Graph the following on a number line:

$2x-5x \leq 12$

Figure 2. The Number Line Problem

The typical procedure for solving this problem is to start with the initial inequality shown below:

3. $2x - 5x \leq 12$

Then the left-hand side is usually simplified by collecting like terms, resulting in the inequality:

4. $-3x \leq 12$.

The standard final step for solving the inequality is to divide each side by -3 and reverse the inequality sign, yielding:

5. $x \geq -4$.

Finally, the number line is shaded to the right of the point representing the value of -4, and a solid dot is drawn on the point representing -4.

Let's consider how we could conceptualize this procedure inferentially. Like with the Ladder Problem, these inferences are often left tacit. Because $2x - 5x = -3x$ for all values of x (and underlying understanding this equation entails other conceptualizations, which are not discussed here), we can infer that the values of x that satisfy (3) are precisely those values of x that satisfy (4). Therefore, solving (4) is tantamount to solving (3). Similarly, using the fact that $a \leq b$ is equivalent to $a/(-3) \geq b/(-3)$ and that $12/(-3) = -4$, we can conclude that the values of x that satisfy (4) are precisely those values of x that satisfy (5). Hence, we can conclude that the values of x that satisfy (3) are the same as those that satisfy (5), and then we can appropriately highlight all values on the number line that are greater than or equal to -4.

Our Framework: Inferential Knowledge and Inferential Decompositions

The two problems in the previous section can be solved by implementing known procedures with little or no attention to why those procedures work. However, as we demonstrated, each step in those procedures relies on an underlying inference. This observation is true in general of any legitimate mathematical procedure. We leverage this observation to define and delineate a type of knowledge that underlies understanding procedures inferentially. In other words, we define our novel construct, ***inferential knowledge,*** to characterize the ***knowledge involved in understanding a procedure as a chain of valid inferences.***

To contextualize and demonstrate the utility of our inferential knowledge construct, we first explain how *inferential knowledge* is novel in relation to mathematics education discourse on knowledge types. Then, we describe and illustrate what we call ***inferential decomposition***. An inferential decomposition is the process by which one makes explicit the often tacit inferences involved in performing a procedure and then characterizes the types of knowledge and understandings (Figure 3) associated with the procedure. We then make the case that performing an inferential decomposition is a valuable activity for both educators and students.

Situating Inferential Knowledge in the Literature

Much of the discourse around procedures within mathematics education has been situated within the procedural-conceptual dichotomy (e.g., Hiebert & Lefevre, 1986). In these works, procedures are commonly characterized as little more than a rote series of steps to be followed. For example, Hiebert and Lefevre (1986) describe procedural knowledge as skill-based, rote, and lacking meaning. In contrast, they characterize conceptual knowledge as meaningful and based on understanding. Star (2005) contributed nuance to this discussion by separating out knowledge *type* (procedural versus conceptual) from knowledge *quality* (shallow versus deep) and thus introduced the notion of *deep procedural knowledge.* Star's deep procedural knowledge, like Hatano's (2003) *adaptive expertise,* accounts for the fact that procedures can be implemented in skillful, teleological (goal-oriented), and non-rote ways. However, even this approach omits any clear indication or discussion of the inferential basis that lies at the core of why procedures work. In other words, the "deep" part of deep procedural knowledge appears to come not necessarily from understanding its inferential basis. Instead, it comes from flexibility and adaptability in implementing the procedure. This means there is little space within the procedural-conceptual literature for highlighting the inferential basis for procedures. In fact, a review of the literature (e.g., Baroody, 2003; Baroody et al., 2007; Hiebert & Lefevre, 1986; Ma, 1999; Peled & Zaslavsky, 2008; Rittle-Johnson et al., 2015; Star, 2005, 2007) on procedural and conceptual knowledge indicates no explicit reference to the notion of procedures being understood as valid inferences.

However, the literature does provide some hint into how some authors might categorize inferential knowledge in the procedural-conceptual divide. Hiebert and Lefevre's (1986) classification of procedural knowledge as *how-to* and conceptual knowledge as *why* seems to suggest that inferential knowledge goes in the conceptual knowledge classification – however, this classification appears not to be associated with procedures, nor is the inferential basis explicitly discussed. On the other hand, Star's (2005, 2007) characterization of procedural knowledge as being knowledge about procedures suggests that inferential knowledge associated with a particular procedure can be viewed as a type of procedural knowledge – indeed, this is the approach that Mirin and Zazkis (2020) take when discussing implicit differentiation. However, Star (2005, 2007) does not provide inferential examples when illustrating the construct of deep procedural knowledge. So, authors using the procedural-conceptual dichotomy do not seem to agree on how to classify inferential understanding of a procedure, nor have they specifically addressed the inferential basis for procedures.

Further, discussing the inferential knowledge associated with a particular procedure, such as implicit differentiation, will often entail discussing conceptualizations (e.g. of functions) that do not directly reference any procedures and are thus not necessarily *about* procedures. While the construct of adaptive expertise (Baroody, 2003) keeps procedural and conceptual knowledge intertwined, this construct appears to be more about transfer and flexible adaptation of procedures to varying contexts than it is about understanding the validity or legitimacy of procedures. One aspect of Baroody's adaptive expertise is knowing when to use a particular procedure, which is not wholly unrelated to knowing when to use the procedure. For example, part of knowing when to use implicit differentiation could relate to recognizing statements of function sameness. Yet, recognizing appropriate situations and understanding the inferential basis for *why* those situations are appropriate are not necessarily the same.

Although not explicitly addressed, we believe our approach, focusing on the inferential bases underlying procedures, echoes ideas hinted at by others in the mathematics education community. For example, Ma (1999) discusses ways that someone might be able to make sense of subtraction algorithms in terms of place value. Peled and Zaslavsky (2008) also seem to hint at the notion of inferential understanding by focusing on the meta-knowledge of procedures, such as in the context of the regrouping procedure when performing subtraction. Although not explicitly referred to as such, this type of understanding is closely related to understanding procedures inferentially. The procedure of regrouping when subtracting 53 by 25 could be understood, for example, by reasoning that a 1 in the tens place is the same as ten 1's in the one's place. In other words, someone could understand facts about place value as warrants for performing a grouping procedure. Another context where the notion of inferential reasoning within procedures is alluded to can be found in the National Council of Teachers of Mathematics (NCTM)'s *Standards and Procedures*. Specifically, in the document titled Procedural Fluency, the NCTM (2023) suggests that an "effective strategy" for solving for x in 4(x+2)=12 involves "using relational thinking to recognize that the quantity inside the parentheses equals 3, thus x equals 1." (p.1). While the NCTM seems to be advocating for this sort of reasoning as an efficient way of getting answers and as part of procedural fluency, we find it notable that they seem to be at least implicitly referring to inferences that one might make in an equation-solving context.

In summary, even if we find where our notion of understanding procedures inferentially falls within the discourse on knowledge types, we note that there is no consistent agreement amongst authors, nor has this past discourse explicitly addressed the inferential basis for procedures. Our approach does not ignore the procedural-conceptual distinctions, nor does it attempt to categorize every aspect of inferential knowledge as procedural or conceptual. Instead, by focusing on the inferential basis for a procedure, we are highlighting *where* the inferences lie within the procedure as a way to approach mathematical teaching, learning, and understanding.

Inferential Decompositions

We delineate three types of inferential knowledge associated with understanding a procedure inferentially: (I) Content-Specific Knowledge, (II) Deductive Knowledge, and (III) Inferential Orientation.

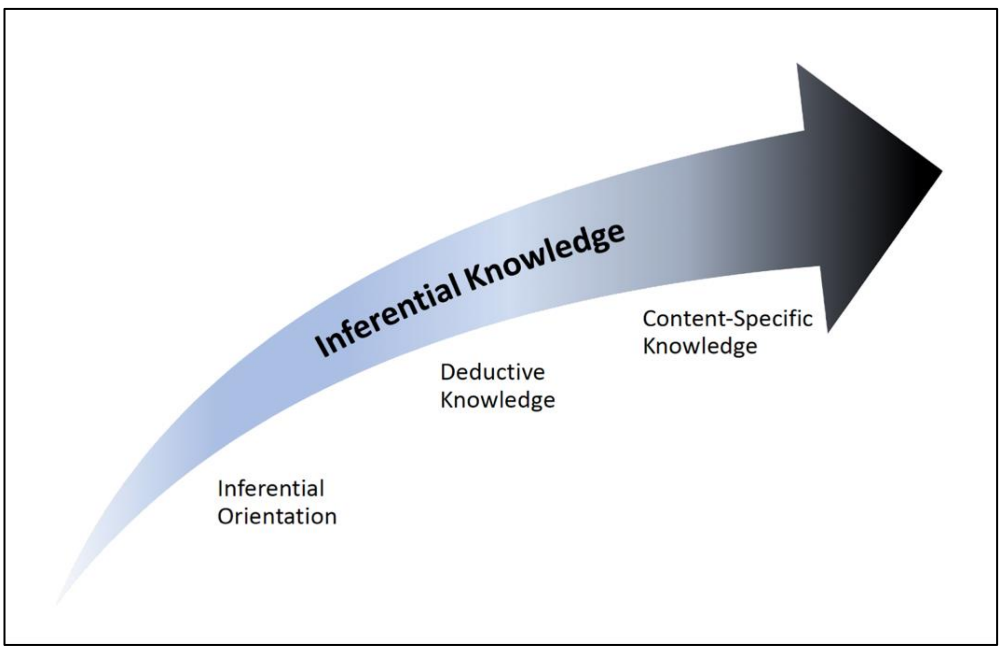

Figure 3: Inferential Knowledge

Using the ladder problem (Figure 1) and the number line problem (Figure 2), we outline *inferential decompositions.* An *inferential decomposition* is the process of identifying the knowledge and conceptualizations, and where they fall in the associated three categories (Figure 3), involved in understanding a procedure inferentially. This involves looking at how one conceptualizes the specific mathematics involved as well as how one understands the logic connecting those inferences and the role of inferences within procedures more generally. Figure 3 reflects how these different layers of knowledge relate to how "zoomed in" the type of knowledge is in relation to the procedure at hand, which we describe in more detail below. It is important to note that the descriptions below serve the purpose of illustrating our constructs of the three different types of inferential knowledge, which in turn helps illustrate the process of inferential decomposition. We are not claiming that these are complete inferential decompositions, nor are we claiming that these are the only ways of understanding the procedures described. Instead, we are illustrating how one might approach deconstructing the types of knowledge and understanding involved in conceptualizing a procedure inferentially.

We define ***Content-Specific Knowledge*** of a procedure as the conceptualizations that enable one to understand the individual inferences associated with each step of a procedure as valid. For example, Mirin and Zazkis' (2020) describe the *content-specific knowledge* involved in understanding implicit differentiation as a valid inference from function identity. This involves knowledge about functions, derivatives, the equals sign, and so on. In other words, this is what we think of as typical mathematical content knowledge and is often the focus of mathematics education research. In doing an *inferential decomposition,* we determine the specific content knowledge involved. By focusing on function and derivative knowledge in relation to implicit differentiation, Mirin and Zazkis have performed an aspect of an inferential decomposition. They then used this inferential decomposition to investigate the various obstacles that students may encounter on their way to developing such conceptualizations. We understand content-specific knowledge as being the most zoomed in of the knowledge types within an inferential decomposition in the sense that it largely focuses on the types of knowledge involved in conceptualizing an individual line, equation, or step in the procedure. For example, content-specific knowledge, in this case, involves how someone understands the equation (1) on its own as a statement of function equality and the equation (2) as a statement of derivative equality. This is the calculus content knowledge someone should have in order to view (2) as a valid inference from (1). In other words, content-specific knowledge is how someone understands the inscriptions and their mathematical referents (e.g. function, derivative) and need not entail how someone understands the relationships between these inscriptions.

We define ***Deductive Knowledge*** to be knowledge of the logical relationships between the different steps of a procedure. This is what is required for understanding the relationships between each line and is needed to make inferences and string them together to achieve a desired goal. In this sense, while content-specific knowledge can be understood as intra-line, deductive knowledge can be understood as inter-line. Returning to the ladder problem example, a series of line-by-line inferences are required to go from the initial statement of function equality, $x^2 + y^2 = 9$, to the final answer $\frac{dx}{dt} = \frac{0.1y}{x}$. Deductive knowledge can also appear in single-line inferences. Consider how someone could reason from line (1) (function equality) to line (2) (derivative equality). They could first have the content-specific knowledge about functions and derivatives that a derivative is determined by a function's graph or that the same function implies the same derivative. They could also have the content-specific understanding that line (1) expresses that two functions are the same. From these two facts, they would then need to conclude that the functions defined on the left side and the right side of line (1) do indeed share a derivative. This sort of reasoning is inter-line and is akin to a modus ponens argument (Same function → Same derivative. Same function. Therefore, same derivative). Similarly, in the number line problem, deductive knowledge is used for concluding that line (3) is equivalent to line (5) on the grounds that they are both equivalent to line (4).

Knowing how to identify and sequence inferences to reach a desired goal is non-trivial and requires a more global view. Our choice of the word *inferences* here is intentional. If the individual steps are chained together skillfully without attention to their inferential basis, then what is happening is inherently not deductive. In such a case, what is happening is akin to what Star (2005) calls "deep procedural knowledge". What we describe as *deductive knowledge* differs in terms of understanding the core activity involved. That is, deep procedural knowledge is goal-oriented, where the goal is to get a result/answer, while deductive knowledge is oriented toward deducing why that same procedure results in that particular answer.

Someone can have strong deductive knowledge *and* content-specific knowledge yet still not understand procedures inferentially. We define ***Inferential Orientation*** as the view *that* a given procedure has a logical structure that *can* be understood as a chain of inferences. This is the most zoomed-out category in that it does not concern specific lines in a procedure. It entails understanding that, at the end of a procedure, we have constructed a chain of inferences to get from the premises we stated in the problem to the deduction (the answer) required by the activity. An inferential orientation reflects a view regarding what procedures, taken as mathematical objects, are. A student can theoretically have a robust understanding of logical arguments with strong deductive reasoning skills and a mastery of content-specific knowledge, yet still not have an inferential orientation due to not viewing implementing mathematical algorithms as grounded in inferences.

The precise delineation for categorizing each particular piece of knowledge is beyond the scope of this paper. The focus of this paper is to shed light on the inferences required to choose, understand, and complete a valid procedure. From this perspective, inferences are the glue that hold together any valid mathematical procedure. If we view procedures as stemming from an inferential basis, then exploring this basis is an avenue for a deeper understanding of procedures. We argue that we should not dismiss procedures as a series of steps (that can potentially be implemented skillfully), but rather treat procedures and inferences as inextricably linked.

Treating procedures inferentially can help students evaluate and interpret their own work. Students are better positioned to interpret their answer in relation to the original problem, and thus also check for reasonableness of their answers, if they attend to the logical relationship between the initial problem being operated on and their result or answer. That is, presenting procedures as inferential reasoning can empower students to verify their answer by a using a series of inferences rather than troubleshooting by revisiting each of the calculations that led them to that answer. Consider, for example, the common mistake in inequality-solving in which students forget to flip the inequality symbol when dividing by a negative number, such as when transitioning from lines (4) to (5) in The Number Line Problem (El-Shara' & Al-Abed, 2010).

Taking an inferential approach enables a student to catch this common mistake by evaluating the original inequality at some number and comparing the truth-value of the resulting inequality at the same number. Relatedly, approaching procedures inferentially is also a useful way for helping students interpret atypical results from procedures. Multiple mathematics education researchers (e.g. Frost, 2015; Sfard & Linchevsky, 1994) observed that students struggled to interpret the results of their solution procedures when such procedures yielded atypical solutions. For example, Sfard and Linchevsky (1994) observe that students tended not to differentiate between dependent and inconsistent systems of linear equations since in both cases "the system disappears" (p. 298). Through the lens of Inferential Knowledge, students did not have the inferential knowledge to interpret their result in terms of the original problem.

Conclusion and Discussion

This work contributes to the literature in three significant ways: 1) It provides a new lens for making sense of a several decades-long debate on conceptual vs. procedural knowledge. 2) Inferential Decomposition is valuable because it parses where the inferences and by extension the concepts are within a given procedure. It also illuminates the varying layers at which that inferential structure occurs. Finally, 3) it provides a tool that could potentially smooth the transition from calculation-centered mathematics to early proof education.

Our construct of inferential knowledge provides a valuable lens for making sense of the procedural verses conceptual debate that's been a theme in mathematics education for several decades. From the perspective of inferential knowledge, procedures are not treated as inherently rote applications of pre-determined steps. Instead, they are treated as a sequence of steps glued together by inferences (content-specific knowledge), which are, then, linked together toward the goal of a logically deductive argument (deductive knowledge) and broadly situated within an inferential mathematical landscape (inferential orientation). Procedures are thus not inherently purely "procedural"; instead, they can become procedural when those implementing them lose sight of or are unaware of their inferential basis.

Inferential decomposition provides a valuable tool for identifying the inferences, and hence the conceptual bases, for procedures. An inferential decomposition performed by an educator can help highlight to both that educator and their students where the inferences and concepts are within a procedure. This may allow for a more conceptual approach to teaching a procedure that is grounded in reasoning and sense-making. Additionally, an inferential decomposition can be used to identify gaps in students' knowledge of the inferences involved in a procedure, which in turn can illuminate aspects of the student's conceptual knowledge. Finally, as a research tool, an inferential decomposition can highlight which inferences within a procedure are less or more common in comparison to other procedures. This may facilitate the creation of activities and interview questions which may lead to a deeper understanding of how students understand certain aspects of procedures inferentially.

The transition to proof-based mathematics both in high school, when students encounter Euclidean geometry, and in post-calculus undergraduate introduction to proof courses is notoriously difficult (Stylianides et al., 2017). We believe that inferential decomposition can be used to help highlight the core inferential structure present in procedure-based mathematics, making the transition to proof less abrupt. Thus, introducing inferences within procedure-centric mathematics may help promote much-needed curricular coherence particularly with regard to this transition (Stigler & Hiebert, 1999; Thompson, 2008). We are not diminishing the differences between calculation and proof, nor are we suggesting that every calculation or procedure be written up as a formal proof. Proofs often require stringing together inferences in novel ways, or in collegiate proof contexts, generating novel inferences. However, both proof and procedure can be viewed as constituting strings of inferences, and highlighting this similarity has the potential to increase curricular coherence and in doing so improve both proof-centered mathematics and calculation-centered mathematics.

HOW IS MATHEMATICAL MODELING USED IN ENGINEERING AND MATH EDUCATION?

Karen Plaster
The University of Akron
KBP9@uakron.edu

Keywords: Mathematical Modeling, Engineering Education, Mathematics Education

Purposes of the study

The purpose of this study was to explore the use of mathematical modeling in engineering and mathematics. I interviewed an engineering professor, a math professor, and a high school math teacher to better understand how they use modeling. As my guide for this study, I used the following research question: What are the pedagogical approaches to utilizing mathematical modeling problems in teaching among an engineering professor, mathematics professor, and high school mathematics teacher? How do these approaches compare across different educational levels and disciplines?

Theoretical Framework

This research was guided by an iterative modeling framework. This involved taking a real-world problem and transferring it into a theoretical context for analysis using a model. The insights gained were then applied back to the real world. This approach is similar to the interdisciplinary math modeling (IMM) framework proposed by Doğan et al. in 2019 and Stacy's mathematisation cycle, which consists of a four-step iterative process: real world, mathematical problem, mathematical solution, and real solution. Additionally, Galbraith et al. (2013) begin their iterative framework for mathematical modeling with a real-world "messy" problem.

Methods

In this qualitative exploratory study, I triangulated the modeling investigation by interviewing an engineering professor, a mathematics professor, and a high school math teacher. Each participant had a minimum of 10 years experience in their field. Through a semi-structured interview process, I asked them to define mathematical modeling, identify how it is used in their classroom, if and how engineering is represented in their classroom, and what they think students need to understand about engineering. The interviews were analyzed using an inductive open-coding process (Saldaña & Omasta, 2022).

Summary

Results of this study show that participants in different disciplines have similar applications of mathematical modeling, challenges with students, and challenges with creating good mathematical modeling. Unsurprisingly, the use or application of mathematical modeling differed between the engineers and mathematics instructors. However, all three participants used mathematical modeling to generate questions about the curricula (Blomhøj, 2019); identified that designing mathematical models takes time and experience (Blomhøj, 2019; Diefes-Dux et al., 2004); and modeling provides students opportunities to persevere (Firouzian et al., 2012; Kashefi

et al., 2012). The study demonstrates the need for more intentional planning when using mathematical modeling to represent engineering. Collaborating with diverse groups of people can boost confidence in teachers and students when using mathematical modeling for coursework.

UNDERSTANDING THE CONCEPTUAL REASONING OF STUDENTS WITH DISABILITIES THROUGH MATHEMATICAL SELF-CORRECTIONS

Lauren Rigby
University of Texas at Austin
laurenrigby@utexas.edu

Keywords: High School Education; Middle School Education; Reasoning and Proof; Students with Disabilities.

A research divide between mathematics education and special education has led to significant gaps in research on the conceptual understanding of students with disabilities (Lambert & Tan, 2017). This study addresses this research gap through an exploration of disabled students' self-corrections of mathematical thinking as an indicator of conceptual reasoning.

Theoretical Framework

Disability Studies scholars consider disability to be a socially constructed disadvantage that can be altered through changes in the environment and in society (i.e. social model) rather than deficits within an individual (i.e. medical model), implying that all students, disabled or not, have the capacity to engage in problem-solving and conceptual reasoning (Lambert & Tan, 2017). Conceptual understanding is vital to students' learning of mathematics (NCTM, 2000) and students with disabilities deserve the opportunity to develop their conceptual understanding.

Methods

Two 9th grade participants, Adam (Moebius Syndrome, high-functioning autism, ADHD, and anxiety) and Cohen (math and reading specific learning disabilities), were individually interviewed in three video-recorded interviews. Each interview comprised of two problem-based, open-ended tasks on rate of change, a topic integral to students' conceptual understanding.

Findings

I used a general inductive approach (Thomas, 2006) to analyze the students' self-corrections. First, I coded moments of self-correction, where the students verbally or physically adjusted their work. Then, I created subcodes for what seemed to prompt self-corrections. Findings show that 66.67% of Adam and Cohen's self-corrections led to improved or fully corrected mathematical thinking. They were prompted to self-correct their work in three different ways: self-detections (61.9%), routine questions (28.6%), and facilitating questions (9.5%). A self-detection prompt occurred when the participant adjusted their mathematical thinking with no feedback or input from the researcher. Routine questions were asked for each task regardless of the correctness of the student's work. Facilitating questions were asked with the purpose of moving the student forward in their thinking after a mistake was made by the student.

Scientific or Scholarly Significance

The participants' ability to self-correct suggests: first, students with disabilities can engage in mathematical reasoning without constant correction and handholding; and second, the mistakes they make can be poor indicators of whether or not they are capable of engaging in deep mathematical thinking. Their ability to correct their thinking was likely a result of time with the task and reflection opportunities created by routine and facilitating questions. Future research should extend this existence proof to include more participants with a wide variety of disabilities.

As graph literacy continues to be necessary to communicate in STEM fields, conventions around such graphs have developed for students to work and reason with. We describe a fifth grader's, Emma's, thinking through non-conventional graphical representations of a linear relationship. We argue that Emma relied on mathematical reasoning when faced with conflict in conventions and was able to make sense of unconventional graphs by using quantitative strategies. Although Emma acknowledged her known conventions of graphing, she was not bound by these conventions but rather leaned on her reasoning about quantities and flexible use of reference frames. We use Emma's activity to argue possible implications for research and teaching regarding graphing conventions.

Keywords: Mathematical Representations, Cognition, Middle School Education

Graphical representations are commonly used in STEM fields, and relatedly, the ability to read and write graphical representations is important for students to progress in STEM coursework and careers (Costa, 2020). These graphical representations commonly draw on conventions. For example, many graphical representations are constructed upon the Cartesian plane, with two perpendicular axes (i.e., x and y axes) with the intersection of the axes at (0, 0), named "the origin". Because such conventions are used widely and often, it is important that students know these conventions and use them to communicate ideas with others. However, despite their effectiveness for communication, too much emphasis on conventions can become a hurdle for students. Researchers have shown that students' meanings for graphs are often constrained to a 'a set of rituals' (e.g., Mamolo & Zazkis, 2012; Thompson, 1992). For example, researchers have noted an over-reliance on the vertical line test to determine if a graph represents a function even in cases where this procedure does not apply (Breidenbach et al., 1992; Even, 1993; Montiel et al., 2008; Moore, Silverman, et al. 2019; Oehrtman et al., 2008). Student adherence to conventions used for the Cartesian plane has similarly provoked struggles while creating/interpreting a polar coordinate system (Sayre & Wittman, 2008; Moore et al., 2014). Further, some researchers have shown that some conventions commonly used in math classes are not consistent with how STEM fields use graphical representations in practice. For example, Paoletti et al. (2022) showed that the origin is typically not (0, 0) in graphs used in several STEM fields. Collectively, these studies show that too much attention to conventions might take away students' focus from more important reasoning that could support their graph literacy.

Although the aforementioned studies provide insight into the complexities students can experience when it comes to graphing conventions coming in conflict with their graph reasoning, we note that these studies involved older students, who have had many years of experience with graphing conventions. In our work, we have been working with Grade 5–8 students who are yet to or are in the early stages of learning about graphs in school. We aim to document how students at this earlier stage are capable of reconciling conflict between learned graphing conventions to view them as conventions rather than as required rules, in conjunction with their budding quantitative strategies and thinking within frames of reference (hereafter referred to as "reference frames" (RFs)). In this paper, we describe a fifth grader's, Emma's, thinking about graphical representations of what we deemed to be a linear relationship. We describe how Emma's attention to graphing conventions, quantitative strategies, and thinking within RFs interplayed throughout her engagement with a graphing task. We argue that Emma relied on her quantitative reasoning when faced with conflicts with learned graphing conventions to make sense of unconventional graphs. We close with a discussion on the implications of Emma's work for future research and teaching regarding students' developing meanings for graph conventions.

Theoretical Underpinnings and Relevant Literature

In this section, we discuss the theoretical underpinnings that guided our task design and data analysis. We also review literature relevant to our specific focus on students' interpretation of $y = 2x$ graphs in both conventional and unconventional forms.

Conventions

Thompson (1992) differentiated students' understanding of conventions as conventions (*conventions qua conventions*) versus students' understanding of conventions (to teachers and researchers) as rules that must be followed (*ritual use of conventions*). We used Thompson's distinction between conventions qua conventions and ritual use of conventions to characterize Emma's attention to graphing conventions in our analysis. That is, we attended to whether Emma viewed certain features of graphs presented to her as mere conventions that could be changed or as rules that need to be followed when constructing or interpreting graphs.

Moore and colleagues examined students' interpretations of simple graphs, like $y = 3x$, constructed in nonconventional variations of the Cartesian plane (Moore & Thompson, 2015; Moore, 2016; Moore, Stevens et al., 2019; Moore, Silverman et al., 2019). Graphing tasks like this were used to develop models of students' graphing activity, with specific attention to what aspects of the graphs were prioritized in students' focus. In doing so, the researchers were also able to examine students' meanings for conventions interplaying with their reasoning about quantitative relationships. Moore, Stevens et al. (2019) provided numerous examples of pre-service teachers (PSTs) whose graphing activity was constrained to maintaining conventions as rules. In many cases, the PSTs' reliance on conventions took precedence over their quantitative meanings for the situation, leading them to claim that mathematically accurate graphs (from the researchers' perspective) were wrong due to the graphs differing from their expected conventions in some way. For example, only 31% of PSTs from the study deemed an accurate graph of $y = 3x$ with x and y represented on the vertical and horizontal axis, respectively, to be an accurate representation of the relationship defined by $y = 3x$. Inspired by this line of work, we designed the "Variations of $y = 2x$" task to vary conventional features of the canonical $y = 2x$ graph and asked students to check whether the graph accurately depicted the relationship between x and y. Variations included changing the axes and/or the orientation of axes like in Moore and colleagues' work. Other features, such as the location of the origin and the scale of each axis, were also varied (see the Methods section for more details).

Quantitative Reasoning and Reference Frames

We conjectured students could rely on their quantitative reasoning to develop meanings for graphing conventions as conventions. We adopt Steffe, Thompson, and colleagues' (e.g., Smith & Thompson, 2008; Steffe, 1991) description of quantitative reasoning, which characterizes *quantities* as conceptual entities individuals construct to interpret their experiential worlds (von Glasersfeld, 1995). Quantitative reasoning, then, entails an individual conceiving of and reasoning about the relationships between quantities (Smith & Thompson, 2008; Thompson, 2011). Engaging with algebraic situations should entail quantitative reasoning (Smith & Thompson, 2008; Steffe & Izsák, 2002). With respect to "$y = 2x$" in our work, a student reasoning quantitatively may quantify a relationship between y and x as multiplicative (i.e., the y-value is always twice the x-value).

In the context of quantitative reasoning, Joshua et al. (2015) defined a RF as "a set of mental actions through which an individual might organize processes and products of quantitative reasoning" (p. 2). Joshua et al. identified three related mental actions—committing to a unit of measure, committing to a reference point, and committing to a directionality of measure comparison (p. 32). Further, Joshua et al. defined a coordinate system as the product of the mental activity involved in conceptualizing and coordinating multiple RFs, which allows individuals "to represent the measures of different quantities simultaneously when those measures stem from potentially different frames of reference" (ibid., p. 35).

Similarly, but more broadly, we use RFs to refer to mental structures used to gauge the relative extent of various attributes in the phenomenon (Levinson, 2003; Lee, 2017; Joshua et al., 2015). Thinking within RFs entails attending to and establishing reference objects, directionality, and having an idea of what and how to measure the quantities being depicted (Joshua et al., 2015; Lee et al., 2019). For example, to create or interpret the graphical representations like those in Figure 1, an individual will need to establish x and y in terms of where they start, in which direction they move/change, and how each quantity is measured (e.g., unit of measure). Relatedly, coordinate systems refer to the geometric coordination of the RFs (e.g., axes). A coordinate system allows an individual to systematically express and coordinate RFs; a graph refers to a collection of points depicted upon the underlying coordinate system. Considering such a collection of points, an individual can hold in mind both quantities' (potentially varying) magnitudes simultaneously (Thompson et al., 2017). The nature of graphs and hence, ways of thinking about a graph, fundamentally depends on the RFs and coordinate systems upon which the graphs are created and how individuals make sense of the quantities depicted.

Lee et al. (2019) documented shifts in how a PST constructed and reasoned within RFs when engaging in graphing activities with non-canonical coordinate systems. Specifically, Lee et al. attended to the PST's reference points and directionality of measure comparison, which shifted from relying on perceptual features of graphs to focusing on coordinated actions such as quantitative relationships. The researchers hypothesized that the PST's shift was supported by perturbations from the unconventional graphs. Building on this work, in our work with Emma, we attended to her RFs, specifically, her attention to some reference point(s) and directionality of measure comparison.

Guided by these ideas, our research question is, “When faced with unconventional graphical representations of $y = 2x$, what reasoning does one fifth grader employ between her conventions, quantitative meanings, and reference frames?”

Methods

In this paper, we present data from a larger project that uses clinical interviews (Ginsburg, 1997; Clement, 2000; Goldin, 2000) to examine students’ current ways of graph thinking. The project goal is to examine middle school students’ graphing activities that could inform theory and practice.

Participant and Data Collection

The participants were recruited locally via social media and ranged from fifth to eighth grade. Four students met with the researchers on a university campus in the southern United States to participate in a sequence of four hour-long individual clinical interviews. Interviews had an interviewer (IR) and witness-researcher (WR) present; they were video-recorded with a focus on student work and any interactions and gestures between the student and IR. We digitized student work through scanning and screen-recordings. The participant we focus on in this paper, Emma, was a fifth grader. Specific to the task, Emma self-reported that in school, she had not seen graphs like the ones from the task. However, Emma did describe exposure in school to using coordinate grids to plot points, where the origin would be placed at (0, 0). Although she had experience with “conventional” coordinate systems in school, these conventions had not necessarily been emphasized yet in relation to linear graphs such as $y = 2x$. We note that Emma reported studying additional mathematics outside of school, and she demonstrated familiarity with linear graphs throughout her interviews.

This paper focuses on data from one task in Emma’s third interview, “Variations of $y = 2x$”, implemented through the online, interactive teaching and learning platform, Desmos. We designed the task while considering the work discussed above with unconventional coordinate systems and graphs. Our task contained four slides, where each slide contained a graph of the line $y = 2x$ with differing orientations of axes, scaling, or origin changes (Figure 1). Specifically, Graphs A and B (Figure 1a and b) showed the x- and y-axis with differing scales, Graph C (Figure 1c) had positive x-values oriented to the left and positive y-axis values oriented downwards, and Graph D (Figure 1d) showed the axes intersecting at (-2, 0). When opening each slide, we asked Emma if the graph represented the relationship between x and y in the equation $y = 2x$ by selecting “Yes,” “No,” or “I don’t know”. Because our goal was to investigate how the student might make sense of the quantitative relationship and not their ability to read an equation, if the student had a difficult time interpreting the equation $y = 2x$, we explained to the student that the equation meant the y value is always twice the value of x.

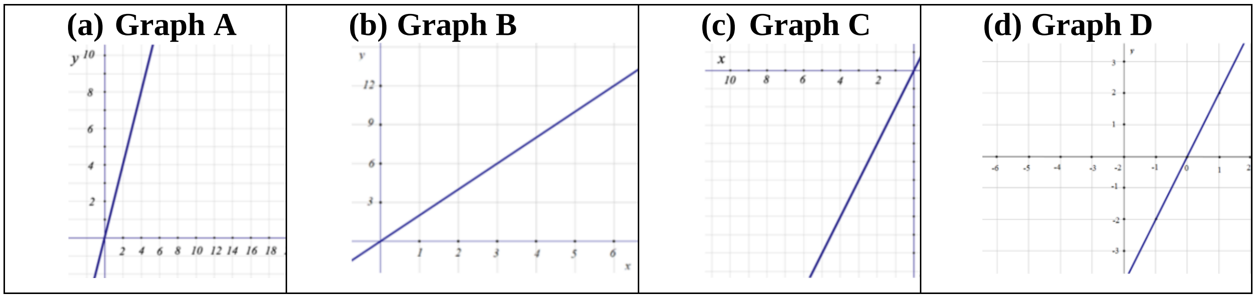

Figure 1: "Variations of *y = 2x*" Graphs

Data Analysis

In our analysis, we created a thick description of Emma's activity with the task (Geertz, 1973). We used this description to build a model of Emma's current meanings through conceptual analysis (von Glasersfeld & Steffe, 1991; Thompson, 2008). As we attempted to build this model, we characterized Emma's quantitative reasoning, attention to conventions, and thinking within RFs. Specifically, we examined Emma's activity for her quantitative reasoning, potential habitual use of conventions, relevant RFs Emma used, and shifts between habitual use of conventions and using conventions qua conventions. During this process, we re-examined previous parts of the description to support our working model, identify possible shifts in Emma's reasoning over the episodes, or negate our original interpretations.

Results

Although Emma expressed her known conventions around graphs, she was able to rely on her quantitative meanings for the relationship $y = 2x$, in conjunction with the use of flexible RFs, to determine if a(n unconventional) graph accurately depicted the relationship. Notably, her flexible use of RFs included interpreting shifts in directionality (i.e., representing positive x-values to the left), unconventional units (i.e., tick marks not representing 1 unit), and different reference points (i.e., unconventional intersection of axes). In all four graphs, Emma consistently used quantitative reasoning and RFs to resolve conflicts that arose when aspects of a graph did not match the conventions she assumed needed to be maintained.

Conventions, Quantitative Reasoning, and RFs Aligned: Graph A

In Graph A (Figure 1a), Emma's meanings for conventions, RFs, and quantitative reasoning aligned. After some conversation about how $y = 2x$ may be represented in a graph, the IR asked Emma what she thought about the relationship as meaning y is always twice x. Emma first implicitly considered if the graph represented a rule in which x was two more then y by checking if the point (0, 2) was on the graph before realizing she should consider if y-values were double x-values. She then moved her cursor to (0, 0) and over horizontally to $x = 2$, claiming, "If x is that [two], y is that [*moving her cursor up vertically to intersect the graph and then horizontally over to $y = 4$ on the y axis*]." With the cursor on (2, 4) on the graphed line, Emma argued that this point was correct based on four being "two times x". Emma decided to answer "yes" to the prompt and provided more explanation to back up her claim, such as (4, 8) being another point on the graph reflecting her quantitative meaning for $y = 2x$ of y being "two times x".

Across her activity, we infer Emma used the x- and y-axis each as a RF. She identified 0-points for each axis, worked with an implicit direction, and understood each tick to represent the appropriate number of units. For example, for Emma, $x = 2$ meant starting at 0 and moving two units right via 1 tick mark jump. Finally, we note Emma relied on a quantitative meaning for the relationship (y is "two times x") to determine if the graph reflected the relationship. Emma continued to use this *quantitative meaning* in the rest of the graphs of the task. In some cases when Emma became perturbed as she addressed a novel graph, the IR referred back to her quantitative meaning to help remind Emma of the connection of the equation to the relationship.

Conventions Superseded by Quantitative Reasoning and RFs: Graph B and C

The unconventional nature of Graphs B and C (Figure 1b, 1c) created perturbations for Emma as she attempted to interpret novel coordinate systems. However, Emma leveraged her quantitative meanings along with flexible reasoning about RFs to interpret both graphs as accurate representations of the relationship $y = 2x$.

In each case, as Emma tried to apply her quantitative meaning, the unconventional nature of the graph created a complexity. When initially addressing each graph, Emma decided that the graphs did not reflect the relationship. In Graph B, this happened as Emma was looking for $x = 2$ and $y = 4$ to touch on the graph; as she moved up from $x = 2$ to the graph, she said, "It doesn't [represent the relationship]. Four would be right there [*motioning over the graphed line above x = 2 between the y-values tick values of 3 and 6*]." We conjecture the point not being at the intersection of two gridlines created a complexity for Emma. As the y-axis was scaled by increments of 3, 4 was not represented on the scale or by a gridline; we infer this broke from the convention Emma (implicitly) used in the prior graph that each tick mark along the y-axis represented a change of 1. Emma rejected Graph C even faster, calling it "wrong" due to its unconventional nature, saying, "From what I see, those [*referring to the x and y values on the left and down of the intersection of the axes*] have to be negative numbers because that is the… I think that's the third quadrant…" In each case, we inferred that conventions around coordinate systems, implicitly in Graph B and explicitly in Graph C, influenced Emma's initial decisions for if the graphs represented the relationship.

However, Emma reconsidered each graph as she returned to her quantitative meanings and adapted her RFs when asked to explain her original decision. In Graph B, Emma reorganized her RFs such that the unit of measure of each tick mark represented matched those depicted. After her last comment above regarding Graph B and her conflict with the point (2, 4), she tilted her head and wondered aloud, "actually, it does [represent the relationship]." She then decided to check that $x = 3$ corresponded to $y = 6$ in the given graph, confirming that the graph represented the quantitative relationship. Emma then returned to checking $x = 2$. She placed the cursor directly above the x-axis and defined the distance between the x-axis and her cursor as a unit length, "the top of the circle [cursor] would be one". She then iterated that length by moving the cursor up three more times, intersecting the graph at the y-value of 4. We infer Emma had re-established her RFs constituting each axis to attend to the non-normative scaling of the y-axis as compared to Graph A. Using this reorganization in conjunction with her quantitative reasoning of checking the pairs of points, she determined that Graph B accurately depicted the relationship.

Emma similarly switched decisions with Graph C by reasoning flexibly with RFs and maintaining a focus on the quantitative relationship. In particular, after verbally identifying the unconventional axes different from Emma's expected signs for "Quadrant 3," the IR asked Emma what her answer to the prompt would be. After a 6-second pause, Emma responded "it does [represent the relationship]." Emma then gestured to the 2 on the *x*-axis down to the graphed line and horizontally over to the 4 on the *y*-axis explaining, "It shows it because the two and the four touch right there, on the line." Emma smiled and decided confidently to answer "Yes." She further demonstrated how when *x* equaled 4, *y* equaled 8 on the line as "another way I can prove it." Although Emma's initial reaction was to reject Graph C, she re-considered her decision after reorganizing her RFs, attending to the changed direction of the values on the *x*- and *y*-axis. This reorganization of her RFs allowed her to use her quantitative meaning for the relationship to confirm Graph C did, in fact, represent the relationship. Emma's work with Graphs B and C evidence her understanding of convention qua conventions, where she leaned on her re-organization and use of RFs and quantitative reasoning to overcome an initial hesitation towards the representation that was depicted differently than she seemed to expect.

Conventions in Conflict with Quantitative Reasoning and RFs: Graph D

The unconventional location of the intersection of the axes in Graph D created a greater complexity for Emma as she considered if the graph correctly represented the relationship. However, as before, she eventually was able to reorganize her RFs and leverage her quantitative meanings to interpret the graph as correct. When first viewing Graph D, Emma expressed concern with the intersection of the axes:

> Why do they have…Um. I think that this line [*traces y-axis on the screen*] has to be moved over more… the *y* line, has to be moved over more [*gestures to the zero on the x-axis*] to the zero because, um, I, well, maybe it doesn't… uh, it does. Um, it has to be, the origin is always (0, 0).

Emma's reaction seems indicative of a ritual use of conventions regarding the intersection of the axes ("always (0,0)"). In fact, her tone changed as she emphasized the origin "*has to be*" (0, 0). However, there was also a note of suspicion that "maybe it doesn't" have to be at zero. Immediately after making this comment, Emma critically investigated between the current origin (Figure 2a) and her desired origin, (0, 0) (Figure 2b). She then discussed (0,0)'s placement, "Hmm. That does… That shows zero, too. That's showing… Hmm, actually… Actually, that shows (0, 0). But I don't think, was it… I don't understand this. How are the, why is the *y* line like that?" We infer that Emma realized the point (0, 0) was on the given graph, which she understood was consistent with the given relationship $y = 2x$. However, the unconventional placement of the *y*-axis persisted in creating confusion as Emma again declared that the graph would not represent the relationship.

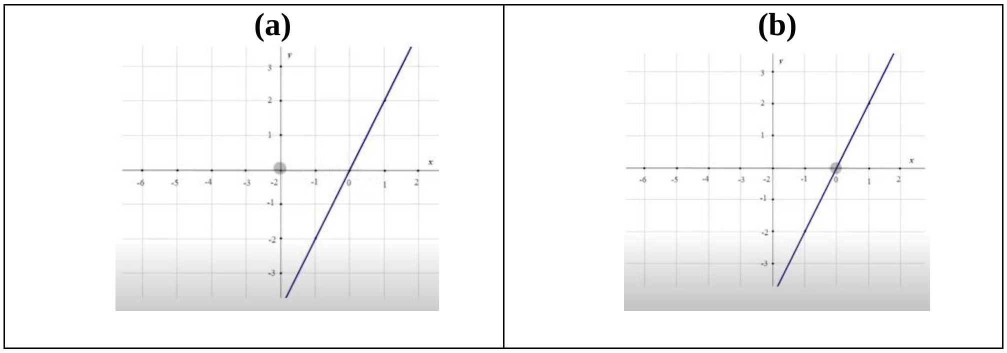

Figure 2: Graph D’s (a) Depicted Origin, and (b) Emma’s Desired Origin at (0, 0)

Emma continued to consider whether the intersection of the axes at (0, 0) was a rule that must be followed in relation to her inferences regarding RFs and her quantitative meaning. As Emma considered Graph D, she motioned along each axis to show that the graph represented should depict $x = 2$ corresponded to $y = 4$. However, we infer that in the moment, Emma still considered the graph to be incorrect. She opted to check another point, moving her cursor along the x-axis to 1, then moving up and horizontal to the y-value of 2. As she did this, she paused and looked closer, “Wait… but it does! It shows it… Hmm, it does.” She then moved on to the point (0, 0) and reasoned that doubling zero should achieve that point, laughing to herself, seemingly with surprise. The IR then asked her where zero should be on the graph, and Emma repeated her original reasoning, “If I could have the zero anywhere, I would have the zero right here [*places cursor on the intersection that currently had* $x = -2$ *in Figure 2a*].” We infer Emma wanted the intersection of the axes to be (0, 0), not (-2, 0). She stared at the screen again for about five seconds and calmly decided, "It does show it both ways, though… because, I can do it with the one and the two [*gestures up to the graph from* $x = 1$]… Oh, one and a half would be about there [*puts mouse between the 1 and 2 on the x-axis*]… One and a half, three [*motioning from the x-axis to the graph at* $y=3$]!” She then pulled herself back and smiled, concluding, “I think it’s actually yes”. We infer that Emma’s initial reaction to the graph involved the intersection of the axes at (0, 0) to be a rule rather than a choice. However, as she focused on the RFs represented by each axis (rather than the intersection point), she reconsidered the graph in terms of her quantitative meaning, concluding the graph accurately reflected the relationship. Although she still expressed preference towards the intersection of the axes to be at (0, 0), Emma treated this as a conventional choice (convention qua convention) rather than a rule that must be followed (ritual use of convention).

Although Emma initially rejected each of Graphs B, C, and D due to something unconventional about each, she eventually reorganized her RFs to consider if the graph reflected the underlying quantitative relationship. Reflecting a conscious awareness of the unconventional nature of such graphs, Emma referred to unconventional aspects of the graphs such as the axes as possible “mistakes” or “there to confuse [me].” But, consistent with understanding graphical conventions qua conventions, Emma understood each graph as reflecting the quantitative relationship defined by $y = 2x$.

Discussion

Addressing our research question, we showed interactions between Emma's meanings for conventions, quantitative reasoning, and use of RFs as she explored representations of $y = 2x$. Emma's strategies were powerful in leading her to reconcile unconventional graphs by focusing on the quantitative relationship and re-organizing her RFs. Emma's flexibility was illustrated through her reasoning through unconventional axes directions, scaling, and origin as she continued to rely on y being twice x and thus checking if appropriate points met on the graph. Emma's activity exemplifies the merit in students grappling with conventions on their own before directly being adopted throughout their schooling; we conjecture such discussions that allow students to consider quantitative meanings for algebraic equations and RFs may be fruitful in supporting students understanding graphing conventions as conventions. Further, such unconventional graphs can also be fruitful for supporting students in moving beyond a ritual use of conventions, such as realizing the intersection of the axes did not have to be "always (0, 0)".

Connecting back to the literature, several researchers have conjectured that students' meanings for algebra and graphs as a set of rituals may stem from a lack of opportunities to construct and reason about relationships between quantities (Moore, Silverman et al., 2014; Moore, Silverman et al., 2019; Paoletti, 2020; Paoletti et al., 2018; Thompson & Thompson, 1995). We note how Emma, as a fifth grader, was focused on a quantitative relationship in her activity, which allowed her to exhibit more flexible reasoning than the PSTs reported on addressing similar tasks (Moore, Silverman et al., 2019; Moore, Stevens et al., 2019). We conjecture Emma's flexibility relative to the PSTs may be due to her having significantly less school experiences adhering to conventions. That is, we conjecture conventions become rules for students when they are always used without explicit conversations or opportunities to consider other choices. In reality, students need this flexibility when faced with unconventional representations found to be applied in real-life contexts (e.g., as in STEM fields), especially as fields continue to evolve unpredictably over time along with possible new developments for representing quantities and needs for students reasoning within those developments arising.

Based on Emma's interactions with the given representations moving beyond conventions to determine the quantitative relationship depicted, we conjecture providing students with such unconventional coordinate systems early in their learning about graphs could support them in developing meanings for conventions qua conventions. However, our sample consisting of one student in one session limits our ability to evidence such conjecture. We call for future research to explore this possibly. Such research can support teachers and researchers in understanding and supporting flexible meanings for graphs that support students across STEM fields and real-world contexts.

Educators and education researchers have looked for many years at methods to improve mathematics achievement for all students and to address gaps in achievement. In a study conducted in the early 1990s, Gray and Tall (1994) showed that math achievement in elementary students correlated with flexible use of numbers, also known as number sense. This study sought to replicate their findings in the context of a US elementary school and incorporate a new cognitive development in understanding students' mathematical thinking, "groupitizing." The results from 76 students in grades 2-5 confirm the earlier finding with a strong association between achievement and number sense. Groupitizing was also found to associate positively with math achievement and strategic flexibility in the use of numbers. These findings have important implications for early childhood mathematics instruction.

Keywords: Number Concepts and Operations

For many years, the average US student has remained in the middle of the pack in international assessments of mathematics achievement (Mullis et al., 2020; OECD, 2023). This middling "average" statistic covers over the more educationally relevant story that US student performance reveals staggering differences across various groupings of students, driven largely by differences in access to high quality educational opportunities and fiscal supports for schools (Reardon et al., 2019). In the 1990's two researchers in the United Kingdom, Eddie Gray and David Tall, provided a keen insight into how high and low achievers think through the most basic aspects of mathematical operations. In their interviews of groups of young children rated 'high' versus 'low' in math achievement, striking contrasts emerged in the step-by-step *thinking process* the two groups employed when showing how they reason through elementary problems. Remarkably, these two groups in the very same grade appeared to use fundamentally different strategies in basic arithmetic problems, even for problems that both groups solved accurately. More recently, cognitive scientists have established profound links between a child's global math achievement and more elemental *cognitive developments in number sense*. 'Number sense', according to Dehaene, is short-hand for our rapid intuitive ability to approximate, manipulate, and understand numerical quantities (Dehaene, 2011).

This study seeks to determine how well Gray and Tall's insights into United Kingdom students, circa the 1980s-1990s, holds true in a US elementary school decades later. Our more contemporary take on their question includes new measures of number sense and strategic flexibility, including recent advances in the cognitive development of “groupitizing”— a child’s emerging ability to conceptualize and enumerate larger sets of objects via flexible combinations (i.e. grouping) of smaller number group concepts (i.e. subitizing).

Research questions:

- To what extent does a student’s overall math achievement reflect their use of arithmetic strategies or step-by-step thinking processes?
- Does cognitive development of groupitizing help explain the emerging influence of “number sense” in the context of arithmetic strategy use?

Perspectives/Theoretical Framework

Number Flexibility

Achievement scores in elementary mathematics have been strongly linked to children’s ability to approach simple arithmetic problems in flexible ways (Gray, 1991; Gray & Tall, 1994). Gray (1991) distinguished different approaches to solving addition and subtraction problems. For example, when given two numbers to add, a child may: (a) *count-all* by applying their counting skills, starting at one, to each number in succession to arrive at the sum (e.g., when finding the sum of 4 and 7, a child will count to 4 and then keep counting 7 more units to get to the sum of 11); (b) *count-on* by starting with the cardinal value of one of the numbers and using the other number as a way to know how many times to increment the count by one (e.g., when finding the sum of 7 and 4, a child might begin with 7 as a whole, then count-up 4 more places in the number sequence to get to 11); (c) *derived fact*: mentally break up one of the operands to enable the convenient use of a memorized fact (e.g., when finding the sum of 7 and 4, a child might decompose 7 into 6 and 1 so they can apply their “6+4=10” knowledge, then increment by 1). Since this strategy depends upon a child’s larger emerging construct of *“number sense”* (McIntosh et al., 1992), for the rest of this paper we will equate use of this strategy with the development of number sense. Finally, a much larger shift in arithmetic processing occurs as older students engage in (d) direct retrieval of declarative memories of *known arithmetic facts*.

In the current study we focus our analysis on strategy (c) described above as critical, since the emergence of number sense strategies has been associated with greater mathematics success, not only in terms of students’ efficiency with simple arithmetic but also their subsequent success in more complex mathematics (Hornung et al., 2014; Jordan et al., 2010). Gray and Tall (1994) found that higher achieving students tend to display more flexible strategies (including the selection of more appropriate procedures), consistent with number sense, whereas lower achieving students rely on the less flexible procedural methods of counting.

Groupitizing and Subitizing

Groupitizing, a novel theoretical construct introduced by McCandliss et al. (2010), refers to rapidly enumerating arrays that are spatially grouped into subitizable subgroups. Groupitizing is typically assessed by presenting 4 to 9 dots and requiring an exact numerical answer, so that even very young children can accurately respond with minimal instructions (i.e., “How many dots all together?”). In the grouped condition the dots are grouped by spatial proximity into obvious subgroups of 1-4 dots. In the ungrouped condition no grouping cues are present. A child’s groupitizing ability is calculated by comparing the speed and accuracy of enumeration between grouped and ungrouped dot arrays. When grouping cues allow a child to enumerate the whole set faster, it is taken as evidence that they are accessing and combining the cardinal values of the subsets, rather than counting the dots in a successive fashion,

Extensive research reveals a grade-level effect in groupitizing abilities. Starkey and McCandliss (2014) studied 378 typically developing children from kindergarten through third-grade and found no evidence for groupitizing in kindergarten, an emerging effect in first grade, and a robust effect in second and third grade. This effect progressively develops across additional years of schooling, through at least 9th grade, as demonstrated by Guillaume et al. (2023), who investigated 1,208 children ranging from beginning of 3rd through the end of 8th grade. Their study demonstrated a remarkable growth trajectory in groupitizing that shows significant within school year growth within every school-year. In addition, groupitizing also underlies complex cognitive processes that are essential for understanding children's overall math abilities. Research indicates that groupitizing not only strongly correlates with neuro-cognitive measures of math fluency, but also outperformed every other measure investigated in its ability to account for unique variance in state mandated standardized test scores for mathematics, even after taking into account socioeconomic, domain-general, and domain-specific factors (Starkey & McCandliss, 2014; Guillaume et al., 2023). These findings collectively emphasize that groupitizing is a continuous construct that grows stronger year-over-year across K-9 schooling and it is fundamental for capturing key features of number cognition and math achievement beyond what is evident in symbolic numerical tasks.

Methods

Participants

Participants in this study were elementary students from a school in the California Bay Area in grades 2-5 and were nominated by teachers as their 'highest' and 'lowest' achieving math students. Teachers were not told what factors to use when selecting 'high' and 'low' achieving students, although most teachers reported using district test scores on a computer based standardized test as their metric for choosing students. Ultimately 76 students were included in the final data.

Data Collection

The research team conducted individual cognitive interviews with students. These interviews consisted of students completing a dot enumeration task on an ipad to measure their groupitizing ability and then they were asked six short arithmetic questions. For the dot enumeration task, dots were randomly set to appear as either grouped or ungrouped arrays. In ungrouped arrays the dots were roughly evenly spaced but appeared random on the screen while in the grouped arrays, the distance between groups was at least three times larger than the distance of dots within any group. For the grouped arrays, the number of subgroups and the maximum number of dots in any subgroup was varied. In total the task asked students to count 90 arrays in approximately three minutes - see Guillaume et al. (2023) for further details. Math problems were printed on a sheet of paper and handed to students so that they could write with a pencil or pen, if desired. They were also provided with small double-sided counters for optional use. Problems consisted of addition and subtraction of single digit numbers, addition and subtraction of a single- and double-digit number, and addition and subtraction of two double digit numbers.

Data Analysis

Using the framework from Gray (1991), students' strategies were categorized as *known fact*, *derived fact* (which we describe as number sense), *count on*/*count back*/*count up* or *count all*/*take away*. Two researchers initially coded independently, and then came together to discuss and reconcile all disagreements. Groupitizing ability is calculated based on the number of items children solve correctly per minute (Guillaume et al., 2023). We classified students into two groups based on their performance: individuals whose performance on grouped arrays improved by more than 10% compared to ungrouped arrays are classified as "high groupitizing"; those who showed minimal improvement on grouped arrays relative to ungrouped arrays are categorized as "low groupitizing". After all student strategies were coded, the data was compiled together with student characteristics such as grade level, whether the student was rated as 'high' or 'low' by the teacher, students' results from the groupitizing task, and students' results and strategy from each math problem. Since many students used different strategies on different questions, each instance of a strategy was treated separately.

Results

The results of this study confirm the conclusions from Gray and Tall (1994) - showing a clear relationship between achievement and number sense in arithmetic. Students, rated by their teachers as 'high' achievers in mathematics, used strategies reflecting number sense on over half the problems (mean=57.1%, 95%CI [49.1, 65.0]) - nearly four times the frequency of students rated as 'low' achievers (mean=15.3%, 95%CI [7.4, 23.2]). Students with high performance on the groupitizing measure also demonstrated higher rates of number flexibility. Specifically, the high groupitizing students also used number sense strategies over half of the time (mean=54.5%, 95%CI [45.5, 63.5]), which was roughly double the frequency with which the low groupitizing students did so (mean=26.7%, 95%CI [16.6, 36.7]). The alignment of these results further supports a relationship between the emergence of groupitizing, students' use of number sense strategies in the context of solving arithmetic problems, and ultimately achievement in the mathematics classroom. Additionally, students who were rated by their teachers as the lowest achievers were significantly less likely to exhibit high groupitizing profiles, and conversely, students rated as high achievers by their teachers were more likely to be identified with high groupitizing ability in the cognitive test. A chi-square test confirmed the significance of this result (X^2(1, n=74) = 15.074, p<0.000).

Discussion

These results replicate the prior study of Gray and Tall (1994) which is now over 30 years old. Students who were rated highly by their teachers in mathematics were significantly more likely to use number sense when solving simple arithmetic problems. As noted in the earlier study, the students rated 'low' in math were in fact often doing much harder work as they attempted to count numbers of increasing magnitude which made the possibility of error much higher and required extra time. The groupitizing effect also replicates Guillaume and colleagues' (2023) findings that increases in groupitizing abilities are tightly linked to increases in estimates of math achievement. This work extends the research on groupitizing by identifying associations between students' groupitizing ability (high versus low) and number sense. It suggests that these skills may share the same underlying cognitive mechanisms.

The results suggest two major implications for teaching and learning elementary mathematics. First, to improve fluency in simple arithmetic, teaching students to visualize how subgroups of numbers (or sets of objects) constitute larger numbers (or sets of objects) may be a powerful and highly inclusive scaffolding device for eventually escaping counting strategies and beginning to employ and master number sense strategies. While verbal memorization of declarative number facts can be helpful in some ways, it seems preferable that students learn how to work flexibly with numbers so that they can make use of a smaller set of learned facts and apply them in many novel situations.

Second, the relationship between groupitizing and number sense suggests that teaching groupitizing and a flexible approach to number, rather than a focus on memorization of facts, will help improve students' number sense. Classrooms across the US typically focus on the memorization of math facts, and the use of worksheets to practice them (Boaler, 2019). This study found that the ways students visually see the composition of numbers, and their use of flexible strategies of decomposition was associated with higher achievement.

Indiana University	Indiana University	Indiana University
imduarte@iu.edu	jrojasv@iu.edu	johnmino@iu.edu

We present three cases of how in-service secondary teachers took up the 5-Practices instructional framework to support mathematics discussions in their classrooms. The data comes from the teachers first implementation of researcher designed and teacher modified mini-units in their classrooms that were part of a 3-year design experiment. The cases illuminate common yet subtly different affordances and challenges that the in-service teachers experienced in using the 5-Practices. They also highlight how the research team adjusted the professional support they provided to the teachers after the first implementation of the mini-units. One outcome of this adjustment was the development of a multi-tiered framework that relates teaching moves, practices, instruction, and instructional routines. The findings and framework contribute to the body of research on how in-service teachers can learn to support mathematics discussions.

Keywords: Core practices, teacher learning, mathematics discussion, design experiments

Mathematics educators have characterized rich mathematical discussions as ones that are centered on students' mathematical reasoning and are aimed at accomplishing specific instructional goals (Jacobs & Spangler, 2017). As such, mathematical discussions have been found to be a vehicle through which students have opportunities to learn substantive mathematics (Boaler & Staples, 2008). Opportunities for learning arise as students clarify (Goos, 2004), refine (Richland et al., 2019), expand (Webb et al., 2014), generalize (Land et al., 2014), and justify (Brodie, 2010) their mathematical reasoning through sharing it with their peers and by engaging with their peers' reasoning. Facilitating productive mathematics discussions relies on complex teaching capacities including making quick decisions, eliciting students' thinking, being responsive to students' contributions, and managing cognitive demand. Given these complexities, researchers have found that teachers often need support to effectively learn to facilitate productive discussions (Boston & Smith, 2009) where this support often occurs through decompositions, representations, and approximations of practice (e.g., Staples & Truxaw, 2010).

We use this paper to report on a cross-case comparison of three experienced secondary teachers who were learning to adapt and incorporate the *5 Practices* (5Ps) (Smith, Steele & Sherin, 2020) into their teaching. The teachers were part of a 3-year design experiment whose aim was to study how secondary in-service teachers facilitated students' *mathematical generalizing*. We introduced the teachers to the 5Ps framework for two reasons: (a) we considered ourselves more likely to see high quality and varied instances of how teachers' supported student generalization if the teachers were also supporting student discussion; and (b) we wanted teachers to have a common instructional framework to support cross-classroom conversations about instruction. The data we report on in this paper is from the first time the teachers implemented researcher-designed and teacher modified mini-units in their classroom. We respond to the following research question: What affordances and challenges did the teachers experience in their re-composition of the 5Ps over the course of implementing their mini-unit?

Literature Review

Many early studies that investigated how teachers facilitated productive mathematical discussions occurred in classrooms with teachers who had considerable content and pedagogical expertise: often the teacher was a researcher (e.g., Ball, 1993, Heaton, 2000; Lampert, 1990). These studies yielded substantial information about teaching practices that support mathematics discussions. Subsequently, mathematics educators transformed this information into practitioner friendly frameworks that could be used to support both pre- and in-service teachers (PSTs and ISTs, respectively) to support mathematical discussions (e.g., Chappin, et al., 2003/2013; Stein, et al., 2008). Researchers have used these frameworks with PSTs in mathematics methods courses (e.g., Ghousseini & Herbst, 2016; Tyminski, et al., 2014) and with ISTs in professional development settings (e.g., Reinsburrow, et al., 2022) to study the PSTs and ISTs learning of discussion-based practices. However, Ghousseini (2015) and Pang (2016) both identified a dearth of research that examines how PSTs or ISTs learn to use discussion-based frameworks *in actual classrooms* (as opposed to in methods courses or professional development settings).

Researchers (e.g., Bağdat & Yanik, 2023; Heyd-Metzuyanim et al., 2019; Kooloos, et al., 2023; Martins et al., 2023) have begun to respond to this lack of research. Within this work, they have reported that practices that occur prior to teaching (e.g., setting goals, identifying tasks, and anticipating) are easier for teachers to learn than those that occur during teaching (e.g., monitoring, selecting, sequencing, and connecting) (Pang). We use this study to contribute to this growing body of research by identifying how teachers adapt and incorporate discussion-oriented practices, specifically the 5Ps, into classroom instruction. We were particularly interested in how the teachers transitioned from using decompositions, representations, and approximations of practice in professional development to implementation of these practices in live instruction.

Analytic Framework

Jacobs and Spangler (2017) define teaching moves as “actions that teachers take that observers can see or hear, such as asking a question, providing a representation, or modifying a task” (p. 778). They differentiate teaching moves from goals, which they define as “the intentions teachers have….(which) typically must be inferred by researchers because they are not usually stated explicitly” (p. 778). Jacobs and Spangler acknowledge that moves and goals take place at different grain sizes. However, they do not introduce a language to differentiate among the different grain sizes. To capture these differences in grain size, we introduce a four-tiered nested framework that preserves Jacobs’s and Spangler’s distinction between observable actions and goals a teacher has for these actions. Moving from smallest to largest grain size, we use the term *teaching move* to mean actions that occur during moments of interaction with students. *Teaching practices* (Smith & Stein, 2017) occur over a longer timeframe within a lesson where multiple teaching moves are embedded in each teaching practice. Teaching practices, then, function together to comprise *instruction* where we use the term instruction to refer to teaching that occurs in a single lesson. We use the term *instructional routines* for patterns in a teacher's instruction that can be discerned over multiple days of instruction. At each grain size, it is possible to characterize both a teacher's observable actions and their goals.

In outlining the 5Ps, Smith, et al. (2020) do not make the same distinctions we do in grain size, but it is possible to interpret the 5Ps relative to these distinctions, particularly the distinction between teaching moves and practices. In Table 1 we define Smith, et al.'s practices that occur while teaching, Practices 2-5—monitoring, selecting, sequencing, and connecting—and give examples of observable actions and goals that are at the practice and move grain size. In Table 1, we omit Practice 0, setting goals/selecting tasks, and Practice 1, anticipating, because they occur prior to teaching, and our primary interest in this paper is what happened while teaching.

Table 1: Monitoring, Selecting, Sequencing, and Connecting Practices (Smith et al., 2020)

5Ps Defined	Actions Related to Teaching Practice	Goal(s) of the Teaching Practice	Actions Related to Teaching Moves	Goals of the Teacher Moves
Monitoring: Attending to student thinking while students work on a problem	• Circulates among groups of students, revisiting groups when appropriate • Asks assessing and advancing questions	• Track student thinking • Assess student thinking • Advance student thinking (p. 86)	• Asks an assessing or an advancing question • Uses a talk move	• Understand student thinking • Move a student toward a learning goal
Selecting & Sequencing: Choosing what student work to discuss and organizing that work in a specific order	• Records the range of strategies from which to choose (selecting) • States the order of student presentations (sequencing)	• Ensure student work to be shared connects to all learning goals • Establish a coherent storyline for the work presented (p. 122)	• Asks a student (privately) if they will share their work • Calls on a specific student to share their work first	• Ensure a student is willing to present • Indicate to an individual student when to share
Connecting: Using student work to make connections to learning goals or connections among	• Asks questions to all presenters to highlight connections to learning goals • Records student observations about similarities	• Connects student work to the full range of learning goals for the lesson • Connects the *set* of selected	• Asks a question to highlight how a particular piece of student work connects to a learning goal(s) • Has students turn-and-talk about	• Makes connections between an individual presenter's work and learning goals

different pieces of student work	and differences across all student work	student work to each other (p. 172)	how a new piece of work is related to their own	• Makes connections between two specific pieces of student work

The four-tiered framework was an *outcome* of the first year of our design work. We introduce it here because it supports what follows. We see the distinctions in grain size as important to framing the claims a researcher is making about a teacher's teaching. That is, it is different to make claims about a teacher experiencing success at the smallest grain size, teaching moves, than it is to make claims about a teacher experiencing the same success at the largest grain size, instructional routines. It is different because the grain size of an action impacts the ease with which a teacher will successfully integrate that action into their instruction. For example, it is easier for a teacher to introduce smaller grain size teaching moves like wait time, re-voicing, asking an assessing question, or inviting students to participate than it is to adopt larger grain size instructional routines like consistently using the 5Ps over the course of a mini-unit. Our aim in this study is to describe instructional routines that we could discern over multiple lessons taught by the ISTs; in particular, we investigate the way that the ISTs fit together practices, from the 5Ps, in instruction, and identify patterns (i.e., instructional routines) related to how they did so. Although important, we have a smaller focus on specific teaching moves and practices.

Methods and Methodology

Design experiment research involves researchers designing an intervention, testing that intervention, and then refining the intervention during subsequent iterations (Cobb et al., 2003). As part of this process, researchers identify conjectures they have that guide the design of the intervention, where one result of a study involves documenting how they modified their conjectures for future iterations of the intervention. We focus on one conjecture we made related to our work with the teachers relative to the 5Ps. *Conjecture:* Decompositions, representations, and approximations of *individual teaching practices* and *moves* within practice was sufficient support for ISTs to recompose these practices in instruction in ways that would support them to develop reliable new instructional routines.

During the summer, prior to implementing the mini-units in their classrooms, all three teachers participated in eleven, 3-hour professional collaboration sessions. The first and third authors designed these sessions to focus on four themes: (a) the mathematical content of the mini-units; (b) student reasoning related to the mathematical content, which included video cases (Burch, et al., 2021); (c) instructional planning for the mini-units using the 5Ps as a guide for this planning (Smith, Steel, Sherin, 2020); and (d) a teacher-appropriate framework for supporting generalization in the classroom (Driscoll, 1999). The mini-units were initially developed by the third and first author (Burch & Tillema, unpublished) and were subsequently modified by the teachers as part of the process of planning for the implementation. Each mini-unit lasted 3-7 days, depending on the length of each teachers' class period (i.e., 45-, 50-, and 70-minutes). All lessons in the mini-unit were videotaped using three cameras: one captured the whole classroom, one captured the teachers' interactions with students, and one focused on a small group of students as they participated in the lessons. The three participating teachers—Celine, Felix, and Hazel—had 30, 21, and 6 years of teaching experience, respectively. We use Table 2 to briefly characterize classroom structures and opportunities for discussion in each teachers' classroom. The observations are based on field notes taken during five visits to each teacher's classroom and an interview about their instruction, which occurred in the year prior to teaching the mini-units. None of the teachers used student driven discussion as the primary organizational tool for instruction in their classrooms, but all incorporated, to varying degrees, elements of discussion.

Table 2: Brief Characterization of Teacher' Instruction Prior to the Project

Celine	Celine relied largely on problems from traditional textbooks in which more open-ended application problems occurred after problems involving a particular skill. Celine's normal instructional routine was to have students begin class in small groups to discuss the previous evening's homework. She, then, introduced new content through a teacher led problem solving session, which she considered a guided-discovery approach. Celine's guided discovery consisted of her publicly solving problems where she directed the solution of the problem, but students were expected to contribute key pieces to the solution of a problem. Celine had carefully identified the key pieces students were expected to contribute based on what they had already worked on. Celine, then, offered students time to solve several similar problems in small groups where she had an array of mechanisms in place to support student to student interactions. She assigned 3-5 homework problems at the end of class to work on outside of class.
Felix	Felix relied largely on problems from traditional textbooks. He began class with two students each presenting a homework problem where students explained their solution to the class. During this time, other students in the class asked the presenters questions. Felix, then, used the student presentations to highlight key ideas that he anticipated other students might have struggled to understand. After student presentations, Felix gave a lecture on the topic for the day, with some students taking notes and others listening to the information. Felix, then, assigned 8-10 homework problems and gave students time to work.
Hazel	Hazel often started her class with an open-ended problem that students worked on individually, in small groups, or as a whole class. She used the problem to hook students and highlight key ideas she intended for them to work on in class that day. Once the class discussed this problem, they typically worked either individually or in small groups on more common textbook problems. The outcome of this work was for students to present their solutions to other students either in small groups or whole class. Hazel, then, assigned students 3-5 homework problems at the end of class to work on outside of class.

For analysis, we mixed the whole classroom video and teacher video into a single video file. One mathematics education faculty member and six graduate students coded 45-minute segments of Celine's mini-unit using the 5Ps framework. After coding a 45-minute segment, the team met to discuss and refine codes where this part of analysis focused on what observable actions corresponded to codes for each practice. The research team continued this process until coding for Celine's entire mini-unit was complete; at this point code definitions were relatively stable. Next, the team coded one lesson from Felix and one from Hazel to make additional minor adjustments in the code book based on differences across the three teachers' instruction. The result of this process was a code book with stable code definition for 10 codes: launch; monitoring; assessing questions; advancing questions; selecting: evidence of teacher choosing student's work; selecting: evidence of what student work was presented; sequencing; connecting to learning goals; connecting student work; and student work time. The research team, then, broke into two subgroups, and used the, now stable, code book to code the remaining lessons from Felix and Hazel's mini-units. This coding occurred similarly to what is described above. To respond to our research question, we used descriptive statistics to capture the percentage of time each teacher spent on each practice, which supported our qualitative interpretations of how the teachers recomposed the 5Ps in instruction and what patterns emerged as instructional routines.

Results

In Table 3, we identify the percentage of time and coding frequency for each code. We use this information to highlight salient features in each teacher's re-composition of the practices in instruction to characterize their instructional routines. It is important to note that none of the teachers wanted to use a monitoring chart (cf. Smith et al., 2020) the first time they implemented their mini-units. Their concerns were rooted in perceived trade-offs between a monitoring chart's helpfulness to organize their thinking and distraction from staying present with their students.

Table 3: Descriptive Statistics Related to Each Practice[4]

	Felix			**Celine**			**Hazel**		
# of Lessons	3			7			5		
Total Time	3:45:59			5:44:16			3:53:15		
	Total Time (hr:min:sec)	**Coverage (%)**	**Code Fre-quency**	**Total Time (hr:min:sec)**	**Coverage (%)**	**Code Fre-quency**	**Total Time (hr:min:sec)**	**Coverage (%)**	**Code Frequency**
Launch	57:00	25.22%	13	57:26	16.69%	33	47:59	20.57%	17
Monitoring	1:08:45	30.43%	16	1:57:57	34.27%	21	1:56:23	49.90%	20
Assessing Questions	7:02	3.11%	11	10:52	3.16%	20	34:31	14.80%	75
Advancing Questions	6:49	3.02%	8	22:03	6.41%	43	47:13	20.25%	59

[4] Percentages exceed 100% because of overlapping codes (e.g., monitoring and assessing questions).

Selecting (Choosing)	11:38	5.15%	11	9:37	2.79%	38	3:44	1.60%	16
Selecting (Presenting)	31:28	13.92 %	11	34:47	10.11 %	39	12:51	5.51%	19
Sequencing	25:33	11.31 %	2	49:48	14.47 %	9	16:06	6.91%	7
Connecting Learning goal	57:31	25.46 %	8	1:41:10	29.39 %	46	35:32	15.23 %	21
Connecting Student work	31:11	13.81 %	9	3:01	0.88%	3	10:11	4.37%	10
Student work time	6:54	3.06%	4	22:12	6.45%	10	0	0.00%	0

Felix spent 30.43% of the total instructional time monitoring students, while they worked on problems. Of that time, he spent the lowest percentage of time asking assessing or advancing questions (i.e., 10.18% and 9.80%, respectively, for a total of 19.98% of his monitoring time[5]). Instead, Felix tended to listen to and observe student-to-student conversations while they worked in small groups. For 15.35% of the time he was monitoring, we double-coded selecting (choosing)—a code we used when there was observable evidence that a teacher was choosing a particular student's work to share later in the lesson. We infer, then, that, while he was listening to and observing student conversation during monitoring, he was also focused on determining what work he would *select* to have students share with the class. Moreover, Felix did not have any sequencing codes that occurred while he was monitoring. This indicates there was no observable evidence that he was considering how to sequence student work while monitoring. We infer from this combination of codes, and our qualitative observations, that Felix was challenged to coordinate asking students assessing and advancing questions (relatively low percentage of his monitoring time) while also aiming to determine what student work to select (relatively high percentage of his monitoring time) and sequence that work (none of his monitoring time). Our inference is that he was heavily focused on what work he would select while he was monitoring over, for example, assessing differences in student thinking.

Among the teachers, Felix had the highest percentage of time coded for selecting (presenting) (13.92%) and the lowest number of code instances (11 coded instances). We used this code when students presented their own work to the class. This combination of codes meant that Felix had *fewer, but substantially longer periods of time* during which students presented their work to the whole class than the other teachers. We attribute the length of student presentations to two factors: Felix spent minimal time asking assessing and advancing questions, which meant that sometimes significant mathematics surfaced for the first time during these presentations; and he, among the teachers, allowed for the most open ended whole class discussion of student ideas.

Felix managed the sequencing practice by having multiple students put their work on the white board at the same time. Doing so meant that he had very few instances of the code

[5] These percentages differ from those in the table because they represent the percent of time he was asking each kind of question relative to the total time he was monitoring rather than relative to the total time of instruction.

sequencing, in part, because all student work was displayed simultaneously with students often comparing multiple pieces of student work to each other at the same time. One affordance of this instructional decision was that Felix had ample opportunity to engage in the practice of connecting student work (13.81% of his total instructional time). This code was double coded with selecting (presenting) for 63.38% of the total selecting (presenting) time. Thus, Felix often actively asked questions of students as they presented their work—questions that focused on making connections to other students' work. We also coded a substantial portion of Felix's total instructional time as connecting to learning goals (25.46%); however, this code was only double coded for 4.6% of the total time coded selecting (presenting). This indicated that Felix often made connections to learning goals after students presented their work either by asking further questions of them or by making his own explicit statements of connection.

Celine spent 34.27% of her instructional time monitoring student work. She spent a relatively low percentage of her *monitoring time* asking assessing questions (9.18%) with a larger percentage of that time spent asking advancing questions (18.64%) for a total of 27.82% of her monitoring time. Celine, like Felix, spent much of her time monitoring by listening intently to small group conversations and observing the work that students produced during this time. One reason Celine had a lower percentage of time coded for assessing questions than advancing questions was she often used her assessing listening as a basis to ask advancing questions.

Celine's data also indicates that she experienced a challenge in coordinating asking assessing and advancing questions with engaging in initial phases of selecting and sequencing while monitoring. However, this challenge expressed itself differently in her re-composition of the practices in instruction than it did in Felix's instruction. That is, in contrast to Felix, only 1.6% of her total time monitoring was double coded with selecting (choosing). Her monitoring, then, included little observable evidence that she was considering what student work she would select.

Celine had a lower percentage of total instructional time coded for selecting (presenting) (10.11%) as compared to Felix (13.92%), but a high number of instances of the selecting (presenting) code (39 coded instances). This set of code combinations indicates that she had *frequent but short times* during which *multiple* students had the opportunity to present their work, and they presented sequentially. She did have a substantial percentage of her total instructional time coded as connecting to learning goals (29.39%). However, the code connecting to learning goals was double coded only 1.4% of the total time the selecting (presenting) code was used. This indicates that Celine tended to have students present their work, and then once they had presented it, she made connections to learning goals by either asking the class additional questions or by making her own explicit statements of connection to the learning goals. This sequential code structure indicates that Celine often prepared questions to ask the class as students presented their work but did not integrate this questioning into student presentations. Another consequence of Celine's students presenting their work one-by-one was that, in many instances, the record of student work was gone after it was presented. As such, it was challenging for Celine to make connections across student work. This is supported by only 0.88% of her total instructional time being coded as connecting student work; moreover, this code was never double coded with the selecting (presenting) code.

Hazel spent 49.90% of her total instructional time engaged in the practice of monitoring, a substantially higher percentage than either Felix or Celine. Hazel also spent 70.28% of the time she was coded as monitoring asking either assessing or advancing questions (29.66% and 40.62%, respectively)—also substantially higher than Felix or Celine. Among the three teachers, Hazel's monitoring practice provided the most concrete, observable evidence that she was using her time monitoring to make sense of details about her students' thinking and, therefore, would be well-positioned to both choose student work to share with the class and to consider a sequence for this work. However, only 0.01% of her monitoring time was double coded with selecting (choosing), meaning there was little observable evidence she was engaged in the initial processes of selecting student work while monitoring and no evidence she was considering sequencing it. This code structure again indicates that Hazel was challenged to coordinate monitoring with the initial phases of selecting and sequencing student work.

We infer a challenge for Hazel was balancing the time she spent monitoring with foreseeing the amount of time she would need to effectively engage her class in whole-class discussion about their work. Of the three teachers, she had the lowest percentage of her instructional time coded as selecting (presenting) (5.51%), as sequencing student work (6.91%), and connecting to learning goals (15.23%). These percentages support our observation that she often did not have sufficient time at the end of her lesson to connect to learning goals even though she did engage in this practice at the end of each lesson. The combination of percent of instructional time with frequency for the selecting (presenting) code indicates that Hazel was in between Celine's frequent, short student presentations, and Felix's less frequent, longer student presentations.

The percentage of instructional time coded selecting (presenting) that was double coded as connecting to learning goals was 59.33%. This indicated that, when students were presenting their work, Hazel was often actively questioning them in ways that supported connecting to learning goals, a phenomenon we attribute to her careful use of assessing and advancing questions while monitoring. Overall, 4.37% of Hazel's total instructional time was coded as connecting student work—again between Felix (Felix had a percentage about 3 times higher) and Celine (Celine had a percentage about 1/5 as much). Hazel, like Celine, frequently had multiple students present their work one-by-one often without having a way to simultaneously display multiple pieces of student work. This organization for presenting student work meant that, while students were presenting, Hazel focused on connecting to learning goals rather than connecting student work, which did not occur as a double code with selecting (presenting).

Discussion

One possible way to read the data is that each of the three teachers, in one way or another, was relatively far away from a high-level implementation of the 5Ps. We caution against this interpretation; we were specifically interested in documenting the affordances and challenges that experienced ISTs faced when coordinating the practices together in *instruction* for the first time, and how to support them in the emergence of new *instructional routines*. With this observation, we return to the *conjecture* that guided our design: Decompositions, representations, and approximations of *individual* practices and *moves* within practice was sufficient support for in-service teachers to recompose these practices in instruction in ways that would support them to develop reliable new instructional routines. During the professional collaboration sessions, the ISTs were all able to engage with the practices individually, demonstrating, for example, what we considered to be high level approximations of each individual practice. However, in their classroom teaching, a substantial challenge they faced was how to coordinate the practices with each other in instruction to produce new reliable instructional routines. Moreover, that was how they judged their success; they judged their success, at least initially, in terms of how the practices fit together within a single lesson, and how multiple days of instruction produced new reliable instructional routines—criteria that were neither explicit for them, nor to us, until they implemented the mini-units. Given these observations, we refine our conjecture: the ISTs needed support, in decompositions, representations, and approximations, that focused more explicitly on coordinating practices with each other to produce reliable instruction and instructional routines.

The three cases offer insight into what this support could look like. That is, one common challenge across all three teachers was to coordinate monitoring with the early phases of selecting and sequencing. This challenge may have been due to the teachers' choice not to use a monitoring chart, however, we do not attribute this challenge only to this decision. Moreover, there were subtle differences in their experience of this challenge, and thus differences in the support that could address it. Felix, for example, while monitoring, was consumed with what work to select, and as such asked a relatively low number of assessing and advancing questions. His listening, while monitoring, was often focused on what work he would choose rather than using an assessing, and then advancing question cycle to help him determine what students were thinking and then to move that thinking forward. On the other hand, Hazel focused extensively on asking assessing and advancing questions, while monitoring. Doing so gave her the most detailed information about her students' thinking and thus prepared her to ask students questions to make explicit connections to learning goals. However, there were very few observable teaching actions focused on preparing to select student work, which was related to her inefficiency in transitioning from monitoring to selecting and sequencing student work. These different challenges call for differences in support each teacher needed.

We close by identifying one contribution of this study. Research reports on teachers' use of the 5Ps often focus on characterizations of an individual practice (e.g., Dunning, 2022; Reinsburrow, et al., 2022; Tyminski, et al., 2014) even in reports where multiple of the practices are considered (e.g., Bağdat & Yanik, 2023). These accounts offer important details about a specific practice, including the distinct goals and uses that teachers have for the practice. We think another important point of focus is on how teachers learn to coordinate the practices together (e.g., Pang, 2016), and how this coordination evolves over time into new instructional routines. Our assertion is supported by Felix, Celine, and Hazel's initial judgements of the success of a given lesson (i.e., their instruction) as based—*not* on their use of individual practices, but rather—on how the practices fit together for them within the lesson and across the mini-unit. Given that experienced ISTs' instruction is rooted in established instructional routines, working with them to experience what they deem to be successful instruction is important as they determine for themselves whether to adopt new practices that alter established routines.

We examined students' thinking of graphs around a graphing task from 14 individual interviews, in terms of three layers—frames of reference, coordinate systems, and graphs—and explored their productive and intuitive strategies. As a result, we present a framework that offers a characterization of students' graphing activities. We then discuss implications of the framework.

Keywords: Mathematical Representations, Cognition, Middle School Education.

Graph literacy is important for students to progress in STEM coursework and careers (Paoletti et al., 2020; Costa, 2020) and for making sense of, and responding to, information in the real world (Yore et al., 2007). Sherin (2000) argued researchers should move beyond identifying students' difficulties to explore students' natural inclinations when developing graphical representations and how these inclinations can be leveraged to support graph literacy. In line with researchers who have focused on asset-based accounts of students' strategies, the work we report in this paper was guided by the question, 'What cognitive strategies and intuitive insights do middle school students invent or draw upon when representing quantities in a graphical representation?' To address this question, we present a framework we developed and refined through analyzing interviews with 14 middle school students on the Family Frenzy graphing task. We close by discussing the broader implications of the presented framework.

Some Relevant Literature and Brief Theoretical Underpinnings

Researchers have identified many difficulties students encounter with graphs. Of relevance to this report, researchers identified that students often treat graphs as literal representations of a situation (Bell & Janvier, 1981; Clement, 1989; Lai et al., 2016; Oehrtman et al., 2008). For example, Clement (1989) described students interpreting a speed-height graph of a bike rider as representing a hill the bike rider traveled over. To explore ways students may reason as they construct graphs, we modified Swan's (1985) "Bus Stop Queue" task (Figure 1a), which requested students to interpret a scatterplot by matching each person in the picture to their appropriate point. Note that height and age were labeled along the horizontal and vertical axis, respectively; from this we inferred one goal of the task was to perturb students who interpreted graphs as literal pictures, i.e., interpreted the height of a point as the height of a person. We modified the task by switching the axes labels (Figure 1b) and asking students to create their own graph, as our goal was to examine students' generative activities and intuitions they can build on.

Our work builds on previous work that examined students' generative activities (diSessa et al., 1991; Sarama et al., 2003; Sherin, 2000). Sherin (2000) described students' intuitive representations when tasked to create a picture to describe a motorist's motion over time. Students' depictions often contained pictorial features (i.e., using symbols such as lines to represent more or less of a quantity) that could lead to ideas akin to conventional graphs. However, as Sherin stated, he did not "attempt to be more specific about how this collection is constituted in detail (for example, in terms of knowledge structures)" (p. 413). In this paper, we account for cognitive strategies students draw upon to identify knowledge structures (i.e., thinking patterns that might be involved in students' graph literacy).

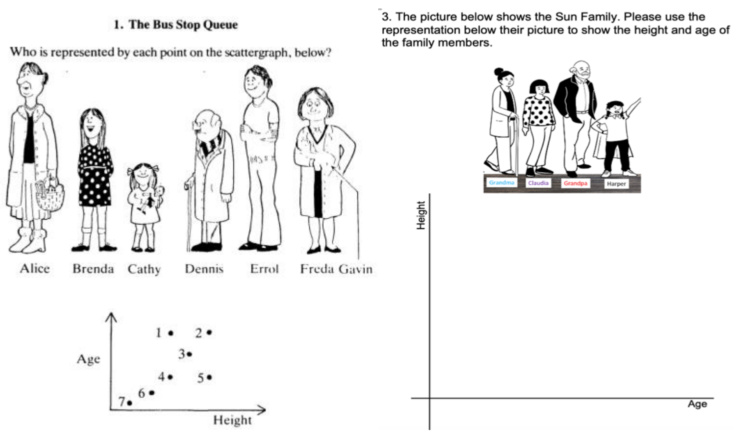

Figure 1: (a) Bus Queue task from Swan (1985); (b) The Family Frenzy task

Frames of Reference, Coordinate System, and Graph

Graphical representations involve spatial depictions of quantities (Thompson, 2011) and are a way to mathematize phenomena. A graphical representation consists of three layers: frames of reference, a coordinate system, and a graph (a collection of points). Frames of reference refer to mental structures used to gauge the relative extents of various attributes in the phenomenon (Levinson, 2003; Lee, 2017; Joshua et al., 2015). Thinking within frames of reference entails attending to and establishing reference points, directionality, and having an idea of what attributes to consider and how to measure them (Joshua et al., 2015; Lee et al., 2020). The nature of graphs and hence, ways of thinking about a graph fundamentally depends on the frames of reference and coordinate systems upon which they are created.

Methods

The data presented here comes from 14 clinical interviews (Ginsburg, 1997) across two projects, both aimed to examine middle school students' (5^{th} to 8^{th} grades) graphing meanings. We collected video recordings, screen recordings, and digital copies of students' written work. The projects recruited students from various mathematical and socio-economic backgrounds. In this paper, we present data from the Family Frenzy task (Figure 1b) which was used in these clinical interviews. We initially examined students' thinking in Family Frenzy and sorted them related to frames of reference, coordinate systems, and graphs (three layers) using the Analytical Framework for Making Sense of Students' Graphical Representations (Lee, 2024). Next, using open and axial techniques (Corbin & Strauss, 1996), we created descriptions of themes within each layer; from these descriptions, we further abstracted and classified the students' strategies, and we present those results in Table 1. We note that the resulting codes are meant to be a holistic characterization of the students' strategies for each attempt they made at the task. Each graphing attempt received a set three of codes where one code was from each category (graphing activity, reference frame activity, coordinate system activity). Results

Students demonstrated a variety of intuitive approaches, which is organized in Table 1. In the table, *representational objects* refers to the (often geometric) objects students physically inscribed on the paper, which included stacked dots, stick people, and bubbles (regions). To distinguish students' inscriptions from the pre-made, two-line segments labeled as Age and Height (what the researchers intended as axes), we call the totality of the two-line segments and the space they span as the *graph space*. We take both the graph space and students' representational objects to constitute their representation of the Sun Family's height and age. We next present one student's strategies to exemplify a subset of these strategies.

Table 1: Summary of Students' Representation Strategies

<table>
<tr><th></th><th>Graphing Activity</th><th>Reference Frame Activity</th></tr>
<tr><td>Height</td><td>• Spatial Transfer: Uses fingers or other physical materials to transfer the height of members in the picture to the graph space and marks the height using representational objects.
• Non-physical Transfer: Estimates relative heights of each member, without using any observable physical action or object to transfer length and indicates such heights in the graph space using representational objects.</td><td>• Pictorial Ordering: Represents height in the order of the members standing in the picture (e.g., Grandma, Claudia, Grandpa, Harper) in the graph space.
• Quantitative Ordering: Represents height in ascending or descending order of heights of the members (can be different order than in picture; e.g., Harper, Claudia, Grandma, Grandpa).</td></tr>
<tr><td>Age</td><td>• Indexing: Estimates relative ages of members based on picture and writes the age of members near the representational object used for height in the graph space. Ages' representations are add-ons to those used for height.
• Non-indexing: Estimates relative ages of members based on picture and indicates such ages using representational objects in the graph space. Ages' representations are independent of (though could be related to) those used for height.</td><td>• Pictorial Ordering: Represents age in the order of the members standing in the picture (e.g., Grandma, Claudia, Grandpa, Harper) in the graph space.
• Indexed Ordering: Represents age in the same order of height in the graph space because age is indexed onto height's representational objects.
• Quantitative Ordering: Represents age in ascending or descending order of ages of the members (can be in different order than in the picture).</td></tr>
<tr><td>Height and Age Together (Coordinate System Activity)</td><td colspan="2">• One, implied axis as an ordered number line: One of the axes in the graph space is acting as an ordered number line while the other is not; 1-D coordination.
• Two, separate, implied axes as number lines: Both axes in the graph space are acting as an ordered number line for each quantity but the two number lines are used individually; two 1-D coordinations.
• Two, overlapping, implied axes as number lines: One axis in the graph space acts as an ordered number line for both quantities; both quantities are represented on a single axis: stacked 1-D coordination.
• Two, coordinated, implied axes as number lines: Each axis in the graph space is acting as an ordered number line for a quantity; both quantities are represented in the two-dimensional space produced by the product of the two axes: 2-D Cartesian coordination</td></tr>
</table>

Thomas' Representation and His Strategies

Six students used a *spatial transfer* strategy when graphing the family's height. Transferring was evidenced by measuring the height in the picture in some manner (e.g., using a ruler, using the span of two fingers) and then marking this measurement directly in the graph space, resulting in a literal copy of the cartoon's height. Figure 2 shows Thomas enacting spatial transfer (and his final representation). Thomas partitioned the Height axis into what he called centimeters. He then used his fingers to measure Grandma's height and then maintained this gap to represent her height on the vertical axis (Figure 2 left and middle). He used this strategy for all the family members, which yielded a set of stacked names on the y-axis (Figure 2 right). Further, this strategy yielded a *quantitative ordering for heights* in that the heights of family members were ordered from shortest to tallest in his representation.

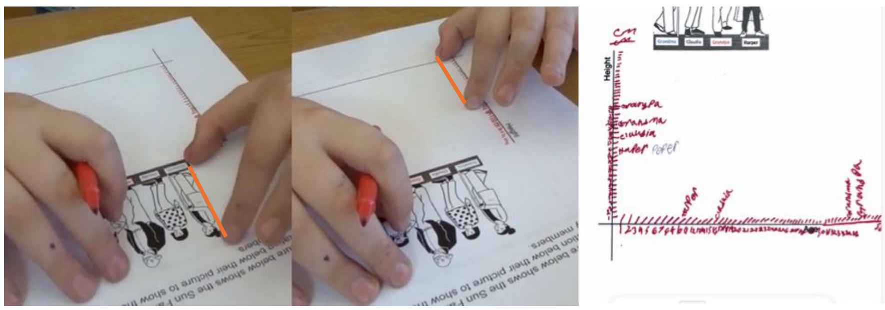

Figure 2: Thomas' Strategy and Final Representation

Thomas used a *non-indexing strategy for age* as he inferred ages based on the picture and represented them along the horizontal axis in the graph space. Specifically, he placed 60 tick marks on the Age axis, and plotted the family members from youngest (Harper) to oldest (Grandpa) along the axis. Thomas ordered the ages in ascending order (see Figure 2 right), and we inferred this order was independent of his representations of height, yielding a *quantitative ordering for age*. Thomas' graphing was indicative of using *two, separate, implied axes as number lines*. Based on how he partitioned each axis into unit-heights and unit-ages and plotted family members' height and age on each axis, we inferred he treated each axis as a number line. Note, Thomas plotted each family member twice, once along each axis. When the interviewer asked if he could find a way to mark each family member only once, Thomas maintained that age and height could not be represented together with a single point. Thus, we inferred his graph space remained as two, separate, implied axes as number lines.

Discussion

We presented a framework characterizing a variety of strategies students used when creating graphical representations given a pictorial scenario. Our framework attends to students' graphing activities of each quantity, height and age before potentially being coordinated together. The framework provides more nuanced "knowledge structures" (Sherin, 2000, p. 413) that students draw on when constructing graphs than previously described, attending to their graphing activities in relation to their reference frame and coordinate system activities. These activities refer to mental actions we inferred from observing students' physical graphing actions. We do not intend our framework to be exhaustive, but instead a starting point for future research that can contribute additional strategies to the framework. We believe the students' strategies in the framework can be leveraged to support students in achieving more conventional graphing meanings. For example, we can build from students' creations of 1-dimensional graphs as conceptual starting points to motivate the potential construction of a 2-dimensional coordinate system from their 1-dimensional graphs. While most research has described students' literal translations as hindering, we view it as a tool that could be productively used and subsequently modified to lead to more productive graphing meanings. We will be further examining these constructions as we continue in our research.

ELICITING EARLY MULTIPLICATIVE IDEAS: USING DIFFERENT TYPES OF ARRAYS AS QUICK IMAGES

Neet Priya Bajwa
Illinois State University
nbajwa@ilstu.edu

Jennifer Tobias
Illinois State University
jtobias@ilstu.edu

In this paper, we present part of a larger study investigating the development of multiplicative ideas in young children before their introduction to multiplication. Arrays were displayed as Quick Images (briefly displayed for 5-10 seconds), including those with hidden and missing amounts, over nine days across 3 weeks. Second-grade students (n=20) were asked to determine the total amount, followed by whole-class sharing and discussions. Using a constant comparative method, we analyzed students' problem-solving strategies reported here. Results indicated an initial reliance on subitizing and counting strategies, with neglect of row/column size in determining the total amount. Students exhibited a shift in attending to rows/columns as composite units, indicating early multiplicative ideas, particularly when making sense of arrays with partially missing amounts. Implications for teaching and research are also discussed.

Keywords: Number Concepts and Operations, Mathematical Representations

Introduction

Multiplicative reasoning holds crucial significance in mathematics, particularly for proficiency in advanced concepts such as algebraic reasoning, ratios, proportions, and measurement, extending beyond the primary grades. Students gradually cultivate multiplicative thinking (Vergnaud, 1994), and making sense of multiplication as part of this thinking requires understanding the iteration or replication of a composite unit rather than a mere enumeration of individual elements (Killion & Steffe, 1989; Steffe, 1992). Specifically, recognizing multiplication as distinct from addition involves acknowledging its binary nature, perceiving the factors as two distinct inputs—the number of groups and the quantity in each group—rather than a singular entity. Scholars contend that students' grasp of the "equal grouping" structure is fundamental to their ability to think multiplicatively (Killion & Steffe, 2002; Sullivan & Mousley, 2001).

Many studies (e.g., Barmby et al., 2009) provide evidence that array models can support students' understanding of multiplication and have the potential to pave a way for multiplicative ideas. In particular, arrays encompass both an "equal grouping" structure and a binary spatial structure with rows and columns as composite units, and thus can offer a visual model "to fully appreciate the two-dimensionality of the multiplicative process" (Young-Loveridge, 2005, p. 39). Unfortunately, the prevailing literature also provides evidence that many children do not perceive the row-by-column spatial structure of an array and resort to inefficient strategies such as counting the objects one-by-one (Battista et al., 1998) and do not consider rows and columns as composites when asked to find the total amount (Barmby et al., 2009). In fact, several researchers have argued that students do not automatically attend to spatial structure but construct it according to how they perceive a situation, shape, or object (Battista & Clements, 1996; Mulligan et al., 2005). For example, when considering a 2-by-3 dot array, students may recognize the total amount as 6 due to subitizing it without needing to consider coordinating the

2 units of 3 each.

Furthermore, tasks in U.S. third-grade textbooks, which is when multiplication is formally introduced, primarily involve direct counting of objects in arrays to determine the total amount (Kosko & Singh, 2018), potentially further constraining the utility of the array representation in fostering multiplicative concepts. Arrays are introduced to students in second grade with the size of the arrays presented under 5-by-5, with a focus on repeated addition. However, research indicates that students tend to count one-by-one when presented with smaller arrays, again ignoring the row-by-column structure the representation affords. Given the research examining the potential of arrays in supporting students' development of multiplicative ideas, our interest was in exploring how arrays could be employed to prompt strategies beyond simple counting to notice the rows or columns as composites. Additionally, in light of some evidence that Quick Images can prompt students to observe the row and column structure of the array when determining the total amount (e.g., Jacob & Mulligan, 2014), and arrays with hidden and missing amounts can reveal how students make sense of the arrays, we leveraged Quick Images as an instructional routine to examine the emergence of multiplicative ideas in young children. Specifically, our research question was:

- How do Quick Images using arrays, including those with missing or hidden amounts, impact students' strategies, particularly, their emergence of multiplicative ideas?

While Quick Images are incorporated in primary education, there is limited focus on using this routine to reveal students' array conceptions and elicit early multiplicative ideas. This paper presents the strategies students employed in transitioning from subitizing and counting to considering rows or columns as composites, along with operating on them, when presented with array images and arrays containing missing objects.

Theoretical Background

We considered learning from an emergent perspective wherein it evolves from participation in social practices, classroom norms, and interactions around the mathematical content employed in problem-solving scenarios. As noted by Cobb and Yackel (1996), children's learning is shaped by their ability to articulate their thoughts to others, while also being influenced by discussions with peers in the classroom. Thus, classroom interactions served as the backdrop where meaning was co-constructed by engaging in social practices and the mathematical content as facilitated by the teacher through prompts and discussion of student strategies.

To identify early multiplicative ideas, we draw from Steffe's (1992) research on unit construction based in children's numerical progression, involving singletons (units of 1), composite units (units larger than 1), and the types of units they construct within their number sequences – rooted in counting activity. Steffe characterizes early multiplicative actions as extensions of children's natural counting behavior, emphasizing that construction of a composite unit marks an essential milestone in early multiplicative reasoning. Specifically, children initially count objects one-by-one (referred to as being at Initial Number Sequence stage). The first milestone is achieved when they move from counting one-by-one to counting repeatedly by the same group size (termed as Tacitly Nested Number Sequence). According to Steffe, within the context of array structures, a student who simply counts by same group size does not necessarily demonstrate multiplicative thinking. To think multiplicatively, a student must also recognize the array as a composite formed of individual units and understand the role of individual units within a row (or column) as an iterative unit (Steffe, 1992). For example, they should be able to count three singles as one unit (the composite or row) and then count the composite unit. Additionally, because arrays are spatial structures, for this study, we considered unit organization with spatial structuring (Mulligan & Mitchelmore, 2009; Mulligan et al., 2005) to identify multiplicative ideas.

Methodology and Methods

This study was conducted with 20 second grade students in a small public elementary school in the Midwestern United States. Students were seen within their whole classroom and were engaged in Quick Image routines for 25-30 minutes 3 times a week for 3 weeks, for a total of nine days, outside of their regular math instructional time. We started with dot images displayed to elicit equal grouping structures on the first day (see Bajwa et al., 2023 for sample images). In each session, 3-4 Quick Image tasks were administered one at a time and displayed for approximately 5-10 seconds. Consequently, students had a limited timeframe to observe the image and were asked to determine the total count of dots/squares/objects within the presented image. After presenting each image as a Quick Image, students were asked to share their solution in whole classroom discussions that focused on students' solutions and strategies for determining the total amount. Thus, we focused on analyzing their collective activity.

Data Collection and Analysis

The gathered data included video recordings of all 9 days of whole class sessions, subsequently transcribed, as well student's written responses on selected tasks that required them to draw a representation prior to discussing their solutions, and notations written on the whiteboard during classroom discussions. Additionally, the dataset included research team field notes and pre-and post-planning meeting notes.

To analyze students' collective activity as part of their classroom discussion, we analyzed the data using a constant comparative method (Glaser & Strauss, 2017). Both authors independently coded transcripts from each of the sessions to identify student strategies used for determining the total amount and then met to compare codes for each session to identify employed strategies, which included instances of counting, adding, and early multiplicative strategies. These codes were then cross-examined with other students to determine if additional ideas beyond those initially identified had emerged.

Results and Findings

Student Strategies Involving Subitizing and Additive Strategies with Complete Arrays under 5-by-5

On Days 1 and 2, students demonstrated additive strategies including repeated addition, chunking, and subitizing to determine the total amount. Specifically, on Day 1, students utilized both subitizing and repeated addition when presented with a 4-by-3 dot array. The teacher introduced the term "rows" for the first time during this session as depicted in the excerpt below. This exchange occurred after the teacher presented the dot card with the array and instructed the class to discuss their observations with their partner. Following the pair-share activity, during which the teacher listened in on students sharing from a distance, the teacher summarized what they had heard several pairs discuss and selected a volunteer to represent a common strategy that was heard. Below is an excerpt from one of the students, Foti. All names are pseudonyms.

Foti: I saw 6.
Teacher: Where did you see 6?
Foti: I saw 6 at the top (referring to the top 2 rows of 3).
Teacher: Okay. Did you see them all the way across, 6 at the top?
Foti: No, I saw three, and then under that 3…
Teacher: Okay, so you saw 2 rows. Then you saw other two rows? (Circling the two rows on the image)

We approached this strategy with caution, recognizing it may entail a form of subitizing, specifically conceptual subitizing, which entails identifying a whole set of objects by quickly (perceptually) subitizing and combining smaller amounts (Sarama & Clements, 2009). MacDonald and Wilkins (2019) note that conceptual subitizing is fundamentally linked to students' construction and coordination of units. By composing two sets (3 and 3 is 6), Foti was likely developing a "units of units" understanding. Subsequent prompts did not clearly establish whether students perceived the 6 first and the 3 as parts of 6 or considered 3 as a row (viewing a row as a composite unit) to reach 6.

Apart from subitizing the number in a row, certain students employed additive strategies. These strategies involved breaking the array into smaller chunks and subitizing groups to determine the total (see Figure 1).

Neha: So, this was 7, I knew that, so there was 3 here, right, and 3 here (top two rows of 3). That was 6. I added these 2, that was 8. Then…there was 4 here. I added 4, and that was 12.

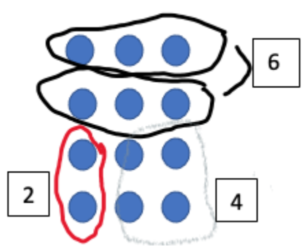

Figure 1. Using Chunking to Find the Total

Neha's strategy included breaking the array into different sized chunks by considering the top two rows and breaking the bottom two rows into a 2 and a 4 and adding those numbers together to find the total amount without considering a row or column as a composite unit. They initially state 7 but pointed to what they saw when figuring out the total, to get to the right answer of 6 dots with the top two rows.

In addition to subitizing and chunking, we also found some students began to use repeated addition or skip counting to figure out the total amount by Day 3. However, we found that not all who skip counted used the size of a row or column. Some students skip counted without considering the size of a row or column. For example, when presented with a 4-by-4 square array on Day 3, we had some students who skip counted by 4s. However, Odelia figured out that the image had 16 squares by skip counting by 2s.

Teacher: You counted by 2s? How did you count by 2s, can you show me where you counted by 2s? (shows Odelia the card again).
Odelia: 2, 4, 6, 8, 10, 12, 14, 16 (moves finger while counting sets of 2 squares, left to right, top to bottom).
Teacher: Okay. So, you went along the rows and skip counted by 2s, like that.

On these initial days, it first seemed that students counted based on the numbers in a row or column. However, as they elaborated their strategies, it became apparent that students weren't consistently utilizing or identifying the amount in a single row or column. This became evident when students, such as Odelia, noted that while they could determine the total in the image, they weren't necessarily focusing automatically on the quantity in one row or column but instead on a number they could readily recognize or subitize – in this case 2. Notably, when using this strategy, students did not engage with three levels of units. In this task, the students were shown the full array (image) instead of being told that there are 16 dots in the full array. Therefore, the students did not need to double-count to note that two repeated 8 times equals 16 as they could refer to the visual of the image to know when to stop. Despite these inconsistencies between what initially appeared and what students were actually focusing on, we found that most students were abandoning counting one-by-one to find the total utilizing other counting strategies, such as, repeated addition, chunking, and skip counting to figure out the total amount in an array by Day 4.

Student Strategies Involving a Row or a Column as Composites in Incomplete Arrays

Students were presented with incomplete arrays with missing parts (or composite arrays) on Day 7. We first presented students with a 5-by-5 composite array (see Figure 2). We were interested in getting students to utilize rows or columns as composites and so when this image was presented the teacher asked students to find the total and utilize what they know about arrays. The use of composite arrays with missing elements indeed draws students' attention to considering the composite of rows or columns in different ways as depicted below.

Arianna: I counted 3 all the way down. So it was 3, 6, 9, 12, 15, 18, and then there was one 3 on the side, so I counted that, which was 21. Then there were 2 left, which was…
Teacher: Like that? 3, 6, 9, 12, 15, 18? [circling 3 squares, from left to right, in each row].
Arianna: Yeah, and then one on the side. That way [finger pointed to the board, circling vertically]…Yeah, then there was a 2 going down. And then I added, so, it was 21 plus 2 got me 23.

Arianna utilized composites of the initial row, made of 3 squares and used skip counting to determine the total. On the other hand, another student (Keena, see below) also utilized arrays but by mentally moving the squares to form a complete array using the given squares.

Keena: See that two right over here [pointing to the column of 2 on the card]? I actually just moved this 2, like, all the way into this space [pointing to the space at the top of the column with 3 squares].

Teacher: So, you moved this up here?
Keena: Yeah, and then I know that there was four here [pointing across card, indicating the number of columns] and there was five here [pointing up and down on card, indicating the number of rows], and it was 20.

Keena used the template of a complete array to visually create a full array by moving the squares mentally. This then led them to notice that using all the given squares a 5-by-4 array could be formed, resulting in the answer of 20. While we cannot say which particular strategy they utilized to get to 20 (e.g., repeated addition or multiplication), this strategy and others, representative of Arianna indicated that students were getting comfortable with creating and utilizing rows and columns as composite to find the total.

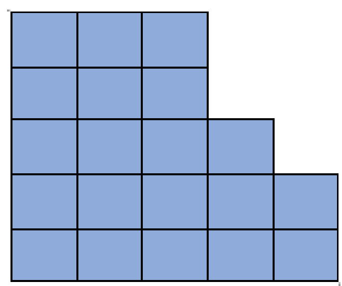

Figure 2. Example of an Incomplete Array

Student Strategies Involving a Row or a Column as Composites in Arrays under 5-by-5 with Missing Objects

We found that when presented with arrays smaller than 5-by-5 with missing elements (See Figure 3, left), students initially resorted to either one-by-one counting or attempted to memorize the number of squares, often facing difficulties in accurately tracking the total count, partly due to the limited time for which the images were presented. These difficulties prompted students to explore alternative strategies when presented with larger arrays. On subsequent days, to get students to consider or invent alternative strategies, we introduced a real-life scenario involving a tray with some seedlings missing (see Figure 3, right). After reminding the students that the image would be displayed for 5 seconds, we posed the question to the students, “How many seedlings can fit into the container?”

Figure 3: Examples of Arrays with Missing Objects

When sharing their strategies, we found that most students regarded the row or column size as a composite unit. Among those few who explored alternative approaches, they drew from their experiences with complete arrays as a reference, disregarding or intentionally ignoring the absence of seedlings to help them determine the total amount. Overall, student strategies varied, from determining the total by forming equal groups unrelated to the row (or column) size to treating the row or column size as a composite, iterating it, and mentioning multiplication as depicted in the excerpt below.

Sage:	20. I counted the columns.
Teacher:	You counted the columns. So, how did you count the columns?
Sage:	[while drawing her finger downward] 4, 4, 4, 4, and 4
Owen:	20. I used multiplication
Teacher:	Okay, you said you used multiplication? Okay, how?
Owen:	So, I counted all of them down, and that was 4, and I counted across and that was 5. So, I did the 4 times 5 and counted by 5. So, I counted 5, 10, 15, 20.

By the last day, we observed that the majority of students demonstrated flexibility in making sense of the total amount in an array despite certain objects missing. In the seedling task, for instance, numerous students determined the total by identifying the size of a row or column as a unit and iterating it to find the total number of seedlings. Notably, there was a shift in language usage as students explained their process of iterating rows and columns. Among those identifying rows or columns, some began using the term "times" to indicate the number of times they added (iterated) the row or column. For instance, one student when figuring out the total in another seedling tray (3-by-9) with some seedling missing, mentioned, “I counted by 3s, so I counted by '3s nine times.'” Intriguingly, a specific student (Owen) even used the term "multiplication." In summary, the introduction to arrays larger than 5-by-5 with missing amounts prompted various responses, with many students engaging in early multiplicative ideas.

Student Strategies Utilizing the Rows-by-Columns in Arrays Over 5-by-5 with Hidden Objects

We found that when presented with a task involving larger arrays with hidden amounts, students began to utilize the row-by-column structure of the array inherent in their strategies. We presented students with an image with windows, an example of a real-world 6-by-10 array. Initially, we presented the windows without the hidden amount. The teacher reminded the students that the image will be showed for a short time. As anticipated, students employed various strategies to determine the total number of windows—many focused on identifying both row and column sizes. After concluding the discussion on the presence of 60 windows, we presented the next card to students using hidden windows as a "challenge card." In this card, we used the same image and obscured windows in the middle of the top three rows (see Figure 4).

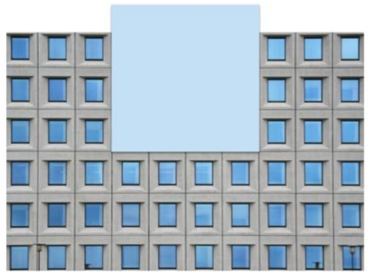

Figure 4: Windows Task - Array with Hidden Amount

Since the students had already established the total number of windows in the picture, they were asked to determine the quantity that was hidden. We found that while students used a variety of strategies, certain students concentrated solely on the hidden section, deducing the number of hidden rows/columns and the size of each column/row.

Omar: 12. Because, I see that there are 1, 2, 3, 4 here and 1, 2, 3 there, so 4 columns of 3.
Teacher: Did you hear what Omar had to say about that? That there were 4 columns, he said, of 3 that were hidden. Austin, did you do something different?
Austin: Yeah, I just pretended to move that down and counted by 3s down.
Teacher: Okay, so you, you imagined that this was actually moved down here and counted this part here? Okay. Alright.

The use of hidden amounts in a larger array resulted in eliciting a variety of strategies. Some students identified the how many rows and columns might be hidden to determine the hidden amount; representative of what Omar did. This indicated that these students may have been considering the hidden amount as an array itself, but we say this with caution as we did not ask students to determine if this was indeed the case. Some identified the number of rows and amount in each column (like Austin) and repeatedly added those.

Discussion and Implications

Quick Images with arrays provided a valuable avenue for students to delve into early multiplicative concepts prior to their formal introduction to multiplication. Initially, smaller arrays of 5-by-5 or less were presented, facilitating subitizing and counting to determine the total. As expected, some students counted the objects one-by-one, some formed various-sized groups, not necessarily tied to the size of a single row or column but instead based on groups they could subitize or effortlessly skip count. As the instructional days progressed and students encountered arrays with missing objects as well as larger arrays exceeding 5-by-5, there was a noticeable shift in most students' approach. They began considering the quantity within a single row and/or column, iterating or coordinating the two to calculate the total but inconsistently. Specifically, by restricting the display time of images and providing multiple opportunities for students to construct and count composites, students began to leverage the spatial structure of arrays. Most found the total by combining both the spatial arrangement (arrays as rows of objects) and numeric composites (row size as a unit). The introduction of arrays with missing or hidden elements further encouraged students to consider the structure of the array as comprised of equal-sized rows and columns, and iterate them to find the total amount in the presented image.

Our results indicated that the presence of arrays larger than 5-by-5 may impact students' development of early multiplicative ideas. More research is needed to determine if the use of composite arrays and/or arrays with hidden amounts fostered that understanding or if this was due to the array itself being larger, because it could not be counted quickly. Additionally, more research is needed examining how the amount of time students have to view an image, especially when the array is larger, impacts the strategies they use to find the total amount. Our results seem promising that a combination of these infused during instruction may contribute to students' development of multiplicative ideas prior to formally being introduced to multiplication.

Conclusion

This paper presented results from a larger study examining second grade students' understanding of multiplicative ideas who have not yet been formally taught multiplication. Initially, students were found to count objects one-by-one, subitize, or use groupings to find the total amount in an array and could do so without attending to a row of a column as a unit. When presented with larger arrays, in particular composite arrays and those with hidden/missing pieces, we found that students began to attend to a row or column as a unit which could then be iterated to find the total amount in the array. Our findings have yielded encouraging results illustrating that young students can consider and utilize multiplicative ideas prior to a formal introduction to multiplication as they engage in making sense of images presented as Quick Images.

CHILDREN'S USE OF MANIPULATIVES WHILE INVENTING NEGATIVE INTEGER MULTIPLICATION STRATEGIES

Camilla Carpenter
Illinois State University
Chcarp1@ilstu.edu

Negative integers are a contextually difficult subject for children to comprehend due to their abstract nature. 35 grade 5 children, from two qualitative studies, invented strategies to solve open-number sentences involving the multiplication of negative integers prior to formal instruction. The strategies that children used were categorized in order of success as (1) direct modeling, (2) repeated addition and subtraction, (3) recalled fact, (4) procedure, (5) counting, and (6) analogy. Upon examining children's invented strategies, the results indicated that manipulative use (i.e. unifix cubes, two-sided chips, and number lines) could inform educators as they provide negative integer operation instruction. Implications for teaching integers and future research are also discussed.

Keywords: Number Concepts and Operations, Elementary School Education, Cognition

The mathematics education field recognizes the importance of examining children's thinking across multiple number domains (Carpenter et al., 2015; Empson & Levi, 2011). Although there is a rich understanding of the ways that children think about whole number operations (Carpenter et al., 2015) as well as negative integer addition and subtraction (Bofferding & Hoffman, 2019; Wessman-Enzinger, 2019a; Whitacre et al., 2017), we lack descriptions of how children think about and invent uses of multiplication with negative integers. Making sense of how children invent strategies to reason with negative integer multiplication is important because it empowers children, educators, and researchers by highlighting the sophisticated mathematics children already know. Because invented integer operation models often differ significantly from traditional models (Wessman-Enzinger, 2019a), examining children's use of operations with negative integers provides vital insight into the knowledge that children already possess prior to formal instruction.

Children invent sophisticated ways of reasoning about integers (Bishop et al., 2014; Bofferding, 2014). However, the transition from additive structures to multiplicative structures can be challenging (Carpenter et al., 2015). As children approach addition and subtraction of integers they often use strategies such as moving forward for addition and backward for subtraction. When multiplying, children are taught to move forward on a number line, therefore when introduced to negative integer multiplication, moving backwards on a number line may seem like an illogical solution. Negative integers are difficult for children to model and create contexts for due to their abstract nature.

Baek (1998) demonstrates that children understand multiplication with greater success when they are permitted to invent their own strategies. These invented strategies can also be used to teach children as they begin to reason with negative integers. As children solve problems involving the multiplication and division of integers, they often invent strategies that make use of counting, repeated addition, or direct modeling (by grouping collections of countable objects) (Carpenter et al., 2015). These strategies provide insight into the ways that students may solve multiplication tasks involving negative integers.

Theoretical Perspective

Cognitively Guided Instruction (CGI) is a framework developed to help educators understand how children's mathematical ideas evolve. Integer addition and subtraction literature indicates that children use several strategies that are derived from the CGI framework. Some of these strategies include, creating analogies (Bishop et al., 2016; Bofferding, 2011; Wessman-Enzinger 2017; Whitacre et al., 2017), using procedures (Bishop et al., 2014), and drawing upon recalled facts. This report will draw upon both single-digit (Carpenter et al., 2015) and multi-digit strategies (Baek, 1998) for multiplication of whole numbers, as well as the CGI strategies for integer addition and subtraction.

Additionally, this report will draw upon the framework, seen in Figure 1, created by Carpenter and Wessman-Enzinger (2018) to analyze children's thinking as they invent ways to multiply using negative integers. This previous study identified the following six categories of strategies that children invented while interacting with negative integer multiplication: (1) *direct modeling*, (2) *repeated addition and subtraction*, (3) *recalled fact*, (4) *procedure*, (5) *counting,* and (6) *analogy*.

Invented Strategy	Description	Children's Representations
Direct Modeling	Children use physical tools or draw pictures in order to solve the integer multiplication sentences (e.g. unifix cubes, chips)	**3 x -4 = __** Repeated Addition and Subtraction	Children describe multiplication as adding or subtracting an integer repeatedly	**3 x -4 =__** Recalled Fact	Children extend their factual knowledge about whole number multiplication quickly to integer multiplication without explanation	**3 x 5 = __** "I just knew it was 15 because I have been doing multiplication for a while and I know that answer"
Procedure	Children invent a rule or algorithm to find the solution (often applying the rule across multiple tasks)	**-2 x 3 = __** "I thought, I will minus out this (the negative sign) and then I will times these two (2 and 3) and after I will add on the minus, so it becomes minus…or I mean negative 6"
Counting	Children count or skip count in sequential orders up or down (i.e. using a number line)	**3 x -4 = __** Analogy	Children connect previous knowledge about whole numbers to integers in order to justify new claims when solving integer multiplication number sentences (i.e., 2 × 4 = 8, so -2 × -4 = -8)	**-2 x -4 = __** "Well, because it wouldn't really make as much sense for a negative multiplied by a negative to equal a positive. It's like, um, I'm not sure how to... it just wouldn't make as much sense. Because if a positive multiplied by a positive would equal a positive, then I would assume that it would be the same for a negative. And, it would be a negative times a negative would equal a negative"

Figure 1: Sample Children's Invented Strategies for Integer Multiplication

Methods

The data presented in this report was gathered from two qualitative studies. The first study, conducted by Carpenter and Wessman-Enzinger (2018) examined how children invent strategies for solving negative integer multiplication prior to formal instruction. The participants consisted of 23 grade 5 students attending a rural school in the Pacific Northwest, United States. The children each participated in one clinical interview (Clement, 2000) and were asked to solve four open-number sentences, all with varying degrees of negative integer inclusion. They were asked to solve each number sentence and describe their strategy, before creating a story to represent their solution path. This study resulted in the production of an inaugural framework that described the ways that children invent strategies to solve negative integer multiplication.

The second study was conducted by Carpenter (2024) to validate the findings of the first study. The participants of the second study consisted of 12 grade 5 students attending a laboratory school in the Midwest, United States. In congruence with the first study, all children participated in one clinical interview. However, as seen in figure 2, half of the participants (6 children) were given the four open-number sentences in the order presented in sequence 1, identical to the order presented in the first study by Carpenter and Wessman-Enzinger (2018). The other half of the participants (6 children) were given the open-number sentences in the order shown in sequence 2. The sequence that each child received was chosen at random and was blind to the researcher. Following their strategy invention for each number sentence, children were asked to create a story to represent their solution path.

Sequence 1	Sequence 2
3 x 5 = __	3 x 5 = __
-2 x 3 = __	3 x -4 = __
3 x -4 = __	-2 x 3 = __
-2 x -4 = __	-2 x -4 = __

Figure 2: Open-Number Sentence Order

The results of the second study confirmed the validity of the framework previously created by Carpenter and Wessman-Enzinger (2018), despite the tasks being presented in a different order and to a different participant pool. While the results of both studies highlighted the sophisticated reasoning present within the strategies that children invented; the present report will provide distinct recommendations for the use of specific strategies and manipulatives that educators should include within their instruction to help students successfully develop an understanding of negative integers and their operations. This report will answer the following research question:

1. What types of strategies do children invent while operating with negative integer multiplication?

Interpreting Negative Integers

Negative integers are a difficult area of study for children to conceptualize. Since negative integers are difficult to represent physically, many children struggle to develop strategies that can represent them in various operations. Conceptualizing negative integers requires children to acknowledge the existence of numbers less than zero (Bofferding, 2014). While there are a few models that can be used to represent the addition and subtraction of negative integers, such as moving on a number line, solving tasks involving multiplication and division can become much more difficult. The children in this report were not yet taught any de-contextualized rules or algorithms about integer multiplication, which is a common practice among classroom teachers when they begin negative integer instruction.

Without prior formal instruction about negative integers and how to operate with them, these children developed insightful strategies that have the possibility to help future educators understand the best methods to introduce children to negative integer multiplication. These invented strategies do not always produce mathematically correct results; however, they are often rooted in logic (Carpenter and Wessman-Enzinger, 2018; Wessman-Enzinger, 2020) and provide useful information about misconceptions that children may have as they make sense of such an abstract concept. Understanding the connections between the strategies that children use and the misconceptions that arise as a result of an invented strategy can provide educators with useful information about the tools they should be presenting to children as they interact with negative integer multiplication for the first time. The successes and challenges that children face as negative integers are introduced into their operations for the first time can be seen in Table 1.

Table 1: Children's Correct and Incorrect Solutions

Task	Solutions		Percentage of Correct Solutions
	Correct	Incorrect	
3 x 5 = __	35	0	100%
-2 x 3 = __	14	21	66%
3 x -4 = __	14	21	66%
-4 x -2 = __	2	33	6%

When presented with an open-number sentence containing two positive integers, all children (100%) were able to successfully invent strategies to solve for the correct answer. This indicates a robust understanding of single-digit whole number multiplication. However, as the open-number tasks involve more negative integers, success in creating a viable strategy for solving drastically declines. Two-thirds of children (66%) correctly solved multiplication number sentence tasks containing only one negative integer. Interestingly, this finding was identical for both tasks containing only one negative integer, despite children receiving the tasks in two distinct ordering sequences. Finally, only two children (6%) were able to invent a strategy to correctly solve a multiplication number sentence containing two negative integers. The decline in children's success while solving each open-number sentence involving negative integers is partially caused by a lack of understanding of how to interpret a negative integer (Fuadiah et al., 2019). As seen in Figure 3, the children demonstrated a wide variety of negative integer interpretations while solving each task.

Negative Integer Interpretations	Children's Responses
Negative integers are equivalent to zero	**-2 x 3 = __** **Addie:** "Negative 2 is I'm guessing its zero and zero times this is zero"
Negative integers are equivalent to nothing	**-2 x 3 = __** **Mia:** "There are three groups with nothing."
Negative sign is completely ignored	**-2 x 3 = __** **Benny:** "I got my answer by counting by 2 3 times, 2, 4, 6 so I counted by 3 and got 6"
Negative sign is equivalent to the subtraction symbol	**-2 x 3 = __** **Cash:** "2 times 3 is 6 and then took away 2 for the negative… I just knew there was a negative 2 so I took away 2"
Two negatives multiplied together will equal a negative.	**-4 x -2 = __** **Jasper:** "I'm pretty sure that a negative multiplied by a negative will just stay as a negative and not go into a positive at all… Well because um it wouldn't really make as much sense for a negative multiplied by a negative to equal a positive. It's like um I'm not sure how to… it just wouldn't make as much sense. Because if a positive multiplied by a positive would equal a positive then I would assume that it would be the same for a negative. And it would be a negative times a negative would equal a negative."
Multiply both integers as positive integers and then add on the negative sign to the product	**3 x -4 = __** **Warren:** "I just crossed out the ... the negative symbol. Multiply 3 times 4 and then... got 12 and just brought the negative symbol back."
Multiply both integers as positive integers and then subtract the negative integer(s) from the product	**-2 x 3 = __** **Jasper:** "You do the multiplication and then you take that and then you make the negative a positive and do… subtract. And the answer for your subtraction problem would be your overall answer."

Figure 3: Children's Negative Integer Interpretations

The broad range of negative integer understanding amongst the children in both studies is far from abnormal. There are many common misconceptions that arise as the children invent strategies for operating with negative integers for the first time. In congruence with previous literature, some children believe a negative integer is equivalent to zero and others ignore the negative sign altogether (Bofferding, 2014). Some children approach the negative sign as equivalent to the subtraction symbol (Stephen & Akyuz, 2012), while others simply assign a negative value to the product after they multiply both integers as positives (Wessman-Enzinger, 2020). However, a less common approach to operating with negative integers is also present within the data. Several children invented a procedure to multiply the integers as if they were both positive and then proceeded to subtract the negative integer present in the original number sentence from the product. The difference between the product and negative integer was then declared as the solution. This understanding builds upon the interpretation that the negative sign and subtraction symbol are equivalent. Children who use this strategy are drawing upon their understanding of whole number multiplication and subtraction, in a logical attempt to make sense of a new symbol (the negative sign) that they have not seen before.

Modeling Negative Integers

Using the framework developed by Carpenter and Wessman-Enzinger (2018), the student-invented strategies are sorted into six categories: (1) *direct modeling*, (2) *repeated addition and subtraction*, (3) *recalled fact*, (4) *procedure*, (5) *counting,* and (6) *analogy*. These strategies are used with varying degrees of frequency and success, as seen in Table 2.

Table 2: Children's Use of Invented Strategies

Invented Strategy	Open-Number Sentences								All Responses Combined		
	3 x 5 = __		-2 x 3 = __		3 x -4 = __		-4 x -2 = __				
	Correct	Total	Correct	Total	Correct	Total	Correct	Total	Correct	Total	Success Percentage
Direct Modeling	9	9	5	8	2	9	0	4	16	30	53%
Repeated Addition & Subtraction	8	8	1	3	0	1	0	0	9	12	75%
Recalled Fact	15	15	0	0	0	1	0	0	15	16	94%
Procedure	0	0	7	16	12	21	0	15	19	52	37%
Counting	3	3	0	4	0	3	0	9	3	19	16%
Analogy	0	0	0	0	0	0	0	4	0	4	0%

As children solve tasks using their invented strategies, they have the most accuracy with the implementation of (1) *recalled fact* (94% correct), (2) *repeated addition and subtraction* (75% correct), and (3) *direct modeling* (53% correct). Despite being used more than all three aforementioned strategies; *procedure* (37% correct) and *counting* (16%) prove to be the least successful strategies other than *analogy* (0% correct) which is not used accurately in any interviews.

Recalled fact is the most accurately used strategy by the children to invent a solution. They also rely heavily on *direct modeling* and *repeated addition and subtraction*. *Direct modeling* demonstrates a child's attempt to physically represent the negative integers within the task, while *repeated addition and subtraction* is used to justify the role of multiplication within the task. Both are important to understand in order to invent a viable solution path for negative integer multiplication. Children's strategies are characterized as a *procedure* when they invent a rule for solving and continue to apply it throughout the other tasks. Although children also produce solutions by inventing *counting* strategies, these solution paths, often involving the use of a number line, are much less successful than the other invented strategies.

