways of understanding and responding to students' cultural and social backgrounds. While the literature has indicated several approximations that provided PSTs with opportunities to practice anticipating and responding to students' thinking, the literature does not suggest how simulated virtual environments and teacher education classrooms prepare PSTs for the social and cultural complexities of school settings.

Scaffolded vs. independent enactment. The literature indicated that PSTs were scaffolded in different ways and in different times (before, after, and/or during lesson enactment). Scaffolding was provided in the form of specific frameworks/protocols, constructed dialogues, instructor-modeled activities, instructor or peer feedback, and lectures and tutorials. For instance, in McDuffie et al. (2014), PSTs were given noticing lenses (i.e., teaching, learning, task, power, and participation lens) to develop their noticing skills. In Ghousseini and Herbst (2016), teacher educators used constructed dialogues and asked PSTs to fill in the portions that were removed from those dialogues. In Bailey and Taylor (2015), teacher educators modeled problem posing in order to enhance PSTs' abilities to elicit and interpret students' thinking. In Leavy and Hourigan, PSTs were given lectures and tutorials on problem-posing skills. Overall, PSTs were scaffolded during approximations, and there were several forms of scaffolding. Since teachers are required to make most instructional decisions individually and independently, scaffolded practices are considered to be less authentic than independently enacted practices (Janssen et al., 2015).

Conclusion

As previously mentioned, eliciting, interpreting, and responding to student thinking was the most highlighted practice in approximations, suggesting that teacher educators attempted to prepare PSTs for responsive teaching through approximations. To develop this practice, PSTs were engaged with their peers, students' work samples, and planted students' errors. Review of the literature also suggested that PSTs' learning from approximations were explained in terms of what PSTs learned at the end of approximations. One example of such learning is the gain in PSTs' skills to respond to students' thinking at the end of approximations (Monson et al., 2020). Since teaching is both improvisational and interactional, which is based on students' thinking (Hunter et al., 2015), how these learned skills prepare PSTs for their actual teaching is a critical aspect of PSTs' learning through approximations. Yet, there is less attention on the literature about to what extent PSTs are able to improvise their responsive teaching skills that are learned through approximations to respond to students' thinking in real time during their teaching.

As discussed earlier, the degree of authenticity is a cause for concern in approximations, and researchers have often considered setting, scaffolding, and decomposition as three dimensions determining the degree of authenticity. Some approximations are more authentic than others, depending on what construct is aimed to be developed through approximations. In the literature, approximations involving role playing are characterized as more authentic than approximations involving simulations, which may only be valid for some specific practices. For example, role play would be more authentic than simulation if it aims is to develop PSTs' practice of 'responding to student thinking' because PSTs engage in a setting similar to the actual practice of role playing. However, approximations involving simulations would be more authentic than role playing if the focused practice is "anticipating student thinking" as PSTs anticipate students' responses while creating virtual scenes. Even though approximations are perceived to be less authentic both in terms of the nature of the activities and the setting of the practice, they seem productive for providing PSTs with opportunities to anticipate students' roles in their classes. Researchers have assumed that scaffolding reduces the authenticity of practices because PSTs do not get direct scaffolding during teaching. This study suggests that scaffolding does not always reduce authenticity; when and how PSTs receive scaffolding would determine the degree of authenticity. As such, if PSTs get feedback before or after engaging in a practice, it serves as scaffolding without reducing authenticity. After all, teachers are expected to get feedback and continue to improve their teaching throughout their teaching careers (Conference Board of the Mathematical Sciences, 2012). However, feedback provided in the middle of practice might decrease the authenticity as PSTs' decisions potentially depend on the feedback.

Based on these findings and discussion, teacher educators may not be able to fully determine the authenticity in approximations based on what PSTs learned at the end of approximations because teachers should be "seen as complex, sensible people who have reasons for the many decisions they make" (Leatham, 2006, p. 100). Even though teacher educators might perceive a practice to be transferable to school, novice teachers might not transfer because they struggle to negotiate the power dynamics within schools and teacher education programs (Trent, 2013). In fact, there is a less attention in the literature about the extent to which PSTs transfer the practices learned from approximations in their future teaching, suggesting a need for extending the research to examine the ways in which approximations can be most productive in informing PSTs' future teaching. Thus, the expansion of an alternative definition of authenticity is needed that incorporates the extent to which PSTs transfer the skills learned from approximations in their future teaching. This alternative conception of authenticity proposes that the degree of authenticity should be based on the extent to which approximations provide a way to recompose small components of a practice in order to improvise practices learned from approximations in school contexts. Collectively, this dimension of authenticity enhances PSTs' ability to enact components of practices in their teaching. With an acknowledgement that this alternative definition does not include all possible dimensions of authenticity, it brings more depth to the current dimensions of authenticity in approximations.

We offer this synthesized framework as a tool to reveal mathematical activity in a non-formal makerspace. In particular, we connect research at different grain sizes to illustrate and explain how mathematics plays a crucial, if often implicit, role in this activity. We begin with describing the Approximate Number System and the Ratio-Processing System, explain how those systems connect to both embodied cognition and Thompson's (1994) conceptualization of quantities. We then examine how prediction and anticipation relate, with a particular emphasis on how social feedback guided the emergent mathematical activity. Finally, we synthesize across the two frameworks, in order to better reveal mathematical activity in low-notation environments, as the first step towards a framework for understanding mathematical learning in non-formal and low-notation contexts.

Keywords: Informal Education, Learning Theory, Technology

Identifying mathematical cognition in non-formal contexts where formal notation plays very little role can be a difficult proposition. In particular, mathematical notation-based performances are often taken as evidence of mathematical learning, and a tempting corollary is that mathematical learning is thus evidenced by mathematical notation. As a consequence, learners engaging in activities that have little or no formal notation can be seen as not engaging in mathematical learning, even when they may be experiencing a *mathematical* activity that merely lacks the explicit outward signs of such learning. In our research on mathematical play in a non-formal makerspace (Shokeen et al., 2020; Katirci et al., 2021), we have developed a new framework for identifying mathematical activity in a low-notation environment, and we share that framework here.

We build a theoretical argument that takes a multi-pronged approach: first, we develop a theoretical framework that builds from two primitive structures in the brain - the Approximate Number System and the Ratio-Processing System (Matthews et al., 2015) - tie those neural structures to Alibali and Nathan's (2012) embodied cognition view of perception and action, and interpret both of those frameworks through Thompson's (1994) conceptualization of *quantities*. Second, we describe a framework based upon prediction (Bieda & Nathan, 2009) and anticipation (Tzur, 2007) as components of mathematical learning, and tie those directly to our work on feedback and failure (Williams-Pierce, 2019). Lastly, we illustrate (or apply) the synthesis of these frameworks as a way to better identify and understand the mathematical activity that is taking place in the social context of an informal collaborative group.

Methodological Background

Our primary methodological approach for this paper is theoretical but we built our theory directly through observing and analyzing video data with the aim of examining it for evidence of mathematical play. In this section, we describe that video data. In the later sections, we provide illustrative examples of that data in order to illuminate how our comprehensive framework revealed mathematical learning and activity.

Our video data is composed of three video records of the same 20 minutes of a collaborative robotics activity with five fourth-grade students (2 M; 3F). Two of the video records were from the perspective of two students wearing GoPro cameras, while the third was a standing camera that captured the entire group's activity from a slight distance. The activity took place within the context of a physical classroom, although it was treated as a non-formal makerspace, and the participants were present voluntarily. The robotics activity had two phases: Phase 1, the group put masking tape on the floor to establish a path for a different group (who did not consent to be videotaped); and Phase 2, the group moved to the masking tape path established by the other group, and sought to measure the path and program a robot, Dash, to successfully travel it. Figure 1 illustrates the group putting down the masking tape path in Phase 1 (A), the iPad interface for programming Dash (B), and an image from the standing camera of the group measuring the path and watching Dash move in Phase 2 (C).

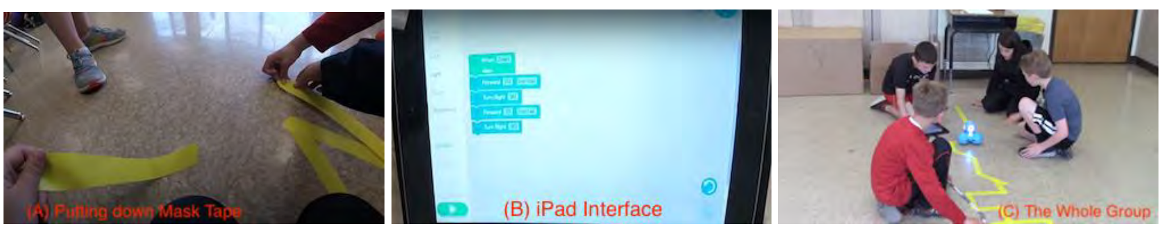

Figure 1: (A) Phase 1; (B) iPad interface; (C) Phase 2.

The research team who analyzed the data is composed of four regular members with varying areas of expertise. Two are experts in embodied cognition, in both physical and digital learning contexts; one specializes in mathematics learning in makerspaces (and originally collected the video data); one specializes in mathematical play. All four have considerable expertise with mathematics learning in both formal and informal contexts. The multidisciplinary nature of the team is how we developed our comprehensive framework over time, as our collaboration during analysis revealed both the need and the expertise for developing this framework.

Theoretical Background A: Approximate Number System to Quantities

In this section, we discuss on how perceptions, gesture, action, and the physical context relate to Thompson's (1994) conceptualization of *quantities*. We begin by describing the underlying neural systems that influence perception of magnitude (section A1); describe how perception, gesture, and action are complexly related in cognition (section A2); then describe how Thompson's quantities (1994) fit into that theoretical system (section A3).

A1: Underlying Neural Systems

Our physical bodies have perceptual systems that influence our cognition. Alibali and Nathan (2012) describe perception and simulations of perception: "When humans perceive objects, they automatically activate actions appropriate for manipulating or interacting with those objects (Ellis & Tucker, 2000; Tucker & Ellis, 1998). Thus, imagining an object can evoke simulations of perception (i.e., of the actions associated with perceiving the object) or of potential actions involved in interacting with the object" (p. 254). These perceptions and the perceptual systems that underlie them can have primitive neurological bases. For example, the Approximate Number System (ANS) ties estimation of a number of objects directly to certain animal neuron activation patterns, including humans (e.g., Dehaene, 1997; Matthews et al., 2015). A human adult, glancing at a set of three objects on a table, immediately subitizes: they know automatically and without conscious thought that there are three objects present (e.g., Miller, 1994). If that human adult is shown three objects repeatedly, the part of their brain responding to those three objects begins firing less actively as the perceiver becomes habituated to the number of objects being subitized. In such situation, if a fourth object is added, there is a small increase in relevant brain activity; whereas if three more objects are added (making six in total), a larger increase in relevant activity occurs. In other words, when the number of objects being perceived increases slightly, there is little increase in brain activity; but if the number increases considerably, so does the brain activity (e.g., Dehaene, 1997; Piazza et al., 2004).

Building upon the ANS, Matthews et al. (2015) describe the Ratio-Processing System (RPS) as a neural system in which we intuitively and immediately perceive and compare magnitudes of objects. (Although Matthews et al. (2015) describes quantities as an inherent quality of magnitude of an object or representation, we instead refer to that as *magnitude*, and reserve the term *quantity* for Thompson's (1994) definition.) With the ANS and the RPS as primitive structures that perceive and compare magnitudes, certain components of perception are built directly into our brains. Building upon those structures into more complex forms of perception (such as recognizing relevant tools in our environment, the social structures of a group, and so on), is more complex. Specifically, perception and action are reciprocal: our perception guides our action, and in turn our action reflects and guides our perception. These actions and perceptions are grounded in our physical environment, including the social, material, and structural aspects of our surroundings (Alibali & Nathan, 2012) *and* our neurological structures (Matthews et al., 2015).

A2: Perception, Action, and Gesture

Perception, whether based upon primitive numerical structures or otherwise, leads to action (such as gesture, physical movement upon the environment, or spoken language), and that action leads back into our perception. This feedback loop of perception, action, and imagining is described as mental simulation (Alibali & Nathan, 2012), and together compose the embodied nature of our cognition. This feedback loop can be evidenced through spoken or written language, physical movements that impact the physical world, or - often - can only be inferred by an outside observer through expression of gestures. These gestures are communicative acts that reveal perception and action in a variety of ways, such as through pointing (deictic) gestures that connect spoken language with objects or people in the physical environment or representational (such as iconic or metaphoric) gestures that directly reflect the state of perceptions and planned actions of the gesture. Consequently, we rely upon action and gesture as both composing and revealing perception, action, and their composite into cognition.

We now describe Thompson's (1994) conceptualization of *quantities*, then tie this conceptualization into Alibali and Nathan (2012) and Matthews et al. (2015) through illustrative examples of our data.

A3: The Role of Quantity in Perception, Action, and Gesture

Thompson (1994) specifically defines *quantity* as a conceptual entity - that is, quantity does not reside in the object, but rather in the perceiver. As noted above, our references to *magnitude* should be taken to refer to both Matthews et al.'s (2015) use of the term *quantity*, and to the *perceived* quality of an object or representation of taking up space (re: Thompson's (1994) definition).

Thompson (1994) goes on to define *quantity* as a schematic that involves "an object, a quality of the object, an appropriate unit or dimension, and a process by which to assign a numerical value to the quality" (p. 184). For example, a piece of masking tape that is "too big" (as stated by Peter; see Figure 2-A) indicates that the speaker perceives the magnitude of the tape, and compares it to some internal standard in order to determine that the piece needs to be shortened (See Figure 2-B&C). This perception and comparison of magnitudes (one physical, one imagined) occurs through Matthews et al.'s (2015) primitive structures. Then, the judgment of "too big" indicates that the speaker is perceiving the length of the masking tape as a *quantity* by Thompson's (1994) definition: the masking tape is the object; the length of the piece of masking tape is the quality they are considering; and the internal standard for magnitude is an appropriate unit or dimension. Although our participants did not have access to a measuring tape in order to assign a numerical value to the quality of length, they would have been able to do that measuring if the tool had been present (as they used such a tool in Phase 2). In other words, the speaker who says "too big" is using quantity as conceptualized by Thompson (1994), and that quantity is perceived and compared with a simulated perception (Alibali & Nathan, 2012) of appropriate unit or dimension. This perception and comparison of length is rooted in the speaker's ANS and RPS: although a lack of discrete or explicit measurement makes it difficult to determine how their ANS is contributing, the comparison of the physical length's magnitude with their imagined unit's magnitude can be directly attributed to their RPS.

Figure 2: (A) "Too big!"; (B) Shortened the piece; (C) Final decision- cut the tape

The speaker's comparison of the magnitude of the tape with their internal standard presents a communicative problem, as they must externalize their internal standard in some fashion for their group mates. One potential method of externalizing might be gesturing what "too long" is - while this does not externalize the internal standard, it indicates what magnitude the speaker is considering to be too much, which implies that the desired length of tape should be shorter. Another potential method was to engage the action of ripping the tape in half: this would serve to indicate what an appropriate length of tape would be, while requiring fellow perceivers to examine the magnitude of a resulting piece of tape in order to evaluate whether the new pieces are perhaps "too short." When a piece was too short, the choice of actions was different: they were crumpled up and thrown away, or used to extend a pre-existing length of tape already on the floor. While these actions and gestures may differ, they each indicate the same perception of magnitude, the quantification of that magnitude, and a comparison to an internal standard.

Now we shift to our second theoretical background.

Theoretical Background B: Prediction to Social Feedback

Now that we've described how perception, action, and gesture relate to magnitudes and quantities, we will focus on detailing prediction (Bieda & Nathan, 2009) and anticipation (Tzur, 2007) as components of mathematical learning, and tie them directly to our previous work on feedback and failure (Williams-Pierce, 2019). We then focus specifically on how prediction, anticipation, feedback, and failure contribute to *social feedback* with illustrations from our data. We focus on social feedback in particular due to its crucial role in the collaborative mathematical activity present in our data. We introduce Theoretical Background B with as little reference to Theoretical Background A as possible, as we plan on focusing on that final step of synthesis in our Synthesis of Theories section. As the majority of the mathematical reasoning that occurs in this activity is grounded directly in perception and quantities, and much of it also involves mental simulation (i.e., aspects of Theoretical Background B), we give less mathematical examples here that do not require attention to quantities or mental simulation.

B1: Prediction and Anticipation

Bieda and Nathan (2009) describe prediction as looking at a pattern, and predicting a later instance of that pattern, whether near or far. The vast majority of our prediction examples in the data are intertwined with students perceiving and simulating quantities, but we present two examples of prediction that rely less upon quantities, both of which revolve around the teacher-facilitator warning the teams that they were running out of time. During Phase 1, the students changed their tape-laying pattern from trying to make the path 'zig-zag' (Shokeen et al., 2020, accepted), to simply placing a single long piece of tape to complete the path across the room. In other words, they were predicting that following their zig-zag pattern would not result in completing a path across the room, so they adjusted their activity accordingly to ensure they reached across the room within the allotted amount of time. A similar moment happened towards the end of Phase 2 when the teacher-facilitator gave a 45 second warning that the activity was almost over. One of the students from the other team was overheard by the target team saying, "We are not gonna make it" and Ryan responded across the room to them as he kept measuring the tape paths: "Neither are we." In that moment, Ryan was looking ahead in time, and predicting that if they continued programming Dash as their current speed, they would not be able to get Dash to the end of the tape path. As mentioned earlier, these are not particularly rich examples, mathematically, but the students are looking at the results of their activity thus far, comparing how much time that activity took, and predicting the results of continuing with exactly the same activity in the short amount of time that is left. In the first example, they modified their activity in order to achieve their goal of getting across the room; in the second example, there was no such modification available to similarly speed up their progress.

We now shift from prediction to Tzur's (2007) description of two stages in mathematical activity: participation and anticipation. During the participatory first stage, the learner has a mathematical understanding that emerges only when prompted by the activity at hand, and cannot be independently demonstrated without the contextual cues or tools. Tzur (2007) describes the "the well-known 'oops' experience" (p. 277) in the participatory first stage, where a student does something, notices a mistake as it manifests in their activity, and goes on to adjust it in the moment. During the anticipatory second stage, however, "the learner can independently call up and utilize an anticipated activity-effect relationship proper for solving a given problem situation" (p. 278) - in other words, they are able to use their mathematical understanding without engaging in the activity first. In our activity, participation and anticipation often manifested through prediction, feedback, and failure. We give specific examples about anticipation and its relationship to prediction in Section B3, as failure and feedback (Section B2) play a critical role in identifying Tzur's (2007) stages within this activity.

B2: Feedback and Failure

Our initial goal when we began analyzing this data was to identify how zones of mathematical play that emerged in concert with mathematical video games (Williams-Pierce & Thevenow-Harrison, 2021) might manifest in this new non-formal context. We began by attending particularly to feedback and failure, as Williams-Pierce (2019) defined failure and feedback as tightly paired in digital contexts and crucial to mathematical play. In particular, it is through failing and getting feedback that players, through their own actions, engage in learning the underlying mathematical content in the game (Williams-Pierce, 2019). This type of paired feedback and failure is instantaneous and often direct, in both videogames and the current activity. For example, in Phase 2, if the path in front of Dash was measured to be 80 cm and the programmer enters that measurement into the code, but Dash goes too far and ends up off the path, Dash's location manifests failure paired with feedback. The programmer then learns from the feedback (*Dash has gone too far*) to input a smaller distance into the program. This occurrence of failure and feedback is similar to that found in videogames, but we also found that *social* feedback played a crucial role in this non-formal collaborative context: students observing Dash's failure to stop at the correct spot on the tape often amplified the feedback of Dash's location - in this case, one student said, "That is a little far away" (*too far*). As a result, the programmer reprogrammed Dash to go 70 cm instead of 80, and Dash stopped at the desired location on the tape path. In short, in this type of situation, the paired feedback and failure may be direct - as in video games - may have social components, or may be fully social.

In fact, in Phase 1 the paired feedback and failure was often fully social. For example, at one moment, Peter was holding the roll of tape, and tearing off pieces to hand out to other students, who spontaneously formed a line to wait their turn for a piece of tape. Ryan, however, tried to cut in line immediately after they had just placed a piece of tape, but Peter did not let them, forcing them to go to the back of the line to wait their turn. This is an example of social feedback and failure: Ryan was essentially informed that they were performing a social activity that was not permitted within this community, and given feedback on how to actually get their next piece of tape in an appropriate fashion. As another example of social feedback, students would often disagree on how long a piece of tape should be, or what angle it should be placed relative to the path. However, this paired feedback and failure relies heavily upon perceiving or mentally simulating quantities, so we will discuss that further in the Synthesis of Theories section.

B3: The Relationships between Prediction, Anticipation, and Social Feedback

Prediction, anticipation, and social feedback have a complex but crucial relationship. For example, when Dash went too far in the Phase 2 example above, the students had input a centimeter measurement that they anticipated and predicted would lead Dash to the correct location on the tape. Consequently, when Dash stopped at the wrong place, the students received that paired feedback and failure, and amplified that feedback and failure through talking about it (e.g., social feedback). However, often feedback and failure are not clearly evident, because if what the students predicted would happen did, they had no need to remark upon it. In situations like this, where feedback and failure are missing, and the students move on to the next step, we concluded that they were content with their previous work. We also posit that this may be an indicator that students have shifted from *participatory* to *anticipatory*, because they have learned/internalized what to do or not to do, which results in no failure and often no social feedback. For example, in Phase 2, students are using a measuring tape and a pencil to measure a part of the path, and then write their measurement of that strip of tape on the path. After measuring and writing down the measurement, they move directly on to measuring the next part of the path without commenting, because they have successfully completed a step of the measurement. Measuring by itself is an activity that can be successful or unsuccessful in itself, even before Dash enacts the measurement – but the data showed no example of the students accidentally flipping the measuring tape to the inches side, or noticing any other potential measuring issues that could happen. This illustrates the other side of the 'oops moment,' because it is a 'we measured the path appropriately and are not surprised by it' moment. Sometimes, the students are successful but remark on their success, such as when Aaron coded Dash to traverse the first three lines and the angles within them, and after Dash ended up in the correct spot, Aaron said, "That's perfect!" We consider this to be an example of social feedback paired with success, rather than failure, and an illustration of the participatory stage rather than anticipatory, because they were at least mildly surprised that it worked (e.g., they lacked confidence in their prediction), unlike when using the measuring tape.

Synthesis of Theories

This section is the culminating synthesis of the theoretical groundings introduced above. In particular, we will describe how quantities and embodied cognition relate to prediction and anticipation, through the lens of failure and feedback in this context. We give two examples - one from each Phase - detailing exactly how the students were engaged in the activity, and conclude with another example that highlights the role of social feedback in particular.

In Phase 1, as students were placing down tape, they were using their perception of length and angle to guide their placement. At one point, Ryan places down tape at what he perceives to be and says is a "ten degree angle." The teacher-facilitator notices, and says it is "too tight" for Dash to traverse. Then Ryan pulls up that tape and re-places it, using his perception of quantities to increase the angle. This is an example of using perceived acceptable quantities of angle: Ryan uses his own perception of length and angle to mark 10 degrees, which he perceives as a perfectly appropriate angle for Dash to execute; then Ryan adjusted his understanding of an appropriate (perceived) angle quantity according to external guidance by the teacher, who knows Dash's limitations. This is an example of participatory first stage, where they have an oops! moment, but the shift to anticipatory second stage occurs immediately, as we see by a complete lack of other too-tight angles in Ryan and the group's remaining activity. Similar quantity and perception-based moments occur around the length of the masking tape, such as when Aaron is placing a long piece of tape, and Peter says, "But that's too long though." Aaron immediately adjusts the tape length by ripping some of it off, so that Peter's perception of an acceptable quantity of tape is respected. All of these interactions are based directly upon perceptions of quantity - whether of length or angle - and involve nuancing each students' view of what an appropriate quantity is for the task at hand.

In Phase 2, as students code a new length of the path for Dash, they are using quantities that have already been evaluated (measured) by their teammates with the measuring tape. However, in re-coding a length that they've already tested with Dash, they are using two different evaluated quantities alongside perceptual quantities. The centimeter measurement written on the path is one evaluated quantity, while the second – how far Dash was programmed to go – is another evaluated quantity, while the comparison between the two is purely perceptual. The two different evaluated quantities are both technically centimeters, but evaluated in two different ways: the first is 'centimeters as measured by the measuring tape'; while the second is 'centimeters as enacted by Dash.' When those two evaluated quantities do not match up, the students must perceptually evaluate the difference between the two, and mentally simulate a comparison that supports them in re-programming Dash accurately. When Dash is programmed, the students are predicting that Dash needs to go the programmed distance in order to reach the correct spot; and they respond to the failure or success of that prediction accordingly, indicating their placement in the participatory or anticipatory stages.

The role of social feedback was particularly crucial, as there was a lack of mathematizing tools: each student had to use their own perception and mental simulation of quantities, as no more precise method was at hand. For example, at one point in Phase 1, the students decided that they wanted to lay the path underneath two chairs that are tucked under a table. As one student began laying the tape underneath the chairs, another student, Hannah, said something in a doubtful tone (not captured on audio), while tracing the floor under the chairs. Aaron says, "No no, that would work" and Ryan agrees, also tracing the floor under the chairs. As Hannah spoke, she was mentally simulating her perception of the size (quantities) of Dash, comparing that mental simulation with her perception of the space available underneath the chair, and visualizing a conflict between those two perception-based simulations such that Dash would run into the chair, rather than go smoothly underneath it. Aaron and Ryan, though, are either engaging in different mental simulations – one in which Dash fits under the chairs – or are merely thinking of Dash following the path (a participatory view), while Hannah was anticipating, and using that anticipation to predict that some issues would arise. Aaron and Ryan keep placing the tape, and then Peter joins to place the last piece of tape that brings the path out from under the chairs. As Peter finishes, he says, "We should move the chairs out, too, if it doesn't fit," and Ryan says, "Yeah." Then, when Phase 1 is ending, and the group is leaving their tape path for the other group to use, this group runs back to remove the chair from the path, indicating that the mental simulations of others (Peter and Hannah) have convinced the others that Dash probably will not fit - in other words, this is a moment of social feedback.

Conclusion

We offer this synthesized framework as a tool to reveal mathematical activity in a non-formal makerspace. In particular, we connected research at different grain sizes to illustrate and explain how mathematics plays a crucial, if often implicit, role in this activity. We began with describing the Approximate Number System and the Ratio-Processing System (Matthews et al., 2015), explaining how those systems connect to both embodied cognition (Alibali & Nathan, 2012) and Thompson's (1994) conceptualization of *quantities*. We then examined how prediction (Bieda & Nathan, 2009) and anticipation (Tzur, 2007) relate, with a particular emphasis on how social feedback guided the emergent mathematical activity. Finally, we synthesized across the two frameworks, in order to better illustrate the implicit mathematical activity in our data.

This theoretical framework is the first step in our efforts to better identify mathematical cognition in low-notation environments. We have connected multiple layers of research that emphasize mathematical cognition, and used it to reveal mathematical activity - and our next goal in this line of research is to connect that non-formal, low-notation mathematical activity with direct identification of the resulting learning. As yet, we do not claim a direct relationship between the revealed mathematical activity and learning, but rather focus on establishing the necessary groundwork for investigating that relationship. However, as increasing numbers of educators examine mathematical learning in informal environments such as ours, we consider the ability to identify the types of implicit, perceptual, and embodied mathematical cognition that emerge from these environments to be a necessary contribution to the field. Additionally, this identification requires using knowledge and frameworks from multiple fields examining different layers - from neurons to social interactions - in order to solidly ground each moment of mathematical activity. We offer this framework as the first step in this endeavor.

The fields of quantitative and covariational reasoning boast a wide range of powerful theoretical tools, which are described carefully in the literature. Less frequent and explicit attention, however, has been paid to writing down detailed, practical guidance for operationalizing these theoretical constructs. Some guidance is provided by covariational reasoning frameworks, but much is left unsaid concerning the inherent complexities and ambiguities involved in analyzing students' moment-by-moment behaviors and what these behaviors convey about their covariational reasoning. In an effort to more clearly link theory to analytic methodology, we share three lessons about analyzing students' covariational reasoning to make research more accessible to newcomers and better address what is often left unsaid in the covariational reasoning literature.

Keywords: Research Methods, Cognition, Precalculus, Calculus

The fields of quantitative and covariational reasoning boast a wide range of powerful theoretical tools. These tools have grown to be complex so they can more productively model students' thinking. The theoretical relationships between these elements are often detailed in theoretical synthesis papers, such as Thompson and Carlson (2017), and in the theoretical framework sections of empirical papers. But less frequent and explicit attention has been paid to writing down detailed, practical guidance for *operationalizing* these theoretical constructs for analysis. Experienced covariational reasoning researchers undoubtedly reflect on these important analytic considerations for each study they conduct; yet, these reflections are rarely reported in the literature.

In this paper, we build on prior work in which we reflected on and critiqued our analytic techniques for studying covariational reasoning to a) improve our own methodologies and analytic techniques and b) increase the accessibility of covariational reasoning research (Drimalla et al., 2020). In line with the theme of this year's PME-NA conference, we have decided to share our own productive struggles with designing and conducting a study that assessed students' covariational reasoning (Boyce et al., 2019). To center the *productive* aspect of these struggles, we will present the content of our reflections in the form of three lessons we have learned. Each of these lessons focus explicitly on developing analytic techniques and operationalizing theoretical constructs in quantitative and covariational reasoning research.

This paper is primarily intended for newcomers to covariational reasoning hoping to learn from our productive struggles. We also invite experts to engage with our experiences and critiques so that we can work together as covariational reasoning researchers to a) make research in this area more accessible to newcomers, b) be more open, clear, and explicit when writing about and sharing our analysis techniques and methodologies, and c) address potential flaws and gaps in the literature.