Although many children demonstrate proficiency with the use of *recalled fact* to produce correct solution paths, it will not be a focus of this report. *Recalled fact* is used almost exclusively with open-number sentences containing two positive integers and is often the result of children memorizing de-contextualized rules which are demonstrated to them by others. Since the children in both studies were exploring negative integer operations prior to formal instruction, it makes sense that they would not know, and therefore not use, any memorized rules for solving tasks involving negative integers. Due to its lack of use among any of the open-number sentences containing negative integers, it will not be highlighted as a recommended strategy in this report. Despite being the most used invented strategy, developing a *procedure* did not produce a high level of solution accuracy. Common procedures included appending a negative sign to the solution, interpreting negative integers as equivalent to zero, and assuming exclusive negativity. An uncommon procedure also presented itself in both studies, however, due to their complexity, these findings will be discussed in future proceedings.

Children developed several different strategies to make sense of negative integer multiplication, however, this report will recommend the use of (1) *direct modeling* (i.e. unifix cubes and two-sided chips) and (2) *counting* (i.e. number line) to current and future educators as they approach negative integer operations with their students. Both strategies use physical manipulatives or contexts to model negative integer multiplication and although they were ultimately coded as *direct modeling* or *counting* because of the manipulatives used, both strategies often also relied on *repeated addition* to complete their strategy. Thus, the recommended use of *repeated addition* is not included as it is embedded within the use of all contextual manipulatives discussed in this report. Understanding how often children use and are successful with these invented strategies, seen in Table 3, informs the recommendation of this report.

Table 3: Children's Use of Physical Manipulatives and Accuracy

Task	Manipulatives Used By Children to Invent Strategies					
	Unifix Cubes		Two- Sided Chips		Number Line	
	Correct Use	Total Use	Correct Use	Total Use	Correct Use	Total Use
3 x 5 = __	6	6	2	2	0	0
-2 x 3 = __	4	5	1	3	0	4
3 x -4 = __	2	4	1	3	0	3
-4 x -2 = __	0	3	0	0	0	9
Cumulative Totals	12	18	4	8	0	16
Percentage of Correct Use	66%		50%		0%	

Children's Use of Manipulatives

Twenty-one children (60% of participants) invented strategies using manipulatives as they attempted to model negative integers physically. Manipulatives are necessary for instruction of negative integers as they provide children with operational context, rather than the rote memorization of rules. Additional guidance for the use of contextual manipulatives such as (1) unifix cubes, (2) two-sided chips, and (3) number lines will be demonstrated through the invented solution paths of three children.

Unifix Cubes

While they are closely related in many aspects, unifix cubes differ from two-sided chips because they lack the binary restriction of just two sides or two colors. Unifix cubes present as 3D objects that come in color groupings of ten and are often used to physically represent whole number operations. Despite being used in almost equal comparison to the number line, this manipulative had a 66% success rate among children who used it to invent their strategies. Children using unifix cubes to model negative integer multiplication apply their whole number multiplicative reasoning of creating groups to construct "groups of" negative integers that represent their solution, as seen in Figure 5.

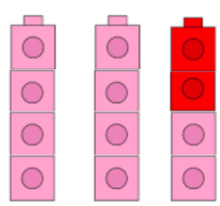

Figure 4: Koda's Use of Unifix Cubes to Solve 3 x -4 = __

Koda invented his strategy by organizing the unifix cubes into three groups of four cubes. He did not assign a negative value to a specific color. Instead, he stated that all cubes were representative of a negative (regardless of color) and used both red and pink cubes in his representation. unifix cubes are used by children to solve each open-number sentence, regardless of the number of negative integers present, making it a versatile tool for negative integer exploration. They differ from two-sided chips in their ability to link together. Because of their ability to connect, children do not use them regularly to create arrays, but invent representations using groups instead.

Two-Sided Chips

Two-sided chips are uniquely qualified manipulatives for representing negative integer operations because of their ability to represent both a negative and positive value using the same object. The children who invent strategies successfully with the two-sided chips regularly assign a negative value to one side of the chip and a positive value to the other. In this study, most children who use two-sided chips do so by inventing strategies that create arrays of negative integers, as seen in Figure 4.

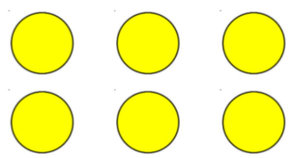

Figure 5: Zach's Use of Two-Sided Chips to Solve -2 x 3 = __

Zach invented a model using an array that assigns a negative value to the yellow side of the two-sided chips. He explained his strategy by saying "I got 2, 4, 6, so my answer was negative 6… I multiplied negative 2 by 3." Two-sided chips encourage children, like Zach, to discover that values less than zero can be modeled with physical objects by assigning a negative value to that object. Surprisingly, this tool is only used by children in three of the four tasks given. Although this manipulative is used less than all others available, children who use two-sided chips in their invented solutions demonstrate the second highest levels of success in solving the tasks. Given the success rate of children who use the two-sided chips, educators should consider these manipulatives as paramount for implementation within their instruction of negative integer multiplication.

Number Line

Although number lines are a useful tool for the instruction of whole number operations, this instrument does not serve as a benefit to children who use it to invent strategies for negative integer multiplication prior to formal instruction. This manipulative is used more than any other by children in the study, however, it also produces a 0% success rate among its users. Children face a variety of obstacles while using the number line, but many instinctively gravitate towards it initially due to their familiarity with it in primary mathematics and whole number operations.

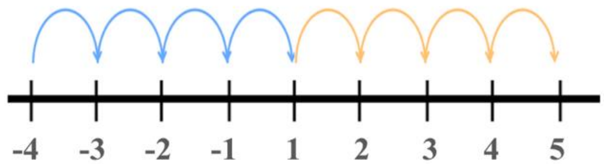

Figure 6: Arlo's Use of the Number Line to Solve -4 x -2 = __

Arlo started their number line at -4 and skip-counted two groups of four until determining a solution of 5. Arlo decided to start skip-counting at -4, because it was the first integer presented in the open-number sentence. This invented strategy presents some successes, but also highlights several challenges that accompany the use of a number line to represent negative integer operations. Arlo's directional movement and total number of "jumps" indicate promising conceptual foundations but fall short of the correct solution due to Arlo's chosen starting point and omission of zero on the number line. Although number lines are regularly used to teach whole number operations, the starting points and directional movements required for negative integer operations are not intuitive for children. Additionally, minor computational errors, such as omitting zero from the number line can cause children to arrive at an incorrect solution, even if they performed all other steps accurately. For these reasons, number lines should be used with caution while providing instruction on negative integer operations.

Discussion and Conclusion

Although the literature examining the ways that children operate with negative integers using addition and subtraction is growing (Bofferding & Hoffman, 2019; Wessman-Enzinger, 2019a), there is a continuous need for research on children's thinking about negative integer multiplication and division. The ways that children interpret the negative symbol has direct implications for how they approach negative integer operations. Future research should examine the ways that children approach the negative symbol that are unique to negative integer multiplication (i.e. multiplying both integers as positive and subtracting the negative integer from the product).

Implications

Although children in both studies were asked to pose stories for negative integer multiplication number sentences, it was not discussed in this report. Storytelling has proven to be an excellent tool to encourage contextual understanding for abstract mathematical concepts. Future research should examine whether there is a connection between the stories children create and the strategies that they invent while solving negative integer multiplication tasks.

Keywords: Mathematical Representations, Number Concepts and Operations.

Researchers have argued that pictorial illustrations of multiplication should contain visual information that highlights the various meanings of multiplication (e.g., equal groups, rectangular array, cartesian product) and its structural elements (e.g., relations between units; Jitendra et al., 2022; Kosko, 2020). Not all illustrations that accompany mathematical tasks are equally effective for learning, however (Berends & van Lieshout, 2009; van Lieshout & Xenidou-Dervou, 2018). First, illustrations designed to serve different purposes (e.g., to represent concepts or to decorate) vary in their effectiveness (Carney & Levin, 2002). Second, the perceptual features in illustrations can be relevant to the target concept or not (Belenky & Schalk, 2014), thereby impacting student learning in different ways (e.g., Kaminski & Sloutsky, 2013; McNeil et al., 2009). The objective of the current study was to analyze the illustrations used in multiplication problems in elementary textbooks. The findings will provide insight into the ways in which the conceptual structure of multiplication is conveyed through illustrations and more generally, how multiplication is taught in elementary classrooms (Porter, 2002).

Third- and fourth-grade textbooks from two publishers (TAM TAM, Deshaies et al., 2022; Lincourt et al., 2022; and Matcha, Borduas et al., 2019a, 2019b) adopted in a large metropolitan area in Eastern Canada were selected for analysis. The textbooks contained 171 exercises, each of which contained either one task or a subset of tasks of the same type. We first coded the exercises as either including a *decorative* illustration or not, defined as one that was not related to the targeted concept but intended to capture student interest (Lenzner et al., 2013). Second, the tasks (n = 573) were coded as: (1) *symbolic* (i.e., words or symbols only) or (2) *illustration*. Illustrations were further coded as either: (a) *representational*, showing the meaning and structure of multiplication (e.g., three bunches of 5 bananas); (b) *irrelevant*, a symbolic problem embedded in an illustration unrelated to the meaning of multiplication (e.g., 3 x 5 = __ placed in an image of a bowling pin); or (c) *organizational*, a structural framework for solving a given problem (e.g., an empty number line to show three groups of 5).

Over half (59%) of the exercises included a decorative image in the margin, revealing a relatively large number of illustrations that were not related to multiplication concepts. The task analysis revealed that of all multiplication tasks, only 25% incorporated a pictorial illustration, revealing a preponderance of symbolic problem presentations. Just over 55% of the illustrations were representational, meaning that only 14% of all tasks contained illustrations showing the structure of multiplication. Of all illustrations, 26% were not related to multiplication and used as a pictorial backdrop for a symbolic problem. Given the existing empirical evidence on pictorial illustrations supporting the understanding of multiplication (e.g., Jitendra et al., 2022), the small percentage of representational illustrations currently used in at least some popular Canadian textbooks is noteworthy. Future research should examine how the distributional frequencies of the different types of multiplication tasks with illustrations may influence student learning.

DEVELOPMENT OF SPATIAL REASONING AND COUNTING SKILLS THROUGH SCAFFOLDING IN A PROGRAMMING GAME

Abigail Erskine
Purdue University
aerskin@purdue.edu

Laura Bofferding
Purdue University
lbofferd@purdue.edu

This study investigates the development of spatial reasoning and counting skills in third-grade students through instructional scaffolding within a programming game. We focus on two pairs of students who engaged in the game Coding Awbie, using number and movement blocks to navigate a grid. Over six 30-minute sessions, qualitative analysis revealed challenges in counting within rows and columns, alongside effective use and potential misdirection caused by game scaffolds. Peers offered suggestions that partially alleviated scaffold-related difficulties. The study's findings illuminate the role and challenges of programming games as instructional tools in enhancing children's spatial cognition and numerical fluency.

Keywords: Number Concepts and Operations, Geometry and Spatial Reasoning, Computing and Coding, Problem Solving

There has been growing recognition of the importance of spatial reasoning and counting skills in children's mathematical development (Baroody & Wilkins, 1999; Battista et al., 1998; Owens, 2015; Siegler & Ramani, 2009). One avenue of exploration for supporting these skills lies in using instructional supports and scaffolding within programming games. Programming games offer a unique environment where children can engage in problem-solving activities that require spatial manipulation and numerical reasoning (Jiau et al., 2009; Ma et al., 2011). These games often embed scaffolds, supportive structures, or cues to assist learners in navigating challenges (Kim & Hannafin, 2011). However, the extent to which such scaffolds effectively facilitate the development of spatial reasoning and counting skills remains an area of inquiry.

Spatial Reasoning and Counting

Spatial development encompasses a child's ability to understand and navigate space (Clements & Sarama, 2009). These abilities are fundamental in mathematical problem-solving, providing the cognitive basis for concepts such as geometry, measurement, and spatial relationships (Mulligan, 2015). Spatial reasoning involves identifying and manipulating objects' spatial characteristics and relationships (Lowrie et al., 2016; Mulligan, 2015). Kocabas et al. (2022) noted that children commonly employ spatial connections to determine an object's location relative to reference points, utilizing mathematical cues like distance. Strategies for counting or adding distances can be either informal or formal, developing as children participate in mathematical tasks. A common problem seen in young learners in both programming and mathematics is the challenge of double counting, where pupils tend to count an object or space more than once (Kocabas et al., 2019; Fuson, 2012; Shumway et al., 2021). In the game used for this study, students have made double counting errors when the game character changed directions, and they counted a corner square twice (Kocabas et al., 2019). Although students have issues with double-counting, there is less detailed evidence on how they overcome their double-counting difficulties.

Theoretical Framework

According to Vygotsky (1978), children's cognitive development is intertwined with their social interactions and cultural context. In the context of programming games like Coding Awbie™, Vygotsky's theory suggests that collaborative peer interactions play a crucial role in how students interpret symbols within the game and respond to scaffolds provided by the game environment (Schunk, 2012). Additionally, Vygotsky's concept of the Zone of Proximal Development (ZPD) is highly relevant to understanding the role of scaffolding in facilitating learning (Vygotsky, 1978). Within the ZPD, students can complete tasks with the support of a more knowledgeable peer or instructor. The scaffolds provided in games, such as modeling, probing, and hints, serve to support students as they navigate the complexities of spatial reasoning and counting within the game environment (Wood et al., 1976; van de Pol et al., 2010).

This study adds to the literature by examining how instructional support and scaffolding within a programming game, Coding Awbie, play a role in third-grade students' spatial reasoning and counting skills. Drawing upon qualitative analysis of six sessions, this research investigates the challenges encountered by students and the efficacy of scaffolds in supporting their learning processes (Van de Pol et al., 2010; Wood et al., 1976). Therefore, we investigate the following research questions: (1) How do third graders utilize instructional scaffolding in developing spatial reasoning abilities? and (2) How do their use of scaffolds (highlighted path) in the game influence their counting and use of programming blocks?

Method

We recruited first and third-graders from a midwestern public elementary school in the US where 45% of students qualified for free and reduced lunch, and 11% were classified as English Language Learners. A total of 55 students, 28 first graders, and 27 third graders, participated. For this paper, we focus on two pairs of third graders: Emma and Quincy, Sophie and Marcus. In the game Coding Awbie, the objective is to move Awbie to gather strawberries while avoiding falling into the water, thereby advancing to the next level. Students use physical programming blocks to control Awbie's actions (walking, jumping, grabbing), direction (up, down, left, right), and number of movements (ranging from 1 to 5). When students place the blocks, with the initial command placed at the top, the screen highlights where the character would go based on the code, an important in-game scaffold. During their six game sessions, pairs played until the end of their 20-minute session. Upon completing a level, students advance to the subsequent one. If students did not complete a level during a session, they restarted it the following session.

Through analysis of video recordings and transcripts of peer conversations during sessions of playing Coding Awbie™, we examined how students used instructional supports and scaffolds within the game to coordinate movements, use numbers, and count spaces. We coded instances where students employed single blocks versus multiple blocks to denote movement, used addition to cover distances, and relied on movement blocks, hints, and highlighted paths. Furthermore, we observed whether students counted spaces manually or relied solely on the highlighted path feature. We analyzed cases where students' use of coding blocks interacted with peer dynamics and instructional supports. We documented changes in students' strategies and interactions, marking shifts in their use of numbers and counting methods, and delved into the spatial characteristics of the game during these transitional moments.

Findings

Using Highlighted Path, Board, and Explicit Hints

The game had hints that helped students to navigate the space with varying success. For instance, Sophie and Marcus thought the highlighted path coming out of trees meant their code would work, even though it had Awbie hitting trees, which did not work (see Figure 1, left). However, when they came to a board with a question mark that revealed an explicit hint, they matched their code to move Awbie accordingly (see Figure 1, right).

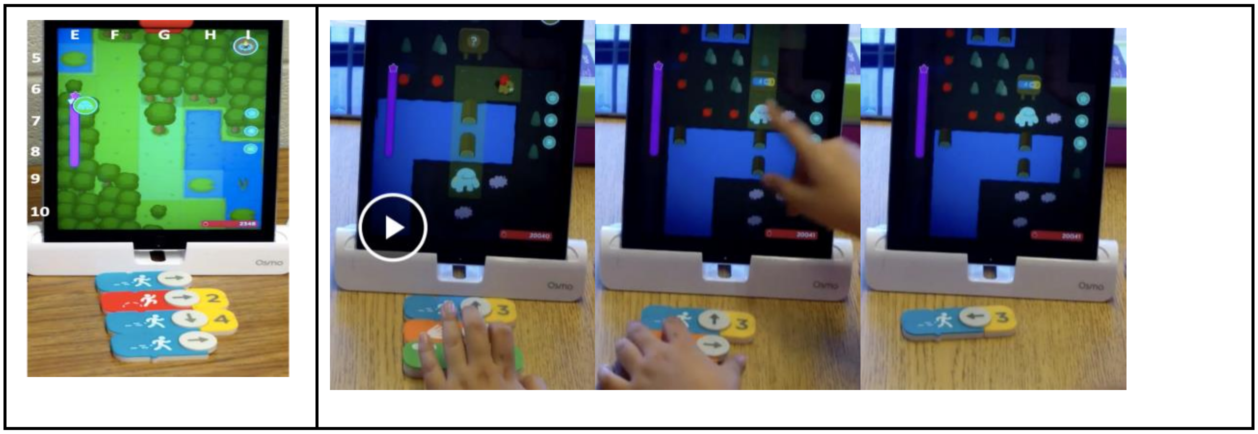

Figure 1: Highlighted Path into the Trees and Using Board Hints

In Emma and Quincy's second program, they traced the screen and used the highlighted path as a guide to check each block as they placed them (see Figure 2, left). Later, they received a hint from the game to guide Awbie off of a lilypad. However, instead of repeating the hint for the next, similar span, they omitted the *walk down 1* instruction and once more stopped on a lilypad.

Using Partners

There were times when partners helped each other. For example, Sophie struggled to understand the rows and columns despite correctly predicting a jump up two spaces from Q16 to Q12 (see Figure 2, left). She mistakenly thought their next move should be a *walk right one* space to Q11, but Marcus placed a *walk up one* instead. Despite Sophie's attempts to use jump blocks, Marcus intervened when she next tried to place *jump right two*, pointing out that it would lead Awbie into the water (on U11). Sophie tried placing two *jumps right one* blocks, but still faced the same challenges, prompting her to let Marcus take over. Quincy also helped Emma change her use of numbers so that Awbie would not jump into the water (see Figure 2, right).

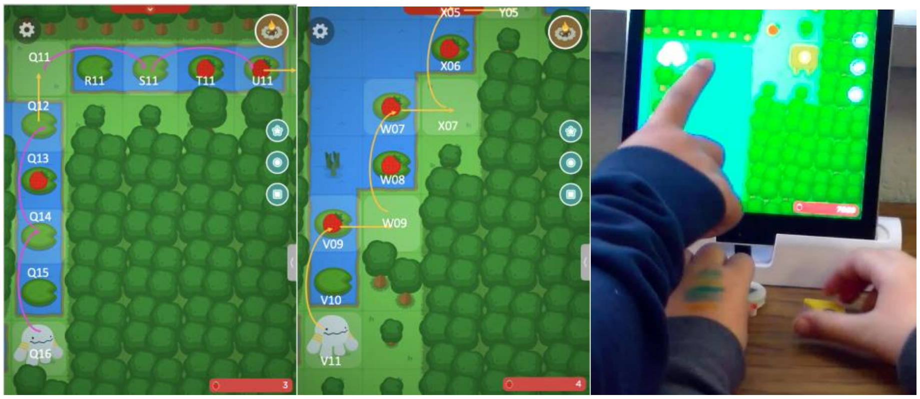

Figure 2: Partner Help and Use of Numbers

Use of numbers and counting

Sophie and Marcus's code to navigate Figure 2 (left) used patterns of numbers to make Awbie's movements through jumps very smooth (*jump up 2, walk up 1, jump right 2, walk right 1)*. As they encountered a new path layout, they strategically adapted their approach. They omitted the numbers, changed the walk direction (see Figure 2, middle) and retained the movement sequence (*jump up, walk right, jump up, walk right, jump up, walk right*).

Emma and Quincy struggled to coordinate their counting to match a lengthy, straight section of the path. Initially, they moved Awbie right twice, successfully reaching a strawberry, but Awbie stopped on a lilypad, causing him to fall into the water and return to his original spot. They adjusted and instructed Awbie to walk right five and three times. Once again, they found themselves on a lilypad with a strawberry, and Awbie fell into the water again. This sequence of events suggests that the duo's challenge might lie in their focus on reaching the next strawberry.

Discussion and Implication

In this study, we investigated the role of instructional support and scaffolding in the development of spatial reasoning and counting skills among third-grade students, focusing on the context of the programming game Coding Awbie^{TM}. Drawing upon Vygotsky's Sociocultural Theory and the concept of the ZPD, we explored how game scaffolds influenced students' spatial reasoning abilities. Our findings revealed that instructional scaffolding was vital in supporting students' spatial reasoning abilities. Through collaborative peer interactions and providing scaffolds such as modeling, probing, hints, and direction, students could navigate the complexities of spatial manipulation more effectively. These scaffolds served to bridge the gap between student's current level of understanding and the desired learning outcomes, facilitating their progression within their ZPD. The use of scaffolds, particularly the highlighted path feature in the game, had a significant impact on students' counting strategies and utilization of programming blocks. The highlighted path scaffold provided students with visual clues and guidance, helping them to overcome challenges related to double counting and spatial structuring. As a result, students demonstrated increased proficiency in spatial reasoning and counting skills throughout the study. The findings of this study have important implications for educational practice and research. Our results underscore the importance of incorporating instructional supports and scaffolding mechanisms into educational games and learning environments.

THE MERGING OF VIVIAN'S FRACTION WORLDS

Lucinda Ford
Texas State University
llf48@txstate.edu

Undergraduate developmental mathematics students' difficulties with fractions, a known gatekeeping topic for this demographic, are well documented. Yet, research on fraction understandings for this population is scarce. In this paper, I synthesize relevant literature regarding undergraduate developmental fraction understandings and related K–12 fraction literature. I then report preliminary findings from a teaching experiment that highlights part of the fraction journey of Vivian, an undergraduate developmental mathematics student, as she constructs an understanding of unit fractions. Vivian merges two separate, but equally valid, fraction worlds as she constructs a unit fraction understanding.

Keywords: Rational Numbers, Undergraduate Education

Many students experience difficulties when working with fractions, a gatekeeping topic for college-level mathematics courses (Mesa et al., 2014; Ngo, 2019). In this preliminary report, I share part of Vivian's journey as an undergraduate developmental mathematics student at a large research institution in the southern United States, as she merged the two fraction worlds she experienced, both of which she deemed as equally valid ways to view fractions. Vivian came to question her own thinking and merged these fraction worlds. This preliminary report comes from a larger dissertation study. I draw from data from a teaching experiment (TE) (Steffe & Thompson, 2000) with an initial task-based clinical interview (CI) (Ginsberg, 1997).

Literature Review and Theoretical Framework

Research on the fraction understandings of undergraduate developmental mathematics students is scarce (Alexander, 2013; Mesa et al., 2014). Studies involving the mathematical thinking of undergraduate developmental mathematics students builds on K–12 research since undergraduate developmental mathematics students study K–12 topics while being college students (Alexander, 2013). Fraction knowledge has been shown to function as a gatekeeper for algebra readiness, though further need for research has been suggested (Booth & Newton, 2012; Ngo, 2019; Siegler et al., 2012). In my study, I draw on the fraction literature of Lamon's (2020) fraction understandings and Steffe & Olive's (2010) fraction schemes.

For the purposes of my study, I define fractions as numbers written in the form of *a/b,* where a and b are not necessarily integers, such that b is not equal to zero (Lamon, 2020; Empson & Levi, 2011). Vivian's fraction story includes the way she understands unit fractions, or the unit of measure when a whole is partitioned into unit fractions. For example, $1/n$ is a unit fraction, where n is a natural number, for a whole that is partitioned into n segments (Hackenberg et al., 2016; Lamon, 2020; Steffe & Olive, 2010). Unit fractions can then be used as building blocks as they are iterated to create composite units (Steffe & Olive, 2010).

Methods

In this paper, I present data from a larger dissertation study. The overarching goal of the dissertation is to get a picture of the way the participant is currently understanding fractions using Lamon (2020) and Steffe & Olive (2010) and then to attempt to create an environment to foster the strengthening of the measurement understanding of fractions (Lamon, 2020). In this section, I will briefly explain TEs, CIs, and the methods used for this study.

Teaching Experiments and Clinical Interviews

A TE is a type of qualitative research that allows the teacher-researcher (TR) a way to have firsthand experience of their participant's mathematical learning and reasoning (Cobb & Steffe, 1983; Steffe & Thompson, 2000). TEs are composed of episodes using tasks designed to test hypotheses the TR has formed about their participant's thinking (Steffe & Thompson, 2000). In a TE, the TR seeks to create an environment to foster a change in thinking (Steffe & Thompson, 2000). But the TR does not assume they are the cause of thinking changes (Thompson, 1979). Thus, the construction of knowledge is the result of the participant's work. The witness's (WR) main job is to observe the interaction between the TR and the participant and may also suggest follow-up questions the TR may not think of (Steffe & Thompson, 2000; Steffe & Ulrich, 2020). The CI is a semi-structured interview that focuses on describing the participant's current thinking and reasoning (Ginsberg, 1997; Steffe & Thompson, 2000). Data for TEs comes from video recordings, the participant's written work, and any field notes taken (Cobb & Steffe, 1983; Steffe & Thompson, 2000; Steffe & Ulrich, 2020). Both ongoing analysis and retrospective analysis are utilized (Steffe & Thompson, 2000).

Participants, Data Collection, and Analysis for This Study

Vivian was recruited from a randomly selected undergraduate developmental mathematics class at a large research university in the southern United States. She participated in a CI that included 12 fraction tasks, divided among two 45-minute sessions. She continued into TE phase of the study, participating in six hour-long teaching episodes. Data was collected during the spring and fall semesters of 2023 in the form of video recordings, Vivian's written work, and field notes taken by the TR and WR. We filmed sessions with two cameras. The primary camera captured Vivian's written work. The secondary camera recorded the interactions between Vivian and the TR. Screen recordings were captured when Fraction Bars software was in use. Ongoing analysis took place during and after each session and retrospective analysis is still underway (Steffe & Thompson, 2000).

Results

I realized that Vivian viewed fractions as living in two different worlds during episodes 3 and 4 of the TE. Once viewed as equally valid, Vivian's and the teacher's worlds merged in episode 5. Note: 1/5 often refers to Vivian's thinking, not necessarily the normative meaning of a fifth.

Vivian's Two Worlds

Vivian demonstrated a discrete view of fractions during her CI. This was evident while sharing her understanding of 2/3, which she described 2/3 as being the majority of something (see Figure 1(a)). Vivian also drew discrete representations of 1/2 and 1/3 when comparing the two fractions during a number line task (see Figure 1(b)).

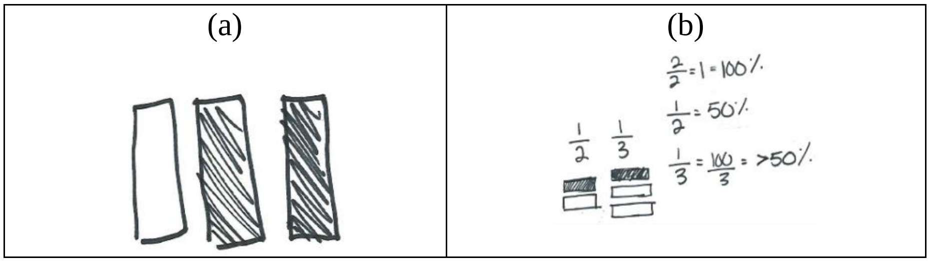

Figure 1: Vivian's representations of 2/3, 1/2, and 1/3 during her clinical interview.

The third teaching episode brought more insight into Vivian's view of unit fractions. Vivian was asked to cut 1/4 from each of four different sizes of rectangles. When explaining how she made 1/4, Vivian said, "It's folded and then folded again so you have four significant parts. I cut one off so that's one of four pieces." Vivian used the phrasings 1/4, "one fourth," and "one of four pieces" interchangeably during this session. Next Vivian was tasked with showing 1/5 using Fraction Bars software. The program had a split function to equipartition units automatically. However, Vivian chose to manually split the unit into five unequal pieces. Vivian pulled out two of her splits and said that each of these pieces was 1/5 (see Figure 2). She used the context of a farmer's field to explain that while the pieces were different sizes and that "one buyer needs to go look somewhere else, but these are both still one fifth." Vivian added, "Comparing this [top] slice of land to this [second from bottom] slice of land, this buyer is getting a lot more land for the same fraction." In short, for Vivian, the size of the piece did not seem to matter.

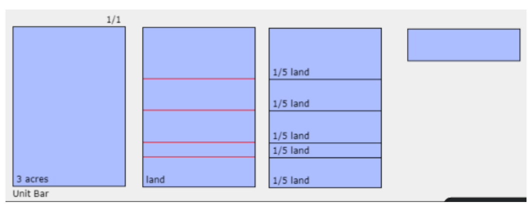

Figure 2: Vivian splits the land into fifths.

However, it wasn't until the fourth teaching episode that I became aware of Vivian's two fraction worlds. When revisiting our task to cut off 1/4 of a paper rectangle, Vivian showed two different ways of finding the 1/4 (see Figure 3). After creating different fourths, Vivian shared that the paper shown in Figure 3(a) is "more precise" than the one in Figure 3(b), saying, "one is bigger than the other so they can't both be 1/4 on a test." Vivian described a teacher's fraction world where it would be incorrect to call both 1/4. Vivian also shared that there were other situations where her folded "fourth" would still be one fourth since there were four pieces using paper folding (see Figure 3(b)). In Vivian's eyes, one section in each figure was equivalently 1/4, even though she recognized that a teacher would view them differently. Vivian later created a farmer's field, where each section was "one fourth but a different size" (see Figure 3(c)). She then defined 1/4 as "an obvious portion because each section is one of four pieces," adding a caveat that the meaning of 1/4 would change if you add in measurements. Vivian focused on the number of pieces in the whole to determine the unit fraction, but not the visual size of the part.

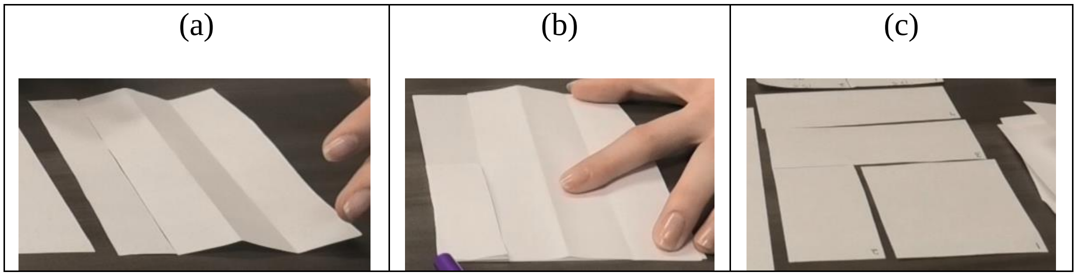

Figure 3: Vivian shows various ways to make a fourth.

Reconciling Two Worlds into One

Near the end of episode 4, Vivian was asked again about whether sections 2 and 3 of Figure 3(c) were still 1/4. Vivian responded, “Yes but no,” since they were each one of four pieces but had different areas. We picked up this line of thinking in episode 5 using Fraction Bars. Taking a cue from Vivian, the first task of the day used the context of a farmer fairly dividing a field for their children to use as they see fit. This scenario was used for three and then five children. Using program functions, Vivian automatically split the field into thirds but manually split the field into fifths (see Figure 4(a)). The WR asked Vivian how many copies she would need to make of one of her fifths to show that a split was really 1/5. Vivian chose one of her fifths and stated that she would need at least five copies to check if it was 1/5 (see Figure 4(b)). Vivian also acknowledged that the computer could have done a better job than she did in splitting the whole. However, she still viewed each split as 1/5 regardless of the method used in the process. Vivian questioned whether her perspective is valid, saying,

> If we’re just gonna take one of the one-fifths, which it happens to be smaller than the other one-fifths, then I don’t think on its own it would be able to create perfectly the pink again if we were to copy it a bunch of times. But does that mean that it’s not one fifth anymore?

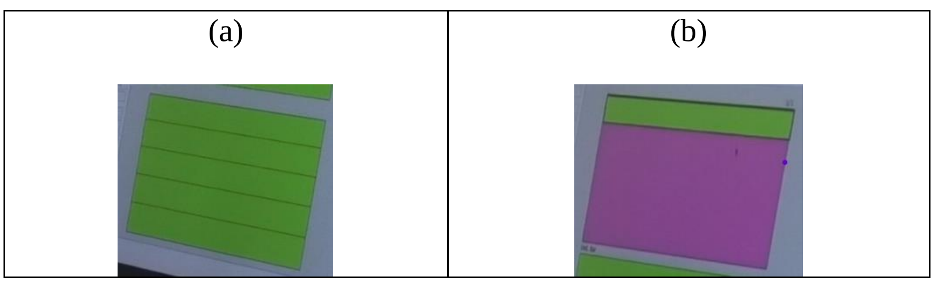

Figure 4: Vivian (a) splits a "field" into fifths and (b) checks if a split is really 1/5.

When asked what she thought, Vivian responded that she did not know, adding, “This whole time I’ve been thinking that this is still a piece of the whole. But if the piece by itself, copied, can’t make up the whole, is it the correct fraction?” We changed the language in our sessions to distinguish between pieces of the whole and fractions. The session continued with creating wholes and splitting them to find various unit fractions. This unit fraction was copied to create the requested fraction of the whole. When checking her work for 5/7, Vivian demonstrated that she needed five copies of 1/7, which could come from any 1/7 of the unit. She also recognized that it took seven copies of the same size pieces of 1/7 to get to the whole.

Discussion

Vivian had a system of working with fractions from the beginning of our time meeting together. This system, which reminded me of Erlwanger's (1973) Benny, included understanding unit fractions as one of *n* pieces. During the fourth episode, Vivian spontaneously started labeling one of her farmer's fields with sided lengths, areas, and perimeters as she showed different ways to find 1/4. It was during this task that Vivian may have begun to realize that the areas need to be the same for unit fractions to be equivalent. This is suggested in her "Yes but no" response to deciding if two different pieces out of 4 were both 1/4.

During episode 4, Vivian stated "The whole is easier to understand when the pieces are the same." However, it wasn't until Vivian was asked if it was important for all the pieces to have the same size to be a fraction that she expressed her question about if her fifth was really 1/5. Vivian's recognizing that 5/7 is five copies of 1/7, using copies from any 1/7, provides evidence that she had established a unit fraction understanding consistent with Seffe & Olive (2010).

Keywords: Technology, Middle School Education, Rational Numbers and Proportional Reasoning

Engaging students in mathematical practices such as collaborative problem-solving, justification, and explanation has long been accepted as beneficial for student learning (Staples, 2007; Stein, Engle, Smith, & Hughes, 2007) As the presence of technology in classrooms continues to grow, students are asked to explain their mathematical ideas through typing and digital tools that can be easily shared and saved (Engelbrecht, Llinares, & Borba, 2020; Thomas & Palmer, 2014). The increased prevalence of student explanations in digital form can offer new opportunities for teachers and students (e.g. the ability to edit/revise explanations, increased access to student work for teachers), but can also provide increased insight into student thinking over time for researchers and teacher educators. Large databases of students' typed explanations have been used to develop machine learning-algorithms to provide feedback to students on isolated items in science education research (Shin & Shim, 2021), yet we know less about student mathematical explanations and how they develop over time and across contexts. Further, students' use of proportional reasoning to make sense of our world does not receive enough attention across different mathematical contexts.

In our analysis of students' digital explanations, we draw from larger design-based research to develop a digital collaborative platform for students and teachers, which allowed students to collaborate with peers and type explanations across multiple connected units of a problem-based curriculum. This research is guided by the following research questions: 1) *What are the characteristics of middle-grades students' digital mathematical explanations of proportional reasoning?* and 2) *How do middle grades students' digital explanations develop across mathematical contexts?* The primary data source is a large database of student written responses to mathematical problems across three curricular units focused on proportional reasoning, created from log files of student actions in the digital platform. We use learning analytics methods (e.g. text-mining) to identify key words of student written text describing proportional reasoning, as well as how characteristics of student explanations (e.g., length, mathematical focus) might change across number and operations, geometry, and algebra/functions contexts. Secondary data include classroom observations and teacher interview recordings to identify larger trends and themes in the students' digital explanations across units. Findings will provide insights into the nature and development of student proportional reasoning, and how teachers can support deep and flexible ways of knowing. Our analysis and findings provide insight into how students communicate their mathematical thinking and understanding, a critical perspective in technology design and the development of machine-learning algorithms for feedback/assessment.

A Visual Approach to Developing Fluency with Multiplication Facts

Dr. Gina Kling
Hope College
kling@hope.edu

Dr. Kate Kline
Western Michigan University
Kate.kline@wmich.edu

The purpose of this study was to determine if visual imagery in the form of Quick Looks could promote the development of multiplication fact reasoning strategies. It was conducted from August to March during one school year and involved three experimental third-grade classrooms who received instruction using visual images. Corresponding control classrooms from the same schools received instruction from the district-adopted curriculum. Using a mixed-methods design, students from experimental and control classrooms were compared with respect to progress towards fact fluency and overall multiplicative understanding. Analysis revealed that the experimental group made statistically greater gains, suggesting that image-based instruction may encourage greater progress towards multiplication fact fluency.

Keywords: number concepts and operations, elementary school education, curriculum

The learning of basic facts, or sums and products of numbers 0-10 and their related differences and quotients, has always been a high priority for elementary school teachers. These early skills form a necessary and significant component of a student's procedural fluency, or "skill in carrying out procedures flexibly, accurately, efficiently, and appropriately" (National Research Council, 2001, p. 5). Although fluency with basic facts functions as a gateway for future mathematical success, "many educators find that children, even in the upper grades, continue to draw tally marks and count by ones as their dominant solution approach in solving problems" (National Council of Teachers of Mathematics [NCTM], 2020, p. 82).

In attempts to address this issue, numerous research studies (e.g., Brendefur et al., 2015; Cook & Dossey, 1992; Thornton, 1978) have established that multiplication facts instruction that is based on students developing reasoning strategies as opposed to rote memorization of isolated facts produced significantly higher levels of fluency. In their study, Brendefur et al. (2015) utilized a cognitive framework focused on Bruner's Three Modes of Representation (1966). Students first explored multiplication strategies with hands-on activities (enactive), then through pictures (iconic), and finally, with number sentences and words alone (symbolic). The idea of using representation to scaffold strategy development also aligns with recent research on the importance of visual imagery. For example, Park and Brannon (2013) found that individuals who were given frequent opportunities to compare approximate sums and differences of dot patterns (i.e., using approximation to determine if the sum of the dots on two arrays is greater or less than the dots on a third array) showed statistically significant growth in their symbolic computational abilities as compared to control groups. They note the results "strongly corroborate the proposition that nonsymbolic-arithmetic ability and symbolic-math ability share cognitive foundations" (p. 2017). Thus activating both visual and symbolic thinking simultaneously during instruction may have promise for enhanced fluency development.

Our study attempted to build upon these findings to explore the use of visual imagery as a means of motivating multiplication fact strategies with third grade students. More specifically, the study utilized dot patterns in equal group or array formations that were shown for 2-3 seconds followed by students sharing how many dots they saw and how they saw it. This "Quick Look" routine utilized carefully designed and sometimes sequenced images as shown in Figure 1 so that key multiplication fact strategies were likely to naturally emerge.

Strategy	Image 1	Image 2	Symbolic Representation of the Strategy
Doubling			4 x 7 = ? If I already know 2 × 7 = 14, I double to get 4 x 7 = 28.
Subtracting a Group			9 x 4 = ? If I know 10 x 4 = 40, then I subtract one group of 4 to get 40 – 4 = 36.

Figure 1: Quick Look Activities: Sequencing Images to Encourage Strategy Development

The purpose of this study was to examine the results of using an enhanced and deliberate collection of lessons with visual imagery in a Quick Look format. This involved a comparison between classrooms who received the Quick Look treatment and those who utilized the existing curriculum. The following research questions involved these ideas and were used to guide the study: 1) Is there a difference in fluency obtained by students who engage in visual imagery activities as compared to students who do not receive this instruction? and 2) Is there a difference in multiplicative understanding obtained by students who engage in visual imagery activities as compared to students who do not receive this instruction?

Theoretical Frameworks

This study drew from various areas of research, including intuitive multiplicative concepts, fact fluency development, and visual mathematics, and thus was grounded in several theoretical frameworks. Various researchers (e.g., Clark & Kamii, 1996; Mulligan & Mitchelmore, 1997; Wright et al., 2012) have developed similar trajectories for classifying intuitive models of multiplication. One limitation of these trajectories is that their levels often differentiated various counting-based methods, such as unitary counting, rhythmic counting, and skip counting, but combined reasoning strategies and recall into a single level. A more nuanced framework was required for the purposes of this study, leading to the development of the Multiplicative Understanding Levels (MUL) shown in Table 1.

Table 1: Sample Codes for Multiplicative Understanding Level (MUL)

Level	Description	Code
Numerical Composite	Counting by 1s using unitary or rhythmic counting	UC or RC
Abstract Composite Unit	Skip counting or repeated addition	SC or RA

Emergent Composite Unit of Composite Units	Recognizes the opportunity to apply a strategy but unable to successfully execute	ECU
Facile Composite Unit of Composite Units	Successfully implements the strategy	FCU

In particular, the distinction between the Emergent Composite Unit of Composite Units (ECU) and Facile Composite Unit of Composite Unit (FCU) levels was not incorporated in any of the previous studies on which this framework was based, but was used in our study to capture the subtle differences in how students make sense of and develop proficiency with fact strategies. For example, if asked to provide a strategy to solve 6 x 8, a student at ECU might just identify 5 x 8 as a viable helper fact but then not know how to proceed, where as a student at FCU could complete the strategy: 5 x 8 + 8 = 48.

While the MUL framework was utilized to capture multiplicative understanding, a three-phase framework adapted from Baroody et al. (2003, 2006, 2009) was used to provide a measure of overall progress towards fact mastery. With respect to multiplication, Phase 1 incorporates any methods that rely on unitary counting, rhythmic counting, or skip counting. In contrast, Phase 2 involves reasoning strategies based on known facts. Phase 3, the Mastery Phase, is reached when children can quickly generate an answer for a fact either through recall or highly efficient strategy application. These two frameworks were useful for measuring student understanding and fluency growth, but Bruner's Modes of Representation (1966) drove instructional design. In particular, our study focused on using discussion of Quick Look images to bridge iconic and symbolic thought as shown in Figure 1. An integration of these theoretical perspectives led to a grounded supposition that attaining a complete concept of multiplication, as well as attaining basic fact mastery, requires students to be able to operate in the symbolic mode with ease. Thus, frequently recording student thinking in words and symbols as they explained how they made sense of the images was an important part of the intervention, facilitating the eventual fading of the iconic as students transitioned to mainly symbolic work (Fyfe & Nathan, 2019).

Methodology

The study took place in three rural/suburban schools in Southwest Michigan, USA, from August to March of one school year. Each school contained one experimental classroom and one or two control classrooms with a total of 26 experimental and 25 control students. The intervention consisted of six experimental lessons taught by Kling that each utilized discussion around 4-6 purposefully sequenced Quick Look images, followed by a written partner activity. These lessons replaced existing lessons with the same objectives from the regular curriculum used in the control classrooms, which primarily used number stories to motivate multiplication fact strategies. There were no other differences in instruction between the control and experimental groups aside from expected natural variation due to different classroom teachers.

Data collection utilized five semi-structured interviews conducted throughout the school year, including a pre-assessment interview at the beginning of the year and interviews following Lessons 1, 3, 5, and 6. The pre-assessment interview included addition and subtraction facts and served as a baseline measure to establish comparability of groups. Interviews 2-5 used a semi-structured protocol consisting of seven bare numeral multiplication facts and one open response task. For the bare numeral tasks, students were asked to explain how they figured each one out, regardless of the speed or accuracy with which they answered. This allowed for both the phase and strategy to be recorded. The recorded phase (1, 2, 3) was combined with a 1 if correct for a total fluency score of up to 4 points per bare numeral fact, 28 points per interview. Mean scores were compared to determine statistically significant differences. The open response tasks prompted students to interpret or apply particular strategies and were coded qualitatively based on MUL. For example, Interview 4 contained the following open response task: *How could you use doubling to help you to figure out 8 × 4? Can you solve it a different way now?*

Results

The first research question explored differences in levels of fluency obtained by experimental and control students. Mean scores for the seven bare numeral items on Interviews 2-5 were compared. Steady gains were made by the experimental group while the control group fluctuated, culminating in the experimental group demonstrating a statistically higher fluency level ($p = 0.047$, $\alpha = 0.05$) on the final interview conducted in March. Furthermore, 77.5% of the tasks were answered by the experimental group using either a strategy or recall (Phase 2 or 3), compared to only 63.4% by the control group, for whom the second most common approach across the tasks was unitary counting (Phase 1). Proportion testing on these results found the experimental group scored statistically higher at the $\alpha = 0.05$ level ($p = .002$). Thus, it is possible that the intervention was more successful in encouraging movement away from counting to the development of reasoning strategies and higher levels of fluency.

The second research question explored differences in multiplicative understanding and thus called for a qualitative approach. Interview open response items were coded for MUL using the coding scheme shown in Table 1, with a particular focus on emergent and facile composite unit of composite units thinking (ECU and FCU) as both were indications of movement towards strategy acquisition. An examination of Table 2 shows that the control classrooms generally had a sizable portion still in ECU, indicating incomplete strategy development. However, when examining FCU, results favored the experimental group as they had statistically higher proportions of FCU on Interviews 2, 3, and 5 (p values shown for FCU only).

Table 2: Summary of MUL Codes: Interview Open Response Tasks

		ECU	FCU	p value
Interview 2	Experimental	3.8%	38.5%	0.036
	Control	12.0%	16.0%	
Interview 3	Experimental	26.9%	50.0%	0.013
	Control	40.0%	20.0%	
Interview 4	Experimental	11.5%	73.1%	0.060
	Control	20.0%	52.0%	
Interview 5	Experimental	0%	73.1%	0.004
	Control	20.0%	36.0%	

Discussion and Conclusion

The purpose of this study was to determine if the intentional design and use of visual imagery in the form of Quick Looks could promote multiplication fact strategy acquisition and fluency development. As summarized above, there were several indicators that the intervention was in fact successful in doing so. This adds to the research on the importance of visual mathematics for learning (Boaler et al., 2016). Visual imagery has promise perhaps because it is accessible to a wide variety of students; even students who are still in the counting phase can make sense of the images and the class sharing of strategies may help provide them with efficient alternatives to adopt in the future. Furthermore, the deliberate connections made between the images (iconic) and symbolic expressions used to represent student thinking during class discussion of the images may have helped promote a deeper understanding of the multiplication reasoning strategies developed in the lessons as well as more flexibility in working simultaneously within each mode of representation. Visual imagery, in the form of Quick Looks, may provide a much-needed pathway for all students to achieve the lasting and meaningful fact fluency necessary for future mathematical success.

ANALYSIS OF STUDENT'S REASONING ON FRACTIONS FROM A VIDEO GAME WITH A COORDINATION CLASS

Boram Lee
University of Texas at Austin
boram_lee@utexas.edu

Given that previous studies about video games and students' math learning focus on the quantitative aspect of students' learning (e.g., post-test scores), this research applies a coordination class from the Knowledge in Pieces framework in order to analyze fine pieces that emerge in students' reasoning around fractions in the context of a video game. This study analyzed one student's reasoning around fractions emerging during the interview about his gameplay. The analysis shows that rich inferences around fractions get activated in different contexts and how unrecognizably the inferences the student employs in each context shift and mix up with other inferences. In order to support students to expand their intuitive understanding of fractions into a more systematic understanding, the rich inferences from students' intuitive reasoning need to be incorporated into instructions on fractions.

Keywords: Rational numbers, Cognition, Elementary school education

Previous studies have demonstrated positive impacts of video games on students' mathematics learning by showing improved post-test scores (Braithwaite, & Siegler, 2020; Denham, 2015; Hulse et al., 2019; Ke, 2008a, 2008b; Kim & Ke, 2017; Litster & Moyer-Packenham, 2020; Liu et al., 2017; Moyer-Packenham et al., 2020; Vogel et al., 2006). It is surprising, however, that few studies analyze any qualitative changes in students' mathematical reasoning emerging during gameplay. Hence, this study proposes to design a math video game around fractions and to conduct a qualitative analysis on students' reasoning about fractions emerging from gameplay with a coordination class theory.

Literature Review

Researchers analyzed rational numbers into several sub-constructs (e.g., Kieren (1980) : part-whole, measure, quotient, ratio and operator, Behr et al. (1992) : part-whole, quotient, and operator) and the subconstructs have been applied in previous studies (Cramer et al., 2019; Lopez-Martin et al., 2022; Moyo & Machaba, 2021; Witherspoon, 2019; Wood et al., 2013). The various facets of rational numbers can be approached with the Knowledge in Pieces (KiP) framework (diSessa, 2002). Knowledge of rational numbers can be framed as a complex knowledge system that consists of various knowledge pieces of different types. Among the possible knowledge types in the system of rational numbers, this study approaches the subconstructs of rational numbers as a coordination class (diSessa & Sherin, 1998; diSessa & Wagner, 2005; Levrini & diSessa, 2008).

Coordination class theory

diSessa and Sherin (1998) introduce a coordination class as one type of knowledge pieces as "systematically connected ways of getting information from the world (p.1171)". There are two sub-classes in a coordination class. The one sub-class of a coordination class is called **extractions**. One example shared by diSessa (2004) is that we notice that an object is bigger or smaller than another object and that the information of size difference relates to mass. The other sub-class of a coordination class is **inferential net**, which is “the set of all possible inferences that lead to determining the relevant information (diSessa, 2004, p.141)”. A specific collection of parts of a full coordination class activated in a specific context is **concept projection**.

For example, let’s say there is a circle that is divided into four equal parts and two of the four parts are shaded. One student might attend to that the four parts are all equal size and only two parts are shaded, which are extractions. The student would coordinate the two extractions with inferences such as ‘the one circle is a whole’ and ‘two shaded parts of the four parts can be represented with fractions.’ These are the inferences that the student projected at the moment from the inferential net of a coordination class of fractions. The student would get to a determining information that the two parts represent $\frac{2}{4}$. The two extractions and the two inferences are one concept projection of a coordination class of fractions by the student in this context with a circle representation. All processes from extractions to information determining about the context from an inferential net are called as **readout** (for more details, see diSessa et al., 2016).

As students accumulate experiences where they apply a coordination class in various contexts, the **span** of the coordination class gets extended. As students construct more expert-like knowledge system by extending the span of a coordination class, they will come to conclude the same valid interpretation of a coordination class across contexts, which is **alignment**. (for more details, see Levrini & diSessa, 2008; diSessa & Wagner, 2005).

Reapproach fractions as part-whole with a coordination class theory

Behr et al. (1992) introduce two interpretations of the part-whole construct: parts of a whole and a composite part of a whole in both continuous quantity and discrete quantity. Behr et al. (1983) analyze children’s reasoning related to the two interpretations with a circle representation and categorize students’ reasoning around fractions into three levels based on whether students can or cannot label each part of the circle with both names. It is not enough, however, to categorize at which level students’ understanding on fractions as part-whole is in terms of why some students can label a given representation with two labels but other cannot, and in what ways students come to be able to label the representation with both labels in what contexts. It is worth analyzing the information students attend to and the inferences they coordinate with when interpreting fractions as part-whole in different contexts beyond just categorizing students’ understanding about fractions as a part-whole into a few levels.

Video games in elementary math education

In this research, math video games refer to games whose designs and goals focus on supporting students to have a designed experience (Squire, 2006) around mathematical concepts introduced in school mathematics (Braithwaite, & Siegler, 2020; Denham, 2015; Hulse et al., 2019; Kim & Ke, 2017; Litster & Moyer-Packenham, 2020; Liu et al., 2017; Moyer-Packenham et al., 2020; Vogel et al., 2006). Even though many studies show that video games are effective for students’ math learning quantitatively (Karki et al., 2022; Kiili et al., 2018; Tsai & Yen, 2016; Zhang et al., 2019), it has not been uncovered enough in terms of what happens in students’ reasoning behind their post-test scores. Given that there is a lack of a qualitative analysis around students’ reasoning around fractions in the context of video math games, this study conducted a qualitative analysis applying a coordination class theory within the Knowledge in pieces framework to focus on small knowledge pieces and coordination that emerge from the process of students' reasoning around fractions in a video math game context.

Methods

This method section is based on the Knowledge Analysis (KA) methodological framework suggested by diSessa et al. (2016).

Empirical set-up

1. Based on the definition of a video-based game as a designed experience (Squire, 2006) delivered on digital devices (e.g., tablets, computers or consoles, etc.) with openness to various ways to achieve game goals, the researcher designed and developed one math video game, Bridge the Cloud, with a Unity 3D game engine. (For more information about the game, please try the game here using a Chrome browser). In the game, players need to make clouds at different locations in order to block stones falling from the sky. To make clouds at position players want, players need to use different numbers for denominator and numerator (Figure 1).

Figure 1: Screenshots of the game, Bridge the Cloud

2. In each 1-hour game session, a student played the game on a given android tablet device for the first 30 minutes while the researcher sat next to the student. The gameplay was recorded using the screen recorder function of the tablet device. For the next 30 minutes, the researcher interviewed the student and asked questions about the student's gameplay. The entire game session was recorded with two camcorders.

3. One 4th-grade student, Jason (pseudonym) was recruited for this study at one public charter school in the southern US and total 10 game sessions (one game session per week) were held in one classroom at the school.

Capture and Reduction

The focus of this study is to observe extractions and inferences, if any, that emerge in students' reasoning around fractions. To serve the purpose, an interview format was chosen because an interview allows researchers to ask additional questions to students about their reasoning. All verbal expressions, written expressions, and gestures were included in the analysis. All the interview sessions were transcribed to capture verbal expressions. Written expressions and gestures that were made along with verbal expressions were documented in transcripts. Verbal and written expressions and gestures were coded as a chunk around a specific reasoning of the student. In the next phase of coding, specific information that the student extracted and inferences with which the student coordinated the information were analyzed.

Results

Unrecognized shifts among inferences related to one whole and one-unit length

When Jason shared his thinking about how the green numbers (numerator) and the blue numbers (denominator) work in the game, the concept of a whole emerged in his reasoning. However, what he referred to as a whole changes quickly and even unconsciously, and a concept of a unit is entangled in his projected concept of a whole. The excerpt in Table 1 shows his reasoning about a whole.

Table 1: Interview excerpt from the 2^{nd} interview session on Sep 15^{th}, 2023

J : Jason & R :Researcher 2^{nd} interview 06:33- 11:28 on Sep 15^{th}	
R: What do you think 3 green and 2 blue are doing here (Picture **A**)? J: Hmm…What do you mean? R: Now, in this box, there is 2 in the blue box and 3 in the green box and the cloud is here (3/2), what do you think this blue 2 and green 3 are doing here? J: hmm. I think ,, what they are supposed to do? Like green makes it longer and blue makes it shorter?	Picture A 
R: I mean blue makes it shorter and green makes it longer right? But why the cloud is here (3/2) not here (pointing at near 1 – left red circle in Picture B) or there (pointing at near 2 – right red circle in Picture **B**) ? J: Because I put 3, and then put 2 in the blue and then that subtracts half the line, I guess? Yeah, half of the line which makes it to going that B: Half of the line... what line? J: This is the whole line (pointing at the one green stick)	Picture B  Picture C Picture D 
B: Wait, you mean this line (one green stick – Picture **C**) or this whole line (the whole number line – Picture **D**)?	J: This line (one green stick from 0 to 1- Picture **E**), that's the whole line, and then if you're subtracting 2 from that line	Picture E 
This shows that the inferences Jason projects in each contextuality shift unrecognizably. When firstly asked what green number 3 and blue number 2 were doing in the given game context, Jason appeared to extract the information that the length of the stick changes with the input of green 3 and blue 2 and he concluded that the cloud was made at the current position because it is half of *the line*. However, when explicitly asked what the line he referred to right after he said half of the line, he suddenly pointed at the line from 0 to 1. At this moment, he appeared to be cued with another inference that a whole means 1 on the number line.

Fractions as both a whole quantity and a selected quantity present

When Jason explained about one-third shown up in the game, he kept explaining a one-third as one selected part among three equal parts that are present at the same time in one whole. So, when he explained one-third of the stick in the game, he brought up that the two other parts were subtracted. This shows that when Jason projected a coordination class of fractions as a part-whole, an inference got activated that a fraction, such as 1/3, represents cardinality contexts involving both a whole evenly divided into three parts and one selected part among the three parts. Wood et al. (2013) showed that students' understanding of fractions includes an operation of removal in addition to equal dividing but did not address why students come to include the subtraction operation in their reasoning. This analysis suggests one possible explanation; if students utilize an inference that fractions represent cardinality contexts where both a whole partitioned into *n* parts and *m* selected parts of *n* parts are present, this inference would lead them to focus on explaining that the *n-m* parts are gone so that they can make sense of why only *m* parts are left.

Discussion and Conclusion

The analysis results highlight that when a student interprets fractions in the specific video game context, how momentarily the inferences one employs in each context shifts unrecognizably. By approaching fractions as a coordination class, small, but rich, inferences that students use or get cued by contextuality can be uncovered. Based on the inferences from students' reasoning, we can figure out what instructional supports students need in order to expand their intuitive understanding of fractions into a more systematic understanding.

The research base remains unfinished when considering how students with specific learning differences develop an understanding of part-whole number knowledge, then leverage it for fraction knowledge. From a conceptual analysis of two students' engagement with six task-based interviews, we provide insight into distinct nuances in each student's partitioning and iterating with whole number and fraction development. Findings indicate students had very different strategies and approaches to their part-whole number strategies, allowing the teacher-researchers very different conceptual resources to consider when leveraging their strengths throughout the study. Implications of these findings suggest an asset-based lens provides all students' equitable opportunities for mathematics learning.

Keywords: Students with Disabilities, Number Concepts and Operations, Rational Numbers.

The research base remains unfinished for students with learning differences, specifically students with learning disabilities and other health impairments, develop an understanding of part-whole number knowledge. Moreover, it is not yet known how students with learning differences leverage their part-whole knowledge for fraction knowledge, and what features of their diverse experiential and cognitive backgrounds (e.g., working memory or processing differences) might interact with their development (e.g., Hunt et al., 2016; Hunt & Tzur, 2017). Current research efforts document elements of students' diverse cognitive backgrounds thought to interplay with students' mathematical learning from an early point in their lives (Compton et al., 2012). These factors are then used to explain learning differences as variations in certain norms that predict performance over time (Vukovic, 2012). This approach to designing intervention has gained much knowledge over the years, yet there is still a great deal of opportunity for improvement. Here we examine how two third grade students with learning differences construct their whole number understandings in relation to their fraction understandings. We expect to provide insight into the conceptual resources students with learning differences enact as they leverage their whole number knowledge for their fraction knowledge development.

Theoretical Framework

The authors of this study frame this work by examining learning patterns in children's part-whole number and fraction understandings, using theoretical account of units construction and coordination (e.g., Hackenberg & Sevinc, 2024; Steffe, 2024; Steffe & Cobb, 1988; Steffe & Olive, 2010). We define *a unit* as a perceptual chunk, sometimes conceptualized as a discrete "one" or a continuous length (Hackenberg & Sevinc, 2024). Steffe and Cobb (1988) described children's construction of pre-arithmetic units through their development of number sequences; they explain counting activity as a means of developing sequential schemes for additive operations with number. Once children internalize their number sequence, they are capable of partitioning number sequences and using counting-on instead of recounting all (e.g., three more than six is seven, eight, nine). This is also described as development of *numerical composites*, meaning students can solve tasks requiring one numerical unit grounded in their number sequence (Steffe, 1994). Once children construct and count with abstract units, they are described as having *one-level of units interiorized*. One-level of units interiorized allows students access to *two-level units with one unit developed in activity* because students can actively distribute the elements of one unit across the elements of a second unit (described as part-whole number understandings, see below for details). Part-whole number understandings would require students to have *two-levels of units interiorized*, freeing up their working memory to attend to pre-arithmetic units in activity. Once a student constructs two-levels of units interiorized they have an assimilatory structure of unitary items embedded in composite units (Steffe, 2024).

Part-whole number understandings is a pervasive issue affecting many elementary mathematics students with learning differences (Landerl et al., 2004; Vukovic, 2012). We define part-whole number understandings as the development of students' understanding of numbers as part of a sequence (i.e., 1, 2, 3, 4, 5) and part of a unit (i.e., 2 and 3 compose 5) in such a way where a number becomes a coordination of counting and grouping operations (Piaget, 1968/1970). When a student solves the problem "How many threes in twelve?" one strategy may be to verbally count, "one, two, THREE (puts up one finger), four, five, SIX (puts up a second finger) …4 times" (Ulrich, 2016, p. 2). This "double counting" technique, involving counting each set of three as 1 group, is an application of internalized part-whole operations, as the parts (one, two, THREE and 4 sets of 3) are operated upon within the whole (12). If students require a sequential recounting of the 12 counters to find the total of 3 sets of 4, we describe that as a less sophisticated part-whole operation.

Fraction understandings are also framed, in part, with units coordination theories providing insight into students' earliest activity when constructing part-whole fraction and fractions as a form of measure understandings (e.g., Hunt et al., 2016; Steffe & Olive, 2010; Wilkins & Norton, 2017). Steffe and Olive delineate students' fraction development as a process of units coordination to characterize varying degrees of sophistication in students' scheme development. Steffe and Olive's work provided insight into students' operations when transitioning from fractions conceived in a part-whole manner versus measurement fractions. Hunt and colleagues provided insight about fraction development among students with learning differences and learning disabilities; they explained why early operations (e.g., partitioning) can range so widely between individual students. We focus next on the wide-ranging scheme development and look at implications for transitioning from whole number schemes to fraction schemes.

Students with learning differences often develop less sophisticated double counting strategies when understanding part-whole number operations (Landerl, Bevan, & Butterworth, 2004; Vukovic, 2012). Nevertheless, these are meaningful and comprehensive counting strategies. In schooling experiences, students with learning differences often need additional support to elicit their conceptual knowledge of part-whole operations from earlier grades; such knowledge is critical as they work to establish part-whole number understandings for numerical computation in upper grades (Butterworth, 2011). The research literature has described the development of number understanding and computational skills among students with learning differences in very different ways than for their more successful counterparts (Lambert & Tan, 2017). In contrast to these patterns of deficit comparison in the literature, we adopt an asset-based lens by identifying and elaborating upon the meaningful activity and scheme development that can allow for a productive bridge from whole number concepts and operations to fraction concepts and operations.

Methodology

Part of a larger pilot study, this paper describes qualitative data from two students, Dalton and Angela, each receiving specialized services for their mathematical learning needs. Dalton and Angela were enrolled in a small rural school in the midwestern portion of the United States. We engaged each student at their participating school in six task-based sessions: three whole number and three fraction task-based interviews. The first and second author worked with the students individually and, at one point, jointly with both students. Excerpts in this manuscript indicate the student by their pseudonym, "Dalton" or "Angela", and the Researcher as "R". We adapted Wright, Ellemor-Collins, and Tabor's (2012) number tasks (interviews one, two, and three) and Hunt and colleagues (2016, 2017) fraction tasks (interviews four, five, and six). After each interview, we transcribed data, conceptually analyzed it, and adapted the subsequent tasks in response to what we understood about the students' scheme development and their interpretation of each task. Conceptual analysis included reviewing the transcripts and identifying the conceptual resources we could attribute to each student based on their verbal interactions, their use of figural representations and their gestures as they engaged in tasks.

Findings

Whole Number Understandings

Dalton. Throughout interview one, Dalton heavily relied on physical activity, finger patterns, and self-created number lines. When asked "how many," he often recounted all items (starting with the number one). When the teacher-researcher covered objects, he sometimes needed to feel through the cloth to count them. Early on, in the first whole number task, Dalton relied on his fingers to stand in for the perceptual items. For instance, Dalton was given the task, *I've covered thirteen counters here. If I took seven of those counters away, how many would I have left?* Dalton responds with the solution "six" and says he first "counted by ones to see what the answer was on my fingers for ones. This is seven (flashing seven fingers), and I figured out that this is seven, and then I knew that was seven (showing how he counted to construct a figurative unit for seven), so I counted fourteen, thirteen, umm ... thirteen, twelve, eleven, ten, nine, eight, seven, six." This explanation suggests that he creates the figurative unit for seven through his counting. By creating this figurative unit, he could focus on reversing his number sequence starting at 13 and counted down to six, exhausting the figurative unit for seven.

We also gave Dalton the task*, So, there's twenty-two counters here. Now if I took five of these counters away, how many would I have left?*. After counting silently and looking at his fingers, he announces, "Seventeen!". When the second author asks, *how did you solve this task?*, Dalton explains:

Dalton: I knew the finger thing for five.
R: Okay.

Dalton: And then I just count ... I did this (shows two hands balled up with zero fingers showing). And I counted to five (flashes five fingers on his left hand) on this (referring to his five fingers on his left hand).
R: Okay.
Dalton:Just to be sure, I counted on this.

R: Can you show me what you were doing?
Dalton: So, I did…
R: Do it again, I guess…
Dalton: … twenty-one, twenty, nineteen, eighteen, seventeen (shows five fingers putting one finger down with each number word).

In this excerpt, Dalton did not need to create a figurative unit for five, as he knew its pattern. We believe this freed up his ability to focus on his reversed number sequence in activity. We gave Dalton, in both strategies, tasks with a known number, a number he could create with his fingers, affording him access to known mathematics and/or created finger patterns.

In the second interview, we gave Dalton tasks asking him to construct figurative material for the subtrahend or for the difference. The design of these tasks pressed him to depend on given perceptual manipulatives. For instance, when asked, *without a number line, tell me how many ones on a number line would you need to jump back from thirty to reach twenty-two?*, he counted backwards by ten and then forwards (e.g., thirty, twenty, twenty-one, twenty-two), answering by stating "twenty-two". To explain his solution to these tasks, he creates a number line, perturbing him to reflect on his counting activity with the number sequence represented on his number line. Strategies like this suggest that he could anticipate the starting number (the minuend) and keep track of the ending number (the difference), in activity. However, he was unable to coordinate this with the reversal of his number sequence. In response to the task, *without using a number line, what is 12 less than 30*?, Dalton stated:

Dalton: Twelve less than thirty. Thirty, twenty, twenty-one, twenty-two, twenty-three, twenty-four, twenty-five, twenty-six, twenty-seven, twenty-eight, twenty-nine, thirty, thirty-one (counts up with fingers to twelve – keeping track of ten fingers and two more). Thirty-one.
R: Thirty-one. So, if you're going on the number line from thirty …
Dalton: Oh, that's up.
R: … and that's twelve ... Oh, okay. So, what can we do to solve this?
Dalton: Hmm ... (holds up one finger and uses his second finger to tap this finger repeatedly while he thinks).
R: So, I'm gonna read it to you again. What is twelve less than thirty? What do you think?
Dalton: Thirty minus twelve. That's basically what it is.
R: Okay.
Dalton: Thirty, twenty, twenty-one, twenty-two, twenty-three, twenty-four, twenty-five, twenty-six, twenty-seven, twenty-eight, twenty-nine ... (counting up by fingers and pauses at twenty-nine).
R: What do you think?

Dalton: How do... how do I keep going from minusing to plus?

Again, Dalton struggles to coordinate the reversal of his number sequence with the two other units (minuend and subtrahend) in this excerpt relying on his known multiples for decades and his forward number sequence. Because he ends his count with a number higher than his starting number of 30, his counting scheme seems to be perturbed when he approaches this.

From Dalton's known finger pattern for five in interview one, we realize one of his conceptual resources may be his known unit for five. We do not yet know to what degree he is constructing and abstracting this known unit for five. For instance, it was unclear if he constructed a numerical composite of five from his numerical sequence (Steffe, 1994) or if he constructed a composite unit for five as a mental object with which to operate on.

Given this, we include the number five in interview three's task to more closely examine his activity and operations possibly associated with five. For instance, we first ask him, *how many fives does it take to create 30?*. Dalton first places counters a line of 30 and describes his grouping as "random," where he segments groups of varying sets of items before adjusting them (adding or taking away one or two) to represent groups of five. Following this, we ask Dalton, *how many counters are covered?* (showing him a line of five with 25 covered). Dalton experiences a perturbation, by first stating "25" as a solution and then changing his solution to "29", describing the group of five as "one." We infer Dalton conceptualizes five as a numerical composite, which we believe was numerical in relation to his numerical sequence (cf Steffe, 1994). As such, we posit he could not use this five as a mental object, pressing him to conceptualize the unit as a unit of "one," which allows him the capability to understand this unit as a component of his number sequence. These are characteristics of Dalton evidencing numerical composites.

Angela. At the beginning of the study, we note that Angela seems to have an internalized number sequence to count on from and some effective strategies with visual representations when solving the aforementioned backwards counting tasks. Additionally, we observe Angela relying on learned procedures or stating known/double facts without fully understanding their relevance to the solution (e.g., using an equation and "borrowing" next door in subtraction). These "tricks" seem to help alleviate her working memory constraints but prevent her from experiencing meaningful perturbations.

When asked *how many groups of five did it take to make 30?,* Angela forms rows of counters to make an array without simultaneously attending to the number of items in each row and the number of rows. Angela created groups of five and explain this was her strategy, "so, they are in a nice row, and they don't get mixed up." Angela then counts all counters and changes her groups by adding one counter to each group. She explains that she knew the groups were the same because "three and three make six," drawing from units of three in coordination with six. At this point, Dalton partitions his groups and adjusts them to represent six groups of five. We observe the following exchange when we ask them *where is the five?*.

Dalton: (Looks back at the first two groups and rearranges the counters and recounts) one, two, three, four, five. One, two, three, four, five.
R: Okay, so how many groups of five do you have [to Dalton]?

Dalton: One, two, three, four, five, six … six. (Places his hands on each group and counts the groups.)

R: Okay, six … six groups [to Dalton]? And then how many groups of five do you have [to Angela]?

Angela: (Counting groups.) One, two, three, four, five. Five.

Dalton: (Counting groups.) One, two, three, four, five, six.

R: Are these groups of five [to Angela]?

Angela: No.

R: So, let's look at Dalton's and let's look at yours [to Angela]. What's different about the way you each solved it?

Dalton: We didn't …

Angela: He did bigger groups. I did smaller groups.

R: What do you mean by bigger groups?

Angela: He got, … I don't know if I have thirty (counts counters in a group). (Counts all counters) one, two, three, four, five, six, seven, eight, nine, ten, eleven, twelve, thirteen, fourteen, fifteen, sixteen, seventeen, eighteen, nineteen, twenty, twenty-one, twenty-two, twenty-three, twenty-four, twenty-five, twenty-six, twenty-seven, twenty-eight, twenty-nine, thirty. I have thirty.

Angela and Dalton continue this exchange to check and verify their total number of counters, the number of counters in each group, and the number of groups of counters before Angela realizes that they "switch swapped!", meaning that she created five groups of six and Dalton created six groups of five. Throughout this third interview, she repeatedly generates items that need to align with one of the units (5 or 30, or 5 or 6) but cannot coordinate both. The characteristics of Angela's activity evidence two-levels of units with one unit in activity.

Fraction Understandings

Dalton. In session 4, we gave Dalton a piece of paper with a yellow rectangle on it to represent a french fry and the task *how do you think we could share a fry between the two of us?*. This leads him draw a line to "split it in half," suggesting that he anticipates using a partitioning strategy. Dalton justifies this by developing two shares stating, "Because that's umm ... the middle (used his finger to go up and down on the paper, over the line he drew – see Figure 1a). So, if, if you cut it right here (pointing to a different section of the fry), it wouldn't ... if I cut it right here, it wouldn't be equal." When the second author asks Dalton how he could *check if the shares were of equal size*, Dalton states that he could "measure it" and creates a ruler with a piece of blue paper (shorter than the yellow fry) by drawing small lines and marking them with numbers 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12 … while counting "two, three, four, five, six, seven, eight, nine, ten, eleven, twelve". As Dalton continues to justify his response, he draws lines at "the end" of the ruler (located by the 12 – see Figure 1b) creating four shares (see Figure 1c).

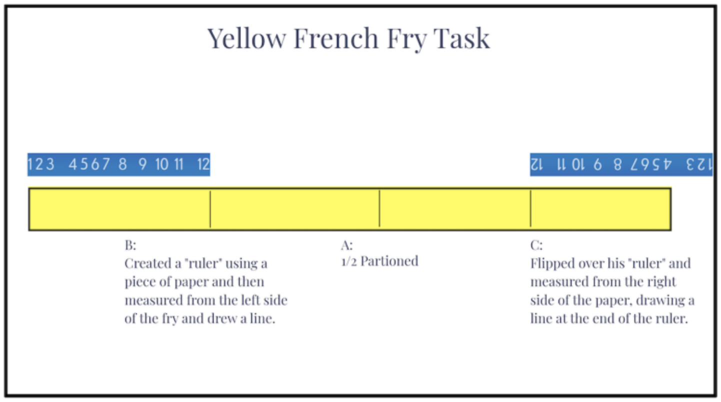

Figure 1: Dalton's "Measurement" When Determining if Two Units are "Equal" in Length

Dalton treats his "ruler" as a discrete object, laying his blue paper ruler on one end of the fry to determine where to mark a second line (see Figure 1b). Then Dalton flips over his "ruler" to align the "one" with the edge of the paper and the opposite end of the "ruler" marks a third line of the fry (see Figure 1c). We find it interesting that Dalton needs his "end" mark of this "ruler" to partition the fry, further evidencing that the entire length of the "ruler" might not have been used at all. We also wonder if Dalton is either iterating the end of his ruler or he is iterating the ruler as one pre-arithmetic unit. As such, by using an auxiliary item in this way, Dalton seemed to engage in some preliminary iteration and did not seem to coordinate the length of the fry or the length of his "ruler" in relation to the two shares.

This relates to Dalton's whole number activity, as he focused on either his iteration or partitioning operations when relying on perceptual or figurative material. When asked to iterate or partition a composite unit or a length unit in activity, his working memory disallows such coordination pressing him to develop early forms of operations (iteration or partitioning) in physical activity, which are separate from his unit development. This suggests Dalton unitizes physical material before focusing on his operations for this material, affording him meaningful whole number activity for his development of fraction knowledge.

Angela. In sessions four and five, we asked Angela to share a fry equally among three people. First, she partitions the fry in half and then adapts this partitioned line to create a third section. In subsequent attempts, Angela guesses and checks until she achieves three shares, always with left-over portions of the fry. She cuts off the end for the third piece to match the others and initially states that the leftover piece "was for the dogs." However, upon further probing on that attempt, she divides the fry piece into three additional shares, treating the remaining portion of the fry as an entire new fry.

Angela: Can I draw something on here (R shakes her head yes)? So, I can show you? It's not going to be that good (Angela draws a large fry on the white paper). So, this is the French fry. FR for French Fry (Angela writes those words on top of her drawing). You have to split it into 3 pieces. So, this is two (Angela draws a line down the middle of the drawn white rectangle).

R: So what part is this then (R, is pointing to the partitioned line of the drawing)?

Angela: This is two.
R: That's two fries?
Angela: Yeah, but if you do this and do this (Angela draws a line trying to split the 1/2 pieces down the middle). That would make 6.
R: Would it make six?
Angela: It would make four. One, two, three, four (Angela counted and tapped on the segmented pieces). I wish it made three. I just noticed it makes four.

At this point, Angela relies heavily upon halving partitioning but reorganizes this activity to intentionally develop a more sophisticated partitioning than a "guess and check." Following this activity, Angela tries to "measure" her original yellow paper fry to determine if her pieces were of equal size.

Angela: Okay. This is the size. Okay, so here's one. I'm going to do it this way (R helps Angela fold the paper). So, you can... Oh, wait, wait, wait, wait. So, this.
R: Hmmm, so what you're doing right now?
Angela: I'm measuring.
R: Oh, you're measuring.
Angela: Back like that. Okay (Refers to the fold she made with the blue paper).
R: I'll hold these down (R held the pens in place so they didn't move while Angela takes and measures each segmented piece of the yellow fry with the blue piece, repeated measure). Okay?
Angela: Stay like that (Refers to the pens and then measures each segmented piece of the fry).
R: Oh, uh oh.
Angela: But you know what you can do? Magic! Magical.
R: Magical. Do you want to fold that again?
Angela: Okay, it fits.
R: It fits? All of them?
Angela: No. See if.... (Keeps trying to measure with the same blue piece to check the size of all the segmented fry pieces). Okay, we just need this to be put right there.

This suggests to us that Angela "measures" her fry length by iterating to determine if her pieces were all the same length. By iterating she develops new means to coordinate her unit size with the length of the fry. Following this, Angela partitions the fry but does so by segmenting the fry into five shares with four partitioned lines. This activity is similar to the whole number task of five groups to create 30, whereby she could attend to the number of units and the total number but not to the group size. In the fraction task, she can attend to the length and to the size of the unit but not to the number of units. This also suggests that Angela is developing preliminary iterating of each unit but could only anticipate one length unit at a time and constructs the remaining units in activity. Given this, we believe Angela has two levels of units with one unit in activity for both her whole number and fraction development.

Discussion and Conclusion

Dalton and Angela each had very different conceptual resources for their whole number and fraction development. Dalton drew from a reliance on physical material but also was capable of counting-on, counting down, and working with numerical units from his numerical sequence (Steffe, 1994). Dalton drew from meaningful whole number understandings when conceptualizing five as a unit, sequencing his unitizing and operations. Dalton also evidenced early forms of iteration, providing him potential access to measurement fraction development in future schooling experiences. These conceptual resources allowed Dalton development with meaningful whole number and fraction activities. Angela was capable of meaningful counting-on, partitioning, unitizing, and iterating with the opportunity to coordinate two levels of units in activity. Angela's more advanced partitioning activity afforded her preliminary part-whole number reasoning and access to some successful fraction development. However, Dalton drew more often from iteration allowing him potentially more opportunities to develop measurement fractions than Angela might. We found that by leveraging both students' conceptual resources over the course of a small set of interviews, they were better positioned to solve more complex part-whole number and fraction problems. Questions remain about how particular nuances in conceptual resources of students with learning differences and their actions forming operations can be leveraged over time to promote more sophisticated mathematical development.

THE INFLUENCE OF USING MANIPULATIVES AS MATH TOOLS OR TOYS IN PLAY CONTEXTS ON CHILDREN'S PART-WHOLE CONCEPTS

Arielle Orsini

Helena P. Osana
Concordia University
helena.osana@concordia.ca

Keywords: Instructional Activities and Practices; Early Childhood Education; Number Concepts and Operations.

Recent research has shown that the ways in which children use manipulatives impact their perceptions of the objects and their subsequent learning in mathematics. Osana et al. (2018) found that when children used manipulatives as representing quantities in a mathematics task, they perceived them as "math tools," but when they played with manipulatives in a non-mathematics environment, they perceived them as toys. Moreover, children's interpretations of manipulatives, as either representing quantities or toys, were resistant to change, even when the same objects were used in a subsequent mathematics lesson. In another study, Donovan and Alibali (2021) found that children's use of manipulatives as math tools was positively related to their subsequent learning about mathematical equivalence. From this research, it is tempting to conclude that children should be discouraged from playing with manipulatives, particularly when the same objects will be used to teach mathematics.

In both studies, the objects' use was experimentally manipulated by engaging the participants in either an instructional mathematics context or a play context, conflating context and the objects' use (math tools vs. toys). Thus, these data do not allow one to conclude that playing with manipulatives will result in perceptions that will hinder children's subsequent learning. Our objective in the current study was to conduct a conceptual replication of Osana et al. (2018) and Donovan and Alibali (2021) by comparing two ways of using manipulatives in teacher-directed play contexts. We hypothesized that children who used and perceived the manipulatives as math tools would outperform their peers who used and perceived them as toys.

We randomly assigned 64 first-grade students to one of two teacher-directed play conditions (math-play and toy-play) or a control condition, where children were not exposed to any manipulatives. In both manipulative conditions, children played a shopping game with beige plastic tiles. In the math-play condition, the manipulatives represented quantity, whereas in the toy-play condition, they were used to play with. We then assessed their perceptions of the objects and their part-whole understanding on two tasks using the same manipulatives from the intervention. The decomposition task (Manches et al., 2010) involved finding all possible two-way decompositions of six and nine. The evaluation task required children to evaluate a puppet's use of part-whole concepts in the strategies it used to solve eight additive word problems.

A significantly larger proportion of students in the math-play condition perceived the objects as math tools (96%) than in the toy-play (5%) and control conditions (0%), χ^2 (4, N = 64) = 48.89, $p < .001$. Contrary to our predictions, however, there were no condition or perception effects on the students' performance on either part-whole measure. Thus, when children in both conditions played with the manipulatives, the effect of using them as math tools or as toys on learning as found in previous research was no longer present. Future research should compare the effects of using manipulatives as representing quantities to using them as toys in both play and instructional contexts to gain a deeper understanding of the conditions under which children's use of concrete objects impacts their learning in mathematics.

COUNTING: AN ESSENTIAL YET OVERLOOKED COMPONENT TO DEVELOPING INTEGER UNDERSTANDING

Kamie K. Stack
University of Minnesota
stack180@umn.edu

Erin E. Baldinger
University of Minnesota
eebaldinger@umn.edu

Keywords: Number Concepts and Operations, Curriculum, Rational Numbers

Developing conceptual understanding with integers is challenging for middle school students (Fuadiah et al., 2019; Khalid & Embong, 2020; Schindler & Hußmann, 2013). Existing curricula traditionally support integer number sense through plotting, comparing, and ordering activities during introductory lessons (e.g., Lappan et al., 2009). Counting activities are notably missing, suggesting that educators assume middle school students can transfer whole number counting skills to integers without intentionally aimed activities. This poster focuses on a preliminary finding from a Design-Based Research (DBR) dissertation project that used an intervention game and contextual model, *Floats & Anchors* (Pettis & Glancy, 2014), as the throughline in an integer unit. The research question investigated: What characteristics of a comprehensive curricular unit best support students' understanding of integers and integer operations?

The *Floats & Anchors* unit consisted of 12-16 lessons implemented in three design cycle iterations with small groups during math intervention or special education mathematics classes. Each design cycle included an initial unit design, critical expert panel discussion(s), classroom implementation(s), teacher interview(s), a student survey, initial analysis, and re-design decisions. The unit was co-taught by a researcher and the classroom teacher(s) to students who were identified by their school as needing additional math support, with many students also receiving special education services. Altogether, 49 middle school students in sixth-, seventh-, and eighth-grade participated in 82 lessons. Data was collected from audio/video recordings of lessons, student work artifacts, transcripts from teacher interviews and expert panel meetings, student survey responses, and reflexive memos. The data was grouped by curricular characteristics (e.g., vertical number lines) and analyzed for evidence of student understanding.

One key preliminary finding emphasized counting as a distinct and essential component of integer understanding at the middle school level. Our study revealed that whole number counting skills did not transfer to integer counting without intentional activities. During the second iteration, students demonstrated a conceptual understanding of integer addition and subtraction by selecting appropriate count-on or count-back directional strategies. However, students were unable to count accurately in the desired direction despite demonstrating mastery with plotting, comparing, and ordering integers earlier in the unit. To address this, we routinely integrated a modified early childhood counting game where students take turns counting from 10 to -10. When the counting activity was first introduced, students consistently needed to reference the classroom number line, demonstrated sustained periods of thinking time (particularly between two and -2), and/or required support from a teacher before they were able to complete their turn. By the end of the third iteration, students demonstrated collective mastery of integer counting. Students could count up and down starting with values beyond 10 or -10, alternate directions with each new round, skip-count by sets of two, five, and ten in both directions, and demonstrate mastery individually with a teacher fluently and without the earlier supports. Moreover, integrating an intentional counting routine positively correlated with students' overall mastery of integers, as demonstrated on the summative assessment from the third iteration.

Keywords: rural, middle grades, professional learning, ambitious teaching, curriculum, policy

We provide an overview of a multi-stage project designed to generate a comprehensive understanding of the state of rural mathematics education and conditions impacting rural mathematics education in middle schools in the United States. We seek to explore: the curriculum resources and instructional practices that are prevalent in middle grades mathematics education in rural contexts; the factors that facilitate or impede efforts to develop local capacity to implement rigorous mathematics teaching and learning in rural contexts; and how state and federal education policies (e.g., assessment instruments, funding priorities, mandates) impact mathematics instruction in rural landscapes. The purpose of the poster is to describe the set-up for the study design and share intentions of the project, along with details related to data collection.

We will present the plan for this four stage study that includes: (a) a survey of rural middle grades mathematics educators (n=1000) to develop a picture and comprehensive understanding of the forms of curriculum resources, instruction, and professional learning experiences reported to be in use in a variety of rural contexts; (b) interviews with teachers, instructional leaders, and administrators (n=80) in selected, diverse rural districts about their perceptions of their district's/school's current mathematics curriculum and instruction, their goals related to their mathematics programs, the resources and opportunities for improving mathematics curriculum and instruction, as well as the challenges they face; (c) case studies of the implementation of a professional development program in roughly 10 districts, the purpose of which is to investigate factors that facilitate or impede efforts to implement rigorous forms of mathematics curriculum and instruction, and to gauge the resources that would be necessary to develop local capacity for a sustained implementation; and (d) establishing a collective dialogue with a range of stakeholders in education policy to gain greater insights into the rural mathematics education landscape and to develop recommendations for enacting rigorous mathematics instruction at geographic scale.

This study draws on research in mathematics education, including literature on curriculum characteristics, curriculum implementation (Jackson et al., 2017), and professional development in rural contexts (Irwin et al., 2010), as well as broader literature on rural education and rural economics (Schmitt-Wilson et al., 2018).

MAPPING POLICIES FOR BECOMING A MATHEMATICS TEACHER

Erin E. Baldinger
University of Minnesota
eebaldinger@umn.edu

Keywords: Pre-service teacher education, Policy

In the US, mathematics teacher licensure is governed at the state level. Each state may have different policies about mandatory elements of teacher preparation. Within each state, educator preparation providers determine how to provide such learning opportunities. In the current era of accountability, the policy conversation around teacher preparation has focused on preparing highly effective teachers (e.g., Aydarova, 2023; Bales, 2006; Cochran-Smith et al., 2018; Tatto, 2021). However, little research has examined the specific laws or rules enacted at the state level. Professional organizations in mathematics education also strive to shape policy and practice around mathematics teacher preparation through reports (e.g., Conference Board of the Mathematical Sciences, 2012) and standards (e.g., Association of Mathematics Teacher Educators, 2017). Given the large number of stakeholders helping to shape mathematics teacher preparation and the potential for state-by-state variation in laws and rules, I ask the following research questions: (1) What laws and rules govern mathematics teacher preparation across the US? (2) How do those laws and rules differ by state or territory?

To answer these questions, I analyzed the laws and rules shaping teacher preparation across the US. Within each state, teacher preparation is governed by laws (written and passed by the state legislature, then signed by the governor) and rules (written by an executive branch agency, such as a Department of Education, which was empowered by the legislature to produce rules that help interpret the laws). Informed by prior research as well as my own work as a teacher educator, I anticipated laws and rules focused on mathematics content requirements and general pedagogical practices. I also anticipated laws and rules directed toward teacher candidates themselves as well as policies directed toward teacher preparation providers. Building on this framing, I engaged in an open coding process (Vollstedt & Rezat, 2019), starting from the specific words in each law or rule, and then looking across codes to generate themes.

Preliminary findings reveal different approaches to regulating mathematics teacher licensure across the US. Some states include detailed lists of content and pedagogical standards within state law or rule. Other states enshrine exams (Praxis or state-specific exams administered by Pearson) and accreditation (CAEP) into law and rule. Another variation across states was the extent to which laws and rules focused on teacher candidates or preparation providers. Indeed, in some states a requirement would be directed toward the candidate (e.g., a teacher must be able to elicit and interpret student thinking), while in other states the requirement would be directed toward the preparation provider (e.g., the program will ensure the teacher can elicit and interpret student thinking). Finally, states use different language to describe licensure and issue a wide range of license types. These variations contribute to a confusing licensure landscape. Despite these differences, there is also significant overlap in the focus of the laws and rules across states, particularly related to pedagogical practices.

Identifying the similarities and differences in laws and rules across the US is critical to understanding the mathematics teacher preparation landscape. Engagement with the laws and rules that shape teacher licensure will enable teacher educators to advocate for research-informed policy that supports preparing teachers to teach ambitious mathematics across the country.

In this paper, we use a systematic approach to explore trends in mathematics education research over the last ten years by sourcing articles from the two highest ranked mathematics education journals: Educational Studies in Mathematics (ESM) and Journal for Research in Mathematics Education (JRME). We examined the methods of research used in articles (quantitative, qualitative, mixed methods), the geographic region in which research was conducted, and the characteristics of research samples. The findings showed that methods of research were balanced in JRME, with a relatively strong tendency toward qualitative research in ESM. Furthermore, the findings revealed that there is little geographic diversity in published research in JRME, with more diversity in ESM. Finally, research sample sizes were larger in JRME than ESM, and both journals showed notable patterns in relation to sample characteristics.

Keywords: Research Methods; Policy

Over the past ten years, there have been technological advancements, ideological shifts, and critical events (e.g., COVID-19), all of which have the potential to change the nature of mathematics education research. It is critical to track changes in mathematics education research to discern how the field is evolving and discern the strengths and limitations of current research approaches. In this paper, we use a systematic approach to explore trends in mathematics education research by sourcing articles from the two highest ranked mathematics education journals: Educational Studies in Mathematics (ESM) and Journal for Research in Mathematics Education (JRME) (e.g., Niven & Otten, 2017; Williams & Leatham, 2017). These two journals are highly respected in the field and provide a reasonably reliable litmus test for trends in mathematics education research. Furthermore, looking at journals from both US and international organizations allows us to see a more complete picture of mathematics education research globally and compare trends between US based and international research. To that end, we ask the following research questions: (1) What methods of research are most prevalent in ESM and JRME over the past ten years and how have these methods changed? (2) Which geographic regions are most represented by research in ESM and JRME over the past ten years and how has geographic representation changed? (3) What are the characteristics of research samples in ESM and JRME over the past ten years and how have these characteristics changed?

Notably, these research questions are significant from the perspectives of the editors of ESM and JRME. For example, ESM's editors signified the importance of publishing research from underrepresented regions (Mesa & Wagner, 2019; Wagner & Prediger, 2023). Furthermore, JRME's editor provided a brief account of the methodologies used by researchers during PMENA 2023 (Herbst, 2023). Examining trends across both journals identifies areas in research that need greater emphasis. For example, are certain populations underrepresented? Is there a need for more qualitative/quantitative research in a particular global region? The different methodologies have different strengths and weaknesses and both make valuable and necessary contributions to research (Choy, 2014). This analysis will make researchers aware of needs in mathematics education that will guide future research and contribute to a more complete corpus of information. Thus, this study examines relevant trends of mathematics education research.

Method

To answer the research questions, we compiled all articles that were published in JRME and ESM from 2014-2023. Then, we coded the articles using a coding scheme that was relevant to the research questions. For Research Question 1, we coded all articles as: (1) empirical; (2) editorial; (3) book review; (4) other (e.g., systematic review, commentary, etc.). Then, we compiled all empirical articles and coded them as quantitative, qualitative, or mixed methods. While there are various methodological definitions, we relied on Gay et al. (2012) for the following delineations of research:

(a) "Quantitative research is the collection and analysis of numerical data to describe, explain, predict, or control phenomena of interest" (Gay et al., 2012, p. 7).
(b) "Qualitative research is the collection, analysis, and interpretation of comprehensive narrative and visual (i.e., nonnumerical) data to gain insights into a particular phenomenon of interest" (Gay et al., 2012, p. 7).
(c) "Mixed methods research combines quantitative and qualitative approaches by including both quantitative and qualitative data in a single study" (Gay et al., 2012, p. 481).

Finally, we calculated frequencies for each methodology and explored differences in methodologies across time.

To answer Research Question 2, we coded each article for the institutional affiliation of Author 1. The institutional affiliation of Author 1 acts a proxy for the geographic region in which the research was conducted. We coded the geographic region of each article according to Rosenburg's (2023) eight official world regions: (1) Asia; (2) Middle East, North Africa, and Greater Arabia; (3) Europe; (4) North America; (5) Central America and the Caribbean; (6) South America; (7) Sub-Saharan Africa; (8) Australia and Oceania. For JRME articles, we coded each article according their geographic region within the U.S. using the U.S. census bureau's regions: (1) Northeast; (2) Midwest; (3) South; (4) West. We calculated frequencies and percentages for geographic regions and explored differences over time.

To answer Research Question 3, we compiled all empirical articles and coded the sample according to its target population: (1) Grades Pre-K-2; (2) Grades 3-5; (3) Grades 6-8; (4) Grades 9-12; (5) Undergrad/Community college; (6) Graduate; (7) Preservice teachers; (8) Adult Learners; (9) Inservice Teachers; (10) Other. In studies where multiple populations were included, we coded each portion of the sample separately. In addition to sample population, we coded each study for sample size, and racial/gender characteristics. We calculated medians, frequencies, and proportions to compare sample characteristics in both journals independently and in conjunction with the other two research questions.

In what follows, we provide quantitative summaries for each research question, providing separate analyses for ESM and JRME.

Findings

Methods of Research

JRME published a total of 250 papers over the past decade. Of those papers, 50% of them were empirical papers, 16% were editorial, 10% were book reviews, and 24% were other (theoretical, meta-systematic reviews, textbook, and content analysis, commentary). ESM published a total of 729 papers. Of those, 63.5% were empirical papers, 4.7% were editorial, 7% were book reviews, and 24.8% were other.

For the empirical studies, we coded each article for the type of methodology used (quantitative, qualitative, mixed methods). Frequencies across time for each methodology are given in Table 1. Over the last decade, JRME maintained a balanced publication of both qualitative and quantitative studies, with the number of mixed studies being consistently comparable. In contrast, ESM published around three times as many qualitative studies as quantitative studies over the last ten years. Furthermore, ESM published considerably more mixed methods studies than quantitative studies.

Looking across time, the number of quantitative studies published in ESM shows an upward trend since 2016, with a decline last year (2023). In JRME, the number of quantitative studies has been about the same for the past 5 years. In relation to qualitative research, there are no discernible patterns for articles published in JRME. For ESM, the number of qualitative studies appeared to increase over time. From the frequency column, we can observe that the total number of empirical studies published in JRME each year has been fluctuating but averaging about 12 articles per year. Overall, the number of empirical articles published in ESM shows an upward trend, averaging about 46 articles per year.

Table 1: Methodology Across Time

	JRME				ESM			
Year	Quant	Qual	Mixed	Frequency	Quant	Qual	Mixed	Frequency
2014	8	5	3	16	8	25	7	40
2015	4	5	3	12	6	21	14	41
2016	1	8	2	11	5	22	12	39
2017	3	3	6	12	7	24	13	44
2018	6	2	3	11	6	20	14	40
2019	5	5	2	12	10	22	7	39
2020	3	5	2	10	9	18	22	49
2021	3	5	8	16	11	25	16	52
2022	5	4	3	12	20	29	14	63
2023	6	5	2	13	9	35	11	55
Total	44	47	34	125	91	241	130	462

Geographic Representation

Table 2 shows the geographic representation for articles in JRME over the last ten years (using the affiliation of Author 1). As illustrated in Table 2, most JRME articles were published by authors in North America (89%), and most of the authors were from the U.S. The journal publishes very few articles from other regions, with Europe ranking second at just 4% of the overall sample. There are no noticeable trends over time in relation to international geographic regions. Table 3 shows that, of articles published in the U.S., more articles are published from Southern regions than any other region, and Northeastern regions account for the smallest number of articles within the sample. It is important to note that many states are counted in the Southern region within the U.S. census bureau that many people would not identify as the "South." Therefore, these results should be interpreted with the U.S. census bureau boundaries in mind. There are no noticeable trends regarding changes in U.S. representation over time.

Table 4 shows the geographic representation for articles in ESM over the last ten years. As illustrated, ESM's geographic representation is somewhat more diverse, with Europe and North America accounting for the majority of articles (43% and 29% respectively). There are some noticeable trends over time in ESM's geographic representation. Namely, articles published from Asia and the Middle East, North Africa, and Greater Arabia regions have trended up over the last ten years.

Table 2: Geographic Representation in JRME over Time

Year	Asia	Middle East, North Africa, Greater Arabia	Europe	North America	Central America and the Caribbean	South America	Sub-Saharan Africa	Australia and Oceania
2014	1	0	3	23	0	0	0	0

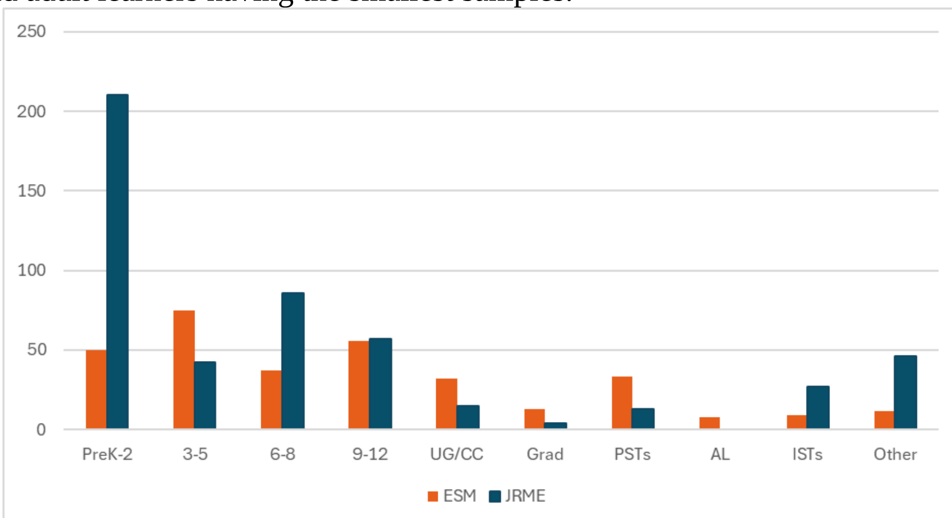
Characteristics of Research Samples

The sample sizes for the research studies examined in this analysis varied greatly. Quantitative sample sizes ranged from 1 to 132,747 while qualitative samples were understandably smaller, with a maximum sample size of 1,813. Mixed method empirical studies fell in between with the largest sample having 6,218 participants. The data were positively skewed with a small number of very large samples. Because of the outliers in the data, we describe sample sizes in terms of median values instead of averages. The median sample size in

JRME was 42 participants while the median for ESM was 25. Figure 1 shows the median sample size for each journal separated by the population studied. The graph shows that JRME had larger sample sizes for students in the preK-2 and 6-8 grade groups, as well as for inservice teachers and the "Other" category. ESM, however, had larger sample sizes for research studying grade 3-5 students, undergraduate students, and preservice teachers. ESM also included the only study focused on non-traditional adult learners. In addition to illustrating how the sample sizes vary according to population category, the figure also suggests that the largest samples in mathematics education were found in research conducted on K-12 students, with research on graduate students and adult learners having the smallest samples.



Note. Grad= Graduate Students UG/CC= Undergraduates/Community College, PST= Preservice Teachers, AL = Adult Learners, IST= Inservice Teachers

Figure 1: Median Sample Size by Population

Because quantitative studies generally have larger sample sizes than qualitative studies, we looked at sample size according to study methodology. Table 5 shows the median sample sizes for each journal while considering the study population and methodology. With the exception of the 9-12 grade category, the quantitative studies in JRME had larger samples than those in ESM. The table also shows the higher sample medians for ESM were due to larger samples in qualitative and mixed methods studies. The sample sizes were also examined to look for changes over time but no discernible patterns were found (see Figure 2). Generally, the sample sizes in JRME fluctuated greatly over the past ten years with lows in 2015 (median = 13) and 2016 (median = 6), and highs in 2014 (median = 96) and 2022 (median = 102). Median samples for ESM had much less variation but showed a slight increase over the past ten years from 18 in 2014 to 29.5 in 2023. Interestingly, both journals had their lowest sample median in 2016.

Table 5: Sample Medians by Study Population and Methodology

	Quantitative		Qualitative		Mixed	
	JRME	ESM	JRME	ESM	JRME	ESM
PK-2	**647.15**	136	**28.5**	10	**232**	129.5
3-5	**443.5**	213	1.5	**12**	72	71
6-8	**961**	350	**18**	7	**129**	102
9-12	198	**271**	10	8	**134.5**	82
UG	**522**	208	5	**13**	**450.5**	85
Grad	0	0	2	**5.5**	11	**24**
PSTs	**1044**	224	12	10	13	**73.5**
AL	0	0	0	1	0	**15**
IST	**93**	59.5	2	3	12	**29.5**
Other	**439.5**	278.5	8	7.5	**59**	36.5

Note. Grad= Graduate Students UG/CC= Undergraduates/Community College, PST= Preservice Teachers, AL = Adult Learners, IST= Inservice Teachers. Bold font indicates notably higher sample medians, but this was a subjective distinction made by the author.

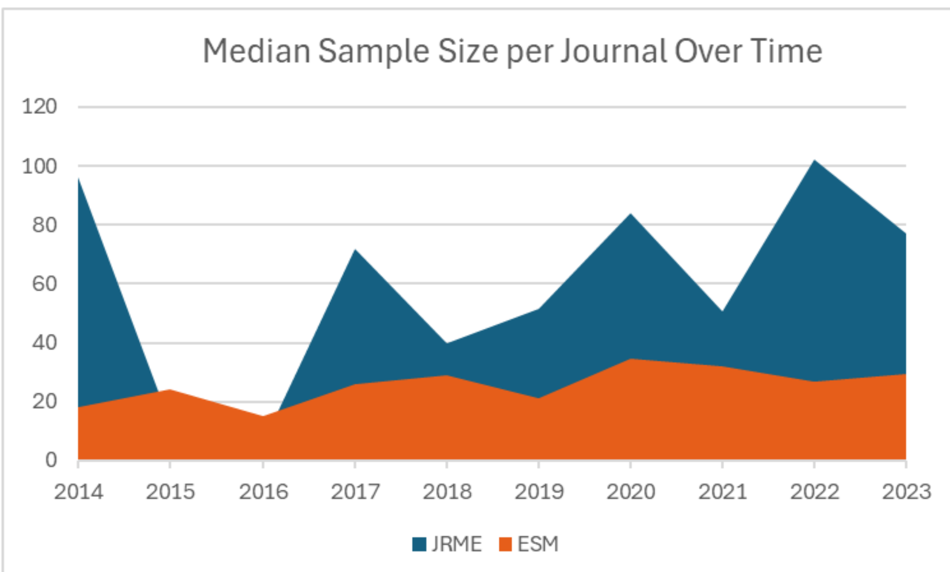


Figure 2: Median Sample Size Over Time

As a final inquiry into the samples that were the focus of study in JRME and ESM over the past ten years, we looked to see how gender and race were represented in the samples. In ESM, only about 50% or fewer of the studies reported gender representation, and student race was reported in less than 20% of the articles. In the articles that did report on gender, there was equal or greater representation for female subjects in 30-50% of the studies, which may be partially due to the majority of PSTs and ISTs identifying as female. Looking at studies on PSTs or ISTs that reported gender demographics, over 60% of the samples identified as female. Similar patterns appeared when looking at the representation of gender and race in JRME articles with a majority of articles not reporting the demographics of their sample. However, the proportion of articles failing to report has decreased since 2020, suggesting a shift in mathematics education research which indicates an awareness of the need to consider the needs of various student populations differently. This shift, however, only seems to be occurring in the United States, as the shift is not observed in the international articles of ESM.

Discussion

In this paper, we examined trends in mathematics education research by exploring methodologies, geographic representation, and sample characteristics for studies published in mathematics education's highest ranked journals (ESM and JRME). The findings highlight several implications for future research.

First, this study showed that methods of research (quantitative, qualitative, mixed methods) were balanced in JRME, with a relatively strong tendency toward qualitative research in ESM. There were few discernible trends over time except that ESM appeared to publish more quantitative studies from 2016 onward. Together, the data reveals methodological diversity in mathematics education research. From the perspective of potential authors, ESM may be more open to qualitative methods than JRME, though more detailed analysis is needed to certify this claim.

Second, this study revealed that many geographic regions are not well-represented by top journals in mathematics education. Mathematics teaching and learning is heavily influenced by culture. Therefore, it is important that the field draw upon research from diverse regions to create new knowledge and global perspectives on mathematics education. Notably, ESM has published more research from some underrepresented regions over time. JRME, on the other hand, seems primarily concerned with national interests. This is, perhaps, unsurprising since JRME was founded by a U.S.-based council. Yet, given the influence of ESM and JRME, the journals might consider placing more emphasis on scholarship from underrepresented regions.

Third, our analysis revealed a fairly consistent difference in sample sizes between studies in the two journals. The research reported in JRME tended to have larger median sample sizes than the research reported in ESM. Additionally, while the median sample sizes in JRME fluctuated significantly, the median sample size in ESM remained fairly consistent over time with a slight upward trend. Though sample size is not generally an important consideration in qualitative research, it is an important consideration in quantitative studies as it contributes to increased statistical power and generalizability. However, large samples can be difficult and costly to obtain, which may contribute to the lack of large quantitative studies from underrepresented regions.

Our analysis also revealed that race and gender are rarely reported for research samples, with the exception of research conducted in North America. Increased reporting in North America could be due to the emphasis on increasing equitable education in the U.S., as well as the diversity of cultures and races within the U.S. Still, 64% of studies in JRME did not report the race of their samples, and gender demographics were only reported for about 50% of the samples. These data may indicate that North American authors have different perspectives and priorities than other geographic regions in relation to reporting the characteristics of samples.

In conclusion, this study showed several important trends in mathematics education research published in ESM and JRME. These findings may support the mathematics education community in identifying areas of strength and improvement moving forward. Furthermore, these findings may support potential authors in choosing appropriate outlets for publishing their mathematics education research.

OPERATIONALIZING RURALITY FOR MATHEMATICS EDUCATION: RURAL-CENTRIC APPROACH

Rurality matters in mathematics education because geographic diversity affects students and teachers in their home, community, school, and district. Researchers have documented a number of factors which differ across rural, suburban, and urban settings, including student achievement, recruitment and retention of teachers, access to resources, and cultural funds of knowledge. However, mathematics educators have mostly focused on urban and suburban settings, often adopting a legacy urban-centric system developed by the U.S. government for applying 'city', 'suburb', 'town', or 'rural' labels to schools. We compare this categorical system with a new method for estimating the extent to which school districts are 'rural-serving'. Results suggest the new metrics offer more rural-centric information for mathematics educators.

Keywords: Research Methods, Professional Development, Rural Education

Introduction and Literature Review

Many educators, researchers, and policy makers appreciate the importance of context in public schooling. The U.S. government maintains demographic and financial data on more than 102,000 public schools (NCES, 2023), labeling 32% as located in a rural area. There is considerable variability in these data across rural areas (Showalter et al., 2023). Many rural schools are challenged by persistent inequities, such as higher levels of poverty and lower levels of educational achievement among historically excluded black and Hispanic students (Johnson et al., 2014; Lavellely, 2018; Lauzon et al., 2015; NCES, 2016). At the same time, students attending rural schools have higher graduation rates compared to their non-rural peers (NCES, 2023a), and, overall, rural children who experience poverty demonstrate higher achievement than their non-rural peers (Showalter et al., 20203). Given the unique challenges and circumstances rural schools face (e.g., limited resources, geographic isolation, technological challenges), leading policymakers and researchers highlight the importance of developing and testing innovative approaches to educational improvement that are specifically tailored to meet the needs of rural schools, teachers, and students (Parks, 2021).

How rural is defined greatly impacts who has access to these innovative approaches and the associated resources (Coburn et al., 2007). For example, our universities recently applied for and received funding for two mathematics education grants focused on supporting and researching outcomes in rural schools. How we define rural significantly impacts who is eligible to receive that support and who is included in rural mathematics education research outcomes. Though there are many ways geographers and others have defined "rural" (Woods, 2004), the historical focus has been on distinguishing rural areas from urbanized areas. Compared to cities, rural areas tend to be more sparsely populated, with more open spaces, differing cultural norms, and greater focus on ‘primary economic activities’ such as farming, ranching, hunting, forestry, mining, and oil and gas extraction (Montoya, 2023). There are many subtleties as local economic, housing, and demographic trends have shifted over time. The most recent *Why Rural Matters* report acknowledged issues with the urban-centric definition of rural adopted by the U.S. Census Bureau more than 100 years ago, highlighting that “…many children attend rural schools in districts that are not designated ‘rural’ by the U.S. Census Bureau.” (Showalter et al., 2023, p.2). We explore: How might mathematics educators might benefit from shifting from a reliance on the urban-centric list of locale types currently used by the U.S. government to a more direct measurement of the extent to which a school district is ‘rural-serving’?

Methods

Our primary data source was a large database of 19,714 public school districts maintained by the EDGE program in the National Center for Education Statistics (2023b). Records for the school districts included geographic boundaries and 12 “locale type” categories derived from the urban-centric definition of locales developed by the U.S. Census Bureau. In this system, school districts can be located within a “City”, distinguished by the population size of the principal city (Large = 250,000 or more, Midsize = 100,000-249,999, Small = less than 100,000). “Suburban” districts are located just outside one of those cities (similarly labeled Small/Midsize/Large by the size of the city). “Town” districts are located within “urbanized clusters” (at least 500 residents per square mile), with labels for their distance from the nearest city (Fringe = less than 10 miles, Distant = 10 to 35 miles, Remote = more than 35 miles). The remaining districts are “Rural”, with similar Fringe/Distant/Remote labels based on distance to the nearest Town or City. We also used “tract” population values from the 2020 U.S. Census. Tracts are relatively small, geographically-stable boundaries in use since 1920, typically corresponding to neighborhoods or natural boundaries, split or merged every 10 years to maintain populations between 1000 and 8000 people.

To obtain our new ‘rural-serving’ estimates for school districts, we used the statistical software system *R* to calculate the geographic overlap of census tracts with each school district. This allowed for calculating a weighted mean population density of each overlap. For each district, we computed the “% Rural-Servings” as the fraction of tracts served by the school district which would be considered non-urbanized by the U.S. Census (< 500 people per sq mi). We optimized the algorithm for computing the geospatial estimates for each district, then summarized the results, comparing the new estimates to the pre-existing locale type labels.

Results

Table 1 and Figure 1 illustrate similarities and differences between the existing Locale Type labels and the new % Rural-Serving measure for school districts. U.S. school districts are highly variable in the numbers of residents they serve (Mean = 55,323 residents, SD = 129,846). Nonetheless, City districts tend to serve greater numbers of residents than Suburban districts. Town and Rural districts tend to serve similar numbers of residents. In the aggregate, Table 1 suggests that Locale Types are broadly aligned to decreasing population density and increasing rural-serving distributions (with the only exception to the ordering being ‘Rural, Fringe’ school districts). However, as indicated in Figure 1, there is large variability in % Rural-Serving in some Locale Types, especially in 'City, Small' and Suburban districts.

Table 1. Summary of U.S. Public School Districts by Locale Type

Code	Locale Type	# Districts	Mean # Census Tracts	Mean Population	Mean Pop Density (people / sq mi)	Mean % Rural-Serving
11	City, Large	186	119	458238	6478	9%
12	City, Midsize	175	54	217581	4357	19%
13	City, Small	392	28	109702	2753	29%
21	Suburban, Large	2446	23	99160	3338	20%
22	Suburban, Midsize	327	19	77073	1369	47%
23	Suburban, Small	239	14	55625	1098	57%
31	Town, Fringe	516	11	43709	502	80%

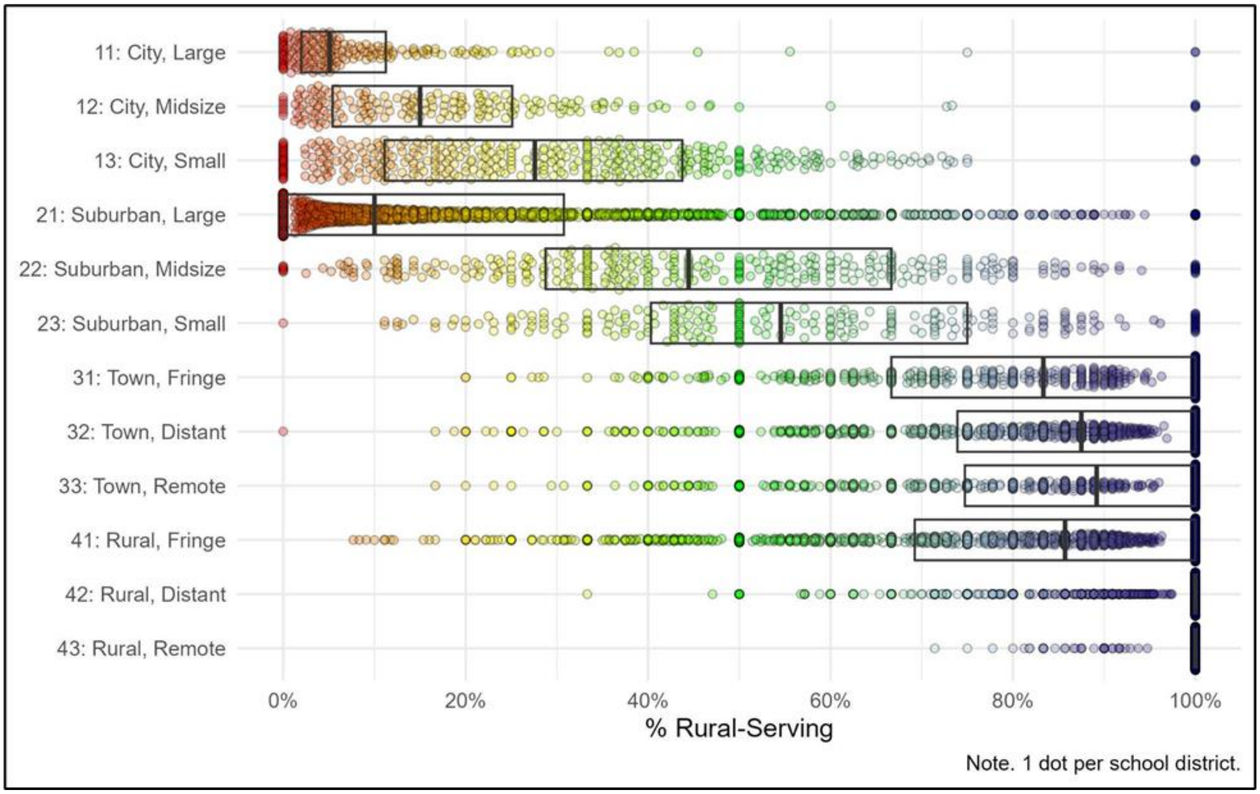

Figure 1. Distributions of % Rural-Serving by Locale Type among U.S. School Districts

Figure 2 compares U.S. maps of the existing Locale Type label and the new rural-centric measure or rurality. The maps highlight the increased precision afforded by % Rural-Serving.

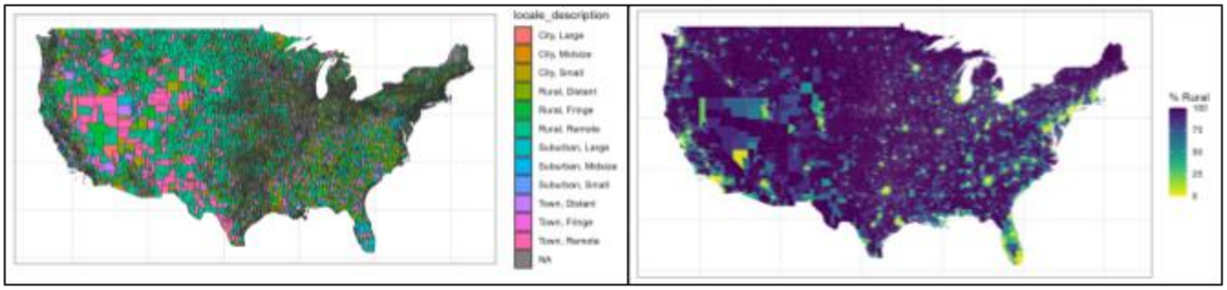

Figure 2. Maps comparing Locale Type (left) and % Rural-Serving (right).

Conclusions

We recommend math education researchers pay particular attention to the extent to which school districts serve rural populations. As indicated by our results, many school districts, especially those located near small cities or in suburban areas have relatively large proportions of rural areas within their districts. In particular, we recommend more mathematics education researchers, policymakers, and program developers adopt a *rural-centric approach* (using the % Rural-Serving or similar metrics) to reach more schools with rural student populations.

Keywords: Policy, Preservice Teacher Education, Mathematical Knowledge for Teaching, Professional Development

Both the Conference Board of the Mathematical Sciences (CBMS) and the Association of Mathematics Teacher Educators (AMTE) provide standards and recommendations for the mathematical preparation of elementary teachers (AMTE, 2017; CBMS, 2012). Considering what professional organizations and state licensing requirements call for in the mathematical preparation of preservice elementary teachers (PSETs), teacher education programs aim to fulfill those requirements in a variety of ways, especially in the coverage, sequencing, rigor, and integration of content and pedagogy in mathematics content and methods courses (An et al., 2021). Individual states tend to have explicit mathematical achievement requirements for PSETs working toward initial teacher certification, but less specific course requirements for their training. With standards that need to be met, but no required course structures in place, access to an interactive platform being created in this study is expected to facilitate PSET preparation programs' decision making process on how to structure their programs, meet the needs of their PSETs and those PSETs' future students, and learn from other PSET preparation programs.

Research Questions and Method

Our study is guided by the following research questions: (a) How do teacher education programs account for the mathematical education of PSETs in the design of their programs?; (b) How do their program structures align with current standards for the mathematical preparation of teachers?; and (c) In a central resource for program design, what features would assist teacher education programs? There are two major components to our initiative: (a) survey administration to build knowledge about various structures of PSET preparation programs, and (b) platform development to foster communication and partnerships among PSET mathematics teacher preparation programs.

Results and Discussion

Our ultimate goals are to connect preservice mathematics teacher preparation programs of all grade levels (K-12) and to support cross-level communication and collaboration. For example, a secondary teacher preparation program and an elementary teacher preparation program could collaborate to build coherent mathematical knowledge for teaching curriculum so that future graduates would deliver coherent mathematical knowledge to their K-12 students. Starting by focusing on the preparation of PSETs will allow us to show and pilot the feasibility and utility of the proposed online platform. Although we will not have any results by the time of the presentation, we will present on our design and seek feedback on the initial phases of our project.

ESSENTIAL DOCTORAL PROGRAM FEATURES IDENTIFIED BY MATHEMATICS EDUCATION UNIVERSITY FACULTY

Scott A. Courtney
Kent State University (USA)
scourtn5@kent.edu

Anita N. Alexander
Bilkent University (Türkiye)
anita.alexander@bilkent.edu.tr

The purpose of this study was to learn from university faculty with a doctorate in mathematics education from across the world about how programs in mathematics education should prepare doctoral students for research and teaching in mathematics education. Online survey responses indicated that 99 mathematics education university faculty from 33 different countries stressed the importance of providing doctoral students with opportunities to examine and compare fundamental theories of learning mathematics; examine current and historical research in the field of mathematics education; and develop broad and deep knowledge of the big ideas ages 2-20 years (i.e., grades preK-14) mathematics.

Keywords: Teacher educators, teacher knowledge.

Over the past 20 years, there has been a significant increase in research into the development of and issues around mathematics teacher educators (MTEs). One subset of MTEs lacking a robust research base is the group of holders and pursuers of doctorates in mathematics education or didactics of mathematics, depending on your geography and background. Existing research on mathematics education doctorates, although limited, has highlighted the great variability in preparation and programs (e.g., mathematics knowledge preparation, research training) and focused on the potential to identify a common core of knowledge and experiences that would prepare graduates for diverse careers (Goos & Beswick, 2008; Kilpatrick & Spangler, 2015; Reys, 2002).

The research presented here is part of a larger project designed to identify features of doctoral programs in mathematics education that remain essential across institutions and countries and have the potential to become part of a core set of experiences, practices, and expertise for any mathematics education doctoral program, regardless of where it is located (Grevholm et al., 2008). In this paper, we report on ongoing international research to collect and examine data about the experiences, practices, and expertise of individuals with or working toward a doctorate in mathematics education. The following questions guide the research presented here: What features of doctoral programs, across countries, do individuals working as university faculty and possessing a doctorate in mathematics education identify as being essential?

Methods

A combination of purposive and convenience sampling was used to identify and contact (via email) potential participants for the larger study, which is composed of individuals with a doctoral degree in mathematics education (or didactics of mathematics) or currently working toward such a degree. Several proceedings from international and regional mathematics education conferences from the past five years (e.g., CERME 13, MERGA 45, NORMA 20, PME 46, PME-NA 45, The Mathematics Education for the Future Project, XVI CIAEM) were used to obtain the email addresses of potential study participants. Next, potential participants were emailed a letter introducing the study and inviting them to click on a link to a consent form and survey (the survey link is still active and available at https://tinyurl.com/DocMathEd). The survey was designed to identify the experiences, practices, and expertise of individuals holding or pursuing a doctorate in mathematics education. It was hoped that respondents would forward the email and link to their colleagues and/or doctoral students, which occurred in several instances.

Participation

Survey participants for this report comprised 99 mathematics education university faculty from 33 countries (e.g., Australia, Canada, Indonesia, Japan, Netherlands, Sweden, U.S.). Each participant self-identified as someone working as a university faculty member and possessing a doctorate in mathematics education (or didactics of mathematics). Forty-one participants (41.4%) received their doctorate in mathematics education from a Department of Education, 23 participants (23.2%) from a Department of Mathematics or Mathematical Sciences, 17 (17.2%) from a Department of Mathematics Education, and 18 participants (18.2%) received their degree in some other department (e.g., Department of STEM Education).

Data Collection

Participants were asked a series of survey questions regarding how important they believed specific features (see Table 1) were to a doctoral program in mathematics education.

Table 1: Doctoral Program Features

Doctoral Program Feature (F)	Doctoral Program Feature (F)
F1 - Analyze, design, and evaluate mathematics curricula	F8 - Develop broad and deep knowledge of the big ideas in preK–14 (e.g., ages 2-20 years) mathematics
F2 - Study the history of mathematics education	F9 - Examine how the big ideas in preK–14 (e.g., ages 2-20 years) mathematics develop in students
F3 - Examine historical, social, political, and economic factors that influence mathematics education	F10 - Utilize technology as a tool of inquiry in mathematics teaching and learning
F4 - Examine current and historical research in the field of mathematics education	F11 - Design learning experiences for students and teachers that utilize technology
F5- Examine and compare fundamental theories of learning mathematics	F12 - Supervise field experiences for prospective (pre-service, student) mathematics teachers
F6 - Examine the influence of curriculum frameworks, standards, and/or competencies on school mathematics programs	F13 - Examine issues of diversity, equity, and inclusion in mathematics learning and teaching
F7 - Examine and compare different forms and purposes of assessment	

Responses were limited to “Very Important,” “Moderately Important,” “Slightly Important,” “Not Important,” and “Not Necessary/Not Required.” All 99 participants responded to 13 of these Likert-type level of importance questions.

Analysis

The Likert-type level of importance questions was analyzed by weighing each possible anchor response as follows: “Very Important” = *4*, “Moderately Important” = *3*, “Slightly Important” = *2*, “Not Important” = *1*, and “Not Necessary/Not Required” = *0*. For example, the question focused on the importance of the doctoral program feature “Analyze, design, and evaluate mathematics curricula” received the following responses: “Very Important” was selected by 31 participants; “Moderately Important” was selected by 34 participants; “Slightly Important” by 22 participants; “Not Important” by two participants; and “Not Necessary/Not Required” by nine participants. Next, a Friedman Test was performed to determine if statistically significant differences existed between participants’ responses (i.e., level of importance) and the 13 program features. Furthermore, Dunn’s pairwise post hoc tests were used to determine which, if any, mean rank pairs of program features were significantly different.

Results

Results of the Friedman Test indicated a significant difference in the selected importance levels between the different program features, $\chi^2(12) = 222.57$, $p < .001$. The mean rank score of each program feature from largest to smallest is as follows: F5 (9.65), F4 (8.43), F8 (8.28), F9 (8.03), F13 (7.24), F3 (7.12), F6 (7.11), F7 (6.59), F1 (6.58), F10 (6.04), F11 (5.55), F2 (5.51), F12 (4.87).

The Dunn’s pairwise post hoc test adjusted by the Bonferroni correction for multiple tests indicated the mean ranks of the pairs indicated by * were significantly different (see Table 2).

Table 2: Dunn’s Pairwise Post Hoc Test Results

	F1	F2	F3	F4	F5	F6	F7	F8	F9	F10	F11	F12	F13
F1	—	1.000	1.000	*	*	1.000	1.000	.097	.449	1.000	1.000	.089	1.000
F2		—	.170	*	*	0.180	1.000	*	*	1.000	1.000	1.000	.076
F3			—	.964	*	1.000	1.000	1.000	1.000	1.000	.214	*	1.000
F4				—	1.000	.918	*	1.000	1.000	*	*	*	1.000
F5					—	*	*	.680	.156	*	*	*	*
F6						—	1.000	1.000	1.000	1.000	.227	*	1.000

F7	—	.103	.474	1.000	1.000	.083	1.000
F8		—	1.000	*	*	*	1.000
F9			—	*	*	*	1.000
F10				—	1.000	1.000	1.000
F11					—	1.000	.097
F12						—	*
F13							—

Dunn’s pairwise post hoc test results indicated F5 was significantly different than nine other features, F12 was significantly different from seven other features, and F4 was significantly different from six other features. Therefore, F5, the feature with the largest mean rank score, significantly differed from 75% of the other features. Item F5 (Table 1) asked participants to indicate the importance (to a mathematics education doctoral student) of examining and comparing theories of learning mathematics. Similarly, F4, the feature with the second largest mean rank score, was significantly different than 50% of the other features, highlighting the importance (to mathematics education doctoral students) of examining current and historical mathematics education research during doctoral studies. Finally, F12, the feature with the smallest mean rank score, significantly differed from 58.3% of the other features, highlighting the relative lack of importance (to mathematics education doctoral students) of supervising field experiences for prospective (pre-service, student) mathematics teachers.

Discussion

As reported here, doctoral programs in mathematics education should, at a minimum, provide doctoral students with ample opportunities to examine and compare fundamental theories of learning mathematics; examine current and historical research in the field of mathematics education; develop broad and deep knowledge of the big ideas in ages 2-20 years mathematics (i.e., grades preK-14); and examine how the big ideas in ages 2-20 years mathematics develop in students. Less consequential are opportunities to supervise field experiences for prospective (pre-service, student) mathematics teachers, study the history of mathematics education, and design learning experiences for students and teachers that utilize technology. This report is part of a larger, international study with the intent to continue the discussion and promote actions toward more cohesive expectations, practices, and expertise for doctoral programs in mathematics education. Such discussions and actions have the potential to develop guidelines for robust mathematics education doctoral programs regardless of the program’s location.

AN ARGUMENT FOR A SYSTEMIC APPROACH TO CHANGE IN THE FIELD OF MATHEMATICS EDUCATION

Madeline Keyes
Boston College
keyesma@bc.edu

Keywords: Systemic Change

The purpose of this poster is to begin a conversation about why systemic change needs to be brought into the field of mathematics education. This is a direct response to the conference's call to envision the future of mathematics education in uncertain times, and our reply is to open a dialogue by connecting systemic change-oriented literature from across fields to expand and adapt the conversations we are having as math educators in our present world of ever-increasing complexity. We additionally provide one possible argument for why mathematics education as a system is complex enough to warrant systemic approaches toward change.

First, it is important to establish a common understanding of the word "system" and how mathematics education interfaces with this idea. There is no single definition of a system; instead, multiple definitions co-exist in a manner that "reflects the multidimensionality of the concept" (Hieronymi, 2013, p. 585). Systems change likewise has many different conceptions but aims to answer "what change is needed, why is it needed, and what might be the unintended consequences" (Abercrombie et al., 2015, p. 9). Systems change discourse has not always upheld deep equity in the way true systemic change requires across individual, interpersonal, institutional, and systemic/societal domains (Petty & Leach, 2020). Gutiérrez (2017) similarly discusses the way that surface-level tinkering around equity in mathematics education cannot yield results in a fundamentally flawed system. Bringing the language of systemic change to mathematics education represents one potential opportunity to begin this necessary process of change.

How do we know that systems thinking is appropriate for the field of mathematics education? The Omidyar Group provides a guide that helps us to answer this question by considering four dimensions of challenge complexity: (1) the more unsure we are about the exact nature of the problem or solution; (2) the more there is a significant diversity of opinion or conflict between opinions and stakeholders; (3) the more "diverse and dynamic interconnections between the problem and the broader environment, which itself is unstable and dynamic (political, social, and economic)"; and (4) the more our goal is "to make sustained change at a broad scale," the more important it is to use systems thinking and design (p. 10). The higher the level of alignment with the above statements, the more appropriate systems level thinking is, argues the Omidyar Group. The multiple iterations of the Math Wars (Schoenfeld, 2004) and politicized backlash to "challenging the status quo" (Gutiérrez, 2017, p. 8) prove that mathematics education is no stranger to conflict due to differing opinions about the nature and purpose of mathematics instruction (Dimensions 1 and 2). Mathematics in education is also tied to broader educational structures, including in many cases standardized testing and accountability structures (Dimension 3). The poster presentation will center on linking research in mathematics education to these four elements of complex problems requiring systems thinking to advance our understanding of mathematics education's place within this discourse. Through this poster, we aim to create open dialogue about how some of the challenges we face in the field of mathematics education interface with existing literature on systems change.

EXAMINING A CASE OF A MATHEMATICS COACH LEARNING SYSTEM

Nicholas Kochmanski
University of North Carolina at Greensboro
nmkochmansk@uncg.edu

Joshua Recore
University of North Carolina at Greensboro
jcrecore@uncg.edu

We report on a case study examining one district's efforts to implement a district-wide system of support for mathematics coaches' learning. Through interviews with school-based mathematics coaches and district personnel, we identified four activities that coaches saw as beneficial in supporting them to enact one-on-one coaching cycles effectively: (1) traditional pull-out professional development sessions, (2) partnerships between pairs of school-based mathematics coaches at different schools, (3) school-based coaching days in which all mathematics coaches worked collectively on issues relevant to coaching practice, and (4) individualized support from the district-based K-12 mathematics specialist. We describe the four activities and what the coaches and a district mathematics specialist perceived to be their function(s) in supporting coaches' learning.

Keywords: Professional Development, Teacher Educators, Instructional Leadership.

One-on-one mathematics coaching can support improvements in mathematics teaching and learning when coaching *is done well* (Campbell & Malkus, 2011; Russell et al., 2020; Kraft & Hill, 2020). However, the work of mathematics coaching differs significantly from mathematics teaching (Kane & Saclarides, 2023; Kochmanski & Cobb, 2023a; Saclarides & Kane, 2023), and many mathematics coaches often transition to the role directly from the classroom with few opportunities to learn to coach effectively prior to working with teachers. Most novice mathematics coaches will therefore require support for their own learning if they are to coach in ways that can significantly enhance teachers' and students' learning (Kane & Saclarides, 2023; Saclarides & Kane, 2023).

Just as teachers can benefit significantly from systems of support that link together different types of teacher learning activities (Cobb et al., 2018), mathematics coaches are likely to benefit from similar systems of support that link together different types of coach learning activities. However, few studies have examined types of professional learning activities that could support mathematics coaches' development, beyond traditional pull-out professional development (Saclarides & Kane, 2023). Further, there is limited research examining how different types of coach professional learning experiences might cohere to form a system of support for coaches' learning. Schools and districts therefore face the daunting prospect of implementing school- or district-wide coaching initiatives without a clear research base that can inform their efforts to support coaches in learning to coach effectively.

In this paper, we address this gap in the coaching literature by reporting on one district's efforts to implement a system of support for mathematics coaches' learning. Specifically, we identify the types of coach learning activities in the coach learning system. We also define the function(s) those activities appeared to serve in supporting coaches' learning. The following research questions informed our investigation of the coach learning system: (1) What types of coach learning activities do mathematics coaches perceive to be beneficial for their learning? (2)

What do mathematics coaches and the district mathematics specialist perceive to be the function(s) of the coach learning activities in supporting coaches' learning?

Conceptual Framework: Toward a Coach Learning System

Teachers can benefit significantly from opportunities to engage in a coherent support system of supports that link together potentially productive teacher learning experiences (Cobb et al., 2018). For example, teachers are likely to benefit greatly when traditional professional development includes and is linked to classroom-based coaching (Rock, 2019). Given these potential benefits to teachers, it stands to reason that coaches are also likely to benefit from a system of support focused on their learning. Several recent studies have examined efforts to support coaches' learning in traditional, pull-out professional development settings (Stein et al., 2021; Swars Auslander et al., 2023), finding that coach professional development (PD) can support coaches in developing effective coaching practices (Stein et al., 2021). Yet, there may be other types of professional learning activities that could support mathematics coaches' development, beyond traditional pull-out PD. For example, coaches could benefit from engaging in collective coaching experiences, just as teachers benefit from collective teaching experiences like lesson study (Lewis et al., 2009) or mathematics labs (Kazemi et al., 2018). Understanding the nature and function of different types of coach learning activities beyond traditional pull-out PD is an important step in defining the elements of a productive coach learning system.

Methods

We employed a case study methodology (Yin, 2017) to answer our research questions.

Focal Case: Apple Valley Schools

We focused our case study on Apple Valley Schools (AVS; name is a pseudonym), which is a mid-sized school district located in the Southeastern United States. We selected AVS for this study because the district employs ten school-based mathematics coaches and a K-12 mathematics specialist, whose primary job function is to support the school-based coaches. At the time of the study, the district was also implementing several distinct coach learning activities. Specifically, AVS was partnering with faculty at a nearby regional university to design and implement pull-out coach PD. University faculty worked with the AVS K-12 mathematics specialist to design coach PD sessions focused on different aspects of coaching practice central to enacting one-on-one coaching cycles effectively. One-on-one coaching cycles are a common coaching routine for which there is significant evidence that they can support teachers' learning when facilitated effectively (Russell et al., 2020; Kochmanski & Cobb, 2023a). The K-12 mathematics specialist also established formal coaching partnerships between pairs of school-based coaches. Further, the specialists implemented school-based coaching days, which were opportunities for the school-based coaches to work together in a common school space.

Data and Data Analysis

We conducted semi-structured interviews with the ten school-based mathematics coaches and with the K-12 mathematics specialist. We used online video conference software to conduct the interviews. Each interview included questions focused specifically on the types of coach learning activities the district was implementing (e.g., pull-out PD, coaching partnerships). The interviews also included questions focused specifically on the purpose(s) of the activities in supporting coaches' learning. Additionally, we asked open-ended questions intended to elicit coaches' perspectives on other types of coach learning activities or learning structures beyond the three primary activities the district was implementing. For example, we asked coaches to respond to the question, “Imagine a district leader was about to begin designing a system of support for coaches. What advice would you give them?”

To answer our first research question, both authors consensus coded each of the ten coach interviews for the types of coach learning activities that the coaches saw as beneficial. We documented our codes in an excel spreadsheet. We also documented the coaches’ descriptions of each type of coach learning activity. To answer our second research question, we open coded the ten interviews with coaches and the interview with the mathematics specialist to characterize the coaches’ and the district mathematics specialist’s perspectives on the function(s) of the coach learning activities. We used open coding because the current coaching literature provides little to no guidance regarding the functions of such activities in supporting coaches’ learning.

Findings

The mathematics coaches in AVS identified four types of coach learning activities that they perceived to be beneficial for their learning: (1) traditional pull-out professional development led by an outside facilitator, (2) peer coaching partnerships, (3) the school-based coaching days, and (4) individualized, school-based support from the K-12 mathematics specialist.

Traditional Pull-out PD

All ten of the mathematics coaches perceived the pull-out coach PD to be beneficial to their learning. The ten coaches noted that it was beneficial for the PD to be led by a university faculty member, and thus a facilitator outside of their district. This meant that the participating coaches had the opportunity to engage with what one coach referred to as a “perspective that was different than the usual district” perspective. Eight of the ten coaches also found it beneficial when the PD sessions centered on case studies of one-on-one coaching. Coaches found the case studies to be especially beneficial when they originated from AVS coaches’ own work, as this meant they could spend more time discussing the nuances of coaching and less time trying to understand the context for the case.

Regarding the function of the PD, all coaches and the district mathematics specialist explained that the purpose of the coach PD was to introduce coaches to new and effective coaching practices. That said, several coaches also noted that the PD enabled the coaches to develop a common framework for and language to describe one-on-one coaching in the district. The coaches explained that this language was often formalized in the resources the PD facilitator shared in the PD sessions. Finally, several coaches also explained that the PD provided them with opportunities to think more deeply about mathematics teaching and learning, especially as the case studies often involved an analysis of mathematics lessons and students’ work.

Peer Coaching Partnerships

Eight of the ten coaches saw the district-initiated peer coaching partnerships as beneficial for their learning. The other two coaches saw potential for this type of partnership to benefit their work but outside circumstances (e.g., scheduling difficulties) limited their ability to realize that potential. All eight coaches who perceived the benefit of the partnerships visited their partner coach’s school. On these visits, the partnering coaches observed lessons together and then met to discuss potential next steps for working with individual teachers. Several coaching partnerships also discussed strategies for facilitating coaching conversations with teachers in the building. For example, one coach mentioned that her partner coach helped her rehearse for an upcoming coaching conversation that she thought might be particularly challenging.

Most of the coaches thought it was helpful to see instruction at different schools, as this helped them see common instructional challenges across the district. Five coaches and the district mathematics specialist saw the partnerships as functioning like a coaching professional learning community (PLC). As one coach put it, while she had a PLC as a teacher, she was on her own as a coach. The district-initiated partnership gave her someone else in a similar role who could serve as a collaborator and a "go-to person." Finally, three of the coaches noted that the coaching partnerships provided another set of eyes on the coaching process. This helped them identify their own coaching biases and look at teaching and coaching in new ways.

School-Based Coaching Days

All ten coaches saw the school-based coaching days as beneficial for their learning. According to the coaches, the school-based coaching days consisted of teams of 3-4 coaches visiting a classroom for a full lesson. The coaches then met afterward to discuss the data they collected during the observation and what they perceived to be next steps for supporting the teacher's learning. Finally, the whole group of ten coaches met to discuss what they noticed in the lessons they observed. The coaches saw the coaching days as opportunities to put into practice many of the ideas discussed in the pull-out PD sessions. As one coach put it, the school-based coaching days were a chance to "develop your craft as a coach." Coaches noted they had opportunities to get better at documenting students' thinking in the lesson and the teacher's actions during the lesson. They also had the chance to work with fellow coaches to connect instruction and students' thinking when identifying next steps for the teacher, which is an important coaching practice (Kochmanski & Cobb, 2023b).

Individualized Support from K-12 Mathematics Specialist

Three of the coaches described it as beneficial to receive individualized support from the district K-12 mathematics specialist. All three coaches were either new to the district or new to their school. The coaches described the individualized support as taking many different forms, from formal school visits in which the specialist helped the coach lead portions of a one-on-one coaching cycle to informal text exchanges where the coach asked the district mathematics specialist for advice. According to the coaches, the primary function of the individualized support was to provide the coaches with opportunities to bounce ideas off an experienced coach and to receive resources they may not have known about previously. The district mathematics specialist saw the individualized support as serving a different function. She noted that it provided her with an opportunity to help the coaches think about the culture of their individual schools, with the goal of making each school a productive place for improvement.

Discussion and Conclusions

This case study of a district-wide effort to support mathematics coaches' learning resulted in the identification of four types of coach learning activities that appear to be beneficial for coaches' learning. Describing these four types of coach learning activities and documenting their functions in supporting coaches' learning is an important step toward a research-based understanding of a productive coach learning system. Future research can build from this study by investigating the learning opportunities these types of activities present to coaches, what it takes to facilitate the coach learning activities effectively, and the conditions necessary for their effective implementation.

MATHEMATICS TEACHER EDUCATORS DEVELOPMENT OF INSTRUCTIONAL ACTIVITIES TO IMPACT PRESERVICE TEACHER CURRICULAR REASONING

Alyson E. Lischka	Signe E. Kastberg	Susan L. Hillman
Middle TN State Univ	Purdue University	Saginaw Valley State Univ
Alyson.Lischka@mtsu.edu	skastber@purdue.edu	shillman@svsu.edu

We address mathematics teacher educators' (MTEs') instructional activity design practice to inform preservice teachers'(PTs') curricular reasoning. Findings from a self-study of three MTEs' instructional activity design in methods courses focus on opportunities for PTs' as curriculum reasoners. We argue MTEs' instructional activity designs are informed by ontological goals for teaching about curricular reasoning, such as curricular agency, and assumptions about curricular contexts.

Keywords: Preservice Teacher Education, Teacher Educators, Curriculum

Mathematics teacher educators (MTEs) develop instructional sequences to inform preservice teacher (PT) curricular reasoning (Tyminski et al., 2013). Though research includes principles for instructional design (Drake et al., 2014) and courses (Saclarides et al, 2022), MTE instructional design practices to support PTs' curricular reasoning are complex and require additional characterization (Ghousseini & Herbst, 2016). As relational (Kitchen, 2005) constructivist (Steffe & D'Ambrosio, 1995) MTEs, we use self-study to describe instructional design practice. Relationships with PTs (Kastberg et al, 2022) and evidence of their pedagogical concepts (Simon, 2008) inform our instructional decisions. We use evidence of PTs' learning to create opportunities for PTs to learn to teach from experience. We have described "layering instructional activities" (Kastberg et al., under review), though instructional activity design remained opaque. Theories of curricular reasoning address how contexts may constrain teachers' curricular decisions. MTE curricular decisions have few constraints (Tran & O'Connor, 2023) such that MTEs' domain of potential action (Brown & Coles, 2020) is broad. This research seeks to address: What informs MTE design of curricular reasoning activities?

Background and Literature

MTEs' instructional activity design process evolves as they internalize their ideas about PTs' learning of pedagogy, theories of mathematics education, and lived experiences as MTEs. In this paper we describe factors MTEs use as they design and enact activity sequences. Examples of MTEs' instructional activity design for PTs (e.g., Ghousseini & Herbst, 2016; Tyminski et al., 2013) illustrate two dimensions: MTEs' use of theories of teacher learning (e.g., Gutiérrez, 2018; Hammerness et al., 2005; Kazemi, 2018) and pedagogies of practice (Grossman et al., 2009). Using self-based methodologies (Borko et al., 2007) MTEs seek to make sense of and represent the intersectional nature of action and knowledge in practice (e.g., Kalinec-Craig et al., 2021). Thus, instructional design is guided by goals and histories of interactions with PTs (Coles, 2013). Jaworski (2021), Chapman (2021), and others address how MTEs' practices emerge and how practice informs MTEs' development. Such accounts characterize the particular (Hamilton & Pinnegar, 2014) providing exemplars of MTE learning and development producing knowledge as "a complex, integrated system and way of being/thinking and as knowing how to act in the teaching process" (Chapman, 2021, p. 415). Our interactions with PTs inform the design and modification of instructional activities in support of PTs as curriculum reasoners. We view MTE instructional activity design as situated and emerging through interactions with PTs.

Curricular reasoning is "thinking processes" teachers use with curricular materials (Breyfogle et al., 2010, p. 308). Curricular materials include print textbooks and online resources (Dingman et al., 2021). PTs must learn to read, analyze, and discuss curriculum (AMTE, 2017) to set goals and select tasks (NCTM, 2014). PTs' use of curriculum includes adhering, elaborating, creating (Nicol & Crespo, 2006), and adapting materials (Lloyd, 2008). This suggests MTEs must provide opportunities for PTs' curricular reasoning.

Mathematics methods includes opportunities for PTs to engage in curricular reasoning with attention to context, autonomy, and agency. Drake et al. (2014) showed reading curricular materials has subskills, with subskill development and recomposition (Sapkota & Max, 2023) during one methods course unlikely (Saclarides et al., 2022; Simon, 2008). Teacher curricular reasoning has variability even when agency is constrained. Tran and O'Conner (2023) identified constraints on teachers' curricular agency including centralized curriculum. Though curricular contexts may appear fixed and curricular autonomy constrained, teachers use curricular agency as they reason with and enact curriculum with learners. We describe our process of designing instructional activity sequences informed by our goal of supporting PTs' use of curricular agency in varied curricular contexts with conscious curricular reasoning and decision making.

Methodology and Methods

We are three white female MTEs, each with over 10 years' experience teaching mathematics methods at different institutions. Our institutional missions range from teaching-focused to research-intensive and our program foci span elementary to secondary teacher certification. We use self-study methodology, defined as self-initiated, improvement-aimed, and interactive using qualitative methods (LaBoskey, 2007) as means to study and improve our practice. Dialogue is a central process used in coming to know (Pinnegar & Hamilton, 2009). Weekly dialogues focused on our practice used "constructivist listening" (Weissglass, 2004) to enable the talker to represent her thinking and dialogue with "critical friends" (Schuck & Russell, 2005) regarding alternative perspectives on shared events.

We used four analytic methods: 1) 10 analytical dialogues (Guilfoyle et al., 2007) during fall 2023 to unpack the "details of the experience of teaching" and theorize about principles of practice from our experience (Brown & Coles, 2020, p. 99), 2) evidentiary maps of the "structure of events" (Jordan & Henderson, 1995, p. 57) in our fall 2023 methods courses involving events and artifacts from our instructional activity design practice, 3) cases of PTs as curricular reasoners to interpret the cumulative impact of instructional activities on PTs' curricular reasoning, and 4) descriptive coding (Saldana, 2016) of our recorded dialogues to search for confirming and disconfirming evidence. These four analytic methods created an evidentiary basis for findings common across three MTEs' design of instructional activities and related contexts.

Findings

This section describes two components influencing our instructional activity design for PTs' curricular reasoning: (1) goal of curricular agency, (2) imaginings of curricular contexts. Data from all three authors' design of instructional activities were used to derive the findings. Here, we represent findings addressing the question: What informs MTE design of curricular reasoning activities? using excerpts from transcripts of dialogic conversations focused on Alyson's experience. The following narrative highlights coming to know how our support for PTs' curricular reasoning was informed by our goal that PTs develop awareness of curricular agency.

My (Alyson) methods course is the second of two required mathematics methods courses in our secondary and middle grades preparation programs focusing on grades 8 – 12 mathematics content. Secondary PTs take this course the semester prior to student teaching and middle grades teachers take it earlier. Enrollment was low in Fall 2023; with three PTs in the course (Claire and Ashley – secondary, Crissy – middle grades; pseudonyms), I had freedom to experiment as I supported development of their ideas about curriculum. I used *Principles to Actions* (NCTM, 2014) as a text, with emphasis on the mathematics teaching practices, knowing the prerequisite course focused on student thinking. Two major tasks of this course are: 1) three teaching rehearsals and 2) two written multi-day lesson plans. No field experience is connected to this course, though PTs are in other field placements while taking this methods course.

I began by wanting to make use of textbooks matching the scope and sequence for courses in the local school system where most of the PTs would find jobs. I wondered how to prepare them to use textbooks as the *approved curriculum* due to state policy. I acknowledged this contextual constraint in a critical friend conversation:

> I'm very conflicted with this because I want to support the school system and that they're making decisions in the best way they possibly can [with scope and sequence documents] . . . But I also think a teacher teaching Precalculus ought to be able to teach circles as the first of the conic sections if they want to. (Conversation, 11/13/23)

I did not want to force PTs to use textbooks – though textbooks can be useful. My goal: PTs develop problem solving lessons with opportunities for learners to make sense of mathematics. Critical friend conversations focused on how I could learn about my PTs' thinking. I started my instructional sequence with a standards interpretation activity. PTs created posters mapping mathematics content across four courses. After this introduction to high school content, I needed evidence of PTs' ideas about curriculum. I was unsure of my goals for PTs' curricular reasoning.

> I'm really wondering if I should give them each a poster paper and say, "think about your lesson plan. Think about what was influencing your decisions about what you included - and what you chose not to include? And see what I get. (Critical Conversation, 10/30/23)

Knowing their thoughts about curriculum would help me clarify goals. I used reflective writing and a concept mapping activity to gather evidence of PTs' curricular ideas to create instructional activities built from these ideas. PTs' work was revealing. Claire focused on order of standards: what learners should know and connect to what is next. Claire questioned who decides the order for teaching concepts and if the sequence of concepts from the textbook could be changed. Crissy reasoned about concept order to simplify concepts for learners to understand. Ashley's curricular reasoning considered what learners *do* know (rather than *should* know) and selected resources based on learners' demonstrated knowledge. In a critical friend conversation Susan wondered about PT agency when Alyson brought up a PTs' question on order of concepts.

Susan: Do you think the PT is asking “Is there one right way to approach it?” Or were they saying, “Do I have the agency to change it when the textbook says this?”

Alyson: A little bit of both, and I think she wants to know why the authors of the textbook put it in that order - she wants to make an instructional decision with more information. (Conversation 11/13/23)

I designed additional layers of activities (Lischka et al., 2023) including textbook analysis. Textbooks and teachers’ editions as curricular resources can be overwhelming. Research findings provide insights about what PTs attend to – but would PTs in my course attend to elements identified in research, or have other ideas? I observed the PTs’ choices during the textbook analysis which led to the rehearsal of launching a lesson using provided curriculum materials.

PTs used textbook sections differently during rehearsals. Claire used a textbook activity but changed the context. Crissy used a textbook example but “simplified” the directions. Ashley used an activity not in the text but planned to use textbook examples later in the lesson. Each of the PTs reasoned about the textbook as a curricular resource, but I wondered about the impact of the rehearsal, or whether they brought curricular reasoning from other courses or experiences?

PTs created two lesson plans on assigned topics to demonstrate learning concepts in this course. PTs considered how they incorporated strategies from class into plans, and selected materials to support instructional goals, within constraints I provided. I struggled with feedback to help PTs find balance between developing conceptual understanding and procedural fluency, torn between telling them to use particular curriculum resources and wanting them to make their own curricular decisions to reach their instructional goals.

PTs final lesson plans had a better connection between conceptual development and procedural fluency. These PTs were provided with more textbook access, and they used the textbooks more than PTs from prior semesters. PTs seemed to be exploring their agency in curricular reasoning. PTs’ end of term reflections showed a desire to “make decisions, get them down and then evaluate after that” (Ashley, Final Self-Evaluation).

Discussion: Agency, Context, and Instructional Design Practice

Research provides evidence of how PTs read (Tyminski et al., 2013) and use curricular resources (Nicol & Crespo, 2006). The complexity of MTEs’ work using learning theories (e.g., Kazemi, 2018), core practices (Grossman & Dean, 2019) and pedagogies of practice (Grossman et al., 2009) to support PT development (Ghousseini & Herbst, 2016) suggests study of MTEs’ instructional activity design practice could provide findings connecting such practice to PTs’ development of curricular reasoning (Breyfogle et al., 2010). We used self-study methodology and qualitative methods to gather empirical evidence of MTEs’ ways of knowing in instructional activity design to impact PTs’ curricular reasoning. We found that MTEs’ instructional activity design was based on ontological goals for PTs’ curricular reasoning, namely supporting PTs’ awareness and use of curricular agency in curricular contexts with varied constraints.

Our findings represented by Alyson’s narrative illustrate ways of knowing involved in instructional activity design for the development of PT’s curricular reasoning, beyond time related tensions in MTE design described by Saclarides et al. (2022). Aligned with findings from explorations of MTEs’ instructional activity design practice for teachers (Ratnayake & Taranto, 2023), we found that MTEs use existing theories of learning and being in making instructional activity design decisions. Alyson’s commitment to working with PTs’ ideas as the basis for curricular reasoning instructional activities was informed by principles of relational practice (Kitchen, 2005) and constructivist teaching (Kastberg, 2014; Steffe & D'Ambrosio, 1995). Yet beneath these decisions was an ontological goal supporting the layers of instructional activity designed to support PTs' curricular reasoning; our goal was for PTs to become conscious of and use curricular agency in curricular contexts informed the series of instructional activities we developed. Assigning topics to the PTs constrained the curricular context as Alyson expected PTs to use curricular agency (Tran & O'Connor, 2023) to address the imposed constraints. Alyson's discussions with PTs focused on gaining evidence of how they were reasoning about standards and textbooks and using those resources to demonstrate agency within constraints. This study builds on prior research (e.g., Tyminski et al., 2013) and points to the need for more research on how MTEs design instructional activities to support PTs' curricular agency in increasingly constrained contexts.

Mathematics teacher educators (MTEs) play a significant role in supporting preservice teachers (PTs) to develop the mathematical content and pedagogical knowledge they need for teaching. We examined what four novice prospective MTEs learn about supporting PT learning when they are part of a Community of Practice (CoP) in a mathematics content course taught through problem solving. We collected data through weekly reflections written by the prospective MTEs, researcher memos, interviews with each participant at three points in the semester, and notes from the CoP twice weekly discussions. We found that the prospective MTEs learned by observing their students' learning and by making sense of their roles in the course taught through problem solving. We also found that the CoP, weekly readings and having an intern role in the course were key to supporting the prospective MTEs' learning.

Keywords: Teacher Educators; Teacher Knowledge; Problem Solving; Mathematical Knowledge for Teaching

Mathematics teacher educators (MTEs) play a significant role in supporting prospective teachers (PTs) to develop the mathematical content and pedagogical knowledge they need for teaching. Research has shown, however, that most of the MTEs in the United States have little experience teaching students at the level of mathematics that they are preparing PTs to teach (e.g., elementary school), and that they receive little to no training or support either in their graduate programs or in their jobs (Masingila & Olanoff, 2022; Masingila et al., 2012).

Mathematics professional organizations (e.g., Conference Board of the Mathematics Sciences (CBMS) in the USA, Association of Mathematics Teacher Educators in the USA) have recommended that PTs develop deep and connected understandings of foundational mathematical ideas and be engaged in doing mathematics that "allows time to engage in reasoning, explaining, and making sense of the mathematics that prospective teachers will teach" (CBMS, 2012, p. 17) and "develop the habits of mind of a mathematical thinker and problem-solving" (p. 19). Masingila et al. (2018) proposed that one way to "foster deep mathematical knowledge development in PTs is to engage them in learning mathematics via problem solving" (p. 431). Since prospective MTEs have typically experienced traditional mathematics teaching and learning in their academic and teaching experiences, we argue that for MTEs to be prepared to support PTs in learning via problem solving, they need to experience, reflect on, discuss with others, and learn from teaching and learning through problem solving.

In this paper, our goal is to contribute to the mathematics education community's understanding of how novice MTEs may be prepared to support PTs in learning via problem solving. Specifically, our contributions are to provide evidence from our four participants of how this learning occurred through this experience. We examined how four novice prospective MTEs learn about teaching and learning mathematics through problem solving when they are part of a CoP comprised of instructors and interns (novice prospective MTEs) working together to support PTs' learning in developing mathematical understandings through problem solving.

We engaged prospective MTEs in an internship with particular design features situated within a Community of Practice (CoP) and the context of a mathematics content course for PTs taught through problem solving. The mathematics content of the course included the concepts of numeration, operations, number theory, and probability and statistics. The course met for 80 minutes twice a week with the 22-28 PTs working collaboratively on problem-solving tasks that the instructor introduced. The instructor and interns facilitated the small group problem solving and the instructor led the PTs in a wrap-up discussion bringing out the mathematical ideas from the tasks. For more information on this course and a second course with content including the concepts of geometry, measurement and rational numbers see Masingila et al. (2018).

Theoretical Framing

The bodies of literature that guided our work involve (a) Communities of Practice, (b) Mathematical Knowledge for Teaching and Mathematical Knowledge for Teaching Teachers, and (c) Learning through Problem Solving. Wenger, McDermott, and Snyder (2002) defined CoPs as "groups of people who share a concern, a set of problems, or a passion about a topic, and who deepen their knowledge and expertise in this area by interacting on an ongoing basis" (p. 7). Through a CoP, members develop and articulate new knowledge in response to questions and problems they have about their practice. A CoP offers a way for its members to engage in negotiating shared understandings, learning, meaning making, and identity. Wenger (1998) identified three dimensions of a CoP: (a) members interact with one another, and determine norms and relationships through *mutual engagement*, (b) members are held together by their understanding of a sense of *joint enterprise*, and (c) members seek to produce, over time, a *shared repertoire* of communal resources (e.g., language, routines, artifacts, stories). The members of our CoP were three instructors (one for each section of the mathematics content course), including a professor who was an experienced instructor of this course and served as the course supervisor, and six graduate students who served as interns. Two of the interns had previously been interns in the companion mathematics course with content of rational numbers, geometry, and measurement. The other four interns were new graduate students in mathematics education. Our CoP also included a graduate student who was part of the research team and had previously served as an intern. Our CoP provided us a space for working together to learn how to support PTs in their mathematical learning and grow as MTEs.

Based on Shulman's (1986) work, Ball and colleagues (Ball & Bass, 2002; Ball et al., 2008) introduced the term *mathematical knowledge for teaching* (MKT) and developed a framework for MKT that expanded on Shulman's descriptions of content knowledge and pedagogical content knowledge to include sub-categories of the mathematical knowledge that teachers need to know. More recently, researchers have examined the mathematical knowledge needed by MTEs to support PTs in developing MKT (Castro Superfine & Li, 2014; Olanoff et al., 2018; Zopf, 2010) – *mathematical knowledge for teaching teachers* (MKTT). Zopf defined MKTT as, "the mathematical knowledge used by mathematics teacher educators in the work of teaching mathematics to teachers" (p. 11), and claimed that, "the major purpose of the work of [mathematics] teacher education is beginning with people who already know some mathematics and developing that knowledge into mathematical knowledge for teaching" (p. 165). Our CoP supported us in developing our collective and individual MKTT and afforded us the opportunity to observe the growth of the novice interns' MKTT.

Problem solving as a concept and a practice has been around for as long as humans have tried to overcome challenges. Mathematics educators and professional associations have long advocated for engaging students in learning mathematics through problem solving. The Conference Board of the Mathematical Sciences (CBMS) (2001) argued that PTs can develop deep understandings of mathematical ideas "with classroom experiences in which *their* ideas for solving problems are elicited and taken seriously, their sound reasoning affirmed, and their missteps challenged in ways that help them make sense of their errors" (p. 17). The CBMS (2012) continued arguing for engaging PTs in problem solving with its recommendation that courses for mathematics teachers should "develop the habits of mind of a mathematical thinker and problem-solver, such as reasoning and explaining, modeling, seeing structure, and generalizing" (p. 19). Teaching through problem solving, however, is quite challenging with the need for the teacher to select and facilitate high-level tasks, scaffold student learning as appropriate, and orchestrate discussions about the mathematics arising from the students' problem-solving work. Masingila et al. (2011) argued that the teacher's responsibility is to "establish a mathematical community in the classroom where everyone's thinking is respected and in which reasoning and discussing mathematical ideas and meanings is the norm" (p. 14). We were interested to see how novice prospective MTEs make sense of the teaching and learning in a mathematics course taught through problem solving.

Research Methods

Our aim in this study was to investigate what novice prospective MTEs learn when serving as interns in a mathematics content course for preservice elementary teachers taught through problem solving. Our research design was a descriptive case study.

Context

The course content focused on whole numbers and operations, number theory, probability, and statistics. The CoP instructional team met formally twice a week, on Mondays prior to the two lessons for the week and on Thursdays after the second lesson, as well as conversations among the CoP members occurred informally before and after lessons.

This course was taught with an emphasis on PTs learning mathematics through collaborative problem solving. PTs worked together in small groups to solve problems with the goal of developing deeper understandings of the mathematics taught in elementary school and their own MKT. The role of the instructors of the course was to facilitate the PTs' problem solving and knowledge development and the role of the interns was to support the instructor and the students in their problem solving.

Data Collection

The participants for this study were the four new graduate students serving as interns. The data collected were (a) weekly reflections written by each novice intern as part of their intern work, (b) weekly or bi-weekly memos from the researchers who were working with the interns in teaching, (c) interviews with each intern individually at the beginning, middle and end of the semester, and (d) notes from the CoP discussions.

For the weekly reflections, the interns were given a published article or book chapter related to teaching and learning through problem solving to read each week. They were asked to reflect on what insights they gained from the article and what insights they gained about both student learning and their own learning through their experience in the two lessons that week. Given the challenge of teaching through problem solving, instructors first serve as interns to experience teaching and learning through problem solving so the instructors had read and reflected on the readings when they were interns. The course supervisor and instructor of record for the internship course (the first author) read and responded to the interns' reflections individually via email. Additionally, she would often mention points raised by the interns in their reflections and bring it to the CoP for discussion during the twice weekly meetings. In this way, the readings were shared texts for the CoP members and situated the discussions of teaching and learning problem solving within the mathematics education literature.

The researcher memos were written individually by three of the authors, each of whom was working as an instructor or experienced intern in one of the course sections, with their observations of the novice interns in the course. The interviews were conducted by the second author who was not serving as an instructor or intern. The purpose of the interviews was to understand each participants' experiences prior to, during, and after the internship.

Data Analysis

Our data analyses were both ongoing and retrospective. We used open coding to inductively develop codes from the data. Ongoing analysis occurred during the semester and was the basis for developing the questions for the midway and end-of-semester interview questions and the testing of emerging hypotheses. Retrospective analysis involved examining the larger corpus of data through a carefully structured review of all the data sources. We used qualitative data analysis methods as described by Creswell and Creswell (2018). Our approach involved preparing the data for analysis, reading through and coding the data, generating themes, and interpreting the meaning of those themes across the data set.

Results

Below we share our findings of prospective MTEs' learning in two categories: (a) MTEs learning by observing their students' learning, and (b) MTEs learning by making sense of their roles in a course taught through problem solving. Note that all names used are pseudonyms.

Observing the Learning of Preservice Teachers

We found that prospective MTEs learned through observing how the PTs in the course developed their mathematical understandings and confidence. We identified the themes related to these observations of preservice teacher learning: learning through collaboration, learning through problem solving, and connecting student learning with course readings.

Learning through collaboration. One intern, Alex, seemed to especially value the way that PTs in the course learned through collaboration. They noted this growth and attributed it to the collaborative nature of the course:

> At the beginning of the course, many students expressed their frustration at the tasks and had less perseverance in struggling with the math. They are now more readily engaged in the learning tasks and, while individual questions might pose a challenge, they are as a group more resilient and likely to continue trying a problem even when it is challenging. Part of this

> growth is owed to their development of good group dynamics, communication, and collaboration. (Reflection Week 6)

Here we see that Alex learned that PTs developed understanding of mathematics through collaboration.

Alex noted the importance of this collaboration early in the course experience. When asked what it would look like for PTs in the course to be successful, Alex said, "effective collaboration is huge, like the fact that [the PTs] work in groups is really important. Again, so that they carry that into their own teaching, sort of having this collaborative mindset" (Beginning Interview). Alex viewed success for these students as learning to be collaborative, not just among peers for their learning, but for developing a collaborative mindset in their future roles as teachers.

Another intern, Cameron, learned to value the collaborative approach of the course. When reflecting on how PTs collaborated, Cameron said, "Almost every student gets involved in classroom activities in their groups and it becomes easier to monitor students by groups and provide help when necessary. Students feel comfortable trying new ideas and discussing their problem-solving strategies among their peers and asking relevant questions when necessary" (Reflection Week 6). Cameron found that collaborative learning made teaching logistically effective and encouraged PTs to share their ideas and ask questions.

Learning through problem solving. Another way that prospective MTEs observed PTs' growth is in the way that PTs developed as problem solvers, both in their mathematical skills and in attitudes toward doing mathematics. For example, Michael shared during a post-class discussion that he observed PTs' developing knowledge as they connected new algorithmic ideas to prior concepts of the course (Researcher Memo Week 6). Similarly, Alex observed a notable change in students' problem-solving abilities by the end of the semester. Alex said, "it's cool to say, you know, very concretely, I could, through my observations, say like, they didn't have these skills at the beginning of the course. And now I think if we put a problem in front of them that they had never seen before, they would apply these strategies of problem solving. It's very cool" (Post Interview). These examples show how MTEs observed PTs develop mathematical knowledge and skills on specific days in the classroom and throughout the semester.

John observed PTs gain confidence in their problem-solving capabilities. In a team meeting near the end of the semester, John shared that at the beginning of the semester, most students would ask the instructor and interns, "Is this right?" when they are working on a task. But now, near the end of the semester, they were confident in their solutions. So much so that even when John said that he does not think they are correct, they replied that they know that their solution is correct (Researcher Memo Weeks 9-10). Cameron, too, observed a shift in students' attitude toward learning mathematics, which he attributed to their learning through problem solving. When asked what he thinks his students are learning, Cameron shared,

> I remember, during the first day of class, most of the students were asked how they think about mathematics. And most of the responses were, mathematics is difficult, boring, not interesting. But then now you could see students come to class, so eager to learn something new, to practice something different, to do problem solving and all that. And you will see the spirit of the class is very high. (Mid-Semester Interview)

Both John and Cameron observed how learning mathematics through problem solving influenced the attitudes of PTs toward their learning.

Connecting student learning with course readings. We found that the course readings were effective in providing shared language in the CoP as prospective MTEs observed student learning. In his second week reflection, John explicitly drew on the course reading to connect with his observations of student learning. John shared,

> Procedural knowledge refers to the step-by-step procedures executed in a specific sequence, while conceptual knowledge refers to the relationships between pieces of information, which enhances flexibility in accessing and using information (Carpenter, 1986). In performing Activity 2.3 and Activity 2.3 (Masingila et al., 2011), students applied procedural knowledge by laying down steps to write big numbers such as 476 in the Babylonian system, and conceptual knowledge by analyzing the relationship between different number systems. (Reflection Week 2)

The terms procedural knowledge and conceptual knowledge represent a common use of shared language within the CoP to make sense of student learning.

In addition to drawing on shared language, participants connected to the course readings through the ideas the readings presented as they observed student learning. Alex, for example, noted that "learning opportunities occur when students must create or discover a method to solve a problem and then justify the validity of their methods to classmates (idea from this week's reading), and I see both of these happening throughout the course so far" (Reflection Week 5). The language and ideas from course readings helped prospective MTEs to make sense of their observations of student learning and provided shared texts to draw on within the CoP.

MTEs Making Sense of Their Roles

In addition to learning through observations of their students' learning, the prospective MTEs in this study learned as they made sense of their roles in this course. We found that the participants learned about teaching and learning through problem solving in general. In addition to this, some participants developed a strategy of prompting PTs to think about their future careers as teachers as the interns began to recognize their roles as prospective MTEs.

Making sense of teaching and learning through problem solving. For three of the participants, their backgrounds in mathematics can generally be characterized as traditional or teacher-centered, and a course taught through problem solving was an opportunity to experience a new pedagogical style. For example, when debriefing with one of the researchers after class during the first week of the course, Michael shared that he had never seen a mathematics course taught through problem solving and that he was eager to learn more (Researcher Memo Week 1). By the end of course, Michael learned that teaching through problem solving involves centering student responses. Michael shared,

> And one of the few things that I discovered in a problem-solving class, we usually encourage students to give us their answers. Because one of the few things that we usually focus on, we're interested in seeing the way students think in different ways and obtaining different answers. And different answers, it is upon them to choose the method they're interested in. (Post Interview)

Having never experienced teaching and learning through problem solving before, Michael explained how eliciting student thinking is a key feature of this approach that he learned.

Cameron described his mathematics experience during his primary school as being teacher centered. Cameron shared, “hardly will the students start with the example themselves. The teacher gives the example, gives the procedure to solve by example, then allows students to solve different examples, the same procedure that they have solved” (Beginning Interview). However, Cameron suggested that this changed slightly in secondary school when teachers began giving “hints” and “guidelines,” which he saw as being closer to a problem-solving approach (Beginning Interview).

John described his prior mathematics experience as being one where teachers were “more focused on [students] passing the exams rather than understanding the concepts” (Beginning Interview). This evidences John’s traditional experience when he was a student of mathematics. Later in the semester, John reflected on his own growth in terms of a shift from a traditional approach to a problem-solving approach. John shared, “to highlight how much I've learned, it has helped me to redefine my role as a teacher of math by trying to center my teaching through problem solving, rather than the lecture method, where I'm the sole person giving up the knowledge” (Mid-Semester Interview). Together, these examples evidence how three of the participants who had not previously experienced teaching and learning through problem solving learned about this pedagogical style when making sense of their roles as MTEs.

Making sense of supporting PTs. Enacting a role as a MTE, for some, meant prompting PTs to begin to think about their future roles as educators. Alex elaborated on this prompting in the mid-semester interview when asked how they see themselves as supporting their students as future teachers. Alex said,

> I try to explain to them, like, the idea is, eventually you'll be engaging students in this type of thinking. So, you know, you need to be going through this yourselves. And experiencing this type of learning, so that hopefully, you'll see the value in, and you'll be able to teach this way someday. And I think more informally, like, during office hours, I've talked with some of the students about their goals. You know, like, by the end of their degree program, or, you know, what their sort of purpose in doing this program is. So, I guess more informally talking with them about, you know, where they want to be in education, what kind of roles they see themselves in schools. (Mid-Semester Interview)

In making sense of their role as an MTE, Alex supported PTs to consider their future roles as educators as they were learning in the course.

John also shared this idea in the way that he made sense of his role as an MTE. John said, “I think the purpose of encouraging my students to just see themselves as teachers in the classroom … they came as students taking math …” and now “they say I’m learning … as a teacher … I’ve really benefitted” (Post Interview). While the interns were not in a position to directly teach pedagogical methods to their students, Alex and John began prompting PTs to consider their future identities as educators. In this way, they made sense of their roles as MTEs as supporting PTs to maintain a long-term vision of their learning.

Discussion

Researchers have argued that one way to support PTs to deep mathematical knowledge is to engage them in learning mathematics through problem solving (Masingila et al., 2011; Schroeder & Lester, 1989). We propose that engaging prospective MTEs in supporting PTs to develop this mathematical knowledge through problem solving is also a problem-solving activity for the MTEs. The prospective MTEs are engaged in problem solving as they learn to support PTs' mathematical development in learning what type of questions to ask, how to support PTs in productive struggle, how to facilitate a class discussion to bring out mathematical ideas that arise through the PTs' problem solving, etc. Thus, the MTEs are also learning through problem solving and their learning is about supporting PTs' mathematical and MKT development while the MTEs themselves develop MKTT.

Van Zoest and colleagues (2006) in their study with prospective MTEs in mentored clinical experiences found that the novice MTEs learned the most through "observing, analyzing, and discussing classroom interactions" (p. 143). Our analysis aligned with this claim as we found that our code that occurred the most frequently in our coding of our data was what we called "observing student learning", in which our participants mentioned notable instances of individual PT or group learning that provided new insights for the intern about what the PTs were learning, their process of learning, their dispositions toward the problem solving work, and/or connections that the PTs were making among mathematical ideas. Our participants wrote about their observations of the PTs' learning in their weekly reflections, they talked with other members of the CoP about their observations and mentioned these in the interviews. Their observations were often brought up, analyzed and discussed during the CoP's twice weekly meetings. We found that observing and reflecting on the PTs' learning in the context of a mathematics course taught through problem solving was a key way that the prospective MTEs learned.

Van Zoest and colleagues (2006) recommended having key readings for the prospective MTEs to support their learning. We found that the weekly readings connected the interns to literature on developing mathematical understandings and teaching and learning through problem solving. The readings provided a grounding from which the interns could situate their observations of student learning as well as the pedagogical strategies that they observed and were trying to enact themselves. Since the readings were shared texts in the CoP, ideas from the readings became part of the shared language used by members of the CoP to discuss challenges and developments in students' understandings and in instructional strategies.

In the same way that "prospective teachers need mathematics courses that develop a deep understanding of the mathematics they will teach" (CBMS, 2001, p. 7), MTEs need opportunities that will enable them to develop a deep understanding of the mathematics that they will teach to PTs and support them in understanding mathematical ideas deeply. As we envision the future for mathematics education in uncertain times, we argue that one site for prospective MTEs to gain this knowledge and pedagogical skills is through a CoP with experienced and novice MTEs working with PTs in which the novice MTEs have an active role in supporting the PTs. The prospective MTEs develop their MKTT in collaboration with the CoP as the PTs develop their MKT. The prospective MTEs learn how to facilitate (a) student thinking with prompting questions, (b) collaboration as a means of active engagement, (c) PTs' problem solving efforts, and to value multiple approaches to solving problems. While it is possible for prospective MTEs to reflect on their teaching alone by observing student learning and examining their own practice, without a CoP and being an active member in the mathematics content course taught through problem solving, there would have been no opportunity to reflect on the actions of others, to receive feedback on their observations and reflections and teaching, or to see other ways of approaching a teaching or learning challenge.

EXPLORING HOW SCHOOL LEADERS CARE FOR TEACHERS OF MATHEMATICS AMID THE PANDEMIC

Keywords: Instructional Leadership, Policy

Teachers' emotions and identities are intertwined (Zembylas, 2003), and have been disrupted by the isolation and stress of the COVID-19 pandemic (Jones & Kessler, 2020). Although some teachers have exhibited resilience during the pandemic, a majority have felt their well-being decreased (Gearhart et al., 2023). Workload stressors including school climate increased stress (Herman et al., 2021; Johnson & Coleman, 2023). Self-care strategies have done little to reduce these impacts (Walter & Fox, 2021). However, relationships with colleagues can be buffers (Blair et al., 2023; Johnson & Coleman, 2023; Stang-Rabrig et al., 2022), highlighting the potential positive impact of a caring coach or leader.

"Nel Noddings is closely identified with the promotion of the ethics of care, – the argument that caring should be a foundation for ethical decision-making" (Smith, 2020, para. 4). Ethical caring ala Noddings is relational at its core; the "carer" turns their attention and energy toward the "cared for." Noddings' (1984, 2013) ethical concept of care informed our analysis.

For this longitudinal study, we conducted 24 interviews with principals, instructional coaches, and teachers in a Title I, urban school district to explore how school leaders cared for math teachers amid the pandemic. Transcriptions were analyzed using Noddings' (1984, 2013) theory of care ethics. Intercoder reliability was maintained during coding (Cofie et al., 2022).

We identified three kinds of care that principals and coaches leveraged to show support for math teachers. Specifically, principals and coaches: (a) implemented new and recycled structures, (b) employed discursive practices, and (c) acted as buffers between district-level mandates and teachers. We also identified challenges that the principals and coaches faced while striving to enact care for teachers, which chiefly consisted of structural constraints, including a lack of time to physically be present with and support teachers. To illustrate, leadership teams at one elementary school implemented a "check in, check out" structure to respond to teachers' needs, as described by Principal Francisco: "We created a check in, check out. Like, if a teacher needed a restroom break, or they just needed a break, there was someone that would go and relieve them." To provide one further illustration, coaches and principals also exercised discursive moves akin to cheerleading. For example, Coach Theresa found opportunities to "give feedback and build that confidence that they were so in desperate need of." Last, coaches also served as buffers between teachers and district-level mandates to preserve teachers' sanity in the face of new initiatives or assessments. Coach Kristin shared: "I felt like I was a naggy voice for teachers…[school leaders had] expectations that I just knew weren't realistic."

The coaching and leadership practices here to support math teachers elucidate how leaders and teacher educators can serve as buffers and advocates for teachers. Further research is needed to elucidate how teachers' social and emotional well-being can be supported by school leaders.

Keywords: Learning Theory, Instructional Leadership

The prevalent belief in education is that individuals possess a distinct "learning style," whether visual, kinesthetic, or auditory, with a significant percentage of educators, up to 80-95%, subscribing to this notion (Nanceckivell et al., 2020). Despite its widespread acceptance, decades of research have failed to provide substantial evidence supporting the idea that tailoring instruction to match an individual's purported learning style enhances their learning outcomes (Pashler et al., 2008). The myth of learning styles has been “busted,” but remains prevalent in educational research (Authors, 2022). However, little is known about how widespread the discussion of learning styles has been within mathematics education. As the world’s largest mathematics education organization with publications since 1907, the National Council of Teachers of Mathematics (NCTM) is very influential in mathematics education (NTCM, n.d.). As Dickey (2020) states, “the legacy of the Council is found in its journals” (p. 82). Given the importance and impact of NCTM’s publications throughout the decades, they are an ideal place to understand how both mathematics education and learning styles have been discussed.

In this study using content analysis, we asked, *what are the characteristics of articles published by NCTM that mentioned “learning styles?”* We conducted searches for “learning style*” in all NCTM journal publications, specifically, The Mathematics Teacher (TMT, 1908-2018), The Arithmetic Teacher (TAT, 1954-1994), Teaching Children Mathematics (TCM, 1994-2019), Mathematics Teaching in the Middle School (MTMS, 1994-2019), Journal for Research in Mathematics Education (JRME, 1970-present), Mathematics Teacher Educator (MTE, 2012-present), and Mathematics Teacher: Learning and Teaching PK-12 (MTLT, 2020-present). We identified a total of 331 articles that met our criteria, with 92 articles in TAT (28.7%), 64 articles in TMT (19.3%), 69 articles in TCM (20.8%), 71 articles in MTMS (21.5%), 29 articles in JRME (8.8%), 1article in MTE (0.3%), and 2 articles in and MTLT (0.6%). Identified articles were published between 1962 and 2023, with 111 of the 331 (33.5%) articles published in the 1990’s. Two hundred and two (61%) articles were full articles about lessons, teaching practices, and related topics, 62 (18%) were book reviews, seven (2%) were reader letters, 29 (9%) were advertisements for professional development, 10 (3%) were author biographies, 14 (4%) were calls for manuscripts, and 7 (2%) were other types of articles. Findings highlight how the prevalence of mentions of learning styles spans decades in NCTMs’ journals, across various grades, populations, and positions of mathematics education leadership. As NCTM publications serve as the leading place for mathematics teachers and mathematics teacher leaders to learn and share ideas, the impact of these references may have been significant in endorsing the consideration of learning styles in mathematics teaching for decades.

Coaching is increasingly seen as a critical component of teacher professional learning programs. However, questions persist about approaches to coaching in mathematics that might better foster teacher buy-in and support scalability. Our study adapted the instructional triangle (Cohen et al., 2003) to the context of math coaching to investigate teacher-coach interactions across nine different school groupings in the context of a school-mandated curriculum-embedded professional learning program. Our findings showed that coaches often described teacher mindsets as a barrier to their work, while teachers focused on their need for content expertise. We also addressed differences between school-based versus district-based coaching approaches, and generalist versus math-specific coaching approaches, suggesting implications for the design and use of math coaching as a lever for instructional reform.

Keywords: Professional Development, Mathematical Knowledge for Teaching, Curriculum, Research Methods

While coaching is broadly defined as a critical component of effective teacher professional learning (PL; Desimone & Pak, 2017; Darling-Hammond et al., 2017), mathematics coaching has not received the same attention in the research compared to coaching in other domains such as literacy (Kraft & Blazar, 2017). Indeed, the impact of mathematics coaches in supporting PL programs within schools is often hidden in research on teacher PL (Hjalmarson and Baker, 2020). This is in part because coaching is highly interactional and adaptive depending on the coach training, school context, and willingness of the teacher participants (Coburn & Russell, 2008; Russell et al., 2020).

This study adapted the instructional triangle (Cohen et al., 2003) to the context of mathematics coaching to unpack these interactions between teachers and coaches, and to indicate how the structure and approach to coaching relates to the perceived benefit of mathematics coaching, according to both teacher *and* coach participants. The ability of math teachers and coaches to mutually and productively adapt their shared work is a critical component in the scalability of coaching models (Russell et al., 2020). As such, this study used teacher and coach interviews in the context of a curriculum-embedded PL program to describe the shared – or divergent – perspectives of teacher-coach groupings. Given that participants' interpretations of policy ultimately inform their behavior in such systems (Desimone, 2002), our findings can be informative for those interested in using math coaching to help support instructional reform.

With this context in mind, we consider the following research questions:

1. In what ways do mathematics teacher and coach descriptions of their shared coaching work align or diverge?
2. What aspects of the coaching environment do teachers and/or coaches describe as beneficial or detrimental to improving teachers' instructional practices?

Theoretical Framework

We leveraged the instructional triangle (Cohen et al., 2003), especially iterations of the instructional triangle as it relates to the work of mathematics teacher educators or coaches (Nipper & Sztajn, 2008; Shaughnessy et al., 2016), to investigate the interactional nature of the teacher-coach experience. The instructional triangle describes teaching (and in our context, mathematics coaching) as "a collection of practices, including pedagogy, learning, instructional design, and managing organization" (Cohen et al., 2003, p. 124) that is inherently influenced by external environmental factors. Importantly, Cohen and colleagues stress that improving teacher learning outcomes depends not on the mere *inclusion* of educational resources, but rather the ways that individuals (e.g., teachers and coaches) are able to work with one another and *use these resources*. Our adaptation of this framework is shown below in Figure 1, and described in our review of the literature that follows.

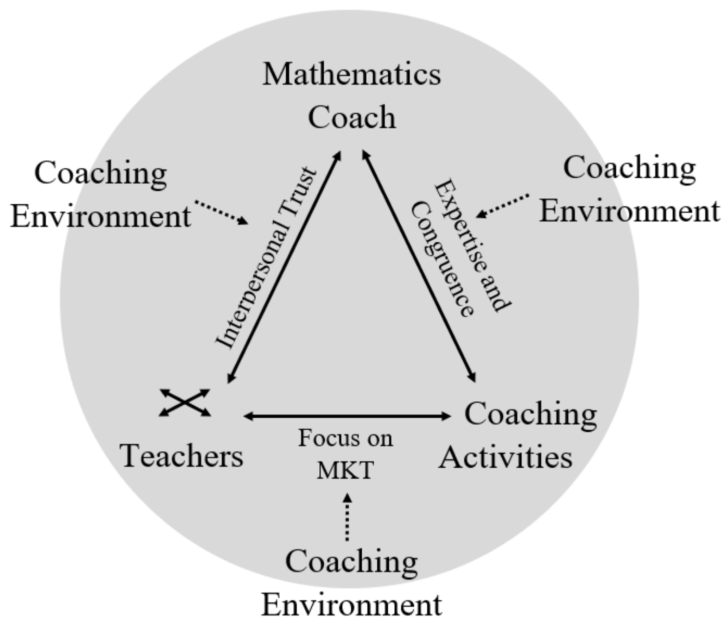

Figure 1: The mathematics coaching triangle

Mutual Adaptation: Alignment Between the Teacher and the Coach

Before examining the various interactions that are mapped onto our mathematics coaching triangle, it is important to note that this framework recognizes the importance of both teachers and coaches as actors within a system aiming for instructional reform. Successful educational reform projects have long been characterized as adhering to mutual adaptation (McLaughlin, 1976), a process “in which project goals and methods [are] modified to suit the needs and interests of participants and in which participants [change] to meet the requirements of the project” (p. 172). More recently, Russell et al. (2020) identified that such adaptations may support the scalability of mathematics coaching programs in particular, so long as coaches are able to adapt to teachers’ perceived buy-in to the coaching without violating the integrity of the coaching model. By considering how both teachers and coaches perceive of their shared work, our approach can indicate conditions where productive mutual adaptation has occurred, or conditions under which teacher and coach interactions have led to “lethal mutations” (Russell et al., 2020, p. 176) of the coaching model.

Teacher and Coach Interactions with Coaching Activities

Coaching activities in mathematics can vary considerably, from emphasizing an understanding of mathematics content itself to strengthening teachers’ understanding of their classroom interactions with students (Nipper & Sztajn, 2008). Activities that attend to both teachers’ mathematics subject matter and pedagogical content knowledge – which together is referred to as mathematical knowledge for teaching (MKT; Ball et al., 2008) – are of particular interest to our work. Teacher PL programs that explicitly focus on MKT have been found to improve teachers’ MKT for both pre-service teachers (Morris & Hiebert, 2017) and in-service teachers (Jacob et al., 2017), although findings connecting such programs to student achievement have been mixed. Importantly, Jacob and colleagues (2017) described decreasing district leadership support for the MKT-focused professional learning program over time as a probable reason for the program’s limited effects on student achievement. Such findings bolster the idea that the effectiveness of teachers’ interactions with their coaching activities are influenced (or constrained) by environmental factors of school and district policy and institutional support, discussed further below.

The nature and quality of a coaches’ own training also influences how they interact with teachers. When the training coaches receive around supporting teacher implementation of new curriculum materials includes active learning, this can enable the coaches to interact more deeply with teachers by attending to MKT (Coburn & Russell, 2008); however, if coaches’ training is of lower quality, their coaching may in turn be incongruent with the goals of district curriculum, and they may pass on this incongruence to teachers. Similarly, teachers whose coaches hold more expertise in attending to MKT are more likely to develop their own MKT expertise (Sun et al., 2014). Such research shows the importance of both the coaches’ own MKT and their congruence with the goals of instructional reform.

Teacher and Coach Interpersonal Interactions

In addition to activities related to MKT and curriculum, aspects of the teacher-coach interpersonal relationship can also influence teachers’ perceptions of their professional learning (Smith & Desimone, 2023) and influence the depth of their engagement with their learning (Coburn & Russell, 2008). Hence, it is perhaps no surprise that the relational aspect has long been considered an important element of effective coaching practices across multiple disciplines (Blazar, 2020; Desimone & Pak, 2017; Ippolito, 2010). Teachers’ social networks with one another (shown in Figure 1 above) also influence engagement in their learning (Coburn & Russell, 2008), though this is outside the scope of our study.

The Coaching Environment

As indicated in Figure 1, the above interactions between teachers and coaches do not occur in isolation; rather, in line with the original instructional triangle (Cohen et al., 2003), our framework presumes that external, environmental factors are impacting the interactions between teachers, coaches, and their shared activities. Two salient factors within the coaching environment that our present study considered were (1) whether the coach is placed full time at a school (i.e., "school-based"), which has been shown to correlate more highly with student achievement compared to when a coach is only part-time and/or has to spread their time across multiple schools (i.e., "district-based"; Harbour & Saclarides, 2020), and (2) whether the coaching role is designed as a generalist or math-specific position. Given the importance of attending to MKT noted above, the expertise and focus of the coach regarding the teaching of mathematics was conjectured to influence the nature of the coaching interactions.

Methods and Methodology

Our data are drawn from the Research on Curricular Alignment Partnerships (R-CAP) project. R-CAP was a multi-year study supported by the Bill & Melinda Gates Foundation, with the overarching aim of understanding how professional learning partnerships (PLPs) – or collaborative partnerships between school districts, PL providers, and curriculum developers – could foster ambitious instruction and culturally responsive (CR) instruction through curriculum-embedded PL (i.e., specific curriculum materials are integrated throughout the ongoing PL activities; Taylor et al., 2015), particularly for minoritized students.

Participants and Protocols

Our teachers (n = 18) and coaches (n = 9) were recruited from participants (n = 479) across six different school districts participating with a PLP as part of the R-CAP project, drawn to reflect teachers with a variety of perceptions about their coaching and school-mandated PL. Because of the participating PLP's focus on ambitious instruction and culturally responsive instruction, we selected teachers based either on their reported normative authority (or buy-in) to their professional learning (Desimone, 2002) or their reported frequency of CR instruction. This allowed for a sample of teacher participants with a variety of experiences with this school-mandated professional learning. This sampling approach is further addressed in Comstock et al., 2022.

Through this approach, we were able to draw from a diverse sampling of teachers from participating PLPs, including those with low normative authority (n = 4; pseudonyms Mrs. Menton, Mr. Brannon, Mrs. Cicero, and Mrs. Wendell), high normative authority (n = 3; pseudonyms Mrs. Leak, Mrs. Dratch, and Mrs. Seale), low frequency of CR instruction (n = 3; pseudonyms Mr. Mendes, Mr. Carrigan, and Mrs. Hembrow), medium frequency of CR instruction (n = 5; pseudonyms Mrs. Klein, Mrs. Muhr, Mr. Biscay, Mrs. Eccles, and Mrs. Gibbon), and high frequency of CR instruction (n = 3; pseudonyms Mrs. Giddings, Mrs. Sturman, and Mr. Hickson). With these teachers selected, we then recruited coaches from the same participating PLPs who had indicated working at these teachers' schools.

Our interviews were designed to elicit responses from both teachers and coaches about the nature of the coaching work, the relationship between teachers and coaches, and facilitators and barriers to implementation. For instance, teachers were asked "How would you describe the quality of your professional relationship with your coach?" while coaches were asked "How would you describe the quality of your professional relationship with your teachers?"

Analysis

We used an embedded case study design (Yin, 2018) to analyze the interview responses from our nine teacher-coach grouping (i.e., for each coach, we interviewed 1-3 teachers that they worked with). In alignment with the mathematics coaching triangle, we coded interview responses to identify descriptions of (1) interactions with different coaching activities identified by the teachers or coaches (2) interactions related to teacher-coach interpersonal trust, (3) references to coach expertise/congruence or the coaching focus on MKT, and (4) environmental factors outside of direct teacher-coach interactions that participants indicated had impacted the coaching work. We then also coded whether these descriptions were described as (1) beneficial or detrimental to teachers' learning and instruction, (2) as a mixture of beneficial and detrimental, or (3) neutral or unclear in relation to the benefit of the activity or aspect. To determine these categories, we looked for references to whether the benefit of an action interaction was described directly (e.g., "that was helpful" or "That doesn't work for my students"), or indirectly (e.g., "I think that my strength is just my emotional intelligence, being able to relate to my teachers and being able to be a trusted advisor for them" or "We just can't get through it all - it's just too much").

Each interview was double coded by members of the research team, identifying coaching activities, teacher-coach interactions, and environmental factors from the participant descriptions. After each teacher-coach grouping was coded by one member, another member would code the same grouping and note any discrepancies in the initial codings. The researcher members would then meet to resolve any disagreements. After this initial round of coding, research members wrote analytic memos (Saldaña, 2013) for each school-based teacher-coach grouping, describing the ways that the teacher(s) and coach aligned or diverged in their descriptions, and the relevant themes across the different participants in each school grouping.

Results

RQ1: Alignment and Divergence of Teacher and Coach Descriptions of Coaching Work

Our first research question focused on how teachers and coaches aligned or diverged in their descriptions of their shared coaching work. We found that teachers and coaches largely agreed about the focus of their coaching work. However, teachers held reservations about the perceived MKT of their coaches, while coaches held concerns about their teachers' mindsets around their learning and instruction. Table 1 and Table 2 show each activity, interaction, and environmental factor described by both teachers and coaches in each teacher-coach grouping, and their perceived benefit (or detriment).

Table 1: Coach-Teacher Groupings with Similar Perceptions

Teacher-Coach Grouping	Similar coaching activity (teacher and coach description)	Similar interactions & environmental factors (teacher & coach description)
Coach: Mrs. Line Teacher: Mrs. Cicero	Assessment (+)	Interpersonal Trust (+)
Coach: Mrs. Koenig Teacher: Mrs. Gibbon	Observe/Debrief (+)	Interpersonal trust (+) MKT focus (+) Coach expertise (+)
Coach: Mrs. Mattingly Teachers: Mr. Biscay, Mrs. Seale, Mrs. Hembrow, Mrs. Sturman	Observe/Debrief (+) Lesson design (+) Co-teaching (+)	Interpersonal trust (+) MKT focus (+) School Policy (#)
Coach: Mrs. Eccles Teachers: Mr. Hickson, Mrs. Tabor	Observe/Debrief (+)	+Interpersonal trust +Coach flexibility

Note. + = Described as beneficial. - = Described as detrimental. # = Described as both beneficial and detrimental. ? = Not described as beneficial or detrimental.

Table 2: Coach-Teacher Groupings with Differing Perceptions

Coach-Teacher Grouping	Similar coaching activity (description by coach, by teachers)	Similar interactions & environmental factors (description by coach, by teachers)
Coach: Mrs. Mallinson* Teachers: Mrs. Giddings, Mrs. Muhr, Mr. Carrigan	Assessment (+, ?)	Coach expertise (–, –)
Mrs. Lees (Coach)** Teachers: Mr. Mendes, Mrs. Klein	Observe/Debrief (+, #)	Interpersonal trust (#, #)
Mrs. Nowak (Coach)** Teacher: Mr. Brannon	Lesson design (+, #)	Interpersonal trust (+, +) MKT focus (+, -)
Mrs. Lyndon (Coach)* Teacher: Mrs. Wendell	Lesson design (+, #)	MKT focus (+, -) School policy (+, -)
Mr. Aras (Coach)** Teacher: Mrs. Fieser, Mrs. Menten, Mrs. Leak, Mrs. Dratch	No similar coaching activities described by both coach and teachers	Interpersonal trust (+, +)

Note. + = Described as beneficial. - = Described as detrimental. # = Described as both beneficial and detrimental. ? = Not described as beneficial or detrimental. * = Generalist (cross-content) coach. ** = District-based coach.

Broadly, we found that teachers and coaches described similar sorts of activities. However, while coaches in each grouping described their activities as supporting the goals of the curriculum-embedded coaching work, there was a split in how teachers perceived these activities. Just under half of the teacher-coach groupings were in agreement about the benefit of these activities, while in the rest of the groupings teachers described both beneficial and detrimental aspects of the activities.

For groupings that aligned regarding the benefit of the coaching activities, teachers and coaches also frequently aligned in describing positive aspects of interpersonal trust and (in two of the cases) the MKT focus of the activities. For groupings that diverged in their descriptions of the coaching work, some trends arose regarding how teachers and coaches described their interactions with one another and with the activities themselves. For instance, when discussing lesson design and planning, Coach Lyndon stated, “I can get in there and give you ideas based on what I'm seeing, based on how the curriculum should be presented” and that “being able to give them my first-hand experience, I think has helped them.” Yet, Mrs. Wendell, a teacher working with Coach Lyndon, described how Coach Lyndon “doesn't have a specialty in one particular area. She's a coach for the whole school.” Despite Coach Lyndon’s belief that she was facilitating lesson planning activities that were beneficial to teachers, Teacher Wendell’s perceptions of the usefulness of those activities appeared to be influenced by Coach Lyndon’s lack of teaching experience or specialization with mathematics teaching (i.e., a lack of MKT). Notably, every teacher-coach grouping where there was disagreement about the benefit of the coaching activities were also school sites with district-based or generalist coaches.

While concerns with coach expertise or the ways that coaching activities supported their MKT were chief among teachers, another trend arose distinctly among coaches. All but one coach (Mr. Aras) described the issue of teacher mindsets as an important aspect of their work. For instance, Coach Koenig described shifting teachers’ mindsets as part of the “biggest barrier” in her coaching and discussed how the teachers she worked with were “not really believing that we can do certain things.” Similarly, Coach Mallinson described how “some of our veteran teachers are just kind of reluctant to try new ways and new things.” The issue of teacher mindsets was mentioned by only one teacher, Mrs. Cicero, who also happened to have a stated goal of becoming a math coach herself. In sum, coaches described teacher mindsets about math instruction to be a major barrier to instructional change, while teachers described a need for specific content and teaching expertise as being the major barrier to their success.

RQ2: Perceived Beneficial or Detrimental Aspects of the Coaching Environment

As noted above, perceptions about the MKT focus or coaching expertise appeared to be a major divergence between the teacher and coach experience. For our second research question about what might be driving alignment or divergence of such experiences, we found that the design of the coaching role – specifically whether the coach was school-based and whether the role was math-specific – related to teachers’ perceived benefit of their coaching.

A common theme that emerged from both coaches and teachers was the importance of the coach in fostering teachers’ MKT which, in turn, was related to the coach’s own MKT. Teacher comments about the MKT focus of their coaching activities often also extended into descriptions of their coach’s perceived expertise in supporting MKT. Teachers with generalist coaches repeatedly described this aspect of the coaching to be inadequate and stifling to their desire to strengthen their own MKT. Indeed, of the four instances where participants discussed the perceived content expertise of their coaches in negative terms, three of these came from teachers with a generalist coach (Mr. Carrigan, Mrs. Muhr, and Mrs. Wendell), while the fourth came from a generalist coach themselves (Mrs. Mallison).

There were markedly different interviews given by teachers with school-based coaches compared to those with district-based coaches who supported multiple schools. Teachers working with district-based coaches expressed frustration at the lack of connection between their teaching context and their coaching interactions. For example, Mrs. Menten described how her coach (Mr. Aras) was "knowledgeable on the curriculum, but he's not knowledgeable on students with special needs." Similarly, Teacher Brannon described how his coaching activities (run by Coach Nowak) "[weren't] what I needed...I would have rather spent time with other seventh and eighth grade math teachers who were specifically [focusing on] the special ed population." These teachers specifically did not see the work with their district-based coach as aligned to the challenges that they felt around working with their students with special needs. On the other hand, teachers who worked with school-based coaches generally described the interactions with their coach as beneficial. Indeed, every school grouping that had teachers and coaches describe similar activities and in similar (positive) terms involved school-based coaches.

Limitations

This analysis should be interpreted in the context of several limitations. First, it was conducted in the context of a district-mandated curriculum-embedded PL program. While we believe that our findings likely extend beyond this particular context, future studies should consider the role of particular policies and reforms. Second, this study occurred in large, urban districts serving predominantly students from minoritized groups. The resources, visions, and challenges of these particular districts may influence our findings about coaches and teachers.

Discussion

Grounded in our adaptation of the instructional triangle to mathematics coaching, we explored teacher-coach alignment in descriptions of their interactions, and how key aspects of the coaching environment were perceived as beneficial or detrimental to teachers in improving their instruction. Our findings showed that teachers and coaches generally described engaging in similar types of activities. However, coaches tended to consider their activities to be beneficial – even when their teachers did not. Because productive mutual adaptation through content-focused inquiry is a promising feature of scalable coaching models (Russell et al., 2020), the teacher-coach groupings that varied in alignment offer clues about how teacher-coach interactions can support such opportunities for mutual adaptation.

A disconnect between focusing the coaching work on *teaching* versus focusing it on *teachers* seemed to be a driving cause of discontent between coaches and their teachers in certain school grouping. This sort of disconnect is not new (see Hiebert & Morris, 2012), but the lens of the mathematics coaching triangle may help to highlight the delicate balance of work required to achieve coaching that is well-received by coaches and teachers alike, and is thus positioned to support productive, mutual adaptation between coaches and their teachers. While almost all coaches described the challenge of shifting teacher mindsets as part of their work, coaches with teachers who found the coaching work beneficial were also those that seemed to foster positive interactions around interpersonal trust with their teachers and around MKT in their activities.

Given that teachers who found the coaching work detrimental rooted such problems in the lack of MKT focus with their coaching, this could indicate an opportunity for more aligned and beneficial coaching. Regardless of whether coaches feel that teachers hold mindset barriers toward instructional change, if they foster strong relationships with their teachers and focus on strengthening teachers' MKT, they may be able to achieve better buy-in from their teachers.

Finally, our findings indicated concerns with more generalist of district-based coaching approaches. Coaches who were hired to support multiple contents were not perceived by their teachers as knowledgeable enough to successfully support teachers' MKT. This indicated how district supported professional learning that carefully attends to aspects of MKT is not only a compelling model for impacting teacher practices and student learning outcomes (Jacob et al., 2017; Morris & Hiebert, 2017), but may also be a model that teachers themselves desire. School-based coaches were also perceived as more beneficial than district-based coaches. Previous studies have indicated that school-based coaches may be better positioned to foster stronger relationships with teacher may also be burdened with more administrative tasks by school leaders that take away time for coaching (Kane & Rosenquist, 2019). Our findings indicate that, at least from the perspective of teachers, school-based coaches were able to foster strong interpersonal relationships *and* facilitate beneficial learning activities. Therefore, while administrative tasks may have still arisen in these cases, they did not appear to prevent buy-in from the teachers regarding the benefit of the coaching work.

Because of the importance of these teacher-coach interactions and environmental factors in our findings, the coaching triangle may be a helpful lens for investigating the complexity of math coaching. By attending to interactions between teachers, coaches, and their shared activities, our hope is that future investigations on PL programs can give further voice to the experiences of both teachers and coaches in defining the effectiveness of such interventions.

Objectives and Purpose

Beswick (2021) describes the importance of mathematics teacher educator (MTE) voice generated from reflection on their learning and development as MTEs. Such a voice provides opportunities for colleagues to "enter the experience" (p. 422) of other MTEs. Drawing from *matricentric feminism* (O'Reilly, 2019; 2021) to frame our epistemological beliefs as mothers and motherscholars (Matias & Nishi, 2018), we understand that we bring our lived experiences as academic mothers into our work as MTEs. Further, a community of practice consisting of MTEs who are mothers can provide emotional and intellectual support that academic mothers desperately need to survive and thrive in academia (e.g., O' Brien Hallstein & O'Reilly, 2012). Our identification as academic mothers in mathematics education (AM-ME) positions us to identify a set of tacit knowledge that comes from the interconnectedness of these two roles. In this poster, we present findings from our research on *the knowledge we gain from our experiences as mothers (who are also MTEs and former teachers)* and *how we use this knowledge as MTEs to leverage pathways for Pre-service Teachers (PSTs) to disrupt the status quo when working with parents, caregivers, and the community in mathematics education*.

Methods

Using collaborative autoethnography (CAE) (Chang et al., 2012), we documented our lived experiences and the ways in which we leveraged our mother experiences in our MTE work. Our team engaged in narrative interviews (Jovchelovitch & Bauer, 2000) in which each member shared their experiences leading up to becoming both an MTE and mother, as well as the experiences when these two identities intersected. Following these interviews, we generated individual reflections around the ways that our mother roles had informed our MTE work in the areas of teaching, research, and service. These data points were used to construct narratives naming the challenges in our mother experiences that produced knowledge used to inform our practices as MTEs working with teacher candidates in methods coursework.

Findings and Discussion

Our experiences as mothers of school-aged children have heightened our awareness of the power and participation dynamics that exist between families and schools. These dynamics are largely rooted in home-school communication structures, such as conferences and communication home to families in relation to student progress, standards, assessments, or instructional practices; however, we note that they also connect to the use of family experience and expertise as a tool to support curricular design. Through our CAE, we unearthed a wealth of knowledge we developed over the years through parenting and interacting with our school-aged children and their teachers and utilized this knowledge to improve our instructional practice to better prepare mathematics teachers to build bridges with families. We hope to share these ongoing reflections and how they impact our work in preparing learning experiences for teacher candidates in methods coursework that center on cultivating reciprocal family relationships.

Chapter 9:

Precalculus, Calculus, and Higher Mathematics

IMPLICIT DIFFERENTIATION IN A COLLEGE CALCULUS CLASSROOM: INTERACTIONS BETWEEN STUDENTS AND LEARNING ASSISTANTS

Rebecca Butler
University of New Hampshire
Rebecca.Butler@unh.edu

Orly Buchbinder
University of New Hampshire
Orly.Buchbinder@unh.edu

Learning Assistants (LAs) are undergraduate students who, having successfully completed a certain course, return to classrooms in a different role – as near-peer tutors who help facilitate their peers' learning in that course. While students in courses with LAs have repeatedly evidenced more positive content-related learning outcomes compared to students in courses without LAs, little is known about how LAs facilitate these positive outcomes. This study explores LA-student interactions around the topic of implicit differentiation, in a university Calculus I course. Findings suggest that LAs help to demystify this topic for students by connecting to previous course material and focusing on computational correctness. These findings help to advance our understanding of the mechanisms of how LAs support student learning of implicit differentiation.

Keywords: Learning Assistants, Calculus, Classroom Discourse, Undergraduate Education

Introductory-level university courses, such as Calculus, aim to equip students with a robust foundation for future careers in science, technology, engineering, and mathematics (STEM) fields. However, Calculus courses were shown to have a high drop, withdrawal, failure rates, and student dissatisfaction with their learning experiences (Bryk & Treisman, 2010). Research suggests that the transformation of these courses (i.e., lowering failure rates and increasing student satisfaction) can be attained through *active learning* strategies such as studio course designs and group problem-solving (Freeman et al., 2014).

One means of facilitating these active learning approaches is through the incorporation of *near-peer tutors* (i.e., undergraduate students who have previously been successful in the course) into course instruction. While near-peer tutors can be incorporated into courses in several ways (Adreanoff, 2016; Otero et al., 2010), the *Learning Assistant* (LA) model of near-peer tutoring has been shown to be particularly effective in supporting active learning pedagogies (Knight et al., 2015). Under this model, near-peer tutors, called learning assistants (LAs) synchronously aid course instruction, typically by facilitating small group interaction around course content. LAs also practice in weekly meetings with course instructors to review the content they will be teaching and in a pedagogy course to learn about and reflect on teaching practice.

There is a growing body of research showing a variety of positive outcomes for students in LA-supported STEM courses, specifically, in Calculus. These include affective outcomes such as more positive attitudes toward mathematics (Castillo et al., 2022), and content-related outcomes such as lower drop, withdrawal, and failure rates (Alzen et al., 2018) and improved course grades (Bullock et al., 2015).

While these positive learning outcomes have been documented, there is little understanding of *how* LAs help facilitate them. Some attribute this to LAs' temporal proximity to the course content due to their recent completion of the course, and/or to their social proximity to student experiences (Alzen et al., 2018; Hernandez et al., 2021). These assumptions are based on research on LAs' classroom actions, such as providing students with feedback and increasing discussion time. However, these action descriptions are not subject-specific, leaving open a question of how LAs facilitate students' leaning of a particular course content.

This study seeks to examine how LAs facilitate student learning of specific mathematical content—implicit differentiation—by analyzing LA-Student interactions within a collegiate Calculus I course. Implicit differentiation, detailed in the following sections, was chosen as the content area since it has been identified as an under researched topic with which calculus students commonly struggle (Martin, 2000). The mathematical challenges characteristic of this topic offer opportunities for LAs to authentically aid student learning, which constitutes a rich research environment. This study explores the following research questions:

1. What mathematical aspects of implicit differentiation do students and LAs discuss during their interactions in Calculus I recitations?
2. What discursive moves accompany the mathematical aspects of implicit differentiation discussed by LAs and students during their interactions in Calculus I recitations?

Literature on Implicit Differentiation

Implicit differentiation is a technique for finding derivatives of equations where y cannot be explicitly expressed as a function of x (e.g., $xy + y^2 = 3yx^2$; graphs of such equations do not pass the vertical line test). Despite the importance of implicit differentiation in differential Calculus and its connections to other key topics such as chain rule and related rates, it received little research attention (Speer & Kung, 2016). Only recently have researchers begun exploring this topic, uncovering many challenges students have with applying implicit differentiation and understating its meaning. Mirin and Zazkis (2019) point to the inherent difficulty of recognizing implicit equations and making sense of applying differentiation to both sides of such an equation. Even when students recognize the need for implicit differentiation, they may struggle to apply prerequisite skills from algebra (e.g., simplifying exponential or radical expressions) and calculus (e.g. differentiation rules) to solve such problems (Borji & Martínez-Planell, 2020; Kandeel, 2021).

Researchers have also begun exploring ways to support student learning of this topic. Borji and Martínez-Planell (2020) studied how students' understanding of implicit curves and implicit differentiation changed following a series of interventions designed within the Action-Process-Object (APOS) theory. Another intervention, which combined the concepts of the chain rule, implicit differentiation, and related rates was designed and tested by Jeppson (2019). Both intervention studies developed highly detailed conjectures about of the learning stages students progress through when learning about implicit differentiation (called *genetic decompositions* in APOS theory, or *hypothetical learning trajectories* (Simon, 1995)). Buchbinder and Allen (in press) further adapted the elements of both learning stages trajectories— by Jeppson (2019) and Borji and Martínez-Planell (2020)—into a framework used in this study (as described below).

The literature points to the growing interest in the mathematics education community in describing and supporting student learning of implicit differentiation. This study aims to extend the description of students' difficulties with this topic by considering how students address and resolve these difficulties in an authentic classroom environment - to the best of our knowledge, to date, there have been no studies that examined this topic in the authentic classroom context.

Also, since LAs have a unique near-peer status with students, the conversations between LAs and students around implicit differentiation may shed new light on student learning of this topic.

Theoretical Framing

We utilize Vygotsky's (1978) sociocultural theory to study LAs and students' interactions around implicit differentiation. Under this theory, learning is a social process, mediated through language, and through interactions with individuals who have more knowledge than the learner. These More Knowledgeable Others (MKOs) facilitate the individual's learning by guiding them through the Zone of Proximal Development (ZPD) – a set of concepts, ideas, and skills outside of the individual's reach, which can only be attained with the help of others. This study frames LAs as MKOs who facilitate students' movement through the ZPD.

In addition to the general emphasis on language as mediating the learning process, we rely on the tools of Critical Discourse Analysis (CDA) to tie together deep linguistic analyses of LAs and students' discourse with the unique sociocultural features of collegiate mathematics classrooms in which the language is used. CDA has been successfully used in mathematics education research (McNeill et al., 2022) as well as in studies on near-peer tutoring (Butler & Buchbinder, 2023; DiMaio, 2020).

We rely on Gee's (2014) formulation of CDA, according to which language fundamentally reflects the lived experiences of the speakers within particular contexts. Linguistic structures of the spoken language, like grammar and words used, reveal individuals' ways of "saying (informing), doing (action), and being (identity)" (p. 2) in the world. We operationalized Gee's first two components of language through a two-fold qualitative coding scheme (detailed below). One part of the coding scheme captures the specific mathematics students and LAs discuss (saying), and the other part describes the actions of these speakers (doing). Gee's notion of "being" is also essential to this study as the information and actions only make sense in the context of the participants' identities as LAs and students in a Calculus I course.

Methods

Setting

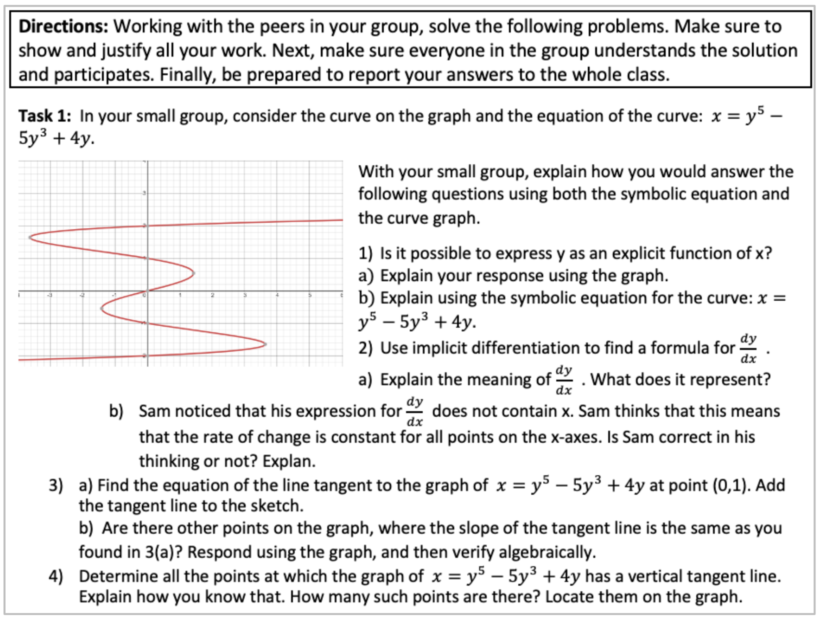
This study is a part of a larger NSF-funded project to transform introductory STEM courses at a large, research-intensive university in the northeast of the United States. In mathematics department, these transformation efforts focus on Calculus I recitations. This Calculus I course follows a lecture-recitation model, with students attending a large lecture (~160 students) taught by a faculty member three times a week and a smaller recitation session (~20 students) led by a graduate teaching assistant (GTA) twice a week. Transforming the recitations involved (a) the incorporation of researcher-designed, conceptually oriented activities focused on fostering metacognitive practices and representational fluency and (b) introducing LAs to facilitate small groups' discussions of problems in these activities.

Data Collection

This study focuses on the Implicit Differentiation activity (Figure 1), adapted from Boelkins et al. (2018). The activity aims to support recognition of the need for implicit differentiation and making connections between symbolic and graphical representations of implicit equations.

The data were collected over two semesters, in nine recitations taught by multiple GTAs, during the implementation of the Implicit Differentiation activity. The activity was enacted toward the end of the semester, so students were well familiar with LAs who had been working with them in recitations since the beginning of the course. In each recitation, one small group of three to four students (volunteers), was recorded using 360-degree table-top video cameras (Buchbinder, in press). Students in these small groups were mostly first- and second-year STEM majors, mostly white, and there was an approximately even split between male and female presenting students. LAs were mostly second- and third-year STEM majors, mostly female, and ranged in LA experience from one to three semesters.

From the total of approximately 7.5 hours of footage, we first identified video clips where the LA interacted with the recorded small group or one of its members. Some clips had to be excluded from the analysis due to low audio quality or if the content of the interaction was not mathematical (e.g., grades, office hours). From this process, a total of 25 minutes and 5 seconds of usable video data were identified for five LAs. semesters. The footage involved 22 separate LAs-student conversations containing 250 utterances. Each utterance was coded using the analytic framework described below.



Directions: Working with the peers in your group, solve the following problems. Make sure to show and justify all your work. Next, make sure everyone in the group understands the solution and participates. Finally, be prepared to report your answers to the whole class.

Task 1: In your small group, consider the curve on the graph and the equation of the curve: $x = y^5 - 5y^3 + 4y$.

With your small group, explain how you would answer the following questions using both the symbolic equation and the curve graph.

1) Is it possible to express y as an explicit function of x?
a) Explain your response using the graph.
b) Explain using the symbolic equation for the curve: $x = y^5 - 5y^3 + 4y$.
2) Use implicit differentiation to find a formula for $\frac{dy}{dx}$.
a) Explain the meaning of $\frac{dy}{dx}$. What does it represent?
b) Sam noticed that his expression for $\frac{dy}{dx}$ does not contain x. Sam thinks that this means that the rate of change is constant for all points on the x-axes. Is Sam correct in his thinking or not? Explan.
3) a) Find the equation of the line tangent to the graph of $x = y^5 - 5y^3 + 4y$ at point (0,1). Add the tangent line to the sketch.
b) Are there other points on the graph, where the slope of the tangent line is the same as you found in 3(a)? Respond using the graph, and then verify algebraically.
4) Determine all the points at which the graph of $x = y^5 - 5y^3 + 4y$ has a vertical tangent line. Explain how you know that. How many such points are there? Locate them on the graph.

Figure 1: Implicit Differentiation Activity

Analytic Framework

Transcripts of the selected clips were coded at the utterance level for mathematical content and actions of the speaker. The specific elements of implicit differentiation discussed were coded using the Implicit Differentiation Knowledge Components (ImDKC) framework developed by Buchbinder and Allen (in press). This framework classifies knowledge components of implicit differentiation according to three types of learning goals: *recognition* of implicit differentiation, *symbolic* manipulation of implicit formulas, and *graphic* representation of implicit curves. These categories are further broken into specific competencies and skills students must be able to perform to meet the broader goals. Further, *algebra* and *calculus* categories were added to capture LAs' and students' talk related prior knowledge (Kandeel, 2021).

To understand *how* LAs and students interact around the various goals of the ImDKC framework each LA and student utterance was coded for the type of discursive action (e.g., asking question, elaborating, explaining). Specifying the discursive actions is important for understanding how the interlocutors frame the implicit differentiation topics and how this framing evolves throughout the discussion (Gee, 2014). LAs' discursive actions were coded at the turn of talk level using the Action Taxonomy for Learning Assistants (ATLA) (Thompson et al., 2020) which catalogs 25 types of LAs' classroom actions (e.g., explain, check knowledge, clarify the goal of activity) across six broad categories: directed facilitation, guided facilitation, feedback, advice, course-related talk, and non-course related talk.

Students' discursive actions are also coded at the turn of talk level; however, due to the absence of a suitable coding scheme for college students' discursive actions, we developed one for this study. Taking ATLA categories as a starting point we used open coding and constant comparative method (Strauss & Corbin, 1998) to develop 11 categories of students' discursive actions such as "explaining work" or "asking for directions." The codes were grouped into three broader categories: asking questions, explaining work or thinking, and following LA directions.

Overall, each utterance or dialog turn was coded in two ways: with an element of the ImDKC framework to capture the mathematical theme, and with a discursive action of the speaker: LA or a student. Following this micro-analysis, we aggregated across all LAs and students for various coding categories to identify trends in the data and respond to the research questions: *what* aspects of implicit differentiation do students and LAs discuss, and *how* do they talk about them?

Results

In this paper, we report on the preliminary results of data analysis to provide an overview of the trends in LA-student discourse across all interactions about implicit differentiation. Table 1 shows the distribution of the ImDKC topics across interactions; Table 2 shows the distribution of discursive actions by LAs and students across interactions.

Table 1: Distribution of ID Topics Across Interactions (N =250 utterances; 22 interactions)

ImDKC Topic	Number and Percent of Utterances[(a)]	Number of interactions[(b)]
Symbolic N_S=65 (26% of all utterances)		
Implicit Equation (S_Eq): View y as an implicit function of x	5 (8%)	2
Chain Rule (S_Ch): Use of chain rule in implicit differentiation	3 (4%)	1
Differentiation (S_Diff): Compute dy/dx	14 (22%)	4
Evaluation (S_Eval): Compute dy/dx at a point	16 (25%)	5
Tangent Line (S_Tan): Compute equation of a tangent line at a point	3 (4%)	1
Procedure (S_Pro) Relate implicit diff. to other differentiation rules	24 (37%)	3
Graphic N_G=91 (36% of all utterances)		

Recognition (G_Rec): Implicit curves don't pass the vertical line test	9 (10%)	2
Tangent Slope (G_TS): Relate dy/dx at point as the slope of the tangent line at that point	32 (36%)	5
Vertical Tangent (G_VT): Implicit curves with vertical tangent lines	14 (15%)	2
Constant Rate (G_CR): Graphical meaning of constant rate of change	16 (18%)	2
Coordination (G_Cor): Coordination between graphic and symbolic representations.	20 (21%)	5
Background Concepts N_B=94 (38% of all utterances)		
Calculus (C) Topics previously learned in the calculus course	33 (35%)	5
Algebra (A) Algebraic operations when performing computations	61 (65%)	9

Notes: (a) The percentages of each code in the first data column are calculated out of the total number of codes in the related ImDKC category: Symbolic, Graphic or Background Concepts. (b) The total number of interactions exceeds 22, since there were multiple codes per interaction.

Table 2: Distribution of Student and LA Discursive Actions (N=250)

	Student Actions			LA Actions		
ImDKC Category	Asking questions	Explaining work or thinking	Following LA direction	Directing	Guiding	Providing feedback or advice
Symbolic	12	5	9	21	3	15
Graphic	15	7	13	28	12	16
Background	18	12	20	23	4	17

Symbolic Goals

Symbolic goals were mentioned in 65 (26%) of utterances across 22 interactions. Of modal categories of codes were *Symbolic Differentiation* (22%), *Symbolic Evaluation* (25%), and *Symbolic Procedures* (37%). *Symbolic Differentiation* (S_Diff) captures talk about finding dy/dx in implicit equations and *Symbolic Evaluation* (S_Eval) captures talk about evaluating this derivative at a specific point. Each of these topics was of particular concern for students since about half of the utterances for each of these codes were spoken by a student. Furthermore, in three out of four interactions involving symbolic differentiation, it was students who initiated the discussion. Similarly, students initiated three out of five interactions around symbolic evaluation.

LA-student conversations also focused on *Symbolic Procedures* (S_Pro) - 24 utterances (37% of symbolic codes). This topic was introduced by an LA in all three of the interactions in which it appeared, with the LA typically explaining procedures of implicit differentiation in connection to previously seen differentiation rules and with students following along the explanations. For example, one LA *directed* a student to "just take the normal derivative of it and then multiply by dy/dx" to complete a problem. The prevalence of this topic reflects the pragmatic role of the LA as a near-peer in classroom discourse with students; LAs explained how to do the computations involved in implicit differentiation in the context of these students' prior knowledge.

The pragmatic nature of these LA-student interactions is also evidenced in their discursive actions around symbolic codes (Table 2). The associated student action codes reveal that students were particularly concerned with correctly performing the algebraic steps of the procedures and arriving at the correct answers. Students primarily *asked questions* (12 of 26 student symbolic utterances), to check with the LA their computations (e.g., "Is this right? Like am I on the right track?") or to ask for guidance about the next steps (e.g., "How would you do, would that just be y?"). In response to these questions, LAs typically *directed* student work (21 of 38 LA symbolic utterances); they explained procedural steps that students should take (e.g. "So then you could just factor out the y prime and solve for it.") While one may hope that LAs would not default to explaining steps, LAs' direct address of students' concern for correctness reflects their effort at aiding students in correctly performing computations on which they will likely be assessed.

Graphic Goals

Graphic aspects of implicit differentiation appeared in 36% of utterances across all 22 LA-students' interactions. Of the graphic goals, *Graphic Tangent Slope* (G_TS) and *Graphic Coordination* (G_Cor) were the most prevalent, 36% and 21%, respectively. That is, when discussing graphical components of implicit differentiation, LAs and students mostly focused on lines tangent to implicit curves and relating graphical features of implicit curves to symbolic representations of these curves and their derivatives.

The category *Graphic Tangent Slope* (G_TS) appeared in five interactions; initiated by LA in four of them. LAs typically either explained how to interpret slopes of tangent lines (e.g., "remember that the derivative is the equation for the slope") or prompted students to use their prior knowledge of tangent lines in this new context (e.g., "So what is the meaning of dy /dx?"). In response to LAs' explanations and prompts, students occasionally explained their thinking (e.g., "You plug in the point and then see if it's equal"), but primarily provided simple factual answers (e.g., LA: "So if I take the derivative of a function, what is that?", Student: "Slope"). Overall, the talk on this topic was characterized by LAs prompting students to recall prior knowledge about tangent lines, and then explaining to students how to apply the facts they know within the new context of implicit differentiation. Since students did not often bring this topic up, it was LAs who supported students' making connections between previous course content and implicit differentiation, helping make these connections explicit.

Another topic initiated mostly by LAs was *Graphic Coordination* (G_Cor), with LAs introducing the topic in four of the five interactions in which it appeared. Typically, LA pushed students to connect their symbolic work to graphical properties. For example, one student asked an LA what value to plug in to find the derivative at a point. In response, the LA directed the student by pointing to the graph and asking "so what point were you looking at originally? (0,1)?" Instead of telling the student how to proceed, the LA probed the student's thinking about the problem by connecting the graph of the implicit curve with symbolic calculation of slope at a point. This shows the LAs aiding student's reasoning across representations and making sense of computations using graphical properties.

In relation to graphical topics, students primarily *asked questions* (15 of 35 graphic student actions) and *followed* LA instructions (13 of 35 graphic student actions). Questions revolved around interpreting graphs (e.g., How are you supposed to explain that they're [vertical tangent lines] vertical?"). In response to student questions, LAs *directed* work (28 of 57 LA graphical actions) and provided *feedback* (16 of 57 LA graphical actions), explaining concepts and correcting or confirming student work, similar to symbolic topics. LAs' discursive actions for graphical topics had a high number of *guiding* utterances (13) compared to the very low counts for symbolic topics (3) and background concepts (4).

Background Concepts: Algebra and Calculus Skills

LAs and students also discussed prior knowledge of calculus (e.g., calculus notation, tangent lines) and algebra skills (e.g., steps in solving an equation, exponent rules). These topics are needed to both understand implicit differentiation and do such computations. These *Background Concepts* were mentioned in 94 utterances (38%), of those, almost twice as many were related to algebra than calculus (61 and 33 utterances respectively) (Table 1). Algebra topics appeared in more interactions (nine out of 22) than calculus topics (five of the 22 interactions).

In relation to background skills, students *explained* their thinking and work on computations (e.g., "Okay I did the (0,-1), but didn't get the same", "5 minus 15, negative 6.") in only 12 out of 50 utterances in the background concepts category. Yet it was the highest compared to five and seven student explaining codes in symbolic and graphic categories. This suggests students may be more comfortable or confidant sharing their thoughts about topics with which they are already familiar. Students also *asked* LAs to check the validity of their work on background concepts (18 of 50 codes) saying things like "So this would be 15?" and "Am I doing this right?".

In response to student thoughts and questions on these topics, LAs typically *directed* student work (23 of 44 LA background concepts utterances), meaning that they explained procedures to students (e.g., "You can use the quadratic equation to solve for y squared"). LAs also provided students *feedback* (17 of 44 LA background concepts utterances) on their work (e.g., "Um, you're on the right track, but something's going wrong in these terms here"). Students appeared receptive to this explanation and feedback with 20 of the 50 student background concepts codes being *following LA* direction. Like with the symbolic goals, LAs were pragmatic in supporting students; their diligent oversight and confirmation (or correction) of students' basic calculus and algebra skills reassured students that they were successfully performing procedures on which they will be assessed.

Discussion

Our analysis reveals that classroom interactions between LAs and students are primarily pragmatic in nature. The topics of LA-Student conversations often revolve around computation, with symbolic and background topics together discussed in the majority of utterances. While this kind of talk could be dismissed as superficial, we interpret the focus on procedural correctness as a shared value between LAs and students as university student peers who know that success in Calculus 1 course hinges on displaying procedural fluency on exams. LAs also helped students consider graphical features of implicit equations by interpreting graphs in the context of computations, connecting to prior knowledge, and prompting students to explain their thinking.

Though some detail is lost by reporting this micro-analysis of classroom discourse in aggregate, this initial report allows us to make sense of the trends seen across various LAs' interactions with small groups as they discussed implicit differentiation. We are currently in the process of analyzing the sequencing of moves within each interaction to provide a sense of how conversations are reciprocally constructed by LAs and students in this setting.

The current study provides a novel insight into LA-student classroom interactions. We extend Thompson et al.'s (2020) taxonomy of LA's actions (ATLA) to student actions as well, and contextualize both types of actions within specific mathematical content. This study also exemplifies several ways in which LAs act as MKOs in a Calculus setting, including through pragmatic focus on computation and by explicitly connecting new ideas to prior knowledge. This emphasis on procedural knowledge could be one aspect of the mechanism contributing to success of students in LAs' supported classrooms, since procedural knowledge of mathematics has been shown to support development of conceptual knowledge (Rittle-Johnson et al., 2015).

Further, this study contributes to our understanding of how students learn implicit differentiation in an authentic classroom environment, compared to prior studies that used local interventions and teaching experiments (Borji & Martínez-Planell, 2020; Jeppson, 2019). LAs' emphasis on prior knowledge reframed implicit differentiation not as a new and potentially intimidating course topic, but as a familiar procedure with some modifications, thus potentially supporting students' emotional and cognitive processing of this topic. Continued analysis of these LA-student conversations at this detailed level will generate much needed insight into both students' real-time learning of implicit differentiation and the content-specific aspects of LA-supported learning.

UNPACKING INFORMATIVE ASSESSMENTS TO YIELD STUDENTS' UNDERSTANDING OF PARTIAL DERIVATIVES USING MATH LITERACY ACTIVITIES

Alexandra Cuadra
Purdue University
fernan87@purdue.edu

Keywords: math literacy, partial derivatives, concept definition, concept image

Mathematical literacy is a critical component of teaching mathematics as its own language. In this study, I will use writing to learn mathematics (WTLM) activities to help students communicate their mathematical thinking and understanding. I will conduct an embedded single-case study with 43 undergraduate students enrolled in a hybrid calculus course, which focuses on integral and multivariable calculus topics. WTLM activities will provide students with an opportunity to explain their understanding either symbolically, procedurally, and/or conceptually. The students' understanding of partial derivatives will be analyzed using my posit framework, which is an integration of the frameworks Concept Definition and Concept Image, and Covariational Reasoning. In my study, I investigated students' initial and developing understanding of partial derivatives within the calculus curriculum. Using WTLM activities, I address my research question: What are students' concept definitions and evoked concept images when learning about partial derivatives in calculus? In this paper, I focus on the WTLM activities I implemented as my data collection sources.

One of my goals was to give students a larger voice in their thinking and understanding and a larger ownership in the learning process by teaching mathematics literacy as part of the learning process. Using writing to learn mathematics (WTLM) activities, students can communicate their mathematical thinking and understanding. The two WTLM activities I propose using are (1) "The Important Thing About…" Prompt [based on Brown's (1949)] Important Book, and (2) My Aspects of Mathematical Phenomena (AMP) – Chart [based on Frayer and colleagues (1969) with contributions of online blogger Musingsofamathteacher (2011)]. It is with these activities, that I can begin to unpack students' understanding of topics such as partial derivatives and address my research question: What are students' concept definitions and evoked concept images when learning about partial derivatives in calculus?

Summary

As I continue to analyze my data, I expect to learn about my students' concept definitions and concept images of partial derivatives. Afterward, I expect to see how these concept definitions and concept images of partial derivatives reflect their understanding. My work on this study will contribute to giving students (1) a larger voice in their thinking and understanding to their teachers through the usage of WTLM activities, (2) the skills to communicate their understanding inside and outside of the mathematics classroom, and (3) a tool to combat the difficulty that comes with abstract mathematical ideas.

Presentamos una secuencia didáctica mediada por la tecnología digital para significar y calcular las raíces reales de una función real en un curso de cálculo diferencial para estudiantes de ingeniería. Para introducir las raíces diseñamos un Escenario Didáctico Virtual Interactivo, que simula un problema real, y usamos el sistema tutorial CalcVisual para apoyar el cálculo aproximado de las raíces. Implementamos la secuencia con una población de 45 estudiantes universitarios en México. Los datos se analizaron mediante los modelos emergentes de la Educación Matemática Realista. Mostramos el progreso en la actividad matemática de los estudiantes a través de cada uno de los niveles de actividad de los modelos emergentes quienes mostraron un avance significativo en la comprensión conceptual y cálculo de las raíces reales.

Precálculo, Cálculo, Tecnología, Experimentos de diseño.

Los polinomios son funciones fundamentales en la matemática, en particular en el cálculo, análisis matemático y álgebra lineal. Una de las propiedades más importantes de una función polinómica, son sus raíces reales y complejas, pero determinarlas no es tarea sencilla e incluso en algunos casos se llega a confundir la función polinómica con la ecuación que se deriva de ella (Dede y Soybas, 2011). Significar el concepto de raíz real de una función resulta determinante por tratarse de un concepto fundamental para la matemática e imprescindible para aplicaciones en procesos de optimización, cálculo diferencial e integral, álgebra lineal, cálculo multivariable y método Simplex de programación lineal, por mencionar algunos. La determinación de las raíces simples o múltiples es un problema complejo y vigente que tiene su origen desde los primeros vestigios de la humanidad, y que siempre ha estado asociado a problemas de variación, acumulación y optimización. Hasta nuestros días se mantienen problemas abiertos sobre el cálculo de raíces, sobre todo cuando son múltiples (Cuevas y Madrid, 2013), y cobra relevancia en el problema de cómo introducir desde el plano cognitivo este concepto en la enseñanza a nivel de precálculo y cálculo (Veuillez-Mainard, 2023). Al realizar una búsqueda sistemática de la literatura podemos constatar que existen pocos artículos que reporten las dificultades de enseñanza de raíces reales, minimizando la importancia y dificultad del concepto. Es conveniente recordar que la resolución de ecuaciones polinomiales generó el álgebra (Puig y Rojano, 2004).

Tradicionalmente el cálculo aproximado de raíces reales era un tema importante que tratar en cursos de análisis numérico donde se practicaban diversos métodos como: bisección, regula falsi y Newton-Raphson para aproximarse al valor de una raíz real. Sin embargo, al popularizarse el uso de herramientas digitales con la avalancha de diversos manipuladores simbólicos virtuales, el significado y proceso bajo el cual se desarrolló permanece oculto, dejando la incertidumbre de qué es una raíz real de una función real. Esto debido a que softwares como: Mathematica, Wolfram Alpha, Matlab, GeoGebra y Photomath, resuelven ecuaciones y encuentran sus raíces en cuestión de segundos. Este reto que la tecnología digital ha puesto en la enseñanza y aprendizaje de las matemáticas permanece sin respuesta, y ha creado el paradigma de ¿qué se debe de enseñar? Cuando los estudiantes utilizan cualquier dispositivo o software para calcular el valor de una raíz real ¿sabrán que la mayoría de las veces encuentran un valor aproximado? ¿qué cuando las raíces son múltiples y cercanas pueden confundirse por errores de aproximación? ¿qué significa gráfica y numéricamente una raíz? ¿en qué se puede utilizar el concepto de raíz real, más allá de calcular su valor? Estos significados, se extraviaron al perderse los métodos de aproximación de una raíz y difícilmente se recuperarán algún día. Nos preguntamos ¿cómo recuperar los significados del concepto raíz de una función real mediante actividades mediadas por la tecnología digital? Nuestra propuesta consiste en el desarrollo y creación de actividades didácticas que permitan recuperar los significados de las raíces reales aprovechando los recursos que la tecnología digital ofrece el día de hoy como la capacidad numérica, gráfica y simbólica.

Marco teórico

Cuando un profesor frente a un grupo de estudiantes explica y anota definiciones, fórmulas y ejercicios en el pizarrón, mientras los estudiantes lo observan, escuchan y anotan en sus libretas lo expuesto por él, a esta enseñanza se le denomina enseñanza tradicional, la cual se ha desarrollado durante varios años. Para evitar este tipo de enseñanza y promover una enseñanza participativa con el objetivo de dotar de un significado a los conceptos matemáticos, Cuevas y Pluvinage (2003) proponen una serie de principios – intranet conceptual, partir de un problema en un contexto real, un plan de acción, implementación de operaciones inversas, la articulación de diversos registros de representación, la validación de resultados y la aplicación del concepto en un contexto diferente al enseñado– para la enseñanza de un concepto matemático. Usamos estos principios para el diseño de las actividades.

Los modelos emergentes son una de las tres heurísticas de diseño instruccional de la Educación Matemática Realista (RME por sus siglas en inglés). Esta heurística describe como una serie de modelos puede apoyar el avance matemático de los estudiantes (Gravemeijer, 2020). La heurística de los modelos emergentes destaca la importancia de comenzar con problemas contextuales que ofrezcan oportunidades para desarrollar un razonamiento específico de la situación y con el potencial de crear problemas cuya solución hace necesario el uso de conceptos matemáticos más sofisticados (Gravemeijer y Doorman, 1999). La actividad matemática inicia con el uso o desarrollo de un modelo derivado del contexto y, con el tiempo, este modelo apoya la aparición de formas de conocimiento matemático formal (Doorman et al., 2012). Los estudiantes transitan por distintos niveles de actividad que van desde el uso de estrategias informales hasta el razonamiento matemático formal (Gravemeijer, 1999). Los cuatro niveles propuestos por la RME son:

1. Nivel situacional (actividad en el entorno de la tarea). En este nivel las interpretaciones y

las soluciones dependen de la comprensión de cómo actuar en el entorno (fuera del entorno escolar).

2. Nivel referencial. En este nivel los modelos-de se refieren a la actividad en el entorno descrito en las tareas. En consecuencia, los modelos que surgen se basan en la comprensión de los estudiantes del entorno real y forman parte de las explicaciones en las que los estudiantes describen cómo interpretaron y resolvieron las tareas centradas en los escenarios de partida.
3. Nivel general. Este nivel comienza a surgir cuando los estudiantes empiezan a razonar sobre las relaciones matemáticas implicadas. Por lo tanto, surge cuando el razonamiento de los estudiantes pierde dependencia de las imágenes específicas de la situación. En este sentido, los modelos-para sirven más como medio de razonamiento matemático que como forma de simbolizar la actividad matemática basada en entornos particulares.
4. Nivel formal. En este nivel se trabaja con los procedimientos y notaciones convencionales. Se alcanza cuando los estudiantes ya no necesitan el apoyo de modelos para la actividad matemática.

Usamos estos niveles para mostrar el progreso en el razonamiento de los estudiantes, sobre el concepto de raíz, al trabajar con las actividades propuestas.

Metodología

Este estudio se desarrolló con base en la Investigación Basada en el Diseño (IBD) por lo que esta investigación implica iteraciones de diseño, implementación y análisis mediante las siguientes fases: preparación y diseño, experimentos de enseñanza y análisis retrospectivo (Bakker, 2018).

Fase de preparación y diseño

Se diseñó una secuencia de cinco actividades para introducir de forma gradual el concepto de raíz real (ver figura 1).

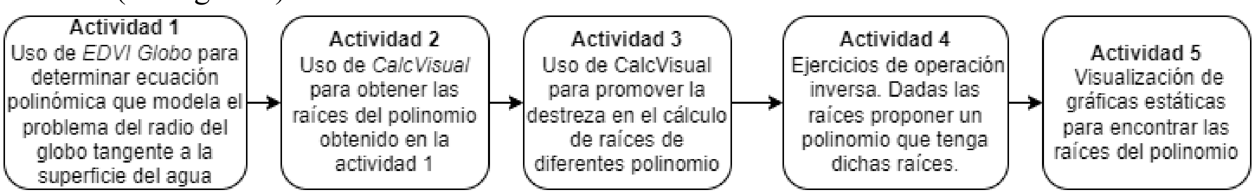

Figura 1: Secuencia didáctica

Como parte de la secuencia, se diseñó un Escenario Didáctico Virtual Interactivo (EDVI), al que denominamos EDVI "Globo" porque simula un recipiente cilíndrico de 10 cm de diámetro con un globo esférico atado al fondo. Este EDVI cuenta con botones para llenar y vaciar de agua el recipiente y botones para inflar y desinflar el globo a partir de los cuales, pueden observar cambios de forma dinámica en parámetros como: la altura inicial del agua con el globo desinflado, la altura del agua al inflar o desinflar el globo y el radio y diámetro del globo (ver figura 2a). En este artículo nos referimos a un EDVI como un manipulativo virtual que permite simular y visualizar diferentes representaciones semióticas de un problema real (Cuevas et al., 2023).

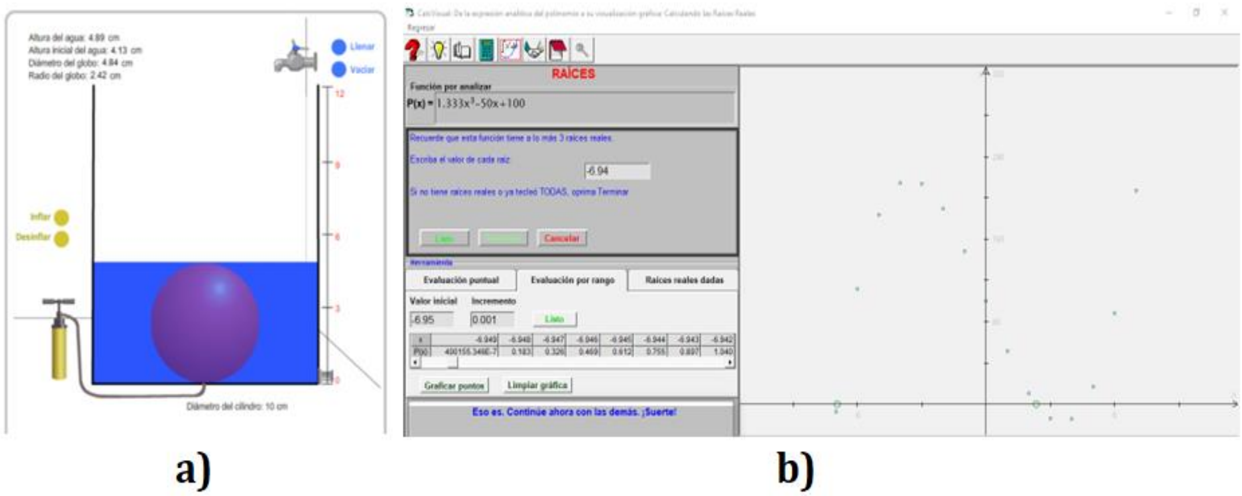

Figura 2. a) EDVI Globo; b) Sistema Tutorial Inteligente CalcVisual

Adicionalmente, se utilizó un Sistema Tutorial Inteligente denominado CalcVisual que apoyará a los estudiantes en el cálculo de las raíces (ver figura 2b). El CalcVisual es un software que no calcula las raíces como cualquier manipulador simbólico. Permite introducir el polinomio y mediante herramientas visualizar diferentes representaciones del concepto de raíz. Por ejemplo, su representación tabular y su gráfica sobre un plano cartesiano. Es importante señalar que, CalcVisual no trabaja con funciones racionales y radicales. Asimismo, se diseñaron Hojas de Exploración y Aprendizaje Guiado (HEAG) para cada actividad, las cuales guían al estudiante en la manipulación de las herramientas digitales y en la construcción del concepto matemático.

Fase de experimento de enseñanza

La intervención didáctica se desarrolló en una universidad pública mexicana con 45 estudiantes inscritos en un curso de "Matemáticas aplicadas a la informática". Las HEAG se enviaron de manera digital a cada estudiante y las actividades se desarrollaron en equipos de 6 integrantes. Después de resolver cada actividad, el profesor seleccionó unas HEAG al azar y realizó una discusión en clase para llegar a las respuestas correctas de forma consensuada. Las actividades fomentan tanto el aprendizaje individual como el colaborativo. Los datos se obtuvieron mediante las respuestas en las HEAG que los estudiantes enviaron al correo electrónico del profesor. Uno de los autores fue el encargado de impartir dicho curso. Los datos se analizaron de manera independiente por los investigadores. Se identificaron estrategias de solución y las respuestas de los equipos se clasificaron en los niveles de actividad (situacional, referencial, general y formal).

Resultados y análisis retrospectivo

En esta sección describimos como progresa el razonamiento de los estudiantes a través de cada uno de los niveles de actividad de los modelos emergentes al trabajar con las actividades propuestas. Debido a la limitación del documento, mostramos las respuestas de dos equipos (T1 y T2) seleccionados al azar.

Actividad Situacional

Como se ha mencionado anteriormente, la actividad situacional implica que los estudiantes trabajen en un entorno real para alcanzar objetivos matemáticos particulares. La actividad en el aula comenzó con la exploración del EDVI "Globo". Clasificamos esta actividad en el *nivel situacional* porque los estudiantes usaron las herramientas disponibles en el escenario para identificar variables, constantes y características cómo: una altura inicial del agua (h_0) con la que el diámetro del globo puede ser igual a la altura del agua (h_a). La tabla 1 muestra las respuestas de los equipos T1 y T2 a las preguntas de exploración.

Tabla 1. Preguntas y respuestas a las actividades de exploración

Pregunta	Respuesta T1	Respuesta T2
¿Qué elementos son variables al inflar el globo?	Radio del globo, volumen del contenido en el recipiente, volumen del globo.	Radio del globo, volumen del contenido en el recipiente, volumen del globo y altura inicial del agua.
¿Qué elementos son constantes al inflar el globo?	Radio del recipiente, volumen inicial de agua y altura inicial del agua.	Radio del recipiente, volumen inicial de agua.
¿Hasta qué valor puede crecer y disminuir el radio del globo (x)?	El radio puede crecer hasta 5cm y disminuir hasta 0cm	El radio puede crecer hasta 5cm y disminuir hasta 0cm.
¿Hasta que altura inicial (h_0) se puede llenar el recipiente de agua?	La altura inicial máxima es de 12 cm	La altura inicial máxima es de 5.47.
Escribe una altura inicial del agua h_0 con la que el diámetro del globo sea igual a la altura del agua h_a.	Si el recipiente se llena hasta una altura de 10cm, el diámetro se expandirá hasta los 10cm.	A una altura de 5.45

En general, los elementos constantes del EDVI son el radio del recipiente, el volumen inicial de agua y la altura inicial del agua. Sin embargo, nótese que el T2 indicó como variable la altura inicial del agua. Inferimos que dieron esta respuesta porque se trata de un parámetro que se puede modificar en el EDVI. Aunque, una vez establecido, al inflar y desinflar el globo este permanece constante. Observe también que, las respuestas a la pregunta 4 son diferentes. Ambas respuestas son correctas, ya que el T1 se enfocó en la h_0 con el globo desinflado, mientras que el T2 primero infló el globo hasta su valor máximo y posteriormente llenó el recipiente con agua. Finalmente, las respuestas a la pregunta 5 nos hacen inferir que los estudiantes confundieron la altura inicial del agua (h_0) con la altura del agua (h_a) aunque se puede observar que sí identificaron valores en los que el diámetro del globo es igual a la altura del agua.

Actividad Referencial

Tras la exploración del EDVI "Globo", la actividad en el aula continuó con el problema de identificar la ecuación polinómica que modela el volumen total del contenido del recipiente, cuando el radio del globo es tangente a la superficie del agua para identificar como solución la raíz de un polinomio. Clasificamos esta actividad como *referencial* porque los estudiantes comenzaron a establecer relaciones matemáticas en el contexto. Esta actividad se dosificó de modo que los estudiantes propusieran ecuaciones para determinar la altura del agua (h_a) en relación con el radio del globo (x), el volumen del globo (V_G), el volumen inicial del agua (V_A) y el volumen total del contenido en el recipiente (V_T). La tabla 2 muestra las ecuaciones propuestas por los equipos T1 y T2.

Tabla 2. Ecuaciones propuestas por los equipos T1 y T2 para modelar el problema del radio del globo tangente a la superficie del agua

T1	T2
$V_G = (\frac{4}{3})\pi x^3$ $V_A = \pi(R^2)\ h_0$ h_a=$2x$ $V_T = \pi(R^2)\ h_a$ $V_T(x) - V_A - V_G = 0$ Donde $V_T(x)$ es el volumen del cilindro con radio x y altura del agua h_a, V_A es el volumen inicial de agua y V_G es el volumen del globo.	$V_G = (\frac{4}{3})\pi x^3$ $V_A = \pi(R^2)\ h_0$ h_a=$h_0 - x$ $V_T = \pi R^2 h_a + V_G = \pi R^2(h_0 - x) + \frac{4}{3}\pi x^3$ $\pi R^2(h_0 - x) + \left(\frac{4}{3}\right)\pi x^3 - V_T = 0$

De las respuestas observamos que ambos equipos identificaron la relación entre el volumen total del contenido en el recipiente (V_T), el volumen sumergido del globo (V_G) y el volumen inicial del agua (V_A). Por ejemplo, los estudiantes del T1 mencionaron que "el volumen total del contenido en el recipiente es igual a la suma del volumen inicial del agua y el volumen sumergido del globo". Además, señalaron que esta relación se podía expresar mediante la siguiente ecuación "$V_T = V_i + V_g$". De forma similar, los estudiantes del T2 indicaron que "el volumen total del contenido del recipiente es igual a la suma del volumen inicial del agua con el volumen sumergido del globo". Sin embargo, ningún equipo llegó a la ecuación polinómica esperada $\frac{4}{3}x^3 - 2R^2x + R^2h_0 = 0$ donde, x es el radio del globo, R es el radio del recipiente y h_0 es la altura inicial del agua. Esta ecuación se desarrolló y explicó en la discusión grupal.

Actividad General

Después de identificar la ecuación polinómica $f(x) = \frac{4}{3}x^3 - 2R^2x + R^2h_0$ que modela el problema del radio del globo tangente a la superficie del agua, se propuso a los estudiantes que usaran CalcVisual para encontrar las raíces del polinomio, con $R = 5$ y $h_0 = 4$, $f(x) = \frac{4}{3}x^3 - 50x + 100$. Clasificamos esta actividad en el *nivel general* porque los estudiantes se enfocaron en representaciones gráficas y tabulares para encontrar las raíces, sin hacer referencia al contexto del globo. Por ejemplo, el T1 respondió "Nuestra función cuenta con 3 raíces, $-6.9493, 2.3430$ y 4.6063. Esto lo conocemos gracias a que al meter la función dentro de nuestro programa graficador, este genera 3 puntos exactos". Por su parte, el T2 mencionó "Este polinomio tiene 3 raíces, $x1 = -6.94, x2 = 2.34\ y\ x3 = 4.60$. En la gráfica podemos ver tres puntos, lo cual significa que cada uno de ellos es parte de una raíz". Nótese cómo en ambos casos mencionan la existencia de puntos en la gráfica del polinomio, los cuales asociaron con sus raíces. Al finalizar esta actividad, pedimos a los estudiantes que validaran sus resultados respondiendo la pregunta "¿Qué raíces tiene sentido para el problema del globo?". El T1 respondió que "las raíces positivas debido a que se no se puede tener un volumen negativo. Los valores de la segunda y tercera raíz el radio del globo es tangente a la superficie del agua". En cambio, el T2 señaló que "todas las raíces son correctas. Sin embargo, para la raíz $x3 = 4.6$ el radio del globo es tangente a la superficie del agua". Las respuestas a esta pregunta se pueden clasificar en el nivel referencial porque los estudiantes interpretaron las raíces encontradas en el problema del globo. El cambio de nivel de actividad va en acuerdo con la afirmación de Rasmussen y Blumenfeld (2007) acerca de que los niveles de actividad no imponen una jerarquía estricta. Sin embargo, es importante aclarar que esta pregunta se hizo con la intención de identificar el significado que los estudiantes estaban dando a las raíces reales en el contexto del EDVI Globo.

Actividad Formal

Después de que los estudiantes realizaron actividades con el uso de CalcVisual para encontrar las raíces de un polinomio, trabajaron con actividades de operación inversa como: "Escribe un polinomio que tenga al menos las siguientes raíces reales: $r1 = 2$ y $r2 = -5$ ¿será ese el único polinomio que tenga al menos esas raíces reales?". Las respuestas de los equipos T1 y T2 se resumen en la tabla 3.

Tabla 3. Respuestas de los equipos T1 y T2 a actividad de operación inversa

Escribe un polinomio que tenga al menos las siguientes raíces reales: $r1 = 2$ y $r2 = -5$	
Equipo T1 Respuesta: $x^2+3x-10$ 1) Se coloca el signo opuesto de las raíces dadas. 2) Multiplicamos los factores que obtuvimos. $(x-2)(x+5)= x^2+5x-2x-10$ 3) Expandimos el producto. $x^2 + 3x - 10$	Equipo T2 Respuesta: $(x-2)$ y $(x+5)$ $(x-2)(x+5)= x^2+5x-2x-10$ $x^2 + 3x - 10$
¿Será ese el único polinomio que tenga al menos esas raíces reales?	
No es el único polinomio que tiene al menos esas raíces porque podemos multiplicar el polinomio por cualquier otro factor lineal y obtendremos un polinomio que tenga las mismas raíces.	No, también puede ser $f(x)(x - 2) = (x^3 +3x-10)(x-2)=$ $x^3-5x^2-4x+20$

Como se puede observar en la tabla 3, los estudiantes escribieron primero los polinomios de forma factorizada y posteriormente realizaron la multiplicación de los factores para proponer un polinomio desarrollado. Clasificamos estas respuestas en el nivel formal porque los estudiantes trabajaron con procedimientos algebraicos desligados del EDVI Globo y el uso de CalcVisual.

La actividad formal también se observó en la actividad 5 que no involucraba el uso de herramientas digitales sino la visualización de gráficas estáticas como la de la figura 3. Esta actividad se diseñó como tarea final para identificar el aprendizaje que los estudiantes adquirieron sobre el concepto de raíz en un contexto distinto al del Globo.

Escala en el eje x es de 1 unidad por marca.

1. ¿Cuántas raíces reales tiene el polinomio de la gráfica?

 a) 0 b)2 c)3 d)No sé

Justifica tu respuesta

____

____

____

____

____

2. Escribe un valor aproximado para cada raíz:

____

____

____

Figura 3. Actividad de visualización de gráficas estáticas para identificar raíces

Los estudiantes iniciaron la actividad 5 en el nivel general porque para responder las preguntas de la figura 3, los estudiantes se enfocaron en identificar los puntos en los que la gráfica corta al eje x como muestran las respuestas de los equipos T1 y T2. Por ejemplo, en T1 mencionaron que “la gráfica está atravesando el cero en el eje de las x tres veces. Por lo tanto, la función de esta gráfica contiene 3 raíces: $-2, 0$ y 3”. De forma similar, el T2 contestó “debes contar el número de veces que la gráfica del polinomio cruza el eje x. Esta gráfica lo cruza exactamente tres veces. Entonces, el polinomio tiene al menos tres raíces: $-2, 0$ y $+3$”. Posteriormente trabajaron en el nivel formal porque representaron el polinomio mediante una factorización para llegar a su representación desarrollada.

Discusión y Conclusiones

Presentamos una secuencia de actividades que ayuda a los estudiantes a transitar de un razonamiento basado en un problema contextual a uno formal sobre el concepto de raíz. Si bien, Gravemeijer (2020) menciona que los niveles de actividad no necesariamente se observan de manera jerárquica, en nuestra investigación observamos que las actividades guiaron el razonamiento de los estudiantes sobre el concepto de raíz de forma secuencial. Es decir, la actividad 1 se trabajó en el nivel situacional y referencial, las actividades 2 y 3 en el nivel general y las actividades 4 y 5 en el nivel formal. Con lo anterior no queremos decir que los estudiantes no pueden regresar al contexto cuando trabajan en el nivel general y formal. Elegimos el contexto del Globo como un contexto con el que los estudiantes pueden significar el concepto de raíz, por ello, inferimos que se trata de una situación que perdura en la mente del estudiante.

Destacamos que, la actividad 1 con el uso del EDVI Globo fomentó el desarrollo del nivel situacional al identificar variables, parámetros y relaciones funcionales. Posteriormente, fomentó el tránsito al nivel referencial en la actividad de determinar la ecuación polinómica que modelaba el problema del radio del globo tangente a la superficie del agua. Este polinomio se usa en la actividad 2 para que los estudiantes identifiquen sus raíces, mediante el uso de CalcVisual, y les den un significado en el contexto del Globo. La actividad 3 fomentó el desarrollo del nivel general al trabajar con el CalcVisual mediante el tratamiento de funciones polinómicas fuera de cualquier contexto. Las actividades 4 y 5 fomentaron el tránsito al nivel formal al desarrollar un polinomio expresado mediante una factorización y localizar raíces en una gráfica. Los estudiantes ya no usan el EDVI Globo pero pueden usar el CalcVisual para ingresar el polinomio factorizado o desarrollado y visualizar representaciones gráficas, algebraicas y tabulares.

Una de las limitaciones de este documento es que se han presentado los resultados únicamente de dos equipos de estudiantes, aunque el análisis del nivel de actividad se ha realizado con los datos de los 45 participantes. De este análisis observamos que 30 estudiantes alcanzaron el nivel formal al trabajar con las actividades 4 y 5. Aquellos que no alcanzaron el nivel formal se debe a dificultades operativas y el uso incorrecto de procedimientos algebraicos.

Otra limitación del estudio tiene que ver con los problemas asociados a la instalación y uso de las herramientas digitales. A pesar de que se proporcionó a los estudiantes el CalcVisual para que lo instalaran en su computadora, algunos tuvieron problemas para instalarlo y no pudieron realizar las tareas en casa que necesitaban el uso de dicho software. Como solución, acudieron a otra herramienta como Wolfram, GeoGebra, etc para resolver las actividades. Aquí, el problema radica en que al usar herramientas como Wolfram los estudiantes obtienen las raíces sin saber cómo. Prueba de lo anterior es que en la retroalimentación con los estudiantes que trabajaron todas las actividades con el CalcVisual, manifestaron seguridad al resolver el examen del curso. En cambio, aquellos que utilizaron otros softwares, no sabían de dónde provenían los datos. En este sentido, el rol del profesor es importante porque debe intervenir para guiar a los estudiantes en el cumplimiento de los objetivos. En este estudio, durante la discusión en grupo, el profesor mostró a los estudiantes cómo usar el CalcVisual y discutió las desventajas de usar otro software.