Theoretical Background

Covariational Reasoning

Carlson et al. (2002), building off Saldanha and Thompson's (1998) quantitative approach to covariational reasoning, described covariational reasoning to be "the cognitive activities involved in coordinating two varying quantities while attending to the way they change in relation to each other" (p. 354). Saldanha and Thompson (1998) further described how two quantities can be thought of simultaneously using the concept of a *multiplicative object*. They wrote, "Our notion of covariation is of someone holding in mind a sustained image of two quantities' values (magnitudes) simultaneously. It entails coupling the two quantities, so that, in one's understanding, a multiplicative object is formed of the two" (p. 299). Thus, covariational reasoning entails constructing two separate varying quantities as well as a multiplicative object, an object formed by simultaneously uniting the attributes of both quantities.

Quantitative reasoning. As covariational reasoning is a form of quantitative reasoning, the construction of quantities is foundational. Thompson (1994) described a *quantity* as a conceptual entity which "is composed of an object, a quality of the object, an appropriate unit or dimension, and a process by which to assign a numerical value to the quality" (pp. 7–8). For Thompson (2011) then, "quantification is the process of conceptualizing an object and an attribute of it so that the attribute has a unit of measure, and the attribute's measure entails a proportional relationship (linear, bi-linear, multi-linear) with its unit" (p. 37). Thus, quantitative reasoning is an individual's conception of quantities and their understanding of how the quantities relate. For example, a person could conceive of the height of an airplane, the distance it has traveled, and the relationship between the two.

Nonnormative graphing schemes. Covariational relationships are often represented graphically and, subsequently, the study of covariational reasoning is further complicated by the variety of ways students understand graphs. Graphing schemes that are the norm amongst mathematics education researchers can differ from students' graphing schemes (Moore et al., 2019). These nonnormative graphing schemes mainly stem from people's different meanings for coordinate systems (Lee et al., 2019), points in the coordinate system (Tasova & Moore, 2020), and curves with respect to the coordinate system (Moore & Thompson, 2015).

To attend to how students represent quantities graphically, Joshua et al. (2015) defined a *frame of reference* as "a set of mental actions through which an individual might organize processes and products of quantitative reasoning" (p. 32). In particular,

> an individual conceives of measures as existing within a frame of reference if the act of measuring entails: 1) *committing to a unit* so that all measures are multiplicative comparisons to it, 2) *committing to a reference point* that gives meaning to a zero measure and all non-zero measures, and 3) *committing to a directionality of measure comparison* additively, multiplicatively, or both. (p. 32, emphasis added)

Students who carry out each of these mental actions when representing a quantity, have constructed not just a quantity, but a framed quantity.

Operationalizing Theoretical Constructs for Covariational Reasoning

Our research group turned to two of the most widely-cited covariational reasoning frameworks—those of Carlson et al. (2002) and Thompson and Carlson (2017)—for guidance on operationalizing the above theoretical constructs to study students' covariational reasoning.

Because this is where we suspect newcomers will begin, too, we start by attending to the combined guidance provided by these frameworks with regards to developing analytic frameworks for covariational reasoning. We then highlight the areas where the literature on these frameworks does not provide clear guidance.

Thompson and Carlson (2017) framework. Thompson and Carlson (2017) offered a framework of covariational reasoning levels based on the theoretical building blocks of quantity, multiplicative object, and variational reasoning. Each level is described based on what a person envisions while carrying out quantitative mental actions. Thompson and Carlson emphasized that when using this framework it is "essential to attend to how students are thinking that quantities' values vary and how they are uniting quantities' values when considering their meanings for covariation" (p. 443). To exemplify what it means to attend to these elements of student thinking, Thompson and Carlson shared examples of student approaches representative of each level of covariational reasoning for the classic Bottle Problem (Swan & Shell Centre, 1985) as well as a graphing task from Castillo-Garsow (2012).

The sample approaches to the Bottle Problem include one specific example of what a student at the gross coordination level might say; however, much of the discussion concerns what students at various levels might envision, focus on, or imagine—all internal processes. Less attention is paid to specific student behaviors that might be indicative of these internal processes.

For the graphing task, three kinds of student graphs are linked to specific covariational reasoning levels. Thompson and Carlson clarified that these graphical answers represent "at most" a certain level of reasoning because, for example, students "might have connected points simply because they thought that this is what one does when sketching a graph" (p. 442). In other words, they highlighted the need for researchers to carefully attend to the mental actions and images a student uses while creating a graph before attributing a corresponding level of covariational reasoning. Specific behaviors that might be indicative of these mental actions as students sketch their graph are not provided, however.

Carlson et al. (2002) framework. The levels of the Carlson et al. (2002) framework similarly highlight "images of covariation" that support particular mental actions. Unique to this framework is that each mental action is tied directly to 1–2 specific indicative behaviors. Some of the behaviors are involved in sketching a graph while others are what students say. Carlson et al. clarified that "Some students have been observed exhibiting behaviors that gave the appearance of engaging in [advanced mental actions] . . . When asked to provide a rationale for their construction, however, they indicated that they had relied on memorized facts to guide their construction" (pp. 361–362). As in Thompson and Carlson (2017)'s framework, then, each behavior corresponds to "at most" a particular level of covariational reasoning.

Critical Analysis of Both Frameworks. A primary benefit of the Thompson and Carlson (2017) framework is that it synthesizes several theoretical constructs found in the (co)variational reasoning literature. However, a newcomer using only this framework may struggle to operationalize these levels in their own research due to the lack of student behaviors tied explicitly to each level of covariational reasoning and the complexity of the theory. This reality reduces the analytic utility of this framework. On the other hand, the Carlson et al. (2002) framework provides specific graphical and verbal behaviors that correspond to each mental action/level but does not account for current theoretical advances in quantitative and covariational reasoning.

After reading the literature on both frameworks, newcomers may still wonder: What are behaviors I can observe that indicate a student has constructed and is (co)varying one or more (framed) quantities? Also, as most examples of indicative behaviors from the literature on these frameworks focus on final products (e.g., the shape of a student's graph), how should one make sense of students' in-the-moment reasoning based on their constitutive behaviors that lead to these products? Such behaviors could be graphical or verbal—as in the Carlson et al. (2002) framework—but may also be gestural and inscriptional (either graphical or non-graphical).

Three Lessons for Analyzing Covariational Reasoning

We asked similar questions while developing and refining our research group's methodologies for analyzing students' covariational reasoning. Our goal was to assess students' levels of covariational reasoning using the Thompson and Carlson (2017) framework, but this proved more difficult than we initially imagined. Although the literature details and carefully connects the theoretical aspects of quantitative and covariational reasoning, practical guidance for connecting this theory to analysis through task design and task analysis is much sparser.

Our Research Context

We learned the lessons we are about to share by reading the literature, through trial and error of analyzing undergraduate first semester calculus students' covariational reasoning for a prior study (Boyce et al., 2019), and through careful, systematic reflection both individually and as a research group (see Drimalla et al., 2020). Conversations with the last author—an expert in quantitative and covariational reasoning who was not a member of our research group—helped us frame and generalize our reflections to ensure that the lessons we learned apply beyond our experiences.

The covariational reasoning task we discuss in this paper is the Reverse Bottle Problem based on the classic Bottle Problem that has been used frequently in covariational reasoning research (Carlson et al., 2002; Paoletti & Moore, 2017; Stalvey & Vidakovic, 2015). The problem statement and the accompanying diagram we provided students is shown in Figure 1, alongside the main prompts we verbally asked participants.

To ground each lesson, we provide examples of student thinking. We focus on one student—Neal—in an attempt to accurately depict the challenges and ambiguities a researcher has to grapple with to analyze even one student's behaviors across a multi-part task.

Imagine this jug has been completely filled with water. It is then left indoors in a sunny window and left untouched until all the water has evaporated.

1) Describe how the height of the water in the jug would change as the volume of the water in the jug decreases.

2) Sketch a graph that gives the height of the liquid in the jug as a function of the volume of the water in the jug.

3) Describe the rate at which the height of the water is changing with respect to volume.

Figure 1: The Reverse Bottle Problem Task

Lesson 1: Use an Additional Analytic Frame to Track the Quantities Students Construct

Thompson's definition of quantity provides a helpful *theoretical* framing of what it means for students to construct a quantity. In practice, though, we found that an *analytic* frame for quantity is necessary to keep track of how students are conceptualizing and representing quantities on diagrams. Two primary difficulties necessitated the addition of an analytic frame for quantity.

First, we suspected that students used different words to refer to the same quantity they had constructed. However, our research team had no common method for gathering evidence that this was the case, leading to a hodge-podge of (implicit and potentially incompatible) perspectives being used, making consensus decisions difficult. A common question that arose is whether a student was simply reciting the words in the prompt or if they had truly constructed a variable quantity. We needed a way to make decisions on this front.

For example, Neal used the word “volume” six times when discussing the Bottle Problem in tandem with the initial diagram; however, he also used the phrase “amount of water” twice. Had Neal constructed two separate quantities? It was only after we used an analytic frame based on the language and gestures participants used that we noticed each gesture Neal used alongside “amount of water” was a subset of the gestures he used exclusively to refer to “volume.” This observation provided strong evidence that Neal was discussing the same quantity despite using different language. By saying “amount of water,” Neal used what we call *fresh* language—unique wording introduced by the interviewee, rather than the interview protocol or the interviewer—further cementing our conclusion that Neal was not merely repeating the word he expected the interviewer would want him to use in his response.

Second, the inclusion of volume necessitated that students construct a 3D quantity, but we initially had difficulty discerning how they represented such a quantity with fidelity when restricted to a 2D graph or diagram. Prior to the interview, Neal had encountered a problem in his class that involved a different shaped bottle being filled with water. The interviewer began by asking him to describe his recollection of that task. Neal initially described the bottle as “circular” (a 2D wording) but, within a few seconds, corrected himself and said that the bottle was “spherical” (a 3D wording). We credit this usage of fresh language as evidence of Neal’s awareness of dimensionality, which is key to understanding the quantities he constructs. Later, we again noted his awareness of dimensionality when Neal used unidimensional gestures to refer to most quantities aside from volume (e.g., “height” paired with a strictly vertical motion; “width” paired with a strictly horizontal motion). The primary gesture Neal used for volume (see Figure 2) appeared to be an attempt to represent the higher dimensionality of the volume quantity he had constructed in two or even three dimensions. This led us to conclude that he was not bound by the strictly 2D representation of the bottle when reasoning about his quantity for volume of the water in the jug.

The lesson. The above two examples provide only a glimpse into the value our research

Olanoff, D., Johnson, K., & Spitzer, S. (2021). *Proceedings of the forty-third annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Philadelphia, PA.

group found in adding an analytic frame to better understand how students conceptualized and communicated about the quantities they constructed. The lesson we learned is not that we needed to use this particular analytic framework for quantity but rather that choosing *an* analytic framework is essential for discerning a) whether a student has constructed a quantity, b) how a student conceptualizes a quantity, and c) how they communicate about their constructed quantity. Because such data are necessary to understand the extent to which students have varied or covaried quantities, we believe an analytic framework is essential for covariational reasoning research.

Lesson 2: Disentangle Graphing Schemes from Covariational Reasoning Schemes

Whenever graphical contexts are used to study someone's covariational reasoning, there is a risk of either over- or under-assessing that student's level of covariational reasoning. For example, some people can sketch a correct graph using their graphing schemes without relying on the highest levels of covariational reasoning (Carlson et al., 2002, pp. 361–362). Without careful analytic tools, a researcher may overassess such a person's capability for covariational reasoning. On the other extreme, students with highly nonnormative graphing schemes may struggle to graphically exhibit their highest level of covariational reasoning (Drimalla et al., 2020), resulting in an underassessment of their capability for covariational reasoning. This issue may persist even when people are asked to explain (their) graphs. Even Thompson (2016)—a seasoned covariational reasoning researcher—was surprised by the range of non-quantitative ways of thinking elicited by a graph explanation task that was carefully designed to assess covariational reasoning (pp. 448–450). These kinds of non-quantitative responses do not indicate a person *cannot* or *does not* reason covariationally; they merely indicate no present evidence of covariational reasoning.

We ran headfirst into these methodological issues when assessing Neal's covariational reasoning level based on his graphical activity. Previously, Neal had spent just under 2.5 minutes establishing a quantitative frame (Moore & Carlson, 2012) and discussing the covariational relationship between the height and volume of water using the provided diagram (See Figure 1). On the other hand, graphing this relationship and crafting an explanation of the graph that Neal found satisfactory and consistent with his prior diagram-based explanation took approximately 20 minutes. We suspect much of this time was spent grappling with nonnormative graphing schemes and frames of reference for the quantities of height and volume, rather than exhibiting Neal's ability to reason covariationally.

Directionality of the x-axis and conventions for slope. Neal first labeled his x-axis with "volume water in jug" and his y-axis with "height of water" then added the words "empty" and "full" to fix a directionality of measure along both axes consistent with normative conventions (i.e., on the x-axis, quantities increase from left to right; on the y-axis, quantities increase from bottom to top). Next, Neal plotted the initial point of his graph at (empty, full) because "the height of the water is at the maximum . . . and we want to start at the maximum point." Moments later, though, he realized that the initial point should be (full, full) and flipped the directionality of his volume axis using labels of "full" and "0" to make it so.

Neal then sketched a curve with the correct shape. However, his justifications for this shape were based almost entirely on "the rate" without mention of any quantities. The interviewer asked Neal to provide a value for the rate of change of height with respect to volume using his graph. Neal explained that the rate of change in the beginning is -1 because "every time it moves down one it goes over one." Here, Neal used the usual convention for calculating slope without attending to the nonnormative directionality of his x-axis. He justified his claim by citing that the graph is decreasing, but then experienced a perturbation, claiming "that's weird," and noting that his x-axis decreased from left to right. But it was not until after the interviewer prompted Neal to add units on each axis that he performed a rise over run calculation and concluded that the slope was, indeed, positive, overriding the normative convention that a graph that "goes down" from left to right must have a negative slope.

The lesson. Neal was one of the only study participants who eventually overrode his normative graphing schemes to justify the graph he drew. Clearly, this is no easy feat, as it took Neal nearly 20 minutes to adapt to these nonnormative conditions and draw covariational conclusions he agreed were consistent with what he had deduced using the bottle diagram.

From this, we learned how important it is to have built-in methodology or an analytic tool to distinguish people's quantitative and covariational reasoning schemes from graphing schemes based on memorized conventions. There are a few ways this could be accomplished: 1) Establish a baseline for a participant's idiosyncratic graphing schemes earlier in the interview to contextualize their covariational reasoning schemes on tasks that likely invoke nonnormative graphing schemes. This could be done using careful task design that gradually increases in difficulty and the extent to which nonnormative graphing schemes likely need to be used. 2) Use an analytic framework for quantity in the graphical context to better foreground any quantitative reasoning that does occur relative to students' (possibly nonnormative) frames of reference and graphing schemes. This approach mirrors Lesson 1.

In our case, we went with option 2 and attended carefully to how Neal represented relevant quantities graphically (in normative and nonnormative ways) using the frames of reference analytic framework. This additional analytic framework enabled us to observe that only after Neal committed to a unit for both height and volume did he recognize that the slope of his graph was actually positive all along. Although Neal had constructed *partially* framed quantities for height and volume early on, it was not until he constructed fully framed quantities that he stopped relying on normative graphing schemes and began to reason with the quantities he had previously represented along the axes.

Lesson 3: Attend to Non-Graphical Behaviors Indicative of Covariational Reasoning

After becoming aware of the delicate issue of using graphs to assess covariational reasoning in Lesson 2 (see also Drimalla et al., 2020), we sought non-graphical behaviors that could be indicative of covariational reasoning. Primarily, we investigated participants' interactions with the bottle diagram (see Figure 1) when they were prompted to describe how the height of the water in the jug would change as the volume of the water in the jug decreases. Often, participants would instead discuss how only one of these quantities varies with time, rather than how the quantities themselves covary. To assess participants' capacity for covariational reasoning, though, we wanted to be as certain as possible that the quantities a student was envisioning as covarying were the water's height and volume. Thus, we distinguish between conceptual time, which is a constructed quantity, and experiential time, which is not. This distinction—of explicitly making a measured note of time—is relevant for understanding individuals' reasoning about multiple quantities (Thompson & Carlson, 2017) since conceptual time is sometimes included as one of the quantities to covary. After all, varying just one quantity (with respect to experiential time) is not **co**variational reasoning. And even if a participant had been covarying a quantity with *conceptual* time, we had no means to determine whether they had constructed time as a quantity. In the following section, we analyze some of Neal's tracing actions and wonder out loud whether his actions are sufficient evidence of covariational reasoning.

Tracing the side of the bottle. After Neal had established some typical gestures for both height and volume, he traced downwards along the final stretch of the right side of the bottle while simultaneously describing the relationship between the height and volume in the final portion of the bottle: "When the jug starts to get thinner the height at which—er, the *rate* at which the height is decreasing is going to raise." Next, Neal singled out a segment of the bottle in the section he had just traced along by drawing a bracket (see Figure 2b) and justified his prior answer: "Because the volume of water which is decreasing at a constant rate will take smaller—uh, sorry—*larger* and *larger* heights [traces vertically down bracket] to contain that equal amount of volume [cups hands in volume gesture, see Figure 2a]." The fluency and simultaneity of Neal's actions, gestures, and verbal explanation led us to believe that these behaviors were evidence Neal had engaged in continuous covariational reasoning. In particular, Neal's selection of an arbitrary sub-interval of bottle in which he discussed that the same volume would take up "larger and larger heights" led us to believe he had envisioned these quantities as having values which change. This seems to indicate Neal was engaging in more than gross covariational reasoning.

But was this sufficient evidence? Alternatively, perhaps Neal was merely using this tracing action as a way to track experiential time. When later drawing the shape of his graph, he often re-traced the side of the bottle, potentially envisioning what the water in the bottle looks like as time passes. Was Neal actually envisioning the values of height and volume as covarying, or just the gross variation in each quantity with respect to experiential time? As we remarked earlier, it was not until the interviewer suggested Neal add a scale to his axes (about 15 minutes into graphing) that he explicitly established units for each quantity. Had he implicitly been thinking in units as far back as when he was first tracing the bottle diagram? Possibly. But there is certainly some ambiguity present which affects the conclusions we can draw from his earlier tracing behavior.

The lesson. In this lesson, we sought to highlight the difficulty of drawing covariational conclusions from a person's observable behaviors. We believe there is great value in attending to non-graphical behaviors to assess covariational reasoning—both because it helps make the theory of covariational reasoning more accessible to newcomers but also because it expands the methodologies available to study covariational reasoning. At present, much of the literature only reports briefly or implicitly on the many ambiguities present in interpreting these behaviors. We hope this changes and encourage other covariational reasoning researchers to make this a reality.

For newcomers hoping to study covariational reasoning *now*, we envision two approaches to help resolve such ambiguities in observable behaviors. First, plan to ask targeted follow-up questions in your interview protocol to clarify whether participants are reasoning about quantities' values. In our case, we had already conducted interviews and could not do this, but in retrospect we suspect that asking Neal a simple follow-up question after he had traced the bottle may have resolved our uncertainty. Second, incorporate additional subtasks to ascertain whether participants are reasoning about quantities' values. To support this endeavor, there is research concerning task design and sequencing in covariational reasoning research (e.g., Johnson, 2015).

Conclusion

By sharing these lessons, we hope to have drawn attention to the unwritten complexities of analyzing students' moment-by-moment behaviors while studying their covariational reasoning. Namely, the importance of attending carefully to the quantities people construct (Lessons 1 & 2), the challenge of disentangling normative graphing schemes from covariational reasoning schemes (Lesson 2), and the ambiguities in interpreting non-graphical behaviors as indicative of covariational reasoning (Lesson 3). Given the long history and complex theoretical nature of quantitative/covariational reasoning research, such conversations are *essential* if we wish to keep this subfield accessible, rather than daunting, to newcomers. We hope we have contributed to this end; however, we cannot do this alone. We welcome others—experts and *especially* newcomers—to write explicitly on these topics and forge more detailed connections between theory and methodology in the covariational reasoning literature.

Attempts to understand and design for mathematics teacher learning have frequently identified key disconnects between teachers' contexts, the professional development experience, and, ultimately, teachers' practice. In this paper, we offer a theoretical approach to understand these discontinuities drawing on Rogoff's (1995) three planes of analysis of sociocultural activity. We then apply these three planes to illustrate one example of a teacher learning environment designed for coherence: side-by-side coaching.

Keywords: Professional Development, Learning Theory

Theoretical Framework

The learning of individuals cannot be separated from those they learn with, those they learn from, or the environment in which that learning occurs (Rogoff, 1995). Learning is embedded in a complex system of interaction and influence among individuals and contexts. To understand this system, Rogoff proposed observing learning in three "inseparable, mutually constituting planes" of activity (1995, p. 139): the *apprenticeship plane, guided participation plane*, and *appropriation plane*. The apprenticeship plane encompasses community activity, including histories, social structures, and cultural organization. This involves taken-for-granted policies, practices, and structures that shape activity. The guided participation plane refers to the ways individuals involved in shared activity "communicate and coordinate efforts" (1995, p. 142). Guidance includes the influence of social interactions and the shared values of the community. The appropriation plane comprises "how individuals change through their involvement" in activity (1995, p. 142). In this plane, individual uptake and transformation of practices is central.

Each of these planes offers one way of understanding learning that occurs in activity, though none alone captures the full system. Indeed, the three planes do not just distinguish layers of activity; they enable understanding how these layers relate to and influence one another as a constantly adapting system. All three planes are needed to understand learning, though researchers can foreground one plane to study its components while still acknowledging the role of the other planes (Rogoff, 1995). While researchers in mathematics education have taken up this analytic approach to examine students' learning environments (e.g., Anghileri, 2006), few have used this approach to shed light on teacher learning or professional development (PD). In this theoretical paper, we explore how applying Rogoff's framework to teacher learning can support designing effective professional development that integrates all three planes.

The apprenticeship plane asks for analysis of the context and systems. We contend that in the case of teacher learning, there are two facets to examine: the context and systems of the teacher learning experience (i.e., the PD setting) and also the context and systems in which the teachers are expected to apply their learnings (i.e., in their classrooms). The guided participation plane of analysis entails examining the relationship and interactions among teacher learners and PD providers. Additionally, analysis of the guided participation plane must account for the relationships among teachers and their students. Finally, the appropriation plane of analysis requires an examination of individual teachers in multiple contexts. In what ways does the teacher appropriate new ideas in the PD setting? In what ways does the teacher appropriate new ideas in their classroom?

The value of applying the three planes of analysis to understand teacher learning is in highlighting areas where discontinuities across the planes might be present. For example, research on PD has shown teachers face challenges in applying ideas from PD settings to their individual instructional contexts (Borko, 2004). There also exists literature that focuses on one plane at the exclusion of some others (e.g., Givvin & Santagata, 2011), thereby potentially missing important facets of teacher learning. Designs for teacher learning that address these discontinuities need to make deliberate connections between the three planes. While this does not mean that all PD activities need to focus equally on all three, an overarching professional learning plan needs to include opportunities to account for and integrate these three planes. Doing so would support teachers to connect their activity in guided participation with the real constraints of their context and thereby support appropriation in their practice.

Integrating the Three Planes of Teacher Learning: The Case of Side-by-side Coaching

We examine one such teacher learning design, side-by-side coaching, to show how it provided opportunities to integrate the apprenticeship, guided participation, and appropriation planes. We first introduce the context of our study and then explore how side-by-side coaching connected the three planes, making them public and salient to both the teacher and coach.

Our description of side-by-side coaching is drawn from a larger study (Munson, 2018) investigating teacher learning. In our study, one coach (Munson) was working individually with three elementary teachers at a single school. The school was situated in a largely bilingual community with a high percentage of immigrant families, and with many families experiencing poverty and homelessness. All of the teachers participated in four weeks of coaching, with approximately two coached mathematics lessons each week. All of the coaching sessions were video recorded and transcribed for analysis. The focus of the coaching in this study was the practice of conferring, in which the teacher talks with small groups of students while they are solving a mathematical task (Munson, 2019).

Apprenticeship plane

Side-by-side coaching is a professional development activity nested within the practice of teacher coaching (e.g., Wei et al., 2009). During side-by-side coaching, the teacher and coach are positioned to co-participate in an instructional practice the teacher wishes to develop, each taking the lead at different moments and engaging in professional discourse about the ongoing events of the classroom and associated teacher decision making. Coaching is responsive to emergent student thinking, classroom interactions, problems of practice, and teacher questions.

Contextually, side-by-side coaching was enabled by two related factors: how the teachers were positioned with agency by their administration and by the coaching itself. This plane was made visible in the teacher-coach discourse when teachers made verbal reference to their larger contexts, bringing them into dialogue with their teaching and professional learning. The district delegated to teachers the authority to choose instructional materials, pedagogies, and the order and pacing of content. Without being bound to district-constructed approaches and timelines for teaching, the teachers had relative agency to engage in their own professional learning alongside students and make instructional decisions based on their ongoing observations of emergent student thinking. This was particularly important given the heterogeneous needs and prior experiences of students in this diverse district. Similarly, side-by-side coaching positioned the teachers to choose when and if to lead instruction and when and if to ask the coach to do so. Teachers could and did make direct and immediate requests to the coach for support, continually co-designing their professional development experience. Teacher agency played a pivotal role in the design of side-by-side coaching as an effective form of PD.

Guided participation plane

Guided participation can include deliberate instruction, incidental noticing, engagement via observation, and joint, hands-on involvement (Rogoff, 1995). All these forms of learning-in-partnership emerged in this case of side-by-side coaching. As in other forms of PD, at the beginning and end of each lesson, the coach and the teacher engaged in conversation together to discuss their goals, questions, and reflections. Beyond these pre- and post-lesson discussions, a key feature of side-by-side coaching is that teacher-coach interactions also appeared in the midst of instruction. The teacher or the coach would pause conferring with students and engage in joint sensemaking or decision-making. For example, during one conversation between a teacher and student, the coach jumped in and said, "What are you noticing? Can we pause for a second?" The teacher responded, "The explanation is based on the numbers, but not on the context." The coach and teacher then determined together the best route forward to support the student.

Side-by-side coaching included the teacher observing the coach and the coach observing the teacher. However, the plane of guided participation was most visible when the coach and teacher engaged in shared instruction and conversation with students. In these lesson segments, the teacher and coach were both vocal participants, asking and answering questions of and from students with relative frequency. The following excerpt illustrates such an interaction, which occurred as a pair of students were working to find the difference between two numbers and the teacher and coach prompted the students to contextualize the operation to support sensemaking.

> Teacher: Can you just say a quick story around these two numbers?
> Student: Matias went to the beach and he found 83 shells. Then his brother Noelle found some more. Noelle put it in Matias' bucket and now Matias has 93 shells.
> Coach: What's the question at the end of that story?
> Student: How many shells did Noelle give to Matias?

This pattern of shared leadership offered unique opportunities for the teacher and coach to learn together, build a shared understanding of student thinking and decide how to respond.

Appropriation plane

Inherent to side-by-side coaching is the goal that teachers will incorporate their learning into their practice in a meaningful way, within and beyond the context of the coaching itself; the interactions are intended to be transformative. Teachers in this study had two venues for appropriation: taking leadership of teaching during side-by-side coaching and connecting coaching to teaching outside the presence of the coach. When the coach was present, the teachers took leadership over instructional practices for bounded moments in which they could try the practices being learned. The coach was positioned side-by-side with the teacher to co-witness these instructional events, and the teacher could recruit the coach back into guided participation or debrief with the coach immediately afterward. In this way guided participation and appropriation were commingled, and the teacher had agency to move between planes.

The side-by-side coaching in this study was interlaced with days in which coaching did not occur and teachers had sole responsibility for teaching. Teachers had the opportunity to connect the interactions within guided participation with their independent teaching as they worked to appropriate the practices being coached. We saw evidence of connections between coached and independent lessons as teachers made deliberate discursive moves to weave these events together, either referencing their appropriation in a prior lesson or their plans for a future lesson when the coach would not be present. For instance, a second-grade teacher told the coach, "the other day we were doing a lesson and [the students] were doing this thing where they were counting forward and then going back, and I was so confused." In doing so, she invited the coach to make sense of student thinking with her, knowing that such strategies might appear again. Teachers also connected to future teaching, as when the coach and teacher discussed making a chart the next day with the task clearly written out after some confusion during the coached lesson; the teacher commented, "I can imagine if we're gonna start dealing with remainders, that it's only gonna happen more often," reinforcing the need for clarity. These connections between lessons with and without side-by-side coaching represented bridges between guided participation and ongoing appropriation.

Bringing the planes together

Because side-by-side coaching is embedded in the daily work of teaching, this coaching activity integrates context, guided participation, and appropriation in a single professional learning experience in a way that other professional development structures might not. While guided participation is the most prominent plane of interaction, with the coach serving as a more knowledgeable other (Wenger, 1998), that participation is fully coherent with the teacher's context for practice and provides continual opportunities for appropriation. We argue that this coherence is mutual, in that while the teacher experiences a more coherent learning environment, the coach gains access to the information necessary to provide that coherence.

Designing for Teacher Learning

Research in teacher learning and PD have long pointed out the discontinuities between the PD learning environment and teachers' practice in the classroom, often attributing these to the design of teacher learning experiences (c.f., Givvin & Santagata, 2011). We argue that one way of understanding the source of these discontinuities is the lack of attention to all three of Rogoff's planes of analysis, which can be seen, alternatively, as *planes of design*. In designing for effective teacher learning, we argue that teacher educators, professional development providers, and coaches must consider how to acknowledge, address, and create opportunities across the apprenticeship, guided participation, and appropriation planes.

Side-by-side coaching offers one structure that can do so, but such activities must be situated within a larger framework for ongoing teacher learning, one that incorporates learning opportunities in and out of the classroom, to learn and enact practices collectively and independently. Sequencing opportunities such that they integrate teachers' larger context with guided participation and opportunities for appropriation across a broad and intentional PD arc could create coherence for teacher learning, particularly in light of the field's call for ongoing and sustained PD (e.g., Darling-Hammond et al., 2017; Desimone, 2009). Side-by-side coaching is then one piece of this larger landscape and proof of concept that such integration is possible.

Those designing for teacher learning should consider questions such as: Where does (or could) the PD design attempt to bridge these planes? What professional learning activities might do so? How can these kinds of bridging activities be integrated into the arc of ongoing PD?

Analytically, we call on researchers to apply the lens of Rogoff's three planes to PD designs to augment previously established ideas about effective professional development.

ABSTRACTS FOR ASSESSMENTS: DESCRIBING A SUMMARY STATEMENT

Jonathan D. Bostic

bosticj@bgsu.edu

Erin Krupa
North Carolina State University
eekrupa@ncsu.edu

Quantitative assessment development is a challenging process. The ways in which an assessment might be used, as well as how its score can be interpreted should be clear to intended users. This manuscript provides a discussion about important and useful elements that should be provided by assessment developers. In turn, this information can foster greater usability and portability of quantitative assessments, which can support scholarship focusing on a specific issue.

Keywords: Assessment

Quantitative research requires the use of measures, instruments, or assessments that allow users to draw conclusions from data they collect. When a research purpose aligns with a previously created assessment, then it seems plausible to use it. On the other hand, if there are no assessments to measure a desired construct, then an individual or team must choose whether to develop one. In either case, a statement describing how to use the assessment might be employed to make scholarly decisions. At present, there is little guidance about what goes into such a statement for potential users of quantitative assessments. The purpose of this manuscript is to present list of recommendations to include in a summary statement for an assessment and then provide an example summary statement to highlight the recommendations.

Related Literature

The *Standards for Educational and Psychological Testing* ([*Standards*] AERA et al., 2014) describe five validity sources: test content, response process, relations to other variables, internal structure, and consequences from testing/bias. Reliability is a related component of the *Standards* but is not one of the five sources. These sources describe categories in which evidence may be grouped in order to make score interpretations and effectively use a measure. The *Standards* note that it is inappropriate to use phrases such as “the validity of the test” or that a test is valid and instead, encourage a focus on validation as “...the degree to which evidence and theory support the interpretation of test scores for proposed uses of tests” (p. 11). Thus, validation is a process and the validity evidence supports or refutes the score interpretations and uses (Kane, 2006; 2016). This may seem like a small language shift but such a shift has serious implications because a valid test conveys a different idea as opposed to a valid score interpretation from a test.

Historically speaking, this shift has been slow to happen in some mathematics education communities. For example, Bostic and colleagues (2019) analyzed *Journal for Research in Mathematics Education* (1970-2017) manuscripts examining elementary students’ learning outcomes to discern (a) whether validity evidence for uses was provided and if so, (b) how was the evidence presented. One result from that analysis was that seven of 97 manuscripts (7%) that used quantitative measurement with elementary students’ outcomes described any validity evidence associated with their instruments. It was most common to describe test content evidence from an expert panel review as well as a reliability statistic. From the 1980s onward, it became increasingly common for *Journal for Research in Mathematics Education* authors to discuss an author-created measure. It is difficult to determine whether the instruments described in these published articles might be useful for a scholar's purpose because it is unclear how to administer, score, and interpret results from the measure. A framework to help measure developers describe these aspects has potential to increase assessment usability and assist scholars seeking to conduct quantitative research within mathematics education contexts. While in-depth descriptions of assessments are still warranted (e.g., validation research), succinct and explicit summaries are needed for readers to quickly and effectively discern whether to consider an assessment for a desired use. Concomitantly, peer-reviewed assessment and validity research within mathematics education contexts has increased substantially in the last five years; hence, a need to have a shared framework for communicating a summary statement related to a quantitative assessment. This manuscript responds to the question: What should a summary statement for an assessment contain?

Method

Context and Participants

This qualitative study stems from work during a NSF-sponsored conference. The conference lasted two days. Attendees were selected from an application process that brought together 41 scholars with expertise in mathematics education, mathematics, psychometrics, or applied measurement. This group included 35 terminally-degreed individuals working in industry and university settings, as well as six graduate students. A major goal of the conference was to identify a set of recommendations for the elements to include in an interpretation and use statement (aka purpose statement).

Data Collection and Analytical Process

A set of elements were initially generated by the conference leaders. These elements were based on important elements highlighted in the *Standards* and provided to conference participants. Conference attendees were asked to draft an example summary statement for an assessment around a construct of their choice using these elements as a starting point. They were asked to note elements to include and eliminate from the provided list, and to add additional elements to discuss for inclusion. This small group work time was followed by a whole group discussion on the common elements to include in the summary statement. These small and whole group recommendations were incorporated in the elements/questions list and the document was further expanded to provide a draft description of each element/question. A revised document was used by small groups of participants to draft a new summary statement and provide feedback on the elements in the revised document. A whole group discussion was held and IUS element suggestions were solicited. The small group notes, example IUSs, videorecordings from the conference, and field notes from the whole group discussion were analyzed following the conference and used to craft a set of reporting recommendations for elements of the summary statement. Four researchers (i.e., the leaders of the conference) used inductive analysis (Creswell, 2012) as a tool to develop the summary statement. The inductive analysis started with re-reading (or re-listening) to materials (e.g., written work and recorded statements from the conference). Step two was to make memos consisting of initial ideas stemming from this examination of the data. Step three was to reflect on those memos as a way to synthesize them into support (or not) for aspects of the summary statement. This is needed as evidence to ground the summary statement in validity. Step four was to search for evidence within the data sets to support components of the summary statement. Step five was to search the data for counter evidence. Impressions with a paucity of counter evidence and a large set of evidence were retained. The sixth and final step was crafting clearly elements to share broadly as a summary statement.

Findings: A summary statement

We present the recommendations for a summary statement first, then describe some of the comments surrounding its development. The ten elements were grouped to better visualize three different aspects of a quantitative measure: Construct articulation, operationalization and administration, and scores. Construct articulation provides justification for measuring the construct and clarifying its importance. Operationalizing and administering the measure is intended to give information about how the measure should be used. Scores and scoring describe aspects related to scoring and the limitations/delimitations related to the measures' scores.

Aspect	Interpretation and Use Element
Construct Articulation	#1. Why measure this construct?
	#2. Why is it important to measure this construct?
Operationalization and Administration	#3. How is the construct measured?
	#4. Who is the target population?
	#5. What is the intended context for administration?
	#6. What are associated costs with using the instrument?
Scores and Scoring	#7. How are scores determined?
	#8. What are intended interpretations for scores?
	#9. How should scores be used?
	#10. What known warnings or cautions are important to consider?

Figure 1. Summary statement to describe score interpretations and uses of a quantitative assessment

There was consensus that the summary statement should be written for an end-user to make a decision about (a) whether the score interpretation from an assessment aligns with an intended use and (b) the degree to which the assessment aligns with a desired purpose. One of the participants working in the assessment industry, Melissa, said that "You still need the details for an instrument and its uses. A summary statement is a quick read." Lucas, a university faculty, said that "This summary statement can tell you whether the instrument actually measures what it says it does. It can also show where there are gaps in the validity argument to further explore." As a result of video, audio, and written data, we reached the conclusion that the summary statement provided necessary and sufficient evidence for potential end-users.

An Instantiation of the Summary Statement

We present an example summary statement for a problem-solving measure developed by an author of this manuscript. There are numerous peer-reviewed manuscripts detailing validity evidence and arguments for this problem-solving measure (PSM); hence, it provides a brief overview for potential measure users and administrators. It should be interpreted cautiously and provide readers with an example of a potential summary statement for an actual instrument.

The PSM3 measures students' problem-solving performance within the context of the third-grade Common Core State Standards for Mathematics (CCSSO, 2011). Past research has demonstrated that problem-solving measures (a) are large-scale in nature (e.g., PISA), (b) measure problem solving but the mathematics content does not align with instructional standards, or (c) measure problem solving without drawing on mathematics content (see Bostic & Sondergeld, 2015). Thus, the PSM3 fills a need as a problem-solving measure that aligns with instructional standards used in many states within the USA. It has 15 items displayed as word problems. Each is presented as a constructed response task. Students are asked to clearly write their answer on a provided line. The target population is English-speaking, grade-level students. PSM3 administration is typically performed during instruction for and can last 120 minutes; however, most students finish within 90 minutes. There is no difference in students' outcomes due to the completing the PSM in one sitting or across multiple sittings (e.g., six, 20-minute sittings). Calculators are not allowed for administration. Those interested in using the PSMs may contact the authors for pricing. Each item is scored dichotomously, which conveys the same information as partial credit scoring (Carney et al., accepted). Respondents' scores may be calculated as percent correct. Scores may also be analyzed using Rasch to explore how students' performance compares to norms. Results from Rasch analysis should be interpreted as information about students' problem-solving performance related to CCSSM content. Such Rasch results also convey students' outcomes compared to peers and norms. PSMs are designed to complement other data about students' mathematics outcomes and be interpreted as a single touchpoint of students' outcomes. PSM data are suitable for research, evaluation, and school-based needs and as seen in this manuscript, robustly address validity *Standards* (AERA et al., 2014). Results are not intended to track students into different mathematics classes.

Discussion and Implications

This summary statement is intended to provide scholars working within mathematics education contexts a shared perspective to convey information about their quantitative assessments. It functions much like an abstract serves a manuscript or proposal – offering at-a-glance information. This summary statement also addresses the five validity sources, which may be further unpacked. For example, the ways in which scores are analyzed using Rasch analysis tells a reader that the PSM3 results are measured in logit units, which cues a reader to deciding whether that suits their needs. One implication from this research is to further engage the mathematics education scholarly community in ways that encourage sharing measures, replication studies, and offer greater access to quantitative measures. Kane (2016) and the Standards (AERA et al., 2014) have recommended that clearly identifying key information about measures has potential to improve measurement practices.

Acknowledgments

ATTENDING TO AIMS IN ALGEBRA: THE JUGGLE STRUGGLE

Yufeng Ying

Brandon K. Singleton
University of Georgia
bksingleton@uga.edu

In this report, we explore the nature of aims for algebra instruction. First, we examine the major aims that have informed algebra education and curriculum reform from the 1960s into the current era. The relationships between aims are marked by compatibility as well as tension. We argue for researching and viewing aims as enacted priorities that are revealed through the everyday choices algebra educators make.

Keywords: Algebra and Algebraic Thinking, Curriculum, Research Methods, Teacher Beliefs

Algebra is a versatile subject. Scholars argue that algebra fosters generalization (Usiskin, 1995) and the recognition and use of structures (Kieran 1989). Algebra instruction can raise students' awareness of social injustice (Gutstein, 2006) and encourage autonomy (Kosko, 2016) and creativity (Chiu, 2008). However, the multiplicity of aims for algebra education can also bring a real challenge to today's algebra teachers: How should we coordinate the many aims for algebra learning? Should teachers organize their teaching with an equal emphasis on all possible aims that algebra education can carry? How do teachers make decisions on the aims that they pursue? The purpose in this paper is to discuss the need to identify and coordinate the many aims for algebra education.

Four Enduring Curriculum Aims

It is helpful to organize aims into a framework that captures the most central and enduring purposes for teaching algebra. One useful framework was developed by Kliebard (2004) while characterizing education during the early twentieth century. Kliebard proposed four major groups: humanists, developmentalists, social efficiency proponents, and social meliorists.

7. Humanists cherished western cultural heritage and the disciplinary value of classical subjects that increase students' mental power.
8. Developmentalists believed that the natural cognitive or psychological development of children should be given first priority when determining teaching content.
9. Social efficiency proponents concerned themselves with the needs of schools in a rapidly changing society, turning to the standardized techniques of industry and business.
10. Social meliorists believed education should actively foster social equity.

These four categories offer a means to explore the aims mathematics educators have emphasized throughout distinct historical periods.

During the 1960s, an array of curriculum projects known as the New Math (Phillips, 2014) took place in which mathematicians sought to ground school mathematics in the structure of the discipline. For instance, algebra during the new math movement was taught as an axiomatic system. Educators emphasized the importance of revealing the inherent and hidden structures behind algebra, such as set theory and concepts from abstract algebra (Herrera & Owens, 2001). Because this curriculum trend was led by mathematicians and emphasized the disciplinary value of mathematics, we might regard their aims during this period as in line with humanists.

By the 1980s, dissatisfaction with New Math made space for alternatives. Constructivism was one important response. Constructivists (e.g., Steffe & Kieren, 1994; Confrey, 1990; Ernest, 1994) felt that the psychological realities of young children, rather than the professional norms of mathematics as a discipline, dictated the aims of teaching and learning mathematics. Through research into student thinking and learning, algebra teachers started to recognize a significant gap between formal mathematics and students' own experiences with mathematics, and topics such as the transition from arithmetic to algebra gained attention in the field (e.g., Filloy & Rojano, 1989; Schoenfeld & Arcavi, 1988). Inspired by prominent psychologists such as Piaget and Dewey, constructivism can be characterized as a shift from the earlier humanist approach toward a developmentalist approach.

In 1983, the National Commission on Excellence in Education published a report titled *A Nation At Risk*, using an alarmist tone to bring national attention to perceived weaknesses in the American education system. The report's galvanizing influence formed the backdrop for efforts to create standards, measurement tools, and accountability policies for systemic educational improvement. These efforts targeted the efficiency of mathematics education as a system, working to cultivate mathematical knowledge as widely and effectively as possible. In the pursuit of efficiency through standardization and accountability, other educational aims were sometimes pushed aside when achievement was used as the indicator of national prosperity (Berliner, 2011). Teachers in algebra classes have felt pressured by the need for test preparation, adopting pedagogies with certain compromises and sacrifices (see Gutstein, 2006).

An ongoing movement in mathematics education that can be associated with aims of social meliorists is known as the "sociopolitical turn" (Gutierrez, 2013). In recent years, an increasing number of socially-minded mathematics educators proposed that teachers of mathematics should use their instruction to take part in solving social problems to create a more equitable society. In algebra education, scholars have promoted more culturally relevant pedagogies and equity-centered problem-solving approaches in teaching (e.g., Ligocki, 2017; Boaler & Sengupta-Irving, 2016; Gutstein, 2006).

The history of algebra education suggests that at a broad level, aims differ, aims can rise and fall, compete for attention, and overlap in complicated ways.

Aims and Priorities

The overview above suggests that there has not been a single, uniform idea about what constitutes "good algebra." Rather, educators' visions of algebra education have fluctuated throughout history in response to different but persisting educational aims. How then should educators navigate the existence of different aims?

We argue the first step in navigating aims is to think of aims as potential priorities. Priorities are objectives that require intentional effort. Consequently, the tension between aims plays out in a subtle dynamic as educators at all levels make countless choices about what should be taught and how. Therefore, the struggle between aims is not only an ideological debate but is also a practical challenge that algebra educators face every day.

To illustrate such a point in more detail, we explore one form of tension in algebra teaching between two fabricated teachers named Jack and Rose. Both teachers are preparing lessons with the main purpose of helping students to become familiar with multiplication.

Jack graduated with a master's degree in mathematics education and enjoyed reading research about students' algebraic conceptions. Therefore, in preparing the lesson, Jack decides to mimic an activity that Kaput (1999) highly praised, where the teacher helped students to informally prove the commutative property of multiplication by using arrays of sticks. Jack structures the lesson by planning to first ask students to use arrays of sticks to represent the products of different integers, such as 4×7. He expects students will likely generate at least two ways of representing the product (4 rows of 7, and 7 rows of 4). Jack will leverage those activities and invite students to think about whether different representations will have different total numbers of sticks. Then, Jack may guide students to realize that reversing the order of multiplication is exactly like rotating the number of rows with the number of columns for arrays of sticks. Since transposing rows with columns does not change the total number of sticks, changing the order of multiplication should preserve the product. In general, Jack may hope the students can both practice multiplication through this project and engage in other desired mathematical activities such as generalizing and creating mathematical representations.

Rose also graduated with a master's degree in mathematics education and enjoyed reading research about equity in mathematics classrooms. Therefore, in preparing her lesson, Rose decides to create a mini social project similar to what Gutstein (2006) has shared. Rose selects water consumption as the central issue. Rose may start to provide students a list of common water-consuming activities along with the average water use of each and ask students to first decide the gallons of water they think are needed for an average person or family per day. (For example, washing one's hands uses 2 gallons of water, so a person who washes his or her hands 4 times per day requires 8 gallons in total.) Then, Rose may provide students with information about how different nations have different average rates of water consumption per individual and ask students to calculate an average person's possible water-consuming activities depending on the country of residence. Through careful sequencing and structuring, Rose hopes that the students not only complete a list of multiplication problems but also use the results of their multiplication to have a broad understanding of the international inequality of water consumption and develop good habits of conserving water.

Jack and Rose may or may not know about any theoretical categories of aims describing their choices. Still, consciously or unconsciously, every pedagogical choice that Jack and Rose have adopted is also a choice between different educational priorities and aligns with different educational aims. Indeed, research on teacher beliefs has widely reported the following: a) teachers develop a complicated set of values and beliefs; b) those values and beliefs guide and influence their everyday teaching, planning, and assessment; c) those values and beliefs frequently do not need evidence to back them up; and d) direct training in certain pedagogical models shifts teachers' beliefs and principles (e.g., Rimm-Kaufman et al., 2006; Kagan, 1992; Richardson, 1996). Building from this literature, we argue that different educational aims act as distinct educational priorities that influence almost every instance of small or large decision making throughout the educational process. Teachers face choices between educational priorities when they are picking which task or activity to implement, researchers face choices between educational priorities when they are deciding which topic to research, and administrators face choices between educational priorities when they are judging which curriculum and policy to use.

Such a conceptualization of aims as educational priorities is consistent with our earlier discussion of the historical fluctuation of aims in the algebra curriculum. Researchers and educators who advocate a particular type of aim rarely deny the value of other possible aims. However, they do tend to make an intentional effort to prioritize their own preferred aim over others during research and curriculum reform. Thus, in a sense, aims are commensurable, as one's choice in picking a certain priority does not suggest one's denial of the value of other priorities. But aims conflict with each other as the options contributing to different aims compete for educators' intentional effort. The question we are left with is how the conceptualization of aims as educational priorities brings new insight into the work of juggling between aims.

Implications and Recommendations for Future Research

We derive several important implications from conceptualizing aims as priorities. The first implication is that aims are not cost-free and tensions between aims will inevitably persist. If competition between aims is viewed as a philosophical dispute, then aims might be reconciled at a theoretical or ideological level by weaving aims together into some grand, comprehensive quilt. However, situating the juggling of aims as an empirical reality of making choices between educational priorities suggests that tensions will persist and prioritizing aims will always have its costs.

Second, the tension and coordination between aims should be informed by research. All teachers, researchers, and policy makers are constantly picking their own priorities in their decision making and selecting their own preferred aims for their work. Consequently, there is a need to develop theoretical constructs in helping educators in all branches to conceptualize the tension and tradeoff between each aim along with an aim's relative affordances and constraints. To make aims an explicit object of research calls for expanding existing branches of research. Much of mathematics education research can be summarized as design science (see Cobb, 2007) in which teacher-researchers attempt to study and improve mathematics teaching and learning by drawing from various paradigms of scientific inquiry. When researchers conduct design science, they choose aims somewhat freely and they study the settings in which those aims can most profitably be observed and improved. Given an aim that is deemed valuable *a priori*, what are the principles by which to attain it? This research is useful, but we call for new research that adopts a different underlying premise: Given a setting with competing aims at work, what are those aims, where do they originate from, how are they prioritized and negotiated, and what are the consequences or implications of attaining or failing to attain each aim? Such research intentionally surveys and coordinates different aims by addressing the "economy" behind various priorities. For instance, not all aims are equally viable in different content areas or settings. Similarly, some aims can be satisfied with a small amount of intentional effort while others require more. Some aims have broad implications, others do not. Knowing the economy of aims helps researchers and practitioners to prioritize aims via a rigorously informed and justified process. (For interested readers, we recommend Pais (2013), Lundin (2012), and Wagner (2017) as some relevant work.)

The third implication is to respect educators holding different aims. This report does not call for a hierarchical ranking of all aims. Rather, research provides perspective to select aims more clearly. This proposal echoes Rorty's (1979/2009) idea of hermeneutic philosophy and Piaget's (2013) view that a central objective of philosophy is the "coordination between values" (p. 3). Research and scholarship about the aims of algebra education do not function as supreme guidance which teachers ought to follow, but rather as an instructive knowledge base that educators consult when selecting values, setting aims, and working to attain them (see Hiebert, 1999). We respect people’s right to pursue different aims, but just as importantly, we hope every choice can become an increasingly informed and justified choice.

RETHINKING AGENCY IN CRITICAL MATHEMATICS EDUCATION

REDEFINIENDO AGENCIA EN LA EDUCACIÓN MATEMÁTICA CRÍTICA

José Martínez Hinestroza
Texas State University
josemartinez@txstate.edu

This paper focuses on critical mathematics education (CME) and its attention to children using mathematics to effect change and develop critical consciousness. Given these tenets, in CME common characterizations of agency as children's ability to act on the world according to their own choices are tautological. A poststructuralist perspective can strengthen and further specify a conceptualization of agency. Accordingly, I argue that in CME agency involves merging, reshaping, and relocating discourses available to the child. Recognizing these emergent discursive practices entails a paradigm shift from viewing children as incomplete individuals in transition to adulthood, toward recognizing the multiple ways in which children can transform their own lives and conditions. I draw on examples from a third-grade classroom to illustrate the analytical possibilities of this CME-aligned, poststructuralist conceptualization of agency.

Keywords: Elementary School Education; Equity, Inclusion, and Diversity

Research on critical mathematics education research has yielded abundant descriptions of children showing (sometimes) newfound confidence. These children take initiative to generate their problem-solving strategies, as opposed to passively following others' strategies. Such descriptions frequently serve to illustrate agency (see, for example, Turner, 2012). These portrayals of agency have served the important purpose of highlighting that children are capable of solving mathematical problems in creative ways that make sense to them. These examples, however, rarely include children who remain silent during class discussions and children who resist teacher requests to engage with mathematical tasks (Langer-Osuna, 2018). Children's initiative and acting on the world seems valued as long as it is directed toward the pedagogical game set in place by the teacher (Valero, 2005). This notion of supporting agency (simplistically defined by now as children taking initiative) while simultaneously enforcing compliance with teachers' expectations is the apparent contradiction that this paper explores. This exploration is particularly important in critical mathematics education (CME) because of its focus on liberation and inclusivity (Frankenstein, 1983; Gutstein, 2007; Skovsmose, 1994). Accordingly, in this paper I propose a conceptualization of agency that honors the commitment of CME to liberation. I argue that in CME agency involves merging, reshaping, and relocating discourses available to children. In the following section, I begin by discussing agency as constitutive of CME.

Agency in Critical Mathematics Education

Grounded on critical theory and critical pedagogy, critical mathematics education questions taken for granted practices that perpetuate the oppression of specific communities (Freire, 1970; Kincheloe, 2004). This commitment is taken into action by continuously developing pedagogies that support liberation (Kincheloe, 2004). Such pedagogies challenge problematic assumptions in the teacher-student dichotomy, according to which the adult takes on the role of knowledge-bearer and decision-maker that liberates the unknowledgeable child. Instead, in CME, students and teachers come together in a relationship of collaboration where each person brings in unique and valuable expertise and skills. Broadening the educational goal beyond developing children's mathematics conceptual understanding, CME reconfigure the student-teacher relationship, the content of instruction, and how children use what they learn (Brantlinger, 2013; Gutstein, 2007; Skovsmose, 1994). In short, students and teachers work collaboratively using mathematics to resist oppression (Gutstein, 2007).

In CME, children and teachers make joint decision about what social situations to study (Brantlinger, 2013). In these explorations, CME rejects the traditional practice of teachers explaining how to solve a problem and children reproducing the procedure presented (Lawler, 2012). Instead, students solve problems in their own creative ways, assessing their own and each other's strategies and determining courses of action to transform social circumstances. Simultaneously, children develop critical consciousness about whose ideas are valued and about their own marginalization in mathematics education (Gutiérrez, 2002; Skovsmose, 2000).

In light of these tenets, defining agency in CME as children taking initiative becomes a pleonasm, as the teacher-child hierarchy is challenged and they both decide Overlooking children who do not engage in these processes in the ways that teachers expect, or insisting that these children conform to the goals and practices the adult in the classroom established results in the agency contradiction discussed above. That is, defining agency as taking initiative and focusing on children who do what they are expected to do involves subjugating children in ways that CME attempts to interrupt. Unexamined definitions of agency can inadvertently maintain well-intentioned practices that, in the end, limit agency, as I discuss in the next section.

Traditional Definitions of Agency

Frequently, agency in CME is defined as children's acting on the world following their own choices (Martin, 2000; Turner, 2012). This definition, however, appears to be incomplete because, as de Freitas and Sinclair (2011) explain, "given the complexity of agency, all definitions will prove to be inadequate" (p. 134). Sometimes, agency is used interchangeably with initiative, choice, and confidence (Davies, 1991). Other times, definitions of agency are implicit, contributing to an "I know it when I see it" approach (see, for example, Boaler & Greeno, 2000). Efforts to elucidate what agency is have narrowed the focus to academic agency, which in CME means mathematical agency. Mathematical agency emphasizes that children can generate and assess their own problem-solving strategies (Lawler, 2012). This focus on intentional thinking, is reminiscent of Valero's (2005) myth of the schizo-mathematics-learner "with a clearly divided self: that one that has to do with mathematics, and the one that has to do with other unrelated things. Of course, those other unrelated things are secondary" (p. 5). Instead of presenting a mathematician identity as available for children, the overemphasis on mathematical agency imposes such identity. Choice—a component of agency—becomes an illusion, as lines of action are limited to those where the child pursues mathematical ideas.

These traditional definitions of agency have implications regarding what is valid evidence of agency. This evidence frequently involves observable behaviors or actions attributed to an individual (Chao & Jones, 2016; Martínez & Ramírez, 2018). Agency, however, is also portrayed as something that an individual senses and feels (Louie, 2019). In either case, agency is defined in a binary: It either is or is not present, felt, or used. Although this approach allows to operationalize analysis of agency, the contradiction mentioned earlier emerges again, as certain instances seem to simultaneously show agency and subjugation. Such is the case discussed before about making a mathematician identity available but also imposing such identity. In the next section, I discuss how a poststructuralist definition of agency can help make sense of this apparent contraction.

A Poststructuralist Definition of Agency in CME

In poststructuralism, discourses are “the complexes of signs and practices that organize social existence and social reproduction. In this view, a discourse delimits the range of possible practices under its authority and organizes how these practices are realized in time and space” (Peirce, 1989, pp. 403-404). Discourses guide what an individual and a social group see as possible. At any given moment, multiple discourses influence simultaneously our interpretations of reality (Davies, 1991; St Pierre, 2000). Although we may not be able of escaping the discourses that influence us, we may become aware of these discourses and their effect in our decisions (Davies, 1991). This awareness allows us to reconfigure and resist discourses (Davies, 1991; James, 2009). In CME, a few studies have begun to advance a notion of agency as children transforming and resisting available discourses (Louie, 2019; Stinson, 2013).

Drawing on a poststructuralist perspective, I propose agency in CME as children acting on the world by merging, reshaping, and relocating discourses available to them. Consistent with CME’s focus on critical awareness, in this conceptualization of agency children become aware of how they are constituted through dominant discourses. Moving awareness to action, children may take up, transform, or resist discourses, including discourses about what agency should look like. This kind of agency allows for children to resist aspects of CME, some teacher decisions, and the imposition of specific identities. This means rewriting master narratives that limit what children and adults see as possible.

In this conceptualization, agency is interpretative and comes into existence as felt, experienced, used in multiple concurrent ways. The adult is no longer the one who gets to decide on the presence or absence of agency. Instead, in any given situation a child can simultaneously feel a sense of agency when interpreted from one discourse and a sense of subjugation when interpreted from another. Both interpretations are legitimate and constitute reality for the child. An adult observer can interpret this situation differently, drawing on discourses available to them. Iterative interpretations from multiple discourses may create a nuanced story of agency.

Classroom Example

I illustrate this poststructuralist definition of agency in CME with an example from a third-grade Spanish-immersion classroom in the Midwest of the United States. There were 21 children in this classroom. The teacher was a Spanish-English bilingual, US-born Latina. I, a Spanish-English bilingual, Latino researcher visited this classroom regularly as part of a larger study.

This example comes from a teaching unit on what it means to take something away, addressing both the mathematical connotation (i.e., subtraction) and other social connotations (e.g., taking away people’s rights or properties). During one of the lessons, the class discussed how to solve five take away eight. While the discussion went on, a child, Anna (names are pseudonyms), went to a cabinet and took a box with linking cubes. She marched to the front of the classroom, carrying the box, and she raised her voice, demanding the class’s attention. Her classmates quieted down. Anna indicated that it was necessary to act out the situation. She grabbed five cubes and said she needed to give eight to me (the researcher in the classroom). She handed out one cube at a time and she counted from one to five, stopping when she had no cubes left. She announced that, since she did not have any more cubes, it was not possible to take away eight from five. The teacher worried that only one child would monopolize the whole class discussion, so she instructed children to think quietly about Anna’s explanation. After a minute, the teacher randomly picked a popsicle stick from labeled with one of the children's names. Reading the name, the teacher called on Joanna, who shrugged and, in a low voice, said that it was not possible to take away eight from five.

Following common definitions of agency, this interaction could be taken as evidence of agency, attributed to Ann as an individual. Ann took the initiative to use the cubes and act out the problem, without any adults or children having told her what to do. An interpretation of Joanna' agency is more nuanced. Although well-meaning, trying to distribute talking time, the teacher unintentionally subjected Joanna to comply with her expectations. Joanna was put in a position where she had to prove she had been following what Ann did and that she had something to say about it. Ann complied with these expectations, but she seemed more interested in deflecting attention. This example illustrates the contradiction between apparently supporting agency while simultaneously limiting the child's possible lines of action to those that complied with the teacher's expectations. Joanna could have decided not to answer, ignore the teacher, or express that she was not interested in the discussion. These lines of action, however, would likely have turned her into the target of an intervention for her to eventually engage with the mathematical task. In short, Joanna is encouraged to express her agency as long as it involves following adult-approved lines of action.

Discussion

Supporting agency on the condition that it be used only on a predetermined endeavor renders agency irrelevant, at best, and illusive, at worst. This is particularly important in CME because of its goal of promoting liberation and because it challenges hegemonic discursive practice. To further align definitions agency and CME tenets, I proposed a definition of agency that avoids presenting some children as agentless. This poststructuralism-informed definition argues for making room for children to merge, reshape, and relocate discourses available to the them. Instead of suppressing discursive practices such as silence, resistance, and apathy, children and teachers can work collaboratively to make sense of why these discursive practices emerge and how they should be handled. This collaboration entails a paradigm shift from viewing children as incomplete individuals transitioning to adulthood, to recognizing them as skillful and active participants who can transform their own lives and circumstances. That is, this entails an authentic and complete engagement with the CME purpose of promoting liberation.