Retomando nuestra pregunta de investigación ¿cómo recuperar los significados del concepto raíz de una función real mediante actividades mediadas por la tecnología digital? Sugerimos que el uso indiscriminado de la tecnología digital en la enseñanza de las matemáticas puede contribuir a la perdida de los significados y aplicaciones de los conceptos matemáticos. Por lo que recomendamos que su aplicación requiere de un cuidadoso diseño didáctico previo a su aplicación. Sugerimos iniciar la actividad en el aula con la simulación de un problema en contexto que permita a los estudiantes dar sentido al concepto matemático de interés. La simulación del problema del globo sumergido en un recipiente permitió al estudiante dotar de significado al concepto de raíz que por su propia naturaleza es abstracto. Usar un software no resolutivo como CalcVisual permite manipular diferentes representaciones de forma simultánea para establecer relaciones entre ellas, lo cual lleva a que los estudiantes adquieran significado del concepto de raíz en su representación tabular, gráfica y algebraica.

Destacamos la importancia de incluir actividades sin el uso de herramientas digitales para corroborar el aprendizaje del concepto de raíz. En este caso las herramientas digitales sirven como herramienta de verificación de resultados. Los estudiantes pueden identificar raíces de gráficas estáticas, obtener su polinomio y, posteriormente, ingresarlo en el software para comprobar los valores numéricos de las raíces. La aplicación de las HEAG es fundamental ya que guían la secuencia de actividades, contribuyendo a la comprensión del concepto de raíz de una función real.

WHAT DOES CALCULATING LOOK LIKE IN CALCULUS? CALCULATING SITUATIONS FOR INTRODUCING DERIVATIVES

Saba Gerami
California Polytechnic State University – San Luis Obispo
sgerami@calpoly.edu

In this study, I present four calculating instructional situations identified within 56 instructional tasks for introducing derivatives proposed by eight experienced college calculus instructors. During four 1–2-hour long interviews, the instructors proposed up to eight tasks for introducing derivatives physically, graphically, verbally, and symbolically, both at a point and as a function. The tasks were analyzed to identify calculus-specific instructional situations framing them. Here, I describe the four identified calculating situations, how they were realized in the tasks through calculus-task units (CTUs), and what mathematical works they expect of students.

Keywords: Undergraduate Education, Calculus, Instructional Activities and Practices, Curriculum

As basic units of instruction and "objects of students' activity" in mathematics classrooms (Ni et al., 2018; Sullivan et al., 2009, p. 859), instructional tasks are often seen as the conceptual bridge between teaching and learning (Christiansen & Walther, 1986; Stein & Lane, 1996). Empirical studies have revealed that the nature of tasks often changes during instruction, and that teachers' decisions about how students worked on the tasks has a significant influence on their learning outcomes. Nonetheless, the research on instructional tasks in first-semester college calculus is lacking. Given that much is at stake for students in these courses (e.g., progression to graduation or majoring in math-required fields), a better understanding of how the content is presented and what learning opportunities are created is imperative for improving students' learning outcomes. In this study, I aim to enhance our understanding of calculus teaching and uncovering how one specific content area—derivatives—is presented to students through instructional tasks. More specifically, I focus on the work of *calculating* in instructional tasks aimed at introducing derivatives.

Theoretical Framework

Using the Brousseau's (1997) notion of didactical contracts to delineate what is normative and what is not, Herbst (2006) introduced *instructional situations* as customary ways by which the teacher's and students' actions and interactions are framed into appropriate units of work regarding the knowledge at stake. Instructional situations regulate the "work on particular kind of tasks for particular objects of knowledge" (Herbst & Chazan, 2012, p. 605) as both distinct problem types used in a course of studies, as well as "the specific norms that regulate the teacher's and students' work on them" (Herbst et al., 2023, p. 402). Herbst et al. (2020) defined *task framing* from the perspective of the teacher in mathematics instruction as choosing a way of handling a problem, or choosing an instructional situation, about the knowledge at stake; once recognized by students, the task framing, that is the instructional situation, allows students to know what kind of mathematical work and interactions they should prototype. For instance, *graphing* is an example of an instructional situation in Algebra I. When students are asked to graph a line in the form of $y = mx + b$, by realizing that the instructional situation is graphing in Algebra I, they access the didactical contract of graphing. Teachers can select from the available set of instructional situations to frame their instructional tasks, consequently launching and organizing students' work (Herbst et al., 2018; 2020). Researchers have identified various customary instructional situations mainly in high school geometry and algebra, such as doing proofs; installing (defining) a new definition or a new concept; installing (introducing) a new theorem, property, or formula; solving equations with known methods; and solving word problems (Chazan & Lueke, 2009; Herbst et al., 2010).

Methods

The data for this study comes from a larger interview study with eight experienced U.S. calculus instructors. During four semi-structured 1–2-hour long interviews with each instructor, I prompted the instructors to propose up to eight tasks for introducing derivatives. Organized by Zandieh's (2000) framework, each interview was dedicated to one representation of the derivative (graphical, verbal, physical, symbolic) and its process-object layers (ratio, limit, function). The process-object layers are hierarchical, as each layer is found by taking the process of that layer over the previous layer as an object. For example, the limit layer is found by the *process of* finding the limit of the ratio as an *object*. The limit layer corresponds to when the denominator approaches zero; the function layer is presented as an array of numbers or set of ordered pairs of differences. The instructors were asked to propose tasks within each representation that would help transition students' conception from one layer to the next within that representation: from ratio to limit, and from limit to function.

The instructors collectively proposed 56 tasks, or what could be better described as 'a set of tasks.' Despite this, I refer to what they proposed in its entirety and to the unit of analysis as an instructional task. To pursue analysis, I first broke down the instructional tasks into their smallest calculus-specific problems, which I call *calculus-specific task units* or *CTUs*. By this, I mean that if I further divided a CTU into smaller tasks, the results would not be recognizable as calculus tasks; instead, they would be recognized as tasks from other content areas preceding calculus in a standard mathematics curriculum sequence. I then used thematic analysis (Saldaña, 2021) to reduce the 37 identified CTUs to 11 instructional situations categorized as four calculating, two exploring/conjecturing, two graphing, two installing, one proving, and one solving equation (see Gerami, 2024). In this study, I focus on calculating situations for introducing derivatives.

Findings

I identified 12 distinct calculating CTUs across all the tasks, which I then reduced to four instructional situations, as shown in Table 1:

Table 1. Calculating instructional situations and along with their CTUs

Instructional Situations	Calculus-Specific Task Units (CTUs)
1) Calculating/ Estimating a value using known formulas or definitions	**C1.** Calculating the average rate of change or average velocity or slope of secant lines or difference quotient given $f(x)$ and/or a table of values for various x_i and $f(x_i)$, or the equation of the curve of best fit based on various x_i and $f(x_i)$ **C6.** Calculating instantaneous velocity at x_0, using equation of

	continuity **C7.1.** Calculating instantaneous velocity or instantaneous growth or the slope of tangent or derivative values or $f'(x_0)$ or $f'(a)$ given $f(x)$, using a limit definition **C7.2.** Calculating $f'(x_0 +/-)$ using the limit definition **C8.** Calculating $f'(x_0)$ or slope of a tangent line at x_0 or a using the formula for $f'(a)$ or $f'(x)$ **C11.** Calculating instantaneous velocity or instantaneous growth or $f'(x)$ using a limit definition
2) Calculating/ Estimating a value by collecting information from graphical representations to use in known formulas or definitions	**C2.** Calculating slope of secant lines to the left and right side of x_0 using the graph of $f(t)$ **C5.1.** Calculating the slope of tangent line at x_0 using the graph of $f(x)$ on plain or grid background **C5.2.** Calculating slope of tangent line at a point x_0 by zooming in
3) Writing an algebraic statement using known formulas or definitions	**C3.** Finding the equation of a secant line **C9.** Finding the equation of a tangent line at x_0 or a **C12.** Finding instantaneous velocity $f'(x)$ using average velocities on consecutive equidistant intervals for a quadratic function
4) Estimating a value using number sense	**C4.** Estimating instantaneous velocity or slope of a tangent line or rate of change or $f'(x_0)$ or $f'(a)$ using a pattern of average velocities or slope of secant lines or average rates of change **C10.** Estimating y-values of f' as slopes of tangents of f

The first instructional situation—calculating/estimating a value using known formulas or definitions—can be seen in calculating CTUs in which information is provided to students, expecting them to put forward known formulas/definitions to calculate the unknown value in the problem. In C1, C6, C7, C8, and C11 students should use various definitions to calculate derivatives at different layers. At stake in these situations is students' knowledge and proficiency to use the formulas to find a numeric value. Given that students derive the final answer by reasoning, their work here is deductive. The second instructional situation—calculating/estimating a value by collecting information from graphical representations to use in known formulas or definitions—requires students to first interact with the graphs of mathematical objects (such as lines and functions) to collect related information about the variables in their known formulas/definitions and then use the information in a known formula to compute the value of a variable. In C2 and C5, students are expected to use the graph of secants, tangents, and functions to find/calculate slope values using $\frac{\Delta y}{\Delta x}$. As well as students' knowledge and ability to use the formulas, these situations make room for students' ability to interact with and use graphs of lines and functions to find information and values needed in their slope formulas. Therefore, students need to know how to extract x- and y-values of various points on given lines or curves. Similar to the first instructional situation, the work is deductive. I use ‘estimating’ in the first two instructional situations when the inputs are non-exact values (e.g., finding rough values for x- and y-intercepts of a function based on a graph) or the output is irrational and students round these values up or down for simplification. This is different than how I use estimating in the fourth instructional situation.

The third instructional situation—writing an algebraic statement using known formulas or definitions—requires students to utilize information (given or collected from graphical representations) and known formulas or definitions to write algebraic expressions/statements or algebraic representations of mathematical objects. Other than knowing the formulas, these situations also make room for the recognition of properties of lines in general, as well as properties of secant and tangent lines in relation to values of rate of change for a function in particular. Because the final solution is not a numeric value in these situations, students must recognize which variables they should substitute numbers for, which ones they should leave as variables, and what the desired algebraic expression looks like (e.g., in the form of $y = mx + b$). This work is also deductive.

The fourth instructional situation—estimating a value using number sense—engages students in a distinct form of calculating in which students use their number sense to estimate a value given a set of related values that were given or were calculated by students. I use *estimating* here in a distinct manner compared to the first and second instructional situations. Here, instructors expect students to use known procedures and/or formulas to collect/calculate multiple values close to the exact solution and decide, or *conjecture*, whether to stop collecting/calculating or keep going to get closer to the solution. Because conjecturing leads to proving or disproving, I did not consider this as a conjecturing situation but rather a special kind of calculating. In C4, after finding slope values of nearby secants around a tangent line, students must generate a ‘good enough’ value as an estimate for slope of the tangent based on the data about nearby secants. In C10, students can demonstrate their knowledge of the graph of a derivative function and recognize the relationship between the points on a derivative function’s graph and the points on the original function’s graph. Because the graphs include information about other points in the domain than what is necessary to solve the problem, students are supposed to choose their points wisely (local max/min, reflection points, x- and y-intercepts) and use their knowledge of the points and their derivative values. Because students can choose which sets of values to use to make their best prediction or educated guess, the reasoning work here is abductive. The expectations placed on students’ deductive and abductive reasoning in these calculating situations can be high, as the ultimate solutions remain unknown to them (Herbst et al., 2010)

I also observed two patterns across instructional tasks. First, calculating CTUs were employed as standalone situations, especially using the limit definition of the derivative at a point (C7) and as a function (C11). This suggests that by using only one CTU in their instructional tasks, instructors aimed to make these two calculating CTUs the primary focus of the instructional tasks rather than a means to achieve other CTUs or learning objectives. Second, I observed that when calculating situations were not the central focus of the instructional task, they functioned as ‘glue’ (or link) between CTUs to connect them in the instructional task. This highlights the integral role calculating situations play in linking other generic types of situations.

Conclusion

Here, I described four calculating instructional situations, how they were typically summoned and incorporated into tasks via CTUs, and the kinds of mathematical work they would engage students with. Although these calculating situations targeted introducing derivatives, they offer insights into the types of calculating situations that are used for teaching college calculus and the kinds of mathematical reasoning students are often expected to engage with, which are vital for improving its teaching via curating tasks that meet the needs of its diverse learners.

"MY" MEANING FOR UNDERSTANDING THIS PROOF: COMPARING STUDENT PERSPECTIVES TO A MATHEMATICIAN-CENTERED MODEL OF COMPREHENSION

Lino Guajardo
Texas State University
lrg74@txstate.edu

Kristen Lew
Texas State University
kristen.lew@txstate.edu

The literature around proof comprehension focuses on the instructor perspective, we delineate from this by considering the student perspective. In this paper, we characterized how 5 undergraduate students consider what it means to understand a particular proof. With these characterizations, we compared the student participants to mathematicians (from the literature) and found close alignment with most ways a mathematician may identify what it means to understand a proof. Additionally, we found two distinct ways a particular participant identified what it means to understand a proof that may not be considered by mathematicians.

Keywords: Reasoning and Proof, Undergraduate Education, Proof Comprehension

In the realm of undergraduate proof comprehension research, scholars have initially focused on assessing or improving students' comprehension of proof through the development of comprehension tests (e.g., Mejia-Ramos et al., 2017), interventions (e.g., Hodds et al., 2014), or alternative written proof representations (e.g., Roy et al., 2017). Few have focused their studies on students (e.g., Dawkins & Zazkis, 2021; Weber, 2015). Considering the student perspective is important for researchers and instructors in developing productive interventions and activities. One way to consider the student perspective is to consider how it may align with the perspective of experts. In this paper, we set out to answer the following research question: In what ways do students' perceptions of what it means to understand a proof align (or misalign) with the literature's findings on mathematicians' perceptions of what it means to understand a proof?

Relevant Literature

Scholars have compared students with mathematicians and their beliefs about proofs in various ways – through comparing reading of mathematical text (Shepherd & van de Sande, 2014), eye tracking on proof reading tasks (Panse et al., 2018), or beliefs about the purpose of reading proofs (Weber & Mejia-Ramos, 2014). While others have investigated student perceptions on proof reading tasks (e.g., Krupnick et al., 2018; Lew & Mejia-Ramos, 2019; Weber, 2010), few have investigated student perceptions in proof comprehension (Weber, 2015).

Studies show students' reading habits do not differ from mathematicians when considering a particular validation or comprehension task (Panse et al., 2018), yet their actions may differ greatly as they are reading (Shepherd & van de Sande, 2014). In considering the student perspective, Weber (2015) found the students used various strategies such as, using examples to understand confusing claims and justifications, attempting to prove the theorem before reading the proof, and ensuring they understood all the terminology used within the theorem statement.

Theoretical Framing

Mejia-Ramos et al. (2012) developed a model that can be used to develop assessments of student proof comprehension. This model has seven types of questions one could ask students, three of which can be categorized as local questions of proof (L1: meaning of terms and statements, L2: logical status of statements and proof framework, L3: justification of claims) and the remaining four can be categorized as holistic questions of proof (H1: summarizing via high level ideas, H2: identifying the modular structure, H3: transferring the general ideas or methods to another context, H4: illustrating with examples). We consider these seven question types as a synthesis of the literature's findings on what it means to mathematicians to understand a proof. We do note that not all of these may be applicable to any given proof.

When researching the beliefs students can have on proof, it is important to acknowledge the possible ways in which students' argumentations are affected by the institutional meaning in which students are exposed (Recio and Godino, 2001). We argue students' beliefs about proof can be impacted by their schooling. In the context of understanding a proof, we believe students define what it means to understand a proof through their experiences in proof-based classes.

Methodology

The data presented is part of a larger dissertation study investigating the strategies mathematics majors employ as they read proofs with the task of understanding the given proof. Five students were recruited during the Fall 2023 semester after having passed an introduction to proof course (ITP) the prior Spring or Summer semester. Table 1 presents the demographic information of the students using their chosen pseudonyms.

Table 1: Participant information

Name	Race/Ethnicity	Gender	Grade Received in ITP
Adrian	White	Non-binary	B
Claire	White	Female	B
Marie	Latin/Hispanic	Female	A
Tifanni	Latin/Hispanic	Female	A
Zeus	Latin/Hispanic	Male	B

Each student met individually with the first author for a series of interviews. For this paper, we focus on the data from one task-based interview in which students were given a theorem statement and its proof and told to think-aloud as they tried to understand the proof to the best of their ability. The proof presented to students was taken from Chartrand et al. (2013) and showed f is bijective if and only if f^{-1} is a function. Once the students felt they understood the proof to the best of their ability, they were asked a series of questions. The focus of this analysis will be on the students' responses to the question, *What does it mean to you to understand this proof?*

Analysis

Student responses were transcribed and characterized into the different ways they discussed a meaning of understanding the proof (MUP) provided. MUPs were coded using Mejia-Ramos et al.'s (2012) assessment framework. When student responses did not align with any of the question types from the assessment framework, we coded a new instance of a MUP (N1 or N2).

Results

Table 2 shows the types of understanding discussed by the participants which did and did not align with the proof comprehension assessment model (Mejia-Ramos et al., 2012).

Each student had identified L1 (meaning of terms and statements) as a MUP. The participants noted this through indicating they had to know the concepts used in the proof. When asked what it means to understand a proof, Marie stated "one is to understand the concepts." All but Zeus had identified L2 (logical status of statements and proof framework) as a MUP. Students typically focused on how specific statements of the proof were proving or working towards proving the theorem statement. For example, Claire states "they're using f and then they talk about things in the inverse and that's how it and that kind of helps wrap it all together that f is one-to-one." Here, Claire is discussing how statements within the proof work together to show the function is one-to-one, a subgoal of the proof identified by Claire earlier in the interview.

Table 2: MUPs Identified by Participants in Relation to Mejia-Ramos et al., 2012

	Local			Holistic				New	
Student	L1	L2	L3	H1	H2	H3	H4	N1	N2
Adrian	X	X		X	X				
Claire	X	X	X	X	X		X		
Marie	X	X	X	X					
Tifanni	X	X	X		X			X	X
Zeus	X								

For three question types of the assessment model – L3 (justifications of claims), H1 (summarizing via high-level ideas), and H2 (identifying the modular structure) – three participants discussed these as being a MUP. In identifying that L3 is needed to understand this proof, participants typically focused their explanations as understanding each line or each step. For example, Claire explains "Well, I mean you do need to understand every line." H1 was identified by students either through the indication of needing to know the key ideas of the proof or in being able to explain the proof to someone else in simpler terms. Marie states that you would have to be able to "explain that from point A to B." Finally, for H2, participants usually noted the need to know the different parts or sections of the proof. Adrian explained "understand how this stuff, like lines 1 through 4 mean that f is one-to-one, that's one step."

Meanwhile, it was not always the case that the participants discussed a MUP that aligned with mathematicians. No participants had identified H3 (transferring the general ideas or methods to another context). Only one participant, Claire, identified H4 (illustrating with examples) as a MUP. Claire stated that understanding the proof would mean "if someone's like, well what about this function and then you could say 'OK well this is how you would show it's one-to-one or onto' […] you can apply it to a different situation and understand how it works."

One participant (Tifanni) also identified two MUPs that do not correspond directly to question types in the assessment model (N1 and N2). We classified N1 as theorem comprehension. In response to being asked what it means to understand the proof, Tifanni initially stated, "understanding what the theorem is saying first." We believe this statement counts as evidence towards L1, as the theorem statement uses key concepts such as inverse and bijection; however, we believe Tifanni is also considering the theorem statement itself as an object worthy of comprehension. We note that Mejia-Ramos et al. (2012) focused their assessment on the proofs and not necessarily on the theorem statements. As such, L1 focuses on key concepts and statements *within* the proof. Because of this distinction, we believe Tifanni's comment reveals a new MUP. We classify this dimension to be theorem comprehension, understanding what the theorem is saying – whether through the meanings of the key terms in the statement or in understanding what the theorem is saying more holistically.

Tifanni also identified N2, which we classified as disciplinary writing norms. We show two instances of Tifanni discussing disciplinary writing norms in different ways. First, in multiple arguments in the proof, the author uses subscripts to distinguish multiple elements (a_1 and a_2 in the domain or codomain) paired to one element (in the codomain or domain). Yet, for one argument, the author decides to use a prime (a and a') instead of subscripts. To an expert, this may just be chalked up as a notational choice that does not change the substance of the proof, for Tifanni, she questioned why the author made that decision (as if it could affect the substance of the proof). Tifanni showed concern with being able to explain to a class on why the author chose this notation. She worries that this impacts how well she understands the proof, as she would feel unable to explain why. For Tifanni, she believes the notation used for variables in the proof is important and the reasoning for this notation impacts how well someone understands the proof. The second instance where Tifanni discusses disciplinary writing norms is related to the structure and order of arguments. Tifanni notes that someone who understands the proof would know why the proof was structured, in terms of order. "Like for example they could have put this part first, but it well maybe it wouldn't make sense to say this thing first before proving that it was bijective which is one-to-one and onto. Like understanding why." In this quote, Tifanni is discussing the importance of the order in which the arguments are made within the proof. We interpreted both instances to be in reference to disciplinary writing norms, an aspect not discussed by Mejia-Ramos et al. (2012).

Discussion

The study presented extends Weber's (2015) findings by comparing student perspectives to mathematician perspectives. The findings report that student and mathematician meanings for understanding a given proof do seem to align in multiple ways. All students identified L1 and all but one student identified L2. At least three students identified L3, H1, and H2. Only one student identified H4 and no students identified H3. Additionally, Tifanni identified two MUPs that were not in the proof comprehension assessment model. The theorem comprehension MUP may be absent from the assessment model due to the model's focus on the proof and not necessarily on the theorem statement itself, but we suspect mathematicians would agree with the need to understand the theorem statement. Tifanni's second new MUP (disciplinary writing norms) could be due to the differing experience mathematicians have with proof writing in contrast to undergraduate students. Tifanni's ITP course was her first exposure to proof – suggesting Tifanni was still learning the proof writing norms at the time of the study. Questioning the notation indicated her need to increase her understanding of mathematical proof writing norms.

We note the sample size is a limitation of the study and that this report focuses only on the MUPs identified by students with regards to a single proof. Indeed, the participants identified H3 and H4 for other proofs in the larger dissertation study, which is outside the scope of this paper.

These misalignments amongst the student participants and mathematicians do indicate two things. First, students may benefit from being given more tasks that focus them on H3 and H4. Second, students are attending to normative styles of writing that mathematicians have become accustomed to. Scholars have identified norms and values the research mathematics community holds in proof and in writing proof (Lew & Mejía Ramos, 2020; Dawkins & Weber, 2017). Instructors hope to have students adopt these norms and values while taking proof-based courses.

Further research is needed in both mathematician perspectives and student perspectives. The larger dissertation study aims to expand on the knowledge of student perspectives in what it means to them to understand proof and the ways they attempt to understand given proofs.

Este estudio investigó el impacto que las actividades de laboratorio del proyecto Cálculo Para Todos tuvo en la comprensión de conceptos de cálculo en estudiantes de segundo año de bachillerato en México. Empleamos una metodología cualitativa para examinar las coordinaciones entre la modelización corporizada de los estudiantes y sus representaciones gráficas. Los datos incluyen un pre y un post test, con ítems de opción múltiple y preguntas abiertas. Los resultados revelaron un cambio positivo en el rendimiento de los estudiantes después de la intervención. Se identificaron múltiples transiciones de aprendizaje influenciadas por la fluidez representacional entre lo concreto y las representaciones gráficas. Este estudio contribuye al entendimiento de cómo los laboratorios pueden promover la comprensión profunda de conceptos de cálculo.

Palabras clave: Modelado, Tecnología, Cálculo, Representaciones Matemáticas, Pensamiento Estudiantil

En muchos países, incluido México, el cálculo se establece como una herramienta clave de la educación matemática en las etapas superiores de la escuela secundaria (grados 11 y 12) y en cursos a nivel universitario (Greefrath et al., 2021). Por un lado, el cálculo sirve como piedra angular para acceder a carreras STEM (ciencia, tecnología, ingeniería y matemáticas) y por otro, como una barrera que propicia el abandono de una trayectoria académica en estas áreas (Burdman et al., 2021) y muchas veces obstaculiza el avance de estudiantes con orientaciones hacia otras áreas como ciencias sociales o humanidades. En respuesta a este escenario, se han generado iniciativas que proponen cambios en la instrucción del cálculo; por ejemplo, la iniciativa *Macalester* (Burdman et al., 2021) utiliza una aproximación al cálculo desde la modelación—este curso reduce el foco en las técnicas de integración y derivación, y en su lugar enfatiza la programación con el software R. Además de destacar la modelación de sistemas dinámicos utilizando ecuaciones diferenciales.

El proyecto *Cálculo Para Todos* (CPT), en el que se basa la presente investigación, se propone como una alternativa factible en la que se entrelaza el trabajo colaborativo con las tecnologías digitales y con los contextos socioculturales de los estudiantes. CPT fue desarrollado a nivel bachillerato por una docente (segunda autora) en el Centro de Bachillerato Tecnológico Industrial y de Servicios (CBTIS) #164 en Ciudad Madero, Tamaulipas, México. El proyecto CPT se encuentra alineado con el nuevo plan nacional de estudios, de la Nueva Escuela Mexicana (NEM). El plan de estudios de la NEM se basa en el compromiso de aprovechar los recursos sociocognitivos de los estudiantes, prestar atención a sus formas de pensamiento emergentes y organizar secuencias de actividades de manera informada por la literatura internacional sobre *progresiones de aprendizaje* (Subsecretaría de Educación Media Superior [SEMS], s.f.).

El objetivo de esta investigación es indagar el impacto que las *actividades de laboratorio* de CPT tuvieron en los estudiantes, en lo referente a la apropiación de conceptos de cálculo al usarlos para modelar fenómenos de cambio desde sus experiencias compartidas. En particular nos preguntamos: *¿cómo los estudiantes coordinan la modelización corporizada y socialmente distribuida de fenómenos de cambio con la representación gráfica de funciones y sus derivadas?*

Antecedentes

Investigadores concuerdan (Lehrer y Lesh, 2003; Moore et al., 2018), que la fluidez representacional puede promover una comprensión más profunda de los conceptos matemáticos al conectar ideas abstractas con situaciones concretas y visualizar relaciones entre variables. Moore y colegas (2013), mencionan que un aspecto importante de la fluidez representacional es la habilidad de trasladar entre y dentro de modos de representación (y cf. Duval, 2017). Estos modos de representación incluyen el uso de modelos concretos refiriéndose a manipulativos físicos o virtuales. Estas investigaciones enfatizan que el uso de modelos concretos y representaciones ayudan a los estudiantes a dar significado a ideas matemáticas y sus aplicaciones. Brady et al. (2022) sugieren que los modelos concretos son parte de un proceso de modelización corporizada, en la que el cuerpo se sintoniza con el objeto físico o virtual (p. ej., un sensor ultrasónico) para generar diferentes tipos de representaciones. Por otro lado, la visión de Kaput y Roschelle (2002), se centra en una visión histórica sobre la evolución cultural de las representaciones, el potencial de los medios tecnológicos y los desafíos de satisfacer las necesidades sociales. Estos autores enfatizan el poder de las representaciones gráficas, dinámicas y ejecutables en el proceso de modelización, como objetos inclusivos y democratizantes, que permiten comprender el cambio y la variación de contextos dinámicos. Además, abogan por el uso de simulaciones computacionales para comprender conceptos del cálculo en contextos concretos. En resumen, desde la fluidez representacional hasta la modelización, el uso de laboratorios para el estudio del cálculo ofrece un entorno dinámico donde estudiantes encuentran oportunidades de construir conceptos abstractos con aplicaciones concretas, explorar representaciones gráficas, y experimentar con simulaciones computacionales.

Metodología

El laboratorio de cálculo consta de un estuche de prácticas basado en tecnología Arduino que, conectado a una computadora, brinda la posibilidad de realizar diferentes experimentos. A su vez, este estuche se divide en tres módulos, el primero orientado al estudio del movimiento unidimensional y la caída libre utilizando un sensor ultrasónico que permite estudiar funciones polinomiales y sus derivadas; las variables a operar son distancia, tiempo y velocidad. El segundo módulo permite analizar el voltaje generado por un mini panel solar con el que se puede analizar el comportamiento de una función senoidal y su derivada; en este caso las variables a operar son voltaje y tiempo. El tercer módulo permite analizar el voltaje producido por un mini aerogenerador (rehilete), cuyos datos tienen un comportamiento exponencial. El prototipo incluye todas las prácticas de laboratorio listas para ser utilizadas en clase con un enfoque transversal (más información en http://calculoparatodos.com/).

Estructura del test

Antes de iniciar con el curso se aplicó un pretest que constó de ocho preguntas de opción múltiple y dos preguntas abiertas en las que se debían elaborar la gráfica de posición y velocidad para un problema en contexto. Al finalizar el curso se aplicó un post test que incluía las mismas preguntas que el pretest. Las dos preguntas abiertas del test se enfocaron en el siguiente problema en contexto:

> "9. Lee cuidadosamente el siguiente enunciado y construye la gráfica de posición vs. tiempo correspondiente: Un robot inicia la toma de datos tocando el sensor (a una distancia 0). Empieza a moverse rápidamente alejándose del sensor, durante un intervalo de 1 segundo. Durante el siguiente intervalo de 2 segundos, disminuye su velocidad hasta que deja de moverse. Mantiene la pausa durante el siguiente segundo. Entonces, se empieza a mover hacia el sensor, durante el siguiente intervalo de 2 segundos, pero, no llega al sensor."

La pregunta 10 solicitó que se construyera la gráfica velocidad vs. tiempo para el mismo enunciado.

El curso en el que se aplicaron las prácticas de laboratorio y los test se llevó a cabo a lo largo del ciclo escolar 2022-2023 en el CBTIS #164 al norte de México con estudiantes de segundo año. En total se trabajó con 194 estudiantes, pero al final solo consideramos una muestra de 163 estudiantes ya que fueron los que resolvieron los dos test (pre y post).

Resultados

El análisis de las preguntas abiertas en los test se realizó mediante una codificación abierta por el método de comparación constante en el pre y post test (Charmaz, 2014; Strauss y Corbin, 1990). En esta etapa codificamos cada ítem en términos de cómo se relacionaba la representación gráfica y la representación verbal/lingüística. Es importante mencionar que nos encontramos en el proceso de analizar que su utilidad va más allá de simplemente identificar los *estados* individuales de los alumnos, ya que nos ha permitido reconocer la importancia de las *transiciones* observadas entre el pretest y el post test. Confiamos en que estas transiciones revelarán el progreso de las formas de pensar y de apropiación del lenguaje del cálculo de los estudiantes cuando describen fenómenos del mundo.

Posterior a la codificación abierta pudimos identificar treinta y cinco estudiantes que respondieron a las preguntas abiertas tanto en el pre como en el post test. Utilizando estos datos pudimos codificar transiciones entre el pre y post test de acuerdo con las modificaciones en la representación gráfica. Elaboramos un libro de catorce códigos que nos permitió catalogar estas transiciones. Éstas nos están ayudando a distinguir transiciones estables en el aprendizaje vivenciadas por los estudiantes antes y después del curso. Para este escrito, elegimos ejemplificar una de las transiciones que ilustran uno de los tipos de pensamiento que encontramos en nuestro análisis.

Transición de “disminuye su velocidad” como ir hacia abajo a la representación correcta. En la Figura 1, se muestran las gráficas de posición del pre y post test que el mismo estudiante elaboró siguiendo el texto del problema 9 (ver sección Estructura del test para el enunciado). En la gráfica del pretest el estudiante puso etiquetas que delimitan las frases en la representación lingüística (AB, BC, CD). Esto indica una estrategia de descomposición del problema que lo ayuda a su comprensión. Si seguimos las etiquetas en la gráfica el segmento de recta que va del origen a A es la interpretación del enunciado “Empieza a moverse rápidamente alejándose del sensor, durante un intervalo de un segundo.” El intervalo de tiempo también concuerda con el segmento dibujado. En esta lógica, el segmento AB corresponde al enunciado “Durante el siguiente intervalo de dos segundos, disminuye su velocidad hasta que deja de moverse.” En este momento la dificultad de representar “disminuye su velocidad” se hace evidente. El resto de los segmentos coinciden correctamente con la representación lingüística.

La gráfica elaborada en el post test muestra puntos sobre la gráfica que corresponden a la descomposición del enunciado, esta vez sin etiquetas. Si seguimos la gráfica en el segundo intervalo [1, 3], se ve una curva que indica que hay una disminución de la velocidad paulatina. Entonces tenemos evidencias de que este estudiante ha avanzado en dos sentidos. Primero, su representación del cambio de velocidad desde alto (positivo) a más bajo (todavía positivo) ahora concuerda bien con la gráfica esperada. Además, el uso de una curva suave refleja un entendimiento profundo del movimiento de los cuerpos reales en el mundo físico. Conjeturamos que las experiencias de capturar movimientos corporales con el sensor ultrasónico han favorecido la sensibilidad a estos matices. Dentro de la muestra de 163, 48 (aproximadamente el 35% del total) representaron “disminuye su velocidad” como en el ejemplo mostrado. Consideramos que estos estudiantes se encuentran en una etapa de transición como la que vivió el estudiante en el ejemplo.

Pre test | Post test

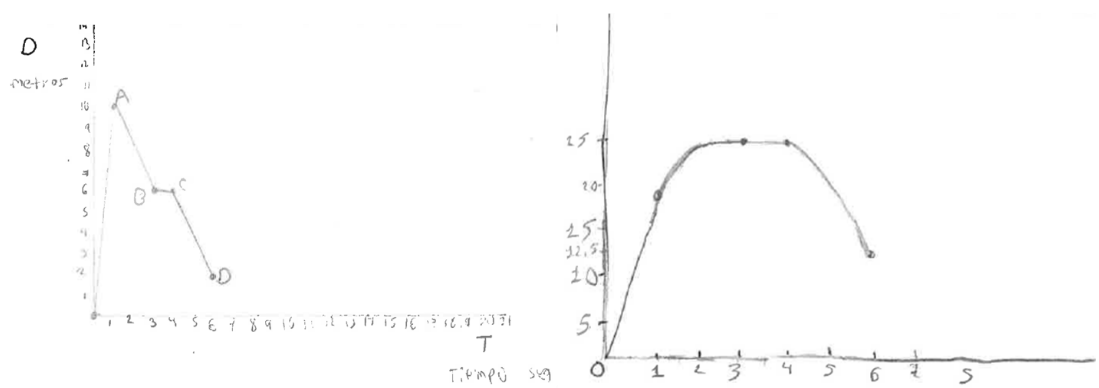

Figura 1. Pretest y post test mostrando Transición de *ir más lento como ir hacia abajo* a la representación correcta de la posición.

Discusión y conclusiones

Nuestro análisis cualitativo reveló la presencia de patrones de formas de pensamiento recurrentes en el grupo de estudiantes y que, en un estudiante fueron influenciadas por las actividades del laboratorio (p. ej., la actividad sobre el movimiento de un cuerpo). Este hallazgo sugiere la existencia de múltiples *transiciones de aprendizaje* que pueden aparecer en este terreno conceptual. Los resultados mostrados vislumbran que estas transiciones están orientadas por la fluidez representacional (Moore et al., 2013) que se da en la coordinación entre la modelización corporizada y la representación gráfica de funciones y sus derivadas (Kaput y Roschelle, 2002). Para fortalecer estos hallazgos, estamos en proceso de análisis de datos adicionales, incluyendo la revisión de grabaciones de video tomadas durante la aplicación de los laboratorios por la profesora, y los trabajos de un subconjunto de los mismos estudiantes, durante una siguiente clase de cálculo integral. Finalmente, consideramos que el proyecto *Cálculo Para Todos* es una propuesta innovadora que revierte la práctica tradicional de pasar de la enseñanza de los conceptos a su aplicación a una práctica en la que, partiendo de las acciones concretas, se significan y resignifican los conceptos matemáticos.

WHAT IS PROOF? COMPARING PRE-SERVICE SECONDARY MATHEMATICS TEACHERS' AND UNDERGRADUATE MATHEMATICS STUDENTS' PERCEPTIONS

Key Words: Reasoning and Proof, Preservice Teacher Education, Undergraduate Education

Due to the shortages of secondary mathematics teachers across the United States, many of them receive little or no preparation for teaching mathematics (Sutcher et al., 2016). More specifically, they are encouraged to seek an alternative pathway to be a certified secondary mathematics teacher to meet their school district's hiring needs (Sutcher et al., 2016). With such hiring needs, undergraduate students with a minor in middle school mathematics are more likely to teach middle school students after graduation. Similarly, undergraduate mathematics students (UMs) will have opportunities to teach middle or high school mathematics after receiving their degree. Taken together, it is important to examine and compare pre-service secondary mathematics teachers' and undergraduate mathematics students' proof perceptions.

Three groups of PSMTs[1] and UMs[2] minor, from a Midwestern university in the United States volunteered to participate in this study. The first group consisted of 15 undergraduate students from the "College Geometry" course in Spring 2020. The second and the third group of participants were from the transition-to-proof course titled "Discrete Mathematics" in Fall 2020 and Fall 2021, respectively. We used each participant's description of what a mathematical proof is from the beginning of the semester to identify roles and characteristics of proof they perceived. More specifically, the undergraduate students were all asked to complete a written class activity titled "Getting to Know You" on the first day of a class that included a question of what a mathematical proof is. Thus, each participants' written work was the primary source of data for categorizing PSMTs' and UMs' descriptions of a mathematical proof.

Regardless the participants' mathematics backgrounds, the two most common roles of proof cited by them were verification and explanation. More mathematics teaching majors and mathematics majors mentioned the roles of systemization and communication than other participants did. Also, the majority of participants focused on the two characteristics of proof—set of accepted statements and modes of argumentation. If PSMTs could be provided with rich opportunities to engage in a variety of proof-related tasks at the undergraduate level, then they are more likely to view proof as a meaningful tool to teach and learn mathematics (Knuth, 2002).

---

[1] PSMTs in this paper refer to a middle school teaching minor, a middle school teaching major, and a mathematics teaching major.
[2] UMs in this paper refer to an undergraduate student with a major or minor in mathematics.

Thus, it would be interesting to study how PSMTs' and UMs' roles of proof affect the ways in which they construct and evaluate proofs.

QUALITY OF WRITTEN JUSTIFICATIONS AND EXPLANATIONS AS AN INDICATOR OF CONCEPTUAL UNDERSTANDING IN AP CALCULUS

Cynthia Kyler
Kent State University
ckyler1@kent.edu

This study explored a correlation between the quality of students' written justifications and explanations on AP Calculus assessments and their achievement on related computational problems. The aim is to provide research that supports AP Calculus teacher's use of written justification and explanation as a teaching and learning tool. The study employs a convergent mixed-methods correlational design. Comparisons are made between the ratings students are given on their written justifications and explanations on the written portions of classroom assessments and their raw scores on computational problems. The two sets of data do not overlap. Written samples were examined using discourse analysis – a well-established qualitative method for analyzing student writing in mathematics (Austin & Howsen, 1979; O'Halloran, 2005; Pimm, 2004). Qualitative data was transformed into ordinal data using a rubric based on Toulmin's model for argumentation (Brockriede, 1960) which diagrams the basic components of an argument. The ordinal data was compared to quantitative data (on a ratio scale) using regression analysis to explore the possibility of a positive correlation. The study used a worldview of pragmatism, which, according to Creswell and Plano Clark (2018), focuses on the "importance of the question asked rather than the methods, and on the use of multiple methods of data collection to inform the problems under study" (p. 37).

Two research questions were explored: 1) How is mathematics conveyed by students in high school Calculus when justifying or explaining their responses? and 2) What is the relationship between the quality of AP Calculus students' written justifications and explanations and their conceptual understanding as demonstrated on computational parts of classroom assessments?

Participants include 28 AP Calculus AB students from the same suburban high school in Ohio. AP Calculus AB is a high school course that covers the content of a first-semester college calculus course. At the course's end, students take an exam for which colleges could award them credit. The assessment instrument for this study was a unit test given during the third quarter of the AP Calculus course.

Initial results of Spearman's rank correlation (2024) indicated a moderate positive association between justification scores and computational scores ($R_s[28] = 0.576, p = 0.005$). After looking at a scatter plot of the data, two data pairs that diverged from the line of best fit were removed. One of these pairs had a written justification score of 1 and a computational score of 3, indicating that this student was much more proficient at computing the answer than explaining its meaning. The other pair had a written justification score of 3 and a computational score of 1, indicating that this student could explain the answer without being able to perform a correct computation. These were the only two students of the original 28 who had these scores. When the Spearman correlation was performed with the remaining 26 data pairs, the results indicated a strong positive correlation ($R_s\ [26] = 0.707, p = 0.001$).

In a small number of cases, the data diverged from the general trend; because of this, I recommend a follow-up study in which interviews are performed with a subset of students from

the original population representing varying score ranges using an explanatory sequential mixed-methods design.

EXPLORING THE USE OF HISTORICAL CONTEXTS IN TEACHING LOGARITHM

Winston Martey
SUNY - University at Buffalo
wnmartey@buffalo.edu

Ji-Won Son
The State University of New York at Buffalo
jiwonson@buffalo.edu

This study investigated the effectiveness of integrating history-infused lessons on students' understanding and attitudes towards logarithms. The theoretical framework drew from sociocultural perspectives and embodied cognition, emphasizing the social and emotional dimensions of learning. Design-based research principles guided the iterative development of history-infused logarithm lessons. Data was collected through pre- and post-assessment tests, interviews, and classroom observations. The findings indicated a significant improvement in students' post-test scores, suggesting a reduction in their fear of logarithms. Additionally, interviews revealed a positive shift in students' perceptions of logarithms, from abstract and intimidating to practical and relatable.

Keywords: History-infused mathematics, logarithms, secondary mathematics education, student attitudes

The research literature emphasizes the importance of logarithms in both advanced mathematics and real-world contexts, including sound measurements (decibels), earthquake magnitudes (Richter scale), star brightness, and chemical properties (pH balance). However, many students struggle to grasp the conceptual underpinnings of logarithms and often resort to rote memorization of rules, as noted by various authors (Berezovski, T., 2008; Kuper & Carlson, 2020; Weber, 2016). The challenges faced by students include interpreting logarithms as the "inverse of exponents" and developing a coherent understanding of logarithmic notation, logarithm properties, and the application of logarithmic functions (Kuper & Carlson, 2020; Berezovski, T., 2008; Chua & Wood, 2005; Gol Tabaghi, 2007; Strom, 2006).

To address these issues, researchers and educators have suggested a variety of strategies. These include using concrete materials (Thompson, 1994), implementing authentic assessments such as project-based learning and computational thinking (Shin et al., 2021), engaging students with game-based learning (Barab et al., 2010), problem-based learning (Hmelo-Silver, 2004), and effective teaching methods (Larmer, 2018). The use of gestures alongside diagrams (Walsh & Hord, 2019), gestures combined with manipulatives (Beilstein, 2019), and incorporating the history of mathematics (Liu, 2003; Poh & Dindyal, 2016; Sampaio & Batista, 2018) have also been recommended. This study aims to bridge the gap in research regarding the teaching of logarithms by utilizing the history of mathematics in combination with gestures. The research questions guiding this study are as follows: (1) How do history-infused logarithm lessons aid in reducing students' fear of logarithms? (2) How do students' perceptions of logarithms change over the duration of the history-infused logarithm program?

Theoretical Framework

This study was grounded in sociocultural perspectives for student learning, a history-infused program, and embodied cognition for evaluating understanding. It focused on social constructivism, which emphasized the role of social interaction in cognitive development and suggested that learning occurred best in a social context. The study also incorporated the dynamic nature of assessment, including formative, diagnostic, prognostic, or summative assessment. Vygotsky's sociocultural perspective underscored the extensive impact of social learning, suggesting that learners did not engage with new knowledge in isolation. Key instructional aspects in Vygotsky's perspective were mediation, scaffolding, and creating a zone of proximal development (ZPD). Building on this, the instructional technique in the history-infused math lessons involved exploratory activities and mediational strategies, including scaffolding based on prior knowledge. This study also emphasized embodied cognition, focusing on how humans used their bodies to express thought processes, like gestures. Students' multimodal approaches, such as gestures, were coded and compiled based on McNeill's typological categories (1992), allowing for a holistic approach to teaching and learning logarithms

Methods

Participants, Settings, and Programs

The study took a holistic approach, incorporating both quantitative and qualitative data collection methods to assess the effectiveness of integrating historical insights into logarithm teaching. This approach was underpinned by design-based research (DBR) principles, enabling iterative refinement of teaching strategies based on observed student interactions and outcomes. The study took place at a private high school in Western New York, United States, with a student-teacher ratio of 12:1. The focus was on 14 students (10 girls and four boys) in Grades 11 and 12, all of whom had prior exposure to logarithms in their mathematics courses.

The curriculum, based on the Precalculus with Limits: A Graphing Approach by Ron Larson (High School Edition, 6th Edition), was adapted to incorporate historical insights into the discovery of logarithms. The goal of the first phase was to develop an initial design of the program, which consisted of three history-infused math lessons. These lessons were developed by integrating the history of logarithms, allowing students to explore historical perspectives on the discovery of logarithms by John Napier, and other mathematicians (e.g., Pythagoras), tailoring students' participation in peer collaboration through the lens of history of mathematics, and improving learner engagement in the instructional process in the form of mini projects on history-infused mathematics. Students were asked to use log tables and watch a video of the process. Students also explored the history of mathematics related to logarithms and did a presentation. In the second phase, the program underwent iterative design to test and refine it. This second iteration, to be conducted in the spring of 2023, involved designing three history-infused modules, each consisting of three lessons with scenario-based problems (e.g., Scenario-based Log) and historical approaches (e.g., Using Log Tables). The historical accounts of the discovery of logarithms will be introduced from existing sources, highlighting how logarithm computations were performed before calculators.

Data Collection and Analysis

Data collection involved pre- and post-assessment tests, interviews, observations, and analysis of classroom artifacts. Pretests assessed students' baseline knowledge, while post-tests measured their understanding after the history-infused lessons. Interviews and observations offered qualitative insights into student engagement, attitudes, and understanding. The study was conducted over two weeks, covering initial assessment, implementation of the history-infused program, and subsequent assessment and interviews. Data analysis was conducted using a mixed-method approach, combining quantitative and qualitative methods. For quantitative analysis, descriptive statistics were computed to compare pretest and posttest scores, and the Wilcoxon Signed-Rank Test was used for inferential analysis to assess the effectiveness of the history-infused lessons. Error analysis of participants' written responses was also conducted. For qualitative analysis, interviews were transcribed using the ELAN annotation tool, and thematic analysis was conducted. Open-coding was done using ATLAS.ti software to categorize data from surveys and interviews. Additionally, gestural analysis was conducted, categorizing gestures based on McNeill's framework, and disagreements between coders were resolved through consensus. The general inductive approach was employed to analyze qualitative data, systematically organizing and summarizing textual data.

Summary of Findings

Analysis of pre- and post-test showed that students' average scores in the posttest (M = 76.2, SD = 17.4) were significantly higher than their average scores in the pretest (M = 50.2, SD = 21.1).

How History-Infused Logarithm Lessons Alleviate Students' Fear of Logarithms:

The analysis of pre- and post-test scores shows that the history-infused logarithm program led to a statistically significant improvement in students' understanding of logarithms. This finding is particularly noteworthy considering the pre-existing fear and apprehension that many students typically harbor towards this complex mathematical concept. Interviews with students provided deeper insights into the impact of history-infused lessons on students' emotional engagement and attitudes towards logarithms. A majority of students expressed that the historical context provided in the lessons made logarithms seem more accessible, relatable, and less intimidating. Many students indicated that understanding the origins and evolution of logarithms gave them a sense of connection to the subject, and a better appreciation for its practical significance. Student L7 articulated this sentiment, saying, "It helped me understand it better because I can be more appreciative of the mathematicians back in the day and it gets me more interested in math, so I will be motivated to learn more about the concepts knowing the philosophers that contributed to it." Incorporating historical narratives and activities into the logarithm curriculum served as a cognitive scaffold for students, allowing them to contextualize complex mathematical concepts within a narrative framework. Students appreciated the opportunity to engage with mathematical ideas in a more holistic and multidimensional manner. Furthermore, the interactive and collaborative nature of the history-infused lessons encouraged students to approach learning logarithms with a sense of curiosity and adventure, rather than fear and reluctance.

Shifts in Students' Perceptions of Logarithms Through History-Infused Logarithm Program:

Through the history-infused logarithm program, students' perceptions of logarithms underwent a noticeable shift. Before the intervention, students primarily viewed logarithms as abstract and disconnected from real-world contexts. They often perceived logarithms as challenging, even forbidding, due to the complex nature of mathematical manipulations involved. The pretest data showed that students had a limited understanding of logarithmic properties and frequently made errors in their application. Common mistakes included misinterpreted language errors and logically invalid inference errors, suggesting that students' conceptual grasp of logarithms was limited. However, post-test data revealed a marked improvement in students' perception of logarithms. Students began to view logarithms as a valuable tool with practical applications, particularly in the context of historical problem-solving. They expressed newfound confidence in their ability to tackle logarithmic calculations and demonstrated a clearer understanding of logarithmic properties and their applications. This shift in perception can be attributed to the rich historical narratives that were integrated into the program, which allowed students to see logarithms as a dynamic and evolving mathematical concept with a rich cultural and historical significance. Students began to appreciate the versatility of logarithms and how they are rooted in the history of human endeavor.

Discussion

The findings of this study echo the conclusions of previous research and contribute to our understanding of the potential benefits of incorporating history into mathematics education. Previous studies have demonstrated that history-infused mathematics lessons can lead to improvements in students' conceptual understanding and engagement (Alibali & Nathan, 2012; Berezovski, 2008; Howell et al., 2017). The findings of the current study extend this research by focusing on students' emotional responses to history-infused lessons and their impact on attitudes towards mathematics. The theoretical implications of this study align with cognitive theories such as Vygotsky's sociocultural theory of learning and Hmelo-Silver's Problem-based Learning (PBL) theory (Kozulin et al., 2003; Hmelo-Silver, 2004). Vygotsky's theory emphasizes the role of social interaction and cultural context in shaping learning, suggesting that the historical narratives embedded in history-infused lessons can provide students with meaningful cultural tools that facilitate learning. Hmelo-Silver's PBL theory focuses on the importance of problem-solving and authentic, real-world tasks in promoting deep understanding. The historical context provided in history-infused lessons can serve as a rich source of problems and tasks that are relevant and engaging for students. From a practical perspective, the findings of this study suggest that incorporating historical contexts into mathematics instruction can have a positive impact on students' attitudes and engagement. By presenting mathematical concepts in a historical context, educators can make abstract concepts more concrete and meaningful for students, leading to increased motivation and interest. Additionally, the emotional engagement fostered by history-infused lessons can help to alleviate students' fear and anxiety about mathematics, creating a more positive and supportive learning environment.

The limitations of this study should be acknowledged. The study was conducted at a single high school, limiting the generalizability of the findings. Additionally, the study focused on a specific topic within mathematics (logarithms), and the findings may not apply to other mathematical concepts. Future research could explore the impact of history-infused lessons on a wider range of mathematical topics and in different educational contexts. Moreover, future studies could investigate the long-term effects of history-infused lessons on students' attitudes and engagement, as well as the role of technology in enhancing the effectiveness of these lessons.

DEVELOPING DIRECTED-LENGTH DEFINITIONS FOR THE TANGENT AND SECANT FUNCTIONS

Tami S. Martin

Kyle J. Kimball
Illinois State University
kjkimba@ilstu.edu

In this study, we examined preservice secondary mathematics teachers' reasoning as they developed directed-length definitions for the secant and tangent functions. We describe their process of developing the new concept definitions and we identify the trigonometric contexts in which their reasoning was embedded. We then describe how those concept images and definitions were used in the preservice teachers' reasoning. The preservice teachers primarily drew from two trigonometric contexts (unit circle and right triangle) as they developed new concept definitions.

Keywords: Cognition, Precalculus, Preservice Teacher Education, Reasoning and Proof

Trigonometry is important for both practical applications and as a basis for higher-level mathematics. The Common Core State Standards for Mathematics and National Governors' Association Center for Best Practices & Council of Chief State School Officers (2010) recommended that high school students learn trigonometric functions. Despite the importance and variety of purposes of trigonometry (Hertel, 2013), there is consensus from the field that the topic is not learned well (e.g., Brown, 2005; Moore, 2014). Thus, teachers need a deep understanding of trigonometric functions.

Trigonometric Stances

Instructors may have a stance toward trigonometry that "establishes boundaries indicating which mathematical ideas" (Hertel, 2013, p. 105) they consider trigonometry. When discussing different trigonometric definitions, Hertel (2013) described three hierarchical stances: (a) right-triangle trigonometry, (b) circle trigonometry, and (c) analytic trigonometry. A circle stance, for example, includes both right-triangle trigonometry and circle trigonometry contexts. In right-triangle contexts, functions are defined as ratios of sides of triangles (e.g., $\sin\theta = \frac{\text{length of side opposite } \theta}{\text{length of hypotenuse}}$), whereas in circle contexts they are defined in relation to the unit circle (e.g., $\tan\theta = \frac{y}{x}$) such that (x, y) is a point on the unit circle. Using a variety of contexts when introducing trigonometric concepts may lead to a more robust understanding.

In addition to using and connecting different trigonometry definitions, researchers have found that students who used quantitative reasoning (Thompson, 1990) and covariational reasoning (Carlson et. al., 2002, p. 354) were able to reason about trigonometric functions more fluently (Moore 2010, 2013, 2014). Given the promise of quantitative and covariational reasoning and the benefits of strengthening connections between different trigonometry definitions and contexts, we expand on Moore's (2014) work of examining the effects of using directed-length trigonometry definitions to improve the teaching and learning of trigonometry.

Toward a New (Old) Context

In the directed-length context, the six trigonometric functions used in modern-day trigonometry (i.e., sine, secant, tangent, cosine, cosecant, cotangent) are all defined as directed lengths of segments along chords, secants, or tangents in a circle (see Figure 1) that depend on the length of the associated arc. We labeled the sine and cosine functions as the chord and cochord, respectively, to highlight the connection to the historical chord and half-chord functions as well as the mistranslation of the word chord into the word sine (Kennedy, 1969). This choice was also made in the classroom lessons for this study. Thus, there are times when the participants refer to the sine or cosine functions as chord or cochord in our results.

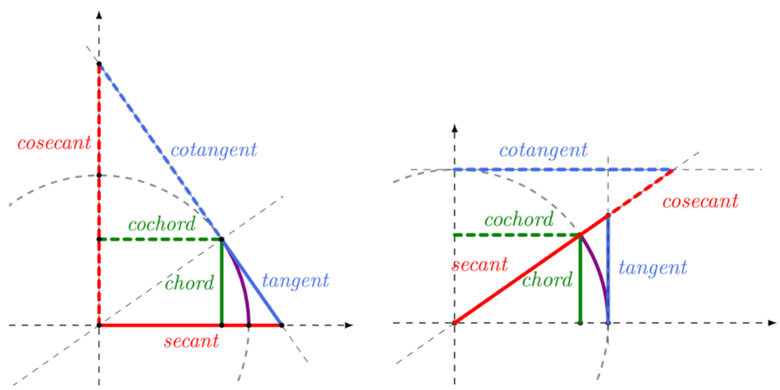

Figure 1: Directed-Length Context of Trigonometry

Hertel and Cullen (2011) found the use of a directed-length approach within a dynamic geometry environment led to a more robust understanding of trigonometric functions. Using a directed-length approach, Cullen and Martin (2018) "focused on the first in a sequence of learning activities in which PSTs reasoned quantitatively about two dynamically changing objects in a circle, and whether those objects could be considered inputs and outputs of a function" (p. 259). In their work, the PSTs engaged in an activity without knowing the task was related to trigonometry. Instead, the PSTs were directed to focus on the concept of function, which they eventually connected to the sine function. Tall and Vinner's (1981) framework of concept image and concept definition was a helpful lens through which to describe how PSTs were making sense of the functions in that study. However, that study's focus was limited to the sine function and the PSTs were not aware that the exploration was related to trigonometry.

In the current study, we tasked PSTs with identifying the needed objects in a dynamic geometric construction (e.g., arcs, lengths of various segments) to define the tangent and secant functions. As the PSTs worked through the activity, they reasoned by determining consistency between their circle stance definitions and a directed-length context. Specifically, we addressed the research questions: Which concept images and concept definitions do PSTs evoke while defining tangent and secant in a novel trigonometric context? How do PSTs reason with their evoked concept images and definitions?

Theoretical Perspective

In this study, PSTs explored a directed-length stance toward trigonometry, specifically seeking to establish consistency between a circle stance and directed-length definitions for tangent and secant functions. Given the focus on the definitions, we relied on concept image and definition (Tall & Vinner, 1981) to guide our analysis. Following Moore (1994) we considered concept image to be "the set of all mental pictures that one associates with the concept, together with all the properties characterizing them" (p. 252). Concept definition "refers to a formal verbal definition that accurately explains the concept in a non-circular way, as might be found in a mathematics textbook" (Moore, 1994, p. 252). In our study, we describe how PSTs leveraged their existing concept images for the tangent and secant functions to support their developing intuitions about a directed-length stance toward trigonometry. Based on Cullen and Martin's (2018) report that PSTs referred to the unit circle when identifying the sine function and Hertel's (2013) findings about the prevalence of right-triangle and circle stances, we anticipated that PSTs' concept images would be primarily anchored in the circle stance. By focusing our analysis on concept images, we hoped to link those concept images to the trigonometry definitions and contexts from which PSTs reasoned during their classroom investigations of the tangent and the secant functions. We identified their concept images as being anchored within two definitions (i.e., right triangle and circle), both from the circle stance provided by Hertel (2013).

Methods

The participants in this study were 23 PSTs, who had completed at least 60 hours toward a degree in mathematics with a focus on secondary education. The setting for the study was a semester-long course—taught by the second author—focused on problem solving connected to the secondary mathematics curriculum and the affordances of technology in those contexts. Full class and small-group discussions were videorecorded. Here, we discuss data from the first and second week of a 6-week instructional sequence on trigonometry. During the sequence, the instructor focused on promoting PSTs' use of quantitative reasoning, encouraging them to focus on objects rather than numeric values.

Prior to this lesson, PSTs determined that a vertical half-chord stemming from a dynamically changing terminus of the arc could be considered an object-centered geometric definition of the sine function. In the lesson examined in this paper, the instructor displayed the same dynamically accumulating red arc (with terminal point C; see Figure 2) in GeoGebra. While gesturing to the dynamically changing arc, the instructor asked the PSTs to identify distinct segments associated with the circle's arc that would represent the tangent function's output and the secant function's output. In this representation, the circle's arc serves as the function's input and the tangent and secant segments, respectively, serve as the function outputs. Although the instructor mentioned this implicit connection between the circle arc and related segments during his lesson, the relationship between two quantities was not repeatedly emphasized. Here, we use the instructor's language that typically refers to the directed-length concept definition of the tangent and secant function as simply the length of the segments along the tangent and secant, respectively.

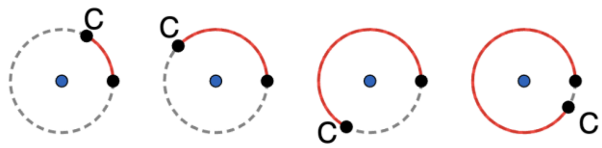

Figure 2: Initial Diagram as Point C Varies

To initiate the exploration into the directed-length approach of trigonometric functions, the instructor asked PSTs to think about the tangent function. To support small-group discussion, the instructor suggested that PSTs consider the following questions.

1. What is “the” definition of the tangent function?
2. When is the tangent equal to zero, undefined, positive, and negative? How do you know?

A similar set of questions helped promote discussion of the secant function after the class negotiated a geometric definition for the tangent function. Our analysis focused on identifying the evoked concept images and definitions during PSTs' reasoning about tangent and secant functions as well as from which context the images and definitions were being drawn. When PSTs referred to sine, cosine, or tangent as ratios of sides of right triangles (e.g., opposite, adjacent, hypotenuse) we classified their concept definitions or images as aligned with a right-triangle context. When PSTs referred to any of the six trigonometric functions defined as ratios of x- and y-coordinates from the unit circle (e.g., $\tan\theta = \frac{y}{x}$), we classified their evoked concept definitions as aligned with a unit-circle context. When PSTs referred to any of the six trigonometric functions defined as ratios involving another function (e.g., $\tan\theta = \frac{\sin\theta}{\cos\theta}$), we examined the way they used these definitions to determine a likely context. When other concept images were evoked, we identified and described likely sources of those concept images. Any disagreements were resolved through team meetings until consensus was reached.

PSTs primarily worked in small groups. The pseudonyms we used for each PST identified their group membership. That is, PST-A1 was a member of Group A. In our analysis we identified the concept definitions and images that PSTs evoked as they worked. We linked those concepts to the trigonometric contexts. Finally, we compared the reasoning used as the PSTs identified definitions for both the tangent and secant functions.

Results

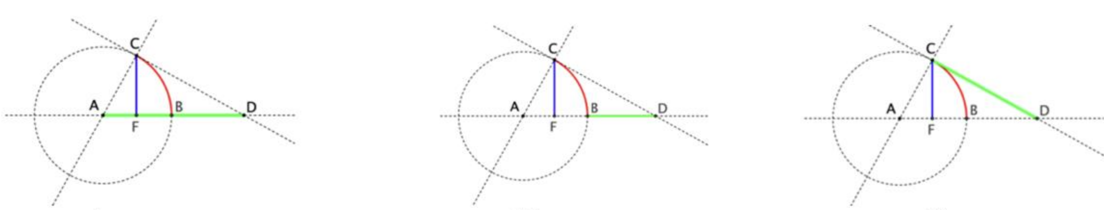
PSTs worked to identify segments that, when paired with the arc, would represent a viable definition for tangent or secant in their emerging understanding of the directed-length context. Their reasoning followed a pattern of exploring in GeoGebra, identifying a segment that might represent one of the trigonometric functions in the directed-length context, then crafting an argument to either justify that their proposed segment was consistent with concept images they held about the tangent or secant, respectively, or discard it because it contradicted their prior knowledge. The definitions PSTs evoked during this process were those native to the right-triangle and circle contexts. However, they also evoked concept images related to benchmark values of each function. Next, we share some of the PSTs’ reasoning in chronological order because the collective argumentation was cumulative. Even so, we observed that when one segment candidate was discarded, the reasoning cycle, starting from identifying a new segment candidate and comparing it to their concept definitions or concept images, was consistent.

Development of a Directed-Length Definition for Tangent

Conversations among members of Group A illustrate the cycle of generating candidates for the tangent function then constructing arguments for or against the candidate segment based on concept definitions and images. An excerpt from a full-class discussion will illustrate their cycle of reasoning. We noted that PSTs drew primarily on the circle stance, encompassing all trigonometry contexts. However, other mathematical concept images were evoked, as well.

PST-A2 proposed that the tangent function ought to be defined as the slope of $\overline{AC}$, rather than by the segment itself. PST-A2 argued "tangent equals sine divided by cosine and so, sine is your *y*-value, cosine is your *x*-value." Here we see the PST reasoning about the tangent moving quickly between and among definitions. When the PST stated "tangent equals sine divided by cosine" we considered $\frac{\sin\theta}{\cos\theta}$ to be evidence that a right-triangle concept definition was evoked with $\sin\theta$ representing the opposite side of the triangle and $\cos\theta$ representing the adjacent side of the triangle. However, it is possible that PST-A2 was simply recalling a memorized definition native to a circle context. Likewise, because the class had previously established that half-chord $\overline{CF}$ (shown in Figure 3) was a representation for $\sin\theta$ in the directed-length context they were exploring, PST-A2 may have been drawing on a component of the newly developing directed-length context as well. When the PST stated "sine is your *y*-value, cosine is your *x*-value," we considered that an indication that he evoked a concept image of slope as "rise over run." Thus, although teasing apart PST-A2's concept images in any given moment could be argued from a variety of perspectives, it does appear that the PST was drawing from several circle-stance ideas and liberally making connections among several mathematical and trigonometric ideas. The PSTs were building their argument by connecting to other concepts images or definitions that they seemed to assume were taken as shared by the group.

The small-group discussion was revisited in a full-class discussion. The instructor asked PSTs to consider when the tangent would be 0. PST-A2 offered "Tangent is zero when sine is zero because tangent is defined as sine over cosine." The instructor recorded the definition at the whiteboard (i.e., $\tan\theta = \frac{\sin\theta}{\cos\theta}$). The instructor then asked the class when the tangent would be undefined. Many PSTs gave a choral response: "when cosine is zero." PST-A3 added "when the denominator is zero something is undefined." This discussion illustrates how PSTs used benchmark values in conjunction with the definition $\tan\theta = \frac{\sin\theta}{\cos\theta}$ to support their arguments about whether certain segment candidates might be viable for the tangent function for a directed-length definition.



A B C

Figure 3: PSTs' Tangent Conjectures

In a subsequent full-class discussion, PSTs from various groups shared the tangent-segment candidates they had considered in their groups. These tangent candidates are shown in green in Figure 3. PST-C2 created line $\overleftrightarrow{CD}$, perpendicular to line $\overleftrightarrow{AC}$ at point C. PST-F1 suggested that segment $\overline{AD}$ (green horizontal segment in Figure 3A), extending from the center of the circle to the point at which it intersected the tangent line $\overleftrightarrow{CD}$, might represent the tangent function. PST-C1 argued that segment $\overline{AD}$ could not represent the tangent function because when the arc has measure zero "the sine is zero, which means the tangent should be zero, but the green segment ($\overline{AD}$) has [nonzero] length at zero." Thus, he used his evoked concept definition, "tangent is sine over cosine," along with a benchmark value for the tangent function to test and reject the first conjecture.

PST-C1 continued his thought process and conjectured that the tangent function could be represented by the green segment $\overline{BD}$ shown in Figure 3B. (We note this segment comprises the exsecant, however, this was not discussed in the class.) This conjecture was abandoned without discussion because PST-F1 conjectured that the green segment $\overline{CD}$ along the tangent line $\overleftrightarrow{CD}$ in Figure 3C represented the tangent function. One small group of PSTs, checking benchmark values, determined that this choice satisfied the requirement that the tangent was undefined at $\frac{\pi}{2}$ because the tangent segment and the horizontal secant are parallel when point C is at the $\frac{\pi}{2}$ position (i.e., the arc was one-quarter of the way around the circle). PST-D1 concurred and added "the length of that green line, as it [point C] gets closer to the point at the top of the circle $\left[\frac{\pi}{2}\right]$, it's going to be increasing to infinity, which is what the tangent line does." In this argument, PST-D1 appeared to be reasoning in a circle context as they spoke about the position of C on the circle in measured terms (i.e., the $\frac{\pi}{2}$ position). We classified this a circle context because they described the position of terminal point C, rather than the measure of the arc, as the independent variable leading to the tangent function output.

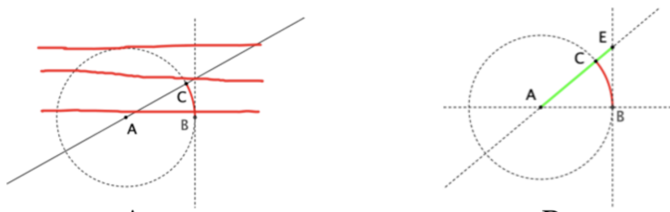
After generating a promising candidate for the tangent function using benchmark values, the PSTs attempted to justify that $\overline{CD}$ constituted the tangent in the directed-length context by showing that it satisfied definitions and concept images from the right-triangle and circle contexts. PST-D2 argued that $\overline{AC}$ and $\overline{CD}$ form a right angle, creating right $\triangle ACD$ with non-right angle $\measuredangle CAD$ (or θ) and reported that $\overline{AC}$ as the radius of the circle could be labeled as one unit in length. Drawing from a right-triangle context, she argued "tangent is opposite over adjacent," the ratio of $\frac{opposite}{adjacent}\left(\frac{CD}{AC}\right)$ must be equal to $\tan\theta$.

In this way, the PSTs' reasoning fluidly incorporated concept images from right-triangle and circle contexts. This pattern repeated in the PSTs subsequent search for an appropriate definition for the secant function.

Development of a Directed-Length Definition for Secant

To help PSTs construct a definition for the secant function, the instructor asked PSTs to consider key features of the secant function, (e.g., when is it zero and when is it undefined?). During small-group discussion, PST evoked two main concept definitions of secant, $\sec\theta =$

$\frac{1}{\cos\theta}$ and $\sec\theta = \frac{hypothenuse}{adjacent}$. These two definitions were central to much of PSTs' reasoning about which objects (segments) might define the secant function in a directed-length context.



A B

Figure 4: PSTs' Secant Conjectures

PST-D2 proposed the first candidate, the interior portions of the parallel red segments in Figure 4A. She argued that the top segment is an undefined secant as it becomes a tangent line to the circle. This candidate was ultimately rejected. However, unlike the first candidates for the tangent function, the red parallel lines were consistent with a concept definition of a geometric object for which it was named, a secant (i.e., a line that cuts a circle at two points). Prompted by the instructor, the class argued that the parallel red segments could not define the secant function because these red segments are bounded by the diameter. The secant function, they argued, grows without bound. Because this candidate was not viable, another PST suggested a different candidate for consideration.

PST-B1 suggested segment $\overline{AE}$ in Figure 4B might define the secant. His argument was based on reasoning from a circle context. PST-B1 argued that when point C moves to point B, segment $\overline{AE}$ will "be one and it will never be lower than one." He explained that as point C reaches $\frac{\pi}{2}$ (circle concept), $\overline{AE}$ will be undefined. PST-B1 compared the length of $\overline{AE}$ to benchmark values of one and undefined to create and support $\overline{AE}$ as a candidate for the secant. With the conjecture surviving the benchmark-checking phase of scrutiny, PSTs worked toward proving that defining $\overline{AE}$ as the secant was consistent with a previously known definition.

PST-B1's argument appears to follow this logic: $\overline{AE}$ could be the secant because $\sec\theta = \frac{hypotenuse}{adjacent} = \frac{\overline{AE}}{\overline{AB}} = \frac{\overline{AE}}{1(radius)} = \overline{AE}$. In Table 2, we parsed PST-B1's logic to identify key elements (in bold) and show their connection to the context from which it was drawn. Even though the reasoning was incorrect, the way he drew on multiple stances was evident.

Table 2: Contexts PST-B1 Used When Reasoning About Secant

Claim	Context	Possible Explanation
"the idea is the **opposite over the hypotenuse**"	Right triangle	This is a description of the sine function based on triangle side lengths.
"that is whatever the **length of the chord (i.e., sine) over one**"	Circle and directed length	Because the PST substituted one for the hypotenuse, the PST seemed to be envisioning a triangle embedded in a unit circle. And "chord" is a directed

		length term for sine.
"So, we want it to be the other way, we want **one over** whatever **the length of our secant** is gonna be."	Right triangle	The PST may have misspoken and meant to say $\frac{\mathbf{1}}{\mathbf{\sin\theta}}$, perhaps because they misremembered the inverse relationship with cosine and secant.
"one right here (referring to $\overline{\boldsymbol{AB}}$); and you have the **hypotenuse** right there (referring to $\overline{\boldsymbol{AE}}$)"	Right triangle (embedded in a circle)	If $\overline{\boldsymbol{AB}}$ has value 1, then the circle is a unit circle. If $\overline{\boldsymbol{AE}}$ is the hypotenuse, then $\triangle\, \boldsymbol{ABE}$ is a right triangle.

Other PSTs contributed to the collective argumentation to complete the argument.

PST-D3: Can't we say its hypotenuse over adjacent? Like 1 over cosine is hypotenuse over adjacent.

PST-B1: That's like kinda like where I am trying to go. We got one (referring to $\overline{AB}$) over the hypotenuse (referring to $\overline{AE}$) and that's why I am thinking that…that's gonna be the length…

PST-A1: So if we are gonna go with PST-B1's idea, then $tan^2\theta + 1^2 = sec^2\theta$.

PST-A1 completed the argument for PST-B1's conjecture (i.e., $\overline{AE}$ is the secant function) by referring to a trigonometric identity, a concept image associated with his circle stance toward trigonometry. Although these identities are not definitions drawn directly from a trigonometry context, they are usually proved using algebraic techniques that draw on equivalent ratio representations of trigonometric functions. From a bird's eye view, one can see that even arguing collectively, the PSTs built the argument while fluctuating between right-triangle and circle concepts to support their reasoning.

Discussion

In this study, we identified PSTs' evoked concept images and definitions as they establish directed-length definitions. PST reasoned from the circle stance (Hertel, 2013), making connections among concepts and definitions from circle, right-triangle, and directed-length contexts as established the new definitions for the tangent and secant functions. Our findings show that having access to the most prevalent trigonometry stance, as well as the sine definition from directed-length context, was sufficient for the PSTs to establish the consistency between the new directed-length definitions and their existing trigonometry stance.

We also described some common ways in which the PSTs used the concept images and definitions. For both the tangent and secant, PSTs used benchmarking with existing concept definitions (i.e., $\tan\theta = \frac{\sin\theta}{\cos\theta}$ and $\sec\theta = \frac{1}{\cos\theta}$) to generate conjectures about which segments were viable candidates for representing the outputs for the tangent and secant functions. To prove (for tangent) and attempt to prove (for secant) their conjectures, PSTs used concept definitions from right-triangle trigonometry to connect an existing concept definition (e.g., $\tan\theta = \frac{opposite}{adjacent}$) to the directed-length context. For the secant proof, PST-A1 leveraged a Pythagorean identity, part of his concept image from a circle trigonometry context. Although these specific uses may be interesting, we found the flexibility with which the PSTs moved between and among different concept images and definitions coming from right-triangle trigonometry and circle trigonometry contexts to be more important. The flexible use of these concept images supported PSTs' reasoning about the tangent and secant functions embedded in the novel directed-length context. This task gave the PSTs an opportunity to establish or continue to build a connected understanding of trigonometry. These connections may help avoid the isolated trigonometry knowledge about which Brown (2005) has warned.

Finally, the reasoning documented in these activities was somewhat consistent with quantitative reasoning. PSTs reasoned about the different quantities (i.e., arcs and segments), but they also referred to numerical relationships when checking benchmark values. As Ellis (2007) suggested, a focus on quantitative reasoning promoted relating actions. This relating action was demonstrated by the PSTs as they worked to develop new concept definitions for tangent and secant. In this process they engaged in relating a variety of concept images and definitions from their existing trigonometry stance. The PSTs in this study evoked concept definitions from both circle and right-triangle trigonometry contexts to develop their directed-length concept definition of tangent and secant. This opportunity to relate between and among the different images and definitions from different contexts should help them better apply their understanding when they encounter new topics (Tall & Vinner, 1981).

Even though PSTs developed a directed-length definition for the tangent and secant functions, future research should investigate: (1) In what ways can a directed-length stance and accompanying concept definition of trigonometric functions be leveraged to help students reason about additional topics (e.g., graphs of trigonometric functions, trigonometric identities, derivatives of trigonometric functions)? (2) How might secondary students develop a directed-length stance of trigonometric functions as their initial trigonometry stance?

A PRELIMINARY INVESTIGATION OF CALCULUS STUDENTS' UNDERSTANDING OF GRAPHICAL OPTIMIZATION

Thembinkosi P. Mkhatshwa
Miami University
mkhatstp@miamioh.edu

This study reports on students' reasoning about a univariate optimization that involves finding the production level at which the cost per yard is minimized when given the graph of a function that represents the relationship between the cost per yard and the number of yards produced by a factory. Determining the production level at which the cost per yard is minimized was straightforward for all the four students who participated in the study. However, explaining how this production level is related to the first derivative of the given function was problematic for most of the students. Implications for instruction are discussed.

Keywords: Optimization problems, graphical optimization, problem solving, calculus education.

Graphical optimization "…is a simple method for solving optimization problems involving one or two variables" (Bhatti, 2000, p. 47). Bhatti added, "for problems involving only one optimization variable, the minimum (or maximum) can be read simply from a graph of the objective function" (p. 47). Unlike algebraic optimization that uses algebraic methods (that may sometimes be sophisticated e.g., when working with complex objective functions) or numerical optimization (that requires some level of technical skills e.g., proficiency in MATLAB programing), graphical optimization is the simplest method for solving univariate optimization problems (UOPs) as it only requires making sense of graphs of objective functions. A UOP is an optimization problem where the objective function is a real-valued function of a single variable.

UOPs are particularly challenging for first-semester calculus (hereafter, calculus) students (cf. LaRue & Infante, 2015). Furthermore, there is a paucity of research on students' thinking about UOPs (cf. Speer & Kung, 2016). A few studies that have examined students' reasoning about UOPs have found that formulating the objective function is often challenging for many students (cf. Borgen & Manu, 2002; Dominguez, 2010; LaRue & Infante, 2015; Mkhatshwa, 2019). Additionally, all these studies have examined students' ability to solve UOPs using algebraic methods. There is still much to be explored about how students might reason about UOPs when given the objective function in graphical form. The research question investigated in this study is: How do difficulties exhibited by students when engaged in graphical optimization compare with difficulties exhibited by students when engaged in algebraic optimization?

Related Literature

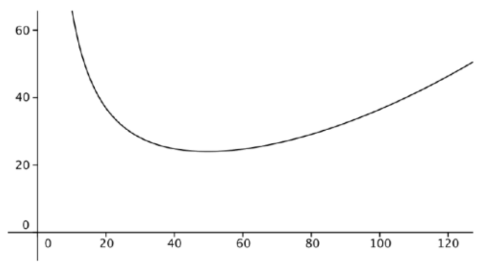
There are three themes that emerge from research that has looked at students' understanding of algebraic optimization when working with UOPs, namely students' difficulties with setting up the objective function, students' difficulties with determining and interpreting critical values and/or extrema, and students' difficulties with justifying/verifying extrema using formal calculus methods (cf. Borgen & Manu, 2002; Dominguez, 201; LaRue & Infante, 2015; Mkhatshwa, 2019; Swanagan, 2012). Findings from a related body of research suggest that difficulties exhibited by students when working with UOPs are directly related to quantitative reasoning

(Thompson, 1993, 1994, 2011). Specifically, these studies have found that students tend to confuse different quantities such as amount quantities [e.g. distance] with rate quantities [e.g. speed] when working with UOPs (cf. Flynn et al., 2018; Mkhatshwa, 2019,2020, 2021; Mkhatshwa & Doerr, 2018; Prince et al., 2012; Rasmussen & Marrongelle, 2006).

Methods of Data Collection and Analysis

Task-based interviews (Goldin, 2000) were conducted with four freshman students (Pseudonyms Adam, Ava, Caleb, and Emily) at a research university in the United States. The interviews lasted for about 14 minutes, on average, and contained two tasks (Task 1 and Task 2). In this paper, we report on how the students reasoned about Task 1:

Task 1 (Cost minimization context): The graph shows $f(x)$, the dollar cost per yard of fabric, given that a certain factory produces x yards of fabric.



a) At what production level is the cost per yard minimized?
b) How can you convince someone that the cost per yard is minimized at the production level you found in part a)? Explain.
c) What can you say about $f'(x)$ at the production level where the cost per yard is minimized? Explain.
d) Why might the cost per yard of fabric increase as the factory produces larger amounts?
e) Why might the cost per yard of fabric increase as the factory produces very small amounts?

The students worked through the task while the interviewer asked clarifying questions about their work. The students were chosen based on their willingness to participate in the study. The students in this study had limited exposure, via course lectures and the course textbook (Haeussler, 2011), to work with UOPs where the objective function is given as a graph such as in Task 1. We further note that the context of cost is commonly used in business calculus courses in the United States. Three students were business majors, and one student was an economics major. Business calculus is a required course for most business or economics majors. Data for the study consists of transcriptions of audio-recordings of the task-based interviews and work written by the four students during each task-based interview session. Data analysis was done in three stages. In the first stage, we used three a priori codes that consisted of the themes on students' difficulties when solving UOPs or difficulties related to quantitative reasoning discussed earlier. In the second stage of the analysis, we used emergent codes that included instances where students reasoned about what they found to be easy or difficult in their attempt to answer the questions posed in the task. In the third stage of the analysis, we looked for patterns in each of the codes identified in the first and second stage of the analysis, respectively.

Results

Determining Critical Values and/or Extrema

Three of the four students correctly determined the critical value of the objective function i.e., the production level at which the cost per yard is minimized. Although not asked, some of these students went on to determine the extreme value of the objective function i.e., the minimum cost per yard. Figure 1 illustrates how one of these students (Emily) responded to prompt (a) of the task whose goal was to assess students' ability to determine the critical value from the graph of the objective function.

Figure 1. Emily's Solution to Prompt (a)

In her response to prompt (a) of the task, Emily correctly identified both the critical value and extreme value of the objective function. In light of the fact that the objective function is not presented on a grid axis, something that could limit one's accuracy when estimating critical or extreme values of the objective function, critical values ranging from 40 yards to 45 yards and extreme values ranging from $20 to $25 dollars are considered to be correct. Only one student, Ava, incorrectly determined the critical value of the objective function as can be seen in Figure 2.

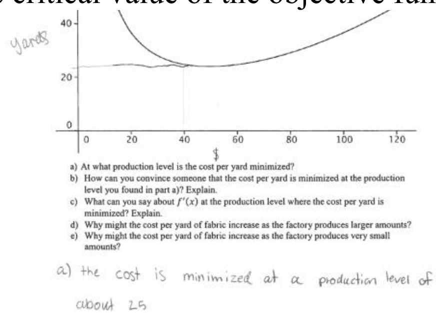


Figure 2. Ava's Solution to Prompt (a)

Specifically, in her attempt to determine the critical value of the objective function, Ava confused two amount quantities namely, the minimum cost per yard and the production level at which the minimum cost per yard is achieved. Another student, Adam, confused a rate quantity with an amount quantity when he confused the derivative of the objective function at the production level at which cost is minimized with the quantity of cost at this level in his response to prompt (c). None of the other students (i.e., Caleb and Emily) confused quantities in their reasoning about Task 1.

Verifying Extrema

All the students provided plausible explanations in response to prompt (b) that asked students to explain how they could convince someone that the cost per yard is minimized at the production level they identified in part (a). The following is a reproduction of one of the students' responses to prompts (b) and (c) on the task. To reiterate, prompt (c) asked students to comment on $f'(x)$ at the production level where the cost per yard is minimized.

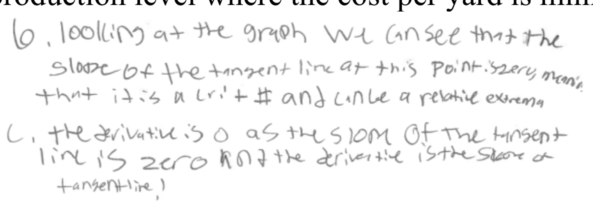

Figure 3. Caleb's Responses to Prompts (b) and (c)

Caleb's claim that "looking at the graph [of the objective function] we can see that the slope of the tangent line at this point [which he identified as $x = 42$] is zero, meaning that it is a critical number and can be a relative extrema" in response to prompt (b) demonstrates an understanding that extrema can be expected to occur where the tangent line to the objective function is zero. This is consistent with his claim that "the derivative [$f'(x)$] is zero…" in response to prompt (c). In response to prompt (c) on the task, the other three students either stated that $f'(x)$ would be positive or that it would be negative, thus exhibiting a poor understanding of concept of the derivative in connection with the critical value of the objective function. Interestingly, only one student (Emily) noted that commenting about $f'(x)$ [i.e., prompt (c) on the task] was particularly challenging when asked about the difficult part in her attempt to respond to the prompts included in the task. It should be noted that Caleb is the only student who used a calculus approach to verify extrema i.e., to explain how he could convince someone that minimum cost per yard occurs at the production level he identified in his response to prompt (a). The rest of the students, and using Ava as an example argued, in response to prompt (b) on the task that "you can look at the minimum point on the graph to find where the cost per yard is minimized."

Understanding the Graph of the Objective Function

When asked about the easiest part when responding to the prompts included in Task 1, all the students made remarks that suggested that making sense of the graph of the objective function was easy for all the students. For example, Adam remarked "…analyzing the graph" while Ava remarked "…finding where the cost is minimized because I looked at the lowest point on the graph." It should be noted that the students' remarks are consistent with their success in identifying critical values and/or extrema and verifying extrema as reported in the preceding subsections.

Explaining why production Cost Might Increase with Small- or Large-scale Production

Only Ava provided a plausible explanation in response to prompts (d) and (e) that asked for possible explanations why the cost per yard of fabric might increase when the firm produces very small or large amounts fabric. This student argued that a very small-scale production could lead to an increase in the cost per yard of fabric "…if there is not enough demand", suggesting that the factory may have to charge more money per yard to make profit. Ava explained that the cost per yard of fabric could still increase even with a large-scale production if the factory "…is not making enough revenue," which is a plausible explanation especially if making or increasing profit is the ultimate goal for the factory. Emily is one student who provided an explanation that we considered to be not plausible. She remarked, "I am not really sure…," in response to prompt (e) on the task that asked about why the cost per yard of fabric could increase when the factory produces large amounts of fabric.

Discussion and Conclusions

A number of studies have reported on students' difficulties with finding critical values or extrema as well as justifying extrema when tasked with solving UOPs using algebraic methods (cf. Borgen & Manu, 2002; Swanagan, 2012). Because of these difficulties, calculus students are often not successful in solving UOPs algebraically. Contrary to these findings, nearly all the students in the present study were successful in finding the critical value or extrema as well as justifying extrema while working with a UOP where the graph of the objective function was provided. To some extent, this may suggest that while students may struggle with solving UOPs algebraically, partly due to lack of facility with some algebraic techniques such as calculating derivatives of complex objective functions, students have better success with solving UOPs graphically not only because they can visualize the objective function, but also because having access to the graph of the objective function supports their quantitative reasoning such as the ease of identifying critical values and extrema. Consistent with findings from previous research on students' thinking about UOPs, two students confused quantities (cf. Mkhatshwa, 2019; 2020). Additionally, three students made remarks that suggested that they had difficulty understanding that the derivative of the objective function ought to be zero at the critical value (i.e., the cost minimizing quantity), something that generally comes easy for students when solving UOPs algebraically. It might be helpful for calculus instructors to expose students to multiple methods of solving UOPs, namely algebraically, graphically, and numerically.

Vague or imprecise language has been shown to hinder students' mathematical understanding. To investigate how imprecise language contributes to student errors, researchers analyzed the work of college freshmen on a trigonometry problem. Findings showed that students struggled with conceptualizing radians and moving from understanding trigonometric functions in the context of triangles to the context of the unit circle. Imprecise diagrams and formulas evidenced students' lack of full understanding. Researchers recommend the use of precise language that prioritizes coherence, consistency, and conceptual clarity.

Keywords: Mathematical Representations, Precalculus, Undergraduate Education.

Students' understanding of mathematical concepts is hindered by vague or imprecise language. The lack of a shared coherent language in mathematics topics causes confusion and impedes students' ability to build on existing knowledge (Popovic et al., 2023). Intentional, consistent, precise language is essential for students to incorporate complex mathematical ideas into their existing understandings (Karp et al., 2015).

Background and Conceptual Framework

In the realm of mathematics education, researchers have undertaken extensive investigations into various facets of teaching and learning trigonometric concepts. Central to these inquiries is an exploration of the challenges students encounter in understanding trigonometry and the origins of these difficulties. Fundamental to this discourse is the observation that students often fail to recognize the radian as a unit of angle measure, instead favoring a dominant reliance on the degree measure (Koyunkaya, 2016; Moore, 2013). Consequently, students have difficulty in interpreting trigonometric functions' outputs when presented with real numbers as inputs (Akkoc, 2008, Cekmez, 2020). This deficiency is compounded by a lack of foundational knowledge regarding the concept of angles (Koyunkaya, 2016).

Another issue identified in students' understanding lies in their inability to establish connections between the contexts of right triangles and unit circles and their application in defining trigonometric functions (Moore, 2009). This deficit underscores the complex nature of comprehending trigonometric functions, which can be caused by various factors. Weber (2008) explains two primary reasons contributing to students' struggles: the challenge of linking triangles to numerical relationships and grappling with functions devoid of explicit formulas to determine their outputs.

Researchers assert that traditional approaches to teaching trigonometry often fall short in fostering conceptual understanding among students, thereby perpetuating learning difficulties (e.g., Moore, 2009; Orhun, 2010; Weber, 2005). Therefore, researchers have conducted studies aimed at devising alternative instructional approaches, including the design and implementation of novel teaching units or the integration of tools such as Geometer's Sketchpad (Moore, 2009; Weber, 2005).

Departing from previous research, in our study, we investigated the underlying imprecise language contributing to misconceptions and errors. We contend that imprecise mathematical language fosters ambiguity, hindering students' comprehension and concept development (Popovic et al., 2022). Adopting the concepts of concept image and conceptual change, we recognize that students' cognitive structures are shaped by their experiences and exposure to mathematical language. The development of concepts encompasses mental pictures, attributes, properties, and associated processes, as well as the linguistic representation of concepts, and inconsistencies within and between concept images and definitions can lead to cognitive conflicts, impeding the formation of an appropriate conceptual understanding (Jaffar & Dindyal, 2011; Lager, 2006; Siemon et al., 2017; Tall & Vinner, 1981). Thus, we advocate for an approach that emphasizes coherent and shared mathematical language to facilitate conceptual development and mitigate learning difficulties across mathematics education levels. Therefore, in this study, we analyze students' mathematical work and reasoning in their solutions to trigonometry problems and infer what type of underlying imprecise language might have potentially led to such misconceptions and errors.

Data Analysis

The sample consisted of 55 students, who were freshmen enrolled in a Precalculus course at a university in the Midwest portion of the United States. Researchers analyzed student work for one problem on a final exam. The problem, created by one of the researchers, stated:

Given that the $\sin(\theta) = -\frac{5}{6}$, where $\pi < \theta < \frac{3\pi}{2}$, calculate the values of $\sec(\theta)$ and $\cot(\theta)$.

Your work must clearly show how you achieved your answer.

One researcher analyzed student work to determine how the imprecise language might have influenced the appropriateness of the solution approach. Two other researchers then analyzed portions of student work for agreement. Researchers discussed discrepancies in coding until 100% agreement was reached.

Findings

Memorized procedures and mnemonics impeded students in moving beyond their conceptions of trigonometric functions as solely the ratios of the sides of a right triangle. This was seen in various ways in student work. Specifically, in the US, the mnemonic SOHCAHTOA is ingrained in students as a way to remember that, given a right triangle with angle A between 0° and 90°, sin(A) is equal to the ratio of the side opposite angle A divided by the hypotenuse of the triangle (see Figure 1). Teachers accept this written in shorthand as $sin = \frac{opp}{hyp}$. This mnemonic was shown in the work of two students. The use of this mnemonic (i.e., the imprecise language) reflects a common oversimplification in trigonometric instruction, where trigonometric functions are often taught in the context of right triangles only, leading to a limited understanding of their broader applications and concepts.

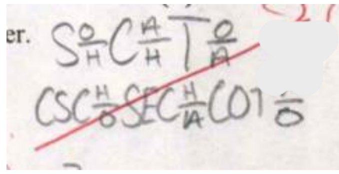

Figure 1: Mnemonic for Trigonometric Ratios

When told $\sin(\theta) = -\frac{5}{6}$, ten students used a right triangle with one side length of 5 and hypotenuse of 6, found the third side length, and used that to determine cos(θ). Students placed a triangle in the plane without relating the hypotenuse to the radius of a circle, even though the angle measurement was provided in radians. Rather than seeing the triangle as having a side length of $\frac{5}{6}$ and hypotenuse of 1, which would have facilitated their understanding of the triangle hypotenuse as the radius of the unit circle, students relied on their understanding of $\sin(\theta)$ as the ratio of the opposite side and the hypotenuse. Given $\sin(\theta) = -\frac{5}{6}$, students automatically drew a triangle with that ratio for one side and the hypotenuse (see Figure 2). This reliance on information from Geometry shows that students were unable to build on their geometric knowledge of triangles in the plane to incorporate trigonometric functions represented in the unit circle. The abrupt transition from using trigonometric functions to describe triangle ratios in Geometry to using the same functions as circular functions in Algebra II caused an inconsistency in the students' concept image (sides of a right triangle) and definitions (unit circle, $\cos(\theta) = x, \sin(\theta) = y$), thus blocking the formation of new understandings about trigonometric functions. This reliance on triangle-based approaches instead of integrating the concept of the unit circle demonstrates a perpetuation of imprecise ratio language used in teaching trigonometry.

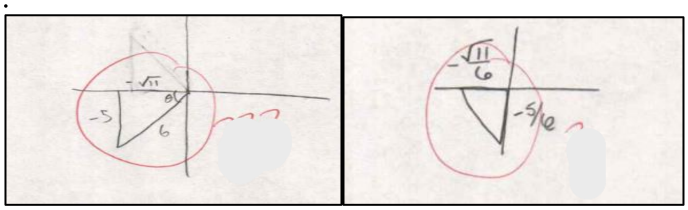

Figure 2: Incorrect Triangle Diagrams

However, the bigger problem here is that there is no triangle with side length of $-\frac{5}{6}$. Rather, an understanding that this is the *x*-coordinate of the point on the unit circle is essential in guiding students to use the equation of the circle. The first triangle shown in Figure 2 also shows evidence that students are taught to see radians as markers on the plane, rather than as angle measures. An acute angle in quadrant three was drawn by 12 students, even though it was given in the problem that $\pi < \theta < \frac{3\pi}{2}$.

Eleven students showed evidence of having memorized formulas for the relationship between trigonometric functions but drew incorrect diagrams. It appears that these students have memorized the formulas but are unable to make a connection to representations of the unit circle (see Figure 2). These students were able to incorporate some definitions into their existing

Kosko, K. W., Caniglia, J., Courtney, S., Zolfaghari, M., & Morris, G. A., (2024). *Proceedings of the forty-sixth annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Kent State University.

schema ($cos\ (\theta)\ = x,\ sin(\theta) = y$), but an incomplete mental picture of the unit circle impeded their understanding of the hypotenuse as the radius of the unit circle.

Students wrote imprecise equations, such as $sec = \frac{1}{sin}$. This was seen in the work of 11 students (see Figure 3). This is believed to be an acceptable equation in high school, without regard for the imprecision evident in the equation. Acceptance of these imprecise representations encourages the interpretation of trigonometric functions as variables, leading to ambiguity and impeding concept development. This understanding of trigonometric functions as variables leads to difficulties when solving trigonometric equations, such as $\sin(x+\pi)\ = \sin(2x) + \sin(\pi)$, where students divide the whole equation by sin (i.e., cross out sin) to get $x + \pi = 2x +\ \pi$.

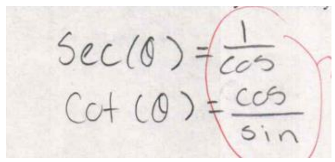

Figure 3: Imprecise Equations

The work and explanations of three students showed that they were logically thinking through their work and understood the connections between the functions. For example, when told $\pi < \theta < \frac{3\pi}{2}$, students explained that the angle would be in Quadrant III, giving a negative value for $sec(\theta)$. However, without a diagram, it is unclear whether these students fully understood the connections to the unit circle. Logically thinking through their work was also evident for four other students, but explanations were not provided to the same extent as for the three students mentioned above. However, these students also drew a diagram to support their thinking, showing evidence of understanding the connection between the unit circle and the trigonometric functions (see Figure 4).

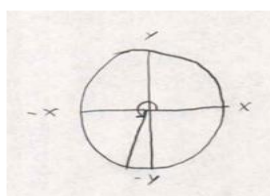

Figure 4: Diagram Supporting Understanding

Conclusions

Our findings underscore the impact of imprecise language on students' ability to navigate the complexities of trigonometry. Examination of student work on the introduction and subsequent study of trigonometric ratios revealed a pervasive reliance on mnemonic shortcuts and memorized formulas, obscuring the conceptual understanding. For example, the use of shortcut formulas such as $sec = \frac{1}{sin}$, without the argument of θ, can lead to insufficient concept development and impede understanding of the concept in a broader or different context. This is evidenced in student representations of a triangle on the plane without relating the hypotenuse to the radius of a circle centered at the origin. The move from the study of triangle side ratios to the study of the unit circle resulted in the use of the same terms in a different context, with new vocabulary. Triangles are replaced with angles that may be equal to or greater than 180°, requiring a restructuring of existing understandings of $\sin(\theta)$, $\cos(\theta)$, and $\tan(\theta)$. Merely substituting triangles with circular contexts without fostering a nuanced understanding of radians and circular functions inhibits conceptual growth. Students' struggles to move to envisioning trigonometric functions in the context of the unit circle was also seen in Moore (2009). It is imperative to champion the use of precise language, one that prioritizes coherence, consistency, and conceptual clarity. By cultivating a shared coherent mathematical language grounded in precision and intentionality, educators can empower students to transcend rote memorization and embrace the rich connections in mathematical concepts.

STATIC AND DYNAMIC: HOW TWO TEXTBOOKS INTRODUCE DERIVATIVE

Allison Olshefke-Clark
University of Delaware
aolshefk@udel.edu

Calculus students often struggle to understand the derivative conceptually, even when they can differentiate fluently. Operating from the premise that underdeveloped covariational reasoning skills may be key in understanding the derivative, this study explores how two calculus textbooks vary in promoting derivatives as dynamic and static. The results of analysis suggest that each textbook provides opportunities for both forms of reasoning, but they vary in their emphasis.

Keywords: Calculus, Curriculum, High School Education, Undergraduate Education

Research over the past few decades demonstrates that calculus students have difficulties making sense of the derivative conceptually, even if they can calculate derivatives fluently (e.g., Orton, 1983; Carlson et al., 2002; Thompson & Carlson, 2017; Epstein, 2013). Thompson and Harel (2021) argue that the underdevelopment of covariational reasoning may be the missing link in students' ability to engage deeply with major calculus concepts including the derivative. Covariational reasoning, or reasoning about how quantities vary simultaneously and in relation to one another, is evident in the Mathematical Association of America's (MAA's) recommended conception of the derivative as dynamic. The MAA emphasizes the need to promote an idea of the "derivative as instantaneous rate of change or as a measure of sensitivity of one variable to change in another," rather than the traditional, "very static interpretation" which does not make explicit a covarying relationship between quantities (Bressoud et al., 2015, p. 18).

This study is motivated by the need for students to experience a dynamic conception when learning about the derivative, and the role that textbooks play in the nature of students' calculus learning (e.g., Liakos et al, 2021; Gerami et al., 2023, Porogrelova, 2022). Recent work suggests that textbooks provide different, and often limited, promotion of covariational reasoning related to the derivative (Mkhatshwa, 2022; Chen, 2023), and this has implications for the opportunities students may have to reason about the derivative in a dynamic way. This study adds to this literature by applying Tasova et al.'s (2018) covariation framework to operationalize a distinction between static and dynamic conceptions of the derivative. Ultimately, the purpose of this study is to uncover how static and dynamic conceptions of the derivative are introduced to students by highlighting the ways two calculus textbooks promote reasoning about quantities related to the derivative as static or dynamic. These distinctions have implications for how students continue to engage and apply concepts as they progress through calculus and beyond.

Methods

I compare the introductory material on derivatives from two widely used Calculus textbooks (according to Open Syllabus Project): *Calculus of a Single Variable* (Larson & Edwards, 2018; hereafter *Larson,* for brevity) and *Calculus: Single and Multivariable* (Hughes Hallett et al., 2013; hereafter *Hughes Hallett*). I address the question: <u>How do two calculus textbooks promote reasoning about the derivative as static and dynamic?</u>

I applied Tasova et al.'s (2018) framework (Table 1) to *Larson's* and *Hughes Hallett's* introductory chapters on the derivative. This framework combines Moore and Thompson's (2015) framework for static and emergent shape thinking with Thompson and Carlson's (2017) framework for (co)variational reasoning. The framework is intended to be used "for coding the extent and nature of (co)variation provided in the narrative" of a textbook (i.e., expository sections, figures, and worked examples; p. 1529). I note I have adjusted the wording of the framework to be 'dynamic' instead of 'emergent,' as 'dynamic' characterizes covariation in non-graphical situations, and more clearly aligns with the MAA's conceptions of the derivative.

This framework outlines how textbooks promote the relationships between quantities and the quantities themselves as varying (dynamic) or not varying (static). A textbook narrative element promotes a *static* conception when it represents a quantity or function as a single object that is interpreted through associated facts or properties (i.e., Perceptual Associations) or as an input/output correspondence between its quantities (i.e., Correspondence). It promotes a *dynamic* conception when it emphasizes a quantity as changing (i.e., Variation) or the interprets the relationship between quantities through their coordinated change (i.e., Covariation). For brevity, I share examples of the most relevant codes in the results (for a thorough explanation of each code, see Tasova et al. (2018)).

Table 1: Analytic Framework (adapted from Tasova et al., 2018, p. 1529)

Static	Dynamic	
	Variation	Covariation
• Perceptual Associations		
• Variable as Unknown	• Continuous	• Continuous
• Correspondence	• Gross	• Gross Coordination of Values
	• Discrete	• Coordination of Values

I identified and coded instances in which the textbooks promoted static or dynamic reasoning about quantity/quantities using the elements of Tasova et al.'s (2018) framework (Table 1). I defined multiple units of analysis based on the component of the textbook being reviewed (i.e., expository sections, figures, tables, worked examples). For example, expository texts were coded sentence-by-sentence, but worked examples were coded as a single unit with the most prominent code. Instances of each opportunity were also tagged with the component type through which it was presented to investigate patterns in the ways conceptions were promoted.

Results

Each textbook provides opportunities for both static and dynamic conceptions of the derivative. However, the textbooks differ in their relative emphasis. Table 2 summarizes the frequencies of opportunities identified as static and dynamic across both textbooks. While *Larson* provides more opportunities overall for thinking about quantities related to the derivative, over 75% of these are static. This suggests *Larson* promotes a more static conception of the derivative. *Hughes Hallett* offers slightly more instances of dynamic than static (38 vs 33, respectively), which suggests there is more balance between its promotion of reasoning about the derivative from both a dynamic and static perspective. For brevity, the remaining results explore only the most notable code for each conception of the derivative.

Table 2: Opportunities for static and dynamic conceptions of the derivative

Frequency	Static	Dynamic	Total
Larson	76.4% (n = 84)	23.6% (n = 26)	110
Hughes Hallett	46.5% (n = 33)	53.5% (n = 38)	71

Instances Promoting a Static Conception of the Derivative

I identified the majority of static instances in *Larson* as Correspondence (70.2% of static opportunities). Only 9% of *Hughes Hallett's* static instances were Correspondence. Further, most examples of Correspondence from *Larson* were associated with worked examples. In general, *Larson's* worked example solutions were more perfunctory than *Hughes Hallett's,* and included less explanation and interpretation of the steps and answers.

Most of *Larson's* Correspondence worked examples followed a similar format. Generally, they indicated students should use an established rule to procedurally generate a derivative function, and then use this derivative function as a new rule to address follow up questions. For example, students are asked to "Find the slopes of the tangent lines to the graph of $f(x) = x^2 + 1$ at the points (0,1) and (-1,2)" (*Larson,* p. 102). The given solution applies the limit definition of the derivative, and though it shows intermediate steps for determining the derivative function, there is no attention to what the limit as $\Delta x \rightarrow 0$ means. Once the derivative function is established, it is simply used as an 'input/output' generator to calculate slopes: "So, the slope at *any* point (c, $f(c)$) on the graph of f is $m = 2c$" (*Larson*, p. 102 emphasis in original). This explanation is a clear example of Correspondence, which "simply provide[s] a rule for students to calculate a unique value of a variable or quantity by using any given value of another variable or quantity," (Tasova et al., 2018, p. 1529); in this case, students are given the opportunity to use the rule $m = 2c$ to calculate "*any*" slope at *"any"* point, with no attention to how the values of this slope are related to the original graph's values, to x, or to each other.

Instances Promoting a Dynamic Conception of the Derivative

Though both textbooks promote reasoning about the derivative dynamically, *Hughes Hallett* provided more opportunities to reason at the highest levels of covariation. In *Hughes Hallett,* Coordination of Values and Continuous Coordination were 42.1% and 18.4% of dynamic opportunities, respectively. *Larson* emphasized lower levels of covariation, with Gross Coordination characterizing 53.8% of dynamic opportunities.

A notable difference between *Larson* and *Hughes Hallett* related to promoting a dynamic conception is that *Hughes Hallett* utilized tables of values within its narrative structure and *Larson* did not include any. Further, each table of values present in *Hughes Hallett* coincided with instances of Coordination of Values or Continuous Covariational reasoning opportunities. Though generating a table from a given or derived rule would be considered an example of Correspondence, the use of tables of values in *Hughes Hallett* focuses on interpreting a complete table. This approach promotes reasoning covariationally as Coordination of Values, as it emphasizes the coordination the values of one variable with values of another across discrete pairs (Tasova et al., 2018). With some additional context or explanation, this reasoning can be elevated to Continuous Covariation by highlighting "simultaneous and continuous change" (Tasova et al., 2018, p. 1530). For example, consider the Continuous Covariational worked example from *Hughes Hallett* shown in Figure 3, which asks students to construct a table of values of an estimated rate based on a given table of values.

Example 3 Table 2.7 gives values of $c(t)$, the concentration (μg/cm^3) of a drug in the bloodstream at time t (min). Construct a table of estimated values for $c'(t)$, the rate of change of $c(t)$ with respect to time.

Table 2.7 *Concentration as a function of time*

t (min)	0	0.1	0.2	0.3	0.4	0.5	0.6	0.7	0.8	0.9	1.0
$c(t)$ (μg/cm^3)	0.84	0.89	0.94	0.98	1.00	1.00	0.97	0.90	0.79	0.63	0.41

Figure 3: Worked example prompt coded Continuous Covariation (*Hughes Hallett,* p. 92)

A preconstructed table of values is used in both the problem statement and the solution (not pictured) and instructs students to reason about how both the concentration and the derivative of the concentration change as time passes (i.e., covariationally). The solution explanation draws attention to both the concentration's direction and rate of change through specific values, initially promoting Coordination of Values. However, the solution further states, "we have to assume that the data points are close enough together that the concentration does not change wildly between them" (p. 93). This description uses the small size of the intervals to draw attention to the simultaneous and continuous nature of the coordinated change, thus promoting Continuous Covariational reasoning. Similar language that draws on small or successively smaller intervals is present in many instances of Continuous Covariational reasoning across both textbooks.

Discussion

Addressing the research question, both textbooks promote static and dynamic conceptions throughout their introductory chapters on the derivative. Therefore, they both provide at least some opportunities for students to come to understand the derivative from both static and dynamic perspectives, though their emphasis differs. *Larson* provides more instances of static conceptions and emphasizes a Correspondence approach to understanding and using the derivative to solve problems. *Hughes Hallett* provides more instances of dynamic conceptions, and this is afforded in part by its use of tabular representation interpretation.

It is important to mention that *Larson* is considered a 'traditional' textbook, and *Hughes Hallett* was written during the reform movement of Calculus education (Hughes Hallett, 2006). Though I found differences between the books, these results should not be used to characterize traditional and reform calculus textbooks more broadly. Future research could analyze additional textbooks with Tasova et al.'s (2018) framework to determine whether there are any major differences between traditional and reform textbooks' promotion of derivative conceptions in general.

Given the influence calculus textbooks can have on teachers' planning and practice (Liakos et al., 2022; Gerami et al., 2023), these results suggest the choice of textbook may influence how students ultimately learn to conceptualize the derivative. This has implications on their ability to apply their knowledge of the derivative to other contexts, such as in science and engineering fields in which a dynamic conception is more productive (Bressoud et al., 2015). Teachers should consider supplementing their textbook with materials that emphasize a more dynamic conception of the derivative as well as materials that demonstrate *why* static ideas about the derivative hold true.

Similarly, curriculum developers should consider alternative methods of fostering the dynamic conception of the derivative; the complexity of representing continuous covariation, an inherently dynamic concept, in static mediums like printed textbooks calls for work that makes the dynamic nature of the derivative more explicit and accessible to students. Recent work (e.g., Weinberg & Martin, 2020; Kertil & Dede, 2020) has begun that explore the dynamic capabilities of software, such as Desmos, for investigating and promoting the covariational reasoning of students of different ages. More work is needed to understand how these dynamic activities can be used to supplement the opportunities presented in textbooks to improve students' understanding of the derivative as dynamic.

MATHEMATICS SELF-EFFICACY IN COLLEGIATE DISCRETE MATHEMATICS

Keywords: Affect, Emotion, Beliefs, and Attitudes

Mathematics self-efficacy (MSE) is a person's belief in their ability to do mathematics, including beliefs such as "I am bad at math." MSE can impact a students' college major choice, perseverance through struggles, and their success or failure in mathematics, with research generally linking high MSE to beneficial outcomes (Gill, 2019; Hackett, 1985; Multon et al., 1991; Pintrich & de Groot, 1990). MSE exists at both a global and local level (Bandura, 1997). Global MSE includes beliefs about broad topics in mathematics, such as "I am good at Calculus." Local MSE is a narrower belief about specific tasks or single problems, such as "I am bad at proof by induction." Past research on MSE has often not been clear about the level of self-efficacy (global or local) and frequently measured only global MSE (Multon et al., 1991). This is an important limitation because students may have mismatched global and local MSE (e.g., holding high global and low local MSE). In addition, MSE has often been explored in the K – 12 population. These results may not apply to the collegiate population and particularly to discrete mathematics students, a course where researchers argue students' beliefs may change (Sandefur et al., 2022). Discrete mathematics is also often students' first introduction to the "axiomatic formal" mode of mathematics, including proof (Tall, 2008). Given the importance of self-efficacy on students' perseverance and success, more research is needed exploring both global and local MSE of discrete mathematics students.

Research Design and Analysis

This study examined the global and local MSE of collegiate discrete mathematics students, with the goal of identifying and qualitatively describing cases where global and local MSE did not align (e.g., high global but low local MSE) and the causes for that misalignment. Participants were 14 students who participated in a semi-structured interview designed to explore their beliefs. Interviews were transcribed verbatim and coded following Campbell and colleagues (2013). The two authors worked together to ensure reliability, achieving 88% coding reliability.

Findings and Implications

We identified cases of misaligned MSE in discrete mathematics; that is, students with high global MSE sometimes had lower MSE for discrete topics or problems (and vice versa). This suggests potential changes to students' beliefs may have occurred because of discrete mathematics, a result backed up by students themselves who sometimes identified the discrete course as changing either their global or local MSE. Sara for example said, "[Discrete mathematics] definitely affected me… it made me realize … there's gonna be stuff that I'm not always 100% good at going into it." Overall, these results, and other data we will share in the poster, suggest that students in discrete mathematics may have mismatched global and local MSE, and some of this mismatch may stem from the nature of the course itself. This work has implications for our understanding and measurement of students' beliefs as well as for how we, as instructors, can support students through belief changes caused by classes that introduce formal mathematical language and proof. As we envision the future of mathematics education, it is vital that we build on work like this that takes students' perspectives and beliefs into account.

Presentamos una secuencia didáctica mediada por la tecnología digital para significar y calcular las raíces reales de una función real en un curso de cálculo diferencial para estudiantes de ingeniería. Para introducir las raíces diseñamos un Escenario Didáctico Virtual Interactivo, que simula un problema real, y usamos el sistema tutorial CalcVisual para apoyar el cálculo aproximado de las raíces. Implementamos la secuencia con una población de 45 estudiantes universitarios en México. Los datos se analizaron mediante los modelos emergentes de la Educación Matemática Realista. Mostramos el progreso en la actividad matemática de los estudiantes a través de cada uno de los niveles de actividad de los modelos emergentes quienes mostraron un avance significativo en la comprensión conceptual y cálculo de las raíces reales.

Precálculo, Cálculo, Tecnología, Experimentos de diseño.

Los polinomios son funciones fundamentales en la matemática, en particular en el cálculo, análisis matemático y álgebra lineal. Una de las propiedades más importantes de una función polinómica, son sus raíces reales y complejas, pero determinarlas no es tarea sencilla e incluso en algunos casos se llega a confundir la función polinómica con la ecuación que se deriva de ella (Dede y Soybas, 2011). Significar el concepto de raíz real de una función resulta determinante por tratarse de un concepto fundamental para la matemática e imprescindible para aplicaciones en procesos de optimización, cálculo diferencial e integral, álgebra lineal, cálculo multivariable y método Simplex de programación lineal, por mencionar algunos. La determinación de las raíces simples o múltiples es un problema complejo y vigente que tiene su origen desde los primeros vestigios de la humanidad, y que siempre ha estado asociado a problemas de variación, acumulación y optimización. Hasta nuestros días se mantienen problemas abiertos sobre el cálculo de raíces, sobre todo cuando son múltiples (Cuevas y Madrid, 2013), y cobra relevancia en el problema de cómo introducir desde el plano cognitivo este concepto en la enseñanza a nivel de precálculo y cálculo (Veuillez-Mainard, 2023). Al realizar una búsqueda sistemática de la literatura podemos constatar que existen pocos artículos que reporten las dificultades de enseñanza de raíces reales, minimizando la importancia y dificultad del concepto. Es conveniente recordar que la resolución de ecuaciones polinomiales generó el álgebra (Puig y Rojano, 2004).

Tradicionalmente el cálculo aproximado de raíces reales era un tema importante que tratar en cursos de análisis numérico donde se practicaban diversos métodos como: bisección, regula falsi y Newton-Raphson para aproximarse al valor de una raíz real. Sin embargo, al popularizarse el uso de herramientas digitales con la avalancha de diversos manipuladores simbólicos virtuales, el significado y proceso bajo el cual se desarrolló permanece oculto, dejando la incertidumbre de qué es una raíz real de una función real. Esto debido a que softwares como: Mathematica, Wolfram Alpha, Matlab, GeoGebra y Photomath, resuelven ecuaciones y encuentran sus raíces en cuestión de segundos. Este reto que la tecnología digital ha puesto en la enseñanza y aprendizaje de las matemáticas permanece sin respuesta, y ha creado el paradigma de ¿qué se debe de enseñar? Cuando los estudiantes utilizan cualquier dispositivo o software para calcular el valor de una raíz real ¿sabrán que la mayoría de las veces encuentran un valor aproximado? ¿qué cuando las raíces son múltiples y cercanas pueden confundirse por errores de aproximación? ¿qué significa gráfica y numéricamente una raíz? ¿en qué se puede utilizar el concepto de raíz real, más allá de calcular su valor? Estos significados, se extraviaron al perderse los métodos de aproximación de una raíz y difícilmente se recuperarán algún día. Nos preguntamos ¿cómo recuperar los significados del concepto raíz de una función real mediante actividades mediadas por la tecnología digital? Nuestra propuesta consiste en el desarrollo y creación de actividades didácticas que permitan recuperar los significados de las raíces reales aprovechando los recursos que la tecnología digital ofrece el día de hoy como la capacidad numérica, gráfica y simbólica.

Marco teórico

Cuando un profesor frente a un grupo de estudiantes explica y anota definiciones, fórmulas y ejercicios en el pizarrón, mientras los estudiantes lo observan, escuchan y anotan en sus libretas lo expuesto por él, a esta enseñanza se le denomina enseñanza tradicional, la cual se ha desarrollado durante varios años. Para evitar este tipo de enseñanza y promover una enseñanza participativa con el objetivo de dotar de un significado a los conceptos matemáticos, Cuevas y Pluvinage (2003) proponen una serie de principios – intranet conceptual, partir de un problema en un contexto real, un plan de acción, implementación de operaciones inversas, la articulación de diversos registros de representación, la validación de resultados y la aplicación del concepto en un contexto diferente al enseñado– para la enseñanza de un concepto matemático. Usamos estos principios para el diseño de las actividades.

Los modelos emergentes son una de las tres heurísticas de diseño instruccional de la Educación Matemática Realista (RME por sus siglas en inglés). Esta heurística describe como una serie de modelos puede apoyar el avance matemático de los estudiantes (Gravemeijer, 2020). La heurística de los modelos emergentes destaca la importancia de comenzar con problemas contextuales que ofrezcan oportunidades para desarrollar un razonamiento específico de la situación y con el potencial de crear problemas cuya solución hace necesario el uso de conceptos matemáticos más sofisticados (Gravemeijer y Doorman, 1999). La actividad matemática inicia con el uso o desarrollo de un modelo derivado del contexto y, con el tiempo, este modelo apoya la aparición de formas de conocimiento matemático formal (Doorman et al., 2012). Los estudiantes transitan por distintos niveles de actividad que van desde el uso de estrategias informales hasta el razonamiento matemático formal (Gravemeijer, 1999). Los cuatro niveles propuestos por la RME son:

1. Nivel situacional (actividad en el entorno de la tarea). En este nivel las interpretaciones y

las soluciones dependen de la comprensión de cómo actuar en el entorno (fuera del entorno escolar).

2. Nivel referencial. En este nivel los modelos-de se refieren a la actividad en el entorno descrito en las tareas. En consecuencia, los modelos que surgen se basan en la comprensión de los estudiantes del entorno real y forman parte de las explicaciones en las que los estudiantes describen cómo interpretaron y resolvieron las tareas centradas en los escenarios de partida.
3. Nivel general. Este nivel comienza a surgir cuando los estudiantes empiezan a razonar sobre las relaciones matemáticas implicadas. Por lo tanto, surge cuando el razonamiento de los estudiantes pierde dependencia de las imágenes específicas de la situación. En este sentido, los modelos-para sirven más como medio de razonamiento matemático que como forma de simbolizar la actividad matemática basada en entornos particulares.
4. Nivel formal. En este nivel se trabaja con los procedimientos y notaciones convencionales. Se alcanza cuando los estudiantes ya no necesitan el apoyo de modelos para la actividad matemática.

Usamos estos niveles para mostrar el progreso en el razonamiento de los estudiantes, sobre el concepto de raíz, al trabajar con las actividades propuestas.

Metodología

Este estudio se desarrolló con base en la Investigación Basada en el Diseño (IBD) por lo que esta investigación implica iteraciones de diseño, implementación y análisis mediante las siguientes fases: preparación y diseño, experimentos de enseñanza y análisis retrospectivo (Bakker, 2018).

Fase de preparación y diseño

Se diseñó una secuencia de cinco actividades para introducir de forma gradual el concepto de raíz real (ver figura 1).

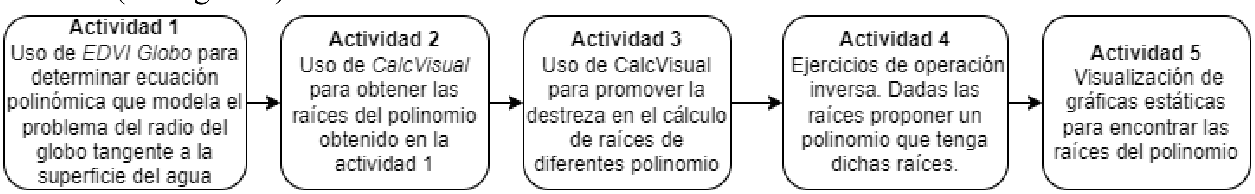

Figura 1: Secuencia didáctica

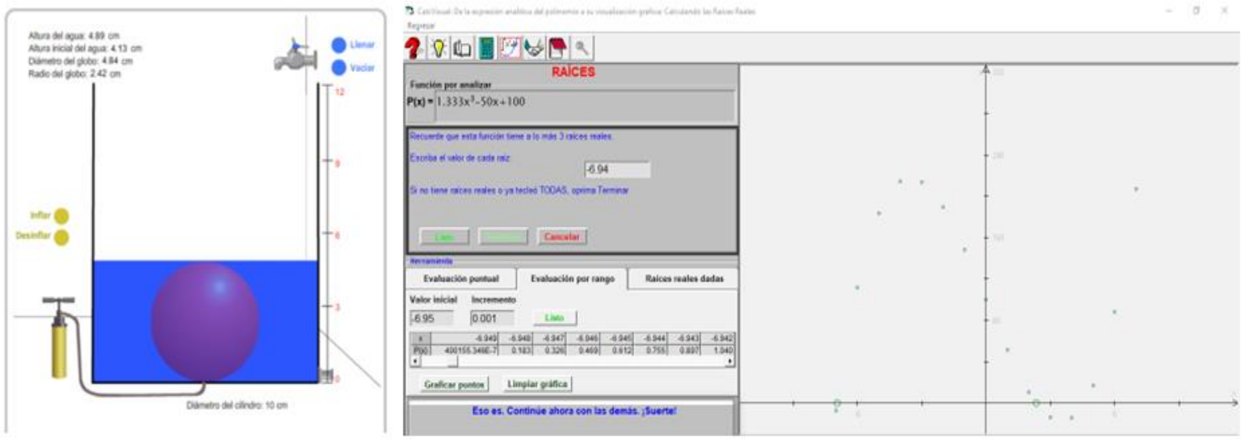
Como parte de la secuencia, se diseñó un Escenario Didáctico Virtual Interactivo (EDVI), al que denominamos EDVI "Globo" porque simula un recipiente cilíndrico de 10 cm de diámetro con un globo esférico atado al fondo. Este EDVI cuenta con botones para llenar y vaciar de agua el recipiente y botones para inflar y desinflar el globo a partir de los cuales, pueden observar cambios de forma dinámica en parámetros como: la altura inicial del agua con el globo desinflado, la altura del agua al inflar o desinflar el globo y el radio y diámetro del globo (ver figura 2a). En este artículo nos referimos a un EDVI como un manipulativo virtual que permite simular y visualizar diferentes representaciones semióticas de un problema real (Cuevas et al., 2023).



a) b)

Figura 2. a) EDVI Globo; b) Sistema Tutorial Inteligente CalcVisual

Adicionalmente, se utilizó un Sistema Tutorial Inteligente denominado CalcVisual que apoyará a los estudiantes en el cálculo de las raíces (ver figura 2b). El CalcVisual es un software que no calcula las raíces como cualquier manipulador simbólico. Permite introducir el polinomio y mediante herramientas visualizar diferentes representaciones del concepto de raíz. Por ejemplo, su representación tabular y su gráfica sobre un plano cartesiano. Es importante señalar que, CalcVisual no trabaja con funciones racionales y radicales. Asimismo, se diseñaron Hojas de Exploración y Aprendizaje Guiado (HEAG) para cada actividad, las cuales guían al estudiante en la manipulación de las herramientas digitales y en la construcción del concepto matemático.

Fase de experimento de enseñanza

La intervención didáctica se desarrolló en una universidad pública mexicana con 45 estudiantes inscritos en un curso de “Matemáticas aplicadas a la informática”. Las HEAG se enviaron de manera digital a cada estudiante y las actividades se desarrollaron en equipos de 6 integrantes. Después de resolver cada actividad, el profesor seleccionó unas HEAG al azar y realizó una discusión en clase para llegar a las respuestas correctas de forma consensuada. Las actividades fomentan tanto el aprendizaje individual como el colaborativo. Los datos se obtuvieron mediante las respuestas en las HEAG que los estudiantes enviaron al correo electrónico del profesor. Uno de los autores fue el encargado de impartir dicho curso. Los datos se analizaron de manera independiente por los investigadores. Se identificaron estrategias de solución y las respuestas de los equipos se clasificaron en los niveles de actividad (situacional, referencial, general y formal).

Resultados y análisis retrospectivo

En esta sección describimos como progresa el razonamiento de los estudiantes a través de cada uno de los niveles de actividad de los modelos emergentes al trabajar con las actividades propuestas. Debido a la limitación del documento, mostramos las respuestas de dos equipos (T1 y T2) seleccionados al azar.

Actividad Situacional

Como se ha mencionado anteriormente, la actividad situacional implica que los estudiantes trabajen en un entorno real para alcanzar objetivos matemáticos particulares. La actividad en el aula comenzó con la exploración del EDVI "Globo". Clasificamos esta actividad en el *nivel situacional* porque los estudiantes usaron las herramientas disponibles en el escenario para identificar variables, constantes y características cómo: una altura inicial del agua (h_0) con la que el diámetro del globo puede ser igual a la altura del agua (h_a). La tabla 1 muestra las respuestas de los equipos T1 y T2 a las preguntas de exploración.

Tabla 4. Preguntas y respuestas a las actividades de exploración

Pregunta	Respuesta T1	Respuesta T2
¿Qué elementos son variables al inflar el globo?	Radio del globo, volumen del contenido en el recipiente, volumen del globo.	Radio del globo, volumen del contenido en el recipiente, volumen del globo y altura inicial del agua.
¿Qué elementos son constantes al inflar el globo?	Radio del recipiente, volumen inicial de agua y altura inicial del agua.	Radio del recipiente, volumen inicial de agua.
¿Hasta qué valor puede crecer y disminuir el radio del globo (x)?	El radio puede crecer hasta 5cm y disminuir hasta 0cm	El radio puede crecer hasta 5cm y disminuir hasta 0cm.
¿Hasta que altura inicial (h_0) se puede llenar el recipiente de agua?	La altura inicial máxima es de 12 cm	La altura inicial máxima es de 5.47.
Escribe una altura inicial del agua h_0 con la que el diámetro del globo sea igual a la altura del agua h_a.	Si el recipiente se llena hasta una altura de 10cm, el diámetro se expandirá hasta los 10cm.	A una altura de 5.45

En general, los elementos constantes del EDVI son el radio del recipiente, el volumen inicial de agua y la altura inicial del agua. Sin embargo, nótese que el T2 indicó como variable la altura inicial del agua. Inferimos que dieron esta respuesta porque se trata de un parámetro que se puede modificar en el EDVI. Aunque, una vez establecido, al inflar y desinflar el globo este permanece constante. Observe también que, las respuestas a la pregunta 4 son diferentes. Ambas respuestas son correctas, ya que el T1 se enfocó en la h_0 con el globo desinflado, mientras que el T2 primero infló el globo hasta su valor máximo y posteriormente llenó el recipiente con agua. Finalmente, las respuestas a la pregunta 5 nos hacen inferir que los estudiantes confundieron la altura inicial del agua (h_0) con la altura del agua (h_a) aunque se puede observar que sí identificaron valores en los que el diámetro del globo es igual a la altura del agua.

Actividad Referencial

Tras la exploración del EDVI "Globo", la actividad en el aula continuó con el problema de identificar la ecuación polinómica que modela el volumen total del contenido del recipiente, cuando el radio del globo es tangente a la superficie del agua para identificar como solución la raíz de un polinomio. Clasificamos esta actividad como *referencial* porque los estudiantes comenzaron a establecer relaciones matemáticas en el contexto. Esta actividad se dosificó de modo que los estudiantes propusieran ecuaciones para determinar la altura del agua (h_a) en relación con el radio del globo (x), el volumen del globo (V_G), el volumen inicial del agua (V_A) y el volumen total del contenido en el recipiente (V_T). La tabla 2 muestra las ecuaciones propuestas por los equipos T1 y T2.