Recognizing agency as interpretive, I provided a classroom example that shows how agency can come into existing in simultaneous and contradicting ways, depending on the discourses from which we draw. From discourses made available to a teacher, an interaction can appear as supporting agency by making room for a child to speak up in class. This interaction, however, can simultaneously be interpreted as subjugating the child to comply with the performative task of showing attention, interest, and mathematical understanding. Agency, then, appears as multifaceted and taking on multiple meanings when considered from the perspectives that specific discourses make possible.

A TWO-LAYERED APOS ANALYSIS OF INEQUALITY NUMBER LINE GRAPHS

Alison Mirin
University of Arizona
alisonmirin@gmail.com

Jodi Frost
Indiana State University
Jodi.Frost@indstate.edu

Reasoning with inequalities and their solutions is important in mathematics. We provide a two-layered APOS genetic decomposition of the meaning of number line graphs as representing solution sets.

Keywords: Algebra and Algebraic Thinking, High School Education, Learning Theory

Inequalities and their solution sets are an essential aspect of various mathematics classes and topics. Number lines display solution sets of real numbers; the number line graph of a statement of the form P(x) displays all values of x that make P(x) true. We say a number c *satisfies* P(x) to mean that P(c) is true. For example, graphing $|x-9|\leq 4$ shows all the numbers between 5 and 13, since these are the numbers that satisfy $|x-9|\leq 4$ (Fig.1)

Figure 1: A number line graph of $|x-9|\leq 4$

In Figure 1, the number line graph is a visual representation of an inequality. Indeed, to graph an inequality on a number line is to graph its solution set. The limited research on solution sets demonstrates that students generally do not interpret inequality graphs as representing solution sets (Bicer et al., 2014; Frost, 2015; Mirin, 2020). We use Action-Process-Object-Schema (APOS) to describe ways that students might understand number line graphs as visual displays of solution sets. This genetic decomposition can provide a basis for an instructional intervention.

APOS is a cognitive framework that helps explain how individuals can develop action and process conceptions to ultimately encapsulate into mathematical objects. Dubinsky and McDonald (2001) explain an action as a "transformation of objects perceived by the individual as essentially external and as requiring, either explicitly or from memory, step-by-step instructions on how to perform the operation." (p. 276). A process comes from interiorizing an action or series of actions. An individual with a process conception can envision "performing the same kind of action, but no longer with the need of external stimuli" (Dubinsky & McDonald, 2001, p.276). We use the word "procedure" in its colloquial form to agnostically refer to both actions and processes. An object is the result of encapsulation of a process: "an object is constructed from a process when the individual becomes aware of the process as a totality and realizes that transformations can act on it" (p. 276). A schema involves actions, processes, and objects and how someone coordinates them. A genetic decomposition is an account of components of a schema. Specifically, it describes how someone can progress to an object conception by first developing an action then process conception.

APOS theory has been used in a variety of contexts, both finite and infinite. For a good example of a straightforward genetic decomposition, see Dubinsky and McDonald's (2001) account of left cosets -- in this case, the procedure being reified is the construction of individual cosets by performing the group operation. Dubinsky et al. (2005) use APOS to explain how individuals come to understand infinite objects using the set $\mathbf{N}=\{1,2,3\ldots\}$. An *action conception* involves enumerating members of the set by adding 1 repeatedly to result in a finite subsegment of **N**. We start with 1, we add 1 to get 2, we add 1 again to get 3, etc., for any finite number of steps. Since, as discussed earlier, an action conception involves actually performing the actions, it would be impossible to obtain the entire infinite set via an action conception. A *process conception*, however, involves interiorizing these actions without performing them and enables the individual to imagine carrying out the procedure *ad infinitum* and hence imagine infinitely many natural numbers. An individual might encapsulate such a process into an object (in this case, the infinite set **N**). The authors explain that encapsulation is what enables individuals to compare cardinalities and perform arithmetic on infinite sets. We observe that, with at least some infinite processes, there appears to implicitly be *two* action-process-object layers; the infinite one discussed (which we refer to as *global*), and a finite one corresponding to each "step" (which we refer to as *local*). Below, we elaborate on these two layers in the case of inequalities.

An Action-Process-Object View of Inequality Graphs

Unlike with the infinite set example described above, enumerating an individual member of our set (in the case of inequalities, a solution set) involves more than simply adding 1 to a number; it involves conceptualizing that number as satisfying the inequality (described in detail below). Additionally, a student must coordinate multiple (usually infinitely many) solutions and understand that these solutions simultaneously make the inequality true (to form a solution set). Accordingly, we use a two-layer approach.

The Local Layer

The *local layer* pertains to individual solutions. *action* understanding at the local layer involves being able to instantiate the inequality (substituting a value for x and computing each side), evaluate as true or false, then plot accordingly if true. For example, a student with a local action conception can plug in, say $x=8$, into $|x-9|\leq 4$, evaluate the resulting inequality ($1\leq 4$) as true, and then plot a single dot to represent $x=8$.

Interiorization enables the student to think about this procedure without carrying out the procedure themself; they can imagine the procedure as having been performed. The student has the knowledge that if they *were* to plug in 8 for x in the inequality, they would end up with a truth-value which could result in a dot on the number line. In other words, when a student is thinking of a process, they are not thinking of step-by-step computation, but instead thinking of the transformation from x-value to truth-value as a whole. Observe that at the local level, the action and process conceptions closely mirror the action and process conceptions for the concept of function as described in Breidenbach et al. (1992). However, instead of a particular value of x being mapped to a number, it is mapped to a truth-value and potentially a dot on the number line. At this stage, students are envisioning whether a particular number will be noted on their number line. A student with this conception understands that *if* they were to plug in a particular value, it would either satisfy or not satisfy the inequality (and if it did satisfy the inequality, then it is graphed).

The object conception is where our account radically diverges from Breidenbach et al.'s single-layer (1992) account of *function*. In the case of function, the object conception is an entire, possibly infinite set of ordered pairs. For our local conception, our object is more akin to a *single* pair; continuing with the example above, the relevant object is our value of x (8), paired with the corresponding truth-value (True) (i.e. the ordered pair (8, True)). The number line dot is a visual representation of this coupling. The local level is concerned only with individual solutions rather than the solution set.

At the local layer, the action, process, and object conceptions entail different conceptualizations of the dot on the number line. With a local action conception, the dot is an artifact of a mathematical procedure that the student performed step-by-step (action). With a local process conception, the dot is an artifact of an envisioned interiorized procedure (process): one that the student might not have performed themself but can envision having been performed. With a local object conception, the dot need not involve a procedure at all; instead, it represents a value of x (e.g. the number 8) statically coupled with a truth-value (True). However, some students with object conceptions might de-encapsulate to attend to the underlying procedures in some problem-solving situations.

The Global Layer

The global layer goes beyond individual values and involves how a student might come to understand the solution set in its entirety. This layer parallels the APOS analysis of the set of natural numbers described above: an action conception accounts for the one-at-a-time enumeration of members of the solution set. Instead of adding 1 like we did with the enumeration of **N**, the following procedure takes place: a value of x is substituted, the inequality is evaluated, a truth-value is noted, and a dot is possibly placed on the number line. An action conception enables this enumeration procedure to be repeated for multiple, but not infinitely many, values of x.

Like with constructing **N**, interiorizing the global procedure of repeatedly considering individual values is what produces a *global process conception*. Someone with a global process conception need not imagine enumerating every single value themself. To continue with our analogy with the construction of **N**, the process conception is what allows someone to imagine 1 being added an infinite amount of times to produce an infinite set. Similarly, the global process conception for graphing inequalities is what enables someone to imagine infinitely many values of x. Thus, a global process conception enables someone to give an infinite enumeration of values of x and the visual representation that that would produce: having a dot on every single number that satisfies $|x-9|\leq 4$ (Figure 1). Through encapsulation a student can move to an object understanding. A student with a global object understanding can produce the complete solution set to the inequality on a number line and recognize that it simultaneously represents all values that make the inequality true. It is at this level that a student can potentially operate on solution sets with Boolean operations (e.g. in absolute value problems) and recognize when operating on an inequality leaves the solution set invariant.

At the global layer, the action, process, and object conceptions entail different conceptualizations of the number line graph. As shown in Figure 2, an action conception only allows for finitely many actions and hence only finitely many members of the solution set. An action conception can result in a number line that looks indistinguishable from an infinite solution set. However, in the student's mind, they are understanding the number line in a way that is closely represented by Figure 2 below:

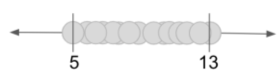

Figure 2: A global action conception of $|x-9|\leq 4$

For a student with a global action conception, their number line graph is an artifact of their finite mathematical activity of repeated work at the local level that they performed themself (plotting various values). Notice that this graph is incomplete, as the student understands it as involving only finitely many values. We can contrast this with a global process conception, in which the number line graph (a visual representation of the solution set) is an artifact of an envisioned infinite process. Like with the global process conception, the global object conception involves understanding the number line graph as complete and representing infinitely many values. However, it differs in that the number line graph need not represent any sort of procedure of instantiating individual values of x; instead, someone with such a conception understands the number line as statically showing the solution set.

Coordinating Layers

Like with other applications of APOS theory, we do not expect a student to progress linearly through each stage. Instead, a student's schema can involve a mix of various understandings at the local and global levels, within some constraints. A student with any of the local conceptions can have a global action conception, for example. How an individual element is enumerated depends on the local understanding of that student - the enumeration could be through substituting and evaluating (local action), envisioning such substituting and evaluating (local process), or simply listing a solution (local object). A student with a local and global action conception understands each individual point as an artifact of their own mathematical activity that they perform themself, and they understand the number line as a record of their repeated mathematical activity of plugging in, evaluating, and plotting individual values. A student with a global action conception and local object conception would understand each individual point on their number line graph as representing a solution to the original inequality, yet at the same time see their number line graph as an artifact of their own finite mathematical activity of enumerating individual solutions. Notice that local-object and global-action closely mirrors the "action" conceptions that Dubinsky et al. (2005) describe for enumerating an infinite set where enumeration of individual elements is straightforward and unproblematic, but the enumeration itself only allows for finitely many steps. While there is not enough space here to elaborate every way in which a student could have a y local conception with a z global conception, global and local conceptions are not entirely independent. For example, it would not make sense for a student to develop a global object conception and a local action conception. This is because it would not make sense to understand the number line graph as representing a solution set without understanding the notion of a point representing an individual solution.

Conclusions and Implications

Our two-layered genetic decomposition can provide the basis for a future learning trajectory, which is much needed in light of the literature that suggests that students do not attend to the ideas of solution, solution set, or truth-value (Bicer et al., 2014; Frost, 2015; Mirin, 2020). The number line can play an important role in this trajectory; it can act as a record-keeping device, which can help the student transition from a global action to a global process conception. This genetic decomposition suggests instructional interventions that involve substitution and evaluation of truth. For example, students often are confused by whether to place a closed or open circle at the endpoints (Bicer et al., 2014; El-Khateeb, 2016). Connecting the number line to the truth-value for that particular substitution would elucidate that if the value satisfies the inequality, a closed circle should be placed on the graph. Importantly, substitution can orient students to attending to the notion of truth-value.

In conclusion, the genetic decomposition outlined here can serve as both the basis for an instructional intervention and a framework for understanding students' development in their reasoning about the relationships between inequalities, solution sets, and number line graphs.

STRUCTURING AND ENUMERATION: A PRELIMINARY DISCUSSION OF SPATIAL-TEMPORAL-ENACTIVE STRUCTURING

Joseph Antonides

Michael T. Battista
The Ohio State University
battista.23@osu.edu

Prior research has identified spatial structuring—the mental process of constructing an organization or form for an object or set of objects—as critical to students' development of spatial-geometric reasoning and understanding. We propose an alteration to this construct to include aspects of structuring that are especially salient in combinatorial enumeration (though also present in geometric contexts). Specifically, we replace "spatial" with "spatial-temporal-enactive" (or S) to include temporal and enactive aspects of forming and iterating spatial composites. Further, enumeration involves numerical structuring—the mental process of constructing an organization or form for a set of computations, formulas, or expressions. In meaningful, conceptualizations-based enumeration, students can link numerical structuring to S* structuring, a process we call S*-numerical linked structuring (or S*NLS).*

Keywords: Cognition; Advanced Mathematical Thinking; Geometry and Spatial Reasoning

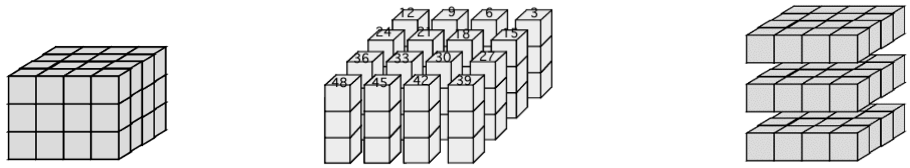
In this paper, we provide a preliminary discussion of a framework for conceptualizing students' thinking and reasoning about enumeration. Our focus is on combinatorial enumeration, though our framework can also be used to analyze student reasoning in additional, non-combinatorial enumeration contexts. We begin with an overview of the original definitions of spatial structuring (Battista & Clements, 1996) as well as numerical structuring and spatial-numerical linked structuring (Battista et al., 2018). We then introduce and discuss spatial-temporal-enactive structuring as an elaborated version of spatial structuring.

Spatial Structuring

Battista and colleagues have argued that spatial structuring is critical to students' progressions toward increasingly abstract and powerful spatial-geometric conceptualizations and forms of reasoning. Originally, Battista and Clements (1996) defined *spatial structuring* as "the mental act of constructing an organization or form for an object or set of objects" (p. 282), which includes, but is not limited to, establishing units, relationships between units, and composite units. In more recent research, Battista et al. (2018) analyzed the relation between spatial and geometric reasoning. In so doing, they identified two additional mental processes: *numerical structuring* and *spatial-numerical linked structuring* (or SNLS). Numerical structuring is "the mental act of constructing an organization or form for a set of computations" (p. 211), and SNLS is "a coordinated mental process in which numerical operations … are performed based on a linked spatial structuring … in a way that is consistent with properties of numbers and measurement" (p. 211).

As an example, consider the task of enumerating unit cubes in the $4\times4\times3$ cube array shown in Figure 1a. The SNLS in Figure 1b suggests a spatial structuring of the array into columns, with 3 cubes in each column. A student with such a spatial structuring might count by iterations of three, a numerical structuring linked directly to their spatial structuring (thus an instance of SNLS): 3, 6, 9, …, 48. Alternatively, a student might spatially structure the array into three 4×4

layers, which they might link to the numerical structuring 3×16, as shown in Figure 1c.



(a) (b) (c)

Figure 1: (a) A $4\times4\times3$ Cube Array, (b) A Column-Based SNLS, (c) A Layer-Based SNLS

Extended Version of Spatial Structuring: Spatial-Temporal-Enactive Structuring

In this paper, we introduce an elaboration of spatial structuring and SNLS, in particular to include combinatorial forms of enumeration. Rather than "spatial" structuring, we focus on an elaborated mental process of "spatial-temporal-enactive" (or S*) structuring. Structuring is a mental process of construction and is thus *active* and occurs *over time*. S* structuring highlights the temporal and enactive aspects of structuring by focusing on the organized sequences of actions and operations that students use to structure and ultimately enumerate spatial composites.

The temporal and enactive aspects of structuring became especially salient through our analyses of students' combinatorial reasoning in contexts where the spatial aspect seemed to be less important. For instance, consider the problem of enumerating the possible outcomes of a six-person race. The task is prominently situated within a temporal-enactive modality; the spatial nature of the task is implicit and is representational in nature. Nevertheless, visualization/imagery occurs in all sensory modalities (Barsalou, 2008; Moulton & Kosslyn, 2009), and even in contexts with a less prominent spatial component, students' mental representations (and mental models) are likely spatial (Winter et al., 2015).

Further, we distinguish two distinct forms of S* structuring that are especially pertinent to combinatorial forms of enumeration: inter-composite structuring and intra-composite structuring. We define *inter-composite structuring* as the temporal process by which an S* structuring is established for the *composites* within a set of spatial composites. We define *intra-composite structuring* as the temporal process by which an S* structuring is established for an *individual* composite (out of units and, potentially, sub-composites).

For example, consider the task of enumerating all possible towers 3-cubes-high, each tower containing 1 red, 1 blue, and 1 green cube. An inter-composite structuring might be: "RGB, RBG; BRG, BGR; GRB, GBR." But a different inter-composite structuring would be: "RBG, BRG, GRB, RGB, BGR, GBR." An intra-composite structuring might be: "I start with a red cube on bottom. Then I connect a blue cube on top of the red, then a green cube on top of the blue." A different intra-composite structuring could be: "I start with a blue cube in the middle. I then attach a red cube to the bottom of the blue cube, then a green cube to the top of the blue cube." Both intra-composite structurings yield the same tower (RBG), but they have important differences. A student using the first intra-composite structuring to construct towers might organize the *set* of towers based on the color of the bottom cube, but a student using the second intra-composite structuring might organize the towers based on the color of the middle cube. Thus, different intra-composite structurings can lead to different inter-composite structurings.

Additionally, we define S*-numerical linked structuring (or S*NLS) in a way that is consistent with Battista et al.'s (2018) original SNLS formulation. S*NLS is the mental process of coordinating S* structuring and numerical structuring in reasoning so that the corresponding

S* and numerical structures are conceptually linked to each other. According to Battista et al., the normal order of activation is S* structuring, *then* numerical structuring. That is, students construct a numerical structuring that is conceptually linked to an established S* structuring. However, meaningful S*NLS reasoning can also occur with the reverse order of activation, as is often the case in combinatorics. For instance, a student may be given a numerical/algebraic expression, then be asked to provide a combinatorial interpretation of the expression—that is, conceptually link the expression to S* structuring processes that describe what the expression might be used to count. Or, the student may be given more than one numerical/algebraic expression and be asked to explain why they can be used to enumerate a given set. One important example of the latter form of S*NLS is in proving that two expressions are equal by arguing (via S* structuring) that each expression counts the same finite set (Erickson & Lockwood, 2021).

We hypothesize that our framework provides an elaboration of Lockwood's (2014) set-oriented perspective and Lockwood's (2013) model of combinatorial thinking. Her model consists of three interrelated components: sets of outcomes, counting processes, and formulas/expressions. A set-oriented perspective emphasizes the role of sets of outcomes in solving counting problems. According to Lockwood (2014), "Individuals with such a perspective would recognize that different ways of structuring a set of outcomes might reflect different respective counting processes" (pp. 31-32). We believe our framework will shed light on the processes by which students structure and conceptualize sets of outcomes, and conceptually link these constructions to appropriate numerical/algebraic expressions. See (Antonides & Battista, in progress) for further discussion.

An Example of Using S* Structuring and S*NLS to Analyze Student Reasoning

We recently conducted one-on-one constructivist teaching experiments (Steffe & Thompson, 2000) with five undergraduate students, none of whom had studied combinatorics previously. Due to COVID-19, the teaching experiments were conducted remotely via Zoom. The goal of each teaching experiment was to instructionally guide each student to construct concepts and forms of reasoning about permutations, partial permutations, and combinations. In a pilot study, we used a sequence of tasks calling for the enumeration of n-cube towers, each containing n different colors of cubes, to motivate students' development of concepts and reasoning about permutations. Given these findings, we used a similar instructional sequence in this study, using squares instead of cubes (often, however, the students would refer to squares as cubes).

One of our students was AR, a third-year preservice elementary school teacher who used she/her pronouns. In her preassessment, and in her first few teaching sessions, AR exhibited a scheme in which she attempted to enumerate permutations by squaring the given number of objects being arranged. For instance, consider AR's response to the Recess Task.

Recess Task: Ms. McFrederick has 24 students in her 5th-grade class. In how many different ways could the students line up to go to recess?

AR: Um … I think you could just do, maybe like 24 times 24 to figure out how many ways they can line up. You can get the answer.

TR: Okay, 24 times 24. Can you relate this problem to a problem about towers of cubes?

AR: Yeah, so, if they were in a line, that could be like a tower. And each student will be able to be in each of the spaces from the tower, or the line I guess. So since there's 24 students, there's going to be 24 spaces for them to line up. And then each student will be able to be in one space, so since there's 24 spaces they can each be in 1 space. So you can multiply all the students by the number of spaces, just like we did.

From AR's description, we infer she conceptualized a given "line" of students as consisting of 24 spaces—a spatial structuring. Further, she reasoned that each of the 24 students could stand, or be placed, in each of those 24 spaces—a spatial-enactive structuring. Based on this S* structuring, AR reasoned multiplicatively: 24×24. However, she struggled to justify why multiplication was appropriate. We interpret this as an example of numerical structuring partially, but not fully, linked to S* structuring, as her S* structuring was (we infer) underdeveloped and consequently unable to support a viable numerical structuring.

To help AR refine and further develop her S* structuring, she was prompted to consider an analogous task with a smaller number of objects being enumerated (cf. Lockwood, 2015) and to write a list of the way in which students could line up (cf. Lockwood & Gibson, 2016).

TR: Do you want to try think about it, at least for now, with smaller numbers? Let's say Ms. McFrederick had just 4 students instead of 24.

AR: Yeah, um. So I believe you can still just do the 4 times 4, 4 students for each of the 4 spaces, maybe.

AR drew four circles arranged horizontally. She wrote "1" under the first (left-most) circle, then said "2, 3, 4." She then crossed out the "1" and rewrote it under the second circle, then wrote "2, 3, 4" under the remaining circles. At this point, AR began to realize there would be more than 16 possibilities.

AR: I think you would approach it differently than just the 4 times 4 then. Because … I think, when you arrange it—so yes, each student can be in each of the 4 spots. Like student 1 can go in all 4 of these spots, but for each time that student 1 is in a different spot, there's multiple ways for them [students 2-4] to be arranged. …

TR: It might be helpful if you just list out all the possibilities using 1, 2, 3, and 4 as your students. And try to list them in such a way that you can be sure that you listed them all.

AR: [Wrote 1234, 1243, 1324, 1342, 1432, 1423, then 2134, 2143, 2341, 2314, 2431, 2413.] So this right here is 12, altogether. And there would be 2 more groups just like this, because we would do the same thing for student 3 being at the front of the line and then student 4 being at the front of the line. So that would be 2 more groups, which would come to 12 just like this. So then we would end up with 24 ways.

We infer that asking AR to construct a list prompted her to organize—that is, establish an S* structuring for—the set of permutations of 1, 2, 3, and 4. Her inter-composite structuring was systematic, and her numerical structuring, 12 + 2(6), was linked directly to her S* structuring—an example of S*NLS.

Summary

In this paper, we have introduced and exemplified an elaborated version of spatial structuring, S* structuring, specifically so that we may accurately capture and analyze the structuring processes that underlie much of combinatorial enumeration. Naturally, due to space constraints and the preliminary nature of this report, we could not include a full discussion of S* structuring and S*NLS. However, a paper is underway (Antonides & Battista, in progress) in which we discuss these ideas in greater depth and provide multiple examples of S* structuring and S*NLS in students' combinatorial reasoning.

MATHEMATICS TEACHER DECISION-MAKING AND THEIR SELECTION OF ONLINE CURRICULAR MATERIALS

Anita Sundrani
University of Houston
asundrani@uh.edu

In this conceptual paper, I reflect on the growing influence of online lesson plan sharing websites on mathematics teachers' curricular decisions. Using the theoretical frameworks of teacher decision-making and curriculum deliberation, I explore individual and group heuristics that may impact mathematics teachers' lesson planning. I then offer a conceptual framework that details the considerations mathematics teachers engage with when choosing online curricular materials. I conclude with the implications and potential contributions to the field.

Keywords: Curriculum, Instructional Activities and Practices, Technology

Introduction

There are differing curricular policies in place for teachers in different districts and schools: several use textbooks, a number of schools and districts have adopted prescriptive curricula, some have created materials for teacher use, and others allow teachers to set up their own units and lessons (Gewertz, 2015; Pittard, 2017; Timberlake et al., 2017). As more instruction moves to online learning platforms and as teachers gain more freedom to provide curricular materials of their own in their classrooms, teachers are more often exploring online spaces for lessons and supplemental materials (Greene, 2016; Pittard, 2017; Tosh et al., 2020). The COVID-19 pandemic has additionally necessitated this approach across the nation. To date, there has been little investigation into teachers' decision-making process while selecting which materials to use from online lesson plan sharing websites and even less at the secondary mathematics level. Understanding teachers' decision-making provides a lens into how curriculum is chosen or created, implemented, and adapted according to student needs and the instructional environment.

Background

Websites such as Google, Pinterest, and Teachers Pay Teachers allow mathematics educators to share best practices, build professional learning communities across states, and support each other in developing instructional materials. However, these online spaces rarely control what lessons are posted on the sites, so there is no indication of true standards-alignment, appropriate breadth and depth of content, and accuracy of that content (Gallagher & Swalwell, 2019; Greene, 2016). Pedagogical and time considerations can also complicate mathematics teachers' decisions to download certain materials (Gallagher & Swalwell, 2019). As a result, teachers may not be utilizing standards-aligned content, or they may not know how to alter these lessons appropriately. Therefore, it is important to identify what impacts mathematics teachers' decision-making process when choosing curricular materials, so they can be supported in becoming critical consumers and making curricular decisions couched in research-based practices.

Theoretical Perspective

This work draws from the theoretical frameworks of teacher decision-making and curriculum deliberation to investigate how teachers choose and use online curricula. Stein et al. (2007) "temporal phases of curriculum use" framework provides insight into what teachers consider when using curriculum. Schwab's (1969) idea of curriculum deliberation at the individual and group levels provides a vehicle into understanding the complexity of decision-making.

Decision-Making

The idea of teacher decision-making has been extensively researched over the past 50 years or so (Holstein & Keene, 2013; Shavelson & Stern, 1981; Smith et al., 2018). Stein et al. (2007) present a framework on the temporal phases of curriculum use to highlight the phases of decision-making when teachers utilize curriculum in the classroom with the aim of student learning. Within each of these four phases, teachers engage in cognitive processes that are influenced by their beliefs, content and pedagogical knowledge, and judgement, thus altering the written curriculum even before it is enacted (Shavelson & Stern, 1981). Additionally, Shavelson and Stern (1981) assert that, during the planning phase of curriculum use, teachers balance activity flow, predictability during the lesson, choice of content, student needs, and instructional style, all while taking into account external pressures from policies, administrators, or other educators.

Mathematics Educator Decision-Making

In addition to teacher decision-making, Dingman et al. (2019) include the dimension of mathematical decisions, "defined as those decisions that influence students' opportunity to learn mathematics, and teachers' reasoning for those decisions" (p. 44). These decisions are made throughout the four phases of curriculum use and researchers have spent decades exploring what decisions teachers make during planning and enactment of lessons and why they make these decisions (Bush, 1986; Choppin, 2011; Dingman et al., 2019). Decisions surrounding curriculum materials are affected by teacher beliefs about the materials, the strategies teachers use to understand the curriculum, how they envision the materials will be enacted, and their capacity to use the materials in the classroom (Choppin, 2011).

Curriculum Deliberation

The cognitive processes of decision-making are mediated by the practice of curriculum deliberation both at the individual and group levels. First introduced by Schwab, curriculum deliberation involves contemplating the practical aspect of teaching and discussing curriculum concerns with a variety of educators to tease out multiple perspectives and approaches to curriculum and instruction, including the roles of the teacher, learner, subject matter, milieu (context), and curriculum-making (Johnston, 1993; Reid, 2010). Researchers have explored how deliberation impacts curriculum enactment and student learning. Johnston (1993) found that teachers' individual decision-making is not confined to instruction in the classroom; they also consider the curriculum through practical and theoretical lenses to connect it to instructional choices. Reid (2010) investigated curriculum deliberation in group-level interactions; his findings revealed that teachers considered the teacher, learner, subject matter, milieu, and curriculum-making process in all of their discussions.

Potential Obstacles to Curriculum Deliberation

While curriculum deliberation can be an invaluable component in curriculum decision-making, there are a variety of potential obstacles to implementing it effectively, both at the individual and group levels.

Individual level. When educators have time to engage in deliberation, they may make better decisions throughout the four phases of curriculum use. Unfortunately, teachers often do not have the luxury of time (Tichenor & Tichenor, 2019) and may rely on existing heuristics to make quicker decisions, namely availability, representativeness, and anchoring and adjustment (Tversky & Kahneman, 1974). The availability heuristic places importance on the frequency of an event (Tversky & Kahneman, 1974). In the context of education, this heuristic could draw teachers to lessons or ideas that they have often seen associated with subject matter concepts before. This could limit a teacher to only considering connections to real-world contexts for which they are familiar, such as teaching slope through the analogy of two runners in a race. The representativeness heuristic links the occurrence and characteristics of an event to another. Using this heuristic, a teacher's confirmation bias could lead to using the strategy of "drill-and-kill" because they were successful in that type of environment when they were in school. This belief could lead to a reproduction of this traditional, behaviorist approach to teaching mathematics. The anchoring and adjustment heuristic involves adjusting an initial value to get to the final answer (Parmigiani, 2012). An educator could exhibit this heuristic by making assumptions about students' prior knowledge and planning a lesson based on that assumption.

Group level. Change is constant in the education field, but rarely is it well-resourced and well-implemented (Calderhead, as cited in North et al., 2018). In particular, changes to curriculum necessitate time for deliberation and shared decision-making. Despite this, teachers have historically been shortchanged on common planning opportunities (Ross, 1993; Tichenor & Tichenor, 2019). As a result, when teachers are given any time for group deliberation, it can lead to social phenomena like "groupthink" – the desire to form a unified approach due to external pressures (Jaeger, 2020). For instance, a mathematics department could feel pressured to plan and "teach to the test" if they perceive the administration to place more importance on standardized test scores over conceptual understanding of content.