Tabla 5. Ecuaciones propuestas por los equipos T1 y T2 para modelar el problema del radio del globo tangente a la superficie del agua

T1	T2
$V_G = (\frac{4}{3})\pi x^3$	$V_G = (\frac{4}{3})\pi x^3$
$V_A = \pi(R^2)\, h_0$	$V_A = \pi(R^2)\, h_0$
h_a=$2x$	h_a=$h_0 - x$
$V_T = \pi(R^2)\, h_a$	$V_T = \pi R^2 h_a + V_G = \pi R^2(h_0 - x) + \frac{4}{3}\pi x^3$
$V_T(x) - V_A - V_G = 0$ Donde $V_T(x)$ es el volumen del cilindro con radio x y altura del agua h_a, V_A es el volumen inicial de agua y V_G es el volumen del globo.	$\pi R^2(h_0 - x) + \left(\frac{4}{3}\right)\pi x^3 - V_T = 0$

De las respuestas observamos que ambos equipos identificaron la relación entre el volumen total del contenido en el recipiente (V_T), el volumen sumergido del globo (V_G) y el volumen inicial del agua (V_A). Por ejemplo, los estudiantes del T1 mencionaron que “el volumen total del contenido en el recipiente es igual a la suma del volumen inicial del agua y el volumen sumergido del globo”. Además, señalaron que esta relación se podía expresar mediante la siguiente ecuación “$V_T = V_i + V_g$”. De forma similar, los estudiantes del T2 indicaron que “el volumen total del contenido del recipiente es igual a la suma del volumen inicial del agua con el volumen sumergido del globo”. Sin embargo, ningún equipo llegó a la ecuación polinómica esperada $\frac{4}{3}x^3 - 2R^2x + R^2h_0 = 0$ donde, x es el radio del globo, R es el radio del recipiente y h_0 es la altura inicial del agua. Esta ecuación se desarrolló y explicó en la discusión grupal.

Actividad General

Después de identificar la ecuación polinómica $f(x) = \frac{4}{3}x^3 - 2R^2x + R^2h_0$ que modela el problema del radio del globo tangente a la superficie del agua, se propuso a los estudiantes que usaran CalcVisual para encontrar las raíces del polinomio, con $R = 5$ y $h_0 = 4$, $f(x) = \frac{4}{3}x^3 - 50x + 100$. Clasificamos esta actividad en el *nivel general* porque los estudiantes se enfocaron en representaciones gráficas y tabulares para encontrar las raíces, sin hacer referencia al contexto del globo. Por ejemplo, el T1 respondió “Nuestra función cuenta con 3 raíces, $-6.9493, 2.3430$ y 4.6063. Esto lo conocemos gracias a que al meter la función dentro de nuestro programa graficador, este genera 3 puntos exactos”. Por su parte, el T2 mencionó “Este polinomio tiene 3 raíces, $x1 = -6.94, x2 = 2.34\ y\ x3 = 4.60$. En la gráfica podemos ver tres puntos, lo cual significa que cada uno de ellos es parte de una raíz”. Nótese cómo en ambos casos mencionan la existencia de puntos en la gráfica del polinomio, los cuales asociaron con sus raíces. Al finalizar esta actividad, pedimos a los estudiantes que validaran sus resultados respondiendo la pregunta “¿Qué raíces tiene sentido para el problema del globo?”. El T1 respondió que “las raíces positivas debido a que se no se puede tener un volumen negativo. Los valores de la segunda y tercera raíz el radio del globo es tangente a la superficie del agua". En cambio, el T2 señaló que "todas las raíces son correctas. Sin embargo, para la raíz $x3 = 4.6$ el radio del globo es tangente a la superficie del agua". Las respuestas a esta pregunta se pueden clasificar en el nivel referencial porque los estudiantes interpretaron las raíces encontradas en el problema del globo. El cambio de nivel de actividad va en acuerdo con la afirmación de Rasmussen y Blumenfeld (2007) acerca de que los niveles de actividad no imponen una jerarquía estricta. Sin embargo, es importante aclarar que esta pregunta se hizo con la intención de identificar el significado que los estudiantes estaban dando a las raíces reales en el contexto del EDVI Globo.

Actividad Formal

Después de que los estudiantes realizaron actividades con el uso de CalcVisual para encontrar las raíces de un polinomio, trabajaron con actividades de operación inversa como: "Escribe un polinomio que tenga al menos las siguientes raíces reales: $r1 = 2$ y $r2 = -5$ ¿será ese el único polinomio que tenga al menos esas raíces reales?". Las respuestas de los equipos T1 y T2 se resumen en la tabla 3.

Tabla 6. Respuestas de los equipos T1 y T2 a actividad de operación inversa

Escribe un polinomio que tenga al menos las siguientes raíces reales: $r1 = 2$ y $r2 = -5$	
Equipo T1 Respuesta: x^2+3x−10 1) Se coloca el signo opuesto de las raíces dadas. 2) Multiplicamos los factores que obtuvimos. (x−2)(x+5)= x^2+5x−2x−10 3) Expandimos el producto. $x^2 + 3x - 10$	Equipo T2 Respuesta: (x−2) y (x+5) (x−2)(x+5)= x^2+5x−2x−10 $x^2 + 3x - 10$
¿Será ese el único polinomio que tenga al menos esas raíces reales?	
No es el único polinomio que tiene al menos esas raíces porque podemos multiplicar el polinomio por cualquier otro factor lineal y obtendremos un polinomio que tenga las mismas raíces.	No, también puede ser $f(x)(x-2) = (x^3$ +3x−10)(x−2)= x^3−5x^2−4x+20

Como se puede observar en la tabla 3, los estudiantes escribieron primero los polinomios de forma factorizada y posteriormente realizaron la multiplicación de los factores para proponer un polinomio desarrollado. Clasificamos estas respuestas en el nivel formal porque los estudiantes trabajaron con procedimientos algebraicos desligados del EDVI Globo y el uso de CalcVisual.

La actividad formal también se observó en la actividad 5 que no involucraba el uso de herramientas digitales sino la visualización de gráficas estáticas como la de la figura 3. Esta actividad se diseñó como tarea final para identificar el aprendizaje que los estudiantes adquirieron sobre el concepto de raíz en un contexto distinto al del Globo.

Escala en el eje x es de 1 unidad por marca.

1. ¿Cuántas raíces reales tiene el polinomio de la gráfica?

   a) 0 b)2 c)3 d)No sé

Justifica tu respuesta

____

2. Escribe un valor aproximado para cada raíz:

____

Figura 3. Actividad de visualización de gráficas estáticas para identificar raíces

Los estudiantes iniciaron la actividad 5 en el nivel general porque para responder las preguntas de la figura 3, los estudiantes se enfocaron en identificar los puntos en los que la gráfica corta al eje x como muestran las respuestas de los equipos T1 y T2. Por ejemplo, en T1 mencionaron que "la gráfica está atravesando el cero en el eje de las x tres veces. Por lo tanto, la función de esta gráfica contiene 3 raíces: $-2, 0$ y 3". De forma similar, el T2 contestó "debes contar el número de veces que la gráfica del polinomio cruza el eje x. Esta gráfica lo cruza exactamente tres veces. Entonces, el polinomio tiene al menos tres raíces: $-2, 0$ y $+3$". Posteriormente trabajaron en el nivel formal porque representaron el polinomio mediante una factorización para llegar a su representación desarrollada.

Discusión y Conclusiones

Presentamos una secuencia de actividades que ayuda a los estudiantes a transitar de un razonamiento basado en un problema contextual a uno formal sobre el concepto de raíz. Si bien, Gravemeijer (2020) menciona que los niveles de actividad no necesariamente se observan de manera jerárquica, en nuestra investigación observamos que las actividades guiaron el razonamiento de los estudiantes sobre el concepto de raíz de forma secuencial. Es decir, la actividad 1 se trabajó en el nivel situacional y referencial, las actividades 2 y 3 en el nivel general y las actividades 4 y 5 en el nivel formal. Con lo anterior no queremos decir que los estudiantes no pueden regresar al contexto cuando trabajan en el nivel general y formal. Elegimos el contexto del Globo como un contexto con el que los estudiantes pueden significar el concepto de raíz, por ello, inferimos que se trata de una situación que perdura en la mente del estudiante.

Destacamos que, la actividad 1 con el uso del EDVI Globo fomentó el desarrollo del nivel situacional al identificar variables, parámetros y relaciones funcionales. Posteriormente, fomentó el tránsito al nivel referencial en la actividad de determinar la ecuación polinómica que modelaba el problema del radio del globo tangente a la superficie del agua. Este polinomio se usa en la actividad 2 para que los estudiantes identifiquen sus raíces, mediante el uso de CalcVisual, y les den un significado en el contexto del Globo. La actividad 3 fomentó el desarrollo del nivel general al trabajar con el CalcVisual mediante el tratamiento de funciones polinómicas fuera de cualquier contexto. Las actividades 4 y 5 fomentaron el tránsito al nivel formal al desarrollar un polinomio expresado mediante una factorización y localizar raíces en una gráfica. Los estudiantes ya no usan el EDVI Globo pero pueden usar el CalcVisual para ingresar el polinomio factorizado o desarrollado y visualizar representaciones gráficas, algebraicas y tabulares.

Una de las limitaciones de este documento es que se han presentado los resultados únicamente de dos equipos de estudiantes, aunque el análisis del nivel de actividad se ha realizado con los datos de los 45 participantes. De este análisis observamos que 30 estudiantes alcanzaron el nivel formal al trabajar con las actividades 4 y 5. Aquellos que no alcanzaron el nivel formal se debe a dificultades operativas y el uso incorrecto de procedimientos algebraicos.

Otra limitación del estudio tiene que ver con los problemas asociados a la instalación y uso de las herramientas digitales. A pesar de que se proporcionó a los estudiantes el CalcVisual para que lo instalaran en su computadora, algunos tuvieron problemas para instalarlo y no pudieron realizar las tareas en casa que necesitaban el uso de dicho software. Como solución, acudieron a otra herramienta como Wolfram, GeoGebra, etc para resolver las actividades. Aquí, el problema radica en que al usar herramientas como Wolfram los estudiantes obtienen las raíces sin saber cómo. Prueba de lo anterior es que en la retroalimentación con los estudiantes que trabajaron todas las actividades con el CalcVisual, manifestaron seguridad al resolver el examen del curso. En cambio, aquellos que utilizaron otros softwares, no sabían de dónde provenían los datos. En este sentido, el rol del profesor es importante porque debe intervenir para guiar a los estudiantes en el cumplimiento de los objetivos. En este estudio, durante la discusión en grupo, el profesor mostró a los estudiantes cómo usar el CalcVisual y discutió las desventajas de usar otro software.

Retomando nuestra pregunta de investigación ¿cómo recuperar los significados del concepto raíz de una función real mediante actividades mediadas por la tecnología digital? Sugerimos que el uso indiscriminado de la tecnología digital en la enseñanza de las matemáticas puede contribuir a la perdida de los significados y aplicaciones de los conceptos matemáticos. Por lo que recomendamos que su aplicación requiere de un cuidadoso diseño didáctico previo a su aplicación. Sugerimos iniciar la actividad en el aula con la simulación de un problema en contexto que permita a los estudiantes dar sentido al concepto matemático de interés. La simulación del problema del globo sumergido en un recipiente permitió al estudiante dotar de significado al concepto de raíz que por su propia naturaleza es abstracto. Usar un software no resolutivo como CalcVisual permite manipular diferentes representaciones de forma simultánea para establecer relaciones entre ellas, lo cual lleva a que los estudiantes adquieran significado del concepto de raíz en su representación tabular, gráfica y algebraica.

Destacamos la importancia de incluir actividades sin el uso de herramientas digitales para corroborar el aprendizaje del concepto de raíz. En este caso las herramientas digitales sirven como herramienta de verificación de resultados. Los estudiantes pueden identificar raíces de gráficas estáticas, obtener su polinomio y, posteriormente, ingresarlo en el software para comprobar los valores numéricos de las raíces. La aplicación de las HEAG es fundamental ya que guían la secuencia de actividades, contribuyendo a la comprensión del concepto de raíz de una función real.

This research explores how undergraduate students interpret mathematical symbols in new contexts when reading diverse mathematical texts across various subareas. Collaborating with experts in mathematical sciences, we collected proof-texts aligned with their specialized areas. These proof-texts were presented to undergraduate transition-to-proof students who had studied logic for mathematical proof while their experience of proofs in advanced mathematics topics was limited. Task-based interviews were conducted outside their regular classroom. This paper examined student encounters with curly bracket symbols in a graph theory context. Our findings suggest the nuanced relationship students have with symbols in proof- texts. While possessing familiarity with certain symbols, this pre-existing student knowledge could influence their accessibility to symbols introduced in unfamiliar contexts.

Keywords: Reasoning and proof, Mathematical Representations, Undergraduate Education

Introduction

Mathematical symbols serve as a fundamental language for mathematical representations, abstraction, argumentation, and communication (Cobb et al., 2000; Eckman, 2023; Harel & Kaput, 1991; Pape & Tchoshanov, 2001). Conventional symbols particularly play a crucial role in communication among individuals by representing normative meanings of mathematical ideas, formulas, and relationships (Pimm, 1995). Teachers and students can use conventional symbols to engage in a shared discourse in the mathematics classroom (Goos, 2004).

Despite the importance of symbolic representations in mathematics, numerous studies indicate that undergraduate students encounter challenges when confronted with reading mathematical expositions and proofs that include mathematical symbols (Dawkins & Zazkis, 2021; Inglis & Alcock, 2012; Shepherd & van de Sande, 2014; Weber & Mejia-Ramos, 2014). Mathematical texts often employ conventional symbols, especially those presenting theorem statements and their proofs. Moreover, advanced mathematics courses at the undergraduate level introduce new symbols for novel concepts or extend known ones in a different or broader context. Students may find these symbols challenging either because they represent newly introduced concepts or because their meanings are expanded to cover new areas. These challenges, arising from potentially unfamiliar or expanded-meaning symbols, may impact students' comprehension of the theorem statements and their proof-texts. This perspective resonates with the broader concept of 'symbol sense' discussed by Arcavi (1994, 2005), involving an individual's understanding, familiarity, and flexible use of (conventional) mathematical symbols.

In line with this standpoint, we address the following research question: *To what extent do undergraduate transition-to-proof students perceive and respond to mathematical symbols when encountering the familiar symbols in unfamiliar subareas of mathematics while reading proof-texts?* This question reflects earlier concerns about students' potential struggles in interpreting conventional symbols in proof-oriented mathematics courses. By investigating the awareness and responsiveness of undergraduate students to conventional symbols across different mathematical subareas, we aim to provide insights into the challenges students face. This study could also offer valuable implications for instructional practices and curriculum development for transition-to-proof mathematics courses.

Theoretical Framework

Our perspective on students' interpretation of conventional symbols aligns with radical constructivism, positing that symbols gain significance only when individuals attribute meanings shaped by their previous experiences (Glasersfeld, 1995). When facing a familiar symbol in an unfamiliar context, students assimilate, incorporating new information into their existing cognitive structures based on their past experiences. If assimilation proves insufficient, students engage in accommodation, adjusting their cognitive structure to integrate subtle distinctions in the meaning of the familiar symbol in the unfamiliar context. This perspective suggests that students who are not the creators of mathematical symbols may not bring the same meaning to symbols as the creator, especially when those symbols are introduced by authoritative creators, such as mathematicians, their classroom instructors, or textbook authors. In this situation, students may face challenges with what Hiebert (1988) suggested as the procedure of connecting symbols with mathematical objects or operations. Specifically, when students encounter a new conventional symbol for the first time, they may not have a connection with the mathematical objects or operations the symbol represents. Students face the challenge of deciphering the intended meaning behind conventional symbols, often without the opportunity to negotiate their meanings (Eckman & Roh, 2024). Far from indicating deficits, the interplay of assimilation and accommodation in response to these cognitive challenges serve as opportunities for deeper comprehension as students actively construct and expand the meaning of the symbols.

To comprehend students' cognitive processes of interpreting conventional mathematical symbols in proof-texts, we introduce the construct of *Symbol Sensitivity*. Symbol sensitivity involves being aware of and responding to mathematical symbols, requiring a nuanced understanding of the semantic subtleties within mathematical contexts. There are empirical studies illustrating student challenges of symbol sensitivity, where students may not be sensitive to distinguishing various mathematical symbols and, therefore, not perceive the resulting semantic differences the authors of the given mathematical expositions intend to convey through the symbols (Eckman, 2023; Roh & Lee, 2011; Sellers et al., 2017).

In contrast, this paper focuses on another critical aspect of symbol sensitivity that we will call *symbol contextual interpretation* (SCI), which is an individual's ability to perceive and interpret distinct meanings of a symbol in different contexts. In certain instances, the same mathematical symbol is employed to convey different semantic nuances across various sub-areas of mathematics. It becomes crucial for individuals to recognize and interpret these distinct meanings based on the specific context in which the symbol is used. For instance, a student may encounter the equal symbol (=) in a mathematical expression involving two functions, f and g. While the equal symbol itself is not new to the student as they have been using it between two numerical values, its usage in the symbolic expression $f = g$ may introduce a new context. In this situation, students need to be aware that the equal sign in the function context conveys a different meaning than the equality between two numerical values. However, students may not always be sensitive to these variations when encountering a familiar symbol (=) in an unfamiliar mathematical context (functions). In some ways, this parallels McGowen and Tall's (2010) notion of *met-before*. That is, meanings often change in mathematics as new contexts are encountered, and a student's *met-befores* can serve to support or hinder. McGown and Tall (2010) illustrate this with the subtraction symbol (-), which is initially associated with a "take away" meaning; however, that meaning is not conveyed in other contexts, such as when dealing with negative numbers.

This paper centers explicitly on exploring students' symbol contextual interpretation (SCI) across various areas of mathematics. By closely examining students' SCI, we aim to gain valuable insights into student challenges in reading comprehension of mathematical texts involving mathematical symbols.

Methodology

Data Collection

As part of a more extensive project (NSF DUE #2141925) focused on curriculum development for transition-to-proof courses at the undergraduate level, we created twenty-eight (28) proof-texts by collaborating with nine researchers across various mathematical sciences sub-areas. In preparation for implementing these proof-texts in a classroom, we first tested them through task-based clinical interviews (Hunting, 1997) with undergraduate students at two large public universities in the United States during the Spring of 2023. Participants were students chosen from transition-to-proof courses or proof-oriented courses to ensure students' understanding of logic for mathematical proof while maintaining limited exposure to proofs across diverse subareas in mathematics. The students are encountering diverse subareas in mathematics for the first time, with proof-texts authored by experts from these new subareas. This presents a dual challenge, as students not only face unfamiliar subareas but also grapple with challenging and novel proof-texts for the first time. We paired students whenever possible to foster meaningful interaction between students and promote dynamic discourse. Each interview extended over 90 minutes, maintaining independence from the participants' course instructors.

Interview Tasks

In each interview, we provided students with one or two proof-texts, each spanning 2-3 pages, encompassing three main components: background information (e.g., definitions, notations, and examples), the theorem statement to be proven, and a proof of the theorem. The interviews were divided into dedicated sections: background information discussion, theorem statement exploration, proof analysis, and a collective reflection post-reading.

The interviewer initiated each component by inviting students to read independently and collaboratively discuss the proof-text with their peers. Students were encouraged to pose questions and use tablets as scratch paper whenever they wanted. Subsequently, the interviewer posed targeted questions that drew inspiration from the proof comprehension assessment model developed by Mejia-Ramos et al. (2012). These questions encompassed both local and holistic comprehension questions. The former involved inquiries about the meaning of terms and statements, identification of the proof framework, and the explicit explanation of implicit warrants in the proof. The latter focused on summarizing the proof, identifying the modular structure of the proof, transferring general ideas or methods to different contexts, and providing illustrations with examples. The primary goal of the interviews was to investigate ways to support students in making sense of these new and challenging proof-texts.

Data Analysis and Results

Our analysis commenced with a thorough review of video recordings of the interview data. The primary objective of the analysis was to identify instances where students encountered challenges while engaging with reading the proof-texts. Through an exhaustive examination of the entire video dataset, we discerned persistent instances where students observed notational usage within proof-texts, akin to recognizing misuses or typographical errors in the proof-texts.

In this data analysis process, a recurrent theme emerged – several students faced similar challenges with understanding, interpreting, and using symbolic expressions in the given proof-texts. These challenges with symbols introduced in the proof-texts occurred multiple times, as exhibited in one of the universities part of the project (24 students with 14 interviews conducted), especially as students read to understand the background information such as definitions, theorems, and examples preceding a theorem to be proven and its proof. The symbols we focused on were those not unfamiliar to the students, but their appearance in unfamiliar contexts created student challenges.

In this paper, we suggest our construct, *symbol contextual interpretation* (SCI), as a type of symbol sensitivity. We use it to analyze an individual student's perception and responsiveness to distinct meanings of such symbols in varying proof-texts. We further delineated *contextual awareness* and *contextual adaptation* as characteristics of SCI. We refer to contextual awareness as an individual's awareness that a symbol can have multiple meanings in different contexts; and contextual adaptation as an individual's fluency in adapting a relevant meaning of a symbol in varying contexts. These characteristics laid the foundation for establishing three categories of student symbol sensitivity in recognizing and interpreting the same symbol's distinct meanings in different mathematics subareas. Table 1 summarizes the characteristics of each category with the number of instances where students exhibited the SCI category.

Table 1. Three Categories of Symbol Contextual Interpretation (SCI)

SCI	Contextual Awareness	Contextual Adaptation	Description	#(Instances)
SCI.0	X	X	An individual adapts only one meaning for a symbol, regardless of the various contexts in which the symbol is used, without indicating potentially different meanings.	9
SCI.1	O	X	An individual is aware that a symbol can convey different meanings in different	6

			contexts but has not developed the normative meaning in the relevant specific context.	
SCI.2	O	O	An individual is aware a symbol can convey different meanings in different contexts and exhibits fluency in adapting its normative meanings in varying contexts.	9

Results

In the rest of this section, we present an illustrative episode from an interview with Ernie and Sally. These students worked together to comprehend a theorem in graph theory, describing the condition for the degrees of the vertices of a graph that can determine the connectedness of a simple graph. As background information before the theorem statement, the proof-text introduced definitions pertinent to the theorem, such as graphs, vertices, edges, loops, parallel edges, degrees of vertices, etc. The curly brackets, {}, were also presented as symbols for the set of vertices, an edge, and the set of edges of a graph. A diagram of graph was provided as another representation, along with the symbolic expression of an example graph G, its vertex set $V(G) = \{a, b, c, d, e\}$ and edge set $E(G) = \{\{a, b\}, \{a, d\}, \{c, d\}, \{c, d\}, \{b, c\}, \{b\}\}$ (see Figure 1). The diagram illustrated five dots, labeled as $a, b, c, d,$ and e, representing five distinct vertices and 5 segments, representing 5 distinct edges of the example graph. Two of the edges connected the same vertices *c* and d, corresponding to the duplicates of two identical curly bracket symbols, $\{c, d\}$, in the edge set $E(G)$. The example graph G also included a loop, as an edge having one endpoint b, corresponding to the singleton set notation $\{b\}$, and a vertex, e, not connected to any of the other vertices of the graph.

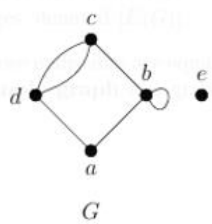
Definition. A **graph** G consists of two sets: a nonempty set $V(G)$ of **vertices** and a set $E(G)$ of **edges**, where each edge is associated with a set consisting of either one or two vertices called its **endpoints**.

Definition. Two vertices u, v are **adjacent** if $\{u, v\}$ is an edge. A vertex u and an edge e are **incident** if u is an endpoint of e. We also say that two edges are **incident** if they share an endpoint (vertex). A vertex is **isolated** if there are no edges incident to it.

Definition. The **order** of a graph is the cardinality of vertices, denoted $|V(G)|$. The **size** of a graph is the cardinality of edges, denoted $|E(G)|$.

Definition. A **loop** is an edge whose endpoints are equal. **Parallel edges** are edges having the same pair of endpoints. A **simple graph** is a graph that does not have any loops or parallel edges.

Example:
Consider the graph G below.



Graph G has vertex set $V(G) = \{a, b, c, d, e\}$ and edge set
$E(G) = \{\{a, b\}, \{a, d\}, \{c, d\}, \{c, d\}, \{b, c\}, \{b\}\}$. The order of G is $|V(G)| = 5$, and the size of G is $|E(F)| = 6$. Graph G has two parallel edges and one loop.

Figure 4 The Excerpt from the Background Information in a Graph Theory Proof-text

The curly brackets, { }, were not new to Ernie and Sally because they had already been acquainted with the symbol when the concept of a set was introduced in transition-to-proof courses that they had taken. However, the proof-text in graph theory introduced the curly brackets in an unfamiliar context to the students, i.e., graph theory. We selected this episode from an earlier moment of the interview to illustrate how Ernie and Sally perceived and responded when encountering the symbol in an unfamiliar context.

Ernie and Sally grappled with the concept of parallel edges represented in the edge set (which uses curly brackets) with repeated pairs. Specifically, unfamiliar with using this symbol to denote "parallel edges" in graph theory, these students found it challenging to interpret instances of the symbol occurring twice in the edge set $E(G)$. Ernie expressed concern about the repetition, while Sally imputed the repetition to two distinct curved segments in the diagram of the graph G, as representing distinct edges, which shared the endpoints c and d. See the transcript below for the students' utterances at the moment.

[1] Ernie: What I don't get, though, is how parallel edges work. If E [$E(G)$] is a set, right, then we can't have duplicate items [$\{c, d\}$] in a [the] set [$E(G)$].

[2] Sally: *(Grabs tablet and begins writing and speaking)* Cause maybe one of them is like pointing from *c* to *d* (*motions writing instrument counterclockwise from the top half of their imaginary circle)* and the other is *d* to *c* (*traces the lower half of the circle in the same counterclockwise direction).*

[3] Ernie: But that's not ordered pairs though (*points to notation of edges on the proof-text)*. I guess it isn't a relation like that, so we don't have a vector, right?

Ernie's SCI regarding Contextual Awareness. Ernie interpreted the letter 'E' in the symbol $E(G)$ for 'the edge set' as the name of a set and extended his understanding of the curly brackets symbol to the definitions and the given example set G (see Figure 1). Ernie was also familiar with conventional rules for using curly brackets in mathematics to denote a set, including the avoidance of repeated elements within the same set or the consideration of repeated elements as representing the same elements (e.g., $\{c, d\} = \{c, d, c\}$). This suggests that Ernie associated the curly brackets with a mathematical meaning, viewing them as a conventional symbol for denoting a set. Despite grasping the mathematical symbol, Ernie encountered difficulties when transferring his principles with the curly brackets symbol to the graph theory context. Specifically, Ernie exhibited a limited awareness regarding specific conceptual nuances within the context. This limited contextual awareness is evident through three distinct instances.

Firstly, from the video recording, we noticed that Ernie directed his attention solely toward the curly brackets symbol in the provided example graph G, while overlooking the accompanying diagram (Figure 1). He did not exhibit any utterances or gestures to establish a representational connection between the two distinct edges in the diagram of the example graph G to the edges in the duplicated symbols $\{c, d\}$ in the edge set $E(G)$. Ernie's exclusive focus on the curly brackets did not position him to leverage the diagram, which may have provided more contextual information about the meaning of the edge set. In this instance, the presence of duplicates of the same symbol in the (edge) set was a barrier to supporting Ernie's comprehension of the concept of edges, rather than aiding his understanding of parallel edges.

Secondly, in the transcript, line 1, Ernie demonstrated a non-conventional principle to the curly brackets when denoting a set. Ernie noticed that in the example graph G, the symbol "$\{c, d\}$" was repeated twice in the symbol for the edge set of G, $E(G)$, and he asserted, "we can't have duplicate items [$\{c, d\}$] in a set." Ernie's utterance indicates that the edge set notation in the proof-text did not adhere to the conventional curly bracket rules for sets in set theory that he was familiar with. He was interpreting the curly brackets in the example not within the graph theory context but rather in the context of the transition-to-proof course where the students at his university initially learned about sets. Ernie is reasonable, bringing in his prior knowledge about avoiding duplicates within set notation. It is unlikely that he had experienced this requirement as a flexible conventional practice aimed at representing unique elements in a set.

Finally, in the transcript, line 3, Ernie responded to Sally's explanation of directional notations involving vertices c and d, by noting that $\{c, d\}$ is not an ordered pair or a vector from point c to point d. This suggests that Ernie expected Sally's directional interpretation to adhere to vector notation conventions rather than the use of curly brackets symbol $\{c, d\}$. Ernie would not allow duplicating an ordered pair, vector symbol, or any symbol within a set notation.

Sally's SCI regarding Contextual Awareness. In contrast to Ernie, Sally exhibited contextual awareness when encountering the duplicates of the same symbol $\{c, d\}$ in the edge set notation. Sally's awareness of the graph theory context was evident in her consideration of both the curly brackets symbol and the diagram depicting the example graph G in Figure 1. By using both representations as resources to understand the parallel edges, she exhibited her nuanced understanding of the symbol in the graph theory context. Her remark in the transcript, line 2, accompanied by hand motions tracing each path in the diagram of the example graph G, illustrated awareness of the context by attending to the curly brackets and bracketed elements in relation to graph theory (and the diagram). Sally recognized that although both edges in the diagram share the same endpoints, they are distinct, the top edge "from c to d," and the other edge "from d to c." That is, they have directionality. Therefore, duplicating the symbol $\{c, d\}$ within the edge set $E(G)$ aligns with Ernie's rule, as each curly brackets symbol represents a distinct edge within the graph G.

Sally's SCI regarding Contextual Adaptation. While Sally demonstrated contextual awareness when encountering duplicates of the curly brackets symbol $\{c, d\}$ in the graph theory context, she exhibited potential interpretative challenges in adapting her interpretation of the symbol to a different graph theory context. Although Sally did not explicitly recognize this potential challenge, evidence of it emerged through her gestures and word choices in this episode. During her examination of the example graph G, Sally's hand motion traced two edges parallel to one another on the diagram for the graph G, attributing a distinct direction to each of them with the same pair of vertices (endpoints). In addition, she correlated these movements with the curly brackets symbols $\{c, d\}$ found in the edge set notation accompanying the diagram of graph G. Thus, Sally interpreted each instance of the symbol $\{c, d\}$ in the edge set symbol as representing a separate edge: one for the top edge and another for the bottom edge in the diagram. Sally's use of the phrase "from [c] to [d] … and from [d] to [c]" indicates that she may conceptualize edges as directed, with each edge having a specific associated direction. Sally appeared to be drawing on the same notions of set as Ernie, but perhaps adding this additional feature made the distinction between the same symbolically represented edge clear. As this is a non-normative distinction, Sally would likely need to continue to expand her contextual meaning if encountering a graph with more than two parallel edges.

A Couple More Examples While a detailed examination was conducted with two students to illustrate contrasting aspects of SCI, Table 2 provides a broader perspective by presenting concise examples across various subareas of mathematics. The table showcases instances of students with different SCI categories, each accompanied by a brief description explaining why their specific case corresponds to the identified SCI. This compilation not only enriches our understanding of SCI but also offers a valuable resource for educators and researchers seeking insights into the diverse manifestations of students' potential challenges with interpreting familiar symbols in unfamiliar mathematical contexts for the first time.

Table 2. More Examples of Students′ SCI

Student	Context	Symbol	Contextual Interpretation	SCI
Patty	Combinatorics	{ }	Perceived the notation within the context of the combinatorics proof-text and described the symbol's meaning using the objects from the combinatorial context, showing adaptivity from her previous transition to proof context to the new combinatorics context.	SCI.2
Nathan	Combinatorics	{ }	Described the use and meaning of the symbol within the contexts of a transition-to-proof course as opposed to the new combinatorics context.	SCI.1

Spencer	Topology	one-to-one	Perceived this term, a symbol, as it was used to describe functions in the context of Topology.	.2	SCI
Cade	Topology	one-to-one	Described this term, a symbol, within the context of a ratio using the symbol colon (:).	.0	SCI
Ronnie	Combinatorics	power set symbol P	Described the symbol script P as a power set as it has been denoted in transition-to-proof contexts.	.0	SCI

Conclusion and Discussion

In the results section, we delve into the challenges experienced by Ernie and Sally as they grappled with a familiar symbol encountered in an unfamiliar context for the first time. Navigating novel situations beyond their prior experiences, the students faced challenges that demanded a nuanced understanding of symbols. We analyzed the students' Symbol Contextual Interpretation (SCI) to understand their sensitivity toward symbols in these contexts. Noteworthy is the collaborative effort exhibited by Ernie and Sally in making sense of these new symbols. This collaborative success suggests the viability of incorporating such challenging proof-texts into a transition-to-proof course. For mathematics education researchers, understanding students' comprehension of notation is crucial for informing the effective implementation of proof-texts in these courses. A key insight from our study emphasizes that introducing students to new symbols extends beyond providing them with texts and definitions; it requires careful consideration of their prior experiences and explicit elucidation of how symbols may take on different meanings. This study highlights the misconception that assumes students in mathematics courses can seamlessly discard prior meanings of symbols, emphasizing the need for a thoughtful approach to incorporating notations when used in new mathematical contexts.

> To emphasize this point further, we reference a quote by Kershner and Wilcox (1950): Whenever nonbasic mathematical words are introduced, they will, of course, be explicitly defined. Whenever technical use is made of these words, the reader must carefully eliminate any preconceptions concerning their meaning and think only of their definitions. This will be difficult, but it is absolutely necessary. Unless all suggestions conveyed by these words from past associations are persistently ignored, a multiplicity of meanings may arise. Our mathematical definitions will be unambiguous and complete (p. 17).

This statement, though seemingly psychologically absurd, reflects expectations placed on students in mathematics courses. It highlights student challenges with isolating definitions from their past associations. Ernie's case exemplifies this challenge as he drew upon his prior understanding of the symbol "{ }" to interpret a new proof-text intending a different meaning. This situation underscores the importance of acknowledging the subtlety and complexity of interpreting symbols across various mathematical subareas in mathematics education literature.

ARGUMENT-MIRRORING PROOFS: A METHODOLOGICAL APPROACH FOR HELPING STUDENTS RECOGNIZE INCOHERENCE IN THEIR THINKING

Steven Ruiz
Arizona State University
slruiz3@asu.edu

This report discusses argument-mirroring proofs – proof-like texts which utilize students' own thinking to provoke perturbations to their schemes. The aim of the study was to characterize the subject's native understanding of continuity, differentiability, and the derivative, use that subjective understanding to generate argument-mirroring proofs, and examine how her thinking evolved in response to these argument-mirroring proofs. The results suggest that presenting the subject with the conflicts in their thinking directly contributed to changes in their conceptions of relationships among continuity, differentiability, and the derivative. This suggests that argument-mirroring proofs might achieve similarly profound results if applied in other contexts.

Keywords: calculus, research methods, cognition, metacognition

This paper details the way in which I developed and used *argument-mirroring proofs*, texts which formalize the subject's previously exhibited thinking about a topic to formulate and justify a claim. In a case study, argument-mirroring proofs were used on numerous occasions to encourage a student to confront and resolve potential sources of incoherence in their thinking.

Theoretical Perspective

The argument-mirroring proof method is broadly informed by constructivism (Glasersfeld, 1988), and in particular, students' *schemes*. Furthermore, I am interested in *perturbations*, instances where the expected result does not occur, and *accommodations*, adjustment(s) made by the subject to their schemes.

Coherence (Thompson, 2008) is the extent to which s student's schemes are compatible with one another. I specifically investigate the schemes which, in my conjectures, had the potential to give rise to incoherence in the subject's cognition. I used argument-mirroring proofs to evoke discordant schemes and provoke perturbation in order to encourage the participate to engage in accommodation. I henceforth refer to these schemes as *schemes targeted for conflict* because I constructed argument-mirroring proofs and other tasks in effort to cause the participant to recognize the conflict. If the participant indicates that one or more of their schemes has been perturbed, a *perceived conflict* has been triggered.

Research Methodology

Overview

The study employed a specific implementation of a constructivist teaching experiment methodology (Steffe & Thompson, 2000). In this implementation sessions alternated between clinical interviews (Clement, 2000), to glean student thinking about the mathematical ideas, and exploratory teaching interviews (Sellers, 2020), to attempt to perturb the subject using argument-mirroring proofs.

Participant and Interview Tasks

Rachel (pseudonym), the lone participant in the study, was an undergraduate mathematics education student at a large public university in the American southwest. In total, Rachel participated in six interviews, each of which lasted between 60 and 90 minutes.

The purpose of the clinical interviews was to build a baseline for Rachel's understanding of continuity, differentiability, and the derivative. I asked Rachel to consider the function $f: [0,4] \rightarrow R$ defined by $f(x) = \sqrt{k - 1 - x^2}$ given a variety of values of the constant k. For each set of parameters, she was asked to describe where the function was continuous and differentiable. She was also asked to find and interpret the value of the derivative where it was appropriate to do so. Her responses indicated her schemes at the time of the session. From these schemes, I selected those which to target for conflict during the exploratory teaching interviews.

The exploratory teaching interviews consisted of three types of tasks. First, I presented Rachel with the schemes I targeted for conflict to confirm that my model of her understanding was accurate. Next, I asked her to consider a function and discuss it in terms of continuity and differentiability. Finally, I presented her with relevant argument-mirroring proofs and asked her to determine whether the proofs were a) valid and b) representative of her thinking.

Data Analysis

Field notes and transcripts were generated from the recordings of each session. Transcripts from clinical interviews were open coded (Strauss & Corbin, 1998) to capture Rachel's schemes pertaining to the concepts. Axial coding was used to compare the schemes which were identified in open coding. In particular, I identified groups of two or more schemes which I would target for conflict in the subject's thinking if they were presented in an appropriate fashion.

Results

I focus on Rachel's schemes I subsequently targeted for conflict with argument-mirroring proofs. In so doing, I highlight moments when she perceived conflicts, adjusted her schemes, and brought greater coherence to her understanding. This discussion is limited to the first two sessions, since they best illustrate argument-mirroring proofs.

Phase 1: Initial Conceptions of Continuity and Differentiability

The first clinical interview yielded an initial state of Rachel's conceptions of continuity and differentiability as well as a set of ideas to target for conflict in the subsequent session.

Transcript 1

Interviewer: Why is the function continuous on the interval [0, 4]?

Rachel: Because it is defined on the interval.

Rachel (later): A function is continuous if the limit from the left is the same as the limit from the right.

Transcript 2

Rachel: If you had a hole in the function, you can still differentiate there.

Interviewer: If you have a hole, is the function still continuous and differentiable?

Rachel: Yes.

In the first transcript, Rachel gives two different descriptions of continuity of a function, one requiring the function to be defined and another only requiring its one-sided limits to agree. Her description of a hole in the second transcript suggests that a function may be continuous at points where it is not defined. From this session, I identified three of Rachel's schemes, shown below, which could potentially result in a perceived conflict.

a) If f is defined at a, f is continuous at a.
b) If $\lim_{x \to a^+} f(x) = \lim_{x \to a^-} f(x)$, then f is continuous at a.
c) Although f is not defined where $x = a$, if $\lim_{x \to a} f(x)$ exists, f is continuous at a.

Items (a) and (b) are indicated by Rachel's responses in transcripts 1 and 2, respectively. Her assertion in transcript 2 that a hole may not preclude differentiability suggests item (c). Since (a) and (b) offer non-equivalent definitions of continuity, I conjectured that targeting these schemes simultaneously would result in a perceived conflict.

Phase 2: Provoking Conflicts among Initial Conceptions of Continuity and Differentiability

When I presented Rachel with items (a)-(c), she agreed that they were representative of the ways she understood continuity and differentiability but indicated no conflict between them. Next, I presented her with the following graph of a function (Figure 1) and asked her to determine where it was continuous, in hopes of triggering a conflict between items (a), (b), and (c) from phase 1.

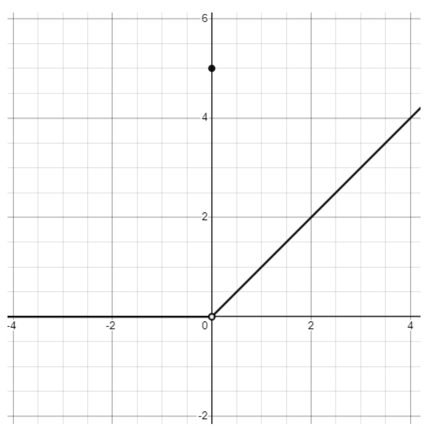

Figure 1: Graph from Task in Phase 2

Claim: f is continuous at $x = 0$.
Proof:
- $\lim_{x \to 0^+} f(x) = 0$
- $\lim_{x \to 0^-} f(x) = 0$
- Since the one-sided limits agree, $\lim_{x \to 0} f(x) = 0$.
- Therefore, f is continuous at $x = 0$.

Claim: f is continuous at $x = 0$.
Proof:
- From the graph, we see that $f(0) = 5$.
- Since f is defined at $x = 0$, f is continuous at $x = 0$.

Figure 2: Argument-Mirroring Proofs from Phase 2

The excerpt below illustrates her perception of the conflict when evaluating the left argument-mirroring proof from Figure 2.

> *Interviewer:* Is the claim [that f is continuous at $x = 0$] correct?
> *Rachel*: I would be inconsistent to deny this.
> *Interviewer:* Is it a problem that the proof doesn't talk about [the point] (0, 5)?
> *Rachel:* It seems like it might be pertinent since the claim centers around $x = 0$…But I can't decide why I think that matters.

Considering the argument-mirroring proof was when Rachel first perceived a conflict. Her certainty that f was continuous at $x = 0$ began to waver during the above excerpt. By the end of the session, Rachel stated that a function is continuous at a point if the value of the function at the point is equal to the limit of the function at the point. As such, I represent the transformation in her schemes below (Figure 3). She accommodated her schemes by striking scheme (c) from her conception and combining the hypotheses from the schemes (a) and (b) to yield a new, unified scheme. After perceiving and resolving the conflict, her conception of continuity became more coherent because it was less susceptible to conflicts.

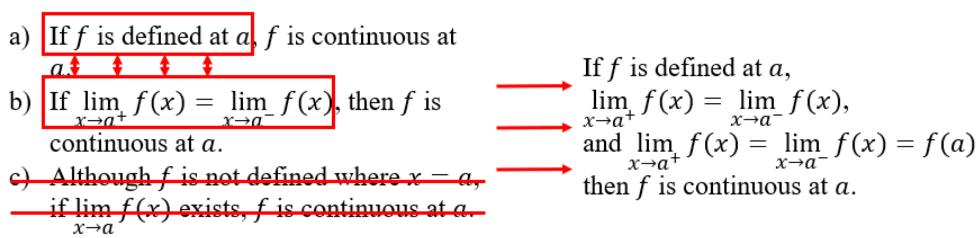

Figure 3: Argument-Mirroring Proofs from Phase 2

Discussion and Conclusion

Rachel's responses to the tasks indicated that her understanding regarding continuity was deeply incoherent. The clinical interviews provided baselines of her understanding. Recall that she affirmed the schemes I presented to her as an accurate initial portrayal of her thinking. The review of the identified schemes, directed tasks, and argument-mirroring proofs in these sessions were designed to trigger perceived conflicts. The argument-mirroring proofs were effective in making the conflicts evident to Rachel. In every occurrence, when Rachel perceived a conflict between her schemes, she immediately worked to resolve it. In the language of Glasersfeld (1988), she responded to the perturbation of a scheme (its inconsistency with some other scheme) by accommodating it (adjusting one or more schemes). Worth noting is that Rachel was never explicitly instructed to resolve any perceived conflicts. When she reconciled her schemes for continuity, her thinking became more coherent (Thompson, 2008). Considering the argument-mirroring proofs was instrumental in illuminating the conflicts in Rachel's thinking. The method of argument-mirroring proofs warrants further investigation with additional participants in different mathematical contexts.

Methodologically speaking, the effectiveness of argument-mirroring proofs as the cornerstone of a teaching experiment (Steffe & Thompson, 200) to trigger Rachel's perception of a conflict was profound. While teaching experiments are common, my protracted execution allows for the argument-mirroring proofs and other activities to be carefully tailored to the participant. This method represents a novel contribution to the field. As such, whether this method yields similar effectiveness with different participants in future studies warrants further investigation.

EXPLORING THE USE OF HISTORICAL CONTEXTS IN TEACHING LOGARITHMS

Winston Martey
SUNY - University at Buffalo
wnmartey@buffalo.edu

Ji-Won Son
The State University of New York at Buffalo
jiwonson@buffalo.edu

This study investigated the effectiveness of integrating history-infused lessons on students' understanding and attitudes towards logarithms. The theoretical framework drew from sociocultural perspectives and embodied cognition, emphasizing the social and emotional dimensions of learning. Design-based research principles guided the iterative development of history-infused logarithm lessons. Data was collected through pre- and post-assessment tests, interviews, and classroom observations. The findings indicated a significant improvement in students' post-test scores, suggesting a reduction in their fear of logarithms. Additionally, interviews revealed a positive shift in students' perceptions of logarithms, from abstract and intimidating to practical and relatable.

Keywords: History-infused mathematics, logarithms, secondary mathematics education, student attitudes

The research literature emphasizes the importance of logarithms in both advanced mathematics and real-world contexts, including sound measurements (decibels), earthquake magnitudes (Richter scale), star brightness, and chemical properties (pH balance). However, many students struggle to grasp the conceptual underpinnings of logarithms and often resort to rote memorization of rules, as noted by various authors (Berezovski, T., 2008; Kuper & Carlson, 2020; Weber, 2016). The challenges faced by students include interpreting logarithms as the "inverse of exponents" and developing a coherent understanding of logarithmic notation, logarithm properties, and the application of logarithmic functions (Kuper & Carlson, 2020; Berezovski, T., 2008; Chua & Wood, 2005; Gol Tabaghi, 2007; Strom, 2006).

To address these issues, researchers and educators have suggested a variety of strategies. These include using concrete materials (Thompson, 1994), implementing authentic assessments such as project-based learning and computational thinking (Shin et al., 2021), engaging students with game-based learning (Barab et al., 2010), problem-based learning (Hmelo-Silver, 2004), and effective teaching methods (Larmer, 2018). The use of gestures alongside diagrams (Walsh & Hord, 2019), gestures combined with manipulatives (Beilstein, 2019), and incorporating the history of mathematics (Liu, 2003; Poh & Dindyal, 2016; Sampaio & Batista, 2018) have also been recommended. This study aims to bridge the gap in research regarding the teaching of logarithms by utilizing the history of mathematics in combination with gestures. The research questions guiding this study are as follows: (1) How do history-infused logarithm lessons aid in reducing students' fear of logarithms? (2) How do students' perceptions of logarithms change over the duration of the history-infused logarithm program?

Theoretical Framework

This study was grounded in sociocultural perspectives for student learning, a history-infused program, and embodied cognition for evaluating understanding. It focused on social constructivism, which emphasized the role of social interaction in cognitive development and suggested that learning occurred best in a social context. The study also incorporated the dynamic nature of assessment, including formative, diagnostic, prognostic, or summative assessment. Vygotsky's sociocultural perspective underscored the extensive impact of social learning, suggesting that learners did not engage with new knowledge in isolation. Key instructional aspects in Vygotsky's perspective were mediation, scaffolding, and creating a zone of proximal development (ZPD). Building on this, the instructional technique in the history-infused math lessons involved exploratory activities and mediational strategies, including scaffolding based on prior knowledge. This study also emphasized embodied cognition, focusing on how humans used their bodies to express thought processes, like gestures. Students' multimodal approaches, such as gestures, were coded and compiled based on McNeill's typological categories (1992), allowing for a holistic approach to teaching and learning logarithms

Methods

Participants, Settings, and Programs

The study took a holistic approach, incorporating both quantitative and qualitative data collection methods to assess the effectiveness of integrating historical insights into logarithm teaching. This approach was underpinned by design-based research (DBR) principles, enabling iterative refinement of teaching strategies based on observed student interactions and outcomes. The study took place at a private high school in Western New York, United States, with a student-teacher ratio of 12:1. The focus was on 14 students (10 girls and four boys) in Grades 11 and 12, all of whom had prior exposure to logarithms in their mathematics courses.

The curriculum, based on the Precalculus with Limits: A Graphing Approach by Ron Larson (High School Edition, 6th Edition), was adapted to incorporate historical insights into the discovery of logarithms. The goal of the first phase was to develop an initial design of the program, which consisted of three history-infused math lessons. These lessons were developed by integrating the history of logarithms, allowing students to explore historical perspectives on the discovery of logarithms by John Napier, and other mathematicians (e.g., Pythagoras), tailoring students' participation in peer collaboration through the lens of history of mathematics, and improving learner engagement in the instructional process in the form of mini projects on history-infused mathematics. Students were asked to use log tables and watch a video of the process. Students also explored the history of mathematics related to logarithms and did a presentation. In the second phase, the program underwent iterative design to test and refine it. This second iteration, to be conducted in the spring of 2023, involved designing three history-infused modules, each consisting of three lessons with scenario-based problems (e.g., Scenario-based Log) and historical approaches (e.g., Using Log Tables). The historical accounts of the discovery of logarithms will be introduced from existing sources, highlighting how logarithm computations were performed before calculators.

Data Collection and Analysis

Data collection involved pre- and post-assessment tests, interviews, observations, and analysis of classroom artifacts. Pretests assessed students' baseline knowledge, while post-tests measured their understanding after the history-infused lessons. Interviews and observations offered qualitative insights into student engagement, attitudes, and understanding. The study was conducted over two weeks, covering initial assessment, implementation of the history-infused program, and subsequent assessment and interviews. Data analysis was conducted using a mixed-method approach, combining quantitative and qualitative methods. For quantitative analysis, descriptive statistics were computed to compare pretest and posttest scores, and the Wilcoxon Signed-Rank Test was used for inferential analysis to assess the effectiveness of the history-infused lessons. Error analysis of participants' written responses was also conducted. For qualitative analysis, interviews were transcribed using the ELAN annotation tool, and thematic analysis was conducted. Open-coding was done using ATLAS.ti software to categorize data from surveys and interviews. Additionally, gestural analysis was conducted, categorizing gestures based on McNeill's framework, and disagreements between coders were resolved through consensus. The general inductive approach was employed to analyze qualitative data, systematically organizing and summarizing textual data.

Summary of Findings

Analysis of pre- and post-test showed that students' average scores in the posttest (M = 76.2, SD = 17.4) were significantly higher than their average scores in the pretest (M = 50.2, SD = 21.1).

How History-Infused Logarithm Lessons Alleviate Students' Fear of Logarithms:

The analysis of pre- and post-test scores shows that the history-infused logarithm program led to a statistically significant improvement in students' understanding of logarithms. This finding is particularly noteworthy considering the pre-existing fear and apprehension that many students typically harbor towards this complex mathematical concept. Interviews with students provided deeper insights into the impact of history-infused lessons on students' emotional engagement and attitudes towards logarithms. A majority of students expressed that the historical context provided in the lessons made logarithms seem more accessible, relatable, and less intimidating. Many students indicated that understanding the origins and evolution of logarithms gave them a sense of connection to the subject, and a better appreciation for its practical significance. Student L7 articulated this sentiment, saying, "It helped me understand it better because I can be more appreciative of the mathematicians back in the day and it gets me more interested in math, so I will be motivated to learn more about the concepts knowing the philosophers that contributed to it." Incorporating historical narratives and activities into the logarithm curriculum served as a cognitive scaffold for students, allowing them to contextualize complex mathematical concepts within a narrative framework. Students appreciated the opportunity to engage with mathematical ideas in a more holistic and multidimensional manner. Furthermore, the interactive and collaborative nature of the history-infused lessons encouraged students to approach learning logarithms with a sense of curiosity and adventure, rather than fear and reluctance.

Shifts in Students' Perceptions of Logarithms Through History-Infused Logarithm Program:

Through the history-infused logarithm program, students' perceptions of logarithms underwent a noticeable shift. Before the intervention, students primarily viewed logarithms as abstract and disconnected from real-world contexts. They often perceived logarithms as challenging, even forbidding, due to the complex nature of mathematical manipulations involved. The pretest data showed that students had a limited understanding of logarithmic properties and frequently made errors in their application. Common mistakes included misinterpreted language errors and logically invalid inference errors, suggesting that students' conceptual grasp of logarithms was limited. However, post-test data revealed a marked improvement in students' perception of logarithms. Students began to view logarithms as a valuable tool with practical applications, particularly in the context of historical problem-solving. They expressed newfound confidence in their ability to tackle logarithmic calculations and demonstrated a clearer understanding of logarithmic properties and their applications. This shift in perception can be attributed to the rich historical narratives that were integrated into the program, which allowed students to see logarithms as a dynamic and evolving mathematical concept with a rich cultural and historical significance. Students began to appreciate the versatility of logarithms and how they are rooted in the history of human endeavor.

Discussion

The findings of this study echo the conclusions of previous research and contribute to our understanding of the potential benefits of incorporating history into mathematics education. Previous studies have demonstrated that history-infused mathematics lessons can lead to improvements in students' conceptual understanding and engagement (Alibali & Nathan, 2012; Berezovski, 2008; Howell et al., 2017). The findings of the current study extend this research by focusing on students' emotional responses to history-infused lessons and their impact on attitudes towards mathematics. The theoretical implications of this study align with cognitive theories such as Vygotsky's sociocultural theory of learning and Hmelo-Silver's Problem-based Learning (PBL) theory (Kozulin et al., 2003; Hmelo-Silver, 2004). Vygotsky's theory emphasizes the role of social interaction and cultural context in shaping learning, suggesting that the historical narratives embedded in history-infused lessons can provide students with meaningful cultural tools that facilitate learning. Hmelo-Silver's PBL theory focuses on the importance of problem-solving and authentic, real-world tasks in promoting deep understanding. The historical context provided in history-infused lessons can serve as a rich source of problems and tasks that are relevant and engaging for students. From a practical perspective, the findings of this study suggest that incorporating historical contexts into mathematics instruction can have a positive impact on students' attitudes and engagement. By presenting mathematical concepts in a historical context, educators can make abstract concepts more concrete and meaningful for students, leading to increased motivation and interest. Additionally, the emotional engagement fostered by history-infused lessons can help to alleviate students' fear and anxiety about mathematics, creating a more positive and supportive learning environment.

The limitations of this study should be acknowledged. The study was conducted at a single high school, limiting the generalizability of the findings. Additionally, the study focused on a specific topic within mathematics (logarithms), and the findings may not apply to other mathematical concepts. Future research could explore the impact of history-infused lessons on a wider range of mathematical topics and in different educational contexts. Moreover, future studies could investigate the long-term effects of history-infused lessons on students' attitudes and engagement, as well as the role of technology in enhancing the effectiveness of these lessons.

CONJECTURNING THE DIVERGENCE TEST FOR SERIES: "MAYBE THEY ONLY WIN IF THEY CONVERGE TO ZERO"

Kristen Vroom
Michigan State University
vroom@msu.edu

Catherine Davis
Michigan State University
davis555@msu.edu

Series are a key part of the calculus curriculum and warrant more research on how students can be supported in using their informal intuitions to conjecture about series convergence. We conducted a teaching experiment with a pair of post-Calculus I students, during which they reinvented claims related to the divergence test using a context problem that we call the Partial Sum Sequence Game. We investigated how the students' collective argumentation for these claims emerged and evolved throughout the sessions.

Keywords: Undergraduate Education, Calculus, Reasoning and Proof

Series convergence is a key part of the calculus curriculum and has applications in computer science, physics, and other disciplines (Earls, 2022). Martínez-Planell et al. (2012) suggest that it is constructive to view series as sequences of partial sums, but this view is challenging for students, and they find it difficult to recognize the connection between sequences and series. This disconnect might explain how students can use informal intuitions to make sense of sequence convergence (Oehrtman, 2009) but might have "mechanical views" of when series converge (Kung & Speer, 2013, p. 428). Rather than viewing series as sequences of partial sums, students sometimes view series as a list of values (Martínez-Planell et al., 2012, Przenioslo, 2006) or as a running total that sums various numbers of summands without coordinating the sum with index values (Eckman & Roh, 2022). These interpretations can support the idea that summands tending towards zero implies the running total will eventually stabilize (Eckman & Roh, 2022).

Textbooks and instruction often introduce series in an algorithmic, decontextualized, and formal way (González-Martín, 2010). We join other scholars who advocate for more innovative approaches (González-Martín, 2010; Morrel, 1992). Scholars have started to take some important first steps in this direction including investigating how students can construct a formal $\varepsilon - N$ definition of series convergence (Martin et al., 2011), create algebraic representations for arbitrary partial sums and infinite series (Eckman & Roh, 2024), and conjecture the comparison test for convergence (Davis & Vroom, 2024). We add to this work by investigating: *How did two undergraduate students reinvent claims related to the divergence test?* Specifically, we investigated how two undergraduates' collective argumentation for two claims emerged and evolved throughout a teaching experiment. These two claims are equivalent to the divergence test and the converse of the divergence test is false.

Theoretical Support

Realistic Mathematics Education's guided reinvention heuristic (Freudenthal, 2005; Gravemeijer, 1999; Gravemeijer & Doorman, 1999) framed the instruction during the experiment (similar to Lockwood & Purdy, 2019). This instruction aimed to support "a process by which students formalize their informal understandings and intuitions" (Gravemeijer et al., 2000, p. 237). A key component to guided reinvention is a context problem in which the problem situation is experientially real to students and evokes students' informal understandings and intuitions about the concepts they reinvent (Gravemeijer & Doorman, 1999).

To investigate how the students' informal intuitions related to the divergence test developed, we studied how their collective argumentation for their related conjectures emerged and evolved throughout the sessions. By collective argumentation, we mean instances when students and/or the teacher-researcher made mathematical claims with evidence that supported them (Conner et al., 2014). Like other scholars investigating collective argumentation (Alzaga Elizondo, 2022; Andrews-Larson et al., 2019; Conner et al., 2014), we adapted Toulmin's (2003) model of argumentation. Toulmin's model dissects arguments with (at least) a combination of *claims* (conjectures being justified), *data* (evidence that supports the claims), and *warrants* (connections between the data and claims). Our adaptation of Toulmin's model included attention to student and teacher-researcher contributions and the possibility of more inter-connected argument arrangements such as sub-arguments. Students' collective argumentation includes but is not limited to valid mathematical proofs (Krummheuer, 1995), and we do not view other forms of argumentation as subordinate to valid proofs.

Methods

Our data comes from a teaching experiment (Steffe & Thompson, 2000) with two first-year undergraduate students Lara and Stella (pseudonyms), a teacher-researcher (the first author), and an observer. We recruited the students from their Calculus I course where Lara earned a 2.5 (on a 4.0 scale) scale and Stella earned a 4.0. Lara was majoring in biological chemistry and Stella double-majoring in psychology and neurosciences. The experiment was eleven 1.5-hour sessions, with the last four focusing on exploring series. We audio and video recorded the sessions, including a synced recording of the students' collaborative digital work and gestures.

The students' exploration of series began with a context problem (Gravemeijer & Doorman, 1999) after students had classified various sequences based on their properties like convergent and increasing (Vroom et al., 2024). The context problem was posed as a game featured in Figure 1. Playing the game involves considering sequences of partial sums (what Lara and Stella called "total distance sequences"). A player wins the game if and only if the sequence of partial sums converges. For instance, $\{n^2\}$ loses the game because it generates a divergent sequence of partial sums. The game paired with the instruction supported a "running total" meaning like Eckman and Roh's (2022) participants with one key difference being that Lara and Stella coordinated the running total with the index (days). The students played the game with several sequences of their choice. As they did so, they voiced predictions about sequences and their properties winning or losing the game. Afterward, the students were tasked to write a "cheat sheet" for the game in which they gave future game players advice about sequences that won or lost the game, as well as wrote some insightful warnings.

Game:
We are conducting an experiment in which we move an object a certain number of feet north per day. A sequence $\{x_n\}$ will tell us how many feet x_n to move the object north on any given day n. To win the game, accurately predict the object's location if the experiment continues indefinitely!

Playing the game with $\{n^2\}$:

n	1	2	3	4	5	…
n^2	1	4	9	16	25	…
Total distance from starting point	1	5	14	30	55	…

$\{n^2\}$ <u>loses</u> the game since we cannot accurately predict the object's location

Figure 1. Partial Sum Sequence Game

Some of the statements on the cheat sheet resembled the divergence test in the game context ("if the original [sequence] converges to any number except 0, the total distance [sequence] will diverge") and the falsehood of its converse ("not all sequences that converge to 0 will win"). We investigated how the students' collective argumentation for these claims emerged and evolved throughout the sessions. We began the retrospective data analysis by re-watching video and re-reading the corresponding transcripts, identifying key episodes that featured the students discussing ideas seemingly relevant to their statements on their "cheat sheet." With these key episodes, we then applied Toulmin's model of argumentation, first identifying claims (C), then data (D) and warrants (W), as well as any other contextual comments that seemed relevant and not captured by the codes. As we did so, we compared new C-D-W to previous ones, noting any connections. Like Conner (2008), we noted who contributed (students, the teacher-researcher, or a combination), and if the warrant was our interpretation of what was implicit in the data. We created Figure 2 through this process, where the symbols ⬚, ▭, ☁, and ➡, respectively denote that student(s) primarily contributed, both student(s) and teacher-researcher contributed, implicit warrant, and a revised claim.

Results

We next present part of the students' conjecturing activity for claims related to the divergence test, focusing on a few key episodes throughout several teaching sessions. Prior to what we will share, Lara and Stella played the game with $\left\{\frac{1}{2^n}\right\}$, which they argued won because "the values [we] are adding on, keep getting smaller, and our total is approaching one." They also claimed that sequences with the "same kind of shape" such as $\left\{\frac{1}{n}\right\}$ and $\left\{\frac{1}{n^2}\right\}$ would also win. Figure 2 summarizes the students' collective argumentation that we will share next.

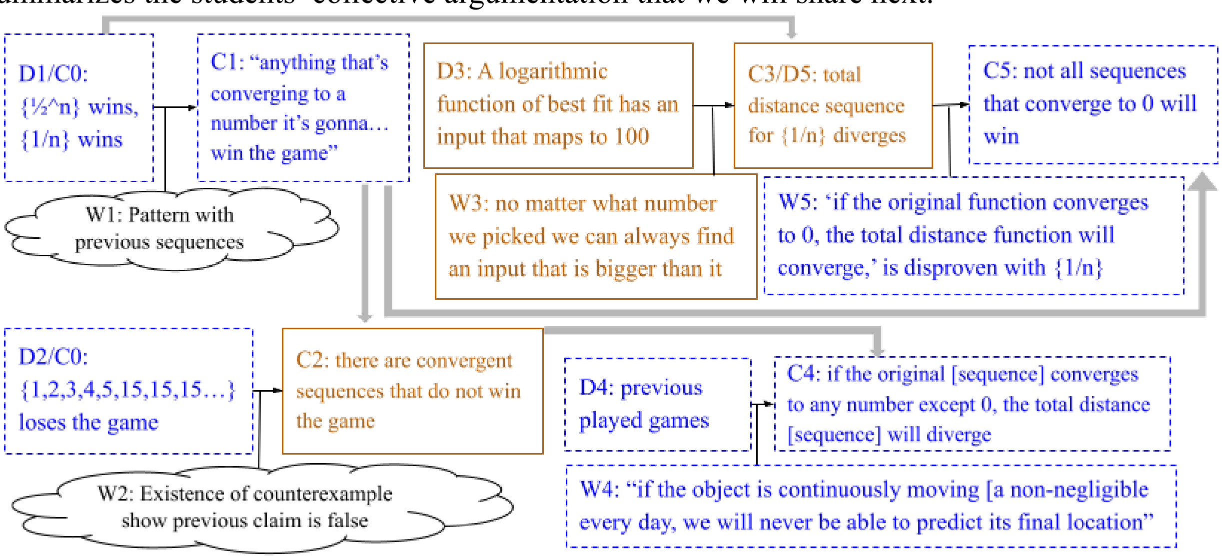

Figure 2. Summary of students' collective argumentation.

After the teacher-researcher asked if they had predictions about types of sequences that would win the game, Lara responded, "anything that's converging to a number it's gonna…win the game" (C1) using the previous claims about sequences that won the game as their evidence

(D1) since this pattern held for them in these cases (W1). The teacher-researcher then asked if they had a converging sequence that would lose the game. Stella pointed to the sequence $\{1,2,3,4,5,15,15,15,\ldots\}$ recalling that they previously "didn't think this one would win" (D2) and the teacher-researcher added, "so we can say that's not always the case" (C2).

Later the students used Desmos to view the first thousand terms of $\left\{\frac{1}{n}\right\}$'s total distance sequence. They started questioning their previous claim that the sequence would win the game (C0). After Stella expressed desire to understand the total distance sequence "pattern," the teacher-researcher supported the students to find a logarithmic function that fit the first thousand terms. The students observed the logarithmic graph, noticing "it's increasing by less" and questioned whether the logarithmic function converged. The teacher-researcher then asked if they would be convinced that it diverged if the function surpassed a certain number. In response, the students set the equation equal to 100 and solved, finding a solution (D3). Lara then responded, "it diverges" (C3). The teacher-researcher questioned, "Do you think no matter what number, y-value, we picked we could always find an x that [maps to something] bigger than that y-value?" The students both responded "yes" (W3) referencing the generality of their algebraic work, and Lara added, "I wish we couldn't… it would make more sense if $\left\{\frac{1}{n}\right\}$ matched $\left\{\frac{1}{n^2}\right\}$."

The students later returned to writing their cheat sheet, discussing a previous claim they revised (C1). Then, they considered sequences to see if a winning sequence converged to a non-zero value. After their unsuccessful search (D4), Stella proposed, "maybe they only win if they converge to 0." She later explained, "if the object is continuously moving every day, we will never be able to predict its final location." After the teacher-researcher highlighted that $\left\{\frac{1}{n^2}\right\}$ required them to move the object every day, Stella clarified that it needed to move "a non-negligible amount" (W4). This resulted in the students writing: "if the original [sequence] converges to any number except 0, the total distance [sequence] will diverge" (C4).

The students continued to discuss how $\left\{\frac{1}{n}\right\}$ converging to 0 meant that "we are moving the object a negligible amount" each day; however, the total distance sequence diverged (D5). Stella explained this was, "not a problem with what we have written [C4]… though it makes it less helpful and more confusing" and elaborated: "if we had written the statement as 'if the original function converges to 0, the total distance function will converge,' it would be disproven by the $\left\{\frac{1}{n}\right\}$ example. [C4] says nothing about functions that do converge to 0, which means $\left\{\frac{1}{n}\right\}$ is not applicable here" (W5). The teacher-researcher suggested that they use this information to write a warning, which the students wrote as: "not all sequences that converge to 0 will win" (C5).

Discussion

Lara and Stella's reinvention of claims related to the divergence test was rooted in their experience with the Partial Sum Sequence Game. Their experiences playing the game with various sequences supported them to revise C1 ("anything that's converging to a number it's gonna…win the game") to C4 (equivalent to the divergent test) and C5 (equivalent to claiming the converse of the divergence test is false). The game with $\{1,2,3,4,5,15,15,15,15\ldots\}$ was important for the students to recognize that convergent sequences could lose (C2). The game with $\left\{\frac{1}{n^2}\right\}$ and $\left\{\frac{1}{n}\right\}$ was also important as they provided evidence that converging to 0 was necessary (C4) but insufficient (C5) for winning the game. We note that although the students claimed that $\left\{\frac{1}{n}\right\}$ lost the game (C3), they were still grappling with why beyond relying on a graph (in a similar way that Eckman and Roh's (2022) participants believed that decreasing summands converge). In our future work, we hope to further support students in this way.

As we continue to analyze our data, we aim to understand a fuller story of how all the students' claims on their cheat sheet emerged and evolved together. For instance, the data we presented here also gives some insight into how the students reinvented claims related to *p*-series convergence/divergence as well as the comparison test (Davis & Vroom, 2024). We plan to expand our analysis to explore further how the students' collective argumentation for their claims related to series tests for convergence emerged and evolved throughout the sessions.

Individuals' quantitative and covariational reasoning form a critical foundation for their construction of STEM concepts and their ability to make critical, data-informed decisions (Karagöz Akar et al., 2022; Yoon et al., 2021). Graphs form a linchpin representation for quantitative and covariational reasoning (Moore et al., 2022). Moore and Thompson (Moore, 2021; Moore & Thompson, 2015) introduced *static* and *emergent* (*graphical*) *shape thinking* to distinguish between students' ways of reasoning for graphs. They described emergent shape thinking to involve understanding a graph as both the process by which it is made (coordinating quantities' covariation) and the product that is made (a trace of that covariation). A student who reasons about a graph emergently can imagine the reconstruction of a graph as a trace in progress, where the trace records the values of the two covarying quantities at different moments. Static shape thinking involves conceiving a graph as an object in and of itself, imagining the graph to be a piece of wire with particular perceptual characteristics (Moore & Thompson, 2015). Static shape thinking involves indexical associations between particular shapes of graphs and learned facts, and thus can imply properties about relationships that those graphs represent. Those relationship properties are not organic to the graph's emergence (Moore, 2021).

Eye-tracking technology is a tool whose use has grown in the past decade, and it has recently shown promise as a tool to gain insights into the phenomenon of the teaching and learning of mathematics (e.g., Brunner et al., 2024; Seidel et al., 2021; Haataja et al., 2021; Roy et al., 2017). Providing inspiration for the presently proposed approach, both Thomaneck et al. (2022) and Waters (2019) used eye-tracking to investigate participants' covariational reasoning in the context of graphing, with Waters and colleagues drawing on the constructs of static and emergent shape thinking as well. Extending this work, we pair eye-tracking technology with the generalized models of static and emergent shape thinking to address the following research questions: *(a) In what ways are eye movement patterns related to students' graphing meanings? (b) In what ways can the use of eye-tracking technology complement current methodologies (e.g., teaching experiments) for exploring and supporting students' graphing meanings?* We are currently designing and conducting interviews to compare eye movement patterns between instances when participants are reasoning statically versus emergently. If the eye movement patterns associated with particular ways of reasoning are understood to some confidence, then eye-tracking data could be used as evidence for (or as a contraindication of) hypothesized meanings. We also envision eye-tracking technologies as contributing to innovative interventions during a teaching experiment. For example, a researcher might show participants videos from their own teaching sessions. Rather than asking them to solely recall their previous thinking as in stimulated recall interviews, researchers could prompt them to discuss how they might have been thinking during the task and how that relates to any observations they make regarding their attentional focus. We envision such an intervention could prompt rounds of focused reflection, which is critical to mathematical development (Ellis et al., 2024). In our poster, we focus on our methodological design and our preliminary findings, and provide examples of eye movement patterns consistent with both static and emergent shape thinking.

This study investigates the interrelationship between emotion and learning in a college precalculus lesson that examined lead poisoning in participants' local community. Through a thematic analysis of students' responses to lead poisoning lessons, the study reveals a range of emotional responses, including empathy, concern, and heightened awareness of social issues. The findings underscore the critical role of emotions in deepening student engagement and commitment to social change, emphasizing the importance of incorporating social justice themes into the precalculus curriculum to foster a more engaged and empathetic student body.

Keywords: Affect, Emotion, Beliefs, and Attitudes, Precalculus, Social Justice, Undergraduate Education

The call to change mathematics instruction in high school and college classrooms has been ongoing (see Bartell, 2013; Gutierrez, 2002; Gutstein, 2003, 2006; Guzmán & Craig, 2019) with arguments from mathematics education researchers for a need to change mathematics instruction from conventional procedural practice to focus more on understanding the world and social issues (Gonzalez, 2009; Wright, 2016). Recent research in the field suggests that students are increasingly engaged in mathematics lessons contextualizing issues of injustices in society (Gutstein & Peterson, 2013; Voss & Rickards, 2016). We imagine the future of mathematics education to lean toward contextualizing students' local environments to make mathematics more relatable to students. In addition to the theoretical arguments and empirical claims in favor of teaching mathematics by contextualizing social injustices, students experience various emotions when they learn about societal inequities (Kokka 2019; 2020). The empirical evidence from Kokka's research necessitates the inclusion of emotions in students' mathematical learning. Our study aims to explore the variable of emotions in students' mathematical learning. Our study is set to explore and inform the mathematics education field about emotions students experience in situ of social justice mathematics lessons.

Mathematics education research has for a long time been focused on reasoning (Roth & Walshaw, 2019), knowledge, and other cognitive factors, with little attention to emotions (Schukajlow et al., 2017), the exception being mathematics anxiety (Zan et al., 2006). A few decades ago, however, there was a shift in focus toward incorporating "affect" into this research. Specific definitions and perceptions of affect vary. McLeod (1992) viewed affect as being connected to cognition and performance. Lewis (2013) perceived affect as a student's attitude toward or enjoyment of mathematics. These slightly earlier perceptions of affect regard students' relationships to mathematics, with less emphasis on other factors that may influence students' emotions in the mathematics classroom. In recent years, mathematics education researchers have also more directly incorporated emotion into their study of affect. For example, students bring emotions with them into the classroom (Kokka, 2019; Valoyes-Chavez & Darragh, 2022). Students experience emotions in a mathematics classroom when learning about injustices (Kokka, 2019, 2022; Valoyes-Chavez & Darragh, 2022). Therefore, it is important to consider students' emotions as a factor that affects their learning in mathematics classrooms. Our study is guided by the research question: *How did learning about a local social justice issue affect students' expression of emotions in a college precalculus classroom?*

Theoretical Framework

We leveraged a combination of two theoretical frameworks for this study: affective pedagogical goals (APG) for social justice mathematics (SJM) by Kokka (2022) and historically responsive literacy (HRL) by Muhammad (2020; 2023). The APG aims to support instructors' preparation of SJM lessons by anticipating students' emotions related to injustices. The idea is to provide a space for students to express their emotions about mathematics and the oppressive systems they interact with; this, in turn, may help students process their emotions to understand and use mathematics to address inequities., For this study, we focused on the affective pedagogical goal (Kokka, 2022) of supporting students' expression of emotions related to the local social injustice issue and ongoing efforts to address the issue. Kokka named this goal "identifying and processing emotions to take action." We consider this the first step in helping students process their emotions to act in SJM lessons.

Muhammad (2020; 2023) defined the historically responsive literacy (HRL) framework as a literacy model with five learning pursuits: identity, skill, intellect, criticality, and joy. Muhammad (2020) defined identity as learning about yourself, and the people around you. Skill refers to the concepts and procedures as outlined in school standards. Intellect is the ability to apply skills to understand social interactions. Criticality is the ability to understand injustices in society and use knowledge to challenge the status quo. Finally, Muhammad (2023) defines joy as experiencing happiness, related to celebration, wellness, and justice. We broadened Muhammad's (2023) framing of joy to include other emotions as students engage in a SJM lesson. For this study, we conceptualize meaningful mathematics learning based on the integration of the five learning pursuits of Muhammad's HRL framework, and Kokka's APG.

Methods

Research Context

The participants were forty-three first-year precalculus students enrolled at a predominantly white university in the Northeastern United States. Students completed a SJM lesson designed from an HRL and SJM framework, that mathematized the lead poisoning issue in Metroville, the city where participants attended university. It was created on Desmos, an online tool for creating and teaching lessons. After the lesson, instructors downloaded and saved the anonymized student responses in a shared OneDrive folder accessible only to the research team.

The SJM lesson had three components: pre-lesson survey, Desmos lesson, and post-lesson reflections and surveys. This paper focuses on analyses of students' responses to the Desmos lesson. The Desmos lesson introduced the students to the lead poisoning issue through a video, showed how lead decay can be modeled using exponential functions, asked students to solve exponential decay problems, and informed students about the ongoing efforts to address lead poisoning in Metroville. We asked students to express and explain their emotions at two instances in the lesson: first after learning about the lead poisoning issue, and second after learning about the ongoing efforts. Students were asked to “Name up to three emotions, if any, you experienced after watching the video and writing about lead poisoning in your hometown. Explain what made you feel these emotions.” Our analyses focused on students’ responses to the two questions that asked students to name emotional responses related to injustices and action.

Thematic Analysis

We employed Braun and Clarke’s (2006) six-phase thematic analysis approach to analyze students’ responses to “Explain what made you feel these emotions” questions from the Desmos lesson. We reviewed students’ responses and the research question, wrote notes/memos about initial impressions, and shared them during weekly research meetings. In the second phase, we coded the data and reconciled coding weekly, using a data-driven approach. The third phase involved developing themes by identifying patterns and grouping similar codes. We created a coding frame document to ensure intercoder reliability, including themes, code definitions, and example data segments. In the fourth phase, we checked theme coherence across the dataset. The fifth phase involved aligning the coded responses of the students with themes to address the research question. In the final phase, we selected compelling data excerpts to support our results and developed solid arguments based on these examples.

Results

Our analyses informed us that students expressed emotions because of lack of awareness about lead poisoning, empathy for children/tenants, knowledge about lead poisoning, and views on existing efforts to address lead poisoning. There were other themes in addition to the four mentioned, but in this paper, we focus on these four themes (see Table 1). Students expressed emotions because of a lack of awareness or experience with lead poisoning, and empathy for families living in lead-poisoned houses. Students also expressed emotions based on their knowledge of the lead poisoning issue, willingness to play a role in helping affected families, and their views on the current efforts to address lead poisoning.

Table 1: Theme Findings and Examples

Theme Name and Definition	Associated Emotions	Examples
Theme 1: Lack of awareness about lead poisoning Students express a lack of awareness about the lead poisoning issue by self or people in general.	Shock, Concern, Sad, Annoyance, Curiosity, Disbelief, No emotion, Disturbed	• *"It is frustrating that people don't put in a effort to help others and fix this issue."* • *"never thought about lead poisoning being a problem"*
Theme 2: Empathy for children/tenants Students express empathy for children, tenants, or families who have lead poisoning or have to live in homes with lead poisoning issues.	Sad, Compassions, Pity, Guilty, Concerned, Anger, Bad, Sympathy	• *"I feel concerned for the welfare of the children still subjected to live in those areas."* • *"It is sad that young children are exposed to major health risks due to their living conditions"*
Theme 3: Knowledge about lead poisoning and/or determination to help Students share their knowledge about lead poisoning and a desire to help solve the cause of lead poisoning issues.	Guilty, Motivated, Shocked, Upset, Disturbed, Sadness	• *"I would say that I feel disturbed about the severity of issue and the potential consequences of lead poisoning"* • *"I feel the emotion of sadness desire to help these people."*
Theme 4: Views on existing solutions efforts to mitigate lead poisoning Students express their views on the current efforts/solutions to solve the problem of lead poisoning.	Optimistic, Happy, Promising, Hopeful, Confidence, Enlightened, Knowledgeable, Grateful, Relieved, Excited, Motivated	• *"I'm happy to see that the problem of lead poisoning is being addressed in the community"* • *"It feels good to know that issue is being addressed and that there is things that are beginning to get done in order to combat the problem."*

Theme 1: Lack of Awareness about Lead Poisoning

The first theme captures students' emotions about a lack of awareness regarding lead poisoning. One student expressed their shock at learning about lead poisoning by stating, "I was unaware that lead poisoning was still a thing and lead poisoning itself is a very dangerous thing to still have around. I can't believe that lead poisoning is still a thing, especially in this day in age." We interpreted this student's response as evidence of shock and lack of awareness about lead poisoning. Some students expressed surprise at how easily one can get lead poisoning.

Theme 2: Empathy for Children/Tenants

The second theme explores the emotions that arise from empathy for the people dealing with lead poisoning. After learning about the lead poisoning issue and how it affects people who live in homes with lead, students expressed empathy for the tenants, families, and children who had to choose between having a roof over their heads or being safe from lead poisoning. Learning that people living so close to them are dealing with these issues brought on a wide range of emotions in the students, such as sadness, compassion, pity, guilt, concern, anger, and sympathy. Notably, students were concerned that children were subject to lead poisoning in their home.

Theme 3: Knowledge about Lead Poisoning and/or Determination to Help

The third theme explores students' knowledge about lead poisoning and their determination to help. This theme includes student responses where they share their knowledge about lead poisoning and a desire to help solve the cause of lead poisoning issues. Furthermore, this theme also includes student responses expressing awareness about lead poisoning health risks and the population that is more vulnerable to being impacted. The theme also includes answers expressing students' willingness to help solve or raise awareness about this issue. As students learned about lead poisoning in Metroville, they demonstrated an understanding of the issue and a willingness to help the cause.

Theme 4: Views on Existing Solutions to Mitigate Lead Poisoning

The theme centers on students' positive emotions when learning about efforts to combat lead poisoning. Characterized by optimism and hope, students feel happy and relieved to know that governments and organizations are actively addressing the issue through specific initiatives, fostering confidence in future solutions. It reassures them that change is possible and that there are viable solutions to the challenges they are studying. Students know that their learning has an impact on the real world, which fosters a sense of self-empowerment, encourages them to take a forward-looking perspective, and allows them to look to the future where their newfound mathematical skills and social awareness contribute to social progress and justice.

Discussion

In summary, this study emphasizes the critical role of emotion in social justice mathematics. By addressing social justice issues, mathematics educators could deepen students' understanding of mathematical concepts and develop empathy, critical thinking, and social responsibility. We argue that a careful study of students' emotional responses to SJM lessons is needed to understand and support their learning. Further research could explore how instructors can attend to students' emotions to support their learning. Making mathematics relatable to students by contextualizing their social environments is the future of mathematics education.

UNDERGRADUATE STUDENTS' PARTICIPATION IN CALCULUS I COURSEWORK AND PEER-LED, COMPLEMENTARY INSTRUCTION WORKSHOP: CASE OF NEIL

Karmen Yu, Ph.D.
Montclair State University
Yuk@montclair.edu

In postsecondary education, Calculus has been historically recognized as a "gateway course" for students to pursuit STEM fields. Responding to this issue, researchers at Montclair State University designed a model of complementary instruction to engage Calculus I students in collaborative problem solving on groupworthy tasks. This multiple-case study seeks to address the question, "How do undergraduate students experience their calculus learning in the parallel spaces of coursework and inquiry-oriented complementary instruction?" The findings of Neil's case study are presented here and include characterizations of the different forms of agentive participation afforded to students in the two spaces, as well as their complementary nature relative to learning calculus with understanding. Implications for dismantling the persistent barriers imposed by calculus on access to postsecondary STEM fields are also discussed.

Keywords: Calculus, Undergraduate Education, Problem Solving, Calculus Thinking

Calculus has the track record of serving as a "gateway course" that contributes to postsecondary students abandoning their pursuit of a STEM career (Hagman et al., 2017). The calculus reform effort in the 1990s emphasized to include fewer topics and incorporate an active learning and teaching approach aiming to transform calculus education to be "lean and lively" (Johnson et al., 2014). Twenty years later, the President's Council of Advisors on Science and Technology (2012) made a similar recommendation in order to provide students the time they need to develop robust understandings of mathematical concepts in order to succeed. Despite the continuing reform effort, the gate-keeping function of Calculus has hardly changed.

Drawing on the Mathematical Association of America's seven recommendations from the Insights and Recommendations (Bressoud et al., 2015), researchers at Montclair State University designed an inquiry-based *complementary* workshop, called Inquiry-Based Instructional Support (IBIS), facilitated by a peer leader (Roth et al., 2001) to run parallel to students' in class learning. During IBIS, students work collaboratively in small groups on groupworthy tasks (Buell et al., 2016) that are non-routine problems to promote conceptual understanding of calculus concepts.

The literature on peer-led cooperative learning models in postsecondary education confirms their effectiveness on students' academic achievement across different undergraduate mathematics courses (Altomare & Moreno-Gongora, 2018; Trenshaw et al., 2019). However, as the literature mainly focuses on evaluating the effectiveness using quantitative methods, there is a lack of insight into why, how, and what about peer-led cooperative learning models that contributes to these successful outcomes. Hence, this study seeks to address the question, *How do undergraduate students experience their calculus learning in the parallel spaces of coursework and inquiry-oriented complementary instruction?*

Perspectives and Methods

This exploratory (Yin, 2003) multiple-case study (Merriam, 1998) is grounded in a situated perspective (Lave & Wenger, 1991) leveraging the "learning as participation" aspect and utilized the concept of figured world (Holland et al., 1998) to examine the change in students' agentive participation and their identity formation (Vågan, 2011). To answer the research question, all of the observation video recordings were transcribed and analyzed using the grounded theory analytical approach (Corbin & Strauss, 2014). To depict a summary overview of each case study participant's enacted agentive participation in class and IBIS, a word cloud with agentive participation codes as clusters was created for each instructional space.

The participants of this study consist of two cohorts of Calculus I undergraduate students whose IBIS attendance is a part of their course requirement. Each cohort has four participants from the same class and attended the same IBIS sessions. Video recordings and field notes were taken for all 24 classes, six workshops, and three focus group interviews (Creswell, 2012).

Findings

The table in Figure 1 shows the various forms of participation enacted in class and IBIS by both cohorts' participants. These participation actions were organized into *high*, *moderate*, and *nominal* interactivity categories to describe students' participatory interactions with others, material resources, or tasks. Next, Neil's case (pseudonym) will illustrate how the participation codes and interactivity categories are used to characterize his participation in both spaces.

		Cohorts A & B		
Categories of Interactivity	Level 1 Codes	Class A	Class B	Cohorts A & B IBIS Workshop

Figure 1: A table of participation actions in class and IBIS for Cohorts A and B.

Neil’s Participation Profile

Neil was a private student both in class and IBIS. He spent most of his time in class *taking notes* and, in both spaces, *working independently* on the task at hand. Regarding the opportunities that the instructor provided for students to participate, Neil refrained from participating 323 times across 23 in-person class observations, for an average of about 14 times per class observation. The class and IBIS word clouds, in Figures 2A and 2B, provide a summary overview of Neil’s participation in both spaces. A comparison of his class and IBIS word clouds shows that his independent participation characteristics tended to be magnified in class.

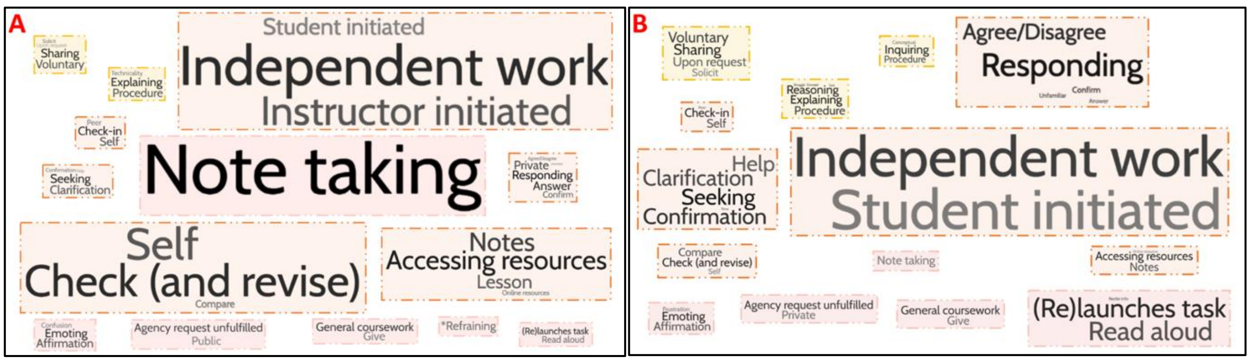

Figure 2: Neil’s class (A) and IBIS (B) participation word clouds

Early in the course, Neil’s participation consisted almost exclusively of *taking notes* and *working independently* on problems posed by the instructor, and then waiting for the instructor or another student to provide a solution. Every so often, as Neil worked on problems independently in both spaces, he would reference a variety of resources, such as his notes and online resources.

The size of the *independent work* cluster in Neil’s IBIS word cloud suggests that though he also tended to work independently in IBIS, groupwork in IBIS offered opportunities and space for him to be a more active and interactive participant. The biggest clusters in his class word cloud are participation actions with moderate interactions with tasks and material resources (e.g., *note taking*, *independent work*, *accessing resources*, and *checking and revising*). In contrast, some of the biggest clusters in his IBIS word cloud are participation actions that have moderate interactions with his peers (e.g., *responding* and *seeking clarification*, *confirmation*, and *help)*. This suggests that more of his interactions in IBIS were with peers than with tasks and material resources. Moreover, as his IBIS word cloud also reveals, Neil was more likely to *respond* to his peers than to initiate interactions with them. He was also more likely to *seek confirmation*, *clarification*, and *help* from his peers than to enact the explainer role. The following excerpt illustrates some of these forms of participation from Neil during IBIS. In this excerpt, his group was discussing a composition function/chain rule problem, given the rates of change of profit per book sale, $p'(s)$, and book sales per month, $s'(t)$.

Table 1: An excerpt of a Chain rule discussion in the third IBIS session.

1	Amelia	Uhm. Well, for [#3] c, I just wrote using the chain rule. I kind of wrote the first part. And then for [#3] b, I just plugged in 4 to s. Like, to $s(t)$ I used 4. And then the answer I plugged it into $p(s)$. And then I just explained that in [#3] c. <...>
2	Neil	I thought you have to put one into the other.
3	Rachel	I did.
4	Amelia	Yea, that's kind of what I did.
5	Rachel	I thought you just have to plug it into the equation it goes with. Like for [#3] a, you just plug it into the $s(t)$. No? For $p(s)$…-cause like it gives you an example.
6	Neil	Yea, you put this portion here into s. <Points to his work on paper>
7	Rachel	So, for [#3] a, you got 16?
8	Neil	Huh? Yea.
9	Rachel	And then for [#3] b, you got 160, too?
10	Neil	Uh huh.
11	Rachel	And then what about [#3] c? What did you do?
12	Neil	You plug this portion into s and that becomes p and then you take the derivative and then you take the derivative becomes $p'(t)$.
13	Rachel	Oh! So, you do 3… <Continues to work on problem independently>
14	Neil	Yea, and then there is…we're done.
Note: <actions>; (unclear utterance); -interruption/cut off-; and [words inserted for clarity]		

In this excerpt, Neil responds to Amelia's (pseudonym) invitation by *sharing* his *ideas* about what to do for this problem (lines 2 and 6). Upon Rachel's (pseudonym) further request for him to share his work with her (line 11), Neil *explains* the *procedures* he took to determine $p'(t)$ (line 12). Even though Neil spent a lot of time in IBIS working independently, in contrast to his class participation, he was also a more active and interactive learner in that space by *sharing* with, *explaining* to, and *seeking* from his peers. As the semester progressed, there was some evolution in how Neil *shared*, *explained*, and what he *sought* from his peers in IBIS.

Overall, even though *note taking* continued to be the dominant form of Neil's participation throughout the semester, as the semester progressed, his participation in both spaces expanded from the predominantly nominal interactions of *note taking* and *working independently* to include both moderate and high interactions (e.g., *seeking*, *explaining,* and *sharing)*. The next excerpt illustrates his participatory expansion trajectory in class from mid-semester. In this excerpt, the class was working on finding the derivative of $f(x) = \sqrt[3]{2x^3 + \sin^2(5x)}$ posed by the instructor. Neil overheard Amelia expressing her confusion and took the initiative to check on her.

Table 2: An excerpt of Neil checking in on Amelia in class.

1	Amelia	I am so confused.
2	Neil	<Overhearing Amelia> Well, what are you confused about?
3	Instructor	<In the background of Neil and Amelia's interaction> Alright. Ah. So, let's quickly differentiate the whole equation.
4	Amelia	Where [does] cosine come from at the end?
5	Neil	<Looks back at his work> When I think about it- When I think about it in 2 pieces, [in terms of] 2 pieces. <Shows Amelia his work>
6	Amelia	Wait. Hold on. Let me finish [writing]. <Looks at Neil's work>
7	Neil	Well, she's talking about quotient (inaudible) first thing (inaudible) the number 2-
8	Amelia	Like, that I got.
9	Neil	Yeah, number 2, then (inaudible) it still has to be opened up (inaudible) so it will be (inaudible) plus (inaudible) sine. The opposite of sine is cosine, so cosine of 5 and then you just grab the last piece, (which is) 5.
10	Amelia	I kind of get it.

In this excerpt, Neil *seeks clarification* on what confused Amelia (line 2). Even when the instructor calls for the class's attention to go over the problem (line 3), Neil and Amelia continue to carry on with their conversation. After Amelia clarifies her confusion (lines 4 and 8), he offers his *explanation* to help her resolve it (lines 5, 6, and 9). This excerpt is one of the examples that illustrates the evolution in the interactivity of Neil's participation. As the semester progressed, Neil also enacted new kinds of *responding*, *sharing*, and *seeking* actions in both spaces.

Discussion and Conclusion

To summarize, this study found a range of agentive participation actions that were further categorized into *high*, *moderate*, and *nominal* interactivity categories based on the quality of their interactions with others, tasks, or material resources. These findings can inform and guide the design and implementation of parallel spaces of coursework and complementary instruction, particularly when the realities of coursework alone impose constraints that do not allow for adequate opportunities for high and moderately interactive participation. Specifically, these findings would be of value to postsecondary calculus educators and program directors who are committed to offering students the kinds of participatory experiences that are productive for their learning of calculus. That way, they can be more mindful in planning, structuring, and designing their calculus programs so as to dismantle the persistent barriers imposed by calculus on access to postsecondary STEM fields.

This pilot case study examined how one teacher educator (TE) enacted written lesson plans from a shared knowledge base to support preservice teachers' (PSTs) mathematical content knowledge (MKT) in a mathematics content course. Using classroom observations, reflective interviews and the TE's reflective journal, we explored the modifications made by the TE during the classroom instruction of a unit on percentages. We report that these modifications did not alter the content of the course and additionally created opportunities for PSTs to learn more than the subject matter knowledge (SMK). These reported modifications were prompted by responding to students' responses during classroom instruction and the influences of former instructors' modifications.

Keywords: Instructional Activities and Practices, Mathematical Knowledge for Teaching, Preservice Teacher Education

Much attention has been given to developing the mathematical content knowledge necessary for teaching among preservice teachers (PSTs). The importance of mathematical knowledge for teaching (MKT) is evident in studies examining its relationship with student outcomes. For instance, teachers' MKT was significantly related to student achievement gains even in elementary grades (Hill et al., 2005), and teachers' MKT was significantly related to students' participation in quality mathematics discourse (Wilhelm et al., 2017).

Given its importance, MKT is a primary concern for teacher preparation programs. As a way to improve the quality of teacher preparation, a shared knowledge base for teacher educators has been proposed to document and collect knowledge about effective teaching in university teacher preparation courses (Hiebert, 2013; Hiebert & Morris, 2009; Morris & Hiebert, 2009). In one case, a program using such a knowledge base reported that graduates from multiple cohorts scored higher several years after graduation on measures of MKT on mathematics topics that were covered in the program compared to topics that were not covered (Morris & Hiebert, 2017; Suppa et al., 2018). Although not causal, the results of these studies suggest the possibility of a positive and sustaining impact on teachers' knowledge of mathematics content.

Adding to this work, we report on preliminary findings from a pilot case study in which we consider the ways a TE enacted written lesson plans from a shared knowledge base in the context of a mathematics content course for K-8 PSTs. We wanted to understand the role of the teacher educator (TE) in creating opportunities for PSTs to learn MKT as the TE implemented these lessons. We were curious about how a TE might balance competing interests to follow the lesson plans and to modify the lesson in the moment to be responsive to student thinking. In particular, we examined what modifications emerged in the TE's implementation of the lessons to consider what changes were made, what opportunities to learn MKT were provided by those changes, and why those changes occurred. The research questions that framed this study were: (1) in what ways does a TE modify written lesson plans when enacted to provide PSTs with opportunities to learn MKT ? and (2) what prompted the TE to make these changes?

Mathematical Knowledge for Teaching

Ball and colleagues (2008) specify the kinds of mathematical knowledge needed for teaching. In their framework, they name domains of mathematical knowledge for teaching (MKT) as subject matter knowledge (SMK) and pedagogical content knowledge (PCK). SMK includes common content knowledge which is the mathematical knowledge not unique to teaching and used in various contexts, horizon content knowledge which refers to understanding connections among mathematical topics, and specialized content knowledge which encompasses mathematical knowledge specific only to teaching. In defining these distinct ways that mathematical knowledge for teaching operates, Ball et al. (2008) propose that these domains can inform teacher education and help course designers refine curricula for mathematics content courses in teacher preparation programs.

Methods

In this pilot case study, we examined a TE's enacted changes to written lesson plans to consider how and why these changes occurred and what opportunities the changes provided for undergraduate PSTs to learn MKT. In this research report, we present preliminary results from this case study based on data collected from one unit of teaching during which the second author was observing the first author's teaching.

Context

The semester-long course on rational numbers is the second in a series of three required mathematics content courses for K-8 PSTs. The lesson plans for this course have been developed over several years within a shared knowledge base. They include information about the goals and rationale for each lesson and insight into PST thinking, such as common questions and misconceptions or expected responses. The first author, a doctoral student and new to teacher education, was the instructor of one course section in the Fall 2023 semester. All course instructors met once a week to debrief each week's lessons, get feedback on teaching, and plan for the next week's lessons by discussing the lesson plans.

Data Collection

We used instructional materials, observations of classroom instruction, and reflections from the TE during a unit on the meaning of percentages to explore our research questions. This unit contained three lessons taught over three 80-minute class sessions mid-semester. For each lesson, we reviewed the shared lesson plans, a student course packet containing practice problems, and a slide deck prepared by the TE. The TE kept a reflective journal about the in-the-moment changes she made during instruction and her rationales for those changes. Additionally, we met after each class for a 10-20 minute audio-recorded debrief interview in which the first author reflected on the lesson. The data was prepared for analysis by transcribing all audio recordings and de-identifying all data of student names. Finally, all lesson data was organized by lesson activity such that comparative analyses could be made across the written and enacted lessons.

Data Analysis

The data analysis took place in three phases. In the first phase, modifications of the written lesson plans were identified within the observation data from the enacted lessons. These were coded for each domain of subject matter knowledge within the framework for mathematical knowledge for teaching (MKT) (Ball et al., 2008). Then, these modifications were coded again to identify the source of change (i.e., how it happened) as initiated by the TE or by students and coded to identify the content of the change (i.e., what was changed) using open coding (Saldaña, 2021). In the third phase, we reviewed the recordings from the lesson observations and created event maps (Green and Bridges, 2018). We defined an event as the tasks and subsequent discussions happening in the classroom when a slide was displayed to the students and made notes about the event. These event maps and the other data were coded using the constant comparative method (Charmaz, 2014) to find common themes of how modifications emerged. Then, the data was re-coded according to the themes established and we coded to find what prompted these modifications.

Results

From our preliminary analysis, we found that the TEs enacted modifications of the written lesson plans, providing opportunities for PSTs to develop mathematical knowledge for teaching (MKT) that responded to their engagement in the class by modifying the setup or sequencing of activities. These modifications also created circumstances for new opportunities to learn additional types of knowledge for teaching. The TE was prompted by student questions and informal exchanges of knowledge with previous course instructors to modify the written lesson plans to suit her and her students' needs.

Opportunities to Learn within Enacted Modifications to Lessons

Modifications to the lessons occurred mostly within the setup of the tasks or the sequencing of the tasks but did not change the content of the tasks. In addition, they created opportunities to engage with mathematical content in deeper ways, promoting opportunities to develop the kinds of rich mathematical knowledge specific to teaching.

The following example illustrates a typical way the TE made modifications while teaching. In the second lesson plan, the instructor was directed to give groups of PSTs time to work on tasks and encourage them to represent their solutions in a variety of ways. In the enacted lesson, the TE prompted PSTs to work on each problem one at a time, chunking the setup of the task to support students in unpacking one problem at a time so they could more deeply consider the efficiency of various strategies. These modifications create opportunities for PSTs to engage in more practice problems with a potentially deeper mathematical understanding of the tasks.

Opportunities to Learn More than SMK. Another significant finding was that the TE's modifications to the lessons created opportunities for additional kinds of learning. In the written lessons, opportunities to learn were almost exclusively directed toward mathematical content knowledge, SMK. Within the enacted lesson, modifications created opportunities for PSTs to also learn norms for mathematical activity and practice thinking like an elementary teacher or student.

One way that this occurred was in a reframing of the homework review, which began each lesson. The TE selected a PST in each class to act as a teacher discussing her solution and asked the class to ask questions as if they were fourth graders. In this routine, the class engaged with their peer's ideas to think about ways to improve their representation of mathematical ideas prompted by the TE asking, "This is about ways to improve this solution, what would make it easier for a 4th grader to understand, what would make it more clear?" This modification to the written lesson creates an opportunity for PSTs to learn about connections between mathematical content and teaching and learning.

What Prompted Changes to Lesson Plans

Based on our data analyses, we found that changes occurring in the enacted lessons were prompted by students' unanticipated questions and responses and by communicating with former course instructors to resolve instructional challenges. As a result, instructional modifications included providing additional verbal and written resources, asking probing questions to the students to guide them to a correct answer, skipping planned tasks, and shuffling the sequence of tasks. We highlight two instances to illustrate these findings below.

Responding to students in the moment. The lesson plans included examples of students' responses and possible instructor's responses. However, on many occasions, students responded in ways that were not predicted in the lesson plans. In one such response, the students asked questions about setting expectations for writing answers in the exams multiple times. In one instance, when Reese [pseudonym] asked about the correct way to write the answer for an upcoming exam. Instead of providing one correct way of answering the problem, the TE explained four different options for answering the question. This moment was captured in the field notes of a lesson:

> *The TE said, "I was going to talk about this a little later but since you want me to talk about it now, let's talk about it". She explained the 4 ways of writing number sentences and then told the students that she expected the students to use one of these ways to write in the exam.*

Often, these instances created opportunities for the TE to work towards establishing norms with the students for mathematical practices. As in the example above, Reese's question prompted the TE to communicate expectations for demonstrating learning in the class.

Influences from modifications made by former instructors. The TE made an effort to reach out to the former course instructors, including doctoral students and department faculty. In these conversations, the TE shared her experiences instructing the course and discussed challenges that she was facing, seeking to understand if they faced similar challenges and how they navigated those challenges. As a result, she learned from former instructors' multiple approaches to addressing the challenges and implemented those approaches in her instruction. In one of the debriefing meetings, the TE gave reference to such modifications.

> *"Yeah, I was talking to Carmen [psuedonym] about this- that the students want me to tell them the norms for drawing and writing. Carmen told me that she had success when she asked the students to consider themselves to be fourth graders; this way they set up their own norms."*

The TE implemented this strategy of asking students to imagine that they were fourth graders or asking them to imagine that they were teaching fourth graders when answering her questions.

Discussion

We view this work as an extension of others who report on the implementation of a shared knowledge base for teacher educators (Hiebert, 2013; Hiebert & Morris, 2009; Morris & Hiebert, 2009) by considering how a TE implements shared lesson plans to create opportunities for PSTs to learn MKT. Understanding the use and modification of these materials highlights the role of the TE in interpreting and enacting the curriculum. In this case, we saw that the TE modified the lessons to respond to the needs of PSTs, which created opportunities to learn more than SMK. These changes are potential sources for the TE to contribute to the shared knowledge base as a newcomer to teacher education.

In the next phase of this case study, we intend to examine opportunities for learning that attend to additional types of knowledge, skills and dispositions that may emerge from the in-the-moment changes that TE makes during the enactment of lessons. Also, in addition to the units on percentages, we will collect data from the units that have been informally reported to be particularly difficult by the students during the instruction. Such inquiries will help researchers to understand how TEs interpret and make use of the shared knowledge base.

HIGH SCHOOL FIELD EXPERIENCE PERSONNEL'S PERCEPTIONS ABOUT MATHEMATICS IDENTITY

Zareen Gul Aga

Field experience personnel, such as cooperating teachers (CTs) and university supervisors (USPs), play an important role in supporting mathematics pre-service teachers (PSTs) to learn about equitable teaching practices. We employed case study methodology to explore the perceptions of CTs and USPs about mathematics identity. A group of CTs and USPs participated in professional development during the Fall 2023 semester to learn about ways to develop students' mathematics identity. In this brief research report we share these CTs' and USPs' ideas about their own mathematics identity, their students' mathematics identity, and how these ideas influence their teaching practice. Our findings have implications for redesigning field experience in teacher education programs.

Keywords: Pre-service Teacher Education, Professional Development.

Objectives of the study

Field experience is an important component of teacher education (Butler & Cuenca, 2012). The various personnel involved in the field experience component of teacher education influence what student teachers learn when placed in actual K-12 classrooms. According to Anderson (2007), cooperating teachers (CTs) have a significant impact on pre-service teachers (PSTs). Moreover, Rozelle and Wilson (2012) reveal that PSTs' teaching practices and beliefs are strongly affected by cooperating teachers. University supervisors (USPs) also have a major impact on PSTs' thinking and their practice as they bridge theoretical learning with practical field experience (Cuenca et al., 2011). Thus, it is important to learn about the perceptions, practices, and beliefs of these field experience personnel to support PSTs' learning (Borko & Mayfield, 1995). In particular, when it comes to teaching mathematics PSTs about equitable teaching practices, it is important to develop a cohesive system of supports where PSTs get the same message from their courses and their field experience. Hence, collaborative work between university and school personnel is needed to prepare PSTs to teach diverse populations (Lee et al., 2010; Maher et al., 2022). Given the important role that field experience personnel play in supporting mathematics PSTs to incorporate these practices we wanted to learn about their own ideas about mathematics identity. In particular, our research question was: *What are field experience cooperating teachers' and university supervisors' perceptions about mathematics identity?*

Theoretical framework

Mathematics identity refers to "the dispositions and deeply held beliefs that students develop about their ability to participate and perform effectively in mathematical contexts and to use mathematics in powerful ways across the contexts of their lives." (Aguirre et al., 2013, p. 14). This identity can influence the beliefs of a student as a, "competent performer who is able to do mathematics or as the kind of person who is unable to do mathematics." (Aguirre et al., 2013, p.

14). Students' mathematical identities are deeply connected to their other identities making it important to welcome all of their selves into the classroom (Ruef, 2020). The five practices of equity-based teaching can guide the development of classroom environments that allow students to feel welcomed and help build their mathematical identities (Aguirre et al., 2013). These practices are: Going deep with mathematics; Leveraging multiple mathematical competencies; Affirming mathematics learners' identities; Challenging spaces of marginality; and Drawing on multiple resources of knowledge. Various researchers have cited the importance of mathematics PSTs' learning about equitable teaching practices (Gutiérrez, 2002; Mintos et al., 2019). If we are to teach PSTs about these practices it is important to help them experience these practices in action during their field experience (Moldavan & Gonzalez, 2023; Sandoval et al., 2020).

Methods

We used case study methodology to highlight the ways in which CTs and USPs conceptualize mathematics identity (Yin, 2009). Our unit of analysis in this exploratory case study is a member of our field experience team: CT or USP. We aim to share their own perceptions about mathematics identity in order to expand existing understanding about how field experience personnel may influence PSTs' teaching practice.

Setting

The study took place at a university in the Mid-Atlantic region of the United States. The university is situated in a rural community. As part of an extended professional development (PD) program, the first author invited high school mathematics field experience personnel to meet virtually. The group met four times during the Fall 2023 semester and engaged in discussions about equitable teaching practices in mathematics classrooms, reading vignettes of classroom scenarios, sharing classroom activities, and providing feedback on each other's teaching practices.

Participants

The participants were three cooperating teachers (high school mathematics) hosting PSTs from the university's teacher education program, and one university supervisor teaching the field experience course for future high school mathematics teachers. The university supervisor was a former high school mathematics teacher. All participants had more than 10 years of teaching experience. Karla was teaching Geometry, Computer mathematics, and AP Calculus; Ranita was teaching Algebra I & II; and Jake was teaching Algebra 1, Precalculus, and Data Science at the time of the study. Jake had also taught Geometry and Algebra II in past years. Lisa – the university supervisor – had taught Geometry, Computer math, and Algebra I when she was a high school teacher.

Data

All participants were interviewed at the beginning and end of the Fall 2023 semester. Semi-structured interviews were conducted, transcribed, and analyzed. In addition, the participants were asked to select at least one equity-based teaching practice to develop students' mathematics identity. They were also asked to share actionable steps that can be taken in their classrooms to support equitable mathematics teaching and develop their students' mathematics identity.

Analysis

Data were analyzed using open coding (Strauss & Corbin, 1998) to look for emergent themes about participants' perceptions of mathematics identity.

Results

In this section we provide accounts of each participant's perceptions about mathematics identity. Data analyses revealed that teachers' mathematics identity may influence their teaching practice and their teaching goals for their students. Teachers' mathematics identity may also influence their opportunities for learning when engaging in PD.

Karla

Karla is a cooperating teacher hosting our PSTs in her classrooms. Thinking about her own mathematics identity, Karla shared that she always identified as being good at mathematics. She liked seeing mathematics as a language and loved the precision mathematics provided to communicate ideas and concepts. Mathematics always made sense to her and was "straightforward to understand." In addition, she enjoyed teaching mathematics to peers. She described her students' mathematics identity as procedure followers who want to memorize algorithms and follow them rather than think through mathematics problems. Karla's goal is to provide students with mathematics problems that foster their problem-solving mindset as she wants them to become "problem solvers and critical thinkers." She mentioned that "giving them (students) a lot of examples of problems that do not have a straightforward algorithm" is needed to help students develop their mathematics identity. She selected going deep with mathematics as her preferred equity-based teaching practice. We see an alignment between Karla's own mathematics identity, her teaching practice and how she resolves challenges in her practice to help students become successful at doing mathematics.

Jake

Jake, a cooperating teacher, always liked to solve real word problems using mathematics and found numbers comforting. When talking about his own mathematics identity he said, "Well, my mathematics identity goes back to when I was in elementary school, I think about third grade when I was required to learn how to add, subtract, multiply and divide fractions. And so I found success in that, I found comfort in that!" In addition to finding numbers comforting, Jake also saw himself as a problem solver. He liked to play problem solving games and explained, "One of my more recent musings about mathematics is that all mathematicians are Gamesman. And I love games. And I love creating parameters and saying, Now, what can I do with that?" His goal is to help students change the narrative about mathematics, and to help them be successful. Jake did not select an equity-based mathematics practice but based on his conversations he seems to be leaning towards affirming mathematics learners identities and challenging spaces of marginality. We see an alignment between Jake's own mathematics identity, and his teaching practice. Jake wishes for his students to see the world through a lens of mathematics and wants them to have discussions about real world problems.

Lisa

Lisa is a university supervisor in the teacher education program. Up until last year she was a high school mathematics teacher and recently took on the role of a university supervisor. She described herself as a problem solver because she likes to think mathematically when encountering challenges. Lisa said that mathematics is "part of who I am, my identity." She always enjoyed teaching mathematics even when in school and liked to help her friends learn math. In contrast she feels that her students (high school) hate math, they don't have any interest in doing mathematics and don't understand why they have to do it. Her teaching focuses on motivating students and helping them reach aha moments. Her goals to develop students' mathematics identity include having students feel good about themselves when doing math. She selected, affirming mathematics learners' identities as her favored equity-based teaching practice. In her current role as a university supervisor, Lisa encourages her PSTs to work with students who struggle with mathematics. She uses her own experience to guide her PSTs in supporting their students.

Ranita

Ranita a cooperating teacher, recalled that she found mathematics to be challenging and did not feel like she was good at math. She shared, "I do math every day but I still really feel like deep down, I was never good at math." Her challenges learning mathematics earlier on in life allow her to empathize with her students when they say they don't like math. She shared that her students lack prerequisite mathematics knowledge and her goal is to develop students' mathematics identity by helping students feel confident and to help them experience success. Based on her own experiences learning mathematics, Ranita believes that helping students feel confident in mathematics is crucial. This motivates her to focus on supporting students to experience success in mathematics exams. She gives them chances to redo their assignments and provides scaffolded practice exercises because she believes that passing mathematics exams will allow students to experience success and develop a positive mathematics identity. Ranita's teaching practice is based on empathy for her students. She believes in building relationships with her students and learning about them. She selected leveraging multiple mathematical competencies as her preferred equity-based teaching practice.

Discussion and conclusions

There were similarities and differences between the four cases. In terms of similarities, all participants except for Karla shared that their students had a strong dislike for mathematics, that it was important to develop relationships with students and to help them experience success. For all the cases, the participants' interest, perception, and background influenced what they learned from the PD meetings. All the participants were able to learn from each other about strategies, tasks, and norms that worked for their students. They were all similar in their goal to help their students be successful, but their teaching practice, understanding of student success, and perception of their role as a teacher differed from each other.

Our findings have implications for PSTs' field experience. CTs and USPs guide PSTs as they try to connect their coursework-related learning to the teaching practice experienced in actual field experience classrooms. PSTs may learn new pedagogical ideas in their methods courses but it is important that these ideas are reinforced and modeled during their field experience (Matsko et al., 2020). For instance, if we want our PSTs to develop equitable teaching practices that support the development of students' mathematics identity, we must learn about pedagogical beliefs held by CTs and USPs. We noticed that all participants were deeply interested in supporting their students' learning; however, they had different ideas about what it meant to develop their students' mathematics identity. Some believed that experiencing success on state tests would do the trick, while others believed that being able to solve real life problems using mathematics might help their students develop a positive mathematics identity. Work is needed to support field experience personnel in their development of equity-based practices. In addition, continued collaboration is needed between MTEs, CTs, USPs, as well as PSTs.

It is through a cohesive network of support that our PSTs can be successful in developing equitable teaching practices. Field experience personnel can influence PSTs' sense of preparedness as teachers (Ambrosetti & Dekkers, 2010; Hamman et al., 2006). MTEs, CTs and USPs must collaborate, to develop tools and procedures in order to become effective mentors for PSTs. This collaboration can help align PSTs coursework and field related experiences. In particular, such an alignment is needed to support PSTs' development of equitable teaching practices that can support the development of students' mathematics identities.

IN-N-OUT OF PRODUCTIVE STRUGGLE

Monica Anthony
Georgia Gwinnett College
Manthony5@ggc.edu

Keywords: Instructional Activities and Practices, Preservice Teacher Education, Teacher Educators, Teacher Beliefs

Productive struggle arises when students persevere in problem-solving, applying their mathematical knowledge in new ways (Hiebert & Grouws, 2007). While teacher educators recognize the importance of productive struggle for mathematics teaching and learning (NCTM, 2014), pre-service teachers (PSTs) may initially have negative perceptions of productive struggle (Warshauer et al., 2021) or try to alleviate struggle for their students (Anhalt et al., 2006; de Araujo et al., 2021; Nicol & Crespo, 2006), rather than seek to create opportunities for productive struggle. PSTs' desire to prevent students from struggling may be rooted in their own negative experiences as mathematics learners (Gellert, 2000).

In this ongoing study, I investigate how direct instruction of the concept of productive struggle, the promotion of productive struggle through rigorous mathematical tasks, and reflections focused on productive struggle, impacts elementary PSTs' understanding of productive struggle and their perceptions of themselves as doers and teachers of mathematics.

Participants were 66 elementary education undergraduate PSTs enrolled in a 14-week course on Algebraic Thinking at a Hispanic-serving four-year liberal arts college in the Southeastern United States in Spring 2022 (21 PSTs) and Spring 2023 (45 PSTs). PSTs regularly engaged in high cognitive demand math tasks. I documented students' problem-solving strategies and behaviors associated with struggle (SanGiovanni et al., 2020; Warshauer, 2015). After completing each task, PSTs wrote reflections on their experiences of productive struggle, using sentence stems (SanGiovanni et al., 2020, p. 151).

This poster reports on PSTs' experiences with a specific math task, the In-N-Out Burger task (Kaplinsky, 2013). End of course reflections asked PSTs to identify: which of the tasks was their favorite, and why; and which task did they find most challenging, and why. 26 PSTs (39%) said the In-N-Out Burger task was their favorite, while 17 PSTs (26%) said it was the most challenging. Compared to the other tasks, this task stands out because of the high percentage of PSTs who both favored the task and found it challenging. For the other tasks, there was an overwhelming majority for either favorite or challenging.

Preliminary findings suggest that some PSTs valued the freedom of the open-ended nature of the In-N-Out Burger task, while others were frustrated by the ambiguity. PSTs enjoyed the In-N-Out Burger task because it was an interesting, real world context; was enjoyable to solve; was challenging; had multiple solution paths; and fostered collaboration and discussion. PSTs who found the task most challenging expressed frustration, confusion, and difficulty getting started. One concern for classroom practice is that PSTs who are uncomfortable with ambiguity may avoid providing similar experiences for their future students. Additional analysis will explore how PSTs' end of course reflections connect to their initial reflection on the task. I will also present the solution paths students pursued, and types of struggle documented in my field notes, seeking connections between observed behaviors and PSTs' perceptions of the task, and their self-expressed experiences with productive struggle.

BEGINNING TEACHER'S TRAJECTORY OF IDENTITY FORMATION IN THE FIGURED WORLDS OF REFORM AND TRADITIONAL INSTRUCTION

Naama Ben-Dor

Orly Buchbinder
University of New Hampshire
orly.buchbinder@unh.edu

Transitioning from a teacher education program to autonomous teaching is a complex process, fraught with challenges. This transition involves developing identities and teaching practices that allow novice teachers to reconcile the reformed teaching world of their teacher preparation program with the more traditional world of school teaching. In this paper, we follow the identity formation of one beginning teacher, Olive, by examining her narratives about her pedagogical actions as she transitions from being a pre-service teacher (PST) to being an intern (INT) to becoming a new teacher (NT). As PST, Olive's narratives about her current and desired actions aligned with reform actions; as INT, a gap opened between her current traditional actions and desired reform actions; and as NT, the gap narrowed as she modified her desired narratives to more traditional ones. We discuss our findings and their scientific significance.

Keywords: Novice Teachers, Teacher Learning, Identity, Reform Teaching

Introduction

University teacher preparation programs aim to prepare future mathematics teachers to enact ambitious pedagogical practices that align with the NCTM's vision of effective teaching and the Common Core Standards for Mathematical Practices (AMTE, 2017). As beginning teachers transition from university to school teaching, they need to reconcile between the world of ambitious (hereafter, *reform*) teaching of their teacher preparation program and the world of school teaching characterized mostly by traditional teaching practices (Jacobs, et al., 2006). The reconciliation between the two worlds can be accomplished by integrating reform practices, to varied extents, into the more traditional school world (Thompson et al., 2013). Indeed, some beginning teachers tend to lean toward traditional practices (Gainsburg, 2012), while others hold on to their reform teaching practices (Conner & Marchant, 2022; Smagorinsky et al., 2004).

The extent to which beginning teachers adopt and integrate reform practices has been linked to their emerging teacher identities and more specifically, to "the kind of teachers selves they have developed and seek to create"(Horn et al., 2008, p. 63). We can learn about identity by considering teachers' narratives about their general current pedagogical actions and their desired ones (Heyd-Metzuyanim, 2019). Moreover, it is important to examine the beginning teachers' identity formation over time and across settings. However, such longitudinal studies are rare, and not enough is known about how the processes of the reconciliation of the two worlds unfold.

In this paper, we analyze the case of one beginning teacher Olive (pseudonym), whom we followed for four years: as a pre-service secondary teacher (PST), as an intern (INT), and as a novice teacher (NT). Olive was chosen because she represents a case of a highly successful beginning teacher, in terms of her mathematical knowledge, pedagogical creativity, and productive dispositions, aligned with reform teaching (as evidenced by her undergraduate coursework). This meant that, relative to other PSTs, Olive had a good starting point in terms of integrating reform practices into the school world. We explore Olive's trajectory of teacher identity formation, building on the theoretical notions of "figured worlds" and pedagogical narratives, which we describe below.

Theoretical Framework

Drawing on Holland et al. (1998) and other scholars (Horn et al., 2008; Ma & Singer-Gabella, 2011), we view the traditional mathematics instruction and the reform teaching, not only as two pedagogical approaches but as two "figured worlds". A figured world is a "socially and culturally constructed realm of interpretation in which particular characters and actors are recognized, significance is assigned to certain *acts*, and particular *outcomes* are valued over others" (Holland et al., 1998, p. 52). To conceptualize the reform and traditional figured worlds, and specifically, their valued actions and outcomes, we drew on the National Council of Teachers of Mathematics' *Principles to Actions* (2014), a central document in the discourse on reform mathematics instruction. Table 1 shows our resulted conceptualization of the two worlds.

Table 1: Conceptualization of the Reform and Traditional Figured Worlds

	Figured World of Reform Teaching	Figured World of Traditional Teaching
Valued pedagogical actions	<u>Examples:</u> providing students with opportunities to explore and problem-solve; supporting students without eliminating their challenge; encouraging them to use reasoning and proving when justifying mathematical claims.	<u>Examples:</u> posing tasks which students are expected to solve using a specific memorized procedure; guiding students step by step through problem-solving; encouraging students to give short answers and respond to teacher only.
Valued pedagogical outcomes	<u>Examples:</u> collaborative explorations, open and reasoned discussions, productive struggle, and student authority.	<u>Examples:</u> memorization, correctness of answers, procedural knowledge, and teacher authority.

To be able to investigate processes of identity formation during the reconciliation of the reform and traditional figured worlds, we examined Olive's narratives about her pedagogical actions. Hence, our claims concern teacher's *narratives* about pedagogical actions, rather than the actual classroom practice We conceptualized four types of narratives a teacher produces about their actions, as shown in Table 2.

Table 2: Conceptualization of Narratives about a Person's Actions

	Narratives about *Specific* actions	Narratives about *General* actions
Desired actions	<u>Example:</u> In this specific lesson, I wish I had encouraged more peer discussions.	<u>Example:</u> I wish to have more peer discussions in my class.
Current actions	<u>Example:</u> In this specific lesson, I encouraged students to talk to their peers.	<u>Example</u>: I always encourage peer discussions in my class.

By distinguishing between narratives about *Specific* actions (first column) versus ones about *General* actions (second column), we drew on a distinction made by Heyd-Metzuyanim and Sfard (2012) between a person's communication about their *specific* performance versus their routine or *general* performance. We see these two types of communication as essential to exploring the formation of *identity*, defined as "narratives about individuals that are reifying, endorsable and significant" (Sfard & Prusak, 2005, p. 16). By distinguishing between narratives about *Desired* actions (first row) versus ones about *Current* actions (second row), we drew on Sfard and Prusak's (2005) distinctions between various types of identity narratives (i.e., actual and designated). Building on their conceptualizations, we distinguish between narratives teachers author about their *current* pedagogical actions, and those authored about their desired pedagogical actions. This focus on personal narratives allows us to adopt the teacher's perspective on her pedagogical practice while we tell the story of her identity formation. Based on our four-fold conceptualization, we ask the following research question: *What was the trajectory of Olive's (specific and general) narratives about her current and desired pedagogical actions in relation to their alignment with traditional and reform pedagogical actions?*

Methods

The data on Olive's trajectory as a beginning teacher came from multiple sources, collated over four years. The PST-period data comprised lesson plans, video recordings and written reflections for the four lessons Olive taught to small groups of high-school students, as part of the capstone course *Mathematical Reasoning and Proving for Secondary Teachers* (Buchbinder & McCrone, 2023). The internship data were collected for two lessons Olive taught in her cooperating teacher's (CT's) classroom. Data sources included video recordings of the observed lessons and debriefing interviews of each lesson. As an NT, Olive was three times observed and interviewed after each lesson; and once, in lieu of an observation, we conducted an extended interview in which Olive shared an activity she enacted in her class and a sample of student work. Supplementary data included Olive's contributions to bi-monthly meetings of the professional learning community (PLC) of all new teachers participating in this study. The video recordings of all interviews and PLC meetings were transcribed for analysis.

To analyze the data, we first identified in the transcripts instances of Olive's narratives about her pedagogical actions. Each narrative was coded as either *specific* to that lesson or describing Olive's teaching in *general*. Further, the narratives were coded as either describing her *current* teaching or what she considered her *desired* way of teaching. This created the four categories conceptualized in Table 2: *current specific, current general, desired specific* and *desired general*. Next, the narratives were coded as aligned with either *reform* or *traditional* teaching practices. The coding scheme was based on content analysis of NCTM's (2014) *Principles to Action*, in which we generated a list of teaching valued actions consistent with reform or with traditional pedagogy (as exemplified in Table 1). Finally, we created a profile of Olive's narratives about her pedagogical actions *in each lesson*. Figure 1 shows one such profile extracted from the debrief interview of Olive's first lesson as NT. The actions aligned with reform practices are shaded in blue and the traditional ones are shaded in yellow.

	Specific	General
Desired	Ensure students leave with deep math knowledge Give students more time to work independently	No narratives about desired general actions
Current	Encourage students to take responsibility for their learning Ask students to provide justifications for their claims Provide activity in which students choose between strategies Let students do the mathematical talking	Encourage students to think independently Provide students opportunities to author their own tasks Teach students in a lecture style Provide activities for students to practice procedures

Figure 1: Profile of Olive's Narratives about her Actions in her First Lesson as NT

Examining these lesson profiles, we tracked changes in Olive's narratives about her pedagogical actions across time points and settings: university (PST), internship (INT), and autonomous teaching (NT). We describe them below.

Findings

PST: Current and Desired Actions Align with Reform Teaching

As a PST, all of Olive's narratives about her current pedagogical actions were specific to the four lessons she taught during the capstone course, and there were no narratives about her current general actions (as she was not yet teaching her own classroom). She did, however, author narratives about her general desired pedagogical actions. All her narratives were coherent with each other and aligned with the reform teaching practices, specifically those related to reasoning-and-proving (Stylianides, 2008). This alignment was evident in all the reflections Olive wrote after her four lessons. For example, in her second lesson, Olive incorporated reasoning-and-proving actions with the mathematical topic of congruent triangles and special segments in a triangle, while introducing students to conditional statements. In her reflection, she wrote:

> Together [with the students] we defined a conditional statement and discussed how they occur in a variety of settings. I also asked for students to provide their own examples of both if/then conditional statements and non-if/then conditional statements, identify hypothesis "P" and conclusions "Q" and determine their truth value, this includes some proofs and some counterexamples.

Olive's narratives about her pedagogical actions in this lesson (current-specific) included reform reasoning-and-proving actions such as providing students with opportunities to author their "own examples"; validate mathematical claims ("determine their truth value"); construct proofs and use counterexamples to refute arguments.

Similarly, Olive's narratives about her general desired pedagogical actions were aligned with reform teaching practices. For example, in her forth reflection, she wrote:

> Indirect reasoning and proving was so much fun to integrate into a lesson, I had never realized before that putting indirect reasoning into any math concept could be relatively easy for a teacher and *absolutely* accessible for students [emphasis in the original]. [...] I should certainly be able to find ways to incorporate it into different types of lessons.

Here, Olive shared her excitement ("so much fun") about the relative ease of integrating indirect reasoning into this specific lesson as well as future lessons ("I should certainly be able to find ways to incorporate it"). She talked about the joy of engaging students with indirect reasoning "in any math concept" and "into different types of lessons." Thus, her desired actions in this specific lesson, and general desired ones (in future lessons) were coherent and aligned with reform actions. A similar pattern was observed in all of Olive's four reflections as a PST.

INT- First Debrief: Traditional Current Actions vs. Reform Desired Actions

As an INT, Olive taught in the classroom of Julia (pseudonym), her cooperating teacher (CT). In her debrief interview, following her first lesson, there were still no narratives about her current general way of teaching, only ones specific to the lesson. These narratives, in contrast to her narratives as a PST, were completely aligned with traditional teaching practices, prevalent in her CT's classroom. This was apparent in Olive's debrief interview when she described her goals for the lesson as follows:

> I would feel accomplished if they [the students] understood how to combine like terms on two sides of the equation, moving chunks with the variable […] I knew that having the variable on both sides would freak them out because they'd only done it with a variable on one side. So that was probably the biggest hurdle to get over today, combining the variable terms.

Olive's narratives in this excerpt (current-specific) were aligned with traditional practices such as making sure that students know how to carry out mathematical procedures ("the biggest hurdle to get over today, combining the variable terms"); and ensuring that students are not too frustrated or confused ("I knew that having the variable on both sides would freak them out"). However, as the debrief progressed, Olive authored narratives about wishing she had taken pedagogical actions that allow students to be more explorative in their learning, saying:

> I'd love to have sometimes an equation up and they'll [the students] suggest something [like] "add 24 to both sides," and it won't make sense, but I wanna just go along with what they're saying […]. [As if saying] "let's just play with the rules for the day" […] and show them why it doesn't make sense. […] They are stuck to doing only moving these [terms], but if you can conceptually understand that we have a scale, and as long as you're doing both things to both sides [of the equation], the answer is going to be the same at the end of the day.