Technology as a Milieu

Digital resources have given teachers the opportunity to make lesson-planning decisions using content available on websites and by consulting individuals they may have connected with on these platforms. These options have added new aspects to individual and group curriculum deliberation and may reproduce the above-mentioned heuristics in this environment.

Individual level. At the individual level, educators may still consider all of the state, district, and school policies, as well as student constraints and needs for each lesson. However, each of the three heuristics (i.e., availability, representativeness, and anchoring and adjusting) take on new forms. For instance, teachers could rely on the availability heuristic to download a lesson that is in line with an activity they have seen multiple times, such as the "design a town" task used in geometry classrooms. Educators could use the representativeness heuristic to search for standards or objective-based lessons and download a lesson plan without confirming its alignment. Lastly, when searching for lesson plans online, a teacher could purchase or download a unit of instruction based on the content of one lesson in the unit. This "tunnel-vision" approach could result in the teacher now using low quality resources or unfamiliar content.

Group level. When the Common Core State Standards were adopted by majority of states in the United States, teachers, feeling isolated and short on time, began to utilize the internet to replace the in-person group deliberative process (Pittard, 2017). Teachers were able to use social media sites like Instagram and Facebook to connect with educators across the nation and do so on their own schedules. However, paid lesson plan websites like Teachers Pay Teachers could offer an interesting look into the "groupthink" theory, as teachers may visit these sites due to external stressors like time and availability of resources. The most noticeable features on each listing are ratings, reviews, and number of followers on each seller's account. This may lead to an overreliance on existing ratings, reviews, and seller popularity for lessons, as opposed to critical consumption of the materials presented on these sites.

Given the complex nature of curriculum use and the decision-making that may occur prior to the implementation in the classroom, I offer a conceptual framework in Figure 1 to understand the process that a teacher may engage in prior to choosing written curriculum to enact in their classroom. This conceptual framework represents the potential stages a teacher goes through prior to using a curriculum in their classroom.

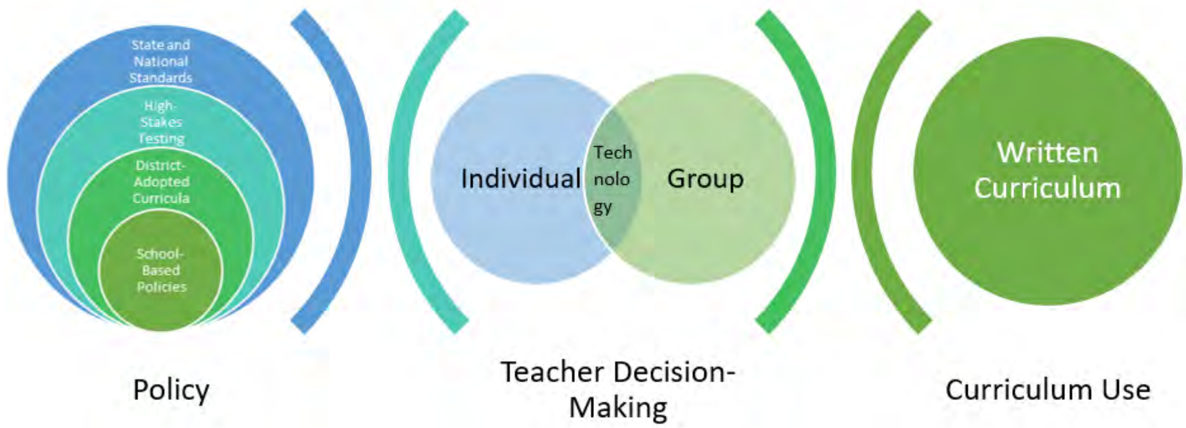

Figure 1: Online Curriculum Selection Stages

The first stage considers policy through state and national standards as the broadest level, followed by state-level high-stakes testing requirements, then district-level curricula specifications, and the innermost circle represents school-based policies. Each of these considerations has a direct or indirect effect on what curricular and instructional materials the teacher uses in their classroom. The state standards adopted and high-stakes testing make up the official curriculum that is to be given priority in instruction. Districts make curricular decisions based on the standards set – some districts provide textbooks and mandated resources, whereas others create suggested materials for use at the school level (Gewertz, 2015). Lastly, schools set the policies that most immediately impact teachers, potentially providing scripted curricula and requiring teachers to use specific teaching strategies (Timberlake et al., 2017).

Once policy restrictions for standards and curricula are established, then the teacher engages in individual decision-making on curricula and may rely on the heuristics of availability, representativeness, and anchoring and adjustment (Tversky & Kahneman, 1974). In addition, group level decision-making may be impacted by the groupthink heuristic. This framework adds the dimension of technology in teachers' deliberative process, as each of these heuristics may exist through online lesson planning decisions as well. Finally, the teacher chooses the written curriculum and begin the curriculum use phases as outlined by Stein et al. (2007).

Implications

Mathematics educators do not teach in a vacuum and their role is constantly changing in response to their environment. Teachers' beliefs, their reasoning about curriculum materials, and their capacity to enact these resources all influence the decisions they make and the opportunities students have to learn mathematics (Choppin, 2011). As teachers continue to engage with curricular materials in online spaces, their decision-making practices are potentially altered by individual and group heuristics. By identifying the heuristics that play the greatest role in these decisions, mathematics teacher educators can prepare pre-service teachers to be critical consumers of mathematics content found in online spaces.

POINTS AND POSITIONS: AN INTERSECTION OF TWO FRAMEWORKS FOR REASONING WITH GRAPHS OF FUNCTIONS

Erika David Parr

Rob Ely
University of Idaho
ely@uidaho.edu

In this theoretical report, we examine the intersection of two previously-recognized dimensions of students' reasoning about how symbolic notations represent elements of graphs of functions. One dimension distinguishes location-thinking, where function notation refers only to a point's location on a graph, from value-thinking, where a point is treated as a multiplicative object. The other distinguishes a nominal interpretation of expressions, where expressions refer to positions in the plane, from a magnitude interpretation, where expressions measure a length. Taken together these dimensions provide four distinct ways students reason about expressions on graphs; each case reveals new meanings indicated by the interplay between the dimensions.

Keywords: Cognition, Mathematical Representations, Graphical Interpretations

The use of visualizations to illustrate concepts is central to the teaching and learning of mathematics (NCTM, 2000, 2014). However, the use of graphical representations, in particular, may pose challenges for students (Leinhardt et al., 1990). To better support student learning involving graphs, researchers have proposed theoretical frameworks to characterize various distinctions in students' graphical interpretations (e.g., Lee et al., 2019; Moore & Thompson, 2015; Paoletti et al., 2018). Yet, these frameworks do not account for how students may connect symbols to graphs and what such symbols represent, which can significantly impact students' graphical reasoning (e.g., Knuth, 2000). We present a conceptual analysis that considers two additional frameworks that account for two dimensions of students' interpretations of symbols on graphs of functions: (1) David et al.'s (2019) value-thinking and location-thinking framework which relates students' interpretation of points and (2) Parr's (in press) description of nominal and magnitude interpretations which distinguishes students' interpretations of expressions to signify positions in graphs. Together, these pairs intersect to create four distinct ways students may think about how graphs and symbolic expressions are related. By examining this intersection of frameworks, we uncover nuances in students' graphical interpretations that may afford or constrain student sense-making of graphical representations.

The Intersection of Two Theoretical Frameworks

Inherent in both theoretical frameworks are notions of notation and interpretation. We frame these concepts in the language of semiotics (Barthes, 1957). A notation such as $f(b)$ is a sign, comprised of the symbols (signifier) and that which they indicate or represent (signified). The signified can be a mental object or another mark or collection of marks (which itself could be a signifier). An interpretation is then the association between the symbol and the signified.

Value-Thinking & Location-Thinking: Two Ways Students Reason about Points

We draw on David et al.'s (2019) constructs of value-thinking and location-thinking to distinguish students' reasoning about points on curves in the Cartesian plane. A student engaged in *value-thinking* views points as representing a pair of values simultaneously, typically an input and output value of a function, consistent with the notion of a multiplicative object (Saldahna & Thompson,1998; Thompson & Carlson, 2017). When a student uses value-thinking, $f(a)$ refers to the vertical component of the associated point on the graph above the horizontal axis, which can be denoted on the vertical axis. A student using *location-thinking* refers to and focuses on the *location* of the point in the plane, rather than reasoning about it as a multiplicative object. Because of this, students engaged in location-thinking often label outputs of a function, such as $f(a)$, at points along the curve, and reason about the output as referring to the location of the point. In other words, they treat the signifier $f(a)$ as referring to a point on the graph. To a student engaging in location-thinking, this referent (i.e., the point) is a monolithic, non-decomposable entity. When value-thinking, the point is multifarious— a multiplicative object of two components, an input and output. By coordinating more meanings for points on a graph, value-thinking more readily affords further mental actions (David et al., 2019; Sencindiver, 2020). Figure 1 (left) summarizes the signification involved in value-thinking and location-thinking.

Magnitude & Nominal Interpretations: Two Ways Students Interpret Expressions in Graphs

A second framing of students' understanding of graphs offered by Parr (in press) describes how students relate expressions (e.g., $f(b)–f(a)$) with graphs. Parr (in press) describes a magnitude interpretation as treating the expression as a measure of a quantity, one that is based on particular positions represented in the plane. A magnitude interpretation of an expression often involves representing an amount of a quantity as a distance or length of a segment on a graph. In contrast, a *nominal* interpretation of expressions treats expressions as labels without quantitative significance, much like the use of labels in an anatomical diagram. A student who interprets expressions nominally may place an expression on a graph to label a particular position in the Cartesian coordinate system. Thus, a nominal interpretation may be limited to a comparison of equality between two expressions based on their spatial positions.

When students use a nominal interpretation of a symbolic expression, its referent (a position in the plane) is a monolithic entity. When they use a magnitude interpretation, this referent is multifarious— the symbolic expression signifies a position, which itself indicates a relevant endpoint for a measurement. A student using a magnitude interpretation mentally constructs a portion of a graph (e.g., a segment, an arc length) from a reference point to the relevant position and uses the expression to also signify the measurement of the length of this portion of the graph. The signification involved in a magnitude interpretation coordinates additional meanings for positions in the plane, which is why Parr (in press) found that it more readily affords further mental actions. Figure 1 (right) summarizes the signification involved in the magnitude and nominal interpretations of expressions in the plane.

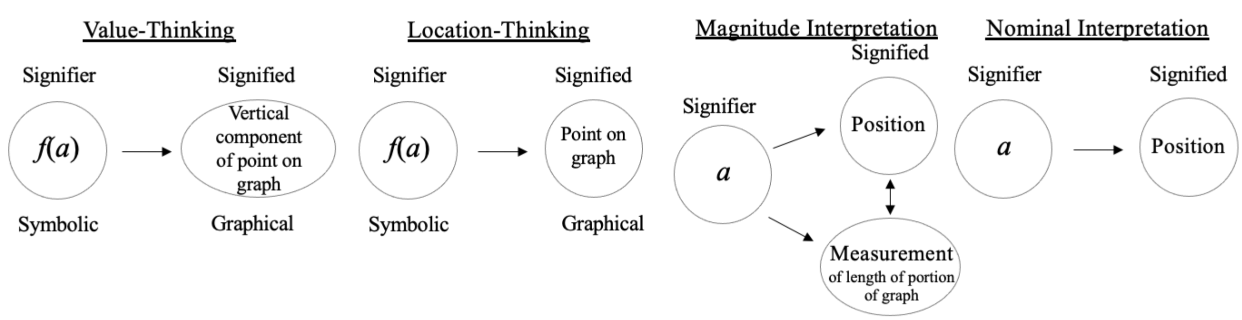

Figure 1: Signification in Value-Thinking and Location-Thinking (left) and Signification in Magnitude and Nominal Interpretations (right).

The Intersection of Interpretations of Expressions and Interpretations of Points

Each of these frameworks describes distinct aspects of students' interpretations of graphs. Table 1 shows how each of these two dimensions intersect to create four ways of thinking and uses function notation as an example in each case. To be clear, the four categories created are meant to characterize a student's thinking with a particular task or in a particular instance, rather than characterize all of the ways a student is capable of thinking. In fact, we suspect that students may demonstrate reasoning indicative of different ways of thinking within the same task. We describe each of the four cases below, focusing on Cases 2 and 3 which became more salient through the semiotic analysis.

Table 1: Four Ways of Interpreting Function Notation on Graphs

		Ways of thinking about points (David et al., 2019)	
		Value-Thinking	Location-Thinking
Ways of interpreting expressions on graphs (Parr, in press)	Magnitude Interpretation	Case 1: $f(a)$ means the measure of the vertical distance from the horizontal axis to the point	Case 2: $f(a)$ means the measure of a distance to the point along the graph from a reference point
	Nominal Interpretation	Case 3: $f(a)$ means the vertical position of a point on the graph	Case 4: $f(a)$ means the position of a point on the graph

Case 1 (Magnitude Interpretation + Value-Thinking):

For the point $(a, f(a))$, a student thinking in these ways reasons with a as the horizontal distance from the origin to the point, and f(a) as the vertical distance, indicated along axes or parallel to them. They reason about the point's position as representing a multiplicative object of two orthogonal distances. As an empirical example, see Micah's reasoning in Parr (in press).

Case 2 (Magnitude Interpretation + Location-Thinking):

A student thinking in these ways would interpret expressions as signifying lengths or distances in the graph, yet would be thinking of points as locations. After such a student identified a point in the plane, they would create labels and reason in ways that do not acknowledge the point as a multiplicative object. For example, a student may associate magnitudes with an arc length between two points, or may measure in reference to other perceivable features presented in the graph. To illustrate this case, we refer to the example of Lisa in Sencindiver (2020). Lisa recognized points in the graph as features to measure between and the curve as a place to measure along. After identifying two points on the curve of a function f, Lisa described $f(a)$ and $f(a+h)$ as arc lengths from the x-intercept to those points on the curve, and $f(a+h)– f(a)$ as the difference of the two arc lengths.

Case 3 (Nominal Interpretation + Value-Thinking):

A student using these ways of thinking interprets inputs and outputs, such as a and $f(a)$, as labels for particular positions, and as horizontal and vertical components of the ordered pair of the point $(a, f(a))$. This student may reason with a point similar to one reporting battleship coordinates, by coordinating two positions to give a third position, still forming a multiplicative object. However, this is not a multiplicative object of multiple distances— a and $f(a)$ are thought of as positions on the axes, without coordinating the distances from the positions on the axes to the origin. Likewise, a student can decouple a point into two positions by projecting vertically and horizontally to positions on the x-axis and y-axis, respectively. We refer to the example of Martha in Parr (in press). She claimed that the $f(c)$ and $f(d)$ she labeled on a monotone decreasing graph were not equal and could never be equal. She explained by saying, "because $f(c)$ and $f(d)$

are separate values… *c* and *d* are gonna be, if they're [*c* and *d*] separate values, like they're [*c* and *d*] labeled separately." Martha engaged in value-thinking and conceived of points as pairs of two positions labeled on the axis. Martha then considered *c* and *d* to be unequal ("separate values") because of how she was interpreting these expressions nominally.

Case 4 (Nominal Interpretation + Location-Thinking):

A student using these ways of thinking interprets expressions, such as $f(a)$, as labels for particular positions, and points as outputs along the curve, signified by function notation. Thus, a student may use an output label, such as $f(a)$, for a position along the curve. This position may correspond with the input *a*, but is not an indication of a measurement along an axis. In reasoning this way, the student may coordinate an input *a* with an output label $f(a)$ (thought of as a point), but in the moment, the student does not conceive of the point as a multiplicative object. For an empirical example of this type of reasoning, see Zack from David et al. (2019). As explained by David et al. (2019), Zack engaged in location-thinking, conceiving of the points he labeled on the graph solely as outputs. Further, Zack interpreted $f(a)$ and $f(b)$ nominally on a constant function, considering them as labels for positions and reasoned about these positions, rather than any measurement associated with these positions. These ways of reasoning led him to conclude that $f(a)$ and $f(b)$, which he labeled at two different points, were not equal.

Discussion

Our theoretical findings shed light on students' ways of interpreting function notation in terms of points and positions on graphs. We elaborate on the notion of "value" in value-thinking by contrasting Case 1 and Case 3. Although value-thinking as described in David et al. (2019) may be interpreted as only referring to Case 1 (value+magnitude), this work highlights the reality that students may conceptualize a point as a multiplicative object of positions on the axes, without reference to measurements as in Case 3 (value+nominal).

The coordination of these two frameworks allows us to see important parallels and interplays between them. Location-thinking's view of *point* is monolithic, while value-thinking's view is multifarious. Similarly, a nominal interpretation of *position* is monolithic, while a magnitude interpretation of it is multifarious. By overlaying these, multiple shades of meaning and signification become apparent that we might otherwise have missed. For instance, in Case 1 (value+magnitude), the meaning of point *and* position are both multifarious for the student, suggesting she has formed *a multiplicative object of coordinated distances* from the axes.

All four cases reveal affordances and constraints for the mathematical activity potentially available to students and suggest ways instructors can support this activity. For instance, Case 4 (location+nominal) may afford reasoning in geometric contexts where horizontal and vertical components are not privileged. However, a student thinking this way may have difficulty reasoning about complex statements involving graphs of functions such as the Mean Value Theorem. Likewise, aspects of reasoning with Case 2 (location+magnitude) afford conceptualizing distance along the curve as a measurable quantity which is critical for multiple topics in Calculus (e.g., arc length, line integrals of vector-valued functions), as well as reasoning about quantities within situational coordinate systems (Lee et al., 2018). However, this sort of thinking may constrain students' activity when a graph is representing information along orthogonal axes. Case 3 (value+nominal) may be sufficient for students in finding numerical values from graphs, in instances when they do not need to construct and reason about other quantities, such as $f(b) - f(a)$, within the graph.

The intersection of the two frameworks we described may help instructors account for differences in students' reasoning about points and positions on graphs. Further research in this area may include teaching experiments to study the extent to which cases of student's thinking afford or constrain their mathematical activity. Such studies may also shed light on what factors support students in transitioning from one way of thinking to another.

A PROFESSIONAL DEVELOPMENT MODEL FOR IN-SERVICE TEACHERS BASED ON IDENTIFICATION PROCESSES AND TEACHER COLLABORATION

Veronica Hoyos
National Pedagogical University, Mexico
v_hoyos@mac.com

Ruben Garza
National Pedagogical University, Mexico
rugarvi24@yahoo.com.mx

Based on data and results that are part of a large longitudinal study, we built a model for the professional development of in-service middle school math teachers in Mexico. This study accounts of information on the general characteristics of the official programs for professional development implemented by the Ministry of Education in Mexico. The empirical work started by identifying teachers' personal philosophies or images of mathematics (Ernest, 2007, 2012), and a blending of theoretical constructs was utilized.

Keywords: Professional development, Teachers' beliefs, Instructional activities, and practices.

Introduction

Hiebert et al. (2003), who suggested that progress can be made by designing programs that could influence the nature and quality of this practice. In addition, Hiebert and colleagues noted that teacher training programs have an expiration period, which makes necessary to continuously review their design and implementation. And, according to Marcelo (2002), initial training provides the teacher with baggage of knowledge that must be complemented throughout teacher active professional life. All of this combined with educational contexts marked by the implementation of large-scale school mathematics curriculum reforms makes imperative to offer professional development programs for in-service teachers (Montecinos, 2003). In this regard, Mexico is particularly not an exception given a constant series of reforms to the school mathematics curriculum (Ministry of Education –SEP by Spanish sigla, 1993; 2004; 2006; 2011; 2018). The main objective in the case study that is presented here was to build a cyclic model of professional development for in-service teachers focusing on the learning of new pedagogical practices (those induced by the introduction of new contents in the curriculum reform) and based on their reflection on what constitutes their profession and practice into the classroom. Finally, it is also important to point out the need, as Cobb (2005) stablished, to approach or to establish links between the theoretical knowledge on teaching and teacher's practices into the classroom.

Characteristics of the Official Teacher Development Programs in Mexico

In the successive changes that have been implemented through the different school mathematics curriculum reforms in Mexico, teachers have been considered always as protagonists of the educational transformation (Ministry of Education –SEP by Spanish sigla, 1993; 2004; 2006; 2011). The central features of the 2011 integral curriculum reform, which concentrate the guidelines and developments of the 2006 reform, in relation to the professional development of teachers, are based on the recognition that reflection and educational practice in the school are key to strengthening the continuous training of teachers and the additional academic staff, and to promote collaborative school management processes. In particular, the different approaches of curriculum reforms have appealed to the commitment and professional development of teachers to consolidate them (SEP, 1993; 2004; 2006; 2011). In this way, teacher professional development has been considered a fundamental axis in the reform process that has been carried out in Mexican middle schools, since it has been highlighted as the possibility of generating substantive transformations in pedagogical practices.

This fact has been fully recognized by the Ministry of Public Education itself, underlining that promoting professional development is the best tool to improve teacher performance in classroom (Ortega et al., 2005). But, unfortunately, all these considerations, recognitions, calls, and underlining of promoting the professional development of mathematics teachers have mainly resulted to be only rhetorical. For example, according to Sandoval (2001), one of the characteristics of the official programs of professional development for in-service teachers in Mexico, has been the scarce teacher's participation. These programs of professional development, according to Martínez (2005), end up being framed in a course, which only acquires meaning for its recipients if it awards points for a promotion on the official teaching career. On the other hand, the additional academic figures (as supervisors) whose formal function is to guide teachers in their work, scarcely attend schools and when they do it, their work is carried out in a purely administrative format. That is the way they do not constitute an important reference in teaching practice and even less they constitute educational support within the framework of teacher professional development (Sandoval, 2001). In this context, the professional development of in-service math teachers has become a model where trainer's activities during the course focus on carefully developing their own new materials and use the organization of the new courses to disseminate reforms' proposals. It is to say that the training model of the official courses for teacher professional development is focused on the trainer and based on the implementation of homogeneous courses.

Theoretical Frame

The Concept of Document in the Documentary Genesis

Based on the documentary genesis by mathematics teachers and in their construction of collaborative design using digital resources, Gueudet and Trouche (2009) have extended the concept of instrumental genesis proposed by Verillon and Rabardel (1995) to the one of documentary genesis. In this respect, it is illustrative the following schematic representation of both concepts (see Hoyos, 2012). Therein, one can notice that the concept of document connects teacher practice with their images of mathematics (Ernest, 2012), really through managing the resources they have at hand, as mathematics curriculum prescriptions, textbooks, digital technology, etc. But "whether one wishes it or not, all mathematical pedagogy, even if scarcely coherent, rests on a philosophy of mathematics" (Thom, 1973, p.204. Cited in Ernest, 2012, p.9). In words of Gueudet & Trouche (2009), and Sabra (2010), the documentary approach provides tools for the analytical study of the processes that underlie the professional development of math teachers, both individually and collectively.

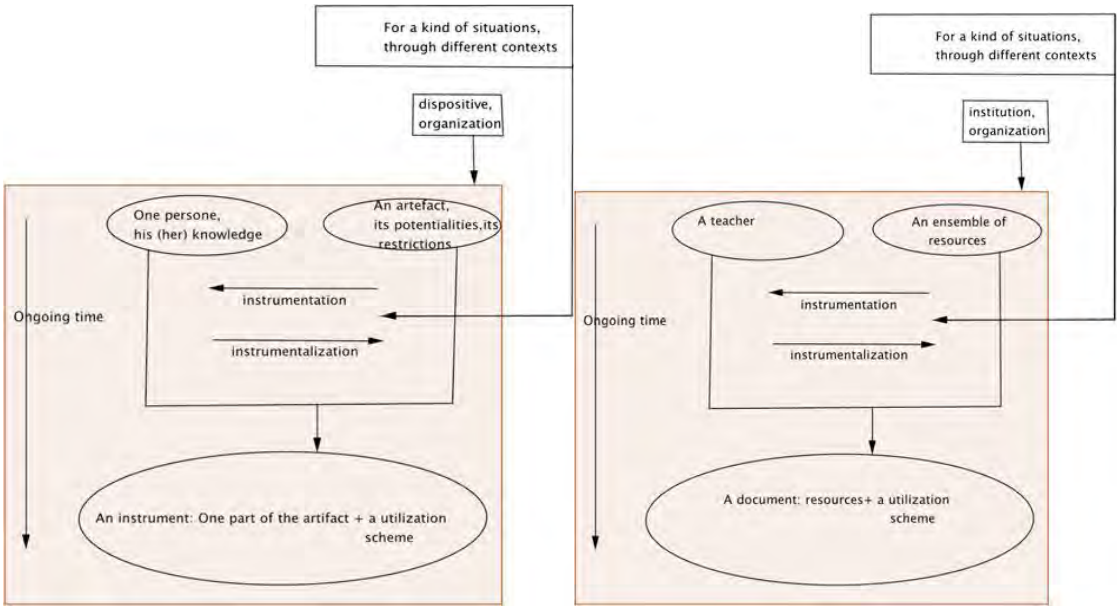

Figure 1: On the Left, Schematic Representation of Instrumental Genesis & Schematic Representation of Documentary Genesis, On the Right. (Extracted from Trouche, 2010. Cited in Hoyos, 2012).

Teacher Personal Philosophies or Images of Mathematics

Ernest (1994) argued that differences in mathematics teachers' practices cannot be explained sufficiently attending only to mathematics knowledge. Such differences may be attributable to particular belief systems about what is mathematics, and on its teaching and learning, which in particular constitutes the rudiments of certain personal philosophies or images of mathematics that teachers maintain, although often these personal philosophies are non-articulated in a coherent manner. Personal philosophies of mathematics provide a general epistemological and ethical framework, under which the conceptions about the teaching and learning of mathematics are considered, and they are subjected to limitations and opportunities of social context.

Identification Processes

The work of Cerulo (1997) provides an antithesis to traditional identity studies, and mainly the works cited here refocus scholarly attention from the individual to the collective. According to this author, many of her reviewed studies have approached identity as a source of mobilization rather than a product of it, and particularly in relation to identification processes, attention to collectives (p.394) has reenergized scholarly interest in the identification process itself. In this way, "a growing literature explores the mechanics by which collectives create distinctions, establish hierarchies, and negotiate rules of inclusion" (Cerulo 1997, p. 394).

Emergence of teacher new collaborative and pedagogical practices from teacher professional development

Although teacher collaboration wasn't considered during the activity developed by participant teachers in a specific professional development program implemented by Hoyos (2012-2016), this program was an important antecedent for the case study presented here, because it highlighted the potential of starting teacher activity during professional development from materializing the knowledge of the teacher about teaching, to move towards another level in the development of new collaborative and pedagogical practices.

Methodology for Construction and Obtention of Data

The case study we are presenting here was developed in two phases. First phase was specifically developed through enacting teacher identification processes to know of collective teacher images of mathematics and about their teaching. The second phase turned around teacher design of new lessons or activities (to be implemented in classroom) on new curricular contents included in the 2006 school mathematics curriculum reform, namely the generalization of patterns, for the learning of school algebra. The participants in this research were 21 in- service math teachers belonging to public middle schools in Mexico City. All of them were experienced teachers in math middle school. Meetings were carried out face-to-face, in an official center for teacher professional development or specific workshops, during the months of October 2007 and November 2008 (in the first phase of the study), and from January to June 2009 (during the second phase of the study). Teachers were always grouped in teams of three, or four participants, and the general objective of the meetings was to analyze the new 2006 official teaching approach for the development of the mathematical contents in the classroom.

First general task

Task 1. Setup in a diagram or schematic drawing the important pedagogical elements you display to address mathematical issues with pupils.

Some of the complete teachers collaboratively produced diagrams are showed next. They were here titled as Diagram 1, and Diagram 2. Each of these diagrams were reached by teacher negotiation within the team to draw a single schema. In fact, each diagram reflected a teacher team product, because of teacher collaboration and negotiation within respective teams. Finally, is important to note that after each team had finalized their drawing, it was implemented a discussion on the meaning of their production. These discussions were managed and registered (by taking notes) by the second author of this paper (R. Garza), who really have played the role of teacher educator, or more precisely, as a teacher team tutor or person in charge of the whole implementation of teacher activities during this investigation.

Elements of Analysis

It is important to highlight that the collective identification process accomplished here, evidenced by teacher production, integrated different levels of elaboration, abstraction, and generality, as well as different forms of representation, those sustained and negotiated by all teachers in the team. Moreover, in the second phase of this study it was important too to note how participant teacher teams used of pedagogical and mathematical resources to collectively create or design new lessons, to articulate and project their teacher identities (Cerulo 1997).

Keywords: Research Methods, Systemic Change

Conducting research is a messy endeavor where the pursuit of new knowledge requires one to play and experiment with data and theoretical framings. This messiness includes bouncing between literature, analysis, and writing. False starts are inevitable and difficult choices are made to start over or attempt unfamiliar directions. Moreover, we have to consider how our positionality, subjectivities, and ideologies further complicate our work and the ethics of conducting research. Cai and colleagues (Cai et al., 2019a; 2019b; 2019c) attempted to clean the messiness of mathematics education research by establishing norms and needed directions for "how to conduct and report high-quality research in mathematics education" (Cai et al., 2019a, p. 114). Maxwell (2013) argued, however, that qualitative research needs to be flexible and is "inductive rather than following a strict sequence or derived from a single decision" (p. 18). Therefore, we question the desire to clean, but instead wish to explore and understand the messiness of mathematics education research.

Siy (2019) called for the mathematics education research community to do more to share both the processes *and* the products of our work by exposing the messiness of research. This includes emphasizing how our failures, reflections, and false starts have led to opportunities. In response to the call, the members of our research group have worked to reflect on our own processes as we work towards a product (i.e., composite counter-stories). We aspire to follow the work of critical race scholars (e.g., Cook, 2013; Solórzano & Yosso, 2002), specifically Pérez Huber (2009), in recognizing our position as critical race researchers and Scholars of Color in academia to "build and develop ways of doing research that counter traditional research paradigms and lead to a more complete understanding of experiences of People of Color within and beyond educational institutions" (p. 640). We believe by demonstrating the messiness of our research, we are challenging the whiteness of academia (see Brunsma et al., 2020). Mathematics education researchers have done little to investigate their own practices (Dubbs, 2021) and thereby, the whiteness of the institution (Martin, 2015).

In this poster, we provide our processes working to amplify the voices and experiences of elementary Raza students learning mathematics in predominantly white schools through composite counter-stories. We position this work within two theoretical spaces: 1) Latinx critical theory (Solórzano, 1998; Solórzano & Yosso, 2002) and 2) Borderlands theory (Anzaldúa, 1987). Our goal is to "reveal our work" (Siy, 2019, p. 17) by intentionally exposing the messiness, misfires, false starts, and challenges we faced.

The use of video data for research is widespread (e.g., Hamel & Viau-Guay, 2019; Nassauer & Legewie, 2021), and new camera technology such as Go-Pros[TM] is becoming more prevalent (**Authors**, 2019; 2021; Burbank et al., 2018). This enables a more subjective, humanistic, collaborative, and participatory approach (Harwood & Collier, 2019; Lahlou, 2011; Pink, 2015). We argue that the use of *multiple* go-pro cameras and analysis of individual views allowed us as researchers to "see" more of an event with each new viewing of video data, affording our research team the opportunity to piece together different student perspectives to form a larger possibility space of "truth" of one event (i.e., perspective taking). We utilized third space as a framework to guide this method of collecting and analyzing data (Gutiérrez, 1999). Specifically, we conceptualized the third space as a hybrid space in which we as researchers attempted to enter the particulars of an event (e.g., human movement) through the perspectives of students wearing Go-Pro cameras, as well as through our ongoing discourse (Simpson & Feyerabend, 2021; Hulme et al., 2019). It is a space that allowed us to frame the emic (participants' view)-etic (researchers' views) as complements rather than in opposition to one another (Pink, 2005).

The video data used to highlight our approach was collected from one group of fifth-grade students (2 female and 4 male students) tasked by their teacher to first construct a masking tape-path for a robot, Dash, to traverse (Phase 1). Next, the group used the app Blockly (Phase 2) to program Dash to stay on a path created by another group of fifth-grade students. Three of the six students volunteered to wear a go-pro camera on their chest, while we also recorded the overall group interaction using one stand-alone camera. The data was analyzed using interaction analysis (Jordan & Henderson, 1995), which added an additional layer of perspective taking through the use of go-pros. In our poster, we provide examples of our approach and highlight how our view of an event moved past individual perspectives to a layered view of the collective. For instance, we initially perceived the group of students as being monopolized by one student, Olive, who positioned herself as "good at this stuff." The analysis of additional video data shifted our perspective to view the group as developing their own collaborative structure within the activity in a way that had not been visible when watching Olive's perspective.

Intersubjectivity and a story line was developed as we called into question interpretations of evidence gathered from earlier views and stitched together a collaborative view of events in which no one learner's experience was absolutely understood or could be separated from the others. Instead taken as a whole the collective event became storied by temporal events for which we had multiple perspectives, such as laying the path and controlling the iPad. Events not captured by multiple videos were conditional and created pockets of subjectivity within the dominant intersubjective narrative. Therefore, this approach, including interaction analysis, afforded us as a research team a space to question our assumptions and "truths" of events with each new viewing of video data from a student perspective. We further contend that collecting and analyzing multiple student perspectives through the use of go-pro cameras is an approach that can enhance various methodologies and theoretical perspectives.

UNDERSTANDING STUDENT BEHAVIOUR AS EVIDENCE OF STUDENTS' CONCEPTIONS AND INSTRUCTIONAL NORMS

Irma E. Stevens
University of Michigan
istevens@umich.edu

Nicolas Boileau
University of Michigan
nboileau@umich.edu

Keywords: Cognition, Learning Theory, Teacher Knowledge

One of the main responsibilities of a mathematics teacher is to support their students in learning mathematics. It is widely accepted that teachers are most effective at this when they base their instructional decisions on their understandings of what their students know at any given point, which they infer from students' mathematical activities (e.g., work, utterances, gestures). To support teachers in making such inferences, researchers of students' conceptions have strived to construct viable models of the *mathematics of students* (Steffe & Thompson, 2000). For instance, some researchers have focused on students' rate of change schemes (Carlson et al, 2002) and others on students' fraction schemes (e.g., Hackenberg & Lee, 2015; Steffe & Olive, 2010). One of the main methodologies used to uncover these conceptions has been the task-based cognitive interview (e.g., Steffe & Thompson, 2000) in which students are asked to complete a series of tasks that are designed to test hypotheses that the researcher develops throughout the course of the interview and/or developed prior to the interview. For the researcher, it is often strategic to choose a novel task rather than a familiar one, as students often default to completing familiar tasks using learned techniques that they believe they are expected to use, which reveal less of the idiosyncrasies of their conceptions and the mental operations involved in their reasoning. While this is a sensible decision for the researcher, the results of such research have been critiqued as difficult to apply by a teacher who is faced with the very problem that the researcher seeks to avoid: interpreting students' understanding of mathematical concepts from their performance on familiar tasks, as most tasks that students are assigned in school are familiar (Doyle et al., 1985).

This was the problem space that drew us—a scholar of student thinking and a scholar of instructional norms (i.e., shared beliefs about what teachers or students will do, and/or ought to do, in situations of a particular type)—together. In this presentation, we invite the audience to think with us about this problem space to develop together a set of possible directions for research. To do so, we consider what teachers and researchers might gain from simultaneously thinking of students' performance on familiar tasks as both decisions to follow or deviate from norms and as evidence of their mathematical conceptions. To base this conversation in a concrete case, we consider a task that is familiar to students in high school algebra: solving a linear equation in one variable. In this case, the more general question becomes: What might teachers and/or researchers gain from considering a student's attempts to solve an equation as both a potential attempt to satisfy the teacher's expectations to solve equations by moving algebraic terms to one side of the equals sign, numeric terms to the other, simplifying both sides, then dividing by the coefficient of x (Buchbinder, Chazan, & Capozzoli, 2019), as well as their conceptions (e.g., of the equals sign, equations, or variables) and the mental operations involved in doing so (e.g., unitizing, covariational reasoning) (Thompson, 2013)? We call researchers to consider the broader question of what researchers and teachers may gain from thinking of student behaviour as influenced by both individual factors (e.g., conceptions) and social factors (e.g., norms). Lastly, we raise questions regarding methods for investigating student thinking and the types of theories that can guide and come from the use of such methods.

THEORETICAL FRAMEWORK FOR A MATHEMATICAL OBJECT IN RELATION TO MULTIPLE COORDINATE SYSTEMS

Inyoung Lee
Arizona State University
ilee28@asu.edu

This study outlines a theoretical framework which describes different ways of thinking involved in mathematical activities such as graphing and symbolizing. Finding a coordinate system as a representational resource, students may engage in two forms of representational activity within a single coordinate system, which I note *"Naming"* and *"Locatin*g". The two forms of students' activity may apply to the situations where there are multiple coordinate systems, offering two perspectives to interpret a mathematical object with multiple coordinate systems, which I note *"Coordinates-open"* and *"Coordinates-closed"*.

Two forms of students' activity within a single coordinate system: *"Naming"* vs *"Locating"*

In "*Naming"*, students 'name' a mathematical object such as point, vector, line, curve located in coordinate space. Students assign numerical value(s) to the object consistently, which a coordinate system defines. The naming activity also applies to a spatial object located in a physical space. An example for the naming activity is a point being coordinatized as an ordered pair (2,-3). On the other hand, in "*Locating",* students 'locate' numerical descriptions such as n-tuples, function equations into a coordinate or physical space in a consistent way which a coordinate system defines. An example of the locating activity is to graph a function equation in a coordinate plane. A coordinate system comes with a unit measure, directionality, and reference point in either way of naming and locating activity.

Two perspectives for an object in relation to multiple coordinate systems: *"Coordinates-open"* vs *"Coordinates-closed"*

The *"Coordinates-open"* view is closely related to the *"Naming"* activity. We consider any mathematical objects as composed of points, and any coordinate system describes those points' locations. Having another coordinate system leads to "Re-Naming" activity while the object's location stays the same in a coordinate plane in this view. In other words, the object's points are "coordinatized" by the system laid atop the object. Even if the coordinate system is transformed to a new system, the objects do not move; rather, they attain new coordinates according to the new system laid atop it.

On the other hand, *"Coordinates-closed"* is closely related to the *"Locating"* activity. We consider any objects as having numerical expressions, and any coordinate system determines those expression's locations. Having another coordinate system leads to "Re-Locating" activity while the object numeric remains the same in this view. The object's shape is defined relative to the coordinate system, which means the object is transformed into a different shape by a transformation that maps points in the first coordinate system to points in the second coordinate system. Even though the transformed object looks different from how it looked in its original, one shape is a different image of the other.

Utilizing the framework described here as a lens to review undergraduate mathematics textbooks (Lay, 2012; Stewart, 2008; Strang, 2019), many textbooks seem to be approaching only from *"Coordinates-open"* perspective when introducing a new coordinate system.

Chapter 15:

Working Groups & Research Colloquia

GROUP DISCUSSIONS DISCUSSION GROUP

William Zahner
San Diego State University
bzahner@sdsu.edu

Jessica Pierson Bishop
Texas State University
jbishop01@txstate.edu

Jennifer M. Langer-Osuna
Stanford University
jmlo@stanford.edu

Anna F. DeJarnette
University of Cincinnati
dejarnaa@ucmail.uc.edu

This inaugural meeting of the Group Discussions Discussion Group will convene to consider current research on group discussions in mathematics. In this series of meetings, the goal of the discussion group will be to share work (both in progress and completed), engage in collaborative analysis of data, jointly identify areas for future research, and establish connections within the PMENA community for future collaborations.

Keywords: Classroom Discourse; Equity, Inclusion, and Diversity

This new working group will focus on students' peer-peer discussions in mathematics classrooms. The primary goals of the working group are (a) to share recent research on group discussions in mathematics and (b) to create a venue in which conference participants can engage in collaborative planning for future investigations of students' group discussions of mathematics. If we are successful, then we anticipate that this working group will lead to future working groups and the creation of concrete products.

Theoretical background and Prior Research

We know that classroom discussions of mathematics can be powerful for fostering student learning (Chapin & O'Connor, 2012; O'Connor et al., 2015). Alongside whole-class discussions, small group, student-student discussions provide a format in which students can learn through participating in talk and interaction. Small group peer discussions differ from whole class mathematical discussions because students must manage the task of negotiating mathematical ideas with peers, without the direct supervision of or support from their teacher. In addition to mathematical negotiations, students also navigate and reinscribe interpersonal and broader social relations during these discussions. When peer discussions appear most productive, students may engage in sophisticated collaborative reasoning and draw upon the group as a resource for sustaining engagement (Barron, 2000; Boaler, 2008).

Prior analyses of peer discussions have drawn on a wide array of theories and frameworks such as positioning theory (e.g., Bishop, 2012; Wood, 2013), Systemic Functional Linguistics (DeJarnette & González, 2015; González & DeJarnette, 2015), and qualitative discourse analysis (Esmonde, 2009; Langer-Osuna, 2015) to unpack the work students accomplish during group discussions. Though these approaches have different theoretical heritages, they all emphasize the role of language in group interactions. When studies of group interactions in mathematics classrooms focus on learning, one critical mediator of learning is language(s) and symbolic tools used to do mathematics collaboratively.

We know from prior research that students in small groups tend to model their teacher's practices in terms of the types of questions posed to one another and the types of help given (Webb et al., 2006). We also know that students can (and do) exercise different types of authority (e.g., intellectual, social) related to status in small groups (Engle, et al., 2014; Langer-Osuna, 2016; Langer-Osuna et al., 2020). And we have models, both within and outside of mathematics education, that support students to engage more equitably and productively with one another (Cleaves, 2008; Cohen & Lotan, 1995; Featherstone et al., 2011; Jansen, 2020; Zahner, 2012) Yet, there are also several open questions for researchers and mathematics educators. For example, What are the appropriate timescales at which to analyze student discussions to answer questions related to equity and productivity in small groups? How might notions of productive group discussions vary according to context, person, or theoretical perspective?

Structure of the Working Group

The working group will be structured so that participants, both live and joining remotely, will have opportunities to engage in collaboration. Additionally, given the hybrid format of the conference we will plan each day's session so that participants can be meaningfully engaged in the discussions, even if they are unable to attend all three sessions, or if they are joining the conference remotely. The organizers plan to mix framing presentations with active group discussions. Applying the best practices from research on using group work in the classroom, we will use strategic grouping in order to bring together participants from diverse settings (geographic locations, type of institutions, research foci, etc.) for discussion. During the discussions we will provide guiding questions as well as create shared spaces (such as Jamboard) that will facilitate collaborative hybrid discussions.

Day 1: Introductions, followed by overview of the state of the field, facilitated by Jessica Pierson Bishop. This will be followed by two illustrative examples of current work (a) a presentation of Langer-Osuna's work related to positioning, identity formation, and "on task" and "off task" work in the context of group discussions (b) a presentation by DeJarnette of current work using SFL to describe how students' positioning and construction of mathematical meanings inform one another during small-group discussions. This will be followed by open discussion time with two guiding questions: (a) What theories and frameworks are you using in your work? (b) What frameworks would you like to learn more about?

Day 2: Introduce a "data dive" activity using data from two different sources. One option will be to examine patterns of small group and whole class talk by examining excerpts of group discussions in a bilingual classroom where the primary language of instruction was English. We will ask, how do group discussions play out in classrooms where students and teachers have different linguistic resources? (facilitated by Zahner). The second option will be an analysis of 6th-grade group discussions in a classroom where the teacher and students will be defining/learning group roles for the first time. Participants will be able to analyze these data using the frameworks introduced on Day 1 (but with the assumption that not all participants attended day 1). These analysis activities will be structured with guiding questions facilitated by the session organizers (45 min). At the end of day 2 we will have an open discussion: What did you learn today? What more would you like to learn? Participants to complete a short survey that will be used to create groups for the final day of the working group.

Day 3: The final day the working group will be structured as a working space for participants. We will form small groups and create break out rooms (both live and hybrid) to allow participants to share their own work, discuss current struggles in their work and set up opportunities to get future feedback on their work.

Narrative inquiry, self-study, and autoethnography (i.e., self-based methodologies) are methodologies used by mathematics teacher educators (MTEs). These methodologies have opened up the field by unpacking and unearthing MTEs' work communicating findings from their practices. Building from our previous working groups at PME-NA 2018-2020, we sustain a community where MTEs can feel supported in their study design, implementation, representation of findings, and publication using self-based methodologies. At PME-NA Philadelphia, we will continue our work at PME-NA Mexico on self-based methodologies to develop perspectives on philosophical underpinnings of self-based methodologies and addressing trustworthiness and authenticity in our reports.

Keywords: Research Methods, Sustainability, Teacher Educators

We are a group of mathematics teacher educators and researchers (MTERs) committed to creating professional development spaces for MTERs to learn and conduct studies using self-based methodologies (Suazo-Flores et al., 2018, 2019, 2020). This motivates us to propose a Working Group at PME-NA 2021, where we can connect with MTERs, collaborate, and receive support on the design and documentation of studies using self-based methodologies (Chapman et al., 2020). Self-based methodologies (Chapman et al., 2020) "privilege self in the research design, recognizing that addressing the self can contribute to our understanding of teaching and teacher education" (Hamilton et al., 2008, p. 17). These methodologies include narrative inquiry (Clandinin & Connelly, 2000), self-study (LaBoskey, 2004), and autoethnography (Ellis & Bochner, 2000). A slowly growing number of research reports using self-based methodologies have been published in mathematics education journals (Kastberg et al., 2018; Di Martino & Gregorio, 2019; Goodell, 2006; Hjalmarson, 2017; Nardi, 2016; Nicol et al., 2020; Nolan, 2018; Xenofontos, 2016) with many more in teacher education journals (Brandenburg, 2021; Brandenburg & Davidson, 2011; Hourgin & Leavy, 2021; Martinie et al., 2016; Schuck, 2009; Simpson, 2019; Stoehr, 2017). These papers include a focus on identity development and practices. For instance, Simpson (2019) described ways her development as a MTER for elementary mathematics preservice teachers from a background in secondary education paralleled that of her students. Nolan (2018) shared her experiences reconceptualizing her practices supervising preservice mathematics teachers. MTERs also have used self-based methodologies to communicate people's experiences with mathematics and call for new approaches (e.g., Nardi, 2016; Stoehr, 2017). We see MTERs' studies using self-based methodology as professional development spaces they create to learn about themselves, their practice, and contribute insights about practical knowledge within the research domain of mathematics teacher education (Chapman, 2020).

In mathematics education, calls for expanding research methodologies and methods used in published work (Cannon, 2020; Inglis & Foster, 2018), highlight the need for MTERs to gain more insight into conducting and reporting research using self-based methodologies. Addressing the current views of so-called rigor in research in mathematics education has the potential to illustrate ways the use of self-based methodologies contributes to mathematics education. In the reporting of such research, two areas of focus can help researchers communicate about their approaches: philosophical underpinnings (Ernest, 2012) and trustworthiness (Lincoln & Guba, 1985). Philosophical underpinnings of self-based methodologies illustrate how researcher's work belongs to the larger body of mathematics education research by connecting such work to the ideas about being, knowing, and feeling that have informed mathematics education. Drawing on expanded notions of trustworthiness called for by Lincoln and Guba (1985) we focus on addressing authenticity in research reports of studies using self-based methodologies (Lincoln & Grant, 2021, in press). Authenticity illustrates ways that our studies, while situated in particular contexts and not generalizable, contribute to ongoing discussions of mathematics teaching, learning, and curriculum. To support the ongoing development of research in mathematics education using self-based methodologies we endeavor to explore these factors of work in progress among the working group members using self-based methodologies. In addition, we will prepare for and organize a collection of research reports from members of the working group for submission to a special issue while also brainstorming new publication opportunities for newer members of our group.

Session Information

We have regularly met to continue creating professional development spaces where MTERs can communicate their findings and experiences using self-based methodologies (Suazo-Flores et al., 2018, 2019, 2020). MTERs are invited to join our Working Group to learn about self-based methodology studies (Chapman et al., 2020) and benefit from discussions to support the design, implementation, analysis, and representation of findings from such studies. Concerning the session activities, on Day 1, we will present literature reviews of self-based methodology studies conducted in the last five years and discuss their philosophical underpinnings. On Day 2, we will invite MTERs to present their studies using self-based methodologies to identify philosophy and Trustworthiness/Authenticity. On Day 3, we will develop action items and discuss new projects such as writing a proposal for PME-International.

This working group is a consistent space for equipping, informing, and challenging mathematics education researchers to "frame equity as a continually evolving process of growth". Since its inception this working group has continued to productively orient, inspire, and organize mathematics education researchers to move toward outcomes in our field that prioritize anti-racist mathematics education as a mechanism for change. The challenge of this working group remains one of moving from collective reflections around issues of equity and diversity in mathematics education to actions that become catalysts for change. We acknowledge that this year's call for "productive struggle" is necessary, however it needs people and community to support such efforts.

Keywords: Equity, Inclusion, and Diversity, & Social Justice

"We frame equity as a continually evolving process of growth rather than as a destination that can be reached." (PMENA, 2019, p. 1)

In recent years many of the major mathematics organizations have created statements or calls to actions for their membership to address issues of equity, diversity, and social justice within mathematics education. Due to the increased racial injustices and Black murders that captured the world's attention beginning in Spring 2020, we also have a sense of urgency for "action to dismantle racism as it exists in our schools, institutions, and even our own organizations, such as PME-NA." (PME-NA, 2020). Specifically, the Access and Equity Principles states, "An excellent mathematics program requires that all students have access to a high-quality mathematics curriculum, effective teaching and learning, high expectations, and the support and resources needed to maximize their learning potential" (NCTM, 2014, p.5). Such calls to action represent both a reality to the future of PMENA membership and the critical expectations for our field in imagining the possibilities for what can be done to strengthen and nurture mathematics education as a whole. But where lies the support? This working group is designed as a space for any who attend to advance in their understanding and abilities to help shape their work toward meeting these calls for more equitable and critical outcomes in mathematics education. A space for all types of knowers to interact around issues relevant to their specific contexts so that all may advance more centrally as a doer of mathematics. To be explicit, the outcome is not to produce a product but to make the space for the building of relationships and awareness of those looking to do this work. Insofar to say, relationships are central to the formation and sustainability of research collectives that need space to productively struggle with others engaged in equity, diversity, and anti-racist lifework.

History of the Working Group

This working group was first formed in 2009. The connection to history along with the focus of the people and scholarship of this working group's longevity has allowed for the tapering of content in each iteration of the working group as it continues to center those in the margins. In 2017 explicit work was done to reset the working group to an acclimation and incubator space where "current issues affecting our field" can be discussed, organized, and introduced "into the bigger conversation about the research of mathematics and mathematics education" (PME-NA, 2019, p. 3). With the unforeseen interruption to this working group due to COVID-19 for PME-NA 42, and the protests and fires that raged due to the continued loss of Black lives in the U.S. in 2020, there remains a greater need than ever to reflect and act upon our complicity in perpetuating inequities in mathematics education.

Organization of the Working Group

Each 90-minute session will build on previous sessions, beginning with a facilitated conversation around the previously stated purpose of the working group to enact and move forward PME-NA's stated purpose to continuously "recenter education" and "recenter equity and criticality" (PME-NA, 2019). The format for the sessions will include:

- SESSION 1-Orientation & Reflection: The working group will start with a brief history of the working group and explicitly state its purpose to be a safe space for collaboration and growth in moving toward the evolving destination of equity in mathematics education (see four actions from June 2020 update to the PME-NA Equity Statement). Using collaborative structures, working group participants will share experiences, challenges, and triumphs over the past year and how they have seen equity as being a part of the work they do in mathematics education. Special attention will be made toward offering those new to the space points of entry to orient themselves to the conversations and questions from within the working group. Finally, questions of interest will be collected, organized, and posted for use during the following sessions of the working group.
- SESSION 2-Interconnectedness & Common Ground: Using participant generated questions and emergent themes, participants will be organized into small groups to engage in knowledge sharing and orientation to provide an asset-oriented perspective on all participants in the working group. Small groups will engage in structured activities to help synthesize critical questions, helpful resources, and productive collaborations for moving forward on areas of common interest.
- SESSION 3-Encouragement & Action: The final day of the working group will be a space for working group participants to continue the work of session two and more open-ended conversation and dialog on areas of interest. Participants will be encouraged to talk about next steps with the emphasis being this is only the start of the conversation, but the connections made extend beyond the limits of any conference and organization.

In the proposed working group, we will build from the foundation of the past two years' working groups as well as our members' continuing collaborations with researchers outside of this group. Specifically, we propose three days of activity, each advancing different aspects of developing the body of mathematical play research. We have planned the three following foci: adapting existing mathematical tasks and curricula to increase opportunities for play (Day 1); adapting voluntary play activity to support mathematical learning (Day 2); and collaborating with members of the EMIC research community through an intra-working-group discussion session to explore play as an embodied approach to mathematics learning (Day 3).

Keywords: Instructional activities and practices; Affect, emotion, beliefs & attitudes; Informal education

Over the past four years, members of this Mathematical Play working group have developed a community of colleagues focused on identifying and characterizing productive theoretical lenses and methodological approaches to investigate students' mathematical play, an important, yet under-investigated domain within mathematics education research (e.g., Holton et al., 2001; Wager & Parks, 2014). Central to this work has been the emergent characterization of mathematical play as (1) voluntary engagement in cycles of mathematical hypotheses with occurrences of failure (Williams-Pierce & Thevenow-Harrison, 2021), (2) often spontaneous and self-directed toward a player's emerging goals (e.g., Wager & Parks, 2014), and (3) supported or discouraged through physical or digital interactions (e.g., Sinclair & Guyevskey, 2018).

In response to shifting demands, our working group made the difficult decision to withdraw from the online conference earlier this year even though our proposal to discuss our respective progress investigating mathematical play had been accepted. Accordingly, in preparation for this year's working group proposal, the co-organizers wish to incorporate the planned presentations from the cancelled working group along with discussions surrounding new directions for mathematical play research. Throughout the past year, our organizing group situated our work based on the degree to which it might be characterized along two dimensions: pure play and structured mathematical instruction. This focus is consistent with what Wager and Parks (2014) discussed as two seemingly contrasting ideologies: increased focus on teacher-directed instruction and scholarship confirming that children learn best in play-based environments (p. 223). Wager and Parks (2014) call to identify practices that bridge the two ideologies. In direct response to these calls, this working group will build on theoretical frameworks for instruction and play by incorporating additional perspectives (e.g., Weisberg et al, 2013; Zosh et al, 2018).

Specifically, we maintain our prior goal to address the divide between play and instruction by discussing theory and collaborating around results from several projects that participating researchers might situate along the dimensions of play and instruction. These conversations will address how specific activities and instructional interventions might support shifts along those dimensions. We will focus on two shifts: firstly, how might an education researcher who has traditionally situated their work within more traditional mathematical tasks alter their existing approaches to afford greater opportunities for play? Secondly, we will address the complement: how might we support the work of educators interacting with students in play-based settings to better foster meaningful mathematical development?

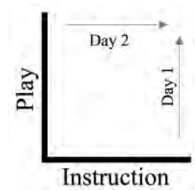

Figure 1: Graphic organization of two shifts – increasing the playfulness of high instructional tasks (Day 1) and increasing the instructional utility of high play tasks (Day 2)

Continuing the success of the prior Mathematical Play PME-NA Working Groups, we have developed the following goals for this year's working group: (1) to engage participant researchers in conceptualizing the two shifts illustrated in Figure 1; (2) to share and discuss existing projects that are making or have made these shifts, specifically identifying frameworks and perspectives to support such shifts; and (3) to summarize these conversations and promote a synergistic dialogue with the EMIC working group.

Day 1 will showcase examples from projects that originated as instructional activities but have shifted toward investigating the conceptual affordances of incorporating more playful activities for students (Ellis and Plaxco leading). The working group leaders will briefly introduce their projects and engage participants in active exploration of chosen tasks from these projects. They will then lead the group on identifying and discussing what play frameworks might be productive for supporting the transition from typical instructional tasks to play-based activities. The group will synthesize this discussion as a starting point to conceptualize how educators might incorporate playful activity within their classrooms.

On Day 2, we will take a contrasting perspective as we explore design and facilitation practices that leverage mathematical play for learning (Reimer, Molitoris-Miller, and Simpson leading). Leaders will engage group members in interactive play and board game activities with a focus on the mathematics that players draw on during their play. Whole-group discussion will focus on the pedagogical approaches and practices to support learning during mathematical play.

On Day 3 we will meet with the EMIC working group (Nathan et al., 2017) to explore areas of overlapping interest and potential convergence (Williams-Pierce leading). Members of both groups will engage in intra-working-group conversations to highlight common theoretical and methodological approaches and identify opportunities for collaborative dialogue (i.e., mathematical play as an embodied way of learning, design considerations for embodied mathematical play, etc.).

The Models and Modeling Working Group was initiated with PME-NA itself in 1978, and it has met frequently since then. This year, we propose to carry the conversation forward in the new Research Colloquium format: our goal is to establish the foundation for articulating a coherent North-American voice in the international modeling community. In fact, we conjecture that a distinctively Pan-American perspective can be articulated, identifying the common emphases and complementary strengths among modeling researchers in North, Central, and South America. The colloquium is a testing ground for this premise, looking toward ICME and ICTMA.

Keywords: Modeling, Problem Solving, Classroom Discourse, Mathematical Representations.

History of the Models and Modeling Working Group

Over the 43 years of its existence, the Working Group has offered researchers in the Models and Modeling Perspective (MMP) a vehicle for coordinating collaborative research, for welcoming new researchers into the community, and for building mentoring relationships. Early in its history, the Group focused heavily on the design and analysis of particular, self-contained activities that enabled groups of learners to engage realistic and deep forms of modeling and that produced an *auditable trail* of thinking, making learners' thought processes visible to teachers and researchers. In this phase of the field's development, a primary focus was elaborating design principles for these *Model-Eliciting Activities,* or *MEAs* (Doerr & English, 2006; Lesh & Doerr, 2003; Lesh, Hoover, Hole, Kelly, & Post 2000; Lesh, Hoover, & Kelly, 1992; Hjalmarson & Lesh, 2007; Zawojewski, Hjalmarson, Bowman, & Lesh, 2008), and articulating images of *idea development* that they promoted (Lesh et al, 2000; Lesh & Doerr, 2003). Quickly, MEAs were recognized for their potential not only as contexts for research into idea development, but also as powerful *learning environments*. This "turn" to connect with classroom ecologies raised questions about how different student groups' work could be "processed" by a whole class, bringing out common themes and connecting them to more conventional mathematical terminology, algorithms, and procedures. The construct of a Model Development Sequence, or MDS emerged in response (Ärleback, Doerr, & O'Neil, 2013; Doerr & English, 2003; Hjalmarson, Diefes-Dux, & Moore 2008; Lesh, Cramer, Doerr, Post, & Zawojewski, 2003), as one of several candidate forms of organizing classroom modeling at a larger grain size (Brady et al, 2020). These questions begin to suggest a distinctive agenda of *research themes* on modeling and idea development, which investigate:

- interrelations among nested social levels (individual, small group, and classroom community; and then, in turn, broader levels of community beyond the classroom)

- forms of learning that can be documented at these distinct social levels,
- larger-timescale emergence of connected networks of ideas through modeling, and
- larger-timescale views of the emergence of modeling as a classroom practice.

The first two of these themes call for investigations of the role and importance of the *social* and *cultural* context of classroom modeling (Brady & Jung, 2021). The last two point to questions about *temporal* and *developmental* dimensions (Brady & Lesh, 2021).

Areas for Discussion in the Colloquium

These perspectives can offer important and complementary contributions to the current international discourse on modeling. The international community is dominated by two strong cognitivist traditions, both of which have been centered in Europe but have gained traction in Australia and Asia. A first tradition, focusing on *applications*, aims at the objective articulated in Hans Freudenthal's phrase, "to teach mathematics so as to be useful" (Freudenthal, 1968); this approach is often described under the heading "modeling and *applications*." A second tradition, focusing on *heuristics*, seeks to formulate generalizable strategies that can support problem-solvers across domains (Polya, 1945). In framing modeling and articulating research questions, these traditions tend to place both social and developmental questions in the background.