In this quote, Olive contrasted her traditional pedagogical actions in this lesson, with desired ("I'd love to …") actions aligned with reform pedagogical practices of encouraging students to explore mathematical rules and use their own methods for solving problems ("let's just play their rules"), and of proving them with opportunities to establish a strong conceptual foundation ("if you can conceptually understand…"). Thus, as Olive transitioned from PST to INT, a gap opened between her narratives about her current traditional actions and desired reform ones.

INT- Second Debrief: Reform/Traditional Current Actions vs. Reform Desired Actions

In the debrief following Olive's second observed lesson, the gap between her narratives about current and desired pedagogical actions narrowed as Olive's narratives about her current actions became more aligned with reform practices, as the next excerpt shows:

> I had decided to do that little, what I called an exploration in the beginning [of the lesson]. […] I kind of pushed to do that just because in the original lesson plan that Julia had written years prior, the idea of flipping the inequality side is not really explored at all […] I wanted them to see it for themselves and to understand, using numbers, why that was the case.

Olive described in this quote how she took the liberty to modify her CT's lesson plan by introducing in it a short "exploration" activity that would help students make sense of the rule for changing the sign of inequality when multiplied or divided by a negative number. This activity aligned with reform practices such as providing students with opportunities to explore rules and to make sense of and justify mathematical claims ("I wanted them to see it for themselves and to understand, using numbers, why that was the case"). Although Olive's narratives about her current pedagogical actions in this excerpt aligned with reform practices, in the rest of the lesson, she followed her CT's lesson plan that was rooted in traditional practices. Olive shared that she would have preferred to continue the exploration activity for the entire lesson, saying: "I wish I could have given a whole 40 minutes to that, you know, but I'm so glad that it got worked in at all". She added: "I would've liked to take some of the conjectures that they said that I didn't agree with and show them why I didn't agree with them." Thus, Olive's narratives about her current specific actions were aligned with both reform and traditional teaching practices, while her desired ones remained purely aligned with reform practices.

NT: Reform/Traditional Current and Desired Actions

As NT Olive was faced with the responsibility of day-to-day teaching, but also was free to experiment with reform teaching on her own. The first lesson we observed was a group activity where students explored parabolas as projectiles in the Angry Birds ® game. In the debrief interview Olive shared her excitement about this activity by saying:

> I'm really enjoying doing this project because I have been doing a lot of boring, I feel like, lecture-style things. And so, this is like an opportunity for me to stop talking, which is really wonderful. […] It is incredible how they [students] can focus, […] and kind of crank stuff out pretty quickly, and without a ton of wrestling from me, which is really nice.

Here Olive described her current general pedagogical actions ("I have been doing") as traditional ("boring lecture-style") contrasting them with reform-aligned current actions specific to this lesson, including giving students a rich mathematical task and supporting them in taking responsibility for their learning ("without a ton of wrestling from me"). However, when the interviewer inquired about incorporating more conceptually rich prompts, Olive replied:

> I guess my hesitation […] I'm playing devil's advocate in the situation, if I went and tried to go off on a conceptual tangent with each kid, I think that they would tune out immediately […] with so many kids […] to try to circulate that room and have a deep conceptual conversation with each of those 28, I don't even think I'd have time in the block to do that.

In this quote, Olive questioned whether it is realistic to pursue "deep conceptual conversations" "with so many kids." While not rejecting the idea, she *implicitly* positioned this kind of reform action as generally non-desirable. Thus, in her first debrief as NT, Olive's narratives about her *desired* actions began to move away from being purely aligned with reform practices.

In the following interviews, Olive's narratives about her current pedagogical actions presented a mixture of reform and traditional actions. For example, in her second NT interview, Olive described a lesson on operations with radicals in the following way:

> I liked that some of it [the lesson] felt exploratory, but then some of it definitely felt like a very telling way of teaching, like just kind of giving them the information as opposed to letting them figure it out".

Here, Olive communicated narratives about her current specific actions as being both reform-oriented ("I liked that some of it felt exploratory") and traditional ("telling way of teaching", "giving them the information").

As time went by, Olive's narratives about her current pedagogical actions, both specific to a certain lesson and general, continued to present a mixture of reform and traditional actions. Olive explained: "I try to start each unit with like a nice little discovery activity of some kind." She talked excitedly about one activity where students discovered the value of Pi, saying: "I didn't want to give too much away. I was trying to teeter a line of 'figure it out yourself." She shared her joy when students "have the best conversations, and they argue, and they don't want my input." These narratives were all aligned with reform practices. However, Olive admitted that these types of reform activities are infrequent among more traditional ones. She said: "I feel like as the unit goes on, it becomes less exploration and more like, here's the content, get it in your head." Thus, Olive's narratives about her current general pedagogical actions aligned also with traditional practice.

As captured already in her first debrief as NT, Olive's narratives about *desired* pedagogical actions changed as well toward more traditional practices. Notably, there was still some gap between current and desired narratives. On the one hand, Olive still strived to enact reform practices, saying "In an ideal world, I would've absolutely loved to do that activity [Pi-exploration] with every section." But on the other hand, reform teaching seemed to be more of a hypothetical ideal for Olive. The next quote illustrates this duality:

> I definitely don't wanna be a person that's lecturing every day, but I also don't necessarily have some super fun exploration planned every day either. There's gotta be like a healthy balance of those two things.

Olive did not want to revert to traditional teaching practices; however, her questioning of the feasibility of enacting reform actions day in and day out became more explicit and upfront. In one of the later interviews, Olive reflected on her trajectory from the university to classroom teaching:

> [In] undergrad and even as an intern [I] made some lesson plans that were just absolutely ridiculous in terms of what I expected the students to understand at a rate or pace that was absolutely unrealistic for the children […] I've definitely become more, I like to consider it, realistic […] sometimes I feel bad about it and sometimes I feel guilty about it. […] I try to maintain high expectations, but I think I, I'm a little bit more realistic.

In this excerpt, Olive framed some of her ambitious, reform-aligned lessons she developed as PST and INT as "ridiculous" and "unrealistic." She positioned her current mixture of reform and traditional actions as "realistic," although admitting she felt "sometimes bad" and "guilty" about this change. Thus, Olive in her second year as a new teacher identified herself as a realistic teacher who strives for a "healthy balance" between the traditional school world and the teacher-education world of reform pedagogy.

Summary and Discussion

Figure 2 summarizes the trajectory of Olive's narratives about her specific/general, current and desired pedagogical actions as aligned with traditional or reform pedagogical practices.

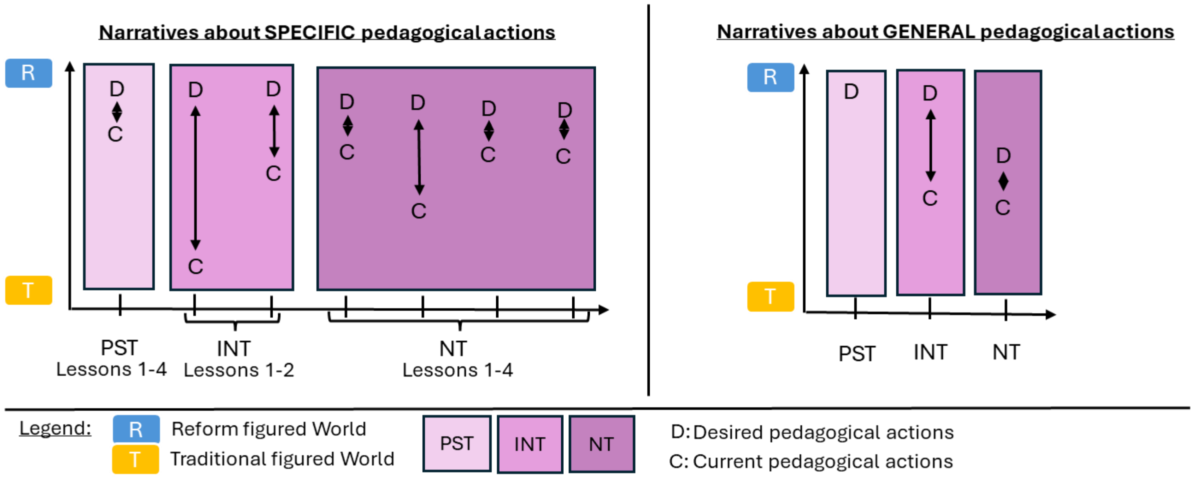

Figure 2: Trajectory of Olive's Narratives about her Pedagogical Actions

We present *specific* and *general* narratives separately, side by side. The vertical axes represent a non-quantified continuum between reform and traditional actions. The position on the continuum is not absolute, but represents general discursive tendencies observed in the data (cf., Truxaw and DeFranco' (2008) Sequence Maps). The narratives about *general* pedagogical actions (on the right) are represented by a single instance per period (PST, INT, NT) based on aggregated data. Also, narratives about *specific* pedagogical actions for the PST stage are collapsed across four lessons. However, each observed lesson as INT or NT is represented separately, to provide greater detail about Olive's narratives during this critical period of her teaching career. The icons "C" and "D" stand for current and desired actions; close placement represents coherence of narratives, while distanced placement represents a gap between current and desired narratives.

As a PST, Olive's narratives about *desired* actions, both specific and general, were aligned with reform practices. The same was true for narratives about her *current* actions in the four specific lessons she taught as PST. This reinforces our choice of Olive as a case of a beginning mathematics teacher, who was both well-prepared and eager to enact reform teaching practices.

Two critical processes followed Olive's promising starting point as a PST. The first one occurred during Olive's internship, when her narratives showed a gap between desired reform actions and current traditional ones (both specific, as seen in lesson 1 as INT, and general). This gap is consistent with previous studies suggesting that novice teachers tend to adopt the traditional teaching practices of their mentors (Bieda et al., 2014; Gainsburg, 2012). In her second lesson as well as the following lessons during her NT period, Olive tried to close the gap by aligning her current traditional pedagogical actions with her desired reform ones (captured in the Figure by the rise of "C" toward "D"). This finding aligns with Horn and colleagues (2008) who foregrounded the link between interns' reform desired images of good teaching and the modification of their traditional teacher identities.

The second process occurred during Olive's NT period. We did not identify a particular turning point in Olive's narratives, but rather a gradual process characterized by two trends. The first one is the fluctuation of narratives about *current* specific practices somewhere in the middle along traditional-reform continuum (captured by changes in the location of "C"). This trend points to Olive's multiple attempts to integrate reform practices in specific lessons revealing the dynamic changes in her narratives about specific actions. These changes are important as they underly the formation of Olive's more stabilized narratives about current general actions aligning with *both* traditional and reform actions. The second trend in Olive's narratives is the gradual shift in the *desired* actions toward more traditional practices (captured by the lowered position of "D" both in relation to specific and general actions). This shift points to Olive's attempts to close the gap between narratives about her current and desired actions by "lowering the bar" and modifying the desired actions to be more "realistic," traditional ones. This finding suggests that even an enthusiastic beginning teacher, like Olive, who is committed to reform practices, may need support in keeping the view of reform practices as desired (Ingersoll & Strong, 2011).

We believe that Olive's longitudinal case of a promising new teacher entering the world of traditional schooling, contributes to a better understanding of the underlying processes of identity formation during the reconciliation of the two worlds. As we continue to investigate trajectories of Olive and other beginning teachers in the larger study, we intend to include further lenses to gain a better understanding of identity formation as interwoven with social and cultural contexts.

EARLY CAREER MATHEMATICS TEACHERS' REFLECTIONS ON THEIR PREPARATION FOR TEACHING

Betsy Berry
Purdue University Fort Wayne
Berrys@pfw.edu

As mathematics teacher educators, we strive to motivate and inspire our students to engage in *ambitious teaching* as described in Principles to Action (NCTM, 2014) and the Taking Action (NCTM, 2027) series published by the National Council of Teachers of Mathematics. We also address and stress the need for strong "foundations of pedagogical knowledge, effective and equitable mathematics teaching practices, and positive and productive dispositions toward teaching mathematics to support students' sense-making understanding, and reasoning." (AMTE, 2017, C 2, P 3)

Ambitious teaching contrasts sharply with the instruction models that most students have found in their mathematics classrooms. As middle and high school learners, they encountered, for the most part, a routine that included homework review, teacher lecture and demonstration followed by individual practice. This routine was further articulated in the *I do, we do, you do,* model of instruction. This disconnect continues in their college courses. (Nguyen & Munter, 2023)

It then becomes our challenge as teacher educators to overcome that model and help our students see themselves as facilitators of learning rather than engaging solely in the practice of direct instruction that they have been exposed to as students throughout much of their learning of mathematics. In their methods courses and in their practicums, our goal then becomes one to ensure that our pre-service teachers have the opportunity to fully engage with the Effective Teaching Practices in all ways. This has become our most important goal, and our students demonstrate their progress in comprehensive unit plan design and implementation of these practices in field experiences and student teaching assignments during their final year of their college program.

What then, do they take with them into their own classrooms from their methods courses and internships? What do they remember, and what do they put into practice in their own teaching? What support and mentoring have they experienced in their first years of teaching? What do they need and how can we help? What can we learn about re-designing our programs when we answer these questions?

This poster session will answer some of those questions and will include the design and results of an interview study with 15 early career middle and high school teachers. Each of these teacher-participants had completed a few months to 5 years of teaching experience at the time of their interview. All were former students in a methods class with the authors and were supervised by them the following semester in their student teaching. The poster will also highlight important aspects of the participants undergraduate preparation for teaching.

This study explores preservice teachers (PSTs) autobiographical reflections on their experiences with math. Findings reveal distinct trajectories, including positive journeys characterized by enthusiasm and satisfaction, discouraged and disheartened paths marked by negative emotions, empowering shifts triggered by positive encounters, and disruptive shifts leading to negative perceptions due to challenging experiences. We discuss the factors that contribute to these trajectories including relationship with teachers and families and PSTs' perceptions of their own aptitude. The narratives point to a need for supporting positive early experiences for children and tailoring instruction for PSTs to attend to their personal math experiences.

Keywords: Preservice Teacher Education, Affect, Emotion, Beliefs, and Attitudes, Elementary School Education.

Early experiences with math play a crucial role in laying the groundwork for teachers' perceptions and connections with the subject. Autobiographies serve as a valuable tool for gauging someone's inclinations toward subjects and tracking changes in their attitudes over time (Ellsworth & Buss, 2000). Autobiographical storytelling, the practice of recounting personal experiences, holds a significant place in social sciences research (Miller, 2000). Studies exploring storytelling in math education have demonstrated that narratives offer insights into individuals' attitudes, beliefs, and identities regarding math that traditional survey instruments fail to capture (Ellsworth & Buss, 2000).

Perspective(s)

Autobiographies serve as a reflective tool, offering teachers a means to understand themselves both personally and professionally (Connelly & Clandinin, 1999). Crafting autobiographies helps students develop a conscious awareness of the connections between their present beliefs, identities, and emotions and their past experiences with math (Drake, 2006; Hauk, 2005; Machalow et al., 2022). Autobiographical narratives can also unveil teachers' orientations toward math (Machalow et al., 2022), as well as their preference for specific teaching methodologies (Ellsworth & Buss, 2000; Hauk, 2005). In this study, an autobiography denotes an individual's written account of their experiences learning math. We asked preservice teachers (PSTs) enrolled in an elementary math methods course to recall events that had positive, negative, or neutral effects on their interest in, attitudes toward, and emotional responses about math, along with their overall sense of competence. Our analysis focused on examining changes in their experiences throughout their multi-year engagement in math. We focused on answering the following research question, *how do PSTs' past experiences influence their interest, attitudes, emotional responses, and sense of competency related to mathematics?*

Methods

Fifteen PSTs enrolled in an elementary math methods course participated in this study. The course's main objective is to equip future educators with the necessary skills to effectively teach in student-centered ways. The activities were specifically designed to encourage PSTs to actively reflect on their own mathematical thinking, facilitating the development of instructional approaches and strategies with students. PSTs were tasked with writing autobiographical accounts of their experiences with math. Prompts were provided to guide the PSTs to explore their perceptions (e.g., How do you feel about math? Why do you think you feel this way? What factors contributed to this feeling? Describe how that person or event influenced your feelings); however, they were free to construct the narratives that best reflected their experiences.

Data Sources and Analysis

PSTs' autobiographies served as the data source. Employing an inductive analytical approach, we engaged in multiple readings of the narratives to identify the core ideas PSTs conveyed about their experiences. Then we looked across the narratives for common themes (trajectories, as explained in the next section) within their stories (Polkinghorne, 1995). We categorized the experiences PSTs described (label of each column) and the nature of the experience (label of the rows; Figure 1).

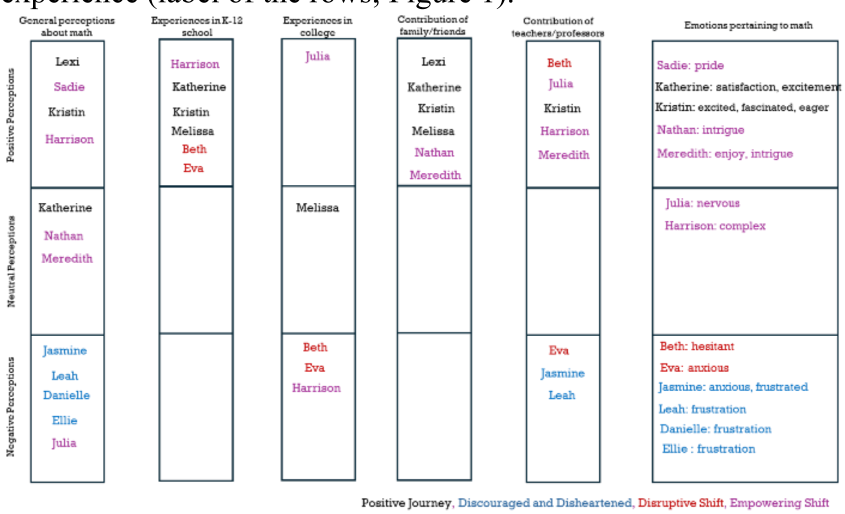

Figure 1: Categorizing PSTs' experiences across distinct areas and associated emotions

Then, we examined each PST's case individually to explore their trajectory more comprehensively. During this phase, our aim was to gain deeper insights into the main influences on the teachers' mathematical journeys over time. To achieve this, we devised a mapping framework that outlined the phases of each teacher's mathematical life and identified perceived influences. This mapping allowed us to track the transitions within mathematical narratives, including positive, neutral, and negative influences/experiences that prompted shifts in their ideas about math. Four distinct trajectories emerged from this analysis (Table 1).

Findings

Table 1 presents the categorization of the PSTs' trajectories accompanied by a description. Next, we describe the distinctive characteristics of each trajectory type.

Positive Journey

Four PSTs – Kristin, Lexie, Melissa, and Katherine - discussed their positive math journeys. Their positive perceptions of their mathematical abilities were based on consistently experiencing success and having empowering experiences in math. Lexie, for instance, described how she effortlessly grasped math concepts and excelled without much difficulty. She attributed this to her innate understanding and confidence in her abilities, stating, "Since I can remember, I've always felt naturally adept at math". Others recounted having exceptionally positive experiences with math during their K-12 schooling. Kristin, for example, expressed her fondness for math, labeling it as her "favorite subject" throughout middle and high school due to her consistent success and appreciation for its logical problem-solving nature. Additionally, they acknowledged the presence of consistent support from parents or teachers. Katherine credited her father for nurturing her curiosity and skills in math, while Kristin highlighted the influence of her 9th-grade algebra teacher, who encouraged diverse problem-solving methods.

Table 1: Types of Trajectories

Trajectory	Description
Positive Journey	Had no adversities in their mathematical journey.
Discouraged and Disheartened	Had predominantly negative early math experiences, interpreting them as indicative of innate mathematical incompetencies.
Empowering Shift	Had predominantly negative early math experiences; then, experienced a critical positive event engendering a positive attitude, belief in mathematical competence, and enjoyment in mathematical endeavors.
Disruptive Shift	Had predominantly positive early math experiences; then, experienced a critical negative event engendering a negative attitude, lack of belief in mathematical ability, and negative emotions about math.

Discouraged and Disheartened

Some PSTs including Jasmine, Leah, Danielle, and Ellie, perceived failure and/or consistently felt discouraged from math experiences, resulting in negative perceptions of math. For instance, despite Ellie achieving high grades in K-12 math, she felt inadequate relative to peers who excelled in mental math which she struggled with. Additionally, this group referenced negative experiences with their math teachers. Leah attributed part of her struggle to male teachers explaining the material in an unhelpful manner, shaping her negative perception of math. A particularly hurtful experience occurred when her high school teacher questioned her work ethic, which made her feel misunderstood and incapable. Consequently, her frustration for math was largely shaped by the teacher's attitude towards her struggles rather than the difficulty of the content itself. Similarly, Jasmine described a decline in her confidence during middle school, feeling overwhelmed as her peers seemingly effortlessly solved algebra equations while receiving little support from teachers. She felt frustrated and abandoned by teachers – "teachers certainly knew I was struggling, but they didn't do anything to help". They all expressed negative emotions, such as anxiety or frustration with no interest in doing any math.

Empowering Shift

Some PSTs - Julia, Sadie, Harrison, Meredith, and Nathan – described negative or neutral experiences until a critical event. A positive experience engendered optimism toward math. Julia, for instance, recounted struggling with math for many years resulting in feelings of shame and anxiety. However, encouragement and support from her middle school math teacher, Mr. S, helped develop confidence in her math abilities by appreciating her unique problem-solving approaches. Nathan described his experiences with math as neutral. A high school friend played a significant role in altering his perception, initially making math intimidating but also broadening his understanding of its potential, ultimately leading to a more positive outlook. These transformative moments instilled a belief in their potential for success and enjoyment in math. This group described a range of emotions related to math including Julia expressing nervousness, Sadie feeling pride, and Nathan and Meredith expressing feelings of intrigue.

Disruptive Shift

Two PSTs, Beth and Eva, described positive perceptions of math, followed by negative experiences that changed their perspective. Before taking pre-calculus in college, Beth considered herself skilled in math, however, struggles in the pre-calculus class altered her perspective, leaving her frustrated and repelled by math, contrasting her previous sense of contentment and competence in math classes. Similarly, Eva recalls being adept at math and enjoying it because it made sense to her. However, her negative feelings toward math arose during college because she felt less capable when it came to abstract concepts. This change in attitude coincided with an experience with a particular math professor who taught at a rapid pace without ensuring understanding before progressing. This encounter induced feelings of anxiety and nervousness towards math. At the time of data collection, both Beth and Eva shared predominantly negative feelings towards math – experiencing nervousness and anxiety.

Discussion

Across the narratives, PSTs described grappling with both challenges and successes in math. We noted that the main influential factors including supportive teachers, familial encouragement, and individual aptitude could have a positive or negative effect depending on the nature of the experience and the PST's interpretation of it. The influence of teachers across K-12 schooling emerges as a significant factor shaping participants' attitudes towards math (Kaur Bharaj et al., 2023), with positive experiences often leading to increased engagement and confidence, while negative experiences served to exacerbate feelings of self-doubt and disinterest. Similarly, as the subject became more complex, depending on the interpretation, PSTs expressed confidence and enjoyment if they made sense of the ideas, while others had feelings of frustration and anxiety as they encountered abstract concepts that they felt inadequate to understand. These feelings lingered and directly influenced PSTs' ideas about math as they were entering the math methods course. The data highlights the complex interplay among PSTs' interpretations of teacher-student math-related interactions, the nature of math and their math-related emotions and attitudes. It underscores the importance of fostering a supportive and inclusive learning environment that empowers all students to engage with and appreciate the beauty of math.

Significance of Study

The findings are significant in two distinct ways. First, they shed light on the experiences underlying attitudes and emotions PSTs have toward math. This deeper understanding of teachers' personal journeys with math underscores the importance of consistent positive learning experiences throughout formal schooling. Second, exploring PSTs' perceptions of math derived from their own math experiences informs our understanding of how these experiences shape how they enter math and math education spaces. With this understanding, teacher educators can better tailor PSTs' experiences in ways that engender a disposition toward math and teaching math that includes student-centered teaching and positive attitudes towards the subject. Ultimately, by acknowledging and valuing teachers' personal experiences with math, education stakeholders can work toward creating effective math instruction that meets the diverse needs of all learners.

EXAMINING THE IMPACT OF INVOLVING UNDERGRADUATE PRE-SERVICE TEACHERS IN RESEARCH

Brian Bowen
West Chester University
bbowen@wcupa.edu

Keywords: Pre-Service Teacher Education

The primary role of a teacher education program is to provide experience for pre-service teachers (PSTs) that will support their professional practice in creating supportive and effective learning environments. Achieving this goal comes with challenges including, allocating sufficient time and resources to support PST's pedagogical and content knowledge (Ball, 1990) and addressing pre-service teachers' prior experiences as a student, a phenomenon aptly and often described as an apprenticeship of observation (Lortie, 1975). Mathematics methods classes have developed approaches to address these concerns using approaches such as lesson study (e.g. Leavy& Hourigan, 2016) and mediated field experience (e.g. Horn & Campbell, 2015). Strategies such as these intentionally engage students in the application of theoretical ideas and provide opportunities for PSTs to reflect on themselves as practitioners.

There is a need to be cautious in assuming that field experiences alone will support PSTs in fully integrating theory into practice. "Field experiences may expose student teachers to a limited repertoire of strategies and to a narrow and unrepresentative sample of students. Preservice teachers may easily come to believe that only the strategies they observe are appropriate, regardless of the students they may eventually teach" (Santagata, Zannoni, & Stigler, 2007, p.4). One approach that may aid PSTs in not adopting a myopic view of instructional practice is to involve PSTs in research. This approach has been utilized in teacher preparation programs for over 30 years in Finland. From their perspective "the aim is not to produce researchers, but rather to provide students with skills and knowledge to complete their own studies, observe their pupils, and analyze their thanking (Toom et. al., 2010, p. 333). To be most impactful the research conducted should be purposeful and meaningful to the PSTs (Zeivots, Buchanan, & Pressick-Kilborn, 2023). Providing opportunities for PSTs to engage in research may be one effective way to address concerns related to teacher knowledge of both content and pedagogy and may also help address pre-established beliefs of teaching that are rooted in past experiences.

The study presented here investigates the ways in which conducting research may be utilized as a means impacting teacher knowledge and beliefs. This study examined two groups (n_1=8; n_2=8) of PSTs in their senior year conducting research on the practicing teachers' perceptions on the role of homework. Homework was chosen as a topic as it was an area of interest and concern to this group of PSTs as they transition to in-service teachers. The PSTs in this study identified a research question, reviewed relevant literature, designed a study, gathered data, analyzed data, and constructed a poster presentation of their results. After completion of their study, PSTs were asked to reflect upon the way in which conducting the research study impacted their own views of homework and on their own views of themselves as teachers. Results from the two PSTs' studies as well as the study of the PSTs will be presented. Notable results from the PSTs' studies suggest a pattern where teachers surveyed believed "homework to be ineffective and did not contribute to student success." Results from study of PSTs indicated conducting research on homework reinforced their previously held beliefs. Results related to impacting PSTs' own self-image as teachers were less clear.

ON NOTICING STUDENT MEASUREMENT THINKING: THE LEARNING JOURNEY OF ALINA

Mai Bui
Texas State University
Mtb104@txstate.edu

Teacher noticing of students' mathematical thinking plays a pivotal role in reform-oriented instruction. Hence, it is crucial to support preservice teachers, who do not generally possess well-developed noticing skills, in learning to notice student thinking. However, this line of research is scarce in the domain of measurement, an important topic in mathematics curricula. In this paper, I report the learning path to notice student thinking about length measurement of a preservice teacher when given various learning opportunities to develop her noticing. Findings suggest that with the support of a framework on student measurement thinking, the preservice teacher's attention and interpretation become broader, deeper, and better aligned with research-based knowledge. However, her learning path does not consistently follow an upward trend.

Keywords: Preservice Teacher Education, Teacher Noticing, Measurement.

Teacher noticing of students' mathematical thinking is at the heart of high-quality mathematics instruction, which promotes adaptive and responsive teaching (Jacobs & Spangler, 2017). Previous research (e.g., Jacobs et al., 2010) has indicated an expert-novice difference in teacher noticing, with preservice teachers typically lacking well-developed noticing skills due to limited teaching experience (Sherin & van Es, 2005; Star & Strickland, 2008). Across the literature, there have been many efforts to support preservice teachers in learning to notice. However, this line of research is limited in measurement (Ergene & Bostan 2022), an important topic in mathematics curricula, especially at the elementary school level. To address this gap, I have conducted a research project to explore how preservice teachers learn to notice student measurement thinking over time when given learning opportunities specifically designed to support their noticing. This paper presents a finding from the project, focusing on the learning path to notice student thinking about length measurement of a preservice teacher, Alina.

Theoretical Framework

Across the literature, there have been various conceptualizations of teacher noticing. This paper adopts Jacobs et al.'s (2010) concept of professional noticing of student thinking, defined as a set of three interconnected skills: *attending to students' strategies details, interpreting students' understanding,* and *deciding how to respond on the basis of students' understanding*. For the scope of this paper, I focus on the first two skills, attending and interpreting, as they are the foundation for deciding skill. Attending refers to the extent to which teachers identify mathematically significant details in students' solutions. Interpreting refers to the extent to which teachers use the specific details in students' strategies to reason about their understanding in a way that is consistent with research on students' mathematical development.

In the definitions of these two skills, the phrases, "mathematically significant details in students' solutions" and "research on students' mathematical development", appear. What do they mean in the context of measurement? To answer this question, I synthesize relevant literature and present a framework on student measurement thinking called Big Ideas of Measurement (BIM)[3]. The framework comprises 16 big ideas that researchers identified as foundational for students to develop a deep and robust understanding of measurement across different attributes. Therefore, I believe that these big ideas are "mathematically significant details" that teachers should attend to and interpret so that they can better support their students' understanding of measurement. This framework was presented in detail in Bui (2023). In this paper, I focus on six big ideas that show up most often when students measure an attribute with non-standard units and measurement tools such as rulers (see Table 1).

Table 1: Some important big ideas of measurement

Big ideas	Description
Identifying the attribute	Knowing/understanding what is being measured.
Identical units	Same-sized units should be used to measure an attribute of an object.
Exhaustive measure	All of the object has been measured without gaps between units or overlapping units
Unit iteration	This includes making copies of units and arranging them, accumulating those units to obtain a measure, and eventually being able to reuse/copy a single unit
Partitioning unit	Units can be partitioned into fractional amounts smaller than one unit
Zero-point	Each instrument has conventional zero-point(s), but any point can serve as an unconventional zero-point on the instrument. To use an instrument with understanding and flexibility, students should understand what is counted and what the numbers on the instrument represent.

Methods

The study context is set within a content course for preservice teachers with a focus on measurement and geometry at a large public research university in Southern United States. The case study participant, Alina, is a Hispanic preservice teacher, majoring in Pre-K–6 bilingual education. Data about Alina's noticing was collected over 17 weeks of Fall 2023 when she had various learning opportunities to develop her noticing (see Table 2). To measure Alina's noticing, she was asked to engage with various artifacts of practice and share her noticing in written form. These artifacts include short videos or work samples of elementary students measuring the length of different objects with non-standard units and with a ruler.

Table 2: Data related to Alina's noticing of student thinking about length measurement

Time	Relevant learning opportunities	Data
Week 1	N/A	Pre-noticing assessment
Week 2	Class 03: BIM framework given and discussed	Exit ticket after class

[3] I borrowed the phrase *Big Ideas of Measurement* from Empson et al. (2006) who used it in course materials and interviews.

	Class 04: Watch 4 videos and discuss student thinking	Handout “Analyzing student thinking about length”
Week 3	Class 05: Watch 3 videos and discuss student thinking	Homework 1
Week 4	Class 08: Discuss preservice teachers’ responses to HW1: What counts as good explanation?	N/A
Week 5	N/A	Homework 2
Week 6	N/A	Exam 1
Week 7	Preservice teachers paired up and conducted the measurement interview with a fourth-grader	N/A
Week 16	N/A	Final exam
Week 17	N/A	Post-noticing assessment

Jacobs et al. (2010)’s scoring scheme and the BIM framework in Table 1 was used to analyze Alina’s attention and interpretation of the big ideas of measurement. I first considered if Alina paid attention to a big idea of measurement or not, and if yes, what the level of detail was. The level of detail can receive a score of 0, 1, or 2 where 0 means attending to very little or almost no relevant details, 1 means attending to some relevant details but may miss some important details, and 2 means attending to almost all important and relevant details to the big idea. Next, I considered if Alina interpreted a big idea or not, and if yes, what the level of evidence and level of alignment to research-based knowledge on big ideas of measurement were. Similarly, the level of evidence and level of alignment can receive a score of 0, 1, or 2 in the same manner as to level of details. For example, if Identical unit receives the scores 1 for *Interpret or not*, 2 for *Level of evidence*, and *1 for Level of alignment*, it indicates that Alina interpreted students’ understanding of measurement (e.g., understand or not), she gave almost all important and relevant evidence for her claim; however, her interpretation of students’ understanding of that big idea was not completely align to research-based knowledge. In addition, I noted if Alina explicitly used the technical terms (for example, Identical unit) in her noticing or not. For example, if she wrote “The student understands the big idea of identical unit”, a score of 1 will be assigned; if she wrote “The student knew that we have to use same-sized units when measuring”, a score of 0 will be assigned. Finally, I calculated the sums for each of the six columns in Table 3 (Attend or not, Level of detail, Interpret or not, Level of evidence, Level of alignment, and Use of technical terms). These sums will be referred to as scores for Breadth of attention, Depth of attention, Breadth of interpretation, Depth of interpretation, Alignment of interpretation, and Use of technical terms from BIM.

Table 3: Coding Alina’s attention and interpretation of big ideas of measurement

Big ideas	**Attend or not**	**Level of details**	**Interpret or not**	**Level of evidence**	**Level of alignment**	**Use of technical terms**
…	0=No, 1=Yes	0, 1, 2	0=No, 1=Yes	0, 1, 2	0, 1, 2	0=No, 1=Yes
…						
Sum						

Findings

Table 4 summarizes the scores for Alina's attention, interpretation, and use of technical terms from the BIM framework over time. Overall, with access to the BIM framework and more learning opportunities to unpack the meaning of the big ideas in the framework, Alina's noticing of students' understanding of the big ideas of measurement became broader, deeper, and better aligned with research-based knowledge on students' measurement thinking. She also used more technical terms from the BIM framework. However, the development of her noticing did not always follow an upward trend. For example, in homework 1 (week 3), Alina's noticing significantly improved compared to her performance on the class's handout and exit ticket in week 2. Two weeks later, when Alina worked on homework 2, the depth and alignment of her interpretation slightly decreased before continuing to develop in week 6.

Table 4: Alina's attention and interpretation of big ideas of measurement over time

Time	Data	Attention of BIM		Interpretation of BIM			Use of technical terms
		Breadth	*Depth*	*Breadth*	*Depth*	*Alignment*	
Week 1	Pre-noticing[4]	2.5	2	1	1	1.5	0
Week 2	Exit ticket	3	5	3	4	5	1
	Handout[5]	4.25	7.25	3.75	5.75	6	4
Week 3	Homework 1	6	9	6	9	10	6
Week 5	Homework 2	6	8	6	5	6	6
Week 6	Exam 1	7	12	6	8	8	6
Week 16	Final exam	6	9	6	9	9	6
Week 17	Post-noticing[2]	5.5	6	4.5	5	5	5

Let us look at two excerpts from Alina's analyses of student measurement thinking in the pre- and post-noticing assessments to see how her noticing changed over time.

> Helena was able to take two different objects or mediums and compare them in order to find Speedy's length… Helena has a general understanding of how to compare two different units. (Alina, pre-noticing assessment)
>
> Reid was able to identify the attribute... His question of "Can I line them up like this" helped me see that he attends to orientation and knows what he is measuring...He was able to produce a measurement with identical units for the most part, up until the end. Based on the video, I was able to see that his reasoning behind this was the fact that Reid wanted Speedy to fit exactly into all of the paperclips lined up… (Alina, Post-noticing assessment)

At the beginning of the semester, Alina's noticing was very general: her description of Helena's strategy was vague, and her interpretation did not point out any specific ideas of measurement that Helena understood. In contrast, in the post-noticing assessment, Alina provided many important details about Reid's strategy through verbal quotes and subtle actions,

[4] The average across 2 types of artifacts: video and work samples

[5] Average across 4 videos

and she interpreted these details to make sense of his understanding of the big ideas of measurement (e.g., identifying the attribute and identical units).

Closing Thoughts

This report shows that access to the BIM framework and opportunities to unpack the meaning of the big ideas from the framework supported Alina in noticing student measurement thinking more broadly and deeply. This finding suggests that BIM could be a potential tool to assist preservice teachers' professional noticing. Future research may explore how preservice teachers with diverse backgrounds learn to notice students' measurement thinking over time and what challenges they face during that journey. Findings from this line of research will provide mathematics educators with more insights into how to design courses in teacher education programs to support preservice teachers' professional noticing of student measurement thinking.

UTILIZING SCRIPTING TO EXAMINE DIFFERENT TYPES OF MATHEMATICS QUESTIONS OF PRE-SERVICE TEACHERS

Jelena Byers
Purdue University
byers40@purdue.edu

Questioning is one core practice mathematics teacher educators (MTEs) create instructional activities to develop. An instructional activity creates visibility around questioning is that of scripting dialog that takes place within a mathematics classroom. Through a qualitative research study, the researcher examined PSTs' mathematics questioning types through two iterations of script writing from one problem situation. Findings illustrated that PSTs commonly used two questioning types: gathering information and probing student thinking style questions. Implications for MTE's instructional activities are summarized and discussed.

Keywords: Preservice Teacher Education, Instructional Activities & Practices, Classroom Discourse

Introduction

Questioning has long been considered a core practice in mathematics education literature (e.g. Vacc, 1993). Preservice elementary teacher (PSTs) approaches to questioning during interviews and discussions have included categorization schemes for types of questions posed (Parks, 2010). Such studies identify how PSTs question in various contexts, yet how PSTs develop questioning through methods instruction is still an open question. One way mathematics teacher educators (MTEs) support questioning development is through approximations of practice (Ball & Forzani, 2009, Grossman & MacDonald 2008; Grossman et al., 2009; Reid, 2011) such as scripting. Herbst (2018) describes scripting as the creation of a dialogue as if for a play. Scripting is a form of rehearsal that requires PST to consider and compose dialogue between themselves and their students. The variety of questions that PSTs elicit during a mathematics lesson is low (Weiland et al., 2014). Engaging PSTs in script writing allows for an opportunity to imagine dialogue between a teacher and students in such a way that MTEs can provide guidance around different questioning types.

Different types of questions such as implicit and explicit questions (Parks, 2010) can be challenging to create while engaging with learners and even in planning lessons. Moreover, when PSTs are developing in their questioning techniques, often times they miss opportunities to foster thinking of their students and their questions are more leading in nature (Weiland et al., 2014). PSTs, with little teaching experience, draw from their interactions as students with their teachers as they plan mathematics lessons. In this paper, I characterize PSTs' questions in a scripting context that provided PSTs with opportunities to draw from their lived interactions while also developing their understandings around pedagogical practices during their methods coursework (Liston, Whitcomb, & Borko, 2006). While there is literature around analyzing questioning of PSTs during interactions in lessons that that they have scripted (Zazkis, Liljedahl, & Sinclair, 2009;) and studies of those who seek to utilize scripting to analyze dialogic teacher moves centered on mathematical tasks (Crespo, Oslund, & Parks, 2011; Campbell & Baldinger, 2022), there are limited findings on utilizing scripting by MTEs to analyze and develop questioning practices of PSTs. To investigate questioning types utilized by PSTs, collaborative scripts of a mathematic lesson were written followed by individual script revisions. I use the following research question to guide my inquiry: *How do PSTs' plan questioning in a script of a mathematics lesson?*

Literature Review

Campbell and Baldinger (2022) suggest to prepare PSTs for teaching, teacher preparation programs must create opportunities for PSTs to participate in activities that mimic strategies in-service teachers utilize upon entering the field. One such way to aid in the development of PSTs' variation of questioning, is to utilize scripting as an instructional activity. In this paper, I first summarize literature on PSTs questioning drawing a distinction between questioning with children and theoretical questioning produced in instructional activities such as lesson planning. I then build upon questioning by utilizing the context of scripting as an approximation of practice MTEs use to create opportunities for PSTs to develop their questioning practice.

Questioning

Lim et al. (2018) described the ability to facilitate classroom discussion and discourse as the "teacher-students' dialogic interactions where students talk about mathematics and develop new understanding of concepts, through teachers' effective use of questioning" (p. 293). Without teacher questions, students struggle to identify the content or practice focus of a learning opportunity. For example, Parks (2020) examined the affects teachers' pedagogical moves had on students access to the mathematics being taught noticing how the teachers' questioned the students correlated to whether the students were probed for correctness or conceptual understanding. Effective questioning supports different phases of a discussion including initiating, orchestrating, and closing (Shaunessy et al., 2019).

Moyer and Milewicz (2002) described questioning approaches PSTs used in interactions with mathematics learners: *checklisting*, *instructing rather than assessing*, and *probing/follow-up questions* (p. 300 – 301). Checklisting occurs when an individual asks planned questions in order, regardless of the response a student provides. Instructing rather than assessing questions, are sequences of questions the teacher uses to lead the students' thinking. This category also includes teacher approaches that abandon questioning in favor of telling students how to approach a situation. Probing/follow-up questions are questions that ask the student to expand upon their ideas. These approaches to questions in the moment of interacting with learners suggest that PSTs need opportunities to build their questioning practice prior to or alongside their interactions with students. In this paper, I focus on questions that PSTs use during their preparation for interaction with students. This work illustrates the importance of MTE awareness of how PSTs typically pose questions and, in turn, create instructional activities to allow PSTs to practice planning and delivering a larger variety of question types.

In contrast to Moyer and Milewicz (2002), Purdum et al. (2015) analyzed PSTs' planned questions in their lesson plans prior to interactions with students. Without interaction with learners, Purdum focused on sorting questions into categories. PSTs planned both closed and open questions. Closed questions are those such that when posed to multiple students, they would all arrive at relatively the same set of responses. An example of this would be if a teacher asked a student to explain what another student had done when presented with a worked out solution to a problem. In contrast, open questions allowed for multiple solutions such as if a teacher asked students to show other ways of modeling their mathematical reasoning for the same problem. Findings aligned with those of Moyer and Milewicz (2002) in that PSTs were limited in the number and type of questions planned as most of the PSTs planned questions that were closed style questions.

Scripting

MTEs use scripting for a variety of purposes. Spangler and Hallman-Thrasher (2014) used scripting to examine PSTs ability to lead mathematical discussion. Zazkis (2017) examined scripts for creativity in mathematics teaching. Campbell and Baldinger (2021) further identified their use of scripting in addition to other instructional activities to prepare PTs for error handling. Such instructional sequences were identified as ways for MTEs to gain insight into PSTs knowledge of students, mathematics, and pedagogy. Lee and Lim (2021) use of scripts to examine PSTs approaches for moving lessons from launch, to exploration, to conclusion. Findings showed PSTs' struggles conceptualizing launches and conclusions of lessons were represented in the scripts Spangler and Hallman-Thrasher (2014) created in an activity sequence using scripts to prepare PSTs for teaching a mathematics lesson to students. PSTs who engaged in thoughtful consideration of the lesson progression, saw sustained improvement in the discussions they led with students (Spangler & Hallman-Thrasher, 2014). Crespo (2018) utilized scripting so PSTs could self-assess hypothesized teacher moves and student responses for revision.

PSTs need opportunities to plan questions if they are to develop utilizing a variety of questions throughout their lessons. Scripting is one opportunity MTEs can use to scaffold PSTs' question variety. MTEs use scripting to support PSTs' learning to plan and facilitate mathematics lessons. In this paper, scripting is used as a context for describing changes in PSTs' questioning during a mathematics lesson. Based on the existing literature focused on PSTs questioning and scripting as a context for development of PSTs practices, scripting might be one way to gain further evidence of PSTs development of questioning practice prior to interactions with learners.

Methods

Participants in the study were enrolled at a small Midwestern liberal arts institution, enrolled in mathematics methods during the spring of their junior year. The context for questioning is situated with the utilization of the five question types within the course text *Taking Action: Implementing Effective Mathematics Teaching Practices K – grade 5* (Huinker & Bill, 2017). During one instructional activity, the participants were divided into four groups of three or four, given a 3rd grade *Illustrative Mathematics* (Illustrative Mathematics, 2016) task, and asked to write a script of a mathematics lesson at the beginning of the semester. The MTE then provided readings and instructional activities to help the PSTs gain understanding of teaching practices as described in the course text. PSTs then independently revised the collaborative script of one of the four groups and provided a rationale for their changes. The collaborative script used for revision and each of the 16 revisions were analyzed and compared as it related to question types posed.

Questions in each script were coded using categories from the course reading: (1) gathering information, (2) probing thinking, (3) making the mathematics visible, (4) encourage reflection and justification, and (5) engage with the reasoning of others (Huinker & Bill, 2017). Examples of these types of questions can be found within the findings and discussion section. Given that only one collaborative group was chosen to be revised, in the analysis, only the revised scripts of those PSTs were highlighted in the findings (scripts 5, 9, and 10).

Findings and Discussion

PSTs' primarily used two question types: (1) gathering information and (2) probing thinking. The third most used question type was (3) engaging in reasoning with others. Two of the 16 PSTs revised the script using all five question types. One PST did not provide any additional dialogue, however, reasoned "the teacher is asking students about their thought process and why they chose the equation they did" or "after students work individually, they will partner up and compare the processes and their answer to a and b". Another PST added the question "Why would that be important?" after each student response. Lastly, when the teachers posed questions to their students, all student responses provided in the scripts were correct.

In examination of the group who provided the initial script for revision, only one of the three PSTs added significant number of additional questions. Script 9 had commentary for all five questioning types and posed a variety of questions. While script 5 targeted four out of five of the questioning types, the PST no dialogue between the student and teacher or student and student. Script 10 also had lacked dialogue of any sort in the revision in that she posed several teacher questions, but no student responses. Both scripts 5 and 10 were similar to their peers in that there was not much diversity in types of questions and the dialogue lacked substance.

Findings illustrate significant differences in questioning activity across PSTs with five students demonstrating four questioning types. PST focused on gathering information such as "What is important from this problem?" (script 16) from students. The second most common question type was probing student thinking which could be seen in script 13 when the teacher asks, "Is there only one way to set up this problem?" In addition, nine of the 16 PSTs included questions engaging in the reasoning of others and how it might support the discussion. One way this was shown was in script three when the teacher asks "Did anyone approach this problem differently and if so how did you approach it?" Only two of the 16 PSTs used a variety of questioning as aligned with findings of Moyer and Milewicz (2002). In script 4, the PST utilized all five question types and posed 11 questions throughout her revised script. In script 9, all five question types were utilized and 17 questions were posed. Both script 4 and script 9 had gathering information as the most used question type which shows similarity to all revised scripts. To build PSTs' questioning MTEs can provide opportunities to pose questions in various circumstances. These opportunities can be designed as approximations of practice (Grossman et al., 2009) in the form of scripting with revisions can support PST questioning development. Future studies could examine the impact of such activities on scripts and the variety of questions posed.

Teacher need to be able to facilitate these mathematical discussions through questioning (Parks, 2010). Findings from this pilot study suggest that PSTs use one or two question types most often. Due to the limited question types, MTEs should consider modeling alternative types of questions so PSTs can increase their own repertoire of questions. The PSTs were idealistic regarding how students respond to teacher questions (i.e. – student responses were always correct). One way to encourage additional questions is to include student errors in the scenario provided to the PSTs as Campbell and Baldinger (2022) did.

Future studies can be more deliberate in choosing to complete this scripting task after having the PSTs engage in discussion around posing purposeful questions (mathematical teaching practice 5) to address the question: *Can scripting tasks help MTEs identify where PSTs need more exposure to different types of questions?* In conclusion, writing a script for a fictional lesson and posing questions is one thing, but examining the questions posed during interactions with learners as Zazkis and colleagues (2009) showed is quite different. Further research can examine questions planned in scripts included in lesson plans and questions posed during the implementation of the lesson. Sequencing activities (Ghousseini & Herbst, 2016) has the potential to impact PSTs questioning.

WHO'S YOUR FAVORITE MATH TEACHER AND WHY?: INSIGHTS INTO WHO PRESERVICE TEACHERS ASPIRE TO BECOME

Stephen L. Caviness
Syracuse University
scavines@syr.edu

In many ways, preservice teachers embody the future of mathematics education. Guided by a conceptual framework of identity in figured worlds, the purpose of this study was to understand preservice teachers' designated mathematics teacher identities by prompting reflections about their favorite mathematics teachers. Data were collected from fifty-three preservice elementary and early childhood teachers who responded to an open-ended prompt about their favorite mathematics teacher. Thematic analysis of these responses resulted in three themes that preservice teachers described about their favorite mathematics teachers: their character, their pedagogy, and their classroom environments. Understanding how preservice teachers envision their futures may help mathematics teacher educators to support preservice teachers in realizing these aspirations or to reshape these aspirations to reflect best teaching practices.

Keywords: Preservice Teacher Education; Teacher Beliefs; Affect, Emotion, Beliefs, and Attitudes

Undergraduate preservice teachers enroll in teacher preparation programs with previously formulated conceptions of what it means to teach well (Lortie, 1975). These preconceived ideas influence preservice teachers' developing teacher identities as they "create future images of their teacher self and draw on remembered strategies they plan to replicate or avoid" (Miller & Shifflet, 2016, p. 27). These future images may be considered designated identities (Sfard & Prusak, 2005), and in the context of mathematics education *designated mathematics teacher identities*. In this study, I define designated mathematics teacher identity as the ways of being that one envisions of a future role as a mathematics educator (Graven & Lerman, 2020). In not so many words, this is a preservice teacher's answer to the question, who will I be when I'm a teacher? Attending to preservice teachers' designated mathematics teacher identities is especially important for mathematics teacher educators, as these identities may support or hinder preservice teachers' learning during their teacher-preparation programs (Caviness & Masingila, 2023). Furthermore, such designated mathematics teacher identities may become actualized when preservice teachers do transition into the field, especially with appropriate supports (Andersson, 2011; Jong, 2016).

In an overview of mathematics teacher identity research, Hannula et al. (2016) asserted that overall findings from the literature base "suggest that teachers' personal histories, such as those of being a learner, undoubtedly shape and become a part of their teacher identities" (p. 17). Therefore, the purpose of this study was to better understand the personal histories of preservice teachers that influence their designated mathematics teacher identities. Specifically, I sought to understand preservice elementary and early childhood teachers' personal histories related to their favorite previous mathematics teacher. I did so by examining the qualities of those mathematics teachers that were described as reasons why they were considered favorites. With this purpose in mind, the research question that guided this study was: how do preservice elementary and early childhood teachers describe their favorite mathematics teachers?

Conceptual Framework

I draw on Holland et al.'s (1998) theorizing of identity in figured worlds to understand preservice teachers' developing identities. Holland et al. (1998) described an individual's identity as constantly forming and reforming throughout their lifetime, shaped by their actions, personal histories, and social influences of the worlds they navigate. Drawing on Vygotsky, Bakhtin, and Bourdieu's work, Holland et al. (1998) outlined three contexts wherein identity is practiced or "authored" in figured words (p. 271). The first context is the figured world itself, which they defined as "a socially and culturally constructed realm of interpretation in which particular characters and actors are recognized, significance is assigned to certain acts, and particular outcomes are valued over others" (Holland et al., 1998, p. 52). Figured worlds are the spaces wherein identities are formed and reformed. In this study, I conceptualized preservice teachers navigating the figured worlds of their previous schooling at the PK-12 level, and the teacher preparation program based at their university.

The second context that Holland et al. (1998) described is one's positionality, with an emphasis on social positions such as gender, race, and cultural backgrounds. Holland et al. made explicit that individuals always exist in multiple figured worlds simultaneously based on their multiple positionalities. Lastly, the third context Holland et al. described was the "space of authoring" (p. 272), which emphasizes that individuals always exert agency when authoring identity. Individuals are shaped by the worlds they inhabit, yet they simultaneously shape their surroundings and do so continuously.

Methods

Fifty-three undergraduate preservice elementary and early childhood teachers at a northeastern university in the United States participated in this study. Participants were recruited from two different contexts:

- A mathematics content course in the fall 2022 semester consisting primarily of first-year undergraduates (n=25)
- A mathematics methods course in the fall 2022 semester (n=11) and spring 2023 semester (n=17) consisting of second-year and third-year undergraduates

Participants were asked to respond to a questionnaire that was designed to better understand their mathematics identities. While all participants voluntarily agreed to have their responses be collected and analyzed as data in a research study, the administration of the questionnaire differed based on the contexts above. In the mathematics content course, my relationship with participants was as a researcher and completing the questionnaire was not a course assignment. In the mathematics methods courses, my relationship with participants was as the course instructor and completing the questionnaire was a course assignment. The questionnaire included several prompts, however, the dataset for this study consists only of responses to the open-ended prompt: *Think about your favorite mathematics teacher (this includes elementary). What about them makes you say they are your favorite mathematics teacher?*

All 53 responses were analyzed in this study following Braun and Clarke's (2021) approach to reflexive thematic analysis. This approach includes six phases beginning with immersion in the data, followed by coding, generating themes, reviewing themes, refining themes, and culminating in writing about the themes developed. Braun and Clarke (2021) described their process as one of getting lost in the data and going back and forth between phases, ultimately, to identify patterns of meaning across the dataset. I report on these themes in the findings section below.

Findings

In my analysis of the dataset, I generated three themes for how participants in this study described their favorite mathematics teachers. These themes are: my favorite math teacher's character, my favorite math teacher's pedagogy, and my favorite math teacher's classroom environment. Each of these themes are elaborated in greater detail below with examples that I selected to best represent the dataset. In addition, each data excerpt presented below represents a different participant, with the goal of presenting a comprehensive look across the dataset.

Character

I found that preservice teachers commonly identified relational characteristics when describing their favorite math teachers. The theme "my favorite math teacher's character" encompasses the personality traits of favorite math teachers and the personable actions these teachers made toward their students. As exemplified in Table 1, the character traits of favorite mathematics teachers included being understanding, supportive, and patient.

Table 1: My Favorite Math Teacher's Character

	Data Excerpts
Understanding	"She was extremely compassionate and understanding…"
Supportive	"She was always available for extra help after and before school and well as [*sic*] during class hours."
	"She also acted as a person I knew I could count on for math and not math related issues."
Patient	"He… was super patient, and he was very personable."

Pedagogy

Many preservice teachers cited the teaching practices of their favorite mathematics teachers as reasons for them being their favorite math teacher. See Table 2 for examples that include differentiating by process to meet the needs of all students (Tomlinson, 2001), and explaining concepts well.

Table 2: My Favorite Math Teacher's Pedagogy

	Data Excerpts
Differentiates by Process	"Some of us could not understand certain methods, so he would teach the one he meant to teach and the ones we would understand. Comparing and contrasting different ways of solving math problems, Mr. [Teacher] was never the type of teacher to get upset with students for doing it their own way."
	"Despite having roughly 100 students, she provided us the opportunity to divulge new material in whichever learning style we preferred."
Explains Concepts Well	"He did a great job of explaining and showing material…"
	"They were really good at explaining things we were confused about."

Classroom Environment

In the prior two themes, participants' responses focused directly on the mathematics teacher. Here the thematic focus zooms out slightly as participants described the classroom environments that their favorite mathematics teachers created. This included how these environments made preservice teachers feel. As displayed in Table 3, the classroom environments of favorite mathematics teachers were safe, fun, and for some, these environments fostered a sense of belonging to mathematics.

Table 3: My Favorite Math Teacher's Classroom Environment

	Data Excerpts
Safe	"I say that he was my favorite math teacher because he didn't make anyone feel dumb for not knowing the answers."
Fun	"They made the class fun and engaging and tried to make us laugh whenever."
Fostered a Sense of Belonging to Mathematics	"I actually felt pretty confident in that class and like I understood the content."
	"My sixth grade teacher was the first person who got me to like math."

Discussion

In this study I sought to better understand the designated mathematics teacher identities of preservice elementary and early childhood teachers by analyzing how they described their favorite mathematics teachers. I based this analysis on the premise that preservice teachers carry their prior experiences as learners of mathematics into their developing roles as teachers of mathematics (Caviness & Masingila, 2023; Lortie, 1975; Ma & Singer-Gabella, 2011; Miller &

Shifflet, 2016). I found that preservice teachers especially valued their favorite math teachers' character, pedagogy, and the classroom environments they created.

In many ways, preservice teachers *are* the future of education. This work takes up the call to envision the future of mathematics education in uncertain times by seeking to understand what preservice teachers envision about their future roles as educators. I have shown one way that researchers might learn about preservice teachers' designated mathematics teacher identities by prompting reflection specifically about their favorite mathematics teachers. Mathematics teacher educators may similarly learn about their students in this way, and it is possible that such learning could be used to foster preservice teachers' developing mathematics teacher identities.

ENGAGING PROSPECTIVE TEACHERS' IMAGINATION IN LEARNING INQUIRY-BASED MATHEMATICS PEDAGOGY

Olive Chapman
University of Calgary
chapman@ucalgary.ca

Inquiry-based teaching represents a contemporary perspective of mathematics education that is important for prospective teachers (PTs) to learn about to meaningfully engage their future students in learning mathematics with understanding. This paper reports on a study of the use of narrative and imagination in PTs' learning of inquiry-based mathematics pedagogy. Participants were prospective secondary mathematics education majors who were exposed to theory about inquiry-based teaching but had limited experience with it as learners of mathematics. Data consisted of their narratives of imagined inquiry-based lessons for mathematics concepts of their choice. Findings indicated that the narratives have the potential of helping them to imagine and understand key aspects of an inquiry-based lesson that they could apply to their future practice.

Keywords: Narrative; imagination; secondary preservice teachers; inquiry-based teaching

Inquiry-based teaching of mathematics continues to be a challenge for teachers to implement particularly if their experience with learning mathematics did not align with this approach to teaching and learning (Artigue & Blomhoj, 2013; Maaß & Doorman, 2013). Prospective mathematics teachers (PTs) also continue to enter teacher education programs with limitations in their mathematical content and pedagogical knowledge needed to support it (Author, 2023). Thus, ongoing research is important for us to understand meaningful ways to support their learning to improve mathematics education. This paper reports on one aspect of a study to explore the use of narrative and imagination in PTs' learning and use of inquiry-based mathematics pedagogy. The focus is on the question: What understanding of inquiry-based teaching secondary PTs are able to develop through creating a narrative of an imagined mathematics lesson that unfolds in real time?

Theoretical Perspectives and Related Literature

A narrative/story (Egan, 1986; Polkinghorne, 1988) is a way of representing experience for oneself or for others. It involves people, settings, and events that take place in a given time frame. It is established in the broad field of education as an important tool in supporting meaningful teaching and learning. It helps people to remember things by making knowledge more engaging, helps us think and do things more effectively, and enlarges our powers to think and understand (Egan, 2008). It aids in the process of meaning making (Clark & Rossiter, 2008) and teaching mathematics (Zazkis & Liljedahl, 2009). Some ways in which narrative has been used in mathematics teacher education include researching mathematics teachers' trajectories as they enter the profession (Frost, 2010), how focusing on healthier narratives can help teachers work toward liberatory futures (Gutiérrez et al., 2023), teachers' reflection on their practice or learning (Author, 2008), PTs' construction of educational meaning through narratives (Dolk & Hertog, 2008), and use of "scripts" in mathematics teacher education (Zazkis & Herbst, 2018). In general, narrative has been used in teacher education mainly as a research method to obtain and analyze data with a focus on researcher constructed and elicited stories. In this study, narrative is used as a cognitive tool to support imagination in PTs' learning.

Regarding imagination, Egan (2008) explained:

> When we speak of imagination, we are referring to the ability to think about what might be possible. It is the "reaching out" feature of students' minds that picks up new ideas, tries them out, weighs their qualities and possibilities, and finds a place for them amidst the things they have already learned. (p. 5)

Vygotsky (2004) also considered imagination to be a process directly connected with meaning making. He explained that everything that relates to interpretation and construction of something new requires the indispensable participation of imagination. Everything we create, "is the product of human imagination and of creation based on this imagination" (Vygotsky, 2004, p. 7). These perspectives of imagination suggest that engaging PTs to use their imagination to learn ideas about inquiry-based teaching that are new to, or different for, them could help them to create meaning of it for themselves in a way that they could live it in their teaching. Narratives serve as tools for engaging imagination (Egan, 1992). In this study, PTs created narratives based on their imagination of an inquiry-based lesson. The assumption is that if they could imagine a complete inquiry-based lesson, they are more likely to be able to adopt it in their practice.

While there are multiple perspectives of inquiry-based learning (Artigue & Blomhøj 2013), there are commonalities, particularly regarding placing emphasis on learners with their autonomy and understanding as the central focus (Jaworski, 2015). Inquiry-based teaching, then, refers to teaching approaches that support students' individual and collaborative engagement in inquiry-based tasks to "foster students' construction of their knowledge through inquiry, exploring, and finding their own path to solution" (Maaß & Artigue, 2013, p. 782). The teacher's role includes:

> orienting students towards questions and problems …; making constructive use of students' prior knowledge; supporting and guiding when necessary their autonomous work; managing small group and whole class discussions; encouraging the discussion of alternative viewpoints; and helping students to make connections between their ideas and relate these to important mathematical … concepts and methods. (Maaß & Artigue, 2013, p.782)

Features of this perspective of the teachers' role formed a basis for analyzing the PTs' narrative regarding their understanding of inquiry-based teaching based on their imagined lesson.

Research Methods

This qualitative study explored the understanding of inquiry-based teaching secondary PTs were able to develop through creating a narrative of an imagined mathematics lesson that unfolds in real time. Participants were 16 secondary mathematics education majors in a mathematics education course in the third semester of a 4-semester, 2-year Bachelor of Education program. They had either a 3-year or 4-year undergraduate degree in mathematics. Their experience in learning school mathematics was not inquiry based. In the course, they were exposed to theories of inquiry-based teaching/leaning, inquiry-based tasks, and questioning/discourse. They explored examples of inquiry-based tasks but not examples of complete inquiry lessons.

The narrative task was intended for the PTs to draw on the theory and experience in the course to imagine their teaching of an inquiry-based lesson. They worked in groups of four to create the narrative to allow them to pool their imagination of how they would live the lesson. They were required to imagine themselves engaged in inquiry-based teaching of a mathematics concept of their choice from the G7-9 provincial curriculum. The guideline included that the lesson should be from a lived perspective and the narrative should include a preamble of the learning objectives for the lesson, class size and classroom organization. The lesson must include a task and intervention in at least three groups (e.g., one stuck; one with no issues; one thinks no issues but has issues). The narrative must have a temporal flow as lived and include dialogues.

Data sources were the four narratives. Analysis included categorizing and coding the narratives to identify the PTs' understanding of inquiry-based teaching. Each narrative was categorized based on the structure of the lesson including the mathematic concept, learning objectives, main task, lesson introduction, intervention in student groups, whole-class discussion, and conclusion. Each category was then coded to form themes based on aspects related to inquiry-based teaching including learner-centeredness (based on type of teacher's questions/ prompts/guidance and students' questions and responses), the inquiry nature of the main task, and framing of the learning objectives. Themes for each category were compared across the four narratives. The designs of the narratives were also analyzed and compared for the temporal flow of the events in the lesson, the characters, use of dialogues and commentaries, and focus on the central themes. Mainly findings regarding key components of the narratives are presented here.

Findings

All four groups of PTs (PT-GA, PT-GB, PT-GC, and PT-GD) were able to imagine key aspects of inquiry-based teaching. The following are summaries of key components of their narratives. Their class sizes ranged from 24 to 32 with students in groups of mainly four.

PT-GA: *Concept* - Grade 7 divisibility. *Learning objectives* – develop conceptual understanding of divisibility, represent divisibility using multiple approaches, understand how to test divisibility of numbers 2 to10. *Main task* – explore the concept using a pile of cubes. *Lesson introduction* – students asked to think about and share whatever they knew about "divisibility". *Intervention in student groups* – three groups considered: could not start, had an incorrect model, had a correct model. The teacher used open questioning and prompts, e.g., "Explain what you mean?" "How are you connecting them?" "Why did you decide to use a rectangle to represent the number six?" "Think about if there are other useful alternatives." *Whole-class discussion* - groups presented and justified their processes with teacher questions, e.g., "How can you be sure that this "splitting things up" model works correctly?" "What does this model indicate about the concept of divisibility?" *Conclusion* – students asked to write a sentence to describe divisibility.

PT-GB: *Concept* - Grade 8 perfect square/square root. *Learning objectives* - develop conceptual understanding of a perfect square/square root, illustrate/classify perfect square/square roots through multiple representations. *Main task* - explore example versus nonexamples with multiple representations. *Lesson introduction* – individually think about then share "What does the word 'perfect' mean to you?" "Do you think the real-life application of 'perfect' applies to mathematical applications?" *Intervention in student groups* – four groups considered: stuck and asked for help, believed they understood but had misconceptions, did well, could not begin. The teacher used open questioning and prompts, e.g., "What are you noticing?" "Try to focus on the other given numbers." "Do you think it's important what shape they make?" "Test your conjectures and ideas by adding new examples and non-examples." *Whole-class discussion* -

groups presented and justified their processes with teacher's questions, e.g., "How did you resolve this conflict?" "Why do you think the shape of the examples matters?" "What does the shape tell us here?" "Did your group come up with any other insights …?" *Conclusion* – students defined a perfect square and square root and worked on worksheets to complete missing items in two tables of multiple representations of perfect squares and square roots respectively.

PT-GC: *Concept* – grade 8 rates. *Learning objectives - i*dentify and describe rates, convert rates to unit rates, express rates using words and symbols, understand rates in everyday life. *Main task* - explore rate by racing on two racetracks set up in the school yard. *Lesson introduction* – students given one minute to figure out who in their group got to school the fastest then share and respond to "how did you get to school today?" "How long did it take you and how do you know that you were the fastest?" *Intervention in students' groups* – Three groups were considered: thought they were doing okay but were not, stuck and needed help, doing okay. The teacher used questions/prompts that were at times closed or directed to the answer or involved telling, e.g., "think about what the number 0.14 means. 0.14 What? Or 0.125 what?" "That means that speed isn't just about how much time you take but it needs something else. Any ideas what that is?" "Start by figuring out how many meters each person ran." "Another way of saying that is 8.3 meters per second. It's a rate … a unit rate." *Whole-class discussion* - no sharing or discussion. *Conclusion* – teacher summarized what they should know about the concept.

PT-GD: *Concept* – grade 9 multiplying exponents. *Learning objectives* - demonstrate understanding of multiplying powers with integral bases and whole number exponents. *Main task* – explore the concept by sorting 32 cards (3 blank, 8 different representations). *Lesson introduction* – teacher asked what an exponent is and what they think happens with something like $1000000^{1000000}$ x $1000000^{1000000}$ then used $5^2 * 5^3$ to take them through a process with questions leading to predicting the rule to be validated through the main task. *Intervention in students' groups* – three groups considered: confused and asked for help, believed they could do the task but needed help, understood the task well. The teacher used open questions and prompts, e.g., "Why did you put those (2 cards) together?" "Maybe think about writing out and expanding each of the exponents." "Try to see if you can notice what they have in common." "Do you notice any patterns"? "Try to see if you can figure out a way to check whether your answers make sense." "What can you do to justify matching 5^2 x 5^1 to 5^2 and 3^2 x 3^3 to 3^6? Try it out." *Whole-class discussion* - two groups shared but no questioning by teacher. *Conclusion* – summarized what they should know about the concept and they answered $1000000^{1000000}$ x $1000000^{1000000}$.

Conclusions

Each group of PTs was able to create an appropriate narrative of an imagined lesson that unfolded in real time. They were able to imagine a lesson with key features of inquiry-based teaching. They had introductions to motivate students with connection to prior knowledge/ experience. PT-GA and PT-GB were able to maintain a learner-centered focus throughout and PT-GC was mostly student centered with limitations during whole-class sharing. These groups had objectives focused on students' understanding and tasks that involved inquiry through noticing patterns and relationships that seemed to help their learner-centered group interventions and whole-class discussion. They used open questioning and prompts appropriately to expose and engage students' thinking. PT-GA and PT-GB also asked questions to stimulate discussion and thinking. PT-GD used an applied task that was more challenging for students to see the concept for themselves and so had to provide more direct guidance at times to get them there during group interventions, which resulted in no whole-class sharing/discussion since the groups had similar process. All groups were able to imagine appropriate student thinking and responses to their questions or prompts and consider alternative processes to explore the concept.

Since the PTs' narratives are approximations of inquiry-based lessons as they unfold in real time, there are obviously gaps regarding details of the lesson (e.g., whole class discussion), but the focus here is on key features of the lesson that they could build on. The narrative imagination offered opportunity for them to make sense of inquiry-based teaching and to begin to develop an image of it in a way that they could apply and build on in their teaching. Future work on the project will include PTs sharing their narratives to learn from each other and observation of sample of the PTs in their practicum and as beginning teachers to gain further insights of the potential of the approach and how to modify it to be more effective as a tool for PTs' learning.

EXPLORATORY CASE STUDY: USING OBSERVATIONAL DATA TO STUDY PRESERVICE TEACHER MATH ANXIETY

Amy Daniel
Montclair State University
daniela4@montclair.edu

Nina Bailey
Montclair State University
baileyn@montclair.edu

Research on preservice elementary teachers' experience of math anxiety has historically utilized narrative, interview, and survey data. Our searches revealed no studies that used observational data, which has the potential to reveal insights that are less reliant on self-perception. Thus, this case study aimed to understand how a highly math-anxious preservice elementary teacher made sense of their math anxiety and how it may have changed in the context of a mathematics content course, and to explore whether or not it was possible to collect observational data that aligned with these understandings and perceptions. Findings reveal that math anxiety was meaningfully observed for this preservice teacher and that these observations provided valuable insight into how her math anxiety changed over the course of the semester.

Keywords: math anxiety, preservice teacher education, interpretation account.

Mitigating the detrimental effects of preservice elementary teachers' (PSETs) math anxiety (MA) has been a persistent concern in teacher preparation programs for decades. Defined as "a feeling of tension, worry, and/or fear in situations involving math-related activities," (Bjälkebring, 2019, p. 1), MA has a well-established link to lower achievement in mathematics (Barroso et al., 2021; Ma, 1999), and is particularly prevalent among PSETs (Hembree, 1990). For these future educators, the negative impacts of their MA may extend to their students. PSETs reporting high levels of MA tend to hold lower expectations for their students (Mizala et al., 2015) and have lower self-efficacy for teaching mathematics (Gresham, 2008). As noted long ago by Dutton (1951), it is vital for math teacher educators to find ways of "breaking this 'vicious cycle'" (p. 89) by supporting PSETs in learning to manage their negative emotions towards mathematics before they become practicing teachers.

To best support PSETs in this way, mathematics teacher educators should understand how PSETs experience MA and how this experience might change through experiences in teacher preparation courses. Researchers have employed interview, narrative, and survey data to both characterize PSETs' experiences with MA and to document shifts in these experiences (e.g., Finlayson, 2014; Hollingsworth & Knight-McKenna, 2018; Olson & Stoehr, 2019). While these data sources are indispensable in studying MA, we were unable to identify studies of PSET MA that further triangulated these data sources with observational data. The purposes of this study are therefore to: (1) understand how a highly math-anxious PSET perceives and makes sense of their MA and how it may change in the context of a mathematics content course, and (2) explore whether it is possible to collect observational data that aligns with these perceptions and understandings.

Review of Literature

Researchers have used survey, narrative, and interview data to characterize and better understand the individualized nature of PSETs' MA. For example, although several studies have found that being in evaluative settings is commonly cited by PSETs as eliciting MA (e.g., Finlayson, 2014; Harper & Daane, 1998; Olson & Stoehr, 2019; Wilson, 2015), Olson and Stoehr's (2019) study suggested that the way PSETs interpret these evaluative experiences may vary greatly. In written narratives, two of the three highly math-anxious PSETs in this study reported experiencing MA in evaluative settings because they had interpreted poor performance on past exams as evidence of their inability to learn mathematics. The third participant, however, experienced MA in relation to being evaluated because of the uncertainty she felt while waiting for the teacher's feedback. Finlayson's (2014) work also illustrated the variability of PSETs' MA experiences. Finlayson analyzed responses to open-ended survey questions from 70 pre-service teachers (many of whom were PSETs) to identify common causes, symptoms, and coping strategies that study participants associated with their MA. Several common themes emerged in each category, but no theme applied to more than half of the participants, and Finlayson's analysis revealed that study participants gave different explanations for similar responses. For example, 23 participants identified a lack of self-confidence as a cause of their MA. Among these, some attributed this lack of self-confidence to a history of inadequate support from teachers, while others described it as a family trait, citing parents who had also struggled with mathematics. These studies suggest that, although many PSETs may report similar MA experiences, the ways they make sense of these experiences can be highly individualized. Because PSETs experience MA differently, it is likely that they also respond to MA-eliciting situations differently, positioning observational data as an underutilized research tool.

Analyzing survey, narrative, and interview data has also allowed mathematics education researchers to develop strategies for reducing PSETs' MA. Some studies suggest that certain kinds of learning activities implemented in teacher preparation courses can positively impact PSETs' reported levels of MA. For example, researchers have reported successfully lowering PSETs' MA by emphasizing the use of manipulatives (Barrett, 2013), implementing inquiry-based learning (Van der Sandt & O'Brien, 2017), and by including a field work course component (Hollingsworth & Knight-McKenna, 2018). Although all of these studies concluded that PSETs' MA was reduced as a result of engaging in these learning activities, none included observational data of how individual PSETs had participated in these activities. Hollingsworth and Knight-McKenna noted this as a limitation of their study, stating that "Much of our analysis relied on self-report. Students may have provided responses they felt the instructor wanted to hear" (p. 324), and then suggested that future research should include observational data to guard against this possibility. However, in our literature search, we were unable to identify any studies of PSETs' MA that utilized observational data.

Analyzing narrative, interview, and survey data has provided researchers with important insights into how PSETs make sense of their MA experiences and helped them to identify effective MA interventions that can be used in teacher preparation courses. Observational data has the potential to serve as a unique research lens, adding depth to current understandings of PSETs' MA experiences. Further, observational data may also uncover aspects of PSETs' experiences that are unattainable when using self-reported data sources alone.

Theoretical Perspective

For this study, we rely on Ramirez et al.'s (2018) *interpretation account* of MA, which argues that "students' development of MA is largely determined by how they interpret … previous math experiences and outcomes (rather than the outcomes themselves)” (p. 151). For example, consider how receiving a failing grade on an exam provokes MA in some students but not in others. One student may interpret the failing grade as evidence of an innate inability to perform mathematically and may become anxious in future mathematical settings. Another student may instead interpret the failing grade as the result of the teacher’s harsh grading policies and become angry instead of anxious. As a theoretical perspective, interpretation account centers student experiences of MA, the ways in which they make sense of these experiences, and how these experiences influence the way they participate in mathematical settings.

Interpretation account suggests that different situations will trigger MA in some PSETs but not in others (e.g., answering questions in front of the class or being stuck on a problem). This means that individual PSETs will have a unique set of *MA triggers*. These triggers, along with the individualized ways in which PSETs respond to encountering these triggers (e.g., disengaging from a task or making jokes) comprise what we refer to as their *MA baseline*. Establishing PSETs’ MA baselines is informed, in part, by their use of *MA aligned language*. Although the language that PSETs use to describe experiences of MA is not uniform, researchers have identified some language that math-anxious individuals commonly use. Stoehr and Olson (2021) compiled a list of MA-aligned language that PSETs used when speaking of mathematical experiences, such as “embarrassed,” “math is not my thing,” and “dreaded math class.” Other researchers have also identified common responses to experiences of MA (e.g, Dowker, 2019), such as rushing to complete a task at the expense of accuracy, avoiding mathematical situations, and disengaging from a mathematical task. Thus, for this study we will adopt interpretation account in tandem with research on MA-aligned language and responses to answer our research questions: How does a highly math-anxious PSET perceive and make sense of their MA and how it may change in the context of their experiences in a mathematics content course? Are these perceived understandings of MA and changes (if any) observable in the PSET’s mathematical interactions?

Methodology

This study followed a single-case study design (Yin, 2009). Because our goal was to explore an unstudied phenomenon (i.e., if MA can be observed and if these observations further triangulate a PSET’s perceived MA), a single revelatory case (Yin, 2009) was most appropriate for our goal. The case was a single PSET, Rose (a pseudonym), and was bounded by time and context; data was collected in a single semester and within a mathematics content course.

Context

This study took place within the context of a terminal mathematics content course for PSETs at a large public university in the northeast United States in Fall 2023. The course content focused heavily on operations with fractions, which has been identified in the literature as a difficult concept for PSETs (e.g., Rosli et al., 2020), particularly those that are math-anxious (e.g., Rayner et al., 2009). The course was student centered and relied heavily on in-class group work and discussion. During whole-class discussions, PSETs compared the different solution strategies that groups had used. The course also used Revision-Reflection Grading (a non-traditional grading system adapted from *Ungrading* by Blum, 2020).

Case Selection

Since our goal was to gain insight into a PSET's MA baseline, their perception of any changes, and how these perceptions may align with observational data, open communication and willingness to discuss MA and related experiences was essential. Thus, of the many highly math-anxious PSETs (as identified by written narratives and validated MA scale), we selected Rose. Rose's candid communication and outgoing personality afforded us a window to explore how her perceived MA aligned with classroom observations of her engaging with mathematics and/or with others while doing mathematics.

Data Collection

The brief version of the Mathematics Anxiety Rating Scale (MARS-B; Suinn & Winston, 2003) was used to select the case as stated above and was also used to determine the baseline MA score for Rose and her group members (for comparison). Rose was identified as highly math anxious (109 out of 150; highly math anxious in this study was defined as having a MARS-B score greater than 90, cutoffs adapted from Sanders et al., 2019), and her group members reported moderate to high levels of MA (48, 85, 85, and 101). Rose and her group members also took the MARS-B at the end of the semester to track any changes in MA level. In addition to the validated scale, we sought to describe their perceived MA. Thus, we asked Rose and her group members to write a short narrative to describe their relationship with mathematics at the start of the semester to serve as a baseline for perceived MA. Similar to the scale, we also requested an end of the semester narrative to track any changes in perceived MA. The prompt read: "Tell the story of your mathematical journey. Describe your relationship with mathematics."

Rose took part in one semi-structured interview. The original goal of this interview was to explore Rose's perceived changes in MA. We thought that the validated scale and narrative would provide sufficient information to describe Rose's baseline MA. However, given the exploratory nature of this case study, her narrative only revealed insight into her triggers but not her typical responses to them. Thus, we altered the design of the semi-structured interview into two parts: the baseline interview and the post interview. In the baseline interview, we sought to corroborate the MA triggers from Rose's narrative (e.g., "Is there a particular kind of classroom situation that you associate with feeling anxious about math?") and identify typical responses to those triggers (e.g., "How has feeling anxious about math impacted your experiences in math classes?"). In the post interview, we sought to elicit Rose's perceived changes in MA across the course of the semester and how she made sense of such changes.

The final data source consisted of two classroom observations (one after the baseline MARS-B and narrative and one mid semester). The goal of the observations was to determine if MA-aligned responses to Rose's baseline MA triggers could be observed. Rose's group was audio-recorded during these observations and field notes were taken with respect to Rose's identified baseline MA triggers.

Analysis

Analysis occurred in two phases: (1) analysis of the baseline data and (2) analysis of the post narrative and interview data. In phase one, the baseline narrative and interview were coded using a priori theoretical coding based on the MA-aligned language from the literature (e.g., Stoehr & Olson, 2021). We then open coded across those codes to extract any potential MA triggers and responses to these triggers. The first observation was used to see if we could observe any of the identified baseline MA triggers and responses during class. We coded the transcript for the presence of any of Rose's identified triggers, and then open coded Rose's responses to those triggers to identify any common themes in her responses to each trigger.

In phase two of analysis, we sought to examine any perceived changes in MA. First, we open coded the post narrative to identify any changes in Rose's responses to her baseline MA triggers. The response themes were open coded for alignment (or not) to her baseline responses. To analyze the post interview, we applied interpretation account (Ramirez et al., 2018) to describe how Rose made sense of any changes in her experience of MA. We used the second observation to corroborate any changes identified in Rose's post narrative and interview regarding her MA triggers and responses. In other words, we aimed to determine if Rose's MA triggers elicited a different response later in the semester compared to earlier in the semester. All code discrepancies were discussed until consensus was reached.

Findings

Rose's MA transformation in the context of a mathematics content course provided an opportunity for us to understand how she made sense of her MA and how it changed, and to see whether or not these changes were observable in her engagement in mathematical tasks and classroom interactions. Rose's MARS-B pre and post-semester scores (109 and 39, respectively) indicated that she began the semester as the most math-anxious member of her group (her group mates scored 48, 85, 85, and 101), and had experienced a drastic decrease in MA by the end of the semester.

In this section, we will discuss how we were able to use Rose's baseline narrative and interview to characterize her baseline MA triggers and responses and will present data from our first classroom observation that was consistent with this characterization. We will then describe how Rose made sense of the reduction in MA that she experienced over the semester, and how these changes manifested in observable differences in the way that she engaged in classroom activity in our second observation. Through these findings we will demonstrate that, at least in the case of Rose, MA was meaningfully observed and that these observations provided valuable insight into how her MA changed over the course of the semester.

Rose's Baseline Math Anxiety Triggers and Responses

When Rose spoke or wrote using MA-aligned language, it often centered on the MA trigger of *being confused by mathematical content.* For example, she wrote in her baseline narrative that she "was always incapable of understanding certain math concepts, which created a lot of anxiety around math class." In her interview, Rose clarified why this was a MA trigger for her, indicating that she interpreted this confusion as a threat to her self-concept as a good student:

> I just never could get it. I would go to extra help. I would stay after. I would study. I would do all the right things… I tried very, very hard. And I just, my grade didn't reflect that… And that was just something that I hated. And I resented math because of that.

Again in her interview, Rose provided insight into how she responded to this MA trigger as she described her experience of confusion with high school precalculus content: "It wasn't going to make sense to me. Like, I didn't want to bother trying because it just, I couldn't wrap my head around it. Like, I felt like it just was a waste of time." Rose's assertion that she "didn't want to bother trying" suggested that one of her baseline responses to feeling confused by mathematical content was disengagement.

Although being confused by mathematical content appeared to be Rose's most prominent MA trigger, her use of MA-aligned language also indicated that *classroom interactions with teachers* were also MA triggers for her. The interactions she described were uniformly negative, and were recounted with an emphasis on the strong emotions that these experiences elicited. For example, Rose wrote in her baseline narrative about a particular occasion when a teacher "called me out in front of the class and not in a positive way." Rose elaborated on this experience in her interview, saying that the teacher "was like, 'I just don't understand why you don't understand it.' Like it, and it was *embarrassing* for me, like, *embarrassing*. … all those kids heard" (italics added to show the emphasis Rose used when speaking). Rose explained that she had interpreted this interaction as an indictment on her ability to understand mathematics: "If she is confused why I don't understand it, like, clearly I should be, I *should* be understanding this." She then described her response to this MA trigger, again in terms of disengagement: "The rest of the year, I just was like … why am I even going to bother trying to understand this?"

During our first classroom observation, we saw evidence of Rose's experience of MA that was consistent with her baseline narrative and interview, both at moments when she expressed confusion and when there was a possibility of interacting with the professor. At one point, when her group had reached an impasse with a mathematical task on fraction addition, Rose expressed her intent to disengage by saying, "I could figure this out. But it's a lot of energy for me that I don't have right now. I'm gonna save my energy." Later, while working on a problem about installing a playground on a fraction of a park's area, Rose used a cooking metaphor her group developed for mathematical thinking to announce her intent to quit working with the group, saying "You cook over there. I'm lost. The kitchen's burning." Then, Rose rubbed her face and, even though the group had not yet completed their problem set, said, "We're done. I've been done." Although she almost always re-engaged and continued to work with her group, Rose's pattern of responding to confusion with disengagement was a consistent and clearly observable phenomenon.

The possibility of interacting with the professor was also an observable MA trigger for Rose. However, rather than responding with disengagement as she had indicated in her interview, we observed Rose responding to this trigger by expressing a desire to keep her work private. For example, at one point, the professor asked the entire class, "One-fourth is how many twelfths?" Rose whispered to a groupmate, "One-fourth is three, three twelfths. I don't want to answer because then she's gonna ask me another question." Towards the end of class, the professor stopped by Rose's group. Although the group was having a productive discussion, Rose responded to the professor's arrival by saying, "you came at the worst time." This desire to hide her thinking from the professor was an MA response that Rose had not identified in either her baseline narrative or interview, but was prominent in the observational data.

Changes in Rose's Math Anxiety

Rose's post narrative and interview were both well aligned with the remarkable drop she reported on her post-semester MARS-B (39 compared to 109 at the start of the semester). In her post narrative, she wrote, "To put simply, my relationship with math has completely changed… [for the] first time (I believe ever) I was made to believe that I am capable of understanding math." In both her post narrative and interview, she specifically addressed her baseline MA triggers. Although she did not directly address changes in the way she responded to these triggers, we were able to observe Rose responding to these triggers in markedly different ways in the second in-class observation.

In her post interview, Rose no longer used MA-aligned language when talking about mathematical content or about being confused by mathematical content. She said: “I was always the person who needed help…And now I'm helping people learn how to solve, like people are asking me, which is something that's never happened before.” Rose also explained that she had begun to interpret experiences of confusion differently:

> People who are good at math were always like, yeah, it's fun. It's like a puzzle. Like, I'm like, what puzzle? Like whatever. And now I kind of understand…because I'm given the opportunity to look at it a different way and look at it in a way that makes sense to me. And I can solve the puzzle all on my own, and I don't need help. And sometimes you need help. And that's okay, like, everyone needs help with math every once in a while.

In contrast to her earlier declaration that mathematics “wasn’t going to make sense,” this statement implied that Rose now viewed being confused as a normal part of the mathematical process, rather than a source of anxiety. Rose credited this transformation to the professor’s practice of highlighting multiple solution strategies, saying, “I always can find a [solution strategy] that's on the board that I know, I understand the way I know how to do it.” This new awareness also seemed to prompt Rose to reinterpret some of her past mathematical experiences:

> Now I know, like, learning from this class, there's a million ways you can explain things like, … me not understanding how to do something in freshman year algebra was not because I was stupid. It's not because I couldn't understand it. It's because I didn't understand it in the way that it was explained to me.

In our second classroom observation, we saw a sharp contrast in the way Rose responded to being confused during group work compared to our first observation. At one point, a groupmate, Ellen (pseudonym), was watching Rose attempt to use fraction strips to evaluate $\frac{3}{10} \div \frac{4}{5}$~~31045~~. Ellen said, “I am genuinely so lost.” Rose replied, “I am too. I’m just gonna model it and see what I come up with here. And kind of just hope for the best here.” After working on the problem for several minutes, Ellen expressed doubt that Rose’s strategy would solve the problem, saying, “I feel like four-fifths isn’t going to go into three.” Rose replied, “Well, here, we’re gonna figure it out. Ready? Let’s figure it out.” This observation was evidence that being confused was no longer the MA trigger for Rose that it had been, as she was now responding to confusion with persistence and encouragement rather than disengagement.

In her post narrative and interview, Rose indicated that her professor had played an important role in her MA transformation. She wrote in her post narrative that the professor had been “a positive light for me this semester.” In her post interview, Rose indicated that the professor had created a classroom environment where she felt valued:

> [The professor] understands, like, a lot of us struggle with math… She makes everybody in that class feel like they’re seen, and feel like they're understood… even if you have times where you don't understand it… [if] you're doing your, she does revisions… So as long as you're putting the effort in, you're getting the grade back, which is what I've always wanted in math…I actually feel like I'm getting the results in this class.

Although this implied that perhaps interacting with the professor may no longer have been a MA trigger for Rose, she did not write or talk about any changes in the way she responded to the possibility of interacting with the professor in class. However, our second in-class observation provided evidence that Rose had indeed experienced a shift with respect to this MA trigger. During a whole-class discussion of the problem $\frac{1}{3} \div \frac{1}{9}$ ~~1319~~, the professor asked students to share their answers and their reasoning. Rose volunteered to explain to the class how she had used fraction strips and said, “So, I took one third … and then I saw how many, or, how many one-ninths fit into the one third, and it’s three, so the answer would be 1/3?” Rose ended her statement in a questioning tone, implying that she was unsure of whether her answer was correct. Her answer wasn’t correct, but that is immaterial in this interaction; her willingness to share her thinking represented an enormous shift in participation for Rose. In contrast to our first observation, when Rose had been reluctant to share an answer that she knew was correct, she now volunteered to share her thinking even when she was not completely sure of her answer.

Discussion and Conclusion

In this exploratory study, we sought to understand (1) how one highly math-anxious PSET made sense of changes in her MA throughout a mathematics content course, and (2) whether these changes were observable in her in-class participation. With respect to our first research question, we found that Rose reported a substantial reduction in her level of MA, a change that was reflected in all of her self-reported data. With respect to experiences of confusion, Rose’s language shifted from reflecting anxiety, resentment, and futility to an assertion that “everyone needs help with math every once in a while.” When speaking of interactions with teachers/professors, Rose described feeling “understood” and “seen” instead of feeling embarrassed. Rose’s new awareness of the existence of multiple solution strategies was pivotal in her MA transformation. Not only did she view this as a source of her newfound mathematical confidence, it provided her a lens through which she could reappraise her past mathematical experiences. She now interpreted her struggles in high school mathematics as a deficit in “the way it was explained,” rather than a deficit in her cognitive abilities.

With respect to our second research question, we found that we were able to observe Rose responding to her MA triggers in ways that both corroborated her self-reported data and provided additional insight into her changing experience of MA. This responded to Hollingsworth & Knight-McKenna’s (2018) call to reduce reliance solely on PSETs’ self-reported MA data. For example, we were able to verify Rose’s self-reported description of disengaging in response to moments of confusion when we observed her saying, “I’m gonna save my energy” and “you cook over there, I’m lost.” In our second observation, we found evidence of Rose’s new interpretation of being confused as a natural part of “solv[ing] the puzzle” when she told Ellen that, even though she was confused, “I’m just gonna model it and see what I come up with here.”

Our observational data also revealed aspects of Rose’s experience of MA that were not present in her MARS-B responses, narratives, or interviews. Although Rose’s interactions with her past teachers and the professor were prominent topics in these data sources, her observed responses to this trigger were not represented in her narratives or interviews. In the first observation, when there was a possibility of interacting with the professor, we saw a desire to keep her answer private when she said, “I don't want to answer because then she's gonna ask me another question,” and “you came at the worst time.” Attempting to keep one’s work private is a

MA response identified by Sanders et al. (2019) and could be viewed as evidence that Rose interpreted such interactions as threatening. During the second observation, when we observed Rose volunteer to share an answer that she was unsure of, it was clear that this was no longer the case. Interestingly, Rose never mentioned how she might respond to interacting with the teacher in her post narrative or interview, which may suggest that she was unaware of how her response to this trigger had changed. If this is the case, it means that, in the absence of observational data, this aspect of Rose's experience of MA was inaccessible, both to herself and to us as researchers. This implies that observational data can not only triangulate more traditional MA data sources, but can also provide unique and otherwise unattainable insights in studies of PSETs' MA.

Our exploratory case study was inevitably limited by the case size. While we gathered robust evidence of Rose's experience of MA that was both corroborated and extended by our observational data, more research is needed to determine if similar insights could be achieved with more reticent PSETs. Also, Rose mentioned that the professor's grading system (Revision-Reflection Grading), unlike traditional grading, enabled her effort to be reflected in her grade. Future research could investigate whether alternative grading systems can reduce PSETs' MA.

The use of survey, narrative, and interview data is well-established as a means to better understand PSETs' experiences with MA (e.g., Barrett, 2013; Finlayson, 2014). We found that there was a symbiotic relationship between these data sources and the observational data we collected. Survey, narrative, and interview data enabled us to establish the baseline necessary to collect meaningful observations of Rose's responses to MA triggers; in turn, the observational data enriched our understanding of Rose's MA transformation. Most notably, the observational data provided insights that were unattainable with survey, narrative, and interview data alone.

EXPLORING PRESERVICE TEACHERS' FOCI AND STRATEGIES FOR ACKNOWLEDGING COMPETENCE IN A SCAFFOLDED COURSE ASSIGNMENT

Rosalie DeFino	Michele Cudd	Wesam Salem
University of Wisconsin – La Crosse	Morehead State University	University of Memphis
rdefino@uwlax.edu	m.cudd@moreheadstate.edu	wsalem1@memphis.edu

Acknowledging competence through the intentional identification and affirmation of students' mathematical strengths and contributions can foster positive math identities and advance equitable math instruction. Using an interpretive qualitative approach, we examine 68 elementary preservice teachers' (PSTs') attempts to acknowledge competence for four focal students in a scaffolded assignment in math methods courses. To characterize PSTs' efforts, we generated descriptive initial codes, and then refined and grouped codes into categories. Our findings can inform teacher educators' pedagogical approaches to cultivating PSTs' proficiency in equity-oriented teaching strategies like acknowledging competence.

Keywords: Preservice Teacher Education, Equity, Inclusion, and Diversity, Instructional Activities and Practices, Elementary School Education

There is a growing body of work focused on recognizing students' mathematical strengths and positioning students as competent to pursue equity in mathematics education (e.g., Iacono, 2018; Jilk, 2016; Johnson et al., 2022; Kalinec-Craig et al., 2021; Skinner et al., 2019). Within this body of work, scholars have identified equity-oriented teaching practices like *assigning* or *acknowledging competence* (Imm, 2022) in which teachers deliberately name students' mathematical strengths and contributions. Such practices aim to support students' development of positive mathematics identities, broaden their participation in math discourse, and deepen their mathematics learning (Aguirre et al., 2013; Featherstone et al., 2011). These practices also reflect visions of equitable math instruction emphasized by professional organizations (Association of Mathematics Teacher Educators, 2017; Huinker, 2020; Huinker & Bill, 2017; National Council of Teachers of Mathematics, 2014). To make tangible progress towards these visions of equitable math instruction, we must learn more about how preservice teachers (PSTs) take on and attempt equity-oriented practices. In this paper, we explore elementary PSTs' early efforts with the practice of acknowledging competence in a structured course assignment.

Research Focus

Building on previous work of our own (DeFino, 2022) and of others in the field (e.g., Jilk, 2016; Kalinec-Craig et al., 2021), we adapted a mathematics methods course assignment originally developed at the University of Michigan to scaffold PSTs' naming of students' mathematical strengths and contributions. For this assignment, PSTs watch a video clip of a math discussion, and then respond to a series of questions and prompts about four specific students' contributions. We were motivated by a shared concern that PSTs often interpret and respond to students' mathematical thinking as either right or wrong, dismissing answers and strategies that are not "correct," and reinforcing narrow and exclusionary notions of mathematical ability (Louie, 2017). Thus, through the assignment, we purposefully push PSTs to identify students' mathematical strengths and contributions beyond the right vs. wrong binary.

In this study, we examine PSTs' responses to this assignment, exploring what sorts of mathematical strengths and contributions PSTs' focus on and what statements they use to acknowledge students' competence. We investigate the following research questions:

1. What mathematical strengths or contributions do PSTs highlight in their draft statements to acknowledge each student's competence?
2. What strategies do PSTs use to acknowledge competence? (i.e., How do PSTs structure their acknowledging competence statements?)

Our aim is to better understand tendencies in how PSTs attempt to acknowledge competence for specific students and scenarios. This study will inform our own instructional designs and offer implications for other mathematics teacher educators working to develop PSTs' skills with equity-oriented instructional practices like acknowledging competence.

Theoretical Framing

This research focuses on the practice of acknowledging competence. Drawing on Cohen and Lotan's (1995) conceptualization of assigning competence, we define acknowledging competence as a deliberate act of naming and validating students' mathematical strengths and contributions. Following Imm (2022), we use the language of "acknowledging" rather than "assigning" to convey the stance that students already demonstrate mathematical competence in a multitude of ways, and it is teachers' responsibility to look for and recognize that competence.

Acknowledging competence involves conscious attention to how students are positioned through classroom interactions and the use of teacher moves and statements to intervene on patterns of exclusion (Chval et al., 2021; Davies & Harré, 1990; Featherstone et al., 2011; Louie, 2017). A key purpose is to position students as capable contributors to the learning process, supporting and encouraging students' participation (Johnson, 2017). For instance, a teacher might verbally emphasize a student's question in a class discussion, highlighting how that question is bringing the class's attention to an important mathematical idea (Johnson et al., 2022). Another key purpose of acknowledging competence is to broaden what students recognize as "smart" or important in mathematics (Featherstone et al., 2011; Jilk, 2016; Kalinec-Craig et al., 2021). This requires teachers to take a more inclusive and holistic approach to assessing and responding to students' mathematical contributions, rather than reinforcing the conventional emphasis on correctness or speed (Horn, 2007; Louie, 2017; Skinner et al., 2019).

Salient in recent research is the connection between acknowledging student competence and advancing equity in mathematics classrooms (e.g., Boaler & Staples, 2008; Johnson et al., 2022). Specifically, Hand (2012) argues that "it is only when teachers become disposed to *attend* differently to classroom mathematical activity that the field of mathematics education will provide a more even playing field for nondominant learners" (p. 235, emphasis in original). In other words, teachers must learn to actively *look for* and attend to students' competence to create more equitable and inclusive mathematics classrooms. To support PSTs in developing this disposition and skill, we pursued an instructional approach that allows PSTs to approximate (Grossman et al., 2009) the practice of acknowledging competence while initially stripping away some of the complexities of classroom teaching (e.g., drafting statements to acknowledge students' competence without the time pressure of responding in the moment). We envision that

PSTs will gradually incorporate acknowledging competence into their math teaching with additional practice opportunities, such as leading math discussions in field experiences.

Methods

This study utilizes an interpretive qualitative approach (Hesse-Biber & Leavy, 2011) to examine PSTs' draft statements to acknowledge specific students' competence in a structured course assignment.

Data Collection

Context. Data was collected from undergraduate math methods courses at two regional public universities in different parts of the United States, one in the upper Midwest and the other in the Southeast. Both institutions are predominately white, enroll many students from rural areas, and have elementary education classes largely composed of women. The first author teaches a math methods course designed to prepare PSTs to teach kindergarten through ninth grade. The second author teaches a math methods course designed to prepare PSTs to teach kindergarten through fifth grade. All three authors collaborated to design learning experiences focused on acknowledging competence. While course instruction and details varied by institution, both courses emphasized the importance of math identity for equity (Aguirre et al., 2013), worked on asset-based interpretations of student thinking, then introduced acknowledging competence as a strategy to affirm student's math identities and position students as capable.

Participants. The 68 participants in this study are PSTs who were enrolled in elementary math methods courses in a recent semester and consented to have their work analyzed for research. The majority, 55 participants, come from three course sections at the first author's university and the remaining nine PSTs are from one section at the second author's university.

Data sources. The PSTs' written responses on a focal course assignment were collected. This assignment is built around a video clip titled "Mamadou-Half-Rectangle" (Mathematics Teaching and Learning to Teach, University of Michigan, 2010). In this video, a class of rising fifth graders discuss what fraction of a larger rectangle a shaded area represents. The assignment identifies four students in the video (one of whom is Mamadou) and poses questions that guide PSTs to consider each student's verbal contributions from an asset-based perspective. Our analysis centers on PSTs' responses to the following prompt: *If you were the teacher, what could you say to acknowledge this student's mathematical competence?*

Data Analysis

A thematic analysis approach (Braun & Clarke, 2006) was used to identify categories and themes within the data. The PSTs' drafted acknowledging competence statements were coded along two dimensions: the focus [*what*] of the statement and the approach [*how*]. All three authors conducted initial coding (Saldaña, 2016) of ten participants' responses, then compiled and sorted codes into categories to generate a codebook. These codes were applied to a second set of ten responses to refine code definitions and categories. Each PST response could receive multiple codes. Using the revised codebook, the researchers are individually coding sets of ten responses and then meeting to discuss and come to a consensus. This process is still underway. Once complete, descriptive statistics will be tabulated, and overarching themes will be identified.

Preliminary Findings

Our collaborative coding process has resulted in a codebook that begins to answer our research questions, characterizing *what* PSTs focused on in their draft acknowledging competence statements and *how* PSTs went about attempting to acknowledge each student's competence. We have found that PSTs focused on a range of student strengths and contributions, some of which were more distinctly mathematical than others. Coding categories describing PSTs' foci consisted of the following: (a) a specific mathematical idea (e.g., recognizing the whole in the problem), (b) a specific process (e.g., explaining another student's thinking), (c) language (e.g., using the term "equal parts"), (d) a community contribution (e.g., "helping us understand"), (e) compliance with classroom norms or behaviors (e.g., listening, sharing), (f) correctness, (g) affect (e.g., eagerness to explain), or (h) being smart (e.g., "You're smart at math."). Some PST responses did not meet our definition of acknowledging competence. In those cases, we coded the focus of PST responses as "not applicable" because they included questions or *solely* consisted of general praise (e.g., "Great job"). Notably, some of PSTs' foci seem more likely to support broadened notions of mathematical competence than others. For instance, statements highlighting contributions students made to the community could help to portray mathematics as a collective undertaking rather than as an individual effort to arrive at correct answers (Featherstone et al., 2011). In contrast, statements highlighting more compliance-oriented behaviors like listening or paying attention seem likely to reinforce conventional notions of "doing school" (Goldin, 2010).

In characterizing *how* PSTs attempted to acknowledge each student's competence, we first categorized PST responses as being statements or questions. We then further categorized statements according to the "strategy" being used to acknowledge competence: thanking the student, specific praise, describing what the student did to the class, making a teacher-centric statement (e.g., "I like how you…"), framing the student's contribution as helpful to the community, affirming correctness (either explicitly or implicitly), or directly stating that the student is smart. Statements that did not meet our definition for acknowledging competence were categorized as orchestrating moves (e.g., "Let's pause to hear more about Mamadou's thinking") or hypothetical statements (i.e., describing the type of thing the PST *would* say without providing specifics). We did not consider questions as instances of acknowledging competence but still tracked the types of questions PSTs listed as eliciting moves (e.g., "Could you say more about what you're seeing as the whole?") or orienting moves (e.g., "Who can repeat Mamadou's thinking?"). Our thinking was that, though not acknowledging competence on their own, such questions could be used in ways that elevate and value student contributions. Additionally, we noted instances in which PSTs explicitly used student names in their responses with the rationale that accurately pronouncing and using students' names is one way to convey that students are seen and valued (Kohli & Solórzano, 2012). These coding categories and subcategories illustrate the variety of strategies that PSTs used in their efforts to acknowledge students' competence.

Interpretation and Implications

In our interpretation of these findings, we do not view any given focus or strategy as inherently good or bad; we maintain that much depends on the details of how acknowledging competence statements are delivered. For example, we recognize instances where explicitly affirming a student's correctness seems productive for highlighting student contributions that might otherwise be overlooked. At the same time, there are other instances where explicitly affirming a student's correctness could reinforce narrow and exclusionary notions of mathematical competence (e.g., emphasizing one "correct" way to solve). We do not think there is just one right or best way to acknowledge competence. Instead, we see these descriptive codes as offering a picture of what PSTs tend to do in their early efforts at acknowledging competence, which can inform our efforts to build on PSTs' productive inclinations and redirect PSTs away from counterproductive foci and strategies. Additionally, our codes offer a conceptual lens for other mathematics teacher educators to analyze and interpret their own PSTs' attempts to acknowledge competence. We envision a future of mathematics education in which learning to actively see and name students' strengths in ways that disrupt and challenge exclusionary notions of mathematical ability is an essential component of teacher preparation — a future in which acknowledging competence is as salient a practice as selecting cognitively demanding tasks or using and connecting mathematical representations. This study offers some preliminary conceptual tools for mathematics teacher educators to engage in serious and ongoing work on acknowledging competence.

AN EXPLORATION OF THE RELATIONSHIP BETWEEN INSTRUCTIONAL TIME AND PERSEVERANCE GROWTH FOR ELEMENTARY PRE-SERVICE TEACHERS

Joseph DiNapoli
Montclair State University
dinapolij@montclair.edu

This in-progress study investigated how time elementary preservice teachers (PSTs) spent studying certain mathematics topics during a content course was related to growth in their perseverance in problem-solving. Using a quasi-experimental design, PSTs from two classes taught by the same instructor engaged in 12 problem-solving sessions each to measure their willingness to initiate and sustain, and re-initiate and re-sustain upon impasse, productive struggle during engagement. There were two conditions: over one semester, the treatment class studied 5 mathematical topics and the control class studied 10 mathematical topics. Preliminary results suggest that PSTs in the treatment class show greater perseverance growth over time compared to PSTs in the control class. This suggests that PSTs' perseverance development may be supported by spending more time studying fewer topics during mathematics content courses.

Keywords: Preservice Teacher Education, Problem Solving, Elementary School Education

Rationale, Background, and Theoretical Perspectives

Mathematics education researchers continue to look for best practices by which to structure elementary teacher education programs, yet consensus continues to elude the field (Garner et al., 2023; Masingila & Olanoff, 2022). Professional organizations like the Association of Mathematics Teacher Educators have published standards for preparing teachers of mathematics (AMTE, 2017), which include coursework recommendations and emphasis on developing future teachers' knowledge of mathematics concepts and dispositional practices. Teachers' mathematical knowledge for teaching directly impacts the quality of instruction their students experience (Hill et al., 2008), thus careful coordination over what elementary pre-service teachers (PSTs) have opportunities to learn in their preparatory mathematics coursework is of critical importance to their development as effective teachers. Yet still, without consensus, PSTs across North America have experienced great variance in the mathematics content and practices they study and for how long they study it (e.g., Hrusa et al., 2020; Malzahn, 2020; NCEE, 2016), which jeopardizes the effectiveness of teacher preparation. In fact, a PME-NA working group, *Mathematics Curriculum Recommendations for Elementary Teacher Preparation*, is devoted to such issues. Aligned to the theme of PME-NA 46, the future of elementary mathematics teacher preparation depends on new research efforts amidst such uncertainty across PST education.

At many institutions, PSTs engage in survey courses aiming to cover the complete spectrum of elementary mathematics content topics (An et al., 2021). These courses are often developed from a knowledge-oriented theoretical perspective, with an emphasis on teaching all the mathematical topics PSTs need to know to teach effectively (Li & Howe, 2021). At other institutions, certain elementary mathematics content topics are purposely omitted to focus more time on high-leverage topics and practices, such as number concepts and problem-solving (Chapin et al., 2021). These courses are often developed from a thinking-oriented theoretical perspective, with an emphasis PSTs learning to reason about, explain, and make sense of the mathematics they will teach (Li & Howe, 2021). Although such variance in coursework still exists, recent research has shown the long-term benefits of spending more instructional time on a smaller set of mathematical topics during teacher preparation (Beckmann & Izsak, 2021; Corven et al., 2022; Gibbons et al., 2018). For instance, Corven and colleagues (2022) examined the relationship between the number of instructional minutes dedicated to mathematics topics in teacher preparation and the specialized content knowledge (SCK, Ball et al., 2008) demonstrated by program graduates. Analyses showed that over 400 minutes of high-quality instruction on one mathematics topic were needed to develop the SCK to teach it well years later. This finding suggests that survey courses may not be effective in fostering lasting knowledge and application.

Although such research is promising, more research is necessary to investigate the affordances and constraints related to the instructional time spent (or not spent) on specific mathematics topics included in content courses for PSTs. Existing research has shown how PSTs develop and retain mathematical understandings by devoting more time studying less topics, but we know very little about other outcome measures of PSTs, including outcomes related to the development of mathematical practices like perseverance in problem-solving. Perseverance, or initiating and sustaining productive struggle in the face of obstacles (DiNapoli, 2023), promotes making sense of mathematics (Middleton et al., 2015; Warshauer, 2014). Students make meaning through productive struggle, or as they grapple with mathematical ideas that are within reach, but not yet well formed; it is imperative for teachers to create learning environments for their students that promote such productive struggles (Hiebert & Grouws, 2007). Recent studies have shown that perseverance in problem-solving can be malleable in students and nurtured, depending on the learning environment, to grow and improve over time (DiNapoli & Miller, 2022; Paurowksi et al., 2024). Learning environments that provided consistent opportunities to productively struggle with mathematics content, and thus, opportunities for students to deliberately practice their perseverance have shown promise. In PST education, PSTs must have consistent opportunities to persevere and develop a disposition and willingness to engage in productive struggle during their mathematics content coursework to be able to empathize with and support their future students to productively struggle to learn mathematics (AMTE, 2017). As such, the research question that guides this in-progress study is: *What is the relationship between mathematics instructional time and perseverance growth for elementary PSTs in a content course?*

Context and Methodology

This in-progress, mixed-methods study used a quasi-experimental design (Patten, 2016) to help describe a relationship between instructional time and perseverance growth for elementary PSTs in a content course. I collected and analyzed data from two distinct groups of participants at a public university in the northeast United States: one Fall 2023 section (complete) and one Spring 2024 section (in-progress) of a terminal Mathematics Content for Elementary Teachers II course. There were two class conditions: a treatment condition (the Fall 2023 section) and a control condition (the Spring 2024 section). There were 30 PSTs in each section, resulting in 60 total participants. I was the sole instructor for each class.

Treatment and Control Conditions

In the treatment condition, PSTs engaged with 5 mathematics topics during one semester, averaging about 400 minutes of classroom time devoted to each topic. The treatment topics were

Conceptions of Fractions, Addition of Fractions, Subtraction of Fractions, Multiplication of Fractions, and Division of Fractions. In the control condition, PSTs engaged with 10 mathematics topics during one semester, averaging about 200 minutes of classroom time devoted to each topic. The control topics were the 5 treatment topics, plus Percentages, Ratios and Proportions, Polygons, Angles, and Area. In both conditions, I taught each lesson following the same style lesson plans which emphasized conceptual learning opportunities.

Data Collection

Each PST in each condition engaged in 12 virtual problem-solving sessions, approximately one per week. In these non-graded sessions, I presented PSTs with a challenging task as part of their individual homework related to that week's lesson (e.g., *If 100 stars represent* $\frac{6\frac{2}{3}}{5}$*, how many stars represent 1 whole?).* PSTs video-recorded themselves thinking aloud as they worked toward a solution. The tasks were designed to evoke productive struggle, and if they did not, PSTs were given a different task that did. If PSTs ever reached a perceived impasse (i.e., they were substantially stuck (VanLehn et al., 2003)), they were instructed to say so. PSTs could stop working on a task at any time. Also, each PST engaged with written stimulated recall prompts (Ericsson & Simon, 1993) about specific moments during each of their problem-solving sessions. Responses to these prompts helped reveal and explain any in-the-moment cognitive and emotional activity that PSTs experienced while working on a task, especially around moments of perceived impasse. In some cases, I followed up with participants even further to gain clarifications about specific moments during problem-solving sessions.

Data Analysis

To analyze each PST's problem-solving session, I used the Three-Phase Perseverance Framework (3PP) (see Figure 1) (see DiNapoli & Miller, 2022). The 3PP has been used in several empirical studies (e.g., DiNapoli, 2019; DiNapoli et al., 2021; DiNapoli & Miller, 2022; DiNapoli & Morales, Jr., 2021) to measure perseverance in problem-solving, or the extent to which students initiated and sustained, and re-initiated and re-sustained upon impasse, productive struggle on a challenging task. The 3PP operationalizes perseverance by considering the ways in which a student makes an initial attempt at solving a problem for which they do not already know a solution pathway, and makes an additional attempt at solving the problem if their initial attempt was unsuccessful and led to a perceived impasse. Theoretically, a student could engage in multiple additional attempts as they encounter multiple impasses. In my analysis, I only considered students' experiences around one perceived impasse during the problem-solving.

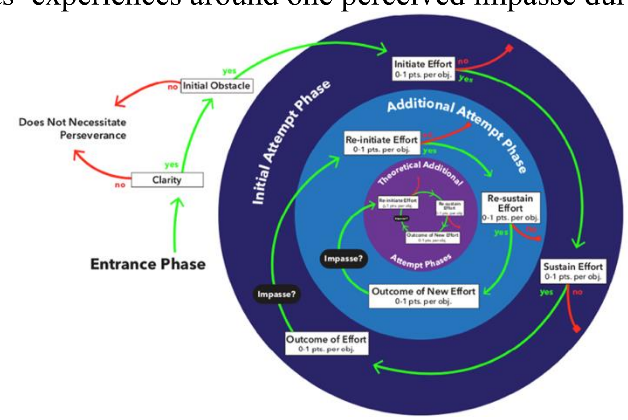

Figure 1: The Three-Phase Perseverance Framework

I used the 3PP to capture if and how a PST initiated (0-1 point) and sustained (0-1 point) efforts toward a solution before an impasse, and if and how those efforts were mathematically productive (0-1 point). After an impasse, I also captured if and how a PST re-initiated (0-1 point) and re-sustained (0-1 point) their efforts toward a solution, and if and how those new efforts were mathematically productive (0-1 point). I relied on PSTs' think-alouds, their written work, and their stimulated recall responses to make scoring decisions. Thus, PSTs could earn 0-6 3PP points per problem-solving session, with 0 indicating no evidence of perseverance and 6 indicating ample evidence of perseverance (i.e., a PST could demonstrate ample perseverance while working with a task through building incremental understanding via effort, yet not completely solve the task). When considering PSTs' improvement, a gain of just one 3PP point is substantial since it could represent perseverance growth in several ways, such as: the difference between not engaging at all vs. initiating some effort (0 points vs. 1 point); initiating some effort but then giving up vs. sustaining that effort (1 point vs. 2 points); sustaining an effort but not making mathematical progress vs. actually making mathematical progress based on that sustained effort (2 points vs. 3 points); engaging in a successful first attempt but giving up upon impasse vs. re-initiating a second attempt after impasse (3 points vs. 4 points); and so on.

Each PST engaged in 12 problem-solving sessions, so each PST earned 12 3PP scores. To help control for pre-existing differences amongst PSTs, my analysis focused on each PST's personal perseverance growth. I used linear regression to model each PST's perseverance growth across their 12 problem-solving sessions. I also used linear models to represent PSTs' perseverance growth per class condition, that is, for PSTs in the treatment and control conditions. My findings focus most on the slopes of these linear models, which represent the average increase of PSTs' 3PP scores per problem-solving session, per class condition. Qualitative analyses are still ongoing.

Preliminary Results and Discussion

PSTs in the treatment condition increased their perseverance by an average of 0.329 3PP points per problem-solving session. This suggests that it took, on average, approximately 3.0 problem-solving sessions for PSTs in the treatment condition to improve their perseverance in problem-solving by one 3PP point. In contrast, PSTs in the control condition increased their perseverance by an average of 0.163 3PP points per problem-solving session. At this rate, this suggests that it will take, on average, approximately 6.1 problem-solving sessions for PSTs in the control condition to improve their perseverance in problem-solving by one 3PP point. Thus, PSTs who spent more instructional time on less topics improved their perseverance growth by more than double the rate of their PST peers who spent less instructional time on more topics.

At this time, it is inappropriate to make any formal claims about the relationship between instructional time and PSTs' perseverance growth since qualitative analyses are still ongoing. These analyses will help reveal some reasons behind why perseverance growth was so different between class conditions. However, these preliminary results might suggest that more time spent on less mathematics topics during PST content coursework can influence the development of PSTs' perseverance in problem-solving, compared to spending less time on more topics. These preliminary findings about developing such mathematical practices in PSTs, alongside existent research about PSTs' development and retention of mathematical understandings under similar conditions (Beckmann & Izsak, 2021; Corven et al., 2022; Gibbons et al., 2018), would strengthen the practical argument for devoting more time on less topics in content courses, and present more comprehensive evidence against the efficacy of survey courses. Furthermore, these findings would emphasize the need for thinking-oriented theoretical perspectives (Li & Howe, 2021) in elementary mathematics teacher preparation. Addressing the theme of PME-NA 46, this could help the field of mathematics education work toward a more certain future of elementary mathematics teacher preparation.

COUNTING ON JUSTICE: ADDING SOCIAL IMPACT TO ELEMENTARY PRE-SERVICE TEACHER MATHEMATICS EDUCATION

Katryne Dubeau
University of Saskatchewan
katryne.dubeau@usask.ca

Mina Wardrop
University of Saskatchewan
mina.wardrop@usask.ca

This brief research report advocates integrating social justice into mathematics education for elementary pre-service teachers (EPSTs). It highlights the importance of this integration in addressing mathematics anxiety and improving attitudes toward mathematics. The report also discusses how negative attitudes and mathematics anxiety can hinder PSTs' ability to teach mathematics effectively, stressing the necessity to incorporate mathematics applications into education method courses. Furthermore, it underscores the relevance of integrating social justice topics into the pre-service teacher mathematics curricula to promote critical thinking and humanization, thereby aiding in addressing educational disparities and promoting confidence in teaching numerical skills. This approach can potentially transform PSTs' attitudes toward mathematics, alleviate mathematics anxiety, and enhance their teaching practices in elementary classrooms.

Keywords: Preservice Teacher Education; Social Justice; Instructional Activities and Practices; Instructional Vision

Negative attitudes toward mathematics and mathematics anxiety can significantly impact mathematics learning by elementary pre-service teachers (EPSTs) (Gonzalez-DeHass et al., 2017). Mathematics anxiety, an adverse physiological reaction to working with mathematics (Luttenberger et al., 2018), is particularly prevalent among EPSTs, who also have the lowest mathematics proficiencies (Novak & Tassell, 2017). However, mathematics methods courses that teach PSTs about mathematics applications have been shown to help reduce mathematics anxiety (Tooke & Lindstrom, 1998). These courses can also integrate other subjects, such as science, social studies, and reading, into mathematics methods courses to positively influence PSTs' attitudes toward mathematics (Bursal & Paznokas, 2006). By challenging PSTs to engage in tasks involving cooperation, problem-solving, personal mastery of mathematical skills, and communication of mathematical facts and relevance (Gonzalez-DeHass et al., 2017), these courses can significantly improve PSTs' teaching abilities and confidence in teaching numerical skills.

Integrating social justice topics into all curricula is relevant since social justice teacher education aims to prepare PSTs to "recognize, name, and combat inequity in schools and society" (Spalding, 2013, p. 284). Social justice education involves critical thinking, humanizing space (Freire, 2003), and creating a space where potentially controversial issues can be discussed and analyzed (Kumashiro, 2000). Mathematics can and should be the tool used to analyze social injustices in a complex world (Greenstein & Russo, 2019). As Gutstein (2006) states:

> [T]he idea of liberation from oppression as the fundamental purpose of teaching mathematics […] Teaching mathematics for social justice flows from the broader notion of liberatory education and has two sets of pedagogical goals; one focused on social justice and the other on mathematics. (pp. 22-23)

While mathematics is thought of as either divorced from the real world (Gutstein & Peterson, 2006), masculine (Rubel, 2016), a disingenuous cognitive domain (Rands, 2013), isolated (Hernandez-Martinez & Vos, 2017) or as a set of rote memorizations (Peterson, 2006), EPSTs should see mathematics as a method to increase student interest in social justice advocacy (Stocker, 2005). In doing so, there could be an increase in PST engagement in mathematical content and methods, thus aiding their understanding of mathematics and possibly lowering their mathematics anxiety.

Incorporating social justice topics into mathematics methods courses for EPSTs not only addresses educational disparities (Fasheh, 1982) but can also aid in reducing mathematics anxiety in EPSTs due to its integrative nature (Bursal & Paznokas, 2006). These courses can offer a more relatable and inclusive approach by emphasizing real-world applications and diverse perspectives on mathematical concepts (Yeh & Otis, 2019), helping future educators build confidence and effectively support students with varied backgrounds (Clark & Brown, 2016). Our research question was: How could learning about social justice mathematics transform PSTs' attitudes and knowledge in teaching mathematics?

Theoretical Framework

The theoretical framework for this study centers around teaching social justice mathematics (Bartell, 2013; Gutstein, 2006) to pre-service teachers in an elementary mathematics methods course. As research has shown (Bursal & Paznokas, 2006; Gonzalez-DeHass et al., 2017; Novak & Tassell, 2017; Tooke & Lindstrom, 1998), EPSTs experience high levels of mathematics anxiety and low enthusiasm for the subject. This, in turn, impacts their students' mathematics learning (Stoehr et al., 2017). Social justice mathematics education allows students of all ages to engage in social justice advocacy while using patterns and relationships taught in their courses instead of a more traditional manner, which mostly focuses on "memorization, regurgitation, standardized testing and reams upon reams of mathematics problems whose content is immaterial" (Stocker, 2005, p. 48). Social justice in mathematics could be particularly relevant in the context of EPSTs who may have their own experiences of mathematics anxiety and may be more likely to pass these anxieties on to their students if they do not see the relevance of mathematics in their lives.

This theoretical framework might also draw on research on reducing mathematics anxiety in learning by promoting a supportive and encouraging educational environment, incorporating real-world examples and applications of mathematics concepts, and addressing the root causes of mathematics anxiety through self-reflection and mindfulness techniques. We also draw on the humanizing framework to "move beyond individual components of mathematical belief (e.g. self-efficacy, confidence, mindset, views of what it means to do mathematics, and others) and challenges us to consider each EPST as a collection of all of these complex views and beliefs" (Skultety et al., 2023, p. 2). Overall, social justice education in mathematics, in the context of this paper, focuses on promoting social justice and equity in mathematics methods courses for EPSTs to equip them with a method that can confront their mathematics anxiety and ultimately improve their attitudes, knowledge, and effective mathematics teaching practices.

Nixing Mathematical Nerves

Mathematics appears to be a subject that elicits either a strong affinity or a strong aversion among individuals (Çetinkaya et al., 2018). This often stems from mathematics being a classroom subject heavily focused on achievement assessment, and the fear of failure often traps individuals in a negative attitude toward mathematics (Çetinkaya et al., 2018). Alkan, Coşguner and Fidan's (2019) study examines how negative attitudes and perceptions of mathematics can impact individuals who go on to teach mathematics. The study indicates that there has been research on how PSTs feel about mathematics and its influence on how PSTs approach teaching the subject. Stoehr, Carter and Sugimoto (2017) also found that PSTs with mathematics anxiety need a mathematics course that connects mathematical content knowledge with teaching knowledge. Therefore, a mathematics methods course which focuses on relieving PSTs' mathematics anxiety should focus on raising confidence in their mathematics content knowledge by focusing on the application (Tooke & Lindstrom, 1998) of mathematical concepts; we contend that social justice mathematics is a way to do so.

Many mathematics educators face the infamous question: "Why do I have to learn this?" (Hernandez-Martinez & Vos, 2017). When mathematics teachers encounter this problem and do not know the reason for teaching mathematical concepts, they may unintentionally perpetuate a negative perception of mathematics. As a result, PSTs should know how to integrate mathematics into various other disciplines, such as social studies or history (Peterson, 2006), emphasizing its relevance to our social world and social justice issues. Changing the views on mathematics for PSTs could lower their mathematics anxiety and directly influence how they teach mathematics to other generations of students. Additionally, this could demonstrate to PSTs and their future students how practical mathematics is in everyday life, making it more approachable, relevant, and engaging (Hernandez-Martinez & Vos, 2017).

Integrating social justice into mathematics methods courses should be more commonly practiced in teacher education programs. Despite common misconceptions, mathematics and social justice education can exist in a harmonized pedagogy (Bond & Chernoff, 2015). If educators of EPSTs deliver this integration of social justice into mathematics to these PSTs, it could impact future generations of teachers and students alike. A shift in the attitude towards mathematics courses for EPSTs has the potential to bring about substantial improvements in the delivery of mathematics education within our system. Teachers and students could realize that mathematics can be used to examine social issues more profoundly and further contextualize their mathematics lessons. This can potentially lead to the alleviation of anxiety experienced by PSTs within mathematics and the likelihood of increased confidence in the teaching of the subject.

Calculating a Confidence Boost

Integrating social justice into mathematics, as proposed by Gutstein (2006), has the potential to alleviate mathematics anxiety and enhance confidence among PSTs, fostering meaningful connections through mathematics. When EPSTs learn to incorporate current social injustices into their mathematics curricula, they may become better equipped to create a more relevant and engaging educational experience for themselves and their students. Establishing connections in mathematics can strengthen the mathematical identity of PSTs and promote a sense of belonging among their students within the mathematical community (Skultety et al., 2023). This approach may facilitate a deeper understanding of mathematical concepts while addressing societal issues pertinent to the students' realities.

The contemporary world presents numerous opportunities for instructing PSTs on analyzing and comprehending social justice issues through mathematics, thereby equipping them to better facilitate their students' mathematical education. Despite the pervasive presence of numerical data in daily life, its relevance may not always be immediately evident (Gutstein, 2006). By teaching PSTs to apply critical thinking skills in mathematics to navigate our society, they may gain greater confidence in addressing complex societal issues and making more informed decisions (Yeh & Otis, 2019). This can be exemplified using news articles on current social issues, such as the increase in the number of gender-based hate crimes in the United States of America (Pollard, 2024), violence rates against Indigenous Peoples in Canada (Lee, 2023), the cost of childbirth in the United States (Rivelli, 2024), environmental racism (DeLaire, 2023), and more. Employing real-world events to establish meaningful connections to mathematics highlights how PSTs can integrate cross-curricular subjects to create impactful experiences for future students.

Equipping EPSTs with the knowledge to integrate relevant global events into their mathematics classes could enhance PSTs' engagement in the subject. By providing a medium for delivering mathematics instruction with greater impact, PSTs may feel more prepared to teach future mathematics lessons, thereby increasing student involvement. This approach ultimately empowers EPSTs, instilling confidence and competence as they enter classrooms where they will be responsible for mathematics education. Consequently, PSTs may be more inclined to embrace the challenges of teaching mathematics in ever-evolving and uncertain global contexts and moments.

Considerations for Social Justice Integration in Mathematics Education for PSTs

Amalgamating social justice into mathematics education for PSTs holds significant potential for reducing mathematics anxiety and improving attitudes toward the subject. Research indicates that PSTs often struggle with mathematics anxiety and negative attitudes toward mathematics, which can impair their teaching efficacy. By incorporating social justice topics into mathematics methods courses, PSTs can appreciate the relevance of mathematics in real-world contexts and engage in critical thinking about social injustices. This approach may address educational disparities and enhance PSTs' understanding of mathematical concepts and their societal significance.

PSTs need to recognize that changes in mathematics teaching pedagogy do not occur instantaneously. For instance, PSTs can begin by integrating activities such as analyzing the number of books authored by People of Colour versus those by White authors. Depending on the students' grade levels, PSTs could analyze the data they discover using various mathematical methods. Integrating social justice into mathematics education could be an important pedagogical strategy, empowering PSTs to become more confident and effective mathematics educators. By equipping PSTs with the tools to analyze social issues through mathematics, they can create more meaningful and engaging experiences for themselves and their future students. Overall, integrating social justice into mathematics education can transform attitudes toward mathematics, reduce mathematics anxiety, and enhance the teaching practices of PSTs in elementary classrooms.

Potential Pushbacks and Limitations

Acknowledging the potential pushbacks and limitations to integrating social justice education into EPST mathematics methods courses is essential. While this incorporation can offer significant benefits, some educators and stakeholders may resist due to differing views on the role of social issues in mathematics instruction and varying values regarding specific social justice topics addressed in the course. Additionally, the differing levels of preparedness and comfort among PSTs in handling sensitive topics can present challenges. Furthermore, limited resources and support from the administration and other educators may hinder the effectiveness and sustainability of this curriculum in PST education programs.

PRESERVICE TEACHERS' REPLICATIONS OF A COMMON FRACTION ERROR

Temitope F. Egbedeyi

Keywords: Teacher Knowledge; Number Concepts and Operations; Rational Numbers.