Applications-oriented perspectives focus on how previously learned mathematical concepts and skills are adapted when attempts are made to use them in "real life" situations. Such problems tend to foreground particular expert solutions that wield the given mathematical tools optimally. In contrast, the MMP tradition has focused on creating problem situations that generate the need for key mathematical constructs and press learners to construct original mathematizations that serve to interpret the situation. Here, the *diversity* in learners' ways of thinking tends to be foregrounded, both in fueling the modeling engine itself and in responding to the range of distinct mathematizations that emerge in MEA solutions.

Heuristics-oriented perspectives aim at generalizable strategies (Schoenfeld, 1992) and typologies – types of problems and learnable categories of response. Such approaches tend to consider strategies in a cognitive vein and view modeling as a procedural skill that can be directly taught (Polya, 1945). In contrast, the MMP is more amenable to a *practice-oriented* view of modeling (Boaler, 2000; Cobb et al, 2001; Kobiela & Lehrer 2015), viewing the teaching and learning of modeling as the development over time of classroom modeling communities.

Our Colloquium will engage the PME-NA community—both prior members of the Models and Modeling Working Group and new participants—in articulating a research perspective that foregrounds social and developmental perspectives that can complement these two traditions.

Organization of the Sessions

As we have done within the former Working Group format, we will attend both to the needs of "newcomers" and "old hands" to the MMP—flexibly adjusting based on the participant group. Our three principal facilitators will describe recent work that foregrounds the classroom community as a learning entity, emphasizing both social and developmental questions, as well as work that considers the classroom as embedded in larger social and cultural systems. Each session will begin with a precis of recent study, followed by structured discussion of issues highlighted by that study. These recent efforts will not be presented as "finished products;" instead, we will share the questions of *theory* and *method* that we have encountered, with the goal of opening the conversation. The broader leadership group will help to direct the conversation toward key messages we want to be articulated at ICME and ICTMA, to represent the research commitments that we are seeing in work across North, Central, and South America.

This Working Group will explore how productive struggle is normalized and engaged in mathematically-rich informal contexts. From debugging in computer programming, to "unknitting" in textile art, to the constant repair of play, and to reconfigurations in dance, we find that struggle is a central and unproblematic element of many inherently mathematical practices. However, the productivity of this struggle and its relation to mathematical thinking is rarely identified and often overlooked. The goal of this working group is to connect scholars whose work has explored contexts for productive struggle that might not have been historically labeled as mathematical, with the goal of exploring overlaps and possibilities for mathematics.

Keywords: Computing and Coding; Informal Education; Integrated STEM / STEAM

Framing and Goals of Working Group

It has been well established that students' ideas about, and relationships to, the field of mathematics develops through their experiences in the world (Bishop, 2012; Boaler & Greeno, 2000). Although there are many experiences in our everyday lives that are richly mathematical, the experiences that are most typically labeled "mathematical" happen in schools. While as a field we are constantly working on refining and reforming mathematics instruction, it continues to be the case that for many students, mathematics is experienced as a discrete body of facts to be learned and remembered; a set of calculations rather than a series of interconnected ideas (Louie, 2017). In that framing, mathematical struggle is often taken as an indication of mathematical incompetence; uncertainty, time, and errors are to be avoided at all costs, and when they do occur, they are hidden away and forgotten. Not only is this stance towards mathematics problematic with respect to what students learn about mathematics (Vogelstein, 2021), it is also damaging to the likelihood of students coming to see themselves as mathematical persons, as these narrow views of mathematical competence routinely work to convince students that their future is *not* mathematical (Ladson-Billings, 1998; Larnell, 2016).

The invitation to *struggle* with mathematics, and the idea that struggle can be *productive*, is an important reframing to the historical cultural practices of school math. And yet we know that changing existing structures is challenging, particularly as doing so requires re-imagining current work. For that reason, we have found it productive to explore mathematical possibilities outside of school math to offer a vision of how cultures of mathematics might be transformed (Brady, Gresalfi, Steinberg, & Knowe, 2020; Gresalfi & Chapman, 2017; Kafai, Franke, Ching, & Shih, 1998; Vogelstein, 2021; Vogelstein, Brady, & Hall, 2019 Wager & Parks, 2014; Weintrop et al., 2016). To that end, this working group will explore the ways that *productive struggle* is normalized and engaged in mathematically-rich non-school contexts. From debugging in computer programming, to "unknitting" and stitch picking in textile art, to the constant repair of play, and to reconfigurations in dance, we find that struggle is a central and unproblematic element of so many practices, practices that are inherently mathematical although potentially not always labeled as such.

This proposal is for a new working group—a new initiative that has not previously been a part of PME-NA. The goal of this working group is to connect scholars whose work has explored contexts for productive struggle that might not have been historically labeled as mathematical, with the goal of exploring overlaps and possibilities for mathematics. For example, the rising popularity of STEM and STEAM initiatives (Takeuchi, Sengupta, Shanahan, Adams, & Hachem, 2020), and the increased focus on the potential of interdisciplinarity, all involve central mathematical practices, and such initiatives have been of great interest to the mathematics education community. We therefore anticipate that this working group will be popular among the many scholars whose work seeks to connect mathematics with other disciplines, and therefore we anticipate that these meetings would easily lead both to future submissions and, potentially, future working group meetings.

Strategies and Activities

Because of the nature of working groups—that participation is unpredictable across three days, we plan to develop a set of activities that build on each other but that each result in a product that can become the focus of the subsequent day, thus allowing newcomers to participate without having attended previous sessions. The first day will create an opportunity for experiencing productive mathematical struggle in mathematically-relevant contexts of debugging, sewing, knitting, play, or dance. For example, if the meeting is in person, we will engage participants in a set of "debugging" tasks with a spherical robot called *Sphero*, invite them to participate in a choreography activity that includes a large mylar square, and/or offer yarn and fabric (depending on skills) to begin to create clothing or squares that cover an object. If the meeting is online, we will provide virtual opportunities to engage in mathematical struggle or share videos of students engaging in such tasks to allow participants to analyze others' debugging activities. In either case, the goal is to experience productive struggle either directly or vicariously, and to produce an account of "what happened," with respect to the struggle and its relationship to disciplinary engagement. This will result in analysis artifacts to be used later in the workshop.

The second day of the working group will invite discussion about these interdisciplinary activities by focusing on the analysis artifacts that were developed in day 1. Each group will share a brief overview of the context they engaged and their thinking about how productive struggle was invited and experienced. The goal of these discussions is to both begin to think about how we see mathematics in interdisciplinary contexts, what *counts* as mathematics in these contexts, and whether and how the struggle that is inherent in these contexts appeared to contribute to the opportunities to learn and engage.

The final day of the working group will push towards synthesis and future work, exploring how the targeted contexts and those that participants are already working to consider whether and how those contexts can be connected to student engagement, or student mathematical engagement. This collective work will focus on identifying productive areas for future research and, perhaps, identifying themes for a future working group or conference. At a minimum, a collective document will be generated to identify a set of questions or concerns that could be explored by small groups over the course of the year.

Argumentation, justification, and proof are conceptualized in many ways in extant mathematics education literature. At times, the descriptions of these objects and processes are compatible or complementary; at other times, they are inconsistent and even contradictory. Regardless of the descriptions of these processes, however, given the importance of argumentation, justification, and proof to the discipline of mathematics, as well as their valued roles as learning practices, it is critical to query the relationship between engaging students in such processes and the promotion of equitable learning spaces and outcomes. This year, working group leaders aim to facilitate discussions and collaborations among researchers to advance our collective understanding of argumentation, justification and proof through an equity and inclusion lens.

Keywords: Reasoning and Proof; Advanced Mathematical Thinking; Equity, Inclusion, and Diversity

Theoretical Background

Given the importance of argumentation, justification and proof to the discipline of mathematics, as well as their valued roles in supporting student sense making and understanding, it is critical to query the relationship between engaging students in such processes and the promotion of equitable and inclusive learning spaces and outcomes. Two constructs potentially crucial for examining the role of these processes in creating more equitable outcomes are access and agency (Gutiérrez, 2002), as these practices can provide students with access to powerful mathematics, and opportunities to come to understand themselves as knowers and doers of mathematics, as well as having their voices matter and influence the classroom. As we seek to promote strong mathematics learning, as well as rehumanize mathematics classrooms, we need to further examine and theorize the relationship between argumentation, justification and proof and equitable engagement. We assert this against a backdrop where mathematics, and its ways of knowledge development, have a history of exclusion that not only impacts participation in mathematics education (Louie, 2017) but also in the discipline more broadly. For example, proof has been positioned as a high-status process, and thus can be positioned as exclusionary (see, e.g., Knuth, 2002; Otten et al., 2020).

History of the Working Group

The *Conceptions and Consequences of What We Call Argumentation, Justification, and Proof* Working Group (AJP-WG) met for the first time during the 37th Annual Meeting of the North American Chapter of the Psychology of Mathematics Education (PME-NA) in 2015

(Cirillo et al., 2015). The group then met for three additional years in 2016, 2017, and 2018 (Staples et al., 2016; Conner et al., 2017, & Conner et al., 2018). The AJP-WG sessions were well-attended each year, and the group has been active in between meetings. Following the 2018 meeting, AJP-WG members began work on an edited book, which will be published in the coming year (Bieda et al., in press). Across the authoring teams of the AJP-WG conference papers, the book, and the white papers (i.e., Cirillo et al., 2016; Staples et al., 2017), over 50 scholars have been involved in the group's work, including many graduate students. A Research Colloquium, where we shared analyses from the forthcoming book, was facilitated at the 2020 conference (Cirillo & Bieda, 2020). We now return to the Working Group format with a focus on AJP through an equity and inclusion lens.

Plan for the Working Group

The sixth gathering of the working group will focus on the degree to which argumentation, justification, and proof (AJP) may or may not promote equity and inclusion in mathematics education. To do this, we will engage participants in vignettes focused on the interrelationship between each construct of AJP and specific aspects of equity and inclusion.

On Day 1, we welcome participants and facilitate introductions. We then focus on justification and how justification can be an *equity practice* in classrooms (in addition to a mathematical practice and a learning practice). We focus on the constructs of *access* and *agency* as we analyze classroom artifacts to consider how justification can support access and agency for students, and thus potentially more equitable outcomes. We also discuss how justification can be positioned as an *inclusive* rather than *exclusive* practice and consider *students'* choices and decision-making processes with respect to their mathematical justifications.

Day 2 will begin with a 30-minute AJP networking activity before shifting into a discussion on argumentation. Mathematical argumentation is a social activity that should be facilitated by teachers providing a context that is positive and supportive for students (Wood, 1999). Discourse in this context can be supported or hindered by either the teacher or students (Kosko, 2015; Kotsopoulos, 2008). However, not all students are provided equitable access to the social and sociomathematical norms of argumentation in mathematics lessons, and students' cultural experiences may influence their comfort level with challenging others' ideas (Civil & Hunter, 2015; Lubienski, 2000). Thus, Day 2 will focus on an interactive discussion regarding the role of relational and cultural factors in promoting (or hindering) mathematical argumentation. Vignettes of mathematical argumentation will be used to facilitate discussion regarding how attention to social and cultural contexts may lead to more equitable participation in argumentation across K-16 mathematics.

On Day 3, we will focus on proof through an equity and inclusion lens. Although some researchers have argued that proof "is not a thing separable from mathematics itself" but rather an essential component of doing mathematics (see, e.g., Schoenfeld, 1994, p. 76), other researchers (e.g., Knuth, 2002; Otten et al., 2020) have provided evidence that classroom teachers sometimes hold exclusionary beliefs about which students should be provided with opportunities to engage with proof. After we act out a vignette that explores this issue, participants will engage in small-group discussions about the consequences of such beliefs through the lens of equity and inclusion. We will then bring the small groups together in a whole-group discussion to debrief and consider strategies for dealing with these tensions. In the last 30 minutes of Day 3, we will look across the WG activities and discussions of the past three days with respect to AJP to make connections and consider next steps for the group.

This working group will engage educators who conduct professional development for, and research on, mathematics teacher educators in the context of inservice mathematics teacher education. One project that will be discussed is a professional development model designed to support mathematics coaches from rural districts. We encourage others who focus on developing teacher educators or designing professional development for teacher educators to join us. Goals for this working group are to share insights from the work of preparing teacher educators, to discuss the challenges of extrapolating understanding of teacher development to the development of teacher educators, and to develop potential collaborations for future work. We intend for this working group to continue into future PME-NA conferences as we build on this initial collaboration to influence our individual work and the field at large.

Keywords: Professional Development, Teacher Educators, Research Methods, Instructional Leadership

Working Group Rationale

There is a need to expand efforts to develop and research the development of mathematics teacher educators, particularly in inservice contexts. Relative to the literature on the professional development of teachers, there is much less literature on growing the capacity of those who design and conduct teacher professional development. Mathematics teacher educators, including coaches, need to develop capacity related to content knowledge, pedagogical knowledge, interpersonal skills, big-picture visioning and planning, and change theory to support teachers in improving instruction and student learning (Saphier & West, 2010). There are few formal training programs for mathematics teacher educators, which has led to the promotion of teachers to coaching positions based on their strengths as classroom teachers, rather than their experience or skills as a coach or trainer (Chval et.al., 2010; Hartman, 2013). Given the lack of formal training opportunities for coaches or other mathematics teacher educators providing professional development, it is reasonable to assume that most mathematics teacher educators learn practices through their experiences in the context of their work. Building on our Working Group in PME-NA42 focused on content-focused coaching specifically, we want to engage in discussions of how mathematics teacher educators develop capacity to work with inservice teachers in varying contexts. While we had some rich discussions with participants at PME-NA42, we want to engage more mathematics teacher educators who work with inservice teachers beyond those who engage in coaching. While we will initially draw from a project focused specifically on developing coaches (NSF Grant DRL-2006263), all authors have extensive experience working with mathematics teacher educators supporting inservice teachers more broadly.

Our Project

We designed, implemented, and researched an innovative fully online professional development model for mathematics coaches. We engaged coaches, as mathematics teacher educators, in a three-part professional development model that included (a) a professional development course on content-focused coaching, (b) one-on-one video-based "coaching the coach" cycles, and (c) a video coaching club (see Carson et al., 2019; Choppin et al., 2020; & Choppin et al., in press). Mentor Coaches - project personnel recruited for their expertise in content-focused coaching - supported the practicing coaches in coaching their colleagues and reflecting on their practice.

We will share key reflections and lessons learned from designing, implementing, and researching the three-part professional development model for mathematics coaches, and the challenges in doing so, in relationship to the implications for supporting mathematics teacher educators more generally. We will share perspectives from Participant Coaches, Mentor Coaches, and facilitators, as well as our main data streams. This sharing can launch discussion and engagement of session participants as they connect to their own work.

Working Group Organization and Structure

In this working group, we will draw on these experiences and those of the participants, to engage in dialogue with the goal of developing a more robust and shared understanding of how to support mathematics teacher educators, the challenges, and gaps in the field with respect to research and practice. Each session will focus on a different component related to designing and researching professional development for coaches and other mathematics teacher educators in working with inservice teachers. Session one will explore models of support and challenges; session two will explore research on supporting coaches and mathematics teacher educators who work with inservice teachers; and, session three will be dedicated to organizing future work. Each session will include opportunities for small and full group discussions, as well as for participants to share their own experiences and projects with the group in service to networking and generating new ideas and learnings related to informing future work. In addition, in session one, ideas for discussion topics will be solicited from the group in order to guide subsequent sessions related to the intention of the working group. This will allow participants to pose and discuss questions important to their work within a supportive and structured environment, and to draw on the talent that will be in the room. Each session will focus on the following themes:

- Session 1: (a) exploring models of developing coaches and other mathematics teacher educators who work with inservice teachers; and, (b) exploring challenges in implementing professional development models for coaches and mathematics teacher educators.
- Session 2: (a) what has been/is being studied related to the development of mathematics teacher educators who support inservice teachers, and what processes are there for research, and, (b) what are areas of need for further contributions to the field.

- Session 3: (a) exploring ideas and interests generated by the group and continuing conversations from the previous day, and, (b) discussing next steps and future possibilities.

To support follow-up and ongoing collaboration of participants, group notes and documents will be shared and distributed via a Google folder that will be set up for this working group. The use of Google documents will allow members to create an institutional memory of activities during the working group that we will continue to use. This shared folder will also provide a shared space for future collaborations and writing projects related to the working group members.

STATISTICS EDUCATION: NEW CONNECTIONS AND FUTURE DIRECTIONS

EDUCACIÓN ESTADÍSTICA: NUEVAS CONEXIONES Y FUTURAS DIRECCIONES

Travis Weiland
University of Houston
tweiland@uh.edu

Christopher Engledowl
New Mexico State University
chriseng@nmsu.edu

In continuing from past working groups on statistics education, this working group will seek to present new findings and connections, as well as work toward future directions. Each day of the working group will be based on a different theme including: international efforts, measurement, and issues of equity and social justice. Each day will start with short 3-5 minute mini-presentations of a few projects in line with the theme, followed by discussion of the theme in statistics education, and ending with a discussion of future directions related to the theme. Such structure affords easy movement of people in and out of the group based on interest and affords more focused discussion and possible future efforts.

Keywords: Data Analysis and Statistics, Measurement, Equity, Inclusion, and Diversity

Statistics education is growing by leaps and bounds. The pandemic has brought data and data-based arguments front and center in the media and people are increasingly able to openly access data for themselves (Ancker, 2020). Data science has also found a new hold in the K-12 mathematics curriculum in various locations (Bargagliotti et al., 2020) and has begun to be researched in educational settings. With the needs of the workforce and society shifting dramatically, there is significant need to think about statistics education's role and transformation in the face of a changing world. This working group is aimed at continuing discussions begun at previous meetings, and also to create space for new work and collaborations. In an effort to create an open environment that can also focus on specific elements of the field, the working group will be structured around three themes.

Themes

The working group will be structured around three main themes: international efforts, measurement, and issues of equity and social justice. Such structure will allow people to freely flow in and out of the group based on interests. The themes will also help focus discussion and create an environment for creating tangible next steps to support scholarship and collaborations.

International Efforts

Statistics education is a field that crosses both disciplinary and geopolitical boundaries (Ben-Zvi et al., 2018). Though there are contextual differences in education from country to country, there is also a lot that can be learned through cross boundary collaborations and considerations. The International Association of Statistics Education (IASE) is one avenue of sharing such work to a broad audience, however this venue is still dominated by English speaking researchers due to it being the dominant language of research. In this theme we will discuss international statistics education as well as consider ways for creating more opportunities for sharing research and collaborating across boundaries.

Measurement

Recently, there have been calls for increased focus on not only the need for developing instruments backed by strong validity arguments, but also for examination of validity evidence for existing instruments and closer attention to instruments being used for research purposes (Lavery et al., 2019). The NSF-funded Validity in Measurement in Mathematics Education Statistics Education synthesis group has spent the past two years documenting instruments used in statistics education research, as well as the types of validity evidence that accompany them. In this theme, we will discuss findings and implications, and broadly discuss issues of validity.

Issues of Equity and Social Justice

The global pandemic and recent protests for racial justice have highlighted the severity of inequities and systems of injustice that operate in society. Because of the centrality of context to statistical practice, the discipline is well positioned to interrogate issues of equity and social justice and create spaces in the often neutrally positioned mathematics curriculum (Author, 2019). In this theme, we will discuss how data investigations can be used to interrogate issues of equity and justice and how we might consider how such issues exist in our own field and scholarship.

Structure of Sessions

Each day will be focused on a different theme but will follow the same basic structure (see Table 1). The session will start with a brief ten minute introduction to the theme. Introductions will be followed by three 5-minute brief presentations of current work related to the theme. After setting the stage with introductions and brief presentations the next 35 minutes will be dedicated to talking about the theme with everyone in attendance. The final 30 minutes of each session will be focused on brainstorming next steps and future directions. The goal is for the next steps time to also involve discussion of possible scholarly products or forming collaborations to support the development of new work or projects in the field.

Table 1: Overview of Session Structure

Time	Day 1: International Connections	Day 2: Measurement	Day 3: Issues of Equity and Social Justice
Introduction to Theme	International Outlets, Conferences, and Themes	Discussion of VMED project	Statistical Investigations of Sociopolitical Issues and Areas of Concern
Brief Presentations	Brief discussion of three projects from various countries	Brief discussion of VMED findings	Brief discussion of current efforts in curriculum development and policy
Discussion	Discuss international collaborations	Discussion of ongoing measurement work and needs	Discussion of issues, outlining current problems
Future Directions	How can international collaborations be started? How can discussion across boundaries be facilitated?	What measurements do we still need? What measurements could we draw upon from other fields? How can we encourage such projects?	How do we incorporate more discussion of issues of equity and social justice in statistics education? How do we diversify the membership of the field and issues under investigation?

Students' construction, coordination, and abstraction of units underlie success across multiple mathematics domains. This working group aims to facilitate collaboration between researchers and educators with the particular aim of extending research on units coordination and construction across numerical contexts and constructs.

Keywords: Cognition, Learning Theory, Number Concepts and Operations

Theoretical Background, Purpose, and History

Units coordination and construction refers to the number of levels and types of units a person can construct and bring into a situation (Steffe & Olive, 2010). In Steffe's 2017 plenary for PME-NA, he substantiated particular needs for investigating how children develop mental operations when constructing and coordinating units. The working group began at PME-NA 2018, with the aim of facilitating collaboration amongst researchers and educators sharing Steffe's concerns about (a) the need for supporting units construction and coordination for all learners and (b) the need for accompanying learning trajectories (curricula) appropriate for students' current level of units across grade levels. The purpose of the working group is to provide opportunities for participants to sharing and build upon units coordination research.

Working Group Goals and Strategies, Past and Present

In the first year of the working group, goals included generation of related research topics of interest to PME-NA attendees, including the role of units coordination in early childhood education, special education, and secondary and post-secondary education, and teacher education. Products included (1) the creation of a website for organizing and collecting tasks used for assessing students' units coordination and (2) links to research papers addressing particular topics relating to units coordination: https://unitscoordination.wordpress.com/.

Since this first working group, we have hosted discussions with novice and experienced researchers who focused much of their work on (1) students' co-variational reasoning when coordinating units, (2) students' probabilistic reasoning when coordinating units, (3) students and prospective teachers' units coordinating, (4) students' algebraic reasoning when coordinating units, and (5) students' engagement with visual material (e.g. hands-on and virtual manipulatives) when constructing and coordinating units. To continue to build on the productive discussions we will focus on issues related to assessments of units coordination in different settings (within classrooms, in virtual and hybrid classroom settings, via written instruments, via clinical interviews, and via individual or paired-student teaching experiments) and continue efforts to bridge emerging research connecting units coordination across mathematical domains.

Session 1: Emerging Assessments with Units Coordination in Discrete and Continuous Numerical Contexts

GOAL: Explore and bring to focus the role of tasks and assessments when examining emerging research investigating connections between units construction and coordination across age groups. ENGAGEMENT: Prior to the working group, we will administer an entry survey of participants to determine interests and goals for collaboration. In the first day's meeting, participants will discuss what constitutes a "unit" and reflect on their own actions with units when solving tasks in discrete and continuous number contexts used to assess and support units construction and coordination (listed on the units coordination website). Participants will form at least three groups, one focused on units construction and coordination with young children, one focused on units coordination with upper elementary and middle school students, and one focused on units coordination of pre-service teachers and their mathematical knowledge for teaching. Participants will share their own tasks, assessments, and modalities used in their work. Notes will be recorded in a Google doc.

Session 2: Connections between Units Coordination and other Constructs

GOAL: Explore and bring to focus the role of tasks and assessments when examining emerging research investigating connections between units coordination and other constructs (e.g., subitizing, co-variational reasoning, quantitative reasoning, algebraic reasoning, combinatoric reasoning). ENGAGEMENT: In small groups, members will discuss how their work across constructs connects to units construction and coordination. The discussions will include both empirical and theoretical connections. Notes will be recorded in a Google doc.

Session 3: Next Steps

GOAL: Embark on planning collaborations of interest to participants. ENGAGEMENT: As a whole group, we will discuss the results from the previous sessions and share prospective projects involving units coordination. Then, form small groups for each of these goals: (1) new directions for participants' research and teaching projects, and (2) creation of content for the webpage. Administer exit survey of participants' interests and goals for collaboration.

EMBODIED MATHEMATICAL IMAGINATION AND COGNITION (EMIC) RESEARCH COLLOQUIUM

The EMIC Working Group aims to connect, engage, and inspire colleagues in this growing community of discourse around pedagogical, technological, theoretical, and methodological developments for advancing the study of embodied cognition for mathematics education. This year, our seventh at PME-NA, we organize our interactions around the theme of "productive struggle" by promoting inclusive mathematics education research and principles through a broad range of embodied activities, practices, and emerging technologies that contribute to teaching, learning, and assessment of mathematical reasoning, and study of these phenomena.

Keywords: Cognition; Design Experiments; Equity, Inclusion & Diversity; Learning Theory; Embodiment, Gesture, Multi-modal Discourse

Pedagogical, technological, empirical, theoretical, and methodological developments in embodied cognition and gesture studies support the continuation of the regularly held Embodied Mathematical Imagination and Cognition (EMIC) Working Group for PME-NA. Members of this group have met annually at PME-NA since 2015 and we are excited to expand into a **research colloquium** this year. The central aims of EMIC are to attract, engage, and inspire colleagues to understand the emerging impact of embodied learning and invite scholars to participate in this growing community of discourse. The group seeks to advance the study of embodied cognition for mathematics education, including reasoning, instruction, assessment, technology, and learning in and outside of formal settings.

Views of learning as embodied experiences have grown from developments in philosophy, psychology, anthropology, education, and the learning sciences that frame human communication as multimodal interaction, and human thinking as multimodal simulation of sensory-motor activity (e.g., Abrahamson et al., 2020; de Freitas & Sinclair, 2014). Four ideas exemplify the plurality of ways EMIC is relevant for the study of mathematical understanding: (1) Grounding abstractions in perceptuo-motor activity as an alternative to amodal symbol systems; (2) Cognition emerges from perceptually guided action; (3) Mathematics learning is always affective, never detached from body-based feelings and interpretations; (4) Mathematical ideas are conveyed via multimodal forms of communication, e.g., gestures, drawing, and objects.

The interplay of multiple perspectives is vital for the study of embodied mathematical cognition to flourish. While there is significant convergence, there remain questions to be addressed through empirical means: (1) When and how can teachers best incorporate principles of embodied design? (2) How can theory inform good assessment practices for nonverbal math knowledge (e.g., intuition)? (3) How do embodied education practices support differentiated instruction? and (4) Does embodiment identify limits to humans' mathematical reasoning?

Past Achievements, Current Organizers, and the Future of EMIC

As Figure 1 and Table 1 shows, several activities in and beyond PME-NA have emerged to connect scholars and provide resources, such as www.embodiedmathematics.com, our web portal. Two NSF-funded workshops for K-16 researchers and instructors grew from this: "The

Future of Embodied Design for Mathematical Imagination and Cognition" (May 20-22, 2019); and "EMIC: Professional Development for Undergraduate Mathematics Instructors" (October, 2021). An edited book is planned for the "Research in Mathematics Education" Series as is a third NSF sponsored workshop. As the EMIC group matures, we are broadening the set of organizers to represent a range of institutions, perspectives, and applications. This enriches the colloquium experience and the long-term viability of the community. Mitchell Nathan (U. Wisconsin) will be this year's coordinator, with organizers: Hortensia Soto (Colorado State University), Erin Ottmar and Avery Harrison Closser (Worcester Polytechnic Institute), Janet Walkoe (University of Maryland, College Park), and Dor Abrahamson (Berkeley).

EMIC 2021: Embodiment in Mathematics for Inclusion

Our 2021 theme is **embodiment is an effective way to promote inclusive mathematics education research and practices**. This past year, members of the EMIC community conducted two online EMIC workshops to disseminate best practices to teachers and parents during the COVID pandemic. We will explore these topics with participants to explore what the research says about how embodiment facilitates grounded and embodied learning and collaboration, instruction and assessment. This includes how everyday household objects and activities, such as games, crafts, cooking, etc. can foster grounded mathematics learning. We will also identify ways that mathematics education is impaired with the loss of co-located, in-person interactions.

To demonstrate additional growth, we will join the Mathematical Play WG on Day 3, building upon the online joint-gathering for the 2020 PME-NA (held June, 2021).

On **Day 1**, we will introduce the aims of EMIC, present our past progress, and discuss the theme for PME-NA 2021 of "productive struggle." As is customary with EMIC, we will anchor this to hands-on and whole-body mathematical activities (e.g., making human-scale polyhedra). Participants will collaborate in small groups to identify how our bodies support mathematical reasoning and communication. Groups will reflect on inclusive activity designs across grade levels and math topics (based on who attends). Organizers will relate these to the 4 EMIC themes: Grounding, emergence, affect, and multimodality.

On **Day 2**, we will explore mathematical reasoning when physical and embodied resources are unavailable. Teachers may draw from their experience with distanced and remote learning in the past year. Reflections will center on accommodations to foster grounded learning, as well as the types of reasoning and assessment that are unavailable to learners and teachers.

On **Day 3**, EMIC will meet with the Mathematical Play WG to consider overlapping interests and questions. The organizers of both will also discuss aims of a joint conference proposal to NSF that is currently under review. The session will include small activity groups with Math Play participants who want to think about their work as embodied and EMIC participants who want to think of their work as math play opportunities. After, we will facilitate an open discussion that reviews Days 1 and 2, considers how our aims overlap, proposes ways to enhance future PME-NA conferences, as well as the broader ways that embodiment, imaginative thinking, and play can be used to promote inclusivity. We will conclude by discussing continued engagement and dissemination opportunities available with both communities.

yvonnexlai@unl.edu

This working group is a continuation of a 2019 PME-NA working group focused on the challenges and opportunities of using simulations of teaching practice as an educative tool for preservice teachers focusing on simulation use in the context of the COVID-19 pandemic. Initially, we will share the takeaways from the 2019 working group. Next, we will discuss our experiences implementing simulated teaching within mathematics methods courses that experienced challenges due to COVID-19 conditions. Finally, we aim to identify the pieces of this work that are worth preserving after the pandemic.