There are numerous assessments of preservice teachers (PSTs) content knowledge of fractions (Erdem, 2016; Huang et al., 2009; Izsàk et al., 2019). Yet, most do not adequately distinguish between common content knowledge and the specialized content knowledge (SCK) needed to interpret children's work with fractions (Copur-Gencturk et al., 2019). One way to examine SCK for fractions is to study teachers' engagement with common fraction errors. These common errors are well-documented, with students are numerous such errors documented over the past 100 years (Behr et al., 1984; Brueckner, 1928; Schumacker & Malone, 2017), but there are few examinations of how teachers' interpretations of them. We selected four well-documented common errors in fraction arithmetic and assigned each randomly to 95 PSTs enrolled in their first mathematics content for a teaching course. This paper reports on a preliminary analysis of one of these common errors completed by 24 PSTs: using proportional addition instead of multiplication to convert fractions for addition/subtraction. When children demonstrate this error, they add the same number to the numerator and denominator (proportional addition) in an attempt to reach a common denominator between fractions (see center example in Figure 1). PSTs were provided two illustrative examples of the common error and then completed a 10-item with the option to use a calculator.

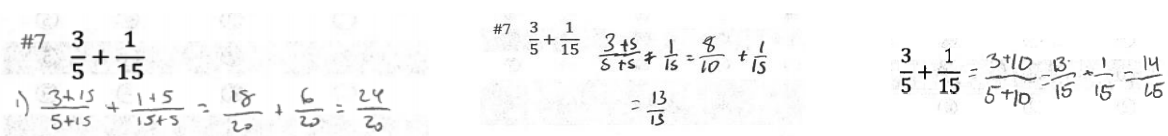

Figure 1: Some PSTs' Efforts in Replicating the Common Error

Independently, the authors coded for the use of addition or multiplication and whether it was implemented proportionally (K=.50) before reconciling codes (see Table 1). PSTs replicated proportional addition about half the time (50.43%), while the 'correct' approach with proportional multiplication was used at 9.57%. PSTs used both addition and multiplication in other ways that deviated from the common error. These attempted replications suggest that PSTs may have wrestled with how a child demonstrating the common error uses addition and does so proportionally (for numerator & denominator). Although PSTs successfully replicated the error half the time, they tended to be quite inconsistent in doing so. Relatively few PSTs actually replicated the common error correctly across all 10 tasks. These PSTs were observed to be able to solve fraction addition/subtraction tasks without difficulty. Thus, results suggest SCK is not a given even if PSTs have the requisite content knowledge. SCK tasks such as this may provide a useful means for assessing and facilitating PSTs' professional knowledge for teaching fractions.

Table 1: Descriptive Statistics for PSTs' Attempts to Replicate the Common Error

Unproportional		Proportional			Mixed
Add for CD	Mult for CD	Add for non-CD	Add for CD	Mult for CD	
10.00%	2.61%	9.13%	50.43%	9.57%	3.91%

Note: CD stands for Common Denominator. Addition & Multiplication are also abbreviated.

“MICHELLE COMES OUT OF LEFT FIELD”: CLINICAL SIMULATIONS AND PROSPECTIVE TEACHERS’ KNOWLEDGE OF STUDENT THINKING

Duane Graysay

scavines@syr.edu

To support prospective teachers (PTs) in developing knowledge of varied ways that students generalize from sequences of figures, we designed three theory-driven sets of protocols and training materials for orchestrating cycles of live, clinical simulations of student thinking about linear and quadratic generalizing tasks. We designed the cycles according to principles derived from Variation Theory (Marton, 2014): create opportunities for PTs to experience contrasting approaches within each cycle, and opportunities to construct general understandings of each approach by repeated experience across cycles. We present several case studies documenting how PTs’ knowledge, as represented by the approaches they anticipated prior to each set of simulations, evolved across simulation cycles in way that were consistent with the predictions of Variation Theory.

The Problem: Preservice Teachers’ Knowledge Base for Enacting Core Practices

The National Council of Teachers of Mathematics (2014) recommends eight teaching practices as core to effective mathematics teaching. Among those are the practices of implementing tasks that promote reasoning and problem solving, posing purposeful questions, supporting productive struggle, and eliciting and using evidence of student thinking. According to the Association of Mathematics Teacher Educators (2017), the capacity to enact those practices is an essential component of being a well-prepared novice teacher.

However, the capacity to enact such practices requires Mathematical Knowledge for Teaching (Hill et al., 2004), including knowledge about how students might approach a particular type of mathematical task and errors or misconceptions that might crop up as students engage in problem solving. According to the tenets of Situated Cognition (Brown et al., 1989), the knowledge that a teacher invokes when supporting students’ productive struggle during problem solving is the knowledge that the teacher has developed from prior experience in similar kinds of situations. The problem is that traditional models of teacher education relegate the experiential component of teacher learning to field placements. Grossman et al. (2009) suggested that separating clinical experience from coursework is problematic and called for teacher educators to make concerted efforts to create better links between the experiences of prospective teachers in field placement and the knowledge gained in their education courses. However, field placements are unreliable as sites in which prospective teachers can implement task that promote reasoning or problem solving – there are multiple types of influences that act to discourage teachers from creating space for reasoning or problem solving in their classrooms (Serrano Corkin et al., 2019). Therefore, in addition to creating stronger connections between field placements and experiential learning opportunities, there is a need for teacher educators to supplement field placements by orchestrating experiences for PTs through which they have opportunities to develop the kinds of knowledge needed to enact the core practices identified by NCTM and others.

We have developed an intervention, theoretically grounded by Situated Cognition (Brown et al., 1989) and Variation Theory (Marton, 2014), for engaging PTs in clinical simulations that we designed to support the development of their Knowledge of Content and Students (KCS) (Ball et al., 2008) for anticipating multiple ways that students might engage in figural generalizing tasks. In this report, we extend from our previous brief report of a single case study (Graysay & Bermudez, 2023) to multiple case studies examining the following research question:

What do PTs learn, by participating in theoretically grounded clinical simulations of student-teacher conversations about student work, about students' approaches to generalizing from figural data?

Theoretical Framing and Simulation Design

Our designs are grounded in a theory of preservice teacher learning that intersects Situated Cognition with Variation Theory. From the perspective of Situated Cognition, to develop knowledge of content and students that will be used in teaching PTs need experiences of engaging in interactions with students in situations similar to those of the interactive work of teaching. From that guiding principle we modeled our intervention after the clinical simulations of Dotger and colleagues (e.g., Dotger, 2010) in which participants converse in a live, interactive setting with an actor trained to present specific statements or actions so that the conversation simulates a particular problem of practice. Because our goal is to support the development of KCS for supporting student reasoning, we chose to simulate students' approaches to generalizing from figural data for two reasons. First, generalizing is an essential mathematical process (Mason, 1996). Second, within the body of research on generalizing, Rivera and Rossi Becker (2008) analyzed students' approaches to generalizing from figural data and described three qualitatively distinct approaches. *Numerical* approaches are those in which the learner, after quantifying an aspect of each figure, proceeds to work with the numerical values without revisiting, drawing, or envisioning additional figures, and without attending to the structure of the figures. In *constructive figural* approaches the learner attends to the structure of each figure as constituted by disjoint components. In *deconstructive figural* approaches the learner attends to the structure of each figure as composed of intersecting components or as the result of the removal of elements from an imagined figure. The latter approach poses a particular challenge for teachers: El Mouhayar and Jurdak (2013) found that preservice and inservice middle grades teachers have difficulty explaining the reasoning behind deconstructive figural approaches.

According to Variation Theory (Marton, 2014) learning requires an experience of contrast, across examples, of the defining features of an intended object of learning while aspects of the examples that are unrelated to the defining features should be held constant. Once the learner has experienced contrast, they should then experience variation in non-defining aspects of examples with the defining features of the intended object held constant, to support generalizing across examples toward a context-independent concept. Based on Variation Theory we designed protocols to train actors with statements and gestures to simulate the three contrasting student approaches documented by Rivera and Rossi Becker (see Table 1) in three cycles, each focused on a distinct task (see Figure 1), leading to nine protocols in total (see Figure 2).

Table 1: Dimension of Approach

Numerical Approach (Nell)	Constructive figural (Suzy)	Deconstructive figural (Michelle)
General Approach: Makes a table of values and looks for patterns in numerical values *Example:* In the Tiling Task (see Figure 1), Nell counts the number of tiles in each Pattern, records the values in a table, notes a pattern of increase in numerals in the table, and extends the table iteratively to find totals for Pattern 4, Pattern 5, and Pattern 20.	*General Approach* Perceives patterns as constructed from disjoint components *Example:* In the Tables and Chairs Task (see Figure 1), Suzy perceives each Pattern as two rows of chairs across the top and bottom of the set of Tables, with one chair at each end of the row of Tables.	*General Approach*: Deconstructs patterns into intersecting components Example: In the Theater Seats Task (see Figure 1), Michelle perceives the figure as a large rectangular array of seats with two triangular arrays removed from each side.

Data Collection and Analysis

We recruited seven prospective secondary mathematics teachers (PTs) for this research and assigned pseudonyms. Blake, Denise, and Taylor were each in the seventh semester of their undergraduate teacher education program. Ezra, Kristy, Max, and Sam were graduate students in a parallel teacher education program. All seven were enrolled in a joint math methods course that met once weekly over fourteen weeks. We implemented our simulations within three cycles of activity. The first cycle (the Tiling cycle) began with a *case analysis* phase in which participants analyzed a narrative case of a teacher working with students on a figural generalizing task similar to -- but distinct from -- the Tiling task. In the *anticipating* phase PTs solved the Tiling task and anticipated how students might solve the task. In the *simulation* phase PTs each engaged in three interactive clinical simulations. In each simulation a single PT met one-on-one with an actor who was each trained to simulate exactly one of the three designated approaches to solving the Tiling task. The cycle ended with a *reflection* phase in which PTs reflected on the simulation experience, focusing on contrasting the simulated student approaches. We then iterated those phases for the Chairs cycle and the Seats cycle.

We hypothesized, per Variation Theory, that PTs would notice differences in student approaches within each set of simulations and begin to develop more general, abstract understandings of each approach across sets of simulations. To test our hypothesis we reviewed transcripts of PTs' statements during the anticipating and reflecting phases of our cycles. We posited that PTs' knowledge of the range of student approaches to generalizing from figural data is evidenced by how each PT approaches generalizing and by the approaches that they anticipate others might use. Therefore, we classified each PT's approach to solving each task and the approaches that PTs anticipated they would encounter in the simulation phase of each cycle, using the categories from Rivera and Rossi Becker (2008). We noted when and how PTs referenced Nell, Suzy, or Michelle when describing an anticipated approach. We compared across cycles to examine whether and how their anticipations of student approaches and their associations of those approaches to specific simulated students evolved across their experiences.

Findings

Graysay and Bermudez (2023) reported tentative findings suggesting that Kristy's understanding of students' approaches evolved from anticipating constructive figural and numerical approaches; to anticipating that the Tables and Chairs simulations would involve three approaches (numerical, constructive figural, and a third unspecified approach); to explicitly anticipating each approach for the Theater Seats simulations based on the names of the simulated students. Though Kristy recognized that Michelle's approach would be different from the other two, Kristy explicitly expressed difficulty anticipating what Michelle's approach would be. In this report we present additional cases to suggest that other PTs in the cohort demonstrated a similar trajectory, including difficulties anticipating Michelle's approach.

The Case of Max

In the anticipating phase of the Tiling Cycle, Max worked with Ezra to share their individual solutions to the Tiling task. Ezra described a numerical approach, and Max described a constructive figural approach:

> Ezra: For pattern four, I did five plus four times four minus one, which got me 17. Pattern five, five plus four times five minus 1. Got 21.
>
> Max: That's an interesting way of looking at it, because I just was looking at like, "Okay, so there's four branches, and then the one in the middle."

In the anticipating phase of the Tables and Chairs cycle, Max asked whether the characters would shift approaches or take similar approaches in the second set of simulations compared to the first set. We take this as evidence that Max had experienced the intended contrast across the three simulations in the Tiling cycle:

Max: And we should expect them to be like similar like, like, we should expect Suzy to work out the problem in a similar way . . . in, like, a Suzy way? . . . She's not going to all of a sudden do it the Nell way, right?
DG: She's not going to do it in a way that anybody other than Suzy would. The Suzy character has a way of doing things. . . . There is a consistent through line.

Max and Kristy anticipated two ways of solving the Tables and Chairs task. Max and Kristy described a constructive figural approach (adding front, back, and then adding sides), though Max had used a more numerical method:

Kristy: What are all the ways this task can be solved? I would say I would say call our method the -- Call this method, I would call it the --
Max: Maybe adding front back and then adding sides.
Kristy: Yeah. Adding front, back and sides. Only looking at the numbers. Looking at the ends as three and the middle as groups of two. And how did you think of it, like?
Max: I looked at— I just was looking at the number of tables.
Kristy: You were just looking at the number.
Max: I just counted first. I guess that's a way -- counting.
Kristy: Yeah. Honestly. Which of these methods students would use? I could see them using any of these methods. Honestly, I think none of them are that weird. I do think that counting and the front back ends are going to be the most common.

In anticipating the Theater Seats simulations, Max identified Michelle's approach from the preceding cycles as the most challenging. Max had listened in on a conversation between Ezra and Sam about which character they found most difficult that began with a comment from Ezra:

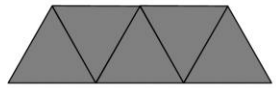
Ezra: I'm going to be honest, every single time, like, I'll think about what I can expect. And . . . it usually is Michelle, where I have the most difficulties. And that's the one where I always have to slow down and like try doing a problem with them at the same time.

This initiated a discussion between Ezra and Sam about which character was most difficult (see the subsequent case of Sam). The first author invited Max, who was listening in, to comment:

DG: [Max], I know that you were listening, and it looked like you were agreeing with part of [the conversation].
Max: I, well, I was agreeing mostly [that] Michelle, Michelle usually comes out of left field for me.

Though Max did not give evidence of anticipating Michelle's way of approaching the Theater Seats task for the third set of simulations, we identified evidence that Max and Sam were able to clearly describe a deconstructive figural approach that they assigned to Michelle in response to a final, post-simulation activity. We provided PTs with the Polygon Problem (see Figure 2) and asked them to respond in pairs or triads, in writing, to the question, "How would each simulated student approach this task?".

Figure 2. The Polygon Problem (Seago et al., 2004)



In response, Sam and Max wrote:

> Nell – make a table comparing number of triangles to perimeter. Notice the difference is always 2. Perimeter = number of triangles + 2
> Suzy – Notice that adding one triangle adds two sides. Perimeter = n + 2
> Michelle – use that each triangle has three sides and subtract inner sides. Perimeter = 3n – 2(n-1).

We note that Max, in collaboration with peers, gradually developed understandings of how each of Nell, Suzy, and Michelle would approach figural generalizing tasks. After experiencing the three sets of simulations, Max and Sam anticipated and described numerical, constructive figural, and deconstructive figural approaches similar to those that they had experienced in their simulations with each character.

The Case of Sam

Sam worked with Taylor and Blake to compare approaches to the Tiling Task. The three PTs agreed on a constructive figural approach:

> Taylor: So I went by the, you know, there's going to be one in the middle each time. And then for pattern one, there was one on each of four sides. In Pattern Two, there are two on each of four sides . . . one plus four [times] *n* being the generalization.
> Blake: Me too, but I did it, I guess a little -- no, I guess I did it in the same way, nevermind.
> Sam: I did the exact same way, 1+4n.

Sam worked with Ezra to anticipate student approaches to the Tables and Chairs task. The pair of PTs gave evidence that they anticipated numerical and constructive figural approaches:

> Sam: Alright what's another way? Can we think of another way.? Let's think of students like just counting, so I bet your way of just focusing on chairs is going to be something that they do.
> Ezra: [Yes] . . . I can't figure it out! I thought I had it . . . and then you're right, it's asking for the tables and each pattern itself is on a table. It's four tables straight to four tables and that increases by one.
> Ezra: I wonder if there's a way we can do it where there's gonna be subtraction. Cause last time they threw me. . . . and there's gonna be three of them. So that means three different ways.
> Sam: Yeah, I don't know what else you're gonna get other than . . . two n plus two.
> Ezra: 2n + 2. And then I doubt they're gonna recognize the n plus three, where n is the number of tables, is two n plus three.
> Sam: Yeah, I feel like I'm just coming up with more complicated ways rather than more logical ways.

Sam and Ezra did not appear to associate each approach any specific simulated student. Though they understood that three different approaches would be simulated in the second round of simulations, they did not anticipate a deconstructive figural approach.

Anticipating the Theater Seats simulations, Sam indicated that they found the constructive figural approach the more difficult to follow. In response to Ezra's statement that Michelle is the most difficult, Sam responded with a different perspective:

Sam: Suzy's always the hardest.
Ezra: Really? You think Suzy is the hardest?
Sam: Because she does everything in her head.
Ezra: True.
Sam: I literally tell Suzy like, write that down. Write that down. . . Sometimes it's more like me figuring out what Suzy is doing, because I'm trying to understand and Suzy's like, "well, this" and I'm like, "okay, like, I guess?"

As we noted in the case of Max, Sam and Max collaborated to anticipate how each simulated student would respond to the Polygon Task. As a team, Sam and Max gave evidence that they were able to describe how each character would respond to that task with a numerical approach (Nell), constructive figural approach (Suzy), or deconstructive figural approach (Michelle).

The Case of Ezra

We have shared data related to Ezra's anticipations of student thinking in the preceding cases. We note that in anticipating the Tiling Task, Ezra and Max expected two different constructive figural approaches. In anticipating approaches to the Tables and Chairs task, Ezra anticipated that the simulations would present three distinct approaches, but did not express what each of those approaches would be. Finally, in anticipating the Theater Seats simulations, Ezra noted that Michelle's approach was the most difficult for them to understand.

The Case of Taylor

Taylor and Blake collaborated in the anticipating phase of the Tiling cycle. Taylor initially perceived the Tiling task constructively as one middle tile in each pattern, with a set of four tiles appended to each end of the "sides" of the pattern. Each subsequent pattern would have another set of four tiles appended to each end:

Taylor: There's going to be one in the middle each time. And then for pattern one, there was one on each of four sides. In Pattern Two, there are two on each of four sides . . . . One plus four [times] *n* being the generalization.

After Blake responded with their approach to the task, Taylor acknowledged the existence of multiple approaches:

Blake: I guess I thought about it a little bit differently. Or probably the same, as I was like, "Yeah, of course, one in the center, and then you add a tile to each side of the squares." . . . .
Taylor: There are multiple ways of looking at it. . . . When you're looking at it individually, you're like, "This is the only one." But . . . I'm sure there's a different one that we're all missing, or something.

Moments later, Taylor anticipated the possibility of a numerical approach:

Taylor: I could see more like the plus four each time thing, like the numerical one.

After the Tiling simulations, Taylor, Blake, and Denise worked together in the anticipating phase of the Tables and Chairs cycle. Taylor approached the Tables and Chairs task using a constructive figural approach, describing the pattern as “six plus two three [times for Pattern 2], four times [for Pattern 3]”. However, Taylor generalized using the pattern number. They then said, “I could also say it's the number of tables minus two that stick out front here.” Taylor then showed evidence that they attributed tabular approaches to Suzy’s or Nell’s characters:

> Taylor: I could also generalize this by saying it's the number of tables minus the two on the ends, times two. And then I get the [unclear]. I also said, you know, you're predicting [Suzy] or Nell will come at it with the table again. Try to just go with it.

We cannot state with confidence whether Taylor’s mention of Suzy, then Nell represents a self-correction regarding the character name or an uncertainty about which character might simulate a numerical approach. However, Taylor provided evidence that they discerned a difference in Michelle’s approach -- specifically that Michelle’s approach was hard to anticipate:

> Taylor: With errors or misconceptions, we have, like, [using] pattern number instead of table number. Is there another misconception? Because [Michelle] came at us with a whole new way of looking at the problem.

At this stage, Taylor approached both tasks using a constructive figural approach. Taylor attributed the use of tabular representation of mathematical insights to Nell or Suzy, without any further distinctions about how each simulated students might approach the task.

The Case of Blake

We have shared some of Blake’s contributions in each cycle in Taylor’s case. We note that in anticipating the Tiling Task, Blake anticipates two different approaches: numerical and constructive figural approaches. Blake also asserted that most students will approach the task numerically when she said: “I feel like most of them actually count though. Once we have that, because that's what I have most experienced seeing students do.” In anticipating approaches to the Tables and Chairs task, it was not clear whether Blake’s approach aligned with a constructive figural approach, though they claimed to have used a similar approach to Taylor’s. Blake also anticipated that Michelle would approach the task in a ”visual” way. Finally, in anticipating the Theater Seats simulations, Blake approached the task with a constructive figural approach and did not verbalize any clear distinctions between all three approaches.

Interpretation and Implications

Variation Theory predicts that the experience of contrast across our simulated approaches will support learners in the first stage of recognizing critical differences among approaches, and that experiencing consistency in approaches across multiple simulations will support PTs in developing general, context-independent understandings of multiple potential student approaches to figural generalizing. Our tentative findings in the case of Kristy (Graysay & Bermudez, 2023) were consistent with that prediction. The additional cases presented in this report provide empirical support for hypothesizing that each case may represent a generalized learning progression related to the experience of variation within and across each set of simulations. However, PTs found a deconstructive figural approach difficult to anticipate until after completing the third set of three simulations. Those difficulties corroborate El Mouhayar and Jurdak's (2013) findings and suggest that PTs need additional experiences to fully conceptualize the deconstructive figural approach.

We propose two directions for future research. First, there is a need for further research to explore conditions under which our findings are generalizable to other PTs, other institutions, and other mathematical topics. Second, the goal of this design is to impact teachers' practices by supporting their knowledge of different student approaches to generalizing. Our data and analysis do not offer insight into whether or how PTs' experience impacted their ways of engaging with authentic students. There is a need for further research to examine whether and how experiencing systematic variation across simulations impacts the ways that PTs interact with authentic students during authentic generalizing.

RESPONDING TO MATHEMATICAL EMPATHY

Suzanne R. Harper

In this ongoing study, we continue to look for opportunities to document mathematical empathy in the discourse of Preservice Elementary Mathematics Teachers. Using a framework for mathematical empathy, we asked: How is empathetic comprehension visible in discourse about mathematical definitions? and How do PSETs respond to public displays of mathematical empathy? Preliminary results indicate that empathetic practice is robust, but difficult to inspire in others. We position mathematical empathy at the intersection of teacher beliefs and mathematical knowledge for teaching with implications for teacher preparation programs.

Keywords: Preservice Teacher Education, Affect, Emotion, Beliefs, and Attitudes

Background

Although definitions serve as foundational elements in mathematics, there exists a scarcity of agreed-upon practices regarding their construction (Torkildsen et al., 2023). Understanding that multiple definitions may exist for the same mathematical concept poses challenges for preservice teachers (Linchevski et al., 1992). When we view of mathematics as a humanistic discipline where mathematics is socially constructed and personal values influence our evaluation of results, it is important for instruction to be participatory. Definitions, in this light, transcend mere mathematical tools; they become teaching instruments facilitating the conveyance of perceived meaning to others. Recognizing meaning as a negotiated construct grants authority to the knower, even as external sources are critically evaluated (Langer-Osuna, 2017).

Teachers acknowledge that the selection of definitions in mathematics classrooms hinges upon pedagogical context (Winicki-Landman & Leikin, 2000). These authors also posit that factors such as curricular approaches, classroom demographics, or the pursuit of clarity and elegance may influence this choice. In order to cultivate a classroom environment conducive to making informed contextual decisions, teachers must be aware of and able to comprehend the perspectives and mathematical thinking of their students; teachers need to see the work of teaching as an empathetic practice. This perspective serves as the focal point of our discussion.

Mathematical Empathy

In a recent study (Cox et al., 2021), we employed a definition of mathematical empathy as "the ability to comprehend another person's ideas and the true meaning or purpose behind them, seeking to utilize the other person’s frame of reference” (Araki, 2015, p. 122). Upon reflection, we question the use of “true meaning” in this definition. We would like to make the learner’s identity and intention more explicit in the interaction, retaining their expertise as primary. Rather than centering the expertise of the listener or the transference of expertise or knowledge, we focus instead on the willingness of the listener to be transparent and cede mathematical expertise to the learner. This is akin to how showing empathy does not grant us the right to claim the emotional experiences and perspectives of those we seek to understand. Therefore, we now define mathematical empathy as *the willingness to cede mathematical expertise to others and see them as someone from whom to learn*.

Teachers engaging in empathetic practice require both an awareness and acceptance that multiple mathematical truths coexist, alongside possessing the pedagogical content knowledge necessary to comprehend these truths. This paper aims to provide a succinct overview of a study exploring the capacity for mathematical empathy among preservice elementary mathematics teachers (PSETs). Through initial analysis, we identified two key empathetic practices: *empathetic awareness* and *empathetic comprehension* (Cox et al., 2021, 2024). *Empathetic awareness* indicates that the speaker believes that there is multiplicity in mathematical perspectives. Awareness can emerge as a belief that others see things differently than we do, or that students will have different mathematical backgrounds or experiences that are worthy of attention. *Empathetic comprehension* indicates the speaker can comprehend from someone else's mathematical perspective.

While instances of empathetic awareness were abundant in the data, observations of empathetic comprehension were comparatively rare. This prompted us to consider whether an expanded dataset could afford more opportunities to investigate this practice. We also pondered how participants might respond to their peers' public demonstrations of empathy. This led us to the following research questions: (1) How is empathetic comprehension visible in discourse about mathematical definitions? and (2) How do PSETs respond to public displays of mathematical empathy?

Methodology

To answer these questions, we expanded our initial data set. We included initial reflections where PSETs were asked to reflect on an instructional sequence and their responses to their classmates' writing.

Instructional Sequence: Defining in a Collaborative Space

Seventy-one participants were recruited from two sections of a geometry course for PSETs (grades PK-3). PSETs explored dynamic quadrilaterals constructed with interactive geometry software (IGS) in a face-to-face environment. The PSETs actively participated in tasks aimed at measuring, describing, and comparing quadrilaterals to support the task of formulating definitions. Initially, the PSETs collaborated in small groups during the class session, then reconvened as a whole class to collectively create definitions for quadrilaterals, kites, parallelograms, rectangles, rhombuses, squares, and trapezoids.

We wanted to capture the firsthand experiences of PSETs creating geometric definitions, while also exploring how this experience might shape their perceptions of the definition's role in a primary education classroom. In order to help PSETs frame their comments as both learners of mathematics and future teachers of mathematics, we first asked them to individually read Keiser's (2000) *The Role of Definition*. The article was chosen as a catalyst for reflection on this experience because it suggested that early presentation of formal definitions can curtail thinking in middle grades classrooms and argued for student-generated, fluid definitions based on concept imagery (Tall & Vinner, 1981) relevant to classroom learning.

Data Collection

Following the in-class IGS activity, the defining discussion and the assigned reading, we asked our PSETs to respond to the following prompt in an online discussion board: "After reading the article, *The Role of Definition*, what new thoughts do you have about the conversations we had in class about defining quadrilaterals? How about using definitions with children?" PSETs understood that both their peers and instructor would review their reflections, with the instructor actively engaged in the discussion. The assignment carried a grade based solely on completion. PSETs were unable to view their classmates' reflections until after submitting their own. Upon completing their reflections, PSETs gained access to classmates' submissions and were encouraged to engage in an online discussion regarding the shared reflections. The data comes from the initial posted reflections (n=71) and responses (n=145).

Framework: Practicing Mathematical Empathy

The initial posted reflections (n=71) were analyzed using grounded theory (Vollstedt & Rezat, 2019) to build and then apply a framework by which to give nuance to what we learned about PSETs' beliefs about the purpose, nature, and origin of mathematical definitions. As we read, we began identifying instances where PSETs expressed something similar to empathy in a mathematical context and coded these practices empathetic awareness and empathetic comprehension (Cox et al., 2021, 2024).

Results

There were twenty-four initial reflections that were coded for evidence of either empathetic awareness (EA) (n=22) or empathetic comprehension (EC) (n=3). One of these initial reflections was coded for both EA and EC, so the total number of initial reflections showing empathy was 24. We gathered all of the responses (n=25) that these initial reflections garnered from classmates and applied the framework (see Table 1).

Table 1: Analysis of Responses to Initial Reflections coded for Empathetic Reflection

Responding to expressions of:	Total Responses (n=25)	Responses showing EA (freq.)	Responses showing EC (freq.)
Empathetic Comprehension	2	0 (0%)	0 (0%)
Empathetic Awareness	23	8 (34.8%)	0 (0%)

Of the 25 responses, few showed evidence of empathetic practice and these were exclusively empathetic awareness. There was no evidence of empathetic comprehension in the responses. Further, initial reflections that showed empathetic comprehension only inspired two responses, and neither showed evidence of empathetic practice at all.

Eight responses, or roughly one-third, showed evidence of empathetic awareness. This is approximately the same frequency of empathy as in the set of initial reflections (24/71 = 31.0%). Consider the following exchange sparked by Lily's public display of empathetic awareness. Note that Natashia showed an empathetic stance in her initial reflection, but this was new for Beckett.

Lily: I enjoyed doing this in class because it gave a broader perspective of how this could be set up in a classroom setting. It is also important to hear what student's peer's ideas are about a definition to think about them in a different way and gain a broader understanding.

Beckett: I agree with what you are saying, especially the last sentence. I concur that it is important understand your peers perspective

Natashia: I agree with that as well. Allowing children to come up with their own definition makes way for their peers to learn how others think as well. For example, at the beginning of the semester when we had to draw the [quick draws] from memory, I found it helpful when our peers discussed how they memorized the [quick draws] versus how I may have. I really enjoyed that activity.

Natashia's response also referenced a Quick Draw activity from the first days of class. The learning objective from this assignment was to "see mathematics through someone else's' eyes." That this activity is referenced in a response where Natashia is honoring her peers' perspectives is an important piece of context.

Inspired by Beckett, we went back to compare the empathetic stances taken by responders on their initial reflection. We found that authors who showed empathy in their responses were three times more likely than not to have also shown empathy on their initial reflection, and those who did not show empathy in their responses were three times more likely not to have shown it in their initial reflection (see Table 2).

Table 2: Empathy across Initial Reflection and Responses

	Initial Reflection	
	Empathetic	Non-Empathetic
Empathetic Response	6	2
Non-Empathetic Response	4	13

Implications and Conclusion

In this follow-up study, we asked how is empathetic comprehension visible in discourse about mathematical definitions. While analysis is ongoing, we have not found any additional instances of empathetic comprehension.

We also asked how PSETs respond to public displays of mathematical empathy. Summarized in Table 2, we are able to say that PSETs do not necessarily adopt an empathetic stance in response to a public display of empathy. Overall, 32% of all responses to empathetic displays showed evidence of empathy themselves. This mirrors the frequency of empathy in the initial reflections. Even though empathy does not seem to inspire more empathy, we do believe that an empathetic stance is robust; PSETs who demonstrated an empathetic stance in their initial reflection maintained that stance when responding to the thoughts of others.

The findings of this study, preliminary though they may be, are important. We are interested in identifying pivotal experiences for PSETs that position them as authors and mathematical authorities and believe that there are many ways to go about that work. As we reflect (as instructors) on the episodes from which our data came, we posit that there is a hurdle to overcome before teachers are able to adopt empathetic stances and thus, teaching practices. A teacher (or PSET) who believes in the sanctity and external completeness of school mathematics, ("someone already knows this, I'm just learning it") may struggle to cede mathematical expertise to children, even as they cheer achievements and mark progress toward learning outcomes.

This study indicates that we can overcome that hurdle with careful attention to creating mathematical opportunities for teachers to claim personal expertise. We support opportunities for PSETs to encounter or experience episodes of teaching that position teachers as learning alongside students. This might include open-ended problem solving with multi-age groups. It might also include exposure to situations where children know more than the adults in the room. The research on math circles might be leveraged to further imagine how we come to learn how to learn from others. We see great potential in using these types of experiences within teacher preparation programs to document and support emergent empathetic practices.

TYPES OF CONNECTIONS BETWEEN ELEMENTARY MATHEMATICS AND LITERACY TEACHING AND LEARNING: A CONCEPTUAL FRAMEWORK

Lisa A Hawley
Grand Valley State University
hawleyL@gvsu.edu

Keywords: teacher knowledge; elementary school education; preservice teacher education

In elementary teacher education, there has been increasing interest in making connections across disciplines (e.g., Muhammad et al., 2021; Prough et al, 2022); however, there does not seem to be clarity on what we mean by connections. This poster will share a conceptual framework of types of connections.

The Case Study: Developing the Framework

This framework was developed as part of a case study of the connections between mathematics and literacy by elementary teacher candidates (TCs) who were taking concurrent mathematics methods and literacy methods courses as a cohort. Of the 18 TCs in the cohort, 13 participated in the case study, which included observations and video recordings of class meetings, collection of coursework, and one-hour focus group interviews with 6 of the participating TCs.

The framework was developed by working iteratively with the data from the case study and the scholarly literature. After initial open coding of the data and the literature, I used the most significant or most frequent codes to construct larger categories that synthesized the themes in the data and literature, using the constant comparison method (Charmaz 2014).

The Framework: Types of Connections

I identified three main types of connections made by the TCs in the case study and by scholars in the literature: (a) curriculum integration, (b) language as a basis for learning mathematics, and (c) similarities in teaching and learning literacy and mathematics.

Curriculum integration includes any learning models or lesson structures that draw on the unique ways of knowing from more than one discipline. Interdisciplinary learning, thematic teaching, and project-based learning are examples of this type of connection (e.g., Parker et al, 2012; Zhou & Kim, 2010).

Language as a basis for learning mathematics includes engaging with mathematical texts (e.g., Beaudine, 2022), using mathematical language to communicate ideas (e.g., Armstrong et al., 2018), using writing to make sense of mathematical ideas (e.g., Caputo, 2015), and mathematizing read-alouds of children's books (e.g., Hintz & Smith, 2022).

Similarities in teaching and learning can include learning goals (e.g., constructing arguments with evidence; Cheuk 2012), thinking skills (e.g., monitoring for sense; Halladay & Neumann, 2012), or instructional practices used in both disciplines (e.g., rough-draft thinking; Jansen, 2020).

Understanding the types of connections that can be made between literacy and mathematics can help elementary teachers, and teacher-educators with elementary backgrounds, to leverage the unique strength of multidisciplinary knowledge to teach mathematics in engaging and conceptually-oriented ways.

SimulaTE is studying teaching simulations as formative assessments of pre-service teachers' (PST) practice of eliciting and interpreting students' mathematical thinking. Preparation and protocols that promote reliability and validity of the simulations as formative assessments will enhance their effectiveness and generalizability. Teacher educators who use the simulations document each PST's performance to generate feedback for the PST in nine categories, arising from a decomposition of the teaching practice into specific component skills or actions. A series of coordinated validation studies include research to determine if the nine categories are distinguishable through the use of the simulation assessments, and can benefit from attention beyond other experiences PSTs have in their teacher preparation programs.

Keywords: Assessment, Mathematical Knowledge for Teaching, Preservice Teacher Education, Teacher Educators

Framing and Purpose of the Study

Ideally, teacher preparation develops candidate's skills and abilities for ambitious instruction that promotes student learning and counters inequities in outcomes. We ground our work in the understanding that frequent opportunities to engage in core practices of teaching, with formative feedback, can develop the knowledge, skills, and dispositions necessary for nurturing young learners of mathematics. Formative assessment provides pre-service teachers (PSTs) with feedback to improve their practice (Grossman, 2010), which is considered crucial for teacher preparation (Darling-Hammond et al., 2005; AMTE, 2017). It requires teacher educators to see teaching practices in action, yet traditional field settings afford neither frequent accessibility nor opportunities for deliberate work on specified facets of teaching. Simulations of mathematics teaching practices are an approximation that can provide early, frequent, and substantive formative assessment opportunities while engaging PSTs in particular facets of teaching.

PSTs begin preparation with views on teaching that need to be surfaced and, in some cases, challenged (Boerst et al., 2020; Shaughnessy & Boerst, 2018; Shaughnessy et al., 2020). Work initiated at the University of Michigan has produced multiple simulations to engage and refine PSTs' practice of eliciting and interpreting students' mathematical thinking. By revealing PSTs' knowledge, skills, and dispositions and providing immediate feedback, the simulations are designed to facilitate growth (Shute, 2008; Hattie & Timperley, 2007). This study's dual purposes are to investigate the decomposition of the teaching practice into measurable components for providing feedback, and to consider whether these skills or actions can benefit from concerted attention beyond other experiences typical to teacher preparation programs.

This study is one of a series of studies generating evidence regarding validity arguments (AERA et al., 2014; Kane, 2001; 2013) for using the simulations as formative assessments. It focuses on two sources of validity evidence (AERA et al.): internal structure (specifically test component interrelationships) and relations to other variables. Initial evidence for two specific claims of the validity argument are addressed here: (1) the nine component skills/actions of the teaching practice can be measured distinctly through simulation performances so that feedback can be specifically targeted, and (2) PSTs' other experiences in teacher preparation do not fully develop the component skills/actions of the teaching practice.

Teaching Simulations as Formative Assessments

Using the teaching simulations as formative assessments involves three interacting roles:

- The PST prepares for, engages in, and debriefs what they learn via the teaching practice of eliciting and interpreting student thinking with a Simulated Student.
- The Simulated Student is an adult prepared to follow a provided profile and to respond in specific ways to anticipated questions and prompts. (Student role)
- The Teacher Educator (TE) documents the PST's performance and provides formative feedback based on the performance. (Proctor role)

Figure 1 illustrates the full formative assessment process. The underlined components in the figure indicate the parts of the process investigated in this part of the validity studies.

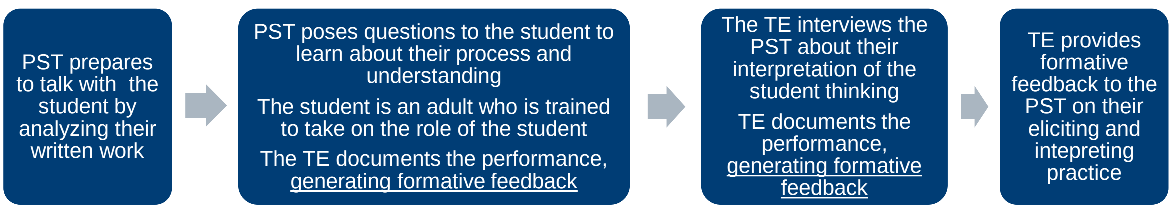

Figure 1: Structure of Teaching Simulations as Formative Assessments

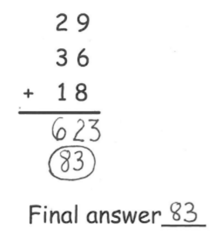
The tasks in the simulations represent core content of elementary mathematics. The student work and specifications of the student role are evidence-based recreations of student thinking about that content (Shaughnessy et al., 2012). Figure 2 illustrates key elements of an assessment.

Mathematics topic: Multi-digit addition



- **The student's process:** The student is using the column addition method for solving multi-digit addition problems, the student is working from left to right.
- **The student's understanding of the ideas involved in the problem/process:** The student has conceptual understanding of the procedure including why combining is necessary (and when and how to combine).
- **Other information about the student's thinking, language, and orientation in this scenario:** The student talks about digits in columns in terms of the place value of the column. The student uses the term "combining" to refer to trading/carrying/regrouping.

Sample PST prompts	Sample Responses
What did you do first?"	"I added the tens: 2 + 3 + 1 and I got 6."
"How did you get from 623 to 83?"	"I had to combine the 6 and the 2."
"Why did you need to combine those numbers?"	"Because they're both tens."

Figure 2: Excerpts from a Sample Teaching Simulation Protocol

The content of the student work in the assessments was purposefully selected to cover mathematics concepts that PSTs are expected to have a strong understanding of and to provide insight into their capabilities. The simulation protocols were designed to reflect non-traditional approaches to solving mathematical problems or student thinking that results in an "incorrect" answer. The four simulation assessments used in this study included:

- Column Addition (CA): As shown in Figure 2
- Common Denominator: Comparing fractions, with an error in creating an equivalent fraction to compare using common denominators
- Common Numerator Correct: Comparing fractions, creating an equivalent fraction to compare using common numerators
- Expand and Trade: Multi-digit subtraction by writing quantities in expanded form and making trades among values before subtracting by place value, with an error in recording the value of a traded quantity

In teaching, "teachers pose questions or tasks that provoke or allow students to share their thinking about specific academic content in order to evaluate student understanding, guide instructional decisions, and surface ideas that will benefit other students" (TeachingWorks, 2024). The work of eliciting student thinking is conceived as: (a) formulating and posing questions to elicit and probe student thinking; (b) listening to and interpreting how students respond; (c) developing additional questions or tasks to pose; and (d) making sense of what students know and can do. Interpreting students' thinking is integral to eliciting, but is a distinct, overarching practice relying on broader information. It is conceived as: (a) sampling from evidence of student thinking and (b) using insight to articulate inferences grounded in the evidence. These practices take place within and across lessons, and in longer cycles of teaching that depends on learning about students to drive instruction (TeachingWorks, 2024).

Drawing on these conceptualizations, the simulation assessment situation and its documentation are based on a the following decomposition of the teaching practice into nine component skills or actions.

- Eliciting Process (EP): Uses questions or prompts to the student regarding their process for solving the task
- Interpreting Process (IP): Describes the student's process for solving the task
- Probing Understanding (PU): Uses questions or prompts to the student regarding their understanding of the mathematics of their process
- PST-Generated Interpretations of Student Understanding (PGSU): Spontaneous description of the student's understanding of the mathematics of their process
- Prompted Core Interpretations of Student Understanding (PCSU): Prompted description of core elements of the student's understanding of the mathematics of their process
- Attending to Student Thinking (ST): Asking questions about the written work and attending to what the student says in response to questions
- Applying Mathematics Knowledge for Teaching (MKT): Generating a task that can be used to confirm PST's understanding of the student's process
- Using Mathematics Knowledge and Skill (MKS): Applying the student's process to a new example, Generalizing about the mathematics/reasoning of the student's process
- Respecting the Student and Their Thinking (RS): Interacting with the student, and describing their work in ways that respect them as learners/knowers/doers of mathematics

To ensure assessment evidence about these specific components arises, the simulated student will disclose aspects of their process and understanding only when the PST deliberately prompts for it. Similarly, the PST is asked during the debriefing interview to recount very specifically what they learned about the student's process and understanding, supporting their claims with evidence they gathered. To further assess their application of mathematical knowledge for teaching and use of mathematics knowledge and skill regarding the targeted content, the PST is also asked to generate a problem to confirm what they learned about the student's process, and to explain the mathematics ideas undergirding the student's process and understanding. An online tool with protocols specific to each assessment (about 75 items) supports the teacher educator in documenting this fine-grained information. This documentation generates a level of performance (1-4) and formative feedback for each of the nine components. The TE can then use the performance levels and feedback to guide a discussion with the PST about areas of strength and potential improvement. The nine components are:

Study Methods and Participants

Data Collection

Data to address the two claims of the validation argument were collected between April 2023 and March 2024. Assessments were administered to 200 PSTs at 14 higher education institutions. Demographic data on participants are shown in Table 1.

Table 1: Characteristics of the Participants

Characteristic (N)	Percent of Respondents
Educational Attainment (199)	
Undergraduate student	96
Undergraduate degree in education or STEM discipline	4
Student Teaching or Internship (199)	
Had not yet begun student teaching or internship	80
Was currently doing student teaching or internship	20
Sex (199)	
Female	93
Male	5
Non-binary/non-conforming	1
Prefer not to answer	1
Hispanic or Latino (199)	
Yes	13
No	87
Race† (199)	
White	87
Asian or Asian American	4
Black or African American	3
American Indian, Native American, or Alaskan Native	1
Native Hawaiian or Pacific Islander	1
Prefer to self-describe	1
Prefer not to answer	1
Age (184)	
Traditional undergraduate-aged student (born 1998 to 2005)	96
Non-traditional undergraduate-aged student (born 1980 to 1997)	4

† Respondents were allowed to select more than one option; therefore, percent of respondents may add to more than 100.

Seven researchers, including authors 1, 2, and 4, prepared to administer the four assessments by learning the student and proctor roles and documenting performances in sample videos. The research team established reliability in both administration and documentation (Boerst et al., 2023; Heck et al., 2023). Researchers were assigned in multiple pairings to conduct site visits for data collection. A pair administered two assessments to each PST, alternating to distribute who served in the student and proctor roles. Each PST completed two of the four assessments, purposefully assigned to ensure equal distribution of assessments. Column Addition was administered to 90 PSTs, Common Denominator to 106, and Common Numerator Correct and Expand and Trade to 102 each.

Researchers' documentation generated a level of performance (1-4) for each component, along with potential feedback for discussion. Descriptive results for performance level scores on the nine component skills/actions are presented in Table 2. For these studies, feedback was not shared or discussed with participants to ensure it did not influence their performance on the second assessment they completed.

Table 2: Component Performance Level Scores

Skill/Action	Min	Max	Mean	SD
EP	1	4	2.95	1.03
IP	1	4	3.12	0.82
PU	1	4	1.85	0.99
PGSU	1	3	1.88	0.79
PCSU	1	4	2.58	1.12
ST	1	4	3.01	0.22
MKT	1	4	3.49	0.89
MKS	1	4	2.89	1.19
RS	1	4	3.79	0.55

Data Analysis, Results, and Findings

The first claim of the validity argument: the nine component skills/actions of the teaching practice can be measured distinctly, was examined in this study using the levels of performance that the documentation tool generates. A lack of correlation among the nine scores would offer evidence supporting this claim. Table 3 summarizes, for the 36 possible combinations of components, the correlations that were statistically significant. All were positive.

Table 3: Significant Correlations Between Components by Simulation Assessment

Comp.	EP	IP	PU	PGSU	PCSU	ST	MKT	MKS
IP	CA CD							
PU								
PGSU	CD CN	CD CN	CA CN ET					
PCSU	CN	CD CN	CA CN ET	CA CD CN ET				
ST	CA CN							
MKT		CD CN		CA	CA			
MKS	CA CN	CA CD CN ET	CD	CD CN	CA CD CN		CA CD	
RS			CD					

No significant correlations were found for 17 combinations of components on any of the assessments, and 5 other combinations produced a significant correlation on only one assessment.

Significant correlations (ranging from 0.20 to 0.55) were found for at least one combination involving each component. However, the most common significant correlations involved one of four components: IP (5 combinations of components, 12 instances across assessments), PGSU (6 combinations, 14 instances), PCSU (6 combinations, 14 instances), or MKS (6 combinations, 14 instances). In fact, only two other combinations—EP with ST in two instances and PU with RS in one instance—produced significant correlations.

Overall, these results provide mixed evidence regarding the claim that the nine components can be measured distinctly via the assessments. The extent to which these components are related has implications for targeting feedback to inform improvement on each component. Four components appear to be related to multiple others, suggesting that providing feedback on these components may be especially important for developing capabilities with the overall practice. Moreover, feedback on these four components might become especially useful by discussing their relevance to other components or the overall practice.

The second claim of the validity argument: PSTs' other experiences in teacher preparation do not fully develop the component skills/actions, was examined by predicting performance levels for each component using information PSTs reported about their progress in their programs. Specifically, the analysis considered their concurrent enrollment (N=96) or completion (N=98) of a mathematics for teaching (MfT) course, as well as their completion of other mathematics courses that are foundational (e.g., college algebra; N=89) or advanced (e.g., calculus; N=108). It also examined their concurrent or completed engagement in a student teaching placement (N=40).

Table 4 summarizes the results of a set of HLM analyses (scores nested within PSTs) predicting the performance level score for each component using data on PSTs' experiences in their preparation programs. Since PSTs were assigned to different pairs of assessments, dummy codes were also included to control for which assessment produced each performance level score. A lack of predictive association between PSTs' experiences and the performance levels on the simulation assessments offers initial supporting evidence for this claim.

Table 4: Positive and Negative Effects of PST Experiences on Components

Experiences	EP	IP	PU	PGSU	PCSU	ST	MKT	MKS	RS
Foundational Math								Neg.	Neg.
Advanced Math									
No MfT			Neg.		Neg.				
Enrolled in MfT				Neg.			Neg.		
Completed MfT									
Student Teaching							Neg.		

For three of the nine component skills/actions, PSTs' experiences in teacher preparation programs did not predict performance level scores. Variations in performance level scores for five of the other components were each predicted by only one type of experience. The remaining component was predicted by two experiences. PSTs who were neither concurrently enrolled in nor had completed a Mathematics for Teaching course with PU (respectively, -0.86 points, p=.008; -1.04 points, p=.002) and PCSU (respectively, -1.27 points, p<.001; -1.39 points, p<.001) suggests that participation in such courses contributes to development of these components of the practice the simulation assessments address. However, very few students who participated in this study (N=5) fell into this category. It is likely that such courses are an early requirement in most elementary education programs, so when participants were considered eligible for this study, they were already enrolled in an MfT course. Two other components showed predicted differences in performance levels between students concurrently enrolled and those who had completed MfT courses: PGSU (-0.18 points, p=0.048) and MKT (-0.24 points, p=0.013). To the extent that this smaller distinction represents differences in progress through teacher preparation programs, the lack of prediction of performance level scores on most components between these two conditions lends support to the validity claim. Further research involving PSTs who have not yet enrolled in MfT classes would be worthwhile.

PSTs' completion of a Foundational mathematics course predicted lower performance level scores on MKS (-0.45 points, p=.010) and RS (-0.13, p=0.036). Rather than calling the validity claim into question, this negative association may suggest that students whose mathematics coursework in college includes foundational content are likely to need more help in using mathematics knowledge and respecting student thinking in their teaching practice. Further research to pinpoint why some PSTs complete these courses and whether it signals something about their general mathematics knowledge would be informative.

PSTs' concurrent engagement in student teaching predicted a lower performance score on MKT (-0.27 points, p=.025). Again, this negative association does not challenge the validity claim. Rather, it might suggest a need to further support PSTs in making use of mathematics knowledge for teaching when they are student teaching. Additional longitudinal research would be informative to understand if entry into student teaching somehow affects PSTs' ability or propensity to apply MKT in the practice of eliciting and interpreting student thinking.

On the whole, these results provide initial evidence that experiences in teacher preparation are not likely to fully develop PSTs' abilities in the teaching practice of eliciting and interpreting student thinking. By extension, the simulation experience and associated feedback on the component skills/actions appears to offer a unique opportunity to support PSTs in more fully developing their capabilities with this practice.

Conclusions and Next Steps

The mathematics preparation of elementary teachers should develop their capabilities to enact teaching practices that support young learners' growth in mathematical knowledge, fluency, and disposition. Coursework and field placements that traditionally make up the bulk of PSTs' experiences in teacher preparation provide opportunities for PSTs to develop foundational knowledge of mathematics and pedagogy and to learn about and engage in these practices to an extent. They do not offer early, frequent, and structured experiences for PSTs to apply what they are learning in low-risk, high-feedback settings to support improvement in their capabilities. Simulations designed for engagement in teaching practices not only offer early, frequent, and structured experiences, but provide a measure of authenticity of PSTs' performance of the practices and opportunities for teacher educators to give immediate feedback to inform learning and improvement (Boerst et al., 2020; Darling-Hammond et al., 2005; Grossman, 2010).

Teaching simulations are resource intensive to develop and time intensive to use for formative assessment in teacher education. Strong validity must undergird their use to justify these investments. Kane's (2001; 2013) recommendations for developing and testing a validation argument require that the specific claims underlying the processes for administering assessments, generating results, and using results be stated and studied. Validation, in this view, is an ongoing process of amassing evidence to support or refute and, if necessary, refine these claims.

Prior work has demonstrated that preparation and support provided in the assessment materials result in consistent enactment of the simulations (Boerst et al., 2023) and reliable documentation of performances (Heck et al., 2023). In this study, the generated results were examined to test two additional validity claims, that (1) the component skills/actions of the teaching practice can be measured distinctly, and (2) PSTs' other experiences in teacher preparation do not fully develop these skills/actions. Analyses of data collected from PSTs in multiple teacher education programs on four different simulation assessments provided evidence supporting both claims, along with some discrepant evidence to be further studied.

Next steps in this validation work include further study of the first claim through an exploratory factor analysis of the items used to generate the component performance level scores. These data will also support analyses to test two additional claims addressing the response process as a source of validity evidence (AERA et al., 2014), within the full validation argument. First, the distribution of the four assessments across PSTs in various programs and their planned administration by multiple researchers serving in the student and proctor role will support a variance components analysis to examine the claim that the performance levels scores are mainly due to variations in the performance and not due to the effects of the specific assessment or the individuals playing the student and proctor roles. Second, data from this process were gathered from back-to-back performances on simulation assessments without sharing or discussing the generated feedback in between. Other data gathered within the larger project offer cases of the same pairs of assessments being administered with sharing and discussion of the generated feedback. These two situations will be contrasted to study the claim that engaging with the generated feedback promotes learning and improvement in performance.

HOW DO INSTRUCTORS DESCRIBE STUDENTS' MATHEMATICAL WORK AND OPPORTUNITY TO LEARN IN GEOMETRY COURSES FOR TEACHERS?

Patricio Herbst	Soobin Jeon	Amanda Brown
University of Michigan	University of Michigan	University of Michigan
pgherbst@umich.edu	sbjeon@umich.edu	amilewsk@umich.edu

We report partial analysis of a survey of instructors of undergraduate geometry courses for teachers, attending to how they described the nature of the mathematical work they engage students in and the opportunities to learn that students had. Analysis of latent construct correlations showed that engagement of students in inquiry into geometry was significantly associated with opportunity to learn about mathematical definitions and conjecturing and engagement of students in the study of geometry was significantly associated with opportunity to learn about axioms and about history of geometry. Latent variable means comparisons showed group differences in claimed opportunity to learn between instructors whose highest degree was in mathematics and those whose highest degree was in mathematics education.

Keywords: geometry, teacher knowledge, undergraduate instruction, inquiry, opportunity to learn, survey

Objectives

We report on an analysis of survey responses from instructors of geometry courses for teachers (GeT) focusing on the curricular choices of instructors. Herbst et al. (2024a) reported on two distinct sets of characteristics of the mathematical work undergraduate geometry students may be engaged in: inquiring into geometry and studying geometry. Here, we investigated whether the type of mathematical work promoted could predict the topics stressed in different classes by looking into correlations between the former and the latter sets of variables and whether the field of highest degree attained by instructors could predict those curricular choices.

Literature Review

The mathematical preparation of teachers is an important component of secondary mathematics teacher preparation. This is so not only because teachers need to know the subject matter they will teach but also because the work of teaching, particularly when teaching for understanding, includes organizing the mathematical environments in which their students will learn and making sense of how students demonstrate their understanding (Manouchehri, 1998). Among the mathematical knowledge teachers need is the capacity to organize and manage mathematical work (Kuzniak & Nechache, 2021).

What knowledge to aim for and what mathematical work to engage prospective teachers in mathematics courses for teachers are important decisions instructors need to make. Though classically secondary mathematics teachers took courses equivalent to the mathematics major, the value of this choice has been questioned (e.g., Proulx & Bednarz, 2008). For a while, mathematics education researchers, mathematicians, and mathematics teacher educators have taken an interest in improving the mathematical preparation of teachers (Bass, 1997; Martin et al., 2020; Wasserman et al., 2023). This interest has been demonstrated in several ways. The promotion of inquiry-based learning in undergraduate mathematics courses has included mathematics courses for teachers demonstrating some learning of mathematical knowledge for teaching (see Laursen et al., 2016; Yoshinobu & Jones, 2013). Also, design research approaches to the teaching of mathematics courses for teachers have endeavored to connect the content of advanced mathematics courses with occasions of use in school mathematics teaching (Buchbinder & McCrone, 2023; Wasserman, et al, 2022). And communities of mathematics teacher educators and mathematicians have worked together to develop shared ownership of the problem of mathematical preparation of teachers as well as create curricular resources (e.g., CBMS, 2001, 2012; Martin et al., 2020; Senk et al., 2004; Usiskin et al., 2003).

Of particular interest to our study is the work of GeT: A Pencil, a community of instructors of geometry courses for secondary teachers (including mathematicians and mathematics educators) who have been working together since 2018 to improve those courses (see getapencil.org; An et al., 2023, 2024). An outcome of the work this group has been a consensual set of 10 essential student learning objectives (SLOs) that are meant to be a common core that diverse curriculum materials and pedagogical strategies could aim to align with. These 10 student learning outcomes are presented in Figure 1.

SLO	Description	SLO	Description
1	Derive and explain geometric arguments and proofs.	2	Evaluate geometric arguments and approaches to solving problems.
3	Understand the ideas underlying current secondary geometry content standards.	4	Understand the relationships between axioms, theorems, and different geometric models in which they hold.
5	Understand the role of definitions in mathematical discourse.	6	Effectively use technologies to explore geometry and geometric relationships.
7	Demonstrate knowledge of Euclidean geometry, including its history.	8	Be able to carry out and justify basic Euclidean constructions.
9	Compare Euclidean geometry to other geometries such as hyperbolic or spherical.	10	Use transformations to explore definitions and theorems about congruence, similarity, and symmetry.

Figure 1. Student Learning Objectives (SLOs)

The pursuit of all of those kinds of improvements can be facilitated by the existence of background information that describes the specific courses which are to be improved. Descriptive studies, such as TEDS-M, have contributed information about the qualities of teacher preparation in mathematics (e.g., Tatto & Senk, 2011) based on surveys and knowledge assessments, aiming to characterize how different nations prepare mathematics teachers. Tatto and Bankov (2018) provided an account of the opportunity to learn mathematics for secondary teachers in the United States based on an analysis of syllabi, noting that a large majority of prospective secondary teacher education programs provided opportunities to learn Euclidean or axiomatic geometry. However, information about what those geometry courses include both topically and in terms of mathematical work was beyond the scope of that study.

As regards geometry courses for secondary mathematics teachers, only two surveys have been conducted in the past. Wong (1970) surveyed leaders of mathematics departments and teacher education programs asking for their level of satisfaction with the geometry preparation of teachers. Grover and Connor (2000) reported on a survey of 108 instructors and were able to describe broad strokes of curriculum choices (e.g., that more than half of the courses emphasized Euclidean geometry from a synthetic perspective and that more than half included lectures with some discussion, but all group work was done outside of class). Herbst et al. (in press) interview study of 32 instructors showed they recognize a tension between sourcing the GeT curriculum from synthetic geometry and from geometry knowledge needed for teaching. It seemed important to develop a new instructor survey not only to update the description from Grover and Connor (2000) after broader emphases on mathematical knowledge for teaching and inquiry-based learning, but also to make more fine-grained claims. Though the survey targets questions about a range of issues on instruction and curriculum, the present report is focused on describing the geometry topics and geometric work students have opportunities to learn and do (for reports on other aspects of the survey see Herbst et al., 2024a, 2024b).

Theoretical Framework

We frame this inquiry using Cohen et al.'s (2003) instructional triangle which considers instruction as a transaction of content among instructor and students. We elaborate the content vertex of the triangle (see Figure 2, lower right) by noting that content is manifest in instruction in two different ways. Content is, on the one hand, a set of instructional goals or knowledge items which are at stake; and content is, on the other hand, the mathematical work that students are asked to do, in the form of problems and other tasks. In particular, different types of mathematical work with the content may be present for the same content. Geometry courses include many theorems about geometric concepts and students may all be expected to know the definitions and be able to prove the theorems. Yet the manner in which they get to attain such learning (the work in which they engage) may vary: In some classes they might participate in constructing the definitions or be given a chance to conjecture the theorems, while in other classrooms the definitions and the statements of such theorems may be given to them. That difference in the kind of mathematical work is an important one to track in geometry. Brousseau's (1997) notion of didactical contract can help distinguish between those classrooms. In particular, the survey as a whole pursues characterizing a contract that we name *geometric inquiry* (inquiry, hereafter) and one that we name the *study of geometry* (study, hereafter).

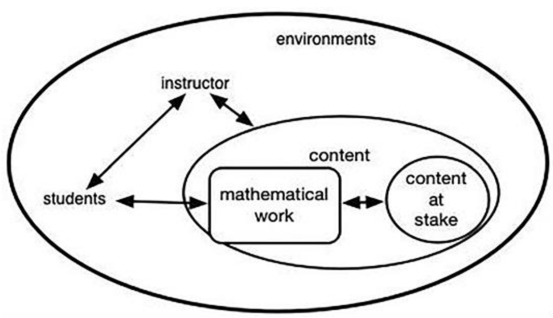

Figure 2. The instructional triangle adapted to include two manifestations of content

Our survey improved upon Grover and Connor's (2000) by taking into consideration the findings from Shultz (2022) about inquiry-oriented instruction (IOI). Shultz (2022) found that instructors' IOI practices were not homogeneous: Whereas some instructors who affirmed using inquiry involved students in conjecturing and defining, others who also affirmed teaching through inquiry interpreted it mostly in terms of student-teacher interaction (e.g., discussions, group work). Our survey built on Shultz's and also included questions that helped gauge the incidence of non-inquiry practices in teacher-student interaction and in the nature of the mathematical work. Our items were designed to answer separately questions about the incidence of different hypothesized factors associated with inquiry and study. Specifically, our survey included items that indicated constructs associated with inquiry and study regarding how instructors interact with students and how students interact with each other, and constructs associated with inquiry and with study concerning the nature of the mathematical work students do, including whether they participate in defining new concepts or rather receive the definitions from instructors. Herbst et al. (2024b) examined the distinctions among study and inquiry contracts in regard to the instructor-student interactions depicted on the left arrow in Figure 2. In this paper, we focus on the horizontal arrow shown in Figure 2 (how students interacted with content, which we call students' mathematical work) and some aspects denoted by the right arrow in Figure 2 (specifically the content that instructors recognized to be at stake).

Methods

To investigate the relationship between the mathematical work students were engaged in (i.e., study or inquiry) and the geometric ideas instructors recognized students had the opportunity to learn about, a survey was designed and distributed among instructors of geometry courses for secondary teachers in the United States. We targeted mathematics departments in all US universities where an undergraduate geometry course is regularly taught and required for students seeking certification to teach secondary mathematics. The survey was sent to all mathematics departments whose website included mention of such a geometry course (n=670). Emails were sent to department heads asking them to forward a link to the survey to the instructor who had taught the course last. We recognize that surveys provide only an approximation of teaching practice (Kennedy, 1999), and that more robust conclusions often need richer data collection. At the same time, a survey affords to see general trends in practice at low cost.

Figure 3 provides a list of the items used to describe students' mathematical work in relation to the constructs study and inquiry. We also used the SLOs (Figure 1) to operationalize what instructors might recognize among the opportunities to learn provided to their students in their courses, creating items that indicated each of the SLOs (see Appendix for some SLO-related items). Items shown in Figures 3 and items associated with the SLOs (see Appendix) were included in a larger survey administered through Qualtrics, which also asked questions about instructor demographics, prior preparation, and experience. The analysis focuses on a portion of the survey about mathematical work assigned to students and students' opportunity to learn the

SLOs, particularly looking at associations between the kind of students' mathematical work and the mathematical content recognized by the instructor to be at stake.

List of items that indicate Study (6-point Likert, from strongly disagree to strongly agree)	
821104	For the theorems whose proofs they had to learn, the proof was fully provided to them.
821105	The corollaries (i.e., consequences) of theorems students were supposed to use were explicitly stated for them.
821106	The constructions students were expected to learn were presented step by step to them.
List of items that indicate Inquiry (same scale as above)	
821204	Students were assigned to write (or improve) definitions.
821205	Students were asked to critique definitions given by either you [the instructor] or the textbook.
821219	Students were asked to critique construction procedures.

Figure 3. Items that indicate study and inquiry

Sample

About a third of the targeted departments had instructors return surveys. Our effective sample consisted of 140 GeT instructors who completed all survey items, including the GeT Instructor survey and a background questionnaire. Our sample participants confirmed they had taught a geometry course required for secondary mathematics teachers in the previous ten years. Approximately 69% had their highest degree in mathematics, while 28% had their highest degree in mathematics education (in both cases, highest degree is a Ph.D. or a Masters); also 35% had prior teaching experience in high school geometry. A sizeable 83% of participants held either tenured or tenure-track faculty positions, while 15% occupied non-tenure roles including lecturers and graduate students.

Results

The consistency of the inquiry and study scales for forms of mathematical work was reported elsewhere (Herbst et al., 2024a). To estimate a measurement model for opportunity to learn, we performed confirmatory factor analysis (CFA) on the items associated with the 10 hypothesized SLO constructs (see Figure 1). Given the limitations of that measurement model, we conducted exploratory factor analysis (EFA) on those same items to construct a new model. We felt the need to go beyond confirming our hypothesized model because some constructs had only two items; inter-item correlations within items indicating some constructs, namely SLO 1 and SLO 3, were too low suggesting poor internal consistency (Furr, 2017), and the item loadings under some of the constructs were low or cross-loaded to other constructs (Worthington et al., 2006).

We initially conducted an Exploratory Factor Analysis (EFA) with a smaller sample (n=118) and subsequently validated our model with additional samples (n=140). Following the identification and removal of items with low loadings, cross-loadings, or loading onto a two-item or one-item construct, we used eigenvalues and Kaiser's criterion to analyze and determine the number of constructs. This process resulted in a new model comprising five constructs with improved inter-item correlations.

Table 1: Correlation between constructs (in each model) and the mathematical work students were engaged in (student and inquiry)

	Study	Inquiry		Study	Inquiry
SLO 1	0.045	0.081*	Axiom	0.263*	0.085
SLO 2	0.039	0.165	Definition	-0.120	0.765***
SLO 3	-0.023	0.083	DGS	-0.252	0.412*
SLO 4	0.266*	0.094	History	0.644**	0.151
SLO 5	-0.105	0.906**	Conjecturing	-0.026	0.284*
SLO 6	-0.245	0.450*	**p<0.05, **p<0.01, ***p<0.001*		
SLO 7	0.372**	0.124			
SLO 8	-0.196	0.241*			
SLO 9	0.270	0.155			
SLO 10	0.019	0.432*			

$^*p<0.05$, $^{**}p<0.01$, $^{***}p<0.001$

In comparison to the fit indices of the hypothesized model (CFI = 0.842, TLI = 0.814, RMSEA = 0.079, SRMR = 0.096), the new model demonstrated significant improvement (CFI = 0.947, TLI = 0.935, RMSEA = 0.062, SRMR = 0.072) (Hu & Bentler, 1999). Examination of individual items under constructs in the new model compared to those in the hypothesized model revealed that SLO 4 (referred to as Axiom in the new model) and SLO 5 (referred to as Definition in the new model) remained unchanged. SLO 6, SLO 7, and SLO 10 differed by only one item from the constructs DGS, History, and Conjecturing, respectively, in the new model. This similarity between the models supports the confirmation that some constructs in the hypothesized model were robust, while others were not.

Given the robustness of these constructs concerning student opportunity to learn, we focused on exploring the relationships between these constructs (in each model) and the mathematical work students were engaged in (i.e., study or inquiry). An item covariance between an item in the Inquiry construct and an item in the SLO 5 construct (or Definition construct in the new model) was added to the model, as suggested by the highest modification index. Adjusting these parameters not only improved the overall model fit but also brought the correlations to standardized estimates (see Table 1). We found a significant association between engaging students in geometric inquiry and giving students opportunity to learn about geometric transformations, digital geometry environments, and the role of definitions in mathematics (SLOs 5, 6, and 10). We also found a significant association between engaging students in the study of geometry and giving students opportunity to learn about Euclid's Elements, and the role of axiomatic systems (SLOs 4, and 7). Conversely, the distinction between study and inquiry did not significantly impact the extent to which instructors claimed their students learned about proof, evaluating arguments, the content of high school geometry, non-Euclidean geometry, or constructions.

Table 2: Latent Variable Mean difference between demographic groups (ME or M)

Received Highest Degree in Field of Mathematics Education (ME) (N=39) or Mathematics (M) (N=96)			
Constructs in hypothesized model	LVM in ME after setting M to 0	Constructs in new model	LVM in ME after setting M to 0
SLO_1	-0.166*		
SLO_2	-0.406*	Argument	-0.284*
SLO_3	0.064		
SLO_4	-0.372*	Axiom	-0.368*
SLO_5	0.336	Definition	0.330
SLO_6	0.418	DGS	0.405
SLO_7	-0.188	History	-0.229
SLO_8	0.116		
SLO_9	-0.535*		
SLO_10	-0.075	Conjecturing	-0.023

* p-value < 0.05

We also conducted a comparative analysis of latent variable means among instructors holding the highest degree in either mathematics (M) or mathematics education (ME) to explore whether their preparation could serve as a predictor for the likelihood of offering opportunities for students to learn content associated with various SLOs. To assess the size of between-group differences per construct, we set the latent variable means in the group with the highest degree in mathematics to zero and estimated the means in the group with the highest degree in mathematics education. Across both models, it became apparent that instructors with highest degrees in mathematics were more likely to engage students in learning axioms (SLO 4), and in learning geometric arguments, such as understanding proofs (SLO 1) and evaluating arguments (SLO 2). Notably, the SLO construct related to non-Euclidean geometry (SLO 9)—whose items indicated the construct named History in the second model—appeared to be associated with instructors holding the highest degree in mathematics.

Conclusion

The results shared provide a glimpse of how instructor claims about the opportunity to learn geometry they provide to their students relates to the kind of mathematical work they organize for them. In turn these results help see a baseline of implementation of the SLOs. Some differences in this implementation are associated with the field in which instructors were prepared. We notice that extending the consensus over the 10 SLOs may require more conversations across the differences among instructors, one of which seems to be their academic preparation. We also notice the need to better measure opportunity to learn; notably, engagement of students in proof (SLO 1), which Ion et al. (2023) showed to be something most instructors agree should be an objective in geometry courses for teachers could not be measured robustly.

Appendix: Sample items indicating opportunity to learn

SLO	Item	Item statement: Students had the opportunity to …
1	4101	… learn to write geometric arguments (e.g., proofs)
2	4105	… check whether proofs were valid
3	4118	…analyze properties of different two-dimensional geometric shapes
4	4106	…work with different axiomatic systems
5	4132	…write definitions
6	4108	…use dynamic geometry software to explore figures.
7	4110	…learn about Euclid’s Elements
8	4114	… perform basic Euclidean straightedge and compass constructions
9	4117	… learn differences between Euclidean geometry and other geometries
10	4126	… apply transformations to analyze mathematical situations

AN ANALYSIS OF ELEMENTARY PRESERVICE TEACHERS' KNOWLEDGE TO SOLVE AREA AND VOLUME MEASUREMENT TASKS

Dae S. Hong
University of Iowa
dae-hong@uiowa.edu

Li Zhu
University of Iowa
li-zhu@uiowa.edu

This study explored elementary pre-service teachers' (PSTs) content knowledge in area and volume measurements. Written pre-assessments and follow-up interviews were conducted with 26 PSTs to explore how PSTs approached and tackled area and volume tasks using a variety of strategies, including conceptual and procedural strategies. Recommendations for supporting elementary mathematics teacher education classes design are discussed.

Keywords: pre-service teachers, area, volume, problem-solving strategy

Introduction

The National Council of Teachers of Mathematics' (NCTM) "Principles to Action" (2014) outlines highly effective teaching practices. Two recommended teaching practices are implementing tasks that promote reasoning and problem-solving and building procedural fluency from conceptual understanding. Among the many topics in mathematics, area and volume provide foundational knowledge and applications that extend to understanding concepts such as multiplication, fractions, as well as advanced topics like calculus and the sciences (Vasilyeva et al., 2013). To enhance students' performance in higher-level mathematics, teachers need a robust content knowledge that enables them to plan and implement effective teaching practices. Previous studies have highlighted curricular limitations in widely-used U.S. textbooks concerning measurement (Smith et al., 2016) and teachers' limited content knowledge in area and volume measurements (Baturo & Nason, 1996; Gutiérrez & Jaime, 1999; Murphy, 2012). These results make it challenging for educators to plan area and volume measurements lessons that promote reasoning and problem solving and developing procedural fluency from conceptual understanding.

Literature Review

How Students Learn Area Measurement and Common Challenges

Several studies have delved into students' understanding and their pathways to grasping area measurement conceptually (Barrett et al., 2017; Sarama & Clements, 2009). Previous research has indicated that there are foundational ideas in area measurement including covering a region without gaps or overlaps with equal-sized units, equally partitioning a region, counting unit measures, iterating combined units, comprehending row and column structures, linking the number of squares to length and width to make sense of the formula, and understanding that the subdivided whole is equal to the sum of its parts (Barrett et al., 2017; Sarama & Clements, 2009). These foundational concepts align well with an area learning trajectory, and students who grasp area measurement conceptually can apply these ideas effectively (Barrett et al., 2017). Additionally, understanding that a subdivided whole is equal to the sum of its parts and that manipulation and transformations of subdivided pieces can conserve areas is crucial (Kospentaris, Spyrou, & Lappas, 2011; Lehmann, 2022).

How Students Learn Volume Measurement and Common Challenges

Students employ several strategies to solve volume measurement tasks, including visualizing a set of unit cubes as (a) rectangular arrays organized into layers, (b) space-filling structures without organizing them into layers (e.g., column iteration), (c) entities in terms of their faces, and (d) employing the volume formula (Vasilyeva et al., 2013). The development of knowledge in volume measurement aligns with area measurement; being able to fill three-dimensional space, comprehend partial layer structures, and iteratively construct partial structures can lead to deriving the volume formula as similar process in two – dimensional space can lead to verification of the area formula (Van Dine et al., 2017). These conceptual ideas are essential components of students' volume learning trajectory, as students who grasp volume measurement conceptually can effectively apply these conceptual ideas (Van Dine et al., 2017; Vasilyeva et al., 2013).

Teachers' Knowledge in Area and Volume Measurements

Despite the importance of teachers' content knowledge, several studies underscore the challenges that pre-service teachers (PSTs) face in developing the knowledge necessary to plan lessons that promote effective teaching practices in area and volume measurements. PSTs lesson plans often have a procedural focus, and they frequently depend on prototypical images of specific shapes to make sense of formulas (Gutiérrez & Jaime, 1999; Hong & Runnalls, 2020; Murphy, 2012). Additionally, PSTs often equate the ability to use formulas correctly in response to area and volume tasks with understanding area and volume measurements (Hong & Runnalls, 2022; Runnalls & Hong, 2019). These studies indicate that PSTs often encounter challenges similar to those faced by elementary students (Kospentaris et al., 2011; Lehmann, 2023). The purpose of this study is to explore the current problem-solving strategies employed by elementary PSTs regarding area and volume measurement content knowledge. Two research questions guide the study:

(1) What multiple conceptual/procedural strategies do elementary PSTs employ to solve area and volume tasks?
(2) How do elementary PSTs struggle when confronted with problem-solving processes while attempting to employ conceptual and procedural strategies?

Methodology

Setting, data collection and analysis

This study took place in an elementary teacher education program at a large Midwestern public university in the United States. The Geometry and Measurement course, taught by the first author, is a 16-week mandatory course for upper-class students in the program. The research design consisted of two phases: 1) a pre-assessment of content knowledge, and 2) semi-structured interviews. The first phase involved 26 PSTs (25 females and one male), and the second phase included eight of them (seven females and one male). All participants volunteered for this study. The pre-assessment consisted of a total of 18 items, which were completed by the 26 PSTs. These 18 items were adapted from the Trends in Mathematics and Science Study (TIMSS) studies due to the poor performance of U.S. students on these selected items. It was essential for PSTs to have strong content knowledge related to the fundamental conceptual ideas addressed by these items. From the initial set of 18 items, we pinpointed three items—4, 9, and 11 (as shown in Figure 1)—on which PSTs displayed a wide range of problem-solving strategies.

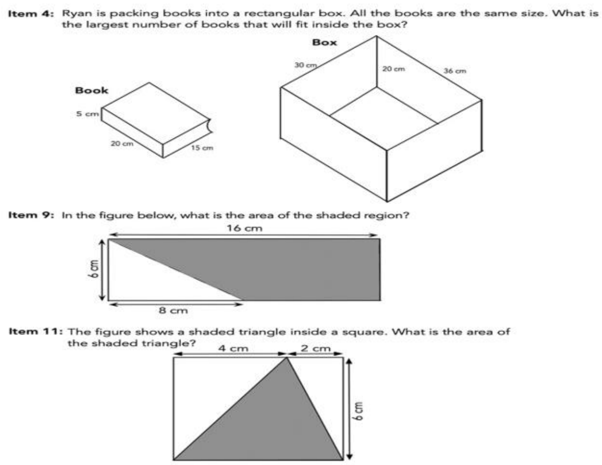

Figure 1: Three items with the greatest response variability (adopted from Foy, Arora, & Stanco, 2013)

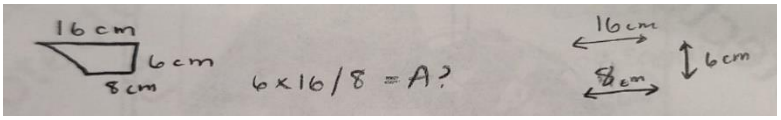
Following the pre-assessment, a semi-structured interview lasting approximately one hour was conducted with each of the eight participants who consented to participate in the second phase. Compared to the pre-assessment, the interview questions were significantly more open-ended as interviewees were encouraged to think about additional possible problem-solving strategies for each item. After all interviews were completed, the PSTs' responses to the three items were analyzed to distinguish among multiple strategies as per previous studies on how students learn area and volume measurements (Table 1) (Barrett et al., 2017; Van Dine et al., 2017; Vasilyeva et al., 2013).

Table 1: Conceptual and procedural responses for area and volume tasks

Problem-solving strategies	
Conceptual	Procedural/non - conceptual
Covering/tiling/filling two and three – dimensions with same sized units (squares or cubes) and linking it to the formula (Item 4) Understanding that the subdivided whole is equal to the sum of its parts (area conservation) (Items 9 and 11). Using array and layer structures (Item 4). Using partial structure of array (squares) or layer (cubes) to iterate or skip counting (Item 4). Recognizing that a triangle covers half the space compared to a square (Item 11). Being able to identify the base and the height of non – prototypical shapes (Items 9 and 11).	Using the formula without conceptual strategies (all three items). Looking for the lengths of the sides of shapes without considering conceptual strategies. Using formulas incorrectly.

We already know a triangle's area is 1/2 times base times height. Because the base of the shaded triangle is equal to the square's side length, which is 6 cm, and the height is also the 6 cm, the area of the shaded triangle is half of a square without doing any calculations. (**Conceptual strategy**)

(**Procedural strategy**)



Book volume is 6×15×20=1800 cubic cm, and box volume is 30×36×20 = 21600 cubic cm. Then 21600/1800 = 12 books. I noticed the height of the book is the same as the height of the box, and the width of the book is exactly half of the width of the box 36/6 = 6, then 2 rows of 6 books is 12 books. (**Conceptual and Procedural strategy**)

Figure 2: Coding Examples

Figure 2 shows examples of coding. The first response pertaining to Item 11 was coded as conceptual. This response shows that this PST was able to indicate why the area formula for rectangle is multiplied by a half and how much space a triangle covers compared to a square. The second written response, from Item 9, was coded as procedural, without considering that the subdivided whole is equal to the sum of its parts, this PST attempted to identify the relevant lengths of sides but struggled to apply the correct formula or use the numbers appropriately. Lastly, the third interview response was about Item 4 and it shows that this PST was able to use the formula to find the volume and at the same time, the idea of filling the box with the book. This can be both procedural and conceptual at the same time.

The two authors independently coded pre-assessment responses and interview responses to ensure the reliability of coding in this study. After the completion of the coding process, consensus between the authors was reached by discussing the responses on which they had had initial disagreements. The final result was 100% agreement for each response.

Findings

Pre-assessment responses to area and volume tasks

Figure 3 illustrates the distribution of PSTs' pre-assessment responses on three items categorized by the type of strategy and correctness. The data indicates over 60 % of PSTs struggle with solving geometry problems using either procedural or conceptual strategies. While it's not surprising to see that more PSTs employed procedural strategies, it is interesting to note that a significant proportion of them were unable to execute procedural strategies correctly (50% on item 4; 43% on item 9; 53% on item 11; and 48% across all three items). When examining conceptual and procedural strategies separately, a similar situation occurred with PSTs who incorrectly used procedural strategies nearly three times as high than those who incorrectly used conceptual strategies (48% vs. 17%). On the contrary, the PSTs were more likely to provide correct answers using conceptual strategies (22% vs. 13%) in overall correctness.

Item 4

	conceptual	procedural
correct	9%	16%
incorrect	25%	**50%**

Item 9

	conceptual	procedural
correct	33%	5%
incorrect	19%	**43%**

Item 11

	conceptual	procedural
correct	19%	19%
incorrect	9%	**53%**

Summary across three items

	conceptual	procedural
correct	22%	13%
incorrect	17%	**48%**

Figure 3: Pre-assessment responses on three items by type of strategy and correctness

For Item 4, we observed that four PSTs employed approaches involving filling, stacking, or using rows with one PST correctly applied these methods, while four PSTs utilized a formula, with two of them applying it correctly. Here are some of the written responses that we were able to find.

> $15 \times 2 = 30\ cm.$ *6 goes into 20 three times. Two rows of books stacked three high = six books.*
> $b \times h\ \ 15 \times 6 = 90\ books.\ 30 \times 20 = 600.\ 600 \div 90 = 6.66$

In the first response above, it's evident that this PSTs attempted to apply conceptual ideas related to filling or stacking three-dimensional space with a reference unit, but struggled to place the books to fill the space without gaps – fundamental conceptual idea of finding a volume. The second response indicates that this PST failed to recognize that the task pertained to the volume concept and instead seemed to apply an area concept. For Item 9 we observed that nine PSTs divided the shape into a triangle and a rectangle (using the idea the subdivided whole is equal to the sum of its parts), with six of them correctly applying this approach. Eight PSTs subtracted the area of the non-shaded triangle from that of the whole rectangle to find the area of the shaded region, and four of them solved it correctly. Three PSTs employed incorrect formulas, such as the Pythagorean Theorem or volume formula, and six made computational errors like $6 \times 16 = 72$ or $6 \times 8 = 24$. Four PSTs identified some relevant lengths in attempts to use the formula but were not successful. Figure 4 displays these responses.

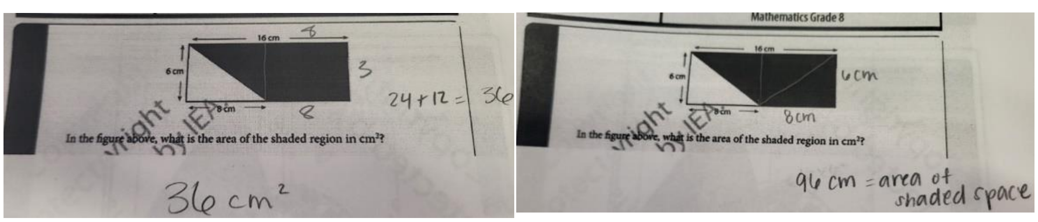


Figure 4: Examples of PSTs' written responses

These responses in Figure 4, including one in Figure 2, demonstrate that these PSTs recognized the need for lengths of sides but were unable to use them correctly. The first response shows that this PST did divide the shape into a square and a right triangle (using conceptual strategy) but was not able to identify correct length. The second response shows that the PST was correctly identify lengths but did not subtract the area of the unshaded part or simply used length × width without considering that the shape is not a rectangle (using procedure without

Kosko, K. W., Caniglia, J., Courtney, S., Zolfaghari, M., & Morris, G. A., (2024). *Proceedings of the forty-sixth annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Kent State University.

considering conceptual strategy of dividing the shape or subtracting the unshaded triangle). The second response highlights that without a conceptual understanding that the subdivided whole is equal to the sum of its parts, PSTs may find it challenging to identify correct procedure to fluently use it, even when they correctly identify the lengths. For Item 11, two PSTs divided 36 by 2, indicating an understanding that a triangle covers half of a rectangle (or square). Other strategies included dividing the square into two right triangles to obtain 18 or simply using the base (6 cm) and height (6 cm) of the shaded triangle to calculate 18 cm² (done by two PSTs – again using the subdivided whole is equal to the sum of its parts). Six PSTs correctly applied the method of subtracting the area of the two corner triangles (6 cm² and 12 cm²) from the area of the square (36 cm²). Two PSTs used the Pythagorean Theorem to find the lengths of the hypotenuse to calculate the area of triangles. Similar to Items 4 and 9, several PSTs provided answers like 24, 36, or 98 without showing their work. The following responses in Figure 5 suggest that some PSTs were unsure about the amount of space covered by an inscribed triangle, uncertain to know why $\frac{1}{2}$ is multiplied for the area of triangle (incorrect use of conceptual strategy of covering) or which formula to apply, unsure about the difference between area of square and triangle (simply using procedure without considering conceptual strategy). Like Item 9, these PSTs attempted to identify lengths but struggled to choose the correct formula.

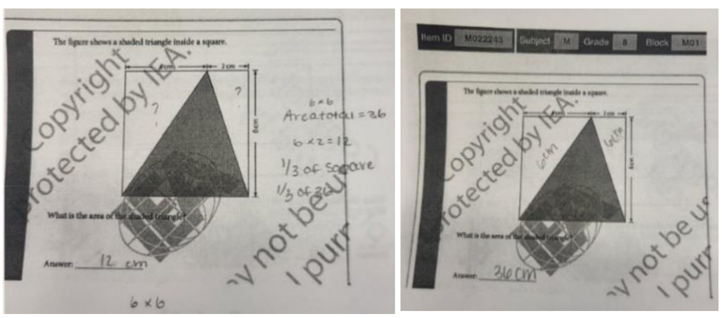

Figure 5: Examples of written response

Finally, another interesting finding is that all PSTs who were unable to provide correct responses to Items 9 (7 PSTs in total) and Items 11 (13 PSTs in total) also couldn't provide correct responses to Item 4. This result may indicate a strong relationship between understanding area and understanding volume, as described in area and volume learning trajectories (Van Dine et al., 2017).

Interview responses to area and volume tasks

With our results from written responses, we were interested in interviewing them to explore their thinking further. The findings revealed their initial struggle and when they were probed further by the interviewer, some of them were able to provide either conceptual or procedural strategies correctly. Consider the following descriptions of their responses on Items 4 and 9:

> *I found the volume of the box first, then the volume of the book, then divided the volume of the box by the book to see how many books can be contained by the box. What I only remember is that I needed to multiply these three*

numbers to obtain the volume, but I found out why it works actually. Maybe because the length and width can be used to determine the perimeter of the outside of the shape measured, and the height indicates the depth of it. So if you multiply all those together, the full shape can be obtained. (Item 4)

I calculated the area of right-angled triangle as 8 times 6, which equals 48 but I don't know what should be done next. (Item 9)

The first response shows that PSTs were able to articulate the procedure (finding volumes of the box and the book and length × width × height) but was not able to clearly state why (mentioning perimeter). Among the 8 PSTs interviewed, four of them eventually used the formula to correctly answer Item 4. The second PST, on Item 9, struggled to explain why and how the formula worked, the formula she mentioned was not correct. For all three items, we were also able to see that more PSTs were eventually able to suggest alternate methods as they were probed by the interviewer. The responses below were not used by the PSTs in the pre-assessment, but they were able to suggest them as the PSTs were asked to think about additional strategies during the interview.

If you stack the books like you would on a bookshelf, it will six across the top because 6 times 6 equal 36. And then 15 is half of 30. It will be two rows of 6 times 2 is 12 (Item 4).

Dividing the shaded region into three smaller congruent triangles, then finding that the area of each small triangle was 24 cm^2 and multiplying by 3 (Item 9).

The area of the shaded region is equal to 75% of the area of the large rectangle (Item 9).

PSTs described additional strategies they used in the interview, such as considering how to fill the box with same-sized unit books for Item 4, counting three unit triangles in the trapezium shape, and the area of the shaded region is 75% of the large rectangle (Item 9), and identifying the base and height of the triangle while considering conceptual strategies for Item 11. Notably, when asked whether the area of the shaded triangle in Item 11 was always equal to half the area of the square without performing calculations, half of the PSTs realized that the triangular area would indeed be equal to half the square's area when they share the same base and equal height. Ultimately, two PSTs on Item 4, five on Item 9, and six on Item 11 proposed correct solutions through multiple conceptual or procedural strategies. In addition to outlining alternative strategies, PSTs were questioned about the rationale behind fundamental formulas, such as volume (volume = length × width × height) and area (area = length × width). Initially, they found it challenging to explain why and how these volume and area formulas worked. For instance, two responses regarding volume for Item 4 included: "*If you multiply the three numbers, you can count the spaces*" and "*Length and width can help to get the perimeter of outside of the shape, and height represents the depth*." Related to area in Items 9 and 11, one PST remarked, "*Area is two-dimensional, so you need to multiply two numbers.*" These responses indicated a lack of clear conceptual understanding. Only a few PSTs provided partial, reasonable explanations when prompted by the interviewer, such as *"Area represents the number of squares, and volume* *represents the number of cubes*". Similarly, when asked by the interviewer which geometry measurement topic was related to each item, fewer than half of them were able to make the correct alignment.

When we asked PSTs to provide definitions of area or volume during the interviews, the majority responded with uncertainty, saying something like, "*I'm not sure what an area/volume formula is, or how the formula can be described*." Others offered definitions such as, "*Area is how many rows of length*." These ambiguous definitions likely contributed to their uncertainty about identifying relevant lengths, and which formulas to use for each task. In summary, Table 2 illustrates the types of incorrect strategies in PSTs' content knowledge related to area and volume, as revealed through pre-assessment and interview findings.

Table 2: PST's incorrect strategies in area and volume measurement

	Pre-assessment	Interview
Incorrect Conceptual	Filling (or stacking) space but with gaps. Not being able to identify area or volume concept. Using a formula that did not identify base and the height	Struggling to understand area or volume conceptually. Struggling to explain why and how a formula worked. Unable to provide appropriate definitions for area and volume measurements
Incorrect Procedural	Using a wrong formula Identifying lengths but not being able to use the appropriate formulas. Making calculation mistakes when using the correct formula Not being able to identify relevant lengths.	Confusing formulas for different shapes

Summary and Discussion

As prior studies have indicated, our PSTs initially preferred procedural-based problem solving strategies (Chamberlin & Candelaria, 2018). PSTs provided unclear definitions of area and volume, unable to identify relevant lengths, and were uncertain about the correct formulas to be used for each task. One implication of this finding is that more PSTs were able to find the correct way to use conceptual or procedural strategies when they were probed, which indicates the importance of providing purposeful questions and scaffolding when implementing lessons, as suggested by NCTM and other study (NCTM, 2014; Wickstrom, 2022). Another interesting finding was that when conceptual strategies were used, it was more likely for PSTs to answer area and volume items correctly. Some of them could not articulate appropriate formulas and even when they were able to articulate them, they were uncertain to use them. Identifying relevant lengths and stating correct formulas for each task is challenging for some PSTs and being able to use them correctly is another challenge that PSTs had. In previous studies, PSTs often equated using formulas for area and volume to understanding these measurements (Hong & Runnalls, 2022). Our results showed that it is not synonymous to think that using formulas can be interpreted as understanding because using formulas is challenging without conceptual understanding. This finding supports finding from previous study that formula might be used without knowing why and for wrong shapes (Vasilyeva et al., 2013; Zacharos, 2006). It demonstrated an interesting relationship between conceptual strategies and procedural strategies; if a PST was unable to use the conceptual strategy correctly, it was more unlikely for them to use procedural strategies correctly. Furthermore, when PSTs were not able to provide correct responses to area tasks (Items 9 and 11), they were not able to provide correct responses to volume task either (Item 4). The conceptual link between area and volume can help them understand that volume can be viewed as an extension of area from 2-dimensional objects to 3-dimensional objects as learning trajectories for length, area and volume are closely related (Van Dine et al., 2017). As shown by the PSTs' responses in both pre-assessment and interview, inadequate understanding of area measurement will very likely lead to challenges in learning volume measurement as described in learning trajectories (Van Dine et al., 2017).

It's not surprising to discover that elementary PSTs often lack content knowledge in area and volume measurement, and their preference for procedural strategies in solving such tasks is expected. However, these findings highlight important implications for mathematics teacher education programs. Considering the well-known limitations in widely used curriculum materials (Smith et al., 2013; Smith et al., 2016), these results become even more concerning. PSTs' limited content knowledge suggests that they face similar learning challenges as their future students (Lehmann, 2023), which can lead to mathematics lessons that may focus mainly on procedural tasks. Even though teachers might prepare procedurally focused tasks, it is also possible that they might not be able to use the procedures correctly by simply memorizing them. This underscores the importance of mathematics teacher education programs enhancing PSTs' conceptual understanding alongside procedural fluency by providing precise definitions of area and volume, and establishing the connections between these definitions and the formulas to explain why each formula works. Also, it will be beneficial to develop lessons to show how area and volume measurements are conceptually related in order for students to be able to link two important measurement concepts.

EXAMINING ELEMENTARY PRESERVICE TEACHERS' RESPONSES TO AREA AND VOLUME MEASUREMENT TASKS

Dae S. Hong
University of Iowa
dae-hong@uiowa.edu

Li Zhu
University of Iowa
li-zhu@uiowa.edu

Keywords: pre-service teachers, area, volume, problem-solving strategy

Introduction

Teachers need various types of knowledge to plan and implement effective teaching practices that promote reasoning and problem solving. Different types of knowledge can pertain to content or pedagogy. In this poster, one area that we are particularly interested in is area and volume measurements. Area and volume are two important topics that have wide range of applications in mathematics and provide foundational knowledge for multiplication, fractions, and the advanced topics of calculus and the sciences (Vasilyeva et al., 2013). Despite the importance of area and volume measurements, US students have not performed well in area and volume measurements (Lehrer, 2003; Mullis et al., 2012; Muillis et al., 2016). Here are research questions that guided us.

(1) What is the discrepancy in problem-solving strategies of PSTs' responses to area and volume measurement tasks?
(2) How does conceptual understanding are utilized to support PST's problem-solving strategies?

We used items from Trends in Mathematics and Science Study (TIMSS) studies to examine PSTs' content knowledge. Our results show that it is challenging for PSTs to use procedures if they are not able to use conceptual strategies. This finding shows the importance of building procedural fluency from conceptual understanding. It is unlikely that PSTs can simply memorize and use procedures correctly because being able to correctly identify relevant lengths and formulas is challenging for PSTs. They need to first identify that area and volume measurements are relevant concepts for the given tasks and also know foundational ideas of covering and space filling to interpret and solve area and volume tasks correctly. Also, solving volume tasks correctly may enable them to solve area tasks correctly as well. This may indicate that foundational ideas in area and volume measurements are conceptually related as demonstrated in learning trajectories (Barrett et al., 2017; Van Dine et al., 2017) and importance of including tasks that show how area and volume measurements are conceptually related to each other. Challenges that we found in this study are very similar to challenges demonstrated by elementary students (Lehmann, 2023), which is concerning.

With our findings, we can recommend that in teacher education program, PSTs need to have opportunities to be exposed to area and volume tasks that promote reasoning and problem solving. They need to be exposed to how foundational ideas in area and volume are related to each formula to build procedural fluency from conceptual understanding.

PREPARING FUTURE TEACHERS: USING MENTOR LESSON PLANS TO SUPPORT TEACHING ELEMENTARY MATHEMATICS FOR SOCIAL JUSTICE

Jermaine R.Hey Howell
Michigan State University
howell97@msu.edu

Keywords: Elementary Mathematics, Social Justice, Pre-Service Teachers, Lesson Plans

Objectives and Perspective

In supporting elementary pre-service teachers (PSTs) to enact pedagogical practices that promote teaching elementary mathematics for social justice, mentor lesson plans can be a useful resource to enhance their learning and teaching competence. Bartell (2013) asserted that through teaching mathematics for social justice, students use mathematics to study the world, increase their knowledge, and learn about issues of social injustices toward developing ideas of equitable practices for creating changes. In most teacher education method courses, PSTs learn how to teach the required mathematics methods and strategies before engaging in student teaching experience. While some PSTs may further be introduced to social justice pedagogies (Freire, 2000; Ladson-Billings, 1995a, 1995b, 2014, 2021; Cochran-Smith, 2004; Paris & Alim, 2014; Paris, 2021) that enforce practices to support, enhance, and sustain the learning of all students inside the classroom. However, to effectively apply their learning, PSTs must explore instructional resources and engage in classroom discourse of ways to enact social justice pedagogies when planning and teaching elementary mathematics. It is for this reason, I suggest the use of mentor lesson plans as an instructional tool during mathematics methods courses to support PSTs learning. This practice will enable PSTs to see how they can plan and write mathematics lesson plans that promote teaching elementary mathematics for social justice.

I position this idea of supporting PSTs to teach elementary mathematics for social justice by using three frameworks (a) Freire's (2000) Pedagogy of the Oppressed with emphasis on the banking and problem-posing education models; (b) Culturally Relevant Pedagogy (Ladson-Billings, 1995a, 1995b, 2014, 2021) with emphasis on the three tenets - academic success, cultural competence, and critical consciousness; and (c) Cochran-Smith (2004) six principles to support PSTs in teaching for social justice.

Methods of Inquiry and Summary

To provide PSTs with mentor lesson plans that promote teaching elementary mathematics for social justice, I make use of the textbook created by Bartell et al. (2022) that provides different elementary mathematics lesson plans that incorporate specific social justice standards, mathematical focus areas, and mathematical concepts. By using these mentor lesson plans, PSTs are provided with a guide that connects their learning of social justice and more specifically, teaching mathematics for social justice. Through this approach, PSTs can begin to develop an understanding of how social justice pedagogies can be integrated into mathematics learning for students in elementary classrooms. The overall goal is to provide a scaffold for PSTs to engage with mentor lesson plans that incorporate the social justice standards in preparation for student teaching experiences.

ARE WE REALLY TEACHING INTEGRATED STEM? EXPLORING UNCERTAINTY IN STEM TEACHER PREPARATION

Jenifer Hummer	Byungeun Pak	Derek Sturgill

jhummer@wcupa.edu	b.pak@utahtech.edu	sturgilld@uwstout.edu

National policies and curriculum documents call for STEM integration into K-12 and teacher education. Certainly, studies have shown that engaging in STEM activities for PSTs is important; unfortunately, their implementation may not be uniform or effective. Analyzing the integration approaches of teacher educators and their method courses may better support PSTs' development of STEM integration and use of STEM-integrated activities. Results indicated that participating educators have various approaches to STEM integration within their methods courses. Yet, commonalities of pedagogical techniques were consistent across course syllabi and participants' interviews.

Keywords: Integrated STEM, Preservice Teacher Education

National policies and curriculum documents call for STEM integration into K-12 classrooms. A product of this integration is that students will better understand connections across STEM disciplines that will prepare them for specialized, high-demand skills (National Research Council (NRC), 2012; National Council of Teachers of Mathematics [NCTM], 2014). Furthermore, the Association of Mathematics Teacher Educators (AMTE) has suggested that effective teacher preparation programs "provide opportunities for candidates to make mathematical connections between various approaches to solving problems and opportunities for candidates to make connections between mathematics and other disciplines" (2017, p. 3). Similarly, the National Science Teaching Association (NSTA, 2020) has noted that STEM education provides opportunities for students to engage with "content in authentic and relevant ways." Therefore, preservice teachers (PSTs) must experience STEM integration and develop pedagogical knowledge, even if this occurs within disciplinary-specific courses.

Experiences with STEM integration must come sooner rather than later within teacher education. As an example, in Bartels et al.'s 2019 study, PSTs who had not participated in integrated STEM lessons could only define STEM disciplines and lacked an understanding of authentic STEM integration. After STEM-integrated lessons were modeled, 13 of these PSTs integrated three or more STEM subjects into their lesson plans and, overall, showed an enhanced understanding of STEM integration. Similarly, Bozkurt and Özyurt (2019) reported on 44 secondary, mixed-discipline PSTs who participated in a 12-week STEM program. Before this program, their PSTs understood STEM disciplines but were unfamiliar with STEM integration. At the end of the 12-week program, all 44 PSTs collaboratively developed and implemented integrated STEM lessons. Nonetheless, the participating PSTs reported challenges with finding materials and implementing STEM activities. However, Bozkurt and Özyurt reported that students were interested in the activities, so they anticipated using integrated activities in their teaching. Overall, these results are important as they show that prior to experiencing STEM integration, PSTs may not understand how to integrate STEM disciplines in their classrooms.

Yet, when PSTs engage in STEM activities and design and implement integrated STEM lessons, they show an enhanced understanding of integrated STEM.

As shown above, designing integrated STEM activities for PSTs is important; unfortunately, due to the lack of integrated STEM curricula, the implementation of such activities may be uncertain as they may not be uniform or effective. While many STEM educators agree that STEM disciplines are connected by ideas and skills and that STEM integration should focus on real-world contexts, the ways that disciplines are integrated into STEM education vary (Moore et al., 2020). Additionally, when STEM activities are multidisciplinary, engineering and mathematics may be given less attention. Furthermore, within the activities, if students are not asked to explicitly describe content concepts, such as specific mathematical ideas, they may not recognize the mathematical concepts that were employed. Thus, English (2016) suggested that teachers need support when they implement integrated STEM activities, especially with respect to highlighting the connection between engineering and mathematics. In addition to the literature showing variation in the content of STEM activities, there is also variation in the pedagogies and implementation strategies that PSTs experience. To understand more about the various approaches to STEM integration, finding commonalities is likely to support the development of authentic STEM integration in teaching methods courses. Thus, understanding how methods courses intend to prepare future teachers to implement integrated STEM activities is important for teacher educators. For this study, we explored: How do STEM teacher educators intend to integrate STEM within their teaching methods courses?

Methods

Twelve STEM teaching methods course syllabi and transcripts from six follow-up interviews of those who submitted syllabi were analyzed using qualitative methods. All but one of the syllabi were designed for secondary PSTs, the remaining for elementary PSTs. The data were analyzed using constant comparative methods and thematic coding in which the researchers conducted a line-by-line analysis of the syllabi and interviews (Strauss, 1987). A hybrid inductive and deductive coding method was used as most codes emerged from the data (Hatch 2002). To serve as a foundation, the definitions of levels of STEM integration (Figure 1) were used to code explicit mentions of any of the STEM disciplines and their respective levels of integration.

Type of Integration	Features
1. **Disciplinary**	Concepts and skills are learned separately in each discipline.
2. **Multidisciplinary**	Concepts and skills are learned separately in each discipline but within a common theme.
3. **Interdisciplinary**	Closely linked concepts and skills are learned from two or more disciplines with the aim of deepening knowledge and skills.
4. **Transdisciplinary**	Knowledge and skills learned from two or more disciplines are applied to real-world problems and projects, thus helping to shape the learning experience.

Figure 1: Increasing Levels of Integration (English, 2016, p. 2)

Through an iterative process of individual coding and team meetings to gain consensus on codes and develop a coding dictionary, the codes were refined. The following actions were taken to ensure trustworthiness: all coding was completed using Dedoose (2021), qualitative analysis software; meetings were held to discuss coded excerpts and resolve disparities; all syllabi were coded by at least two researchers; and at times, syllabi and interviews were coded simultaneously by all researchers. Through this process, themes emerged that described levels of STEM integration and emphasized pedagogical techniques across the various courses.

Results

We present our results related to the levels of STEM integration as defined by English (2016) and pedagogical techniques. While there were examples of higher levels of integration such as transdisciplinary and interdisciplinary, the levels of STEM integration varied (Table 1). Most syllabi focused on multidisciplinary or disciplinary levels of integration within the course descriptions, standards, weekly calendars, and assignments. The few instances of transdisciplinary integration included students solving real-world problems through tasks or projects. PSTs would learn about how to teach "solving human and environmental problems through mathematics" (Yu-ri's syllabus). There were many references to a single discipline or two or more disciplines. This was evident through the discipline-specific reading assignments for mathematics or science PSTs. Julie's syllabi course descriptions serve as an example where mathematics and science are explicitly mentioned in which students build capacity to teach the societal uses of mathematics and science as well as "the use of technology across mathematics and science content" In these syllabi, PSTs would make connections across mathematics and science but may not have opportunities to use them in an interdisciplinary or transdisciplinary nature. These examples represent instances that were coded throughout the syllabi.

In addition to levels of integration, the syllabi included several references to student-centered pedagogy. For the purpose of this report, we have included student-centered strategies with at least 50 occurrences in the coding such as equity, discussion or discourse, designing, and opportunities for reflection (see Table 1). As one of our highest occurrences, the equitable practices consisted of a variety of features such as cultural relevance and responsiveness, differentiation of instruction, building a positive classroom environment, and supporting students with disabilities. For instance, 10 of 12 syllabi mentioned that culturally responsive teaching approaches would be studied or discussed. Nine syllabi also included that differentiated instruction would be part of the course. Additionally, we noted that PSTs would learn a variety of teaching methods such as how to design and implement hands-on activities, facilitate discourse and discussion, lead inquiry activities, and appeal to students' interests. For example, eight of the syllabi noted that PSTs would learn methods like how to teach in ways that "all students investigate, collaborate, communicate and defend their explanations" (Julie's syllabi) as well as how to select resources for supporting inquiry and problem solving. Thus, throughout the syllabi, the instructors intended to teach in ways that support STEM Education methods that are grounded in constructivism (NSTA Board of Directors, 2020).

Table 1: Overall Themes in STEM Teaching Methods Syllabi

Theme	Frequency	Theme	Frequency
Level of Integration		***Student-Centered Pedagogy***	
Transdisciplinary	20	Equity	143
Interdisciplinary	23	Discussion/Discourse	57
Multidisciplinary	58	Designing	136
Disciplinary	89	Opportunities for Reflection	69

To further understand the syllabi results, follow-up interviews were conducted with participants who submitted syllabi. The interviews provided further insight into the STEM methods instructors' intentions for STEM integration. Some of the instructors noted that while they wanted to include more of the higher levels of integration, their students were going to be teaching siloed STEM content courses (e.g., algebra, biology, chemistry, physics). Thus, while they did their best to incorporate integrated STEM activities, they also had the tension of preparing their students to teach within their content areas. As evident in Julie's interview: "Sometimes I have to be like, 'Okay, here's the integrated [task]. Now, how would you silo it?' Because I have to be real about what their teaching contexts are." The interviews also revealed that, given the current curricular demands for K-12 teachers (e.g., standardized assessments), they found it best to focus on STEM pedagogies such as how to implement hands-on activities and provide opportunities for authentic problem solving. For example, Lana said, "I emphasize high leverage teaching practices or best practice strategies, but I think any of those right? I mean, like, student-centered. Lots of student voice in the classroom…working with different people every single day, getting kids up and moving. So, you know whether it be in math [or] science, whether doing labs or experiments, but getting kids up, so movement, collaboration." Here we can see how Lana considers best teaching practices focused on discussion and hands-on activities in her STEM teaching methods class while also balancing the need to prepare her students to teach siloed STEM courses.

Discussion

The findings learned from this analysis contribute to a better understanding of approaches to STEM integration and will inform the design of future STEM teaching methods courses. We can see from our research that while efforts are being made to incorporate integrated STEM into teaching methods courses, there are outside factors that influence the levels of integration. While the levels of integration may need some improvement, our findings also revealed that student-centered pedagogies were a main feature of the syllabi and intentions of the instructors. This is a positive finding, as these pedagogies align with preparing students to apply 21st Century Skills (NSTA Board of Directors, 2020). In particular, PSTs are learning how to support the solving of open-ended and authentic problems that require multiple STEM disciplines, working collaboratively with other disciplinary experts, and maintaining perseverance to work with evolving technologies and solve environmental issues.

Due to the small sample size, our results are not generalizable. This sample size was small in part because, after an extensive search for STEM methods courses within teacher preparation programs and broad calls for participation, teacher educators from only six U.S. programs with STEM teaching methods courses responded. However, these results provide the broader STEM education community with ideas on which to build. We recommend that STEM integration continues to increase throughout all levels of education and within teaching methods courses. To address the uncertainty of how students are experiencing STEM integration within classrooms, we also suggest that further research be done within STEM content courses in K-16 education. As a concluding thought, we suggest that as more STEM teaching methods courses are developed, our findings and recommendations can inform course design and implementation.

Acknowledgments

Thank you to the participants who allowed us to explore STEM integration through your course syllabi and then shared your thoughts with us through the interviews.

AN EXPLORATORY MIXED METHODS STUDY ABOUT TEACHER CANDIDATES' DESCRIPTIONS OF CHILDREN'S CONFUSION, STRUGGLE, AND MISTAKES

Keywords: equity, diversity, and inclusion; pre-service teacher education; research methods

This poster focuses on data from a program called SEE Math (Support and Enrichment Experiences in Mathematics; Kalinec-Craig et al., 2021; Kalinec & Rios, 2023), which is a revised version of the TEACH Math (Teachers Empowered to Advance Change in Mathematics; Turner et al., 2012) research group's case study of a child's thinking. Elementary teacher candidates (TCs) in SEE Math select a child in their field placement and engage in a series of problem solving tasks that support children's funds of knowledge, their broader mathematical thinking, and their Torres' Rights of the Learner (e.g., you have the right to be confused; to claim a mistake and revise your thinking; to speak, listen, and be heard; to write, do, and represent what makes sense to you; Torres, 2020; Kalinec-Craig, 2017). As a summative assessment for the methods course, the TCs conduct a 15-minute Mock Parent Teacher Conference (MPTC) to share what they learned about the child's thinking over the course of the program. The purpose of this study was to answer the following research question: How do elementary teacher candidates (TCs) describe children's confusion, (productive) struggle, and mistakes in their MPTC in humanizing ways (Goffney & Gutiérrez, 2018) and/or as rights of the learner?

The authors of this exploratory, embedded, mixed methods study began by collecting the saved transcripts from the MPTCs from 64 TCs across three semesters (spring 2020, fall 2020, and spring 2021). Analysis began by applying a natural language process called "topic modeling" to create a collection of words (named as topics) that described the entire data set; 50 topics (with ten keywords words each) were selected (Rios & Kavuluru, 2018). Only topics involving confusion, productive struggle, and mistakes were included in the final analysis. The second author applied a sentiment analysis procedure to the subset of the topic indices to explore the sentiment language (e.g., positive, neutral, and negative) used by the TCs when describing confusion, productive struggle, and mistakes. Finally, the first author applied a systematic, thematic analysis (Saldaña, 2020) to understand the contextual nuances of the TCs' descriptions in the MPTC.

Findings from the study showed that topics associated with confusion, productive struggle, and mistakes were typically assigned a higher negative sentiment than that of the other topics from the transcripts. Yet the qualitative thematic analysis showed, "the TCs used rehumanizing language that centered on children's confusion, (productive) struggle, and mistakes as a normal, albeit messy and complex, part of the learning process that centers on the child's humanity and rights as a learner." For example, one TC stated in her MPTC that her student, "… let me know when he didn't understand something or when he had questions. And this is totally normal. And those are his rights as a learner to ask questions or be confused." The study concluded that there is more to learn about how TCs describe children's confusion, productive struggle, and mistakes in ways that rehumanize how children learn mathematics. Our poster will focus this underexplored, but important mixed methods approach to understanding large bodies of textual data: a process that combines natural language processing models such as topic modeling and sentiment analysis with qualitative research methods.

EXPERIENCES IN INFORMAL LEARNING ENVIRONMENTS AND SECONDARY TEACHERS' CREATIVITY IN LESSON DESIGN AND ENACTMENT

Laura B. Kent
University of Arkansas
lkent@uark.edu

This poster session shares the results of a study that examined eight secondary mathematics teachers' use of contextualized situations in their lesson design based on participation in a STEM discovery learning center. Eight secondary mathematics teachers are participating in a six-year project focused on the development of agency and authentic practice (Priestley, et al., 2015; Frost, 2016). Their experiences co-facilitating activity-oriented lessons in summer STEM camps prior to their degree program and STEM fairs throughout their graduate level licensure program influenced their use of realistic and creative mathematics problem situations in their formal classroom settings both as preservice and inservice teachers.

The foundation for this study was derived from two perspectives in mathematics education: contextualized problem situations and creativity in problem and lesson design (e.g. Sriraman, 2009; Sevinc & Lesh, 2022). Among other components, Sevinc & Lesh (2022) described mathematically rich and contextually realistic problems as having opportunities for sense making and creativity (p. 679). Their study provided evidence that preservice teachers increased in their understanding of how to develop mathematically and contextually rich problems over the course of a semester-long methods course but suggested that additional research is needed.

This study answers the following research questions:

1. How did preservice teachers initially respond to written questions about the feasibility of applying activities from the summer STEM camps to formal classroom instruction?
2. What types of contextually rich and creative problem-solving lessons did they incorporate into their classroom instruction?

The summer camp lessons involved hands-on activities centered around themes such as making stained glass from jolly ranchers as part of an exploration of medieval times. The graduate level licensure program required the preservice mathematics teachers to create their own STEM fair project and also guide students in their internship settings in their development of projects. Data sources included observations, reflective essays, lesson plans and focus group interviews. Initial responses to the STEM summer camp experiences indicated hesitancy to incorporate hands-on activities into formal classroom lessons due to perceptions that there might not be enough time or resources to include during daily instruction. However, views began to shift towards the end of their licensure program and into their first two years of teaching as they recognized the positive impacts of mathematically rich and contextually realistic problems on their own students.

Acknowledgments

The research described in this paper was supported by the National Science Foundation Robert Noyce Teacher Scholarship Program under Grant Number 2050256. The opinions, findings, conclusions, and recommendations, however, are those of the author and do not necessarily reflect the views of the National Science Foundation.

RELATIONSHIPS FIRST HIGH DOSAGE MATHEMATICS TUTORING: WHAT CAN WE LEARN FROM A LITERATURE SYNTHESIS?

Sumner@colorado.edu

This paper shares a synthesis of the literature related to the application of a relationships-first approach to high-dosage math tutoring. In the context of our research, high-dosage tutoring is delivered multiple times per week during the school day by paraprofessionals who work with students in historically under-resourced schools. We apply a critical perspective to frame the importance of attending to interpersonal relationships during tutoring. We then explain the core ideas of small group interactions, dialogue, relational interactions, care and belonging and provide a synthesis of these constructs. The literature synthesis presented is intended to be applied to research-based efforts aimed at supporting tutors working to increase their skills for cultivating strong interpersonal relationships and enacting equity oriented pedagogy.

Keywords: Equity, Inclusion, and Diversity, Communication, Classroom Discourse, Affect, Emotion, Beliefs, and Attitudes

The opportunity for students to develop positive personal relationships as part of their content-based interactions during math tutoring is often presented as the keystone of a human tutoring model, providing support that cannot be offloaded onto current or forthcoming technologies, even ones using modern Artificial Intelligence. This is especially true in high dosage tutoring contexts where the same tutor works with a designated group of students throughout an academic year. Research demonstrating that strong teacher-student bonds can enhance student motivation and engagement, and positively impact learning outcomes (Davis, 2003; O'Connor & McCartney, 2007) underscores the value of a relationships-first human tutoring model.

One component of the University of Colorado Boulder (CU) and Saga Education research project is focused on contributing to the professional growth of novice tutors learning to cultivate strong personal relationships with their students. Specifically, the CU and Saga research team is studying discourse-based interactions in the tutoring context and incorporating this knowledge into artificial intelligence (AI) models to generate feedback to help tutors and the coaches who work with them improve their effectiveness. Leaning into the keystone benefit of human tutoring, the primary focus for tutors' professional growth centers on improving tutors' use of discourse and dialogue about mathematical concepts and supporting tutors' ability to cultivate increasingly caring and supportive relationships with their students. One goal of this research is to support tutors to learn how to weave interpersonal relationship building throughout the time they spend working with students on mathematical content for the dual purpose of increasing students' math learning and supporting students' general well-being.

Context and Overview

Historically, tutoring has been primarily available to those who hire private tutors to support enhanced academic success for students whose families can afford to pay for this service (Nelson-Royes, 2015). Providing tutoring to a more economically diverse population of students has been shown to be a valuable strategy for reducing achievement and opportunity inequities and supporting students' emotional well-being (Carlana & La Ferrara, 2021). In recent years tutoring, and particularly high-dosage tutoring provided in school during the school day, has been promoted as a way to support students and help address achievement inequities – this effort has increased in the aftermath of school closures and online learning during the Covid-19 pandemic (Carlana & La Ferrara, 2021). This increased attention and momentum has led to a rapid increase in the availability of tutoring during the school day for students who are less likely to be able to afford the cost associated with hiring a private tutor. As of 2015, 32% of US high schools required academic tutoring for at least some of their students (US Department of Education, 2017). More recently the U.S. Education Secretary, Miguel Cardona, has advocated for all students who are academically behind grade-level to receive high-dosage tutoring (at least 90 minutes per week), and COVID relief funds have provided a source of funding to support tutoring services in schools (Stavely, 2022).

The increase in human tutors working with students during the school day has several unique affordances. First, opportunities for students to work in small groups, for an extended period, with a knowledgeable math adult, tend to be rare in traditional classrooms. In an example of a context in which some students may receive small group instruction and where students have opportunities to engage with highly trained adults providing personalized support - students who receive special education services - the supporting teachers may not have the math knowledge necessary to effectively bring about high levels of learning, and not all students receive this support. Tutors who deliver high dosage tutoring can provide unique benefits by bringing high levels of math content knowledge to a small group tutoring context that is provided to all.

Second, tutors provide socio-cultural and relational support that is not always possible in classrooms. The population of people hired as tutors is more diverse than the teaching workforce (Contreras, 2022) and more demographically aligned with the population of students they are working with. The population of tutors whose professional growth our research supports includes 54% people from nondominant backgrounds, 19% of whom identify as Latine. These demographic characteristics increase the likelihood of students working with tutors with whom they share identity group memberships and/or cultural backgrounds, affinity and experiences. The combined scenario of working for extended periods of time in small groups paired with the potential for common experiences associated with shared identity group memberships and cultural backgrounds creates a powerful and unique opportunity for tutors to support students both academically and personally in ways that complement and augment other supports that exist in traditional school settings.

Theoretical Perspective

Our work is grounded in the perspective that incorporating interpersonal relationship building throughout tutoring sessions in ways that are integrated with content instruction contributes to supporting students' well-being and plays a central role in students' increased understanding and knowledge about math. Foregrounding interpersonal relationships supports students' thriving as both math learners and as developing young adults.

A critical perspective casts a powerful lens to understanding these theoretical commitments and thus better supporting this development. A critical perspective focuses attention on how math instruction that supports the "mathematical identities, excellence and literacies of marginalized students" (Gutiérrez, 2008, p. 357) may differ from instruction that leads to increased test scores and reduced participation gaps. Despite a longstanding call in math education research literature for math teaching to incorporate a critical perspective (e.g., Gutiérrez, 2007; Martin, 2003), math tutoring continues to be almost exclusively oriented toward increasing students' knowledge of math content with insufficient attention paid to how tutors and students relate to each other as more complete human beings. Gutiérrez's (2009) provides an initial framework for understanding equity in math that explains the importance of relationship building in high-dosage human tutoring contexts.

Gutiérrez's (2009) framework consists of two axes: the dominant axis includes the dimensions of access and achievement, and the critical axis includes the dimensions of identity and power. Tutoring models align with the dominant axis via their aim to increase students' content knowledge. By providing students with access to learning opportunities tutoring may increase students' achievement of academic success in math which may be indicated on assessments showing absolute increases in learning outcomes or reduced differences in achievement between identity groups. Tutoring models that only attend to mathematical content, without attending to interpersonal relationships, fail to account for the critical axis, including the impact of students' experiences with identity and power dynamics on their learning.

In delineating what is required in equitable math, Gutiérrez calls attention to the need to engage with students' unique identities and the power dynamics at play in math learning spaces. Engaging in math teaching and learning in ways that reflect distributed power structures can support more student-centered learning, students' agency and students' mathematical identities and sense of belonging. Students have been shown to benefit from opportunities to bring their lived experiences to bear on the task of learning math in ways that align with their personal identity group memberships and individual perspectives and experiences (Esmonde, 2009; Battey et al. 2016; 2018; Ford et al. 2014).

Dialogic learning spaces are an example of attention to both the dominant and critical axes. These spaces are built around rich and generative interactions between instructors and students that enable people to get to know each other's unique ways of thinking and doing math. The goal is supporting students to develop conceptual understandings of math that are rooted in their individual perspectives and lived experiences.

Literature Related to Relationship-First Instruction

A commitment to building strong interpersonal relationships in the context of high-dosage math tutoring has been justified using a broad range of evidence from research literature. Gutiérrez's framework provides a scaffold to situate additional components that are especially relevant to the classroom in general and tutoring specifically. Looking at the dominant axis, the incorporation of tutoring into a student's daily practice increases access and provides more support to increase achievement. Since tutoring inherently takes place in small groups it can bring about specific benefits unique to small group instructional contexts including increased opportunities for dialogue. Examining the critical axis, we draw from literature on relational interactions, care and belonging as relevant components necessary for attending to students' experiences of identity and power dynamics, and we observe that each of these elements is interrelated and critical to student success and wellbeing.

Small groups: creating a context for learning and growth

Tutoring constitutes a unique context in which students are working in small groups, but they have the full-time participation of an adult who holds extensive math content knowledge. Research on small group mathematical activity, and equity and inclusion in small groups working on mathematical tasks, may apply to the tutoring context, recognizing that the tutor's full-time participation differs from the role a teacher plays in a classroom setting. The presence of a tutor could potentially undermine the opportunity that is normally available to students working in small groups to exercise agency over how they engage with mathematical content. However, the small group setting offers opportunities for a skilled tutor to facilitate dialogue, engage in relational interactions, convey care, and cultivate a sense of belonging.

Esmonde (2009) proposed a theoretical framework for understanding Opportunities to Learn during small group learning activities. This framework consists of four points about how learning happens: "(a) through participation, (b) in relation to a social ecology, (c) through processes of identity development, and (d) through communicating about mathematical content" (p. 1011). In Esmonde's conceptualization, participation refers to students' opportunities to "move on a trajectory toward more central and competent participation in classroom practices" (p. 1011). Social ecologies in small groups account for the forces that contribute to the social construction of identity within the norms and dynamics of a single small group, along with external influences on identity development such as intersections of race, class, gender, sexuality, language communities and more. Students' identities can be influenced by their experiences engaging in dialogic learning, by their teacher's enactment of relational interactions and expressions of care, and by the degree to which they feel a sense of belonging in the math learning community. Finally, with respect to communicating about mathematical content Esmonde considers the role of shared meaning making in the processes used by small groups working on mathematical activities. Esmonde's (2009) framework provides a way to account for identity and power - Gutiérrez's critical axis - in math learning, paying particular attention to the experiences of students who are members of nondominant identity groups and considering how students can experience agency in math learning that is relevant within their unique life experiences.

Dialogue: connecting student and tutors together

The term 'dialogue' is often used loosely in reference to discussion or conversation between teacher and students or between multiple students. However, the literature on dialogic teaching and learning has some important characteristics worth attending more closely. Dialogic teaching and learning "characterizes an epistemological relationship," (Freire and Macedo, 2003, p. 191), "a process of learning and knowing" (p. 193) in which all participants have agency in the nature of the learning that occurs and how that learning develops. Billings and Fitzgerald (2002) observed that dialogic discourse can generate a "reciprocal flow of ideas involving actions and reactions of group members [that] may lead to new understandings not held by any group member in advance of the discussion" (p. 909). The learning that results from collective sensemaking through dialogue moves beyond transactional learning that flows primarily from tutor to students. In other words, dialogic discourse results in learning that is multidirectional which reflects participants unique perspectives, experiences and ways of thinking.

Development of a dialogic learning space is initiated by a teacher or tutor who is skilled at supporting student agency and who cultivates norms of participation that enable movement from peripheral to central roles of participation while considering students' identities and experience of shifting power and authority dynamics. Webb et al. (2019) observe that a teacher's role in creating inclusive and dialogic small group learning environments includes helping students know how to engage in active listening; ask and answer questions; brainstorm suggestions, ideas and opinions; explain and evaluate ideas; use persuasive talk; summarize conversations, and much else (p. 177). Xu and Clarke (2019) describe the importance of teachers considering cultural differences related to students' identities and life experiences that may influence students' participation and interactions with persons in positions of authority and may subsequently impact how students engage in a dialogic learning space. Langer-Osuna and Esmonde (2015) describes complexities of the shifting authority relations present in collaborative and dialogic math learning communities. The role of a teacher or tutor in cultivating a dialogic learning experience extends well beyond the creation of group-worthy tasks to include how these tasks are enacted through the intentional use of dialogic moves.

Relational interactions: attending to how tutors communicate

Literature on relational interactions specifically describes how teachers relate to and interact with their students (Battey, 2013; Battey et al. 2016; 2018). Relational interactions factor into the establishment of care, as will be described below, and they shape students' math learning experiences. Teacher content knowledge and implementation of instructional practices have been shown to be impactful for student learning (Battey, 2013; Battey et al. 2016; 2018), but relationship interactions are equally impactful. A teacher may have extensive content knowledge and be skilled at using an extensive repertoire of instructional strategies, but if they do not establish and maintain supportive relational interactions, students may not thrive. Consideration of the nature of relational interactions is especially relevant for students who identify as members of minoritized groups in society and who are more likely to be learning math from educators whose identity group memberships and cultural backgrounds differ from their own. If teachers' approaches to relational interaction are rooted in different cultural experiences or expectations this may result in relationships with these students that feel less personal or less familiar (Battey et al. 2016; 2018; Ford et al. 2014). Battey et al. (2016) specifically highlight how teachers perceive their African American and Latine students as more confrontational and spend more time disciplining their behavior as compared to their white peers. Ford et al. (2014) addresses the potential differences in how authority is established between White and Black teachers, and how this may impact their relationships with their students. While relational interactions are integrated with the concept of care, they can be more precisely descriptive of how a teacher connects with their students.

Battey et al. (2016; 2018) identified five components of relational interactions that help build such "caring relationships," with a particular lens on instructing minoritized students. These include framing math ability, acknowledging student contributions, attending to culture and language, addressing behavior, and setting the emotional tone. These dimensions can be tracked by looking at specific forms of dialogic acts or conversational moves. A teacher who takes a positive approach to enacting each of these components can create a supportive learning environment. However, the converse is true as well; if a teacher takes a negative approach, it can diminish the student's willingness to engage and restrict their opportunities to learn. For example, in a case study looking at an elementary math teacher's class, Battey (2013) observed positive framing of ability when the teacher encouraged students on a specific math problem, reminding them of their accomplishments on similar problems. Conversely, negative framing occurred when the teacher was sarcastic and questioned students' basic math skills. Relational interactions highlight how communication can have an immediate impact on students.

Care: establishing authentic relationships

A fundamental component of relationships is the element of care, or attending to the needs of others (Bartell, 2011; Potvin et al, 2022; Maloney & Matthews, 2020). Within an educational context, Noddings (1984, 1988) has applied care theory to describe the teacher-student dynamic. When a teacher shows genuine care and compassion, this can significantly impact the student's educational experience for the better (Bartell, 2011; Maloney & Matthews, 2020).

However, there are many different critical components needed to successfully develop an authentic caring relationship (Bartell, 2011). Caring for a student means attending to their wellbeing at a personal level, and not just caring for their academic success (Maloney & Matthews, 2020). Noddings (1988) describes the need for 'engrossment', meaning the teacher must understand the students' motivations and feelings and provide positive acknowledgment to form a reciprocal relationship. Similarly, Maloney & Matthews (2020) emphasize the need for empathetic care, which is "teacher's authentic expression of identifying with the challenges of their students and prioritizing students' well-being above their own" (p. 408). Maloney and Matthews (2020) found that when students experienced care as transactional or superficial, they were less invested in the class. However, when students felt empathetic care, they felt more connected to the class, that their input was valued, and that math was relevant to them. Whether a teacher shows genuine care for a student as a person, and not just for their academic performance, has ties to greater investment; students want to do better for teachers who care for them (Bartell, 2011; Maloney & Matthews, 2020).