Keywords: Simulation, Preservice Teacher Education, Online and Distance Education, Technology, Classroom Discourse

It is essential for preservice teachers (PTs) to have authentic practice-based experiences during their professional preparation (Ball & Forzani, 2009; Forzani, 2014). Among the three key components of professional education (Grossman, Hammerness, & McDonald, 2009), approximation of practice provides "opportunities to rehearse and enact discrete components of complex practice in settings of reduced complexity" (Grossman et al., 2009, p. 283). Approximations of practice provide opportunities for PTs to learn from their mistakes, experiment with various instructional approaches, and enhance their teaching knowledge and skills (Girod & Girod, 2008). Because PTs are not interacting with actual students, they can develop their professional skills in a safe environment without worrying about the possibility of negatively impacting student learning. Simulations have become a popular means of providing approximations of practice in a variety of professions, including medicine, aviation, and the military. The impact of using simulations to improve teachers' practices has been investigated in recent years (e.g., Straub et al., 2014; Howell & Mikeska, 2021). Challenges emerging from the COVID-19 pandemic of 2020, however, have brought simulations, and particularly digital simulations, into the mainstream as never before, with widespread endorsement from professional organizations such as the American Association of Colleges for Teacher Education ([AACTE], 2020). It has also, in response to difficulty in accessing field placements, led to the rapid expansion of their use in lieu of work with children, a use that was never intended in the design of most such simulations. We see this as productive struggle; while necessity in the face of unprecedented challenge may have been the primary driver of this rapid expansion in simulation use it has also allowed us to learn from this natural experiment in simulation use and re-imagine what we may want to retain from the approach as we emerge from the pandemic and re-invent our approaches to teacher preparation.

Focus of Work

This working group seeks to explore the following questions:

1. What affordances and/or challenges did you see in using, adapting, and integrating digital simulations before the pandemic?

2. How and why did the affordances and/or challenges change during the pandemic?

3. What affordances and/or challenges do you see in using, adapting, and integrating digital simulations after the pandemic?

Organization and Plan for Active Engagement

The overall goal of this continued working group is to expand the community of researchers, teacher educators, and practitioners from the initial working group to explore how simulations of practice can be optimized to provide opportunities for teacher learning during the pandemic and in a post-pandemic world. Prior to convening in Philadelphia, we will ask participants to complete a brief survey on their experiences using teaching simulations. We will use this information to frame the working group discussions.

The working group will consist of three sessions during the conference followed by virtual meetings through the following year. We organize the sessions and focus roughly along the timeline of before/during/after, focusing first on what is known about simulation design and use, next on foregrounding emergent learnings from participants' uses of simulation during the pandemic, and finishing by looking forward to where we collectively see value in the approach moving forward. In each session, participants will have opportunities to share their experiences and collaboratively design simulation tasks based on lessons learned from the community.

Session 1. A Principled Start: Pre-Pandemic Simulation Design and Best Practice

In this session, we will begin by sharing the takeaways from a 2019 PME-NA working group focused on the challenges and opportunities of using simulations in a pre-COVID-19 pandemic. The 2019 working group explored three key topics: the theories of action by which teacher learning is expected to result from engagement in simulation activities, design principles grounded in those theories of action, and how to leverage simulations to measuring the development of mathematics knowledge for teaching (MKT), teaching practice, or other valued outcomes.

Session 2. Meeting the Challenge: Affordances & Challenges in Simulation Use during COVID-19

We will then transition into our experiences using simulations during the COVID-19 pandemic and within the context of restricted access to field experiences. Specifically, the facilitators and participants will share lessons learned from redesigning methods courses around simulation-based activities, including the participation of a subset of the authors in grant activities that were conceptualized to provide exactly such opportunities (Bondurant, 2020; Lee & Freas, 2020; Schwartz, Lee, Gonzalez, & Belford, 2020).

Session 3. Crisis to Opportunity: Simulations in Post-Pandemic Teacher Preparation

Finally, we aim to discuss the components of simulation experiences that are worth preserving after the pandemic. Participants will reflect on how the simulated experiences compared to their pre-pandemic PT field experiences. They will share how they plan to incorporate simulations in their programs moving forward as well as their justifications for these decisions.

This new working group seeks to produce research-based recommendations that support teacher preparation programs in providing an effective curriculum for the mathematics instruction pre-service elementary teachers receive.

Keywords: Preservice Teacher Education, Teacher Educators, Mathematical Knowledge for Teaching, Elementary School Education

Standards and policy documents from professional organizations (AMTE, 2017; CBMS, 2012), accreditation bodies (e.g., CAEP, 2018), and governmental authorities (e.g., Michigan Department of Education, 2020) set forth mathematics coursework recommendations and requirements for elementary teacher preparation programs to follow. Mathematics courses for PSTs are critical because teachers' mathematical knowledge for teaching makes a difference in the quality of instruction their students receive (Hill et al., 2008). However, there remains variation in what mathematics elementary pre-service teachers (PSTs) in the United States study and to what depth (Malzahn, 2020). Such variation also exists in Canada, which has a provincially decentralized approach to coursework standards for teacher preparation (NCEE, 2016). Although Mexico now has a more centralized approach to teacher preparation, teacher training colleges have been slow to change their practices in response to the 2013 educational reforms (Hrusa et al., 2020). Across North America, some institutions implement survey courses that attempt to teach the entire breadth of elementary mathematics, whereas programs like the Elementary Mathematics Project (EMP; Chapin et al., 2021) focus on mathematics content identified as "high-leverage" (TeachingWorks, n.d.) and intentionally omit other topics.

Organizers of this working group (Corven et al., 2019; DiNapoli et al., 2018; Hiebert et al., 2017) have presented conference sessions detailing results of research on specialized content knowledge (SCK) retained by graduates of an elementary teacher preparation program. Corven et al. (2019) found that the amount of classroom instructional time on topics addressed in teacher preparation explained over 13% of within-person variance in graduates' SCK for those topics immediately after graduation. This relationship persisted up to two years after graduation. Quantitative models suggested that (on average) about 450 minutes of high-quality instruction on one mathematical topic were needed to develop the SCK to teach it well. Following each presentation, rich discussions arose regarding how to use these results to improve elementary mathematics teacher preparation. One presenter noted that the program's faculty had made the decision to intentionally restrict the content "covered" by their elementary mathematics courses based on *their* perceptions and opinions of importance of the topics for elementary PSTs. He suggested convening a working group to synthesize a broader range of perspectives on the issue and to develop research-based recommendations that could be adopted by teacher preparation programs and adapted to local contexts. This new working group is meant to fill that purpose.

Goals of the Working Group

The goals of this working group are two-fold. First, we want to serve as a forum to share research results that could inform the design of a more unified curriculum for elementary mathematics teacher education. Second, we want to develop a document that sets out specific recommendations for such a curriculum. We believe this curriculum skeleton document (e.g., a scope and sequence of topics with a recommended range of instructional time for each topic) would serve multiple purposes. First, it would be a resource for mathematics teacher educators designing content and methods courses in their local contexts that provides more specific guidance than the AMTE (2017) and CBMS (2012) recommendations. Second, it would help mathematics teacher educators advocate to remove structural barriers to implementing these recommendations (e.g., increasing the required number of mathematics content or methods courses elementary PSTs must take), either at the institutional or the governmental level.

We expect that the work of this group will span multiple PME-NA conferences. Our focus at this conference will be on critically examining what mathematics content should be taught in courses for elementary PSTs. In other words, we want to come to a consensus on what topics should be taught (or not taught) and approximately how much time should be spent on each. Meetings at future conferences will consider recommendations for the "how" of teaching this content because what happens during the instructional time is also important (Copur-Gencturk et al., 2019; Stallings, 1980). Once the recommendations stabilize and research supporting them is provided, we would present a colloquium at a future PME-NA conference to share the curriculum skeleton document and the underlying research.

Organization and Presentation Plan

The first session will start with a discussion among all participants about their elementary teacher preparation programs, the contexts in which they exist, and challenges they are facing in ensuring elementary PSTs are prepared to teach mathematics well. This discussion will generate a list of concerns that all participants will think about to prepare for future sessions. The organizers will then give a brief overview of research on the effectiveness of elementary teacher preparation related to mathematical knowledge for teaching. We will share theoretical frameworks, including the EMP design principles (Chapin et al., 2021) and knowledge- vs. thinking-oriented approaches to teacher preparation (Li & Howe, 2021), to ground our work.

During the second session, participants will collaboratively generate content, structure, and instructional time recommendations for ideal elementary content and methods courses. At the end of this session, we will see where there is consensus and where there is disagreement. In the final session, we will share the results of our analysis of the recommendations and lead a discussion about them. Finally, participants will discuss ideas for how the previously generated list of concerns could be addressed in a recommended mathematics curriculum for elementary teacher preparation in North America (while still attending to important differences in local and national contexts), and research findings that support those recommendations or practices.

By the end of the conference, the group will have produced a working draft of a curriculum recommendations document that will be shared with all participants. We will collaborate to design and organize pilot studies that could provide evidence supporting the recommendations. Finally, we will discuss next steps for the working group (e.g., organizing a special issue of a journal or an edited book with research that highlights the importance of depth rather than breadth for elementary mathematics teacher preparation). Additionally, we intend to continue this work with broader participation from the mathematics teacher educator community by organizing a similar working group for the 2022 AMTE conference.

This working group is a new initiative aimed at providing a structure for Mathematics Teacher Educators (MTEs) to engage in Continuous Improvement Lesson Study (CILS), a process of MTE professional development that involves working collaboratively to design a lesson, improve preservice teacher (PST) learning, and MTE practice. The goals this year are to share the CILS process and experiences, and form sub-groups of MTEs with common interests to engage in the CILS process to develop an educative lesson. The eventual goal is to collaborate with sub-groups to share lessons and experiences in an edited book or a special issue of a journal.

Keywords: Teacher Educators, Preservice Teacher Education, Mathematical Knowledge for Teaching, Professional Development

The Continuous Improvement Lesson Study (CILS) Process

The CILS process integrates lesson study (Lewis & Hurd, 2011) and the Continuous Improvement process (Berk & Hiebert, 2009). Lesson study is a collaborative process of investigating instruction with the goal of improving student learning through a single lesson. This teacher-driven professional development focuses on analyzing student learning and leads to enhanced instructor knowledge (e.g., Watanabe, 2004; Demir et al., 2013). Lesson study consists of four phases: 1) study the curriculum and formulate goals, 2) plan the lesson, 3) teach the researched lesson, and 4) reflect on learning (Lewis & Hurd, 2011). While traditional lesson studies occurred with participants physically located in the same room to observe the intricacies of the research-based lesson, there have been attempts to broaden the geographic implementation of lesson studies with the use of technology (e.g., Soto et al., 2019).

Hiebert and colleagues at the University of Delaware developed a model for improving MTE lessons and instruction at their university (Berk & Hiebert, 2009). The model includes an iterative process of “planning, enactment, analysis, and revision” guided by three principles: 1) specify critical learning goals for PSTs; 2) collect and use evidence of students’ learning to drive revisions; and 3) gather and store knowledge in a final version of the lesson that becomes a shared product (p. 339). Unlike traditional lesson studies where the primary outcome of the process is student and teacher learning, the primary outcome is the educative lesson itself.

We have integrated these two methods of researching and improving instruction and student outcomes, lesson study and continuous improvement to inform an integrated process that we call Continuous Improvement Lesson Study (CILS). This new, integrated process (Figure 1) follows the lesson study process (blue) and incorporates the iterative processes of continuous improvement (yellow) that results in a final lesson product. The incorporation of continuous improvement within lesson study allows for a focus both on PST learning and on lesson revision as a lesson is taught multiple times by each participating MTE. In addition, we have included research (green) as a part of this iterative process because we found returning to literature to situate PST learning after reflecting on the teaching of the lesson was imperative for our lesson revisions (Appelgate et al., 2020).

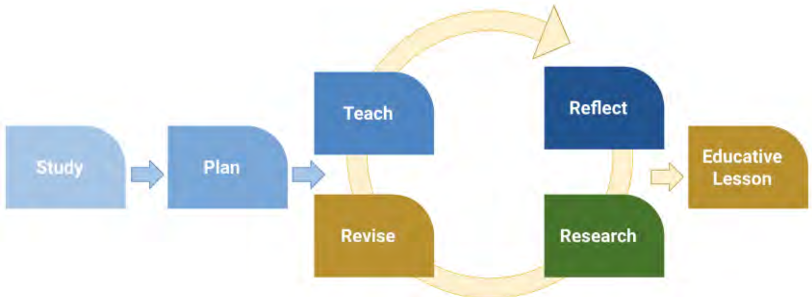

Figure 1: The Continuous Improvement Lesson Study (CILS) Process

We have found that engaging in the CILS process supports MTEs to develop an educative curriculum and collaborative teaching environment. MTEs are engaged in the act of teaching teachers mathematical knowledge for teaching (MKT) (e.g. Ball et al., 2008) thus we are working to develop our own mathematical knowledge for teaching teachers (MKTT) (Castro Superfine et al., 2020) throughout the process. Unlike with lesson study and the continuous improvement method, CILS is designed to be used by MTEs across institutions, and therefore most of the meetings and lesson outcomes are shared with each other virtually (Soto et al., 2019).

Working group Organization

This working group is a new initiative that aims at providing a structure for the participants to engage the CILS process to improve their practice. Table 1 contains the proposed structure. The plan will be to continue meeting at future PME-NAs with an eventual goal of publishing a special journal issue or an edited book.

Table 1: Overview of the Proposed Working group Session

	Activities	Take-Aways
Session One	1. Introductions and Agenda 2. Overview of CILS and goals of the WG 3. Sharing of resources; discussion of potential topics for the subgroups 4. Formation of subgroups and work time	1. Formation of subgroups 2. Resources for the next session
Session Two	1. Subgroup sharing from previous session 2. Work time- solidifying topic, research focus, and resource brainstorming 3. Brief sharing of the subgroup work	1. Topic Chosen 2. Finding resources to share
Session Three	1. Subgroup sharing from previous session 2. Work time - sharing and developing a plan for future meetings and collaboration	1. Research Focus of the subgroups 2. Future plans for

	3. Brief sharing of subgroups 4. Final reflections and plans for future working groups with eventual goal of a special issue or edited book	collaboration and sharing with ME community

AUTHENTICITY IN MATHEMATICS EDUCATION ASSESSMENT

Priscila D. Corrêa
University of Windsor
priscila.correa@uwindsor.ca

Richelle Marynowski
University of Lethbridge
richelle.marynowski@uleth.ca

P. Janelle McFeetors
University of Alberta
janelle.mcfeetors@ualberta.ca

We propose the establishment of a new working group that critiques a means-end view of assessment in K-12 mathematics education and recognizes the human endeavor of learning through authenticity in assessment. Through engagement in assessment tasks and discussions, we aim to develop a shared understanding of authentic assessment that leads to the creation of guiding principles and example tasks.

Keywords: Assessment

Assessment "is a process whose primary purpose is to gather data that support the teaching and learning of mathematics" (NCTM, 2014, p. 89) that requires a holistic view of students' mathematical proficiencies (Kilpatrick, Swafford, Findell, 2001) and identities as mathematics learners (Heyd-Matzuyanim & Sfard, 2012). Despite well-established perspectives, classroom assessment practices in mathematics struggle to align and evolve from an emphasis on measurement to learning-through-assessment (McMillan, 2013).

Goals and Strategies

We have two goals with related strategies for the working group:

- Develop a shared understanding of authenticity in mathematics education assessment and illustrate with specific examples; to be reached through discussion built on theoretical framings and lead to establishing collaboration for research through commitment to action;
- Develop guiding principles for what authentic assessment looks like in mathematics and types of associated tasks; to be reached through collective experience and discussion and lead to outlining a paper with guiding principles to be fleshed out and published.

Theoretical Background

We are revisioning authentic assessment as a movement away from a product-based view of assessment to an ontological view of assessment. Vu and Dall'Alba (2014) stated "authentic assessment is not an end in itself; rather, it is an opportunity for students to learn to become who they endeavour to be" (p. 779). This working group will explore authentic assessment with the framing of the opportunities that assessment provides to both students and teachers to become who they endeavour to be. Mathematics teachers in K-12 classrooms are working within constraints of assessment discourse around timing (formative/summative) and means-end (utilitarian) purpose of solely informing toward occasioning assessment to be educational. For some of these teachers, the constraints that they find themselves working within do not fit who they want to be. We offer in this working group a way for mathematics educators to reconceptualize authentic assessment as a process that both teachers and students engage in that promotes "calling things into question, challenging assumptions, and engaging in renewal" (p. 788). Additionally, DeLuca and Wickstrom (2021) envision assessment as pedagogy where assessment is integrated with learning not as an event to happen after learning.

When challenging assessment methods in mathematics education it is necessary to acknowledge mathematics as a multidimensional subject. Kilpatrick et al. (2001) indicates five strands of mathematical proficiency that should be sought after in both instruction and assessment. Understanding mathematics learning from a comprehensive and diversified perspective contests individual, discrete assessments, moving towards the idea of balanced sets of assessments. The working group will invite mathematics educators to use the framework of the five mathematical proficiencies to attend to the multifaceted growth of students' mathematical learning. In keeping with the conference theme, we will engage with the productive struggle of teachers to engage authentically with assessment and with their students.

Session 1: Authenticity of Assessment in Mathematics Education

The session's aim is to develop an initial understanding of authentic assessment in mathematics education. The first session of the working group will use the conceptualization of authentic assessment from Vu and Dall'Alba (2014) as a provocation for the participants to consider. Questions we will discuss (90 min) include: How can an assessment allow both a student and a teacher to be authentic and develop authenticity as a human being in the world? What assessment practices do we engage in that are due to the constraints of the environment we work within? Are those practices consistent with our beliefs about teaching and learning and what we value as teachers? Can we change our assessment practices to reflect our evolving beliefs and understandings? At the end of the session, we will articulate our beginning understandings of authentic assessment with these questions in mind.

Session 2: Being and Becoming Mathematically Proficient

The session's aim is to reflect on what authentic assessment in mathematics entails and on how it can support students to be and become mathematically proficient. After a brief introduction about the strands of mathematical proficiency (15 min), participants will engage in a discussion that challenges the taken-for-granted procedural approaches in mathematics assessment and considers the multidimensionality of mathematics learning (30 min). Participants will share examples of where they have seen the strands of mathematical proficiency assessed and will analytically reflect on that practice through the lens of authentic assessment (45 min). The use of the strands of mathematical proficiency to inform and improve assessments is not a widespread practice (Corrêa & Haslam, 2021) and will be further explored in the working group. The session will enable the refinement of the guidelines for authentic assessment, providing participants with deeper underpinnings to join session 3 activities.

Session 3: Enabling Teachers and Students to Grow

The session's aim is to identify a range of assessment tasks that promote growth as a moment of authenticity. We will engage participants in a geometry assessment task (15 min) that exemplifies a novel concept: generative assessment. Generative assessment (GA) includes tasks which move beyond evaluating student competency and informing teaching decisions, to sponsoring teacher- and student-growth through interactions (McFeetors & Marynowski, 2017). Participants will evaluate a GA task, share their own examples of similar tasks, and develop awareness of how assessment can also be moments of growth (30 min). These interactions will culminate in a discussion about what qualities of tasks make them GA and the range of various tasks that could entail GA as authentic assessment, and in the production of authentic assessment guidelines (45 min). Participants will reflect on their research in mathematics assessment to commit to incorporating authentic assessment in project design and/or data analysis.

Follow-up Activities

As a continuation of the activities proposed during the conference, the working group will publish a theoretical paper with guidelines for authentic assessment in mathematics education. Moreover, we intend to bring back results of incorporating authentic assessment in research to a working group in the 2022 conference.

The Working Group on Gender and Sexuality in Mathematics Education has convened during the three previous PME-NA conferences. These meetings have resulted in a shared foundational knowledge of the research area and have helped us to develop understandings related to how linguistic and conceptual choices in gender and sexuality research influence research methods, results, and interpretations. At the June 2021 PME-NA conference, we aimed to expand our communal knowledge to more fully utilize theories of gender and sexuality within our work in mathematics education, attending to and problematizing the concept of identity. The October 2021 working group is organized to continue these discussions while also focusing on emerging conceptual and methodological frameworks. Members of the working group will continue to develop partnerships in order to respond to theoretical and methodological dilemmas.

Keywords: Gender; LGBTQIA+; Equity, Inclusion, and Diversity

The Working Group on Gender and Sexuality in Mathematics Education has met during the past three PME-NA conferences to develop a shared knowledge base of the current research on this topic, the theories that surround this work, and the ways that language and research methodology influence the work that is being done. As a result, many research collaborations have formed through this Working Group. Furthermore, a special issue on the topic of innovations within this work will be published in early 2021 in the *Mathematics Education Research Journal* (MERJ), with many members of this Working Group serving as contributors to the special issue. As a means to continue moving forward in this area of research, we have designed the October 2021 PME-NA Working Group sessions to focus on the emerging frameworks discussed in this MERJ special issue. Although this Working Group includes the presentation of prior work, it is not a colloquium because the presentations are meant to serve as a launching point to provoke and stimulate conversations so that the Working Group members may grapple with theoretical and methodological dilemmas. The goal of this discussion-based design is to support all attendees of the working group to continue to think about their own research in innovative ways that will advance the field.

Theoretical Background

In previous research on gender in mathematics education, scholars have studied girls' and women's experiences in mathematics (Forgasz et al., 2010), distinctions between sex-based and gender-based studies in mathematics education (Leyva, 2017; Lubienski & Ganley, 2017), and sociocultural factors that affect achievement and participation (Leyva, 2017). Additionally, scholars have considered the role of identity research in mathematics education (Damarin & Erchick, 2010; Darragh, 2016) alongside the theorization of identity in gender and queer studies (Butler, 2004). In this Working Group, we continue to develop our understandings and the implications of such theoretical framings and methodologies. Our working group this year will be guided by the following guiding questions: (a) What has been and what are the current foci of gender and sexuality research in mathematics education? (b) How might emerging theory inform the methodologies of these foci? and (c) How might evolving theories and methodologies create new areas to explore?

We offer working group participants Risman's (2018) conceptualization of *gender as social structure* as a heuristic to engage with the guiding questions. Risman argued that gender operates as "a stratification system that has implications at the individual, interactional, and macro *levels* of analysis" (p. 30). At each of these three levels, there are both material and cultural *aspects* which creates six dimensions of gender and sexuality research. Although this conceptualization was developed to discuss gender, we may utilize the heuristic to also discuss sexuality. Sexuality can be made analytically distinct from gender; however, Butler (2004) argued the two are inextricably entangled. In Risman's (2018) model, it is important to recognize that "social structures not only act on people; people act on social structures" (p. 30). As such, we invite critique on these dimensions. Further, *paradigm of inquiry* (Stinson & Walshaw, 2017) will be offered as an additional resource for participants to identify and reflect on their interests and methods in relation to others, in order to discuss and advance their work.

Organization and Structure of the Working Group

The organization and structure of the working group were created to provide a common grounding of the field of gender and sexuality in mathematics education, while also maximizing participation so that members can engage in meaningful conversations that pertain to their work.

Day 1: We will begin Day 1 with a brief presentation of *gender as social structure* (Risman, 2018) and *paradigms of inquiry* (Stinson & Walshaw, 2017). Kersey (2020) and Przybyla-Kuchek (2020), two authors from the MERJ special issue will share examples of applied emerging theories and methodologies used in their work. After the presentations, an assigned discussant in the Working Group will engage the participants in conversations surrounding this work, particularly in relation to the guiding questions.

Day 2: In continuing the conversations from Day 1, we will extend the discussion of emerging theories and methodologies to consider the field's direction more broadly. Moore (2020) and Wiest (in press), two authors from the MERJ special issue will share their research. A discussant for each article will then engage the working group participants in conversations surrounding this work, particularly in relation to the guiding questions.

Day 3: We will discuss future directions, share resources, and develop plans for Working Group members to collaborate over the next year. Jennifer Hall, a co-editor of the MERJ special issue, will briefly present an updated perspective on the trends of gender and sexuality research in mathematics education, based on the experience as a co-editor of the special issue. We encourage members to continue to create strategic partnerships to pursue interests and projects to share at future PME-NA meetings. The day will be organized as a combination of whole-group discussion and small break-out groups based upon the needs of Working Group participants. We encourage working group participants to read the four noted MERJ articles prior to the working group sessions in order to get the most out of our time together.

NEW[ISH] WORKING GROUP: TEACHING MATHEMATICS FOR JUSTICE AND LIBERATION IN THE CONTEXT OF UNIVERSITY COURSES

Eva Thanheiser

Amanda Sugimoto
Portland State University
asugimo2@pdx.edu

Goals

There are three goals for this new[ish] working group: 1) To continue to create a community of mathematics teacher educators (MTEs) who are (or are interested in) collaboratively teaching mathematics for justice and liberation (TMJL) in their university content and/or methods classes. 2) To continue to collaboratively select/develop/modify TMJL tasks and implement those in mathematics content/methods classes. 3) To research the implementation of the TMJL tasks. At PME-NA 2020 the inaugural meeting of this working group led to the following:

Refocusing of Teaching Mathematics for Social Justice (TMfSJ) to Teaching Mathematics for Justice and Liberation (TMJL), building on the work of Paolo Freire (1996,). Mathematics for liberation focusses on justice and aims to avoid re-traumatization by exploring harm done. Contexts are examined with the goal of liberation rather than oppression, thus a focus is not on examining actions of harm but on how mathematics was used to justify the harm, as well as creating learning opportunities that center on the joy, resiliency and and ways of knowing learners bring, particularly those typically marginalized in classrooms, to promote critical literacies, agency, and action. In the 2020 working group we identified 3 main themes to examine further: (1) Understanding histories (of math, math ed, TMSJ work, etc.) in order to move to liberation, (2) Math as a tool (for liberation, curiosity, etc.), not an obstacle - what does this mean for the classroom (broadly), the system, etc. (3) Investigating data towards liberation

Examining Struggles Implementing TMJL Tasks. In our group we began examining the following issues: (1) Navigating Student or Colleague Pushback to TMJL, (2) Setting up the (TMJL) Classroom Community for Shared Authority and Participation, and (3) Balancing Content and Context Goals

Examining Contexts of TMJL Tasks. We began examining: Gentrification, Mutual Aid, Tracking, Black and Asian Solidarity.

Strategies to Reach Those Goals

Our goal for this working group is to continue to create a community of MTEs who will collaboratively develop and implement TMJL tasks in their university courses and research the implementation for (in no particular order): (a) preservice teacher (PT) learning about the mathematics, (b) PT learning about the context, (c) impacts on PTs' view of mathematics and/or teaching mathematics, and (d) the potential for TMJL in university methods or content courses to ignite a call for action.

Background

Mathematics educators face a moral and ethical imperative to support students in their struggles to make sense of and mobilize against injustices in and out of the mathematics classroom (Stinson, 2014; Turner et al., 2009). In alignment with this call to action, we framed our first working group with the Teaching Mathematics for Social Justice framework (TMfSJ). The TMfSJ framework was grounded in: (1) the commitment to connect school mathematics to issues of social (in)justice, and (2) the conviction that mathematics can be taught through the study of social justice issues in order to develop PK-12 students' mathematical literacy, critical consciousness, and positive mathematical identities (Chao & Marlowe, 2019; Esmonde, 2014; Gutstein, 2003; Raygoza, 2016; Turner et al., 2009). This second working group builds upon the TMfSJ framework by positioning school mathematics as a tool for justice *and* liberation (TMJL). The potential and power of mathematics as a tool for liberation has a storied and rich history in the mathematics education community (e.g., Jett, 2009; Martin, 2010; Moses & Cobb, 2001) and in the larger scholarly community and society (e.g., Anderson, 1970; Freire et al., 1997). Mathematics for liberation intentionally moves away from mathematics tasks that are rooted in contexts of oppression and marginalization, e.g., the causes and impacts of redlining, to mathematics tasks rooted in the stories and collective power of historically marginalized voices and communities, e.g., the need for and impact of mutual aid networks (Yeh et al., 2021).

Many PTs enter their coursework believing that mathematics is neutral or universal (Greer, Verschaffel, & Mukhopadhyay, 2007; Keitel & Vithal, 2008). Yet, given the intersectional diversity of PK-12 students and human history of oppression and colonization, it is vital for MTEs to intentionally plan and implement learning opportunities for PTs to critically unpack the pervasive and misleading belief that mathematics is somehow neutral and classroom spaces are safe spaces (Frankenstein, 1983; Gutiérrez, 2013; Yeh & Otis, 2019). One pedagogical tool is to have PTs experience TMJL tasks in their mathematics courses so that they can develop their own critical consciousness about oppression and liberation alongside their content knowledge (Ball et al., 2008; Gutiérrez, 2017). TMJL tasks also open pedagogical space for MTEs and PTs to consider the power and possibilities of implementing TMJL tasks with the PK-12 learners with whom the PTs will work in their future classrooms (Bartell, 2013; Jong & Jackson, 2016). We seek to explore PTs learning *about* TMJL as well as *through* TMfSJ in this community of MTE at PME-NA while also continuing to collaborate on challenges inherent in the work, e.g., PT resistance when integrating issues of social (in)justice into mathematics (Aguirre, 2009; Ensign, 2005; Felton-Koestler, Simic-Muller, & Menéndez, 2012; Rodríguez & Kitchen, 2004).

Participant Engagement

Session 1: 1) Organizers will present on outcomes of PME-NA 42. 2) Participants and organizers will continue to discuss the successes and struggles in implementing TML tasks. 3) We will introduce one/several context(s) to focus on for the next two sessions (continue PME-NA 42 contexts and/or add new ones) as well as an online media platform for continued participation. **Session 2:** Entry points for TMJL tasks: 1) We will discuss various entry points (focus on math and/or context) for TMJL tasks. 2) We will collaboratively engage in the use of one context in our classes and potential tasks that could go with that context. 3) Participants will share their own experiences and how they may envision using such a context in their class. **Session 3:**1) We (in small groups) will collaboratively create/adapt TMJL task(s) to participants' localized contexts to use in their teaching. Participants will leave with a more nuanced understanding of TMJL tasks/implementation. 2) We will set up structures to follow up via online media after implementations. 3) The goal will be to meet at next year's PME-NA.