To establish this level of care and understand a student personally, teachers must understand not only the student's identity and background but also their lived experience in the context at large. This is especially important for BIPOC students and any student in a marginalized or systematically oppressed community. To not acknowledge the challenges that have been built into these students' lives is to ignore a major factor in their educational experience (Maloney & Matthews, 2020). This also means teachers should be aware of their own teacher identity and any potential biases they may hold, especially as they are the ones in the position of power within the teacher-student relationship (Bartell, 2011). It is not enough for a teacher to care, the student must also feel cared for to establish an authentic connection (Bartell, 2011). Care in the classroom clearly has many nuances (Bartell, 2011), but is an essential part of maintaining healthy relationships (Potvin et al., 2022).

Belonging: bringing together all members of tutoring groups

Belonging is a multifaceted social construct that typically relates to the perception of inclusion and support within a community and is seen as a basic human need (Allen et al, 2021;

Gray et al. 2018). The sense of exclusion or isolation has been related to poor quality of life and depression (Allen et al., 2021). Thus, establishing a sense of belonging is important for young people, especially in socially interactive academic settings where they spend a significant portion of their time (Barbieri & Miller-Cotto, 2021). Not only is belonging associated with overall wellbeing, but it has also been found that the sense of belonging in a math setting is associated with better academic performance (Gray et al., 2018; Allen et al., 2021; Penuel et al., 2023; Barbieri & Miller-Cotto, 2021). Barbieri and Miller-Cotto (2021) found an association specifically between a sense of belonging in math and subsequent scores. Penuel et al. (2023) found that a student's sense of belonging predicted their level of contributions. This differed by race with White and Asian students contributing more than their Latine peers.

Similar to the findings on care and relational interactions, a sense of belonging is especially impactful for BIPOC students (Barbieri & Miller-Cotto, 2021; Penuel et al., 2023; Gray et al. 2018). Matthews et al. (2021) posits that there are seven key dimensions - 3 interpersonal and 4 instructional - that constitute Belonging Centered Instruction. Educational institutions have historically been a place of exclusion for students who are members of minoritized identity groups, and these experiences can undermine their opportunities to develop a sense of belonging. However, when care is established and positive relational interactions occur, this can bolster a student's sense of belonging. These concepts are interwoven together; when a student feels that a teacher genuinely cares about their wellbeing (often by using positive relational interactions) then the student may feel more belonging and be motivated to contribute and engage (Barbieri & Miller-Cotto, 2021; Penuel et al., 2023; Gray et al. 2018; Maloney & Matthews, 2020).

Relationship Focused Tutoring: Alignment of Constructs with Critical and Dominant Axes

To help us understand the role that each of the previously described constructs can play as components in a relationships-first high dosage tutoring context, we consider the alignment of key aspects of each construct with the dominant and/or critical axis. Notably, each construct contributes to both axes and helps expand Gutiérrez's framework by suggesting how educators can attend to access, achievement, identity, and power. Table 1 shows this alignment.

Table 1: Alignment of Constructs with Dominant and Critical Axes

	Small Groups	Dialogue	Rel. Interact.	Care	Belonging
Dominant	movement toward central participation	student agency	-framing ability -acknowledge contributions	positioning learning content as good for the self	supports academic success
Critical	attention to student's individual needs and experiences	-shifting authority relations -multi-directional learning	-attending to culture and language -set emotional tone	-attend to student wellbeing and lived experiences -empathetic care -potential biases	supports feelings of membership in learning community

Tutoring by nature involves working in small groups. As Esmonde's (2009) framework explains, small group interactions can support students to move toward more central roles of participation which enhances their access to learning opportunities and potentially academic achievement, the components of the dominant axis. Small group learning contexts also provide opportunities for individualized interactions that attend to students' unique identities and lived experiences, the components of the critical axis.

A dialogic learning space increases students' opportunities to engage with teachers' and tutors' ways of conceptualizing and doing math which has the potential to support access and achievement through students' participation in sense-making about mathematical ideas. The multidirectional nature of the learning generated through dialogic discourse depends on students' opportunities to contribute their own unique conceptualizations and lived experiences in relation to the math they are learning. Learning that results from dialogic interactions is reflective of the ideas, insights and perspectives of all participants and relies on shifting power dynamics and authority structures around who holds and contributes knowledge.

Regarding relational interactions, the ways that educators frame math ability, acknowledge student contributions and address behavior support students' access to learning opportunities, while educators' attention to culture and language and strategies for setting the emotional tone incorporate aspects of the critical axis of equitable math.

Educators' expressions and demonstrations of care attend to the dominant axis' components when they are concerned with how learning mathematical content is good for the students. When educators' enactment of care extends to attending to students' well-being, demonstrating empathy, learning about and being responsive to students' lived experiences, acknowledging and correcting potential biases and engaging in deep and authentic connection the critical axis components of identity and power are being addressed.

Finally, educators' who support the development of students' sense of belonging as it relates to established and accepted practices of doing math are attending to the dominant axis components of access and achievement, while educators' who cultivate learning environments in which students' sense of belonging as unique and valued members of a community of learners are attending to the critical axis components of identity and power.

Conclusion

In the context of high dosage math tutoring in which tutors bring a relationships-first approach to their interpersonal interactions with their students it is helpful to have a clear understanding of what is involved in cultivating strong and productive tutor-student relationships. We propose that a more equitable and inclusive form of math tutoring can be achieved by explicitly considering how tutors engage with students in ways that attend to both the critical (identity and power) and the dominant (access and achievement) axes of equitable math by first building strong positive relationships with students and then leveraging those relationships throughout their interactions about math content. This paper contributes a synthesis of research related to how professionals who work in instructional roles can build relationships that support students' well-being as a mechanism to contribute to increased math learning. This synthesis of the separate but related constructs described in this paper helps to explain how tutors can build positive interpersonal relationships in a high dosage tutoring context, supports the design of professional learning opportunities and contributes to the professional growth of tutors working to improve their skill at supporting and engaging with their students.

How preservice teachers (PSTs) learn to visually represent fraction multiplication with partitioning is an ongoing area of research. Our study investigated what strategies 15 elementary PSTs used to solve and model two non-unit fraction multiplication tasks before instructional guidance. We found the majority of PSTs used algorithmic approaches to provide solutions and often did not provide an explanation or a visual representation to support their reasoning. Two special cases provided insights into challenges PSTs may face when depicting and partitioning the unit within area models. These findings have implications for purposeful sequencing of fraction tasks and intentional instruction around representing and partitioning units.

Keywords: Mathematical Representations, Preservice Teacher Education, Rational Numbers, Teacher Knowledge

Relevant Literature and Purpose

Area models are a core pictorial representation used throughout the scope and sequence of K-12 mathematics (Lischka & Stephens, 2020). Preservice teachers' (PSTs') ability to use representations fluently will directly impact their future students' conceptual understanding and procedural fluency as representations are the vehicle that students use to understand the abstract concepts central to mathematics (Pape & Tchoshanov, 2001). In the domain of rational numbers, area models have been used to investigate PSTs' conceptions of decimal multiplication (Rathouz, 2011), fraction division (Leitch, 2023), fraction multiplication (Gichobi, 2018), fraction addition (Lee & Lee, 2023), understanding of fraction multiplication through problem posing (Yeo & Lee, 2022), and the connections between fractions, geometry, and measurement (Lee & Lee, 2021). For fraction multiplication using area models, PSTs often struggle with producing visual representations of fraction concepts; connecting representations is crucial for the development of their content knowledge (Thurtell et al., 2019). Some of the challenges with fraction multiplication include: (a) insufficient foundational fraction knowledge; (b) interpreting fraction multiplication; and (c) recognizing the unit they are partitioning for accurate division and subdivision of factors (Son & Lee, 2016). This literature recognizes the importance of investigating the development of PSTs' use of area models for fraction multiplication.

For this report, we investigated the following research question: What strategies do elementary PSTs use when multiplying fractions before instructional guidance? This question contributes to a larger ongoing cross-institutional study focused on examining the relationship between the fluency in which elementary PSTs use area models with whole numbers influence the use of area models with fractions. Specifically, we examined PSTs' fluency with area models in relation to their ability to both solve fraction multiplication tasks and communicate their reasoning.

Theoretical Background

The mathematical experience and content knowledge that PSTs bring to their preparation programs must be strengthened to develop their pedagogical content knowledge. Pedagogical content knowledge should include the effective use of representations and the ability to develop procedural fluency from conceptual understanding (Ball et al., 2008). When adding fractions, PSTs often relied on procedural knowledge to solve the tasks and then represent their answers with an area model (Lee & Lee, 2023). When multiplying fractions, PSTs frequently used more familiar, algorithmic approaches as opposed to those that support the development of conceptual understanding (Gichobi, 2018). Although PSTs may have the procedural knowledge to compute the correct answers for fraction operations, they may lack conceptual understanding to transfer their thinking into different representations. Using only algorithms has been shown to limit PSTs' understanding of how the unit is important in fraction multiplication (Izsak, 2008). To make sense of traditional fraction algorithms, PSTs should engage with using area models to build fluency with fraction operations. To become well-prepared mathematics teachers, PSTs need opportunities to connect procedural fluency with conceptual understanding (NCTM, 2014).

Methods

Participants and Settings

Our participants included 15 undergraduate elementary PSTs (14 females and 1 male) who were enrolled in the second of a two-course sequence consisting of elementary mathematics content taught by one of the authors at a small, Midwestern university in the United States. The first course focused on whole number concepts and operations, and this second course focused on rational number concepts and operations. The concepts covered in these courses included a focus on understanding why familiar mathematical procedures work to support PSTs in developing conceptual understanding and pedagogical content knowledge for teaching.

Data Sources and Analysis

To investigate strategies PSTs used for multiplying two fractions before instructional guidance, they were given a paper-and-pencil pre-test prior to course work regarding rational number operations. The pre-test consisted of two non-unit fraction multiplication tasks: $\frac{2}{3} \times \frac{3}{4}$ (required no additional subdivision) and $\frac{2}{3} \times \frac{4}{5}$ (required additional subdivision), and PSTs were directed to solve them using an area model. Additional directions on the pre-test included: (a) in your area model, only use additional subdivision when it is necessary; (b) do not use algorithms to solve the problem; (c) make sure to draw each step of your solution, provide a brief narrative explanation for each step, and write symbolic notations that will help the reader understand how you solved the problem; (d) clearly mark your final solution.

We used an inductive coding by initially identifying key themes then iteratively generated new codes and themes (Creswell, 2013; Saldaña, 2016). First, we independently explored the data to visually inspect for trends in PSTs' strategies, writing analytic memos on initial thoughts regarding how to categorize PST solutions. We debriefed by discussing responses and refined categories for coding: Provision of narrative explanations, accuracy of response (conceptual, computation, and visual aspects), types of visual representations, and algorithmic approaches. Using these categories, we focused on two cases of visual representation for further examination.

Findings

Our preliminary pre-test findings revealed nuances associated with PSTs' use of the fraction multiplication algorithm and their adoption of area models to represent fraction multiplication. First, we briefly summarize those representations and algorithms. Then, we share two cases that allowed us to examine PSTs' emerging use of visual representations with correct solutions but whose models did not fully depict how they arrived at their solutions.

Summary of PSTs' Fraction Multiplication Strategies

We tasked the 15 PSTs with multiplying two pairs of fractions using area multiplication, accompanied by narrative explanations. Only 40% of the PSTs attempted to use visual representations for both tasks, and approximately 25% offered narrative explanations on both tasks. About a third of PSTs relied on algorithms for both tasks, some correct and some incorrect (e.g. "cross-multiplying"). The majority (around 60%) provided incorrect solutions, attributable to conceptual model errors, procedural strategy errors, or calculation mistakes. For instance, two PSTs used cross-multiplication, and some employed inaccurate common denominator strategies.

Variations in Visual Representations

The distribution of PSTs across different representation types for two distinct fraction multiplication tasks is summarized in Table 1. Only six PSTs attempted visual representations for each task, and one PST attempted a visual representation for only Task 1.

Table 1: Types of Visual Representations Used by the Number of PSTs

	Types of Visual Representations			
	One Rectangle with Length and Width Labeled as Factors	Area Model to Represent Each Factor Separately	Rectangular Area Model with Partitioning and Subpartitioning	Strips / Cuisenaire Rod Model
Task 1	3	2	1	1
Task 2	3	2	1	0

From Table 1, we observe that approximately half of the PSTs who attempted visual representations drew rectangles with the length and width each representing a fraction (the two factors). Two PSTs drew separate models for each of the factors and avoided subpartitioning their models to explain the multiplication process. These approaches were accompanied by algorithmic approaches to generate the product of multiplication. In Figure 1, Danielle (all names are pseudonyms) used a variation of this approach with circular area models representing $\frac{2}{3}$ and $\frac{4}{5}$ alongside a "multiply across" method to produce 8/15 as the answer. Danielle proceeded to draw a rectangular area model to represent the solution incorrectly with only 7 of the 15 squares shaded.

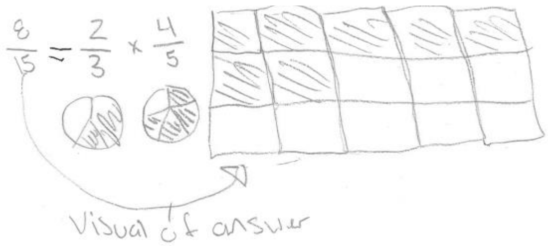

Figure 1: Danielle's Area Model Representation to Show ⅔ × ⅘

Interestingly, one PST drew strips or rods to represent two fractions. For obvious reasons, PSTs who employed two separate models for the two factors appeared to struggle with how to further partition to find the answer. Only one PST used partitioning and subpartitioning in their visual representation when solving the tasks. Amanda seemed to have used two different approaches for Task 1 and 2. Amanda's first model involves partitioning and subpartitioning the unit (Figure 2, left). However, how her model represents a unit (the whole), ⅔, but ¾ is not clear. It is possible Amanda first drew a rectangle and partitioned it into thirds horizontally and shaded two parts to show ⅔, followed by partitioning the whole rectangle again into fourths (one vertical partition and one horizontal partition) and shaded three parts to show ¾. Subsequently, Amanda may have double-shaded overlapping parts and counted these parts (of which some are conceptually unequal but in Amanda's visual representation look about equivalent in area) to generate the solution of 4/8 = ½. With three types of shading and unequal partitioning, it is hard to interpret her process of subpartitioning and finding the answer, even though the solution is correct. Amanda's model of ⅔ × ⅘ clearly shows her process of partitioning and subpartitioning the rectangular area model. It appears that she used the larger rectangle as a unit, initially employing horizontal partitioning to show ⅘ of the unit, followed by vertical partitioning to represent ⅔, thus showing 8/15 of the unit (whole) through double shading. It is interesting to see why Amanda chose to use two potential distinct ways to represent fraction multiplication.

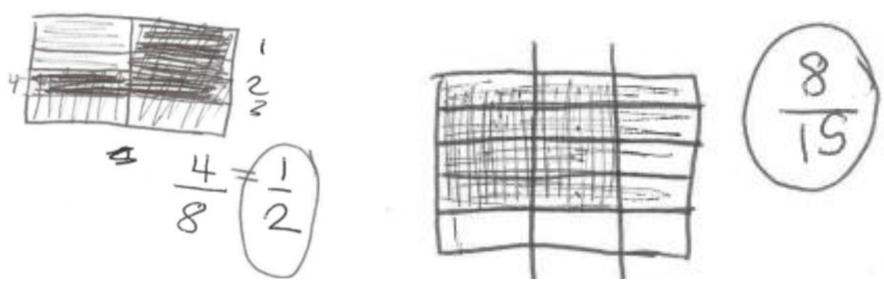

Figure 2: Amanda's Area Model Representations to Show ⅔ × ¾ (left) and ⅔ × ⅘ (right)

These findings highlight the inconsistencies PSTs may have in their current understanding of representing fraction multiplication, s specifically with depicting and partitioning the unit.

Implications

Many of our PSTs did not attempt to visually represent the fraction multiplication tasks and instead utilized algorithmic approaches. Similar to existing literature (Son & Lee, 2016), PSTs erroneously found the common denominator when multiplying fractions. PSTs rarely provided an accompanying narrative to explain their thinking in visual representations. Extending upon prior literature, Amanda's approaches demonstrated the difficulties PSTs face when identifying the unit in need of partitioning. We suggest that subsequent instruction emphasizes the importance of beginning with the unit of reference or involve real-world contextual problems that can assist in identifying the unit of reference. Amanda's inconsistent partitioning could result from the experience of partitioning even-numbered denominators both vertically and horizontally, which is not possible with odd denominators. Math teacher educators should then carefully consider the use of multiplication tasks involving both even and odd denominators with area models. We acknowledge these are preliminary findings drawn from PSTs' pre-tests on fraction multiplication. To further explore PSTs' conceptions of fraction multiplication, we will examine their growth following instruction and how it endured throughout the semester.

FROM NOTICING TO NURTURING: THE TRANSFORMATION OF PST FEEDBACK THROUGH INTERNATIONAL COLLABORATION

Hea-Jin Lee
The Ohio State University at Lima
lee.1129@osu.edu

S. Asli Özgün-Koca
Wayne State University
aokoca@wayne.edu

This qualitative case study explores the impact of Collaborative Online International Learning (COIL) experiences on the ability of pre-service teachers (PSTs) to provide evidence-based noticing and responsive feedback in mathematics education. The research demonstrates that engaging in COIL activities improved PSTs' attentiveness and the quality of their feedback, with an emphasis on conceptual-responses-oriented feedback. Furthermore, the study highlights the influence of group interactions during COIL experiences on these enhancements. The implications of the findings are significant for teacher education programs, emphasizing the importance of offering personalized feedback and cultivating a deeper understanding of mathematical concepts. The study underscores the value of collaborative learning experiences in enhancing teachers' expertise and advocates for further research in this field.

Keywords: teacher education, collaborative online international learning, noticing and feedback

Purpose of the Study

Assessing students' learning progress in a formative manner is essential for educators as it allows them to pinpoint areas that need attention, offer personalized feedback, and prepare for upcoming instructional sessions (Bailey & Drummond, 2006). Analyzing students' incomplete thought processes can provide valuable insights for instructors to tailor pedagogical approaches and improve educational outcomes (Peltier & Peltier, 2020). PSTs who encounter challenges in creating flexible and effective mathematical lessons may lack the necessary preparation to meet the diverse needs of their future students, underscoring the significance of enhancing teacher education programs to better equip PSTs with essential skills and knowledge (Lee & Kim, 2022; Mason, 2002). The study aimed to explore the impact of Collaborative Online International Learning (COIL) experiences on PSTs' capacity to provide evidence-based noticing and responsive feedback in mathematics education. Specifically, it aimed to evaluate the changes in the noticing patterns and feedback approaches of PSTs following their participation in COIL, with a focus on promoting conceptual-responses-oriented feedback. The research questions that guided the study were:

1) How does participation in COIL activities impact PSTs' noticing student thinking and providing feedback?
2) What are the effects of the COIL activity on the alignment between PSTs' noticing levels and the quality of feedback provided?

Theoretical Perspectives

Analyzing students' cognitive processes through observations of their work can provide educators with valuable insights. This approach enables educators to grasp students' understanding of mathematical concepts, facilitate deeper learning, and address any misconceptions through thoughtful feedback (Ball, 1991; McLaren et al., 2012). However, identifying error patterns can pose challenges, and solely evaluating work may not effectively support student comprehension (Peltier & Peltier, 2020). When delivering feedback, teachers should prioritize ensuring student comprehension, promoting alternative strategies, linking current and underlying mathematical concepts, and encouraging critical reflection (Jacob & Empson, 2016). Additionally, it is essential for teachers to highlight student strengths, be responsive by inviting elaboration, introducing diverse perspectives, fostering collaboration, and restating reasoning (Daro et al., 2011). The interdependent relationship between responsiveness, thinking, noticing, and feedback quality underscores the importance of developing noticing skills to enhance interactions and feedback (Jacobs et al., 2011; König et al., 2022).

Social interaction among PSTs plays a crucial role in fostering successful collaborative activities, facilitating learning through discussions, reasoning, reflection, critical thinking, and comprehension (Garrison et al., 2001; Kreijns et al., 2003; Liaw & Huang, 2000; Northrup, 2001). Collaboration positively influences noticing abilities, enabling future teachers to observe, interpret, and appreciate student reasoning from diverse perspectives, thereby enhancing decision-making through an understanding of group dynamics (Abdu & Slakmon, 2023). The use of digital tools has enabled global collaborative learning participation, particularly in virtual exchanges involving intercultural interactions. Engaging in virtual exchanges can stimulate innovation, promote internationalization, and provide networking opportunities (Creelman & Löwe, 2019; Jager et al., 2019). COIL fosters meaningful connections and global collaborative problem-solving for teacher education (Potter & Bragadottir, 2020). In online preparation, composing narratives and receiving feedback assist in identifying learning opportunities for PSTs. Sharing narratives and receiving responses aid in developing discernment and refining practices (Sjöblom et al., 2023). However, instructors involved in COIL should possess knowledge of learning content, pedagogical strategies, and appropriate technology for their COIL experiences. Recognizing and highlighting the differences in learners' cultural backgrounds are essential for creating an inclusive COIL environment (Bae, 2022).

Methods

The research study utilized a qualitative descriptive case study methodology to address the research inquiries and provide a comprehensive account of the case by examining documents (Yin, 2014). The study involved 19 seniors enrolled in an elementary licensure program (the PreK-5 grade range) at a small university in the midwestern region of the United States. The research focused on a COIL activity designed to enhance PSTs' abilities to analyze and comprehend their students' mathematical strategies and errors, and to deliver meaningful feedback and responsive lessons. The PSTs were organized into small groups of 5-6 individuals, comprising PSTs from both a U.S. university and a Spanish university. These groups participated in a collaborative four-phase activity, which included individual work, interactive online collaborations, group report development, and reflection on the COIL experience.

The data collection process aimed to examine the impact of COIL on the PSTs' ability to notice errors/strategies and provide feedback. Prior to the study, the PSTs received instruction on number sense, the four basic operations, and teaching strategies. They were presented with six student solutions involving the four basic operations selected from The Assessment Project (http://map.mathshell.org): Ava (Addition), Jacob (Subtraction), Mason (Division), Aiden (Multiplication), Abigail (Division with numbers including 0), and Mia (Subtraction using expanded form). The initial data collection involved individual written responses from the PSTs during an in-person mathematics methods class. The second set of data included group responses collected electronically after the COIL experience. Throughout the data collection, the PSTs were instructed to: (1) identify error patterns by analyzing the student solutions and (2) provide constructive feedback to enhance student comprehension.

For data analysis, the study employed the general inductive and deductive approach (Creswell, 2013) centered around noticing literature (Jacobs et al., 2011; König et al, 2022). The data analysis process involved reading the data separately by each researcher, discussing the patterns, developing the coding framework, coding the data, and finalizing the coding process. The analysis was guided by a literature review, memos, and ongoing discussions. The analytical framework and coding structure was adapted from Lee et al. (2024) and modified for the research context. The codes include levels of noticing student strategies (Level 0-no attention to student strategies and errors; Level 1-partial or incomplete attention; Level 2-attending to student strategies and errors; and Level 3-fully unpacking student strategies and errors with additional discussion), levels of feedback quality (ranging from Level 0-providing minimal details but planning to correct errors to Level 3-probing guidance and building on student thinking), the mathematical aspect (procedural/ or conceptual), and connectivity.

Results

Unpacking and Supporting Student Thinking

The COIL activity positively impacted PSTs' observational skills and analytical abilities in mathematics education. Before COIL, most PSTs were at Level 1, focusing on basic student strategies. After COIL, there was a notable shift: Level 1 PSTs decreased from 52% to 19%, while Level 2 increased from 44% to 48%, indicating progress towards more detailed analyses. Level 3 PSTs increased from 2% to 31%, showing significant growth in addressing complex student reasoning. Average noticing levels improved post-COIL for Mia, Abigail, Aiden, Mason, Ava, and Jacob, indicating enhanced attention to various mathematical topics especially subtraction and division. The findings suggest that COIL positively influenced PSTs' ability to comprehensively analyze student work, leading to improved support in mathematics education.

The COIL activity positively influenced feedback quality by encouraging more tailored responses based on students' original thoughts. Following COIL, feedback levels increased, signifying a shift towards more meaningful feedback practices that delved deeper into students' reasoning to enhance learning effectiveness. Pre-COIL, feedback predominantly at Level 1 (60%) focused on corrections, with some at Level 2 (34%) offering detailed responses. Post-COIL, Level 1 feedback decreased to 55%, while Level 2 increased to 40%, reflecting enhanced responsiveness. Few PSTs provided Level 3 feedback addressing intricate student reasoning. Notable improvements in feedback levels were observed post-COIL for Mia, Abigail, and Aiden, showcasing heightened quality and specificity. The impact of the COIL activity on feedback quality varied across different math topics and student works, underscoring the significance of thorough noticing for delivering advanced-level feedback.

Before COIL, PSTs heavily focused on procedural aspects in noticing (99.0%) while neglecting conceptual elements. After COIL, there was a shift towards a more balanced approach, with noticing incorporating both procedural and conceptual aspects, increasing to 12.2%. Feedback predominantly emphasized procedural aspects (88.2%) pre-COIL, with minimal attention to conceptual aspects (3%). Post-COIL, feedback on procedural aspects slightly rose to 89.5%, while feedback on conceptual aspects dropped to 0.0%. This shift towards more conceptual understanding, especially in Level 3 responses, underscores the importance of enhancing feedback to address conceptual comprehension in student work. Despite improvements in noticing both procedural and conceptual aspects, a decline in conceptually-focused feedback post-COIL was observed, necessitating further enhancements. Maintaining an alignment between noticing and feedback is vital for effective teaching practices and student learning.

Cross Analysis: Noticing vs. Feedback

Table 1 presents a cross-analysis of PSTs' noticing levels and feedback quality. The comparison revealed that most PSTs were at Level 2 for noticing and Level 1 for feedback. Before COIL, PSTs were primarily at Level 1 for both noticing and feedback. However, after COIL, there was a significant improvement in PSTs' noticing abilities and feedback quality, with an increase in higher levels of noticing and feedback. International collaboration, as exemplified by PST#4 and their group's strategic development of Aiden's thinking, played a crucial role in this enhancement. The shift towards higher levels of attending and quality of instruction post-COIL indicates a positive impact on PSTs' professional development, teaching practices, and student outcomes. The study emphasized moving towards a constructive approach in feedback, focusing on arithmetical errors and alternative correct methods in student work. By fostering Level 3 proficiency in both noticing and feedback, educators can provide a more comprehensive learning experience. The investigation aimed to understand the factors contributing to PSTs' advancements in noticing and feedback, with significant progress observed after COIL.

Table 1. Cross Analysis of Noticing Levels and Feedback Levels Before and After COIL

			Count of Level of Noticing			
			0	1	2	3
Count of Feedback Quality (Level)	0	Before COIL	0	1	0	0
		After COIL	0	0	0	0
	1	Before COIL	0	35	23	0
		After COIL	2	11	29	2
	2	Before COIL	0	12	20	1
		After COIL	0	5	9	17
	3	Before COIL	1	3	1	0
		After COIL	0	0	2	2

Discussion, Implications, and Conclusion

The study found that COIL experiences had a significant impact on PSTs' ability to notice and provide feedback on student work in mathematics education. Before COIL, PSTs mostly attended to student thinking at the procedural level, but after COIL, there was a shift towards conceptual level noticing and higher attention to student strategies and errors. This shift was evident in the feedback provided, with conceptual responses becoming more prominent. COIL discussions facilitated positive changes in PSTs' noticing and feedback, highlighting the value of collaborative learning experiences in developing teachers' expertise.

The study's implications for teacher education programs include the need to incorporate collaborative learning experiences like COIL to enhance PSTs' ability to provide evidence-based noticing and responsive feedback. Teacher educators should emphasize the conceptual aspects of operations and encourage PSTs to move beyond procedural thinking. Providing opportunities for PSTs to engage in collaborative discussions and analyze student work can lead to improvements in their ability to identify error patterns and provide constructive feedback. In conclusion, the study demonstrates the positive impact of COIL experiences on PSTs' ability to notice and provide feedback on student work in mathematics education. Collaborative learning experiences can enhance PSTs' expertise and contribute to the improvement of mathematics education practices. Teacher education programs should continue to leverage collaborative learning experiences to cultivate PSTs' capacity for evidence-based noticing and responsive feedback.

ELEMENTARY PRESERVICE TEACHER PERCEPTIONS OF USING TECHNOLOGY TO MODEL EQUITY ISSUES

Kristy Litster
Valdosta State University
klitster@valdosta.edu

This research explores the perceptions of 32 elementary preservice teachers (PSTs) in a mathematics methods course when using real-world digital data to design grade 3-5 tasks that elicit mathematical models relating to issues of equity. Specifically, this research explored PSTs choices relating to types of equity issues, types of digital resources, task design to encourage mathematical modeling, and self-reflection on the experience. Results showed PSTs who focused on multicultural topics generally used qualitative digital sources such as images, articles or videos to set a tone or theme for the math tasks rather than encouraging modeling to explore the topic. In contrast, PSTs who explored social justice issues were more likely to support math modeling using quantitative statistical data from online sources. Self-reflections indicated appreciation and awareness of strengths and weaknesses relating to modeling equity issues.

Keywords: Social Justice; Preservice Teacher Education; Modeling; Technology

Elementary mathematics education should reflect the world students live in, to include cultural experiences and issues of social justice (Beard, 2021; Felton-Koesler et al., 2017; Kretz, 2023; Litster et al., 2018; Williams & Roth, 2019; Xenofontos, 2020). Teachers are key to making this happen. However, "while social justice education has been professed, teacher training on social justice education is still not prominent in teacher education programs" (Suriel & Litster, 2022). Thanheiser & Sugimoto (2020) propose that preservice teachers (PSTs) can and should be developing a joint understanding of both mathematical knowledge and social justice issues in the teacher preparation courses to support this effort as PSTs move into their own classrooms. They noted that while most of the PSTs in their courses were able to create meaningful problems that included a social justice focus by the end of their study, only about half provided the source of their data. Without a data source, students may ignore the context or not believe the numbers in the context. Currently, we have a culture of "answer getting" when working with story problems where students are more likely to put on blinders to everything beyond the numbers (Bushart, 2018). An additional problem when working with story problems is the believability of the numbers within the problems themselves. Gary Schulz illustrated this cultural problem in his 1987 Peanuts comic strip when he has Sally note "only in math problems can you buy 60 cantaloupes and no one asks what the hell is wrong with you" (Schulz, 2023). Researchers recommend asking numberless word problems and adding in the numbers later to connect the numbers and the context (e.g., Carle, 2023; Bushart, 2018). Technology can be a great way to add in those numbers and provide a verified data source to extend mathematical understanding to real-world and social justice contexts (Kolb, 2017).

Thus, the purpose of this inquiry was to explore elementary preservice teachers' (PSTs') perceptions of using technology to encourage mathematical modeling to explore various issues of equity.

Theoretical Framework

Mathematical Modeling is the act of using mathematics to answer "big, messy, reality-based questions" (Bliss & Livertini, 2016, p. 7). Modeling real-world tasks can be a powerful tool to help students explore mathematics and issues of equity (Aguirre et al., 2019). This interdisciplinary conjunction of mathematics and other knowledge can help students engage in effective learning opportunities, meet the diverse needs of students, and engage in culture responsiveness (Litster et al., 2023; Williams & Roth, 2019). There are different levels of integration with lower levels focusing on thematic applications to situate the relevance of mathematics within the world and higher levels focusing on authentic applications of mathematics (Litster et al., 2023). Mathematical modeling showcased that authentic application of mathematics to reflect the world students live in.

The number of one-to-one devices in elementary classrooms has been increasing over the past decade, with school closures due to the COVID pandemic exponentially increasing those numbers (Grey & Lewis, 2021). However, an increased use of technology does not always indicate that the technology is being used effectively (Kolb, 2017). Kolb's (2017) Triple E Framework provides one lens for intentional technology use to engage, enhance, and extend student learning. PSTs can use technology to extend student learning for real-world contexts such as multicultural education or social justice issues by accessing real data such as demographics. PSTs can use technology to enhance student learning for these same contexts by using sites that allow students to organize and model real data to explore ideas and contexts.

In their metanalysis of empirical studies utilizing social justice in mathematics education, Xenofontos et al. (2020) found that there is a variety of ways social justice is conceived and what it includes. With so many definitions to choose from, this study chose to utilize Hammond's (2020) Distinctions of Equity framework, which provides a clean and simple framework for PSTs to consider different equity issues and their purposes. In this framework, there are three distinctions of equity: multicultural education focusing on social harmony, social justice focusing on critical consciousness, and culturally responsive education focusing on independent learning. According to this framework, PSTs that wanted to focus on multicultural education could consider tasks that focus on celebrating diversity, creating positive social interactions across differences, or exposing students to other cultures. PSTs that wanted to focus on social justice education could consider tasks that focus on exposing current social or political issues, exploring social or economic inequities, or recognizing historical patterns in society practices.

Methods

This study utilized a three-phase qualitative process (Saldaña, 2013) to analyze perceptions of 32 undergraduate preservice teachers enrolled in a senior mathematics methods teacher preparation course when designing grade 3-5 tasks that elicit mathematical models relating to issues of equity. The specific research questions were:

- What types of equity issues did PSTs choose to explore?
- What types of digital resources did PSTs use to collect or evaluate real world data?
- How did the activity design encourage or discourage mathematical modeling to explore and reason about real-world issues?

- What were preservice teachers' perceptions on their experiences designing and implementing their activity?

Prior to designing their tasks, participants explored examples and non-examples of elementary math modeling (SIAM & COMAP, 2016), purposes of mathematics integration (Litster et al., 2023), and using technology to extend student learning (Kolb, XXXX). Participants also analyzed physical and digital examples of using math to explore multicultural and social justice issues. Finally, participants discussed any societal implications or considerations that should be made when exploring issues of equity in public or private schools. Participants created their task designs within digital slides, using letter dimensions (8.5x 11 in) to allow for easy printing. They were limited to 3 slides for their instructions and worksheets; however, there was no limit to the digital content that could be accessed via links within the instructions or worksheets. The task designs were uploaded to a course discussion board and each participant tested 5 assigned tasks and provided feedback to their peers. Approximately half of the participants chose to implement a variation of their designed tasks with children in local schools in the Southeast region of the United States. Finally, participants reflected on their experience designing, testing, and implementing their tasks.

The researcher collected PSTs' task designs, peer work when testing designs, and reflections. These were qualitatively coded in three phases using structural, process, magnitude, pattern, and thematic coding (Saldana, 2018?). In phase 1, task designs were structurally coded to identify type of equity issues and technology used. In phase 2, peer work was analyzed using process and magnitude coding to identify presence or lack of mathematical models. Task designs were then analyzed using pattern coding to identify features across designs that encouraged or discoursed mathematical modeling. In phase 3, PST self-reflections and peer feedback were analyzed using pattern and thematic coding to identify PSTs' perceptions on strengths and areas of need..

Results

Results relating to RQ1: types of equity issues can be found in Table 1.

Table 1: Types and Categories of Issues Present in PST Task Designs

Multicultural (N= 17, 54 %)	Social Justice (N=11, 34%)	Other (N=4, 12%)
Family Traditions	Income Disparity	Global Warming
Cultural Traditions	Populations Redlining	Weather
Cultural Symbols	Bullying	Air Pollution
Cultural Foods	Women's Suffrage	Animal Shelters
Clothing/Blankets	Black Heroes	

As seen in Table 1, the majority of PSTs (54%) chose to focus on exposing students to multicultural topics such as cultural lifestyles and artistic expressions. About a third of the students focused on present day or historical social justice issues. A small percentage (12%) of students focuses on non-equity issues such as the environment or animals. Results relating to

RQ2: types of technology used can be found in Table 2.

Table 2: Types and Examples of Technology Used in PST Task Designs

Technology Type	Examples
Statistical Data (N= 12, 38%)	Populations, Income, Weather, Temperature, Expenditures, Bullying
Examples & Resources (N=15, 47%)	Images, Blogs, Articles, Videos
Collaboration/ Sharing (N=4, 12%)	Padlet, Google slides/docs, Jamboard
Submit Answers (N=1, 3%)	Google Forms

As seen in Table 2, the majority of PSTs (47%) used technology to access qualitative examples and resources. This is not surprising as these types of technology align to multicultural explorations. The second highest type of technology (38%) was statistical data, which relates well to social justice and environmental issues. Other PSTs used collaborative sites to share simplified data or examples and allow students to set up their mathematical models. One PST used technology to submit answers. Results relating to RQ3:mathematical modeling can be found in Table 3.

Table 3: Math Modeling in Tasks by Equity Types

Modeling in Design	Multicultural (N=17)	Social Justice (N= 11)	Other (N=4)	Total (N=32)
Supported Math Modeling	1 (6%)	9 (82%)	3 (75%)	13 (41%)
Modeling Framework BUT Never Returned to Original Question	1 (6%)	1 (9%)	1 (25%)	3 (9%)
Used Topic as Theme for Math Solutions	15 (86%)	1 (9%)	0 (0%)	16 (50%)

As seen in Table 3, most of the tasks that focused on multicultural issues did not support mathematical modeling (86%). These task designs used the topic as a theme for the math. For example, one PST created story problems with topics from different countries (i.e., pesos in Mexico, sarees in Indiam kimchi in Korea). In another example a PST had students read an article about American Thanksgiving dishes using turkey, potatoes, or pumpkins that were inspired by dishes from around the world. She then asks fractional questions using the article as the theme (e.g., What fraction of the dishes involve turkey?). Most of the tasks that focused on social justice or non-equity issues did support math modeling (82%). For example, one PSTs had students explore population and income statistics for different neighborhoods to explore inequities in redlining. In another example, a PST had students explore the highest priority needs for animal shelters, the cost of those items, and potential ways to fund the purchases (e.g., if everyone donated $1 . .).

Results from the pattern analysis of designs that did support modeling showed that all the designs contained an open-ended original question to explore. For designs that followed with a scaffolded exploration to focus on specific aspects of the data, the last question repeated the original open-ended question. Designs also contained two or more of the following features: social justice or environmental topic, mathematics topic focused on operations or comparisons, used real-time statistical data from various websites or videos, used a collaboration site that required students to show and justify their work using words, numbers, and/or pictures.

Results relating to Q4: PST perception on their experience identified three themes: perceived benefits of this assignment, perceived areas of need when working with equity topics, and perceived areas of need when working with technology. One common benefit PSTs noted from designing and implementing their tasks or testing the tasks for their peers was that they enjoyed being exposed to different cultures, past issues of equity, and current issues of equity they were not familiar with. They enjoyed learning something new in addition to the math. Several PSTs built upon this idea and noted that trying out their peers' tasks helped them revise some misconceptions they previously had about various cultures or events. PSTs noted that they appreciated knowing the information was real, not something the textbook made up. Other PSTs liked the change of pace from "traditional learning." Several of the PSTs who tried out variations of their tasks with K-5 students also noted that their students had these same perceptions of enjoyment from the change of pace, learning new ideas, and using real applications of the math. Many PSTs liked how they were able to use evidence from student work (peers and K-5 students) to see students think critically about different topics and the mathematics associated with those topics. Similarly, PSTs who tried out a task that utilized a collaborative site appreciated how they were able to see the critical thinking and models of that other people created using the same data in different ways.

There were six areas of need that PSTs perceived are essential when designing and implementing tasks relating to multicultural or social justice issues. First, students may need more time to fully explore the topic. Second, students may need scaffolds such as a time limit or worksheet so they don't get too distracted learning about the topic that they never use any math during the lesson. Third, don't assume students understand their own culture. Many PSTs were surprised at issues within their own city, state, or country. Other PSTs were surprised that their peers or students couldn't think of any cultural symbols, traditions, or foods in their family. Fourth, PSTs noted that tasks that were more open engaged students in choices about what they wanted to explore and how to explore it. They found that closed tasks seemed to just focus on the math numbers or shapes. When working with these tasks, they had a hard time identifying what issue of equity the task was trying to explore. Fifth, building on the fourth idea, PSTs recommended that tasks exploring equity issues should use questions and follow-up questions to ensure students are making connections between the math and the equity issue. Many PSTs who did not do this in their initial task reflected that this was something they wish they had added, or in the case of those who taught a variation of their task, was something they changed before trying the task with K-5 students. Sixth, PSTs noted that you should not try to force a math and equity connection. They perceived that not all math works well to explore issues of equity and not all issues of equity are best explored using math.

There were six areas of need that PSTs perceived are essential when working with technology. First, students need clear directions on how to use or navigate the sites. Building on this idea, the second perception is that for complex websites, teachers may need to pull the data from the site and reformat it on a single page for use by younger students, students who struggle with the technology, or students who get easily distracted or overwhelmed. Third, when using collaborative websites, teachers must ensure open access for all participants. Fourth, you may need more that one digital resource to fully explore a topic of issue. Fifth, teachers need to ensure their students understand how to use basic technology features such as copying and pasting, taking a screenshot, using digital drawing tools, font sizes on text boxes, inserting information into a table, creating a graph, resizing shapes, etc. This perception came from both their own experiences trying out tasks as well as seeing what their peers tried or avoided within their own tasks. Building on ensuring digital fluency, the sixth perception was that students may skip an aspect of the task they don't want to do or don't know how to do easily with the technology.

Discussion and Implications

In summary, PSTs who designed tasks to explore multicultural issues of equity were more likely to use qualitative resources such as images and articles to learn more about the culture. They were also more likely to use the topic as a theme without explicitly connecting the cultural aspects to the mathematics, which may explain by most of these task designs did not support mathematical modeling. In contrast, PSTs who designed tasks to explore social justice or environmental issues were more likely to use quantitative statistical data using operations or comparisons to make judgments on inequalities. These task designs were more likely to support mathematical modeling. Regardless of whether PSTs felt their own task design was successful or not, they were able to identify several key ideas relating to benefits of having students create mathematical models to explore multicultural and social justice issues and areas of need when exploring issues of equity or using technology.

PSTs perceptions of benefits and areas of need directly impact teachers who may wish to explore issues of equity in their classrooms or use technology to support mathematical modeling of real data. They may also impact MTEs who want to help PSTs incorporate modeling, technology or equity issues into their math lessons. Teachers may want to start with a multicultural or social justice questions – what they want students to learn about or explore. This can help guide their task design to ensure focus on the topic. They should also examine the topic to determine the inherent mathematics already embedded within their question (comparisons, operations, whole numbers vs decimals, etc.). Doing this can help them determine whether the math can be used to model the issue for an authentic application of the math or whether the topic better situates the relevance of the mathematics within the real world (Litster et al., 2023). For authentic situations, teachers may want to focus on using models and justifications to support their response to an open-ended question. For relevant situations, teachers may want to apply a sequential approach by focusing on one area and then the other, making connections as you go or at the end of the project.

THE INFLUENCE OF PEERS' THINKING ON PRESERVICE ELEMENTARY TEACHERS' ENGAGEMENT WITH OPEN MATHEMATICS TASKS

Emily A. Mainzer
York College of Pennsylvania
emainzer@ycp.edu

Andrea McCloskey
Pennsylvania State University
avm11@psu.edu

This brief report describes preservice elementary teachers' self-reports of the influence of peers' thinking on their engagement in four mathematics tasks of varying openness. This report draws from a larger study that—in an effort to research certain types of mathematical tasks that are widely used but have not been systematically researched—investigated factors that were influential to preservice teachers' engagement. In the larger context of this study, peers' thinking was an unexpectedly strong and consistent influence on engagement. Preservice teachers' self-reports led to findings that peers' thinking enhanced their cognitive and affective engagement in the tasks. The ways peers' thinking was influential seemed to be related to the relative openness of each task. During discussion of the most open tasks, preservice teachers were more likely to report 1) that peers' thinking inspired them towards further cognitive engagement and 2) stronger affective reactions to peers' thinking.

Keywords: Instructional Activities and Practices; Affect, Emotion, Beliefs, and Attitudes; Preservice Teacher Education

Certain types of mathematics tasks have recently become popular with mathematics teachers and others in the mathematics education field. These educators offer considerable anecdotal evidence of the tasks' positive impact on learners' engagement—and related research suggests the tasks' value—but the tasks and their impacts have not been thoroughly and systematically researched. Our larger study sought to cast light on this Black Hole of research (Matney et al., 2020) by investigating preservice elementary teachers' (PSTs) engagement in "Which One Doesn't Belong?" (WODB, Danielson, 2016), "Notice and Wonder" (N&W, Fetter, 2021; Ray-Riek, 2013) and "How Many?" (HM, Danielson, 2018) tasks. The novelty of these tasks seems to be that they are open to a considerable degree, meaning that learners have a wide range of choices in terms of how they respond to the tasks. Practitioners report that when discussing these tasks with their learners, they notice increased engagement and from a wide range of students (Danielson, 2016; 2018; Illustrative Mathematics, 2021; Newell & Orton, 2019; Ray-Riek; Rumack & Huinker, 2019).

When studying PSTs' engagement in four tasks of varying openness, we asked the questions: 1) "How do elementary PSTs engage with open mathematics tasks?" and 2) "What factors influence PSTs' engagement with open mathematics tasks?" We expected that the PSTs in our study would engage similarly to K-12 students, and that openness would play a significant role in eliciting that engagement. We found that PSTs did engage in a manner similar to that described of K-12 students and the openness of the tasks was a crucial factor in PSTs' engagement. However, being able to hear and interact with peers' thinking as a result of the tasks' openness was also consistently a strong influence. In this brief report, we focus on this unexpectedly strong influence.

Theoretical and Conceptual Framework

In focusing on peers' thinking as one influence amidst a multitude of influences on learners' engagement, we consider the classroom as an activity system (Engeström, 2015) that includes teachers, learners, materials, the physical environment, and their interaction (e.g., Gresalfi et al., 2009). This perspective emphasizes "what someone does in a particular activity is always done in relation to what one has opportunities to do" (Hand & Gresalfi, 2015, p. 191). Peers' ideas affect what one has opportunities to do during mathematical activity, which in turn shapes what one does during the activity.

Understanding the classroom as an activity system is congruent with Middleton et al.'s (2017) conceptualization of mathematical engagement. They considered engagement to be "in-the-moment relationship between someone and her immediate environment, including the tasks, internal states, and others with whom she interacts" (p. 667). The conceptualization includes behavioral, cognitive, and affective dimensions. At PME-NA 45, Middleton (2023) shared that he is increasingly understanding engagement to also consist of a social dimension, as during mathematical activity, "learners play off their peers, reacting to and modifying behavior to support each other and to get value added from the collaboration" (p. 7). The role of peers' thinking connects to a social dimension of engagement.

The larger study investigated PSTs' engagement in mathematical tasks of varying degrees and types of openness. While this brief report focuses on the influence of peers' thinking within that research setting, the ideas shared by peers were shaped by the space created by the openness of the tasks. We regard openness as having three dimensions (see Figure 1). The first two dimensions clarify the 'open-start' dimension of previous frameworks (e.g., Leikin, 2018; Mitchell & Carbone, 2011; Pehkonen, 1997; Silver, 1995) by distinguishing between ways to enter or focus the task (entry points) and the strategy or method to use when engaging with the task (strategies). The third dimension of openness addresses the number of possible endpoints (solutions) of a task. Our framework also incorporates the degrees along which tasks can be open as suggested by Mitchell and Carbone (2011).

Methods

The study from which this data was drawn was conducted across two semesters at a large Mid-Atlantic university in four sections of an elementary mathematics methods course for undergraduate PSTs. All sections were taught by the same instructor. For each task, we identified a section (n=16, 17, 23, 10) whose engagement with the task was generally representative of the other three sections' engagement with the same task. Our overall methodological approach was pragmatic (e.g., Coyle, 2010; Frost & Nolas, 2011; Morgan, 2007) drawing on ethnography's (Macgilchrist & Van Hout, 2011) emphasis on participant voice, case study's (Merriam, 1998) thorough investigation of a clearly defined phenomenon and grounded theory's (Glaser & Strauss, 1967) principle of being data-driven.

Tasks

In collaboration with the course instructor, we chose four tasks of varying openness for PSTs to engage with and discuss. We describe them here in order of relative overall openness. The first task was a word problem (WP) of high cognitive demand (Smith & Stein, 1998) that asked PSTs to find the number of cupcakes and boxes a baker used given parameters for number of boxes, number of cupcakes, and number of cupcakes that could fit in each box. The WP allowed for multiple strategies and had one correct answer. The purpose of including the WP was to provide a comparison to the tasks that had a wide range of possible answers. The second task was a WODB that presented four addition expressions, each of which had multiple reasons it might not belong with the others. The third task was an HM task. PSTs were presented with an image of a large box of chalk and were directed to choose something to count in the image and to choose how to count it. The fourth task was a N&W, in which PSTs were asked to share what they noticed and wondered about three packages of toilet paper that all advertised larger rolls. The relative openness of each task along three dimensions is depicted in Figure 1.

Data Collection and Analysis

I observed each task session in person. During each session, the instructor introduced the task, the PSTs worked independently on the task, and the instructor facilitated a whole-group discussion of the task. Following each session, PSTs completed a semi-structured questionnaire that asked them questions about their engagement with and experience of the tasks. For example, PSTs answered questions such as, “Describe the strategies you used during the task and discussion,” “Describe any emotions you were feeling while work on the task and during the class discussion,” and “Was the way you thought and felt during this task similar of different from when you have engaged with math in the past? Please explain.” Questions varied slightly on between task sessions based on PSTs’ responses to previous questionnaires.

Entry Points		Strategies		Solutions	
	One entry point		One strategy	WP	One solution
WP HM WODB	Multiple but limited entry points	WP	Multiple but limited strategies		Multiple but limited solutions
N&W	Unbounded entry points	HM WODB N&W	Unbounded strategies	WODB HM N&W	Unbounded solutions

Figure 1: Relative Openness of the Four Tasks Along Three Dimensions

This brief report focuses on data collected from PSTs’ questionnaire responses. We inductively coded PSTs’ questionnaire responses for influences on their engagement using a constant comparative approach (Glaser & Strauss, 1967). When an influence appeared in multiple PSTs’ responses for a task, we included it in our findings. For example, if a PST mentioned being excited by the possibility of multiple answers, we coded that mention as evidence for the influence of the task’s openness. If a PST described finding others’ ideas interesting, we coded that description as evidence of the influence of peers’ thinking.

Findings

Peers’ thinking emerged as an influence on PSTs’ engagement across all four tasks. Table 1 shows the percentage of PSTs for each task session whose questionnaires provided evidence of being influenced by their peers’ thinking. This theme was most present in PSTs’ responses to the HM and N&W questionnaires. The theme was also present in more than half of PSTs’ responses to the WODB questionnaire. The theme was present, but less so, in the WP questionnaire responses. Across all four task sessions, peers' thinking was largely a positive influence. The main task session in which peers' thinking had a negative influence was the WODB.

Table 1: Self-Reported Influence of Peers' Thinking Across Tasks

	WP (n=16)	HM (n=17)	WODB (n=23)	N&W (n=10)
Influence Overall	38%	94%	57%	70%
Positive Influence	38%	88%	57%	70%
Negative Influence	0%	6%	17%	0%

The positive influence of peers' thinking generally fell into two categories: appreciation of peers' thinking and peers' thinking motivating further engagement with the task. Table 2 lists the percentage of PSTs who expressed the influence of their peers' thinking in these ways.

Table 2: Self-Reported Positive Influence of Peers' Thinking Across Tasks

	WP (n=16)	HM (n=17)	WODB (n=23)	N&W (n=10)
Appreciation	38%	82%	57%	40%
Further Engagement	6%	18%	39%	40%

When PSTs demonstrated appreciation of peers' thinking, they made statements such as it was "cool to see other ways that people were solving the same problem as me" (Carly, WP) or "I enjoyed seeing how different peers chose different things and ways to count" (Rachel, HM). Evidence of peers' thinking spurring further engagement in the task included responses such as, "[I] was adapting my thinking to others to make sense of things" (Lila, WODB) and "I was constantly looking at the images when people were making notices and wonders to see if I could build off of that in any way" (Andrew, N&W). PSTs were most likely to go beyond appreciation and report peers' thinking as spurring further engagement on the WODB and N&W questionnaires.

An interesting phenomenon that occurred in the responses that expressed appreciation was that one or more PSTs in each of the most open tasks (HM, WODB, and N&W) described their reaction to peers' thinking with unusual intensity. In PSTs' responses to the WP, they described their reactions with words such as "liked," and "interesting." While PSTs also used similar terms in their descriptions of the influence of peers' thinking for the other three task sessions, some PSTs also used words like "amazed," "surprised" and "fascinated." For example, Becca reported feeling "very much in awe" during the WODB task session because "there were so many new ways that other people were coming up with that I… did not see before." During the N&W task session, Liz was "fascinated at how [her] other classmates were really digging deeply into what they noticed and wondered." Lily was "floored" by the creative responses her peers shared during the HM task session.

The main negative influence across any tasks had to do with ways PSTs were influenced by peers' thinking during the WODB task session. This influence involved additional categories that did not occur in PSTs' responses to the other task session questionnaires: being either encouraged or discouraged when comparing their own ideas to peers' thinking. Two PSTs (9% of 23 PSTs) mentioned being encouraged by peers' thinking, particularly in hearing ideas that made them realize their own ideas were valid. Four PSTs (17%) felt discouraged at some point by peers' thinking. Katherine shared that she "did feel a little bit less smart…for focusing on the surface level differences… while my classmates were discussing sums and multiples and patterns." Mae had a similar experience, explaining she "felt like [her] thinking was…not thorough enough" and that she was "trying to keep up… because [she] wasn't seeing these number sentences like a lot of [her] peers did." Notably, all four of these PSTs also described being positively influenced by their peers' thinking at some point in the discussion.

Discussion and Implications

The influence of peers' thinking is an especially striking result as the questionnaire did not directly ask PSTs about peers' thinking. Being asked questions about their engagement with the task and discussion prompted PSTs to bring up their thoughts and feelings about others' ideas. This phenomenon underscores how central hearing peers' thinking was to PSTs' experiences. The openness of the tasks seemed to work in tandem with the influence of peers' thinking, as PSTs were more likely to report the influence of peers' thinking after engaging in discussion of the most open tasks. In the most open tasks, PSTs were also more likely to use more intense affective language to describe peers' thinking and were more likely to report going beyond merely appreciating peers' thinking to being spurred to further engagement.

This brief report pinpoints an aspect of the use of open mathematics tasks that influences engagement. Hearing peers' responses may be a key factor in open mathematics tasks eliciting the kinds of engagement that practitioners purport they elicit. In this case, it is crucial to prioritize discussion as part of the facilitation of these tasks. The significant impact of peers' thinking in this study also supports further exploration of the social dimension of engagement, particularly in terms of PSTs' engagement with one another's ideas. Ultimately, we as mathematics teacher educators want our PSTs to not only experience joy and fascination as a result of others' mathematical engagement, but to feel drawn to be part of that mathematically vital experience themselves.

FINDING PERSEVERANCE IN EGYPTIAN FRACTIONS

J. P. Mannix
Ball State University
jpmannix@bsu.edu

Christopher Austin
Ball State University
christopher.austin@bsu.edu

Keywords: Preservice Teacher Education; Rational Numbers & Proportional Reasoning

Students of all ages, including many adults, have long complained about fractions. The mere structure and definition of fractions have baffled students and caused them to doubt their mathematical abilities for generations, as evidenced by the focus on rational numbers in various guiding documents (e.g., AMTE, 2020; NGA, 2010; NRC & MLSC, 2001) and myriad studies centered on students' ability to reason with rational numbers (e.g., Davis, 2003; Heller et al., 1990; Thompson & Saldanha, 2003). Additionally, perseverance has played a prominent role in mathematics education, so much so that the first Standard for Mathematical Practice, as outlined by the Common Core State Standards (NGA, 2010), encourages students to "make sense of problems and persevere in solving them" (SMP.1). However, perseverance is not a trait that humans are born with; it is a behavior that is developed over time, under the right conditions, and when provided with proper tools (Middleton et al., 2015). Middleton and colleagues outline four core aspects of perseverance: (1) interests and identity; (2) setting goals; (3) utilizing resources; and (4) anticipating consequences.

Early in a math course for elementary education majors taught by the authors, students solve contextualized (e.g., brownies) equal sharing problems involving Egyptian fractions. In class, students work in small groups to find a solution, and report the amount of a share each person will get in the form of an Egyptian fraction. As homework, students are asked to solve two similar problems and find at least two distinct solutions then answer several reflection questions about their experience solving the problems.

There were 91 students enrolled in this course in the Spring 2024 semester, 86 of whom submitted the assigned problems and reflection. After reviewing the submissions and giving students grades and feedback, we compiled the student responses and coded the submissions for common themes based on the four aspects of perseverance outlined by Middleton and colleagues (2015). Though analysis is ongoing, we have found student responses that align with each of the aspects of perseverance. Some responses have discussed how students' identities (Aspect 1) *prevented* them from persevering. Most of these responses center on students not feeling like so-called "math people" and getting stuck after trying one approach. Some students cited a goal (Aspect 2) of getting the job done as their reason for persevering, while others stated that they were motivated by consequences (Aspect 4), like bad grades, if they didn't finish. Finally, several students cited different resources (Aspect 3) they used to finish the task, including referring to previous examples or asking friends for help.

The reflections analyzed in this study have already revealed evidence for each of the four core aspects of perseverance when working on a task involving Egyptian fractions. These findings indicate that problem-solving tasks that challenge students to think outside of their comfort zone, like the Egyptian fraction problems, can be beneficial in many ways. Not only can they help students explore mathematical concepts more deeply, but they can also provide a site for students to reflect on their experiences in ways that point them to productive pathways towards perseverance. Based on the findings in this report, we anticipate future studies will focus on how other activities in this course provide opportunities for students to persevere.

Quantitative reasoning's emergence as a foundation for students' mathematical development has generated a need for supporting teachers' capacity to teach for such reasoning. In this paper, we discuss a meanings perspective on working with prospective and practicing teachers in order to support their constructing meanings that foreground quantitative reasoning. Our meanings perspective, referred to as competing meanings, involves a problematization of extant meanings, the construction of alternative meanings, and a critical comparison of each. Here, we present our perspective and informing theories. We also draw on our empirical work to provide tangible and research-based examples of our competing meanings perspective.

Keywords: Cognition, Preservice Teacher Education, Teacher Knowledge, Learning Theory.

Students' quantitative reasoning refers to the ways in which students conceive of and reason with measurable attributes constituting some phenomenon or context (Smith III & Thompson, 2007; Thompson, 2011; Thompson & Carlson, 2017). Addressing number concepts, fractional reasoning, proportional reasoning, algebraic reasoning, rate of change concepts, and function concepts (e.g., Karagöz Akar et al., 2022; Steffe & Olive, 2010; Thompson & Carlson, 2017), researchers have identified quantitative reasoning as a bedrock for students' mathematical development. These same researchers have highlighted that the various factors influencing students' educational experiences do not sufficiently engender or support students' quantitative reasoning. Whether with respect to improved curricular materials, continued knowledge development, or targeted pedagogical practices, a pressing need is better understanding how to prepare teachers in supporting their students' quantitative reasoning.

Over the past decade-plus we have engaged in a research program to understand not only students' quantitative reasoning, but also that of prospective and practicing teachers. Our primary research emphasis has been understanding the relationship between teachers' mathematical meanings and their quantitative reasoning, including how to engender teachers' quantitative reasoning so that it might be leveraged to support shifts in their meanings. We have specifically sought to support shifts reflecting those meanings identified by researchers as critical for K-16 students' mathematics. We report on a perspective for supporting such shifts in this paper.

We term our perspective *competing meanings* due to its simultaneous focus on teachers' extant meanings, the meanings we seek to engender and center when working with teachers, and interactions between those meanings we seek to provoke. In what follows, we first provide background theory that informs our perspective including Piaget's epistemology (Piaget, 2001), Thompson's theory of meaning and quantitative reasoning (Thompson, 2016; Thompson & Carlson, 2017), and Harel's notion of intellectual need (Harel, 2013). Drawing on those informing theories, we outline the perspective of competing meanings as it relates to working with teachers, whether prospective or practicing. We support an operational approach to competing meanings by also providing a tangible example of it, both in the context of task design and research participant themes. We close with potential implications and future work by drawing specific attention to areas of theory left to flesh out or connect with.

Informing Theory and Background

Our perspective is informed by Piaget's genetic epistemology, including von Glasersfeld's (1995) extension of it. We focus here on the constructs of *assimilation*, *perturbation, accommodation*, and *equilibration*, and we point the reader to Dawkins et al. (2024) for an extensive collection of Piaget's theory in mathematics education. Assimilation is the process by which an individual conceives a present experience via their current conceptual structures (von Glasersfeld, 1995). It is a constructive process that shapes an experience so that it affords and is constituted by those structures. In some cases, assimilation to extant conceptual structures results in an unexpected experience, which engenders a state of perturbation (von Glasersfeld, 1995). A perturbation can stem from several causes. For one, an individual might obtain an unexpected result after enacting a conceptual structure, thus yielding a sense of perplexity. As another example, in enacting a conceptual structure, an individual might become aware of some experiential feature that leads to their questioning the efficacy or relevance of that structure.

Having experienced a perturbation, an individual engages in activity to reconcile that cognitive state. One form of reconciling a perturbation involves affective and coping responses, such as anxiety leading to disengagement (Tallman & Uscanga, 2020). Another form of reconciliation is that of accommodation, which can take on several forms. To name a few, the conceptual structure used in assimilation could be modified, an alternative conceptual structure could be enacted, or a novel conceptual structure could be constructed (von Glasersfeld, 1995). Regardless, accommodation is an act of learning via the elimination of a perturbation through a cognitive construction or reorganization. It often entails sustained, and effortful, cognitive engagement. Piaget hence referred to the process of accommodation as one of equilibration that establishes a cognitive state of equilibrium (von Glasersfeld, 1995).

In service of operationalizing the aforementioned Piagetian constructs, Thompson introduced the intertwined theories of quantitative reasoning (Thompson, 2011) and meaning (Thompson, 2016). With respect to the latter, Thompson's (2016) theory of meaning is rooted in Piaget's genetic epistemology and refers to an organization of operations, images, and other meanings. As it relates to the act of teaching, Thompson's theory of meaning is connected to that of Silverman and Thompson (2008), who outlined a developmental process that spans the construction of personalized knowledge to the transformation of that knowledge to incorporate student meanings and pedagogical implications. That is, Silverman and Thompson recognized the importance of teachers' mathematical meanings including teachers' construction of *key developmental understandings*, which are understandings critical to the development of coherent and generative mathematical concepts (Simon, 2006). Before using Thompson's theory of quantitative reasoning to further illustrate this perspective, we note that the perspective emphasizes mathematical knowledge as a dynamic, in-the-moment implicative base of *knowing* for action, as opposed to a static, declarative base of *knowledge* for action (Liang, 2021; Thompson, 2016).

Thompson's (2011, 2012) theory of quantitative reasoning provides one framework for situating Piaget's genetic epistemology, meaning, and key developmental understandings. *Quantitative reasoning* is reasoning that involves conceiving situations in terms of measurable attributes (i.e., quantities) and relationships between those attributes (i.e., quantitative relationships). Quantitative relationships form the basis for the construction and abstraction of mathematical objects (Moore et al., 2022; Smith III & Thompson, 2007). *Covariational reasoning* is a particular form of quantitative reasoning that involves constructing and coordinating quantities that vary in tandem (Carlson et al., 2002; Saldanha & Thompson, 1998; Thompson & Carlson, 2017). A growing number of researchers have identified important nuances in student and teacher thinking in this area (see Karagöz Akar et al., 2022 for a collection of contributions and researchers). Using the framework by Carlson et al. (2002), one meaning entailing covariational reasoning involves assimilating a situation via *directional* and *amounts of change* relationships. For instance, Ellis et al. (2015) explored students' meanings for exponential relationships in the situation of (magic) plant growth and the quantities height and time. The students' meanings involved their constructing the directional covariation of quantities (e.g., as time increases, height increases), and coordinating additive changes in one quantity with multiplicative changes in the other (e.g., as time increases additively, height increases by increasing amounts while preserving a constant ratio for a constant time period). Here, the operations constituting the meaning for exponential relationships involve conceiving the variation in each quantity, coordinating those two variations to construct and compare changes in each, and considering how the constructed covariational relationship is relevant to different contexts (e.g., a growing plant, a Cartesian graph, or a table).

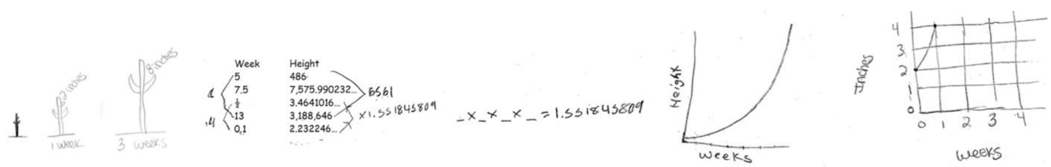

Figure 1: Students' coordinating height and time (Ellis et al., 2015, pp. 143, 147, and 149)

Our work is also informed by Harel's (2013) *intellectual need*. We use intellectual need to clarify the perturbations targeted by our competing meanings perspective. Harel defined intellectual need as "a perturbational state resulting from an individual's encounter with a situation that is incompatible with, or presents a problem that is unsolvable by, his or her current knowledge" (2013, p. 122). Importantly, Harel's intellectual need refers to a state of perturbation that affords learning, and is thus not merely a state of confusion. A researcher is positioned to claim an individual has experienced an intellectual need when the meanings needed to reconcile an experienced perturbation are within the individual's zone of proximal development, whether that development be in the context of reasoning or domain practices (Harel, 2013; Weinberg et al., 2023). With respect to the work here, intellectual need orients us toward not only seeking to engender perturbations, but also having in mind the ways in which teachers' available reasoning can act as an asset in reconciling that perturbation. Furthermore, intellectual need draws our attention to forms of perturbations that promote their reflective comparison of meanings that caused the perturbations and those that reconciled those perturbations.

In summary, Piaget's and von Glasersfeld's framings of knowing provide us guiding cognitive mechanisms. Thompson's perspective on meaning, with Silverman, Thompson, and Simon's descriptions of how meanings inform teaching, further clarify our attention to the ways an individual's personal meanings may be organized and transformed so that they are generative and flexible during the act of teaching. Theories of quantitative and covariational reasoning provide us concrete constructs by which to specify and differentiate mathematical meanings. Lastly, Harel's notion of intellectual need aids us in clarifying the type of perturbations we seek to engender with teachers. Namely, we focus on perturbations that necessitate the enactment of alternative meanings to reconcile them (i.e., equilibration via accommodation). Furthermore, we focus on the transformative learning experiences that occur when a process of equilibration is accompanied by a subsequent perturbation that motivates reflectively comparing meanings.

Competing Meanings

Our competing meanings perspective identifies one form of learning via particular forms of intellectual need and, hence, perturbation and accommodation. Stated generally, the competing meanings perspective includes an individual experiencing a problematized extant meaning; enacting an alternative meaning; and, through additional processes of perturbation and accommodation, comparing the extant meaning and alternative meaning (Figure 2).

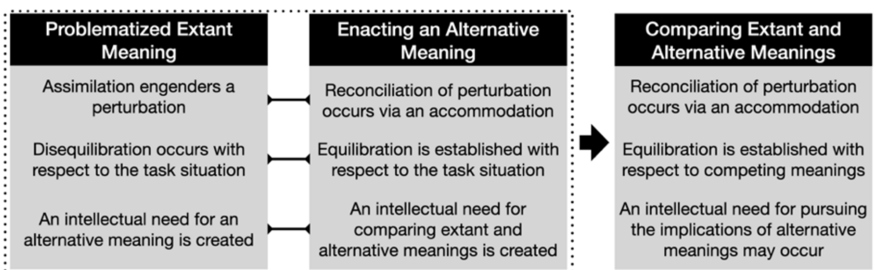

Figure 2: The competing meanings perspective

A problematized extant meaning first occurs via an act of assimilation that engenders a perturbation and an intellectual need for an alternative meaning. Then, via enacting that alternative meaning, the individual reconciles their perturbation with respect to the task situation associated with the initial perturbation. Critical to the competing meanings perspective is that a subsequent state of perturbation then occurs. Whereas the initial intellectual need was respect to the goal-oriented activity of the task, a subsequent round of intellectual need is created at the level of meanings; the individual becomes perplexed as to why their extant meaning results in a perturbation while the alternative meaning does not. The disparate nature of the meanings is thus at the root of the perturbation and associated intellectual need. By disparate, we mean that, *in that moment*, the individual infers that their two held meanings entail important differences and incompatibilities that are not trivial to resolve. This perplexity positions the individual to take each meaning as an object of thought and hold them against each other (i.e., competing meanings) in order to reconcile that perturbation. Yet an additional intellectual need might result from this process, motivating the individual to explore the implications of that reconciliation, particularly if the alternative meaning is novel and viewed as a potentially more productive meaning. We return to this point in the closing of the paper.

To situate and illustrate the perspective, we start with an abstract and abridged example. Consider a hypothetical student or teacher, who we name Blinder. For a particular concept, Blinder has constructed a meaning that we denote by M_a (we remind the reader that a meaning might be composed by a system of meanings), which has served as productive throughout his schooling experience. Entering our class or professional development, we might intend, for a variety of reasons, that Blinder construct an alternative meaning. We denote this alternative meaning by M_b. In working with Blinder, we determine that he holds meaning M_a and that meaning M_a and M_b are disparate; M_a is not a foundational way of thinking for M_b and, in fact, can inhibit the construction of and ability to teach for M_b. This raises the question: how do we engage with Blinder in a way that honors M_a and affords constructing M_b? This is a situation we have been presented with frequently in research, teaching, and professional development settings with students and teachers (e.g., Moore, Stevens, et al., 2019; Tasova, 2021).

Using Linearity to Illustrate the Competing Meanings Perspective

Consider linear relationships as an example topic to contextualize the abstract presentation above. Our work has adopted a quantitative reasoning perspective to center a meaning for linear relationships that involves constructing a constant rate of change. A constant rate of change between two quantities means that as the quantities' magnitudes covary, their amounts of change exist in a proportional relationship. For any arbitrary change x (e.g., Δx), y changes by a scaler factor m of that change (e.g., $m \cdot \Delta x$). If that arbitrary Δx is then scaled by a factor c, the change in y is scaled by the same factor, yielding a corresponding change in y of $c \cdot m \cdot \Delta x$. This is a critical and productive meaning (i.e., M_b), yet our and others' work with teachers and students suggest that this is not always a typical meaning (Byerley & Thompson, 2017; Lobato et al., 2003; Moore, Silverman, et al., 2019; Thompson & Thompson, 1996; Zaslavsky et al., 2002).

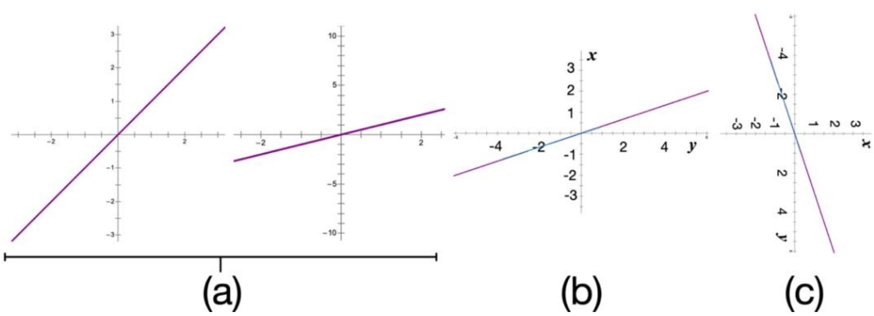

Figure 3: (a) Two graphs of $y = x$ and (b-c) two graphs of $y = 3x$.

A common extant meaning (i.e., M_a) for linear relationships is shaped-based (Ellis & Grinstead, 2008; Moore, 2021; Moore, Stevens, et al., 2019; Nagle & Moore-Russo, 2013; Zaslavsky et al., 2002), which entails reasoning about linear relationships in terms of properties of slope like movement and direction in association with learned formulas (e.g., $(y_2 - y_1)/(x_2 - x_1)$). These associations are forms of declarative knowledge, as opposed to symbolizing abstracted covariational relationships. An example of this is an individual comparing the visual

Kosko, K. W., Caniglia, J., Courtney, S., Zolfaghari, M., & Morris, G. A., (2024). *Proceedings of the forty-sixth annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Kent State University.

steepness of two lines to conclude the former has a greater rate of change than the latter (Figure 3a). As another example of this meaning, an individual could conceive Figure 3b as having an incorrect rise-and-run and Figure 3c as a negative slope or rate of change because of its downward, left-to-right direction (Moore, Silverman, et al., 2019; Moore, Stevens, et al., 2019).

Returning to the question raised above, in working with individuals holding a shape-based meaning, M_a, as their dominant meaning, we intend to both honor those shape-based meanings while determining how to support their constructing a rate of change meaning, M_b. Our goal is also to support their constructing M_b so that it becomes a meaning they view as important and productive (for them and their students), and more so than that of the shape-based meaning. Before describing an approach that draws on the competing meanings perspective, we recognize one way to support M_b is to use tasks in which M_a is not relevant, but M_b is. Similarly, one might use tasks that target M_b through focused, closed-ended questions and design. In our experience, such tasks are useful to engender M_b and possibly draw connections with M_a. Yet, such tasks can be so contrived as to feel too disjoint from the classroom for teachers. Relatedly, those tasks do not problematize M_a and generate an intellectual need for M_b so that the latter becomes their predominant or habitual meaning. With respect to teachers, for the tasks they envision teaching, M_a remains just as relevant, is more familiar or habitual, and is often more cognitively efficient. Our solution to this issue is to use tasks that not only afford or target M_b, but also draw the meanings M_a and M_b into competition with each other. Doing so requires that the task is designed so that M_a is still relevant to the task. Furthermore, we intend the enactment of M_a to lead to a conclusion that not only invites further thought, but that also stands in opposition to the conclusion derived from enacting M_b. This underscores the competing aspect of competing meanings. The initial perturbation should not leave the teacher viewing M_a as entirely problematic or unrelated, as it is through viewing M_a as still relevant despite some perturbation that the individual is positioned to compare its viability against that of M_b.

We use the graph in Figure 3b to illustrate how we have attempted to target the cognitive process in Figure 2 and draw meanings into competition with each other in the context of linear relationships. When working with teachers, we present this task in two parts. We first provide the graph as illustrated in Figure 3b, but *without* the axes-labels "*x*" and "*y*". We explain that a student provided the graph (without labels) as a solution to graphing "$y = 3x$", and we ask them to consider how the student might have been thinking. After the teacher has exhausted the number of ways they can hypothesize as to how the student might have been thinking (see Moore, Silverman, et al., 2019 for examples), we then provide Figure 3b with "*x*" and "*y*". We explain that the student added the labels to clarify their solution. We ask the teacher to comment on the graph, and we conclude the task asking how they would respond to the student as their teacher. We note that Figure 3c is created by most teachers when making sense of the solution due to their rotating the graph to horizontally orient *x*. If the teacher does not rotate the graph, we rotate the graph and ask them to consider it in that orientation, as well.

The task incorporates the competing meanings perspective by using the following principles: (a) it sensibly affords assimilation to M_a and M_b; (b) in the event that M_a is enacted, it is likely to result in a perturbation, but still be viewed as relevant to the task; (c) in the event that M_a engenders a perturbation, M_b is likely available to the student or within their zone of proximal development; (d) the enactment of M_b can reconcile a perturbation stemming from M_a; (e) the teacher has the opportunity to reflectively compare the affordances and constraints of M_a and M_b;

and, critically, (f) the teacher is likely to perceive the task, M_a, and M_b as relevant to their instruction. Relating these task features to the cognitive account in Figure 2, (a) and (b) occasion problematizing an extant meaning; (a), (c), and (d) relate to accommodation via the enactment of an alternative meaning; and (b), (d), (e), and (f) support reflecting on and comparing extant and alternative meanings. Furthermore, the task embodies the *competing* aspect of competing meanings by using a situation in which M_a and M_b yield sensible, yet different conclusions. Enacted as is, M_a results in classifying the solution and its rotated version (Figure 3c) as inaccurate representations of $y = 3x$ (e.g., the "slope" is wrong in Figure 3b and 3c), while M_b affords accepting both as accurate (e.g., each is the set of points so that y is three times as large as x and for any change in x, y changes by three times that amount). This in-the-moment incompatibility aids comparing the generativity and generalizability of each meaning including weighing which is better viewed as derivative of the other (e.g., slope as an implication of rate of change is more generative and generalizable than rate of change as an implication of slope).

Data Illustrations

Although this is chiefly a theoretical report focused on a particular form of learning and cognitive activity, it represents generalizations from a collection of empirical studies with students and teachers. The studies and their methodologies entailed semi-structured clinical interviews (Ginsburg, 1997) and various forms of teaching experiments (Steffe & Thompson, 2000), and are summarized in Moore et al. (2022) and Moore et al. (2024). Here, we draw from our empirical data with prospective teachers working the aforementioned task.

We use Table 1 to provide emblematic examples of each competing meanings component presented in Figure 2. Due to space constraints, we use quotes and only a brief narrative situating those quotes. We point the reader to our work referenced above for more detailed narratives of the students' actions and meanings. With respect to a problematized extant meaning, the example quote is from a participant, Lizzie, who conceived Figure 3b as having a "positive slope" and Figure 3c as having a "negative slope" due to their direction of rise and run (i.e., M_a). For both graphs, Lizzie checked points to verify the accuracy of the formula $y = 3x$. This, when paired with the slope discrepancy between the given and rotated graph, left her perturbed and calling into question the viability of her thinking on the task ("this is so annoying"). With respect to enacting alternative meanings (i.e., M_b), Tatiana's quote illustrates that by conceiving the graph via quantitative and covariational operations, she determined the graph to be a viable representation of $y = 3x$. This occurred after having not determined what was to her a satisfactory way to produce the unlabeled graph. In attributing a viable way of reasoning to the student solution, it also supported her reflecting on that meaning in terms of its flexibility. This is a key foundation for the reflective comparison of meanings.

The problematization of an extant meaning can occur in a reflexive process with the enactment of alternative meanings. Similarly, the phenomenon of reflectively comparing extant and alternative meanings does not always immediately follow that process. It more often occurs iteratively across a sequence of tasks. With that said, the provided quote is from Ada and it occurred after engaging in several tasks across an instructional sequence. It illustrates that by comparing extant and alternative meanings, she came to view rate of change as a dominant meaning. She conceived slope as a visual property (i.e., M_a) derivative of and thus subordinate to rate of change (i.e., M_b). This enabled her to consider a graph like that in Figure 3c as having a rate of change of 3 and, hence, a positive slope. Furthermore, she could couch her appraisal of the graph in terms of differentiating between the underlying mathematical concept of rate of change and common communicative practices (i.e., conventions). Such appraisals are critical to learning mathematics (Moore, Silverman, et al., 2019). As the participant Thomas described when privileging rate of change, “it’s smart [of a student] to understand that it’s not glued.”

Table 1: Quotes Associated with each Competing Meanings Component

Component	Graph Considered	Quote
Problematized Extant Meanings	Figures 3b-c (with labels)	Lizzie: I’m rising this three…then I’m running negative one…the slope is negative again…this is so annoying.
Enacting Alternative Meanings	Figure 3b (with labels)	Tatiana: Oh…we have a clever kid over here…so it now technically is *y* equals three *x*…not the standard way of doing it…They see the relationship between *x* and *y*.
Compare Extant and Alternative Meanings	Figure 3c (with labels)	Ada: …even though it looks like a negative slope…we call it slope because it’s visual and it’s easy to visualize a negative and positive slope. But that’s only visual on our conventions of how we set it up…slope is rate of change, we can still see that for like equal increases of *x* we have an equal increase of *y* of three. And so for equal positive increase of one we have an equal positive increase of three. And so, it is a positive slope.

Closing

We presented one learning form that identifies how two meanings might be brought into comparison via processes of assimilation, accommodation, and perturbation. We illustrated how such a process involves different forms of intellectual need, including that with respect to solving a task, comparing meanings, and considering the implications of those meanings. We also illustrated the competing meanings perspective through a task and emblematic participant activity. The competing meanings perspective is still in its infancy as a construct. Moving forward, we envision a need for further connecting to other extant constructs and perspectives, the results of which will continue to shape and develop the idea of competing meanings.

We have concentrated much of our research focus on the first two aspects competing meanings and relatively less on the nuanced ways in which teachers compare extant and alternative meanings (cf. Paoletti, 2020). A reflective comparison of meanings is a developmental process that occurs across a sequence of experiences, and it is through such a process that key developmental understandings are constructed and associated pedagogical implications are anticipated (Silverman & Thompson, 2008; Simon, 2006). We envision a fruitful area of inquiry to be more detailed investigations into how the competing meanings perspective might be used to engender such reflective comparisons and, accordingly, the construction of key developmental understandings. Furthermore, we view a need for further relating this process to the development of mathematical knowledge for teaching. Here, we do not make strong claims regarding the development of mathematical knowledge for teaching. There are numerous factors other than a teacher's knowledge that mitigates their instructional practices and the meanings they target in their classroom. But, literature identifies the critical role of meanings and teachers being reflectively aware of them (Liang, 2019, 2023; Tallman & Frank, 2020; Thompson, 2016), and the competing meanings perspective is one potential tool to support the transformation of knowledge to that which informs instructional action.

For the purpose of adhering to the space constraints of the current report, we situated our work in the theories that directly informed its emergence and development. There is significant literature on learning, conceptual change, and perturbation, and thus an additional need is to further situate the notion of competing meanings within that literature. For example, Vinner and Dreyfus (1989) proposed *compartmentalization* as the phenomenon in which a learner has two potentially conflicting meanings. Noah-Sella et al. (2022) have since extended this phenomenon to incorporate Thompson's theory of meaning and explore calculus students' integral meanings. Their perspective foregrounds cases in which a researcher perceives a potential conflict or relationship between meanings, but the participant does not. The competing meanings perspective might contribute a way by which one considers how to support a student or teacher in bringing that conflict to the surface. As another example, researchers have productively pursued characterizing learning using Piaget's forms of reflective abstraction (Ellis et al., 2024; Simon et al., 2010; Tallman & O'Bryan, 2024), including theorizing its role in constructing mathematical knowledge for teaching (Liang, 2021, 2023). We envision that drawing connections with this work will provide insights into how aspects of the competing meanings perspective are related to crucial abstraction processes.

In our mixed-methods study we investigated how prospective elementary school teachers (PSTs) in the early stages of their preparation learn mathematical content and also learn to assess/attend and interpret students' mathematical thinking when analyzing students' written work on a mathematical task in the domain of fractions. We implemented an activity focused on building the PSTs' assessment reasoning. Data from 44 PSTs were used to analyze the PSTs' assessment skills using an adapted framework by Talanquer et al. (2015). Analysis using a linear model was conducted on the PSTs' pre and post Mathematical Knowledge for Teaching using the Learning Mathematics for Teaching instrument and the level of PSTs' assessment skills. Findings provide evidence that there is a significant association between the level of assessment skills and content knowledge at the end of the course than at the beginning of the course.

Keywords: Assessment, Mathematical Knowledge for Teaching, Preservice Teacher Education, Teacher Noticing

Introduction and Background

The practice of formative assessment has been identified as critical for improving teacher effectiveness and student learning outcomes (Black & Wiliam, 2009). However, prospective teachers need support in developing such an important pedagogical skill which involves interpreting students' mathematical thinking (Boerst et al., 2019). This mixed-methods study aims to characterize and differentiate how elementary school preservice teachers (PSTs) interpret students' mathematical thinking when analyzing students' written work on a formative assessment task in the domain of fractions. Additionally, we explore any connections between the intervention focused on building PSTs' assessment skills in the domain of fractions and the development of their mathematics knowledge for teaching (MKT). The mathematics content course which serves as the setting for this study affords opportunities to introduce PSTs to the required mathematics content with an eye towards teaching and interpreting elementary students' mathematical thinking. We were interested to see whether such a content course in general and the activity focused on building PSTs' assessment reasoning in the domain of fraction, in particular, would help the PSTs develop their MKT specifically in the domain of fractions (Ball et al., 2008; Stylianides & Ball, 2008; Thames & Ball, 2010). Research questions that guide our study are: (1) What are the levels of the PSTs' overall assessment skills along the different dimensions within the categories of evaluate/attend and interpretation when analyzing students' mathematical thinking on a written task in the domain of fractions? (2) What connections exist, if any, between PSTs' assessment reasoning skills and their MKT, as measured by the Learning Mathematics for Teaching (LMT, 2004) instrument?

Methodology

This mixed-methods study was conducted in a large Hispanic-Serving public university in the southern United States during the fall 2021 semester. The participants in the study consisted of 44 PSTs enrolled in their first mathematics content course for prospective elementary and middle school teachers. The data collected were (1) PSTs' written assessment of an elementary/middle school student's work on a formative assessment task that focused on identifying fractional values of area shapes. The formative assessment and the sample student work were part of the collection of tasks and student works found in *Balanced Assessment* (Schoenfeld, 1999) and (2) the pre- and post-test scores of the Learning Mathematics for Teaching (LMT) specifically the Content Knowledge (CK) and Knowledge of Content and Students (KCS) in the domain of Number Concepts and Operations (Hill et al., 2008).

To answer the first research question, we analyzed the PSTs' written assessments of student work based on our adapted version of Talanquer's Framework (Talanquer et al., 2015) for evaluating and interpreting student understanding in the assessment of written work. In our framework there are four evaluative dimensions (*evaluation stance, specificity in the evaluation, analysis of coherence, use of evidence*) and four interpretive dimensions (*quality of interpretation, productive thinking, scope of the evaluation, mathematical accuracy*). Talanquer's Framework was originally intended for use within science education, but it was informed by mathematics education, including the Jacobs et al. framework (Jacobs et al., 2010) during its development. The framework provides more layers of differentiation in scoring of 'Attend' and 'Interpret' features of the Jacobs et al. teacher noticing framework thereby allowing to better capture the subtle differences in PSTs' assessment capabilities. The framework also allows for analyzing the interpretations of PSTs' student thinking by levels and with detail that is domain specific. We thus found Talanquer's Framework adaptable to our setting in our mathematics education study. We noticed that PSTs' assessment capabilities vary within each level, so instead of assigning a discrete score by level we decided to assign a score within an assigned interval for each level. We provide one example of an adaptation that we made noted in italics from the Talanquer Framework in Table 1.

Table 1: Interpretive dimensions (*soundness of interpretations characterized along these dimensions*) and levels of sophistication in PSTs' assessment of student understanding.

Interpretive dimensions	Novice [0,1]	Emerging (1,2]	Advanced (2,3]
Quality of the interpretation	Interpretations cannot be supported with the evidence available *or claims are minimally supported by re-stating students' answers without unpacking the meaning in*	Interpretations are built, but the evidence provided is limited, superficial or formulaic.	Reasonable interpretations of student understanding are built given the available evidence.

	students' responses	

Two of the authors first met to establish the modified codes described above and coded six PSTs' written assessment reports together to get a sense of our coding scheme. We then separately coded all of remaining 38 participants' written assessments. After coding, we met to reconcile any differences and came to an agreement. Throughout the coding process we maintained 90% or better reliability. We used a linear regression model to answer the second research question to explore associations between the change in the pre/post LMT scores and the level of assessment skills demonstrated by the PSTs in the domain of fractions.

Findings and Conclusions

Findings of our first research question capture the subtle differences in the PSTs' assessment reasoning skills along four dimensions within the category of evaluation/attend and four dimensions within the category of interpretation in analyzing students' mathematical thinking on a written task in the domain of fractions. Furthermore, we were able to differentiate our PSTs' assessment skills into three levels of sophistication for evaluating and interpreting student thinking along these dimensions. On average PSTs' (N = 44) score within the interval [0, 3] on the construct of overall assessment skills came out to be 1.53, which puts them on average in the middle of the emerging level spectrum. The table below provides a summary of the average scores of the PSTs along different dimensions within the two categories of the overall assessment skills - evaluation/attend and interpretation.

Table 2: PST average scores on Evaluative and Interpretive dimensions

Evaluative/ Attend dimensions	evaluative stance	specificity in evaluation	analysis of coherence	use of evidence	Overall Evaluative/ Attend Skill
Average Score	1.54	1.46	1.51	1.46	1.49
Interpretive dimensions	**quality of interpretation**	**productive thinking**	**scope of evaluation**	**math accuracy**	**Overall Interpretation Skill**
Average Score	1.60	1.54	1.47	1.61	1.56

When differentiating the PSTs' overall assessment skills into three levels of sophistication for evaluating and interpreting student thinking along these dimensions, we found that 34% (15 PSTs) were at the Novice level, 39% (17 PSTs) were at the Emerging level, and 27% (12 PSTs) were at the Advanced level. Furthermore, PSTs' overall interpretation skill average score came out to be slightly more (4.7% more) than their overall evaluative/attend skill average score.

The student work that PSTs were asked to analyze was focused on identifying the fractional parts of a square subdivided into four equal smaller squares and each of the smaller squares divided into fractional pieces. Below we provide sample excerpts of the PSTs' analysis at different levels of sophistication along the 'Quality of the interpretation' dimension using the coding scheme given in Table 1.

Novice Level: "None of the fractions in the square are the actual fraction that it needs to be, but in the mind of the child, I understand how student B got most of the answers." (PST 415)

Emerging Level: "It is clear that they (Student B) had difficulty understanding larger fractions and reasoning for dividing up a whole piece into many smaller and uneven pieces." (PST 428)

Advanced Level: "I noticed one main recurring issue, which was them thinking of it as four individual squares rather than one as a whole. For example, in part one, they incorrectly stated that A and B were each equal to one half. They are correct that A and B are one half of one fourth, however if Student B was looking at the big picture, letters A and B would be equal to one eighth. Those two eighths would be equal to one fourth of the entire square. As you can see, Student B solved the square in four different individual parts. Each fourth of the entire square was equal to one, when in reality the entire square should have been equal to one." (PST 421)

In addressing the second research question, changes in PSTs' MKT were assessed using two versions, Pre and Post, of the instrument created by the Learning Mathematics for Teaching Project (2011). The instrument contains items from two subscales: Content Knowledge (CK) and Knowledge of Content and Students (KCS). We obtained separate estimates of the PSTs' ability scores overall and for each subscale by using an IRT model and item parameters obtained as part of a nationally representative sample of middle school teachers (see Hill 2007). PST's exhibited significant gains overall (0.7, $p < .001$) and in CK (1.2, $p < .001$), but not in KCS (-.1, $p = .499$). To explore the relationship between the level of sophistication of the PST's assessment of student work (L_i) and their MKT (Z_i), we fit the linear model:

$$Z_i^{(Post)} = \beta_0 + \beta_1 L_i + \beta_2 Z_i^{(Pre)} + \beta_3 L_i * Z_i^{(Pre)} + \epsilon_i$$

where $i = 1, \ldots, 44$. The results for the model with CK scale are shown in Table 3 below.

Table 3: Coefficients Linear Model for Post Content Knowledge

Coefficient	Estimate	Std. Error	*p*-value
Intercept (β_0)	-.31	.56	.581
Level of Sophistication (β_1)	.76	.28	.009
Content Knowledge: Pre (β_2)	.43	.30	.160
Interaction (β_3)	.21	.15	.166

Adj-$R^2 = .71$, $F = 35.71$, $df = 3, 40$, $p < .001$

The overall F-test and Adj-R^2 indicate the model is statistically significant and performs well at explaining variation in the post CK subscale score. When controlling for pretest score, the level of sophistication is a significant predictor of post test score. Comparing the estimates and the *p*-values, surprisingly, the level of sophistication of the PSTs' assessment of student work is more strongly associated with the post test score than the pre-test is. That is, the data provides evidence that there is a more significant association between the level of assessment skills and content knowledge at the end of the course than at the beginning of the course. Although we cannot claim a causal relationship between the level of assessment of student work and content knowledge, the results look promising for investigating further this claim. We plan to strengthen the design by including a comparison (control) group in the next phase of the project.

Our findings suggest that analyzing PSTs' assessment capabilities can be enriched by considering different dimensions along the evaluative/attend and interpretive strands of the construct. By capturing the subtle differences in assessment skills teacher educators can better support PSTs' assessment reasoning. The significant association between the level of sophistication of the PSTs' assessment of student work and content knowledge when controlling for incoming knowledge suggests that providing opportunities to learn how to assess students' mathematical work, impacts PSTs' mathematical knowledge positively. This result provides evidence, although taken with caution, that including more opportunities to learn how to assess and analyze student work as part of the teacher education curriculum is an effective instructional practice to improve mathematical learning.

PROSPECTIVE TEACHERS' USE OF MULTIPLE TEACHER MOVES IN NUMBER TALKS

Byungeun Pak
Utah Tech University
b,pak@utahtech.edu

Byeonguk Han
Portland State University
byeonguk@pdx.edu

Number Talks (NTs) may offer support for prospective teachers (PSTs) to engage in ambitious instruction. There has been a call for more empirical studies on NTs on the part of teachers. There are only a few studies on PSTs' teacher moves during their enacted NTs in field placement classrooms. In this study, we analyzed 22 PSTs' enacted NTs to identify themes associated with teacher moves used by those PSTs in their NT implementations. We found that revoicing and clarification teacher moves were dominantly used throughout 152 strategy segments in 48 NTs enacted by 22 PSTs. We also found how different teacher moves were used in each strategy segment in which individual students shared their strategy one after another and by PSTs, and how additional teacher moves were used with the dominant teacher moves. Discussions and implications are offered about mathematics teacher education and research.

Keywords: Number Talks, Elementary School Education, Instructional Activities and Practices, Preservice Teacher Education

Purpose

In the U.S., there has been an increase in using Number Talks (NTs), brief daily instructional routines (10-15 minutes in length) in which "students mentally solve computation problems and talk about their strategies" (Humphreys & Parker, 2015, p. 5), in mathematics classrooms. Despite such popularity, the instructional routines have not been well-studied empirically. In their extensive literature review, Matney, Lustgarten, and Nicholson (2020) called for empirical studies on the efficacy of NTs on student learning. Some studies have addressed the call by working with (novice) teachers' NTs in terms of, for example, the math-talk learning community (Woods, 2022), relationships with ambitious instruction (Pak, Cavanna, & Jackson, 2023), and formative assessment (Han & Thanheiser, 2021).

In this paper, we investigate teacher moves used by prospective teachers (PSTs) in their NTs in their field placement classrooms. Studies on mathematical discourse (e.g., Arnesen & Rø, 2022; Chapin, O'Connor, & Anderson, 2013; Franke et al., 2015; Herbel-Eisenmann, Steele, & Cirillo, 2013; Kazemi & Hintz, 2014) have shown the positive impacts of teacher moves on students' conceptual understanding. Given that, student learning in NTs also may depend in part on teacher moves, which can offer students opportunities to reason and make sense of strategies. Among the four phases (Introducing, Collecting Answers, Idea Sharing, and Closing) of the NT routines (Pak et al., 2023; Parker & Humphreys, 2018), the Idea Sharing phase, which begins when teachers ask students to share their strategies and ends before teachers conclude the NT, involves multiple teacher moves that foster student reasoning. As such, we focus on the Idea Sharing phase to investigate teacher moves used by PSTs in their enacted NTs. PSTs need to learn how to engage in ambitious mathematics instruction (Kazemi, Franke, & Lampert, 2009; Lampert, Beasley, Ghousseini, Kazemi, & Franke, 2010). One way to begin to engage in ambitious mathematics instruction would be learning to effectively use teacher moves in the Idea

Sharing during NTs. As for studies on NTs, little attention has been paid to PSTs' NTs in general and teacher moves used by PSTs in the Idea Sharing phase in particular. In this paper, we would like to contribute to understanding PSTs' use of multiple teacher moves in the Idea Sharing phase. As such, the purpose of this paper is to explore teacher moves PSTs use in the Idea Sharing phase in their enacted NTs. Understanding PSTs' use of multiple teacher moves in the Idea Sharing phase can support mathematics teacher educators with an interest in PSTs' teacher moves in NTs to enhance more effective ways for PSTs to use teacher moves in their NTs.

Conceptual Perspectives

In this paper, we draw on two conceptual perspectives to offer an understanding of how we approach PSTs' use of multiple teacher moves in the context of NTs, especially the Idea Sharing phase. The first perspective is related to the idea that multiple teacher moves work together to facilitate mathematical discourse more productively (e.g., Arnesen & Rø, 2022; Ellis, Özgür, & Reiten, 2019). Ellis et al. (2019) developed the Teacher Moves for Supporting Student Reasoning framework, classifying talk moves into four categories: eliciting, responding, facilitating, and extending. This framework places individual teacher moves on a continuum based on their potential to support student reasoning. Mainly, it underscores the collective interplay of these teacher moves across categories to develop a learning environment that honors student reasoning and sense-making. Drawing on the framework, Arnesen and Rø (2022) found teacher moves with different levels of potential, high and low, to support student reasoning. They offered multiple illustrations of how an experienced teacher used high-potential teacher moves (e.g., requesting justification and indicating relationship) along with low-potential teacher moves (e.g., unraveling student input and acknowledging contribution) to share intellectual authority with students as the teacher facilitated mathematical discussion. Even though we do not fully use the teacher moves identified in their works in this paper, the findings suggest that effective support for student reasoning often involves using multiple teacher moves together. We extend the idea to NTs in this paper because it is also important for teachers, particularly PSTs who need to learn how to use multiple teacher moves together, to support students to make mathematical reasoning more accessible to other students in the context of NTs.

The second perspective pertains to teacher moves used by novice teachers in the Idea Sharing phase during NTs. The Idea Sharing phase is where teacher moves can be used to support students in sharing their reasoning behind their strategies. Two studies (Pak et al., 2023; Murata et al., 2017) entailed findings regarding multiple teacher moves in the context of NTs. In a systematic analysis of 17 videos of NTs enacted by seven beginning elementary school teachers over three years, Pak et al. (2023) identified strategy segments and strategy-plus segments in the Idea Sharing phase. A strategy segment begins when a teacher asks an individual student to share his/her strategy and ends when the teacher moves to another student's strategy. A strategy-plus segment begins when a teacher asks other students to contribute to the initial strategy shared by an individual student and ends when the teacher moves to another student's strategy. To explore what beginning teachers could do to engage multiple students in each other's strategies, Pak et al. (2023) focused solely on strategy-plus segments to find teacher moves used by the beginning teachers. Murata et al. (2017) identified multiple teacher moves used by two beginning elementary school teachers during NTs over five months. They focused on teacher moves used in the whole NTs including the four phases (Introducing, Collecting Answers, Idea Sharing, and

Closing). The teacher moves used in the Idea Sharing phase included feedback evaluation (teacher responding to student talk to offer feedback to the student about the idea), strategy explanation (teachers extending student thinking beyond what the student said), and process questions (questions about strategies and thinking process). Understanding teacher moves by (novice) teachers in NTs, especially in the Idea Sharing phase, is still at the beginning stage. Particularly, teacher moves used by PSTs in the Idea Sharing phase have been under-documented. These two perspectives led us to explore how PSTs used multiple teacher moves together in strategy segments in the Idea Sharing phase.

Methods

Context, Participants, and Data Sources

The research site was in a mathematics methods course for elementary school teachers at a small southwestern university. Data regarding the course submissions was gathered in Spring 2023 as part of a research project that investigated how to support PSTs in learning to implement the eight mathematics teaching practices (National Council of Teachers of Mathematics, 2014).

Twenty-nine PSTs agreed to participate in data collection, including electronic submissions of course assignments, including the Number Talk Project. In their informal weekly reflection, they reported that they had never heard about NTs before and it was the first time for them to learn about NTs. The Number Talk Project consisted of PSTs engaging in a learning cycle to plan, rehearse, and implement their NTs plan. At the end of the learning cycle, PSTs video-recorded themselves enacting their revised NTs plan in their field placement classroom. PSTs also submitted a written reflection paper based on examining their NT video.

In this paper, we only used videos of NTs because the videos allowed us to more clearly see and hear what PSTs did in the Idea Sharing phase than in other written submissions (e.g., NTs plan, reflection/analysis paper). Videos of NTs enacted by 22 out of 29 PSTs were available for analysis for this paper. Some PSTs did more than two NTs, which meant they posed more than two problems. We obtained a total of 48 NTs enacted by 22 PSTs as data sources.

Data Analysis

There were five steps we took to analyze the transcripts of videos of NTs using a thematic analysis (Saldaña, 2015). First, we identified the Idea Sharing phase in terms of two sub-categories: strategy segments and strategy-plus segments. We used the work of Pak and colleagues (2023) to identify the sub-categories. Second, we analyzed 10 NTs enacted by four PSTs to create an initial analytic code of teacher moves in the strategy segments and strategy-plus segments. Since we identified only one teacher move used by one PST in one strategy-plus segment, we decided to focus our analysis on teacher moves in strategy segments because our interest is in PSTs' use of multiple teacher moves. We used both inductive and deductive coding to code the data (Hatch, 2002). We began with teacher moves identified in the prior studies such as Arnesen and Rø (2022), Chapin et al. (2013), and Murata et al. (2017). We particularly drew on Murata et al.'s (2017) teacher moves such as feedback evaluation, strategy explanation, and process questions because they emerged from novice teachers' NTs. We decided to exclude process questions (e.g. "How did you solve to find out what the answer was?" "So now what should we do?) from our potential codes because process questions are used to help students proceed with their explanation rather than helping them reveal their reasoning behind strategies. Third, we applied the initial analytic codes to the rest of the NTs (38 NTs). We went through an iterative process of individual coding and team meetings to reach a consensus on codes and develop codes of teacher moves in strategy segments. As a result of the process, the codes were refined (see Table 1). Fourth, we quantified teacher moves by PSTs, NTs, and strategy segments. Fifth, we compared and contrasted teacher moves within and across teacher moves by PSTs, NTs, and strategy segments to identify salient patterns. We ensured trustworthiness by having weekly meetings to discuss coded transcripts and to resolve disparities and by coding all transcripts by authors.

Table 1. Codes for Teacher Moves Used by PSTs in Strategy Segments

Teacher moves	descriptions	examples
Revoicing what a student said	PSTs repeat what a student said when they shared their strategy.	Student: 3 times 30 equals 90. PST: 3 times 30 equals 90.
Asking students questions for clarification	PSTs ask students to clarify the process of getting the answer.	How did you take away zero? Divided what by 10?
Asking students to justify their reasoning	PSTs ask students to explain the reasoning behind their strategy. This code usually involves a why question.	Why did you divide 70 by 10? Why did you multiply it by 10?
Responding to students' self-correction on mathematical mistakes	PSTs responded to students to support students in realizing their mistakes on their own. PSTs also wait patiently for students.	PST: That is alright. Student: Because I added 3 at the start. You have to take 3 off. PST: Yes, but you added 3 to 67 and made it 70. If you didn't take away 3 from 232, we still have an extra 3.
Mentioning a brief connection between strategies	PSTs briefly mention a connection they see between strategies in the form of questions.	So you took this one and [pointing out another strategy recorded on the board] you kind of did it this way, right?
Recapping a student's strategy for the whole class	PSTs summarize an individual student's strategy for the whole class.	She stacked in her head and she had to borrow. But she knew that borrowing from the zero, there is nothing to borrow from zero.

Findings

In this section, we present four findings to demonstrate how 22 PSTs used multiple teacher moves in the strategy segments. As mentioned earlier, we found only one teacher move used by one PST in one strategy-plus segment, which is not included in the findings. To illustrate the findings, we use frequency tables and an excerpt.

First, we found that seven different teacher moves were observed across 152 strategy segments within 48 NTs enacted by 22 PSTs (see Table 2). The two teacher moves (*revoicing and clarification)* were frequently used by PSTs. We call the two teacher moves as the dominant teacher moves. All 22 PSTs used revoicing 146 times in total throughout 94 strategy segments in 44 NTs. Clarification was used 54 times throughout 43 strategy segments in 27 NTs by 17 PSTs. The other five teacher moves (*asking students to justify their reasoning, responding to students' self-correction on mathematical mistakes, mentioning a brief connection between strategies, recapping a student's strategy for the whole class, and asking students to make connections between mathematical ideas*) were less frequently used by the PSTs. We call the five teacher moves as the additional teacher moves. Asking students to justify their reasoning was used by three PSTs 14 times across seven strategy segments in five NTs. Responding to students' self-correction on mathematical mistakes was used by two PSTs three times in four strategy segments in three NTs. Mentioning a brief connection between strategies was used three times in three strategy segments in three NTs by three PSTs. Recapping a student's strategy for the whole class was used 10 times in 10 strategy segments in nine NTs by eight PSTs. Asking students to make connections between mathematical ideas was used once throughout the entire data.

Table 2: Frequencies of Teacher Moves by PSTs, NTs, and Strategy Segments

Teacher Moves	Instances Total	152 Strategy Segments	48 NTs	22 PSTs
Revoicing what a student said	146	94	44	22
Asking students questions for clarification	54	43	27	17
Asking students to justify their reasoning	14	7	5	3
Responding to students' self-correction on mathematical mistakes	4	4	3	2
Mentioning a brief connection between strategies	3	3	3	3
Recapping a student's strategy for the whole class	10	10	9	8
Asking students to make connections between mathematical ideas	1	1	1	1

Second, we found that the PSTs used at least one teacher move in 114 strategy segments

(75%) and no PSTs used more than three teacher moves in any strategy segments (see Table 3). Among 114 strategy segments, 75 strategy segments (66%) contained one teacher move, 31 strategy segments (27%) contained two teacher moves and eight strategy segments (7%) contained three teacher moves.

Table 3: Number of Strategy Segments by Number of Teacher Moves Used

Number of dominant and additional teacher moves	None	1	2	3	Total
Number of strategy segments	38	75	31	8	152

Third, we found that each PST used different teacher moves throughout NTs. In terms of each PST's use of different teacher moves throughout NTs, three PSTs used only one type of teacher move (revoicing), 10 PSTs used two different teacher moves, five PSTs used three different teacher moves, three PSTs used four different teacher moves, and one PST used five different teacher moves across the NTs (see Table 4). For example, PST2 used both revoicing and clarification moves in the first strategy segment. The same PST did not use any teacher move for the second and fifth strategy segments, used the clarification move for the third and fourth strategy segments, and used the justification move in the sixth strategy segment in her first NT. In her second NT, PST2 did not use any teacher move for the first strategy segment and used the revoicing move in the second strategy segment. So, PST2 used at most two teacher moves in one strategy segment and used three different teacher moves (revoicing, clarification, and justification) throughout the NTs.

Table 4: Number of PSTs Who Used Different Teacher Moves Throughout NTs

Number of dominant and additional teacher moves	1	2	3	4	5
Number of PSTs	3	10	5	3	1

Fourth, we found that a few PSTs were able to use the dominant teacher moves in combination with additional teacher moves in strategy segments. Twelve PSTs only used revoicing and/or clarification without using any additional teacher moves and 10 PSTs used other additional teacher moves at least once along with the two dominant teacher moves across the NTs. Among 114 strategy segments that had at least one teacher move, 106 strategy segments (93%) contained either revoicing or clarification moves and only 8 strategy segments (7%) had teacher moves without revoicing or clarification teacher moves. Among 31 strategy segments PSTs used two teacher moves, 30 of them included either revoicing or clarification. Only one strategy segment had two additional teacher moves (recapping and asking students to make connections) without revoicing and clarification (see Table 5).

Table 5: Number of Strategy Segments With(out) Dominant Teacher Moves

Dominant teacher moves	0 additional teacher move	1 additional teacher move	2 additional teacher moves	Total
Revoice, no Clarify	56	7	1	64
Clarify, no Revoice	12	0	0	12
Revoice and Clarify	23	7	0	30
Neither used	38	7	1	46
Total	129	21	2	152

Table 6 shows PSTs' use of teacher moves when they used three teacher moves in one strategy segment. Among eight strategy segments, seven included both revoicing and clarifying and one PST used the revoicing move but clarifying. PST3 used revoicing, clarification, and brief connection in one strategy segment, and used revoicing, clarification, and recapping in three strategy segments, and used revoicing, clarification, and justification in one strategy segment. PST4 used revoicing, clarification, and justification in one strategy segment and used revoicing, clarification, and recapping in another segment. PST 21 used revoicing, brief connection, and recapping in one strategy segment.

Table 6: PSTs' Use of Three Teacher Moves Across Eight Strategy Segments

PSTs	Number Talks	Strategy segments	Revoicing	Clarifying	Justify	Brief Connection	recapping
PST3	1st NT	2nd	2	1		1	
	2nd NT	2nd	2	1			1
		3rd	2	2			1
	3rd NT	1st	1	3			1
		2nd	4	1	1		
PST4	1st NT	1st	2	1	3		
	2nd NT	3rd	1	2			1
PST21	2nd NT	2nd	2			1	1

We present an excerpt below to illustrate how PSTs used three teacher moves. The excerpt shows how PST3 used three teacher moves such as revoicing, clarification, and recapping in the third strategy segment in her second NT. She posed the second problem (4 x 140), followed by the first problem (8 x 70). In the excerpt, PST3 called on a student to share her strategy.

T: Okay, let's hear from Emma
S: So, what I did is. I figured out that 8 times 70… um... 8 times 70 and 4 times 140 are equal, you put both of those out
T: Okay.
S: If you take away the zero from 70 and 140, then 7 is half of 14, so I do times 2
T: **Times what by 2,**
S: 4 times 2
T: **So you did 4 times 2,**
S: 4 times 2 is 8, and then… (student thinking)
T: Okay, so **how do we get from 140 to 70?**
S: divide it by 2?
T: Okay. And that 70.
S: So it is 8 times 70.
T: Okay. **So Emma doubled our 4 to 8 and halved our 140 to 70 because we already saw that problem, right?** Do we agree that that strategy works?

In this excerpt, PST3 used the revoicing move once ("So you did 4 times 2"). She also used the clarification move twice ("Times what by 2?" "How do we get from 140 to 70?"). The PST used the recapping move once ("So, Emma doubled our 4 to 8 and halved our 140 to 70 because we already saw that problem, right?).

Discussions and Conclusion

Our analyses revealed four findings related to PSTs' use of teacher moves in their enacted NTs, all of which related to teacher moves occurring within the 152 strategy segments in the *Idea Sharing* phase of the NTs routines. Specifically, we observed the PSTs' teacher moves in terms of two dominant teacher moves and five additional teacher moves. We also found that a few PSTs used multiple teacher moves in strategy segments. These findings offer potential insights for the field of mathematics teacher education as we seek to support PSTs to engage in ambitious mathematics instruction. We offer two discussion points in terms of mathematics teacher education and research, respectively.

First, these findings suggest a need for PSTs to learn to use multiple teacher moves in the strategy segments. We agree that novice teachers need to move beyond strings of strategy segments in which students simply share one strategy after another (Pak et al., 2023). As we briefly mentioned in the data analysis section, the data only included one strategy-plus segment in the whole data. The analysis also shows that a few PSTs can only use multiple teacher moves. We conjecture a relationship between strategy segments and strategy-plus segments: Teacher moves in the strategy segments can serve as a springboard to help multiple students engage in each other's mathematical ideas in the strategy-plus segments because multiple students' engagement depends on how much individual students are supported by teachers with opportunities to reveal their reasoning and make sense of strategies. As such, our findings offer implications for mathematics teacher education. Specifically, mathematics teacher educators need to provide opportunities for PSTs to learn to incorporate multiple teacher moves into strategy segments to promote students' reasoning and sense-making.

Building on the first discussion point, second, these findings suggest a yet-uncharted research area regarding the effective use of multiple teacher moves in the strategy segments on the part of PSTs. We highlighted ways 22 PSTs used multiple teacher moves in strategy segments. This paper contributes to our understanding of teacher moves in the strategy segments. Many of the 22 PSTs were able to use teacher moves perceived by researchers as effective for student reasoning (for example, revoicing (Chapin et al., 2013) and justification (Thanheiser et al., 2021)). This paper extends Murata et al. (2017) and Pak et al. (2023) to explore multiple teacher moves in strategy segments. Murata et al. (2017) identified multiple teacher moves in the whole NTs. Pak et al. (2023) did not investigate the nature of strategy segments in terms of teacher moves. Due to a lack of data, however, the paper did not explore the efficacy of using multiple teacher moves in NTs, especially strategy segments, on student learning about mathematical concepts. As Matney et al. (2020) argued, it is essential to understand the impacts of NTs in general and multiple teacher moves in particular on students' reasoning and sense-making. We suggest that further research be on ways to support PSTs to learn to more effectively use multiple teacher moves in the strategy segments in the Idea Sharing phase.

DEVELOPING ELEMENTARY PRESERVICE TEACHERS' MATHEMATICAL PRACTICE: ATTEND TO PRECISION

Kaleigh Pate
University of West Alabama
kpate@uwa.edu

Keywords: Mathematical Processes and Practices, Pre-Service Teacher Education

Purpose of Research and Connection to Literature

This poster proposal represents a research-in-progress examining the Standard for Mathematical Practice 6: Attend to Precision. Mathematics, as a discipline, demands precision as a tool for accuracy and rationalization (Otten et al., 2019). The purpose of this study is to develop elementary preservice teachers' ability to attend to precision through a series of professional learning seminars, written mathematical tasks, and micro teaching demonstrations. A review of literature revealed four key themes demonstrating the benefits to both teachers and students when precision is explicitly emphasized in mathematics instruction. First, attending to precision supports students' learning and understanding (Engledowl et al., 2015; Leatham et al., 2016; Brunn et al., 2015). Second, attending to precision supports the sequential nature of learning mathematics (Kieran, 2007). Third, attending to precision promotes effective communication. Common language demands in mathematics include asking students to analyze, describe, or justify mathematical concepts and ideas (CCSSI, 2010). Lastly, attending to precision supports effective engagement with other Standards for Mathematical Practice (SMPs).

Methods

Participants for the current study were recruited through enrollment in junior and senior block cohorts of an elementary education preparation program. Nine elementary preservice teachers engaged in pre- and post- questionnaires, researcher-led seminars, written discourse tasks, a micro teaching demonstration, and focus group interviews. Data was collected over a span of eight weeks and analyzed qualitatively to answer the research questions: 1) How do ePSTs attend to precision? 2) How do the tasks and experiences within this study influence ePSTs' perspectives and abilities to attend to precision? and 3) How do researcher-led seminars support the development of ePSTs' attend to precision?

Preliminary Findings and Implications

This study aimed to examine how elementary preservice teachers develop the specialized skill, attend to precision, through a series of seminars, engaging tasks, and micro teaching demonstrations. Additionally, this study sought to understand how ePSTs' perspectives toward precision in mathematics changed over the duration of the study. Preliminary findings of the study include the impact of participants' Mathematical Knowledge for Teaching (Ball et al., 2008) on their ability to attend to precision, emphasis on students' prior knowledge in facilitating an attention to precision in teaching, and participants' heightened awareness to the importance of mathematical discourse and use of strategies in their instruction. Additionally, participants were reflective of their teaching demonstrations with respect to knowledge gained through the researcher-led seminars and expressed a need for more exposure and practice with Standards for Mathematical Practices (CCSSI, 2010). Potential implications seek to provide insight for future design of learning seminars within teacher preparation programs and suggestions for integrating Standards for Mathematical Practices (SMPs) into PSTs' coursework and experiences.

PRESERVICE TEACHERS' CONCEPTUALIZATION AND ENACTMENT OF THE INVESTIGATIVE APPROACH

Tracy Proffitt
Virginia Tech
tprof8@vt.edu

Modiu Olaguro
Virginia Tech
olaguro@vt.edu

Keywords: Preservice Teacher Education; Teacher Educators; Instructional Activities and Practices

Background

Teacher educators have the responsibility of deepening preservice teachers' (PSTs) mathematical content knowledge while also casting a vision of effective mathematics instruction. This research takes place in a middle school math methods course in which the investigative approach is presented as an ideal pedagogical model. The investigative approach "involves purposeful, inquiry-based, and meaningful instruction and, thus, can foster all aspects of mathematical power: a positive disposition, the processes of mathematical inquiry, and understanding" (Baroody & Coslick, 1998, p. 1-27). PSTs were taught about the investigative approach through brief lectures, textbook readings, homework assignments, and modeling. Students were given opportunities to demonstrate their developing conceptualization of the investigative approach by writing an essay, planning and teaching two 15-minute mini-lessons to classmates, and reflecting on their mini-lesson teaching experience (Amobi & Irwin, 2009; Lucero et al., 2023). We wanted to determine which elements of the investigative approach PSTs were able to use with fidelity to inform future instruction and research, so we developed the following research questions to guide the study:

- How do preservice teachers describe the investigative approach?
- What observable practices do preservice teachers use in their mini-lessons?
- How do PSTs' understandings of the investigative approach relate to practices observed?

Methods, Results, and Implications

This poster reports on a case study that examined two PSTs' level of fidelity to the investigative approach through an analysis of their written descriptions of the investigative approach, recorded mini-lessons, and post-teaching reflections. Codes were generated from the data through open and axial coding (Glaser & Strauss, 1967). More specifically, the data were analyzed to highlight what the teachers knew and did not know about the investigative approach, as well as identify observable practices that did and did not match the investigative approach.

The data collected from the PSTs' essays on the investigative approach indicated that they were accurately able to describe its focus, lesson structure, and basic instructional strategies. Their mini-lessons included some observable practices that matched what they had learned and written about the investigative approach such as real-life contexts and effective questioning. The second mini-lesson was somewhat more student-centered than the first for both PSTs. However, the structure of the tasks chosen ultimately limited their opportunity to enact the mini-lessons in a way that we would consider truly investigative. Based on these results, we suggest providing greater support to PSTs in the task selection process. This could be done by providing exemplars and analyzing them in small groups, modeling the task selection and development process for the class, and the instructor or peers offering written or verbal feedback on task selection before lesson implementation.

A TEACHER RESIDENCY PROGRAM EMPHASIZING STEM EDUCATION IN RURAL COMMUNITIES: WHAT WE LEARNED

George J. Roy	Kristin E. Harbour	Jennifer Crooks-Monastra
University of South Carolina	University of South Carolina	University of South Carolina
roygj@mailbox.sc.edu	kharbour@mailbox.sc.edu	crooksj@mailbox.sc.edu

Keywords: Equity, Inclusion, and Diversity; Elementary School Education; Systemic Change; Preservice Teacher Education

Trends in initial teacher preparation have pointed-out that traditional pipelines (i.e., undergraduate programs) found at institutions of higher education in the U.S. are not producing enough teachers to fill the deficit created by teachers leaving the profession (U.S. Department of Education, 2015). Furthermore, the need for teachers in rural communities is especially significant (Villegas et al., 2012) where historically there has been an on-going challenge in the recruitment and retention of teachers in schools located in these areas (Aragon, 2016; Barton, 2012; Monk, 2007). In this poster session, we will report on our findings on a university residency that was designed to address the challenges of recruitment, preparation, and retention of P-12 teachers of mathematics in the rural communities in our state (D'Amico et al., 2022; Roy, et al., 2023).

Carolina Transition to Teaching Residency

The Grow Your Own (GYO) residency was committed to developing and sustaining reciprocal relationships with partner districts in rural communities that met the following criteria: (1) more than 20% of children living in poverty, (2) teacher turnover rate greater than 15%, and (3) located in counties qualifying as Opportunity Zones. The [Blinded] residency program was designed for individuals [henceforth residents] that held an undergraduate degree in a field other than education, and who were interested in transitioning to the teaching profession. During the 18-month program, residents were be provided both professional and financial support as they were immersed in a year-long teacher residency while simultaneously pursuing a Master's Degree in Education. The residency was followed by support for residents in obtaining teacher certification during their first three years teaching in one of our partner districts located in rural communities in our state.

Findings

Carolina Transition to Teaching residency program employed a Grow Your Own (GYO) approach to promote a teacher workforce that is more representative of the rural communities in our state (Villegas, Strom, & Lucas, 2012). At this point, twenty-seven individuals have graduated from the program within the first three cohorts and began teaching in rural, high-needs partner school districts across the state, clustered along a historically significant areas of teacher need in our state. Moreover, across the four cohorts of the program, nearly all residents (i.e., 91.5%) have identified from underrepresented groups in the teaching profession in our state. Lastly, due to a GYO recruitment approach, 60% of all enrolled residents in Cohorts 1-4 previously held an instructional assistant or substitute positions within the partner district in which they were they fulfilled their residency.

Micayla Gooden
Texas A&M University
good7509@tamu.edu

Michelle Kwok
Texas A&M University
michkwok@tamu.edu

Research has shown that engaging teachers in problem posing is a worthwhile tool for learning how to teach mathematics. There is a rich body of literature focusing on pre-service teachers in one-step problem posing. Despite the difficulty that multi-step word problems present to students and teachers alike, there is less scholarly research investigating misconceptions surrounding two-step word problems. Thus, grounded in prior research on one-step problem posing and linguistic metalanguage, we qualitatively identify pre-service teachers' two-step problem posing misconceptions, and provide implications for practice and future research.

Keywords: Pre-service Teacher Education, Number Concepts and Operations, Elementary School Education, Instructional Activities and Practices

Objectives

In comparison to one-step word problems, two-step word problems provide students with additional challenges (Vershaffel et al., 2000; Van de Wall et al., 2019). First, multi-step word problems require students to identify an unstated *hidden* question and answer it before addressing the *written* question (Huinker, 1992). The *hidden* question provides students with the additional task of deciphering the underlying operations that are needed to solve the unstated question (Verschaffel et al., 2009; Van de Walle et al., 2019). Research has also shown that in addition to solving two questions, two-step problems often include more complex language structures, making them more difficult to understand and solve (Van Dooren et al., 2013; Verschaffel et al., 2009). The complexity of two-step word problems highlights the need for more research on how to support learners in solving these types of word problems.

One approach is to engaging teachers in problem posing themselves, shown to be a worthwhile activity for learning how to teach mathematics (Cai et al., 2020; Cai & Hwang, 2020; Calabrese et al., 2024). Investigating samples of pre-service teachers' (PSTs) problem posing provides insight into their conceptual and procedural understanding (Crespo, 2003). However, teachers can sometimes pose over simplistic problems or, on the other hand, include information that is irrelevant or is mathematically unsolvable (Leung & Silver, 1997; Silver et al., 1996; Stickles, 2011). Our study seeks to identify the linguistic and mathematical features of two-step word problems that present challenges for posing clear, solvable word problems by answering the research question: *In examples of PSTs' posed two-step word problems, what misconceptions were present? What do these misconceptions reveal about the key characteristics of two-step word problems?*

Perspectives

Being able to solve word problems requires a complex interaction between understanding mathematical, linguistic, and contextual features (Daroczy et al, 2020; Lin, 2021). Research has highlighted word problems as the most challenging tasks that students encounter in mathematics (Verschaffel et al., 2020). The language that describes the situations of word problems has been found to pose greater obstacles than the mathematical concepts involved in solving (Kintsch, 1987; Wyndham & Säljö, 1997). Often, clarity in word problems is defined by student understanding and performance (Fuchs et al., 2008); thus, presenting clear word problems enhances students' mathematical thinking and problem-solving skills (Barwell, 2009). Researchers suggest that factors such as comprehension, cultural and linguistic considerations, context, and numerical complexity, can all impact a student's ability to understand and solve these word problems (Daroczy et al., 2015; Daroczy et al., 2020). These studies highlight the complexity of posing a clear word problem, which can be a challenging task for PSTs.

Method

The participant sample for this study were undergraduate PSTs enrolled in a mathematics problem solving course designed for education majors (n=56). The problem solving course is guided by Polya's (1945) steps for problem solving, the Common Core (2010) addition/subtraction and multiplication/division taxonomies, problem posing (Silver, 1994), the written/hidden question (Van de Walle et al., 2019), and linguistic metalanguage (Halliday, 1975). PSTs participated in individual and collaborative one- and two-step problem posing activities to gain a deeper understanding of mathematical concepts. The data source for this study is a structured two-step problem posing task from the final exam. PSTs were given the following prompt for posing: "Write a two-step word problem that utilizes the structures: 1) Take from-Change unknown; 2) Array-Rows unknown." PSTs were also asked to write the hidden question in a separate space from their final word problem, which was also transcribed for analysis.

To analyze the data, the research team inductively identified instances of linguistic and mathematical distractors. We built on our findings from a previous study of the linguistic patterns of one-step additive problems (Author, 2022), to guide us to identify the salient patterns of two-step problems. We drew on Systemic Functional Linguistics (SFL), a social semiotic language theory that has been shown to support students and teachers talk about the functions of language and how it shapes meaning in the subject areas (Fang & Schleppegrell, 2010; Halliday, 1975; Halliday & Matthiessen, 2013). Initially, we coded five sample word problems together and discussed initial patterns and discrepancies to obtain inter-rater agreement. We engaged in constant comparative analysis (Strauss & Corbin, 1997) of PSTs' two-step word problems to code the remaining sample. Once we identified our final coding scheme and no new patterns were identified, we reviewed all of the word problems once again to ensure that the codes were accurately applied.

Findings

PSTs' misconceptions regarding two-step problem posing contained three key characteristics: 1) *requirement* of the hidden question; 2) *alignment* of the written and hidden question; and 3) distinct *linguistic* and *numerical distractors* that could impede requirement and alignment. The *requirement* of the hidden question describes the PSTs' posed problems that require two steps to solve the problem. In other words, one is required to solve for the hidden question in order to solve the second step of the problem. *Alignment* describes the connection between information provided and what the question (hidden and written) is asking for. *Linguistic distractors* describe linguistically unclear characteristics of the posed problems such as unclear referents, inconsistent verbs, atypical phrasing, inference required, and grammatical errors (see Table 1). *Numerical distractors* include characteristics such as an extra numerical referent (i.e., quantity) and missing numerical information (see Table 1). Further, PSTs demonstrated the aforementioned two-step misconceptions across four separate cases. These cases elucidated the moderation of distractors (i.e., linguistic and numerical) on the requirement and alignment of the hidden and written questions when PSTs posed two-step problems that were change (take from)-change unknown and array-number of rows unknown.

Table 1: Linguistic and Numerical Distractors

Linguistic Distractor	**Definition**
Unclear referent	The referent(s) are described inconsistently. Can also be described through multiple synonymous terms.
Inconsistent verbs	Inconsistent use of verbs throughout the word problem (e.g., planted, dead, have).
Inference required	In order to solve the problem, the student must draw implicit conclusions about the actions or conditions of the referent.
Atypical phrasing	Non-standard phrasing (e.g., order of information, novel word choice)
Grammatical errors	Punctuation or spelling errors that may or may not change the meaning of the word problem.
Numerical Distractor	**Definition**
Extra referent	An extra numerical referent is included in the problem that does not change the meaning of the problem.
Not enough information	There is not enough numerical information present to solve the problem.

Case 1 represents problems in which there is not a requirement of the hidden question to solve for the written question, nor alignment between the information presented in the problem and what the written question is asking for. In this case, the misalignment comes from having to solve for Stephanie's organization of ruined stickers; therefore, this question is solvable, but not logical. In addition, the PST did not write their hidden question, which could have contributed to their misaligned problem.

A common misconception for PSTs was posing two separate one-step problems, illustrated by Case 2. In other words, the information gathered was from solving for step one of the problem was not required for solving for step two. On the other hand, there were instances where PSTs posed two-step problems with a requirement of the hidden question, and alignment of the information given and the questions, but numerical distractors that made the problem unsolvable as in Case 3. The PST posed a problem where it was necessary to track Carl's flowers, making the question required and aligned. However, the PST did not provide an important detail: the amount of flowers that Jenny had after giving some to Carl. This leaves the problem unsolvable.

Table 2: Cases of Two-Step Problem Posing Misconceptions

Case	Hidden Question	Written Question	Requirement	Alignment	Solvable	Distractor
1	Did not write one	Stephanie has 42 stickers. While arranging them into equal rows and columns in her sticker book, she dropped some water on them. She now had only 20 stickers that weren't ruined. Saddened, she continued organizing her stickers into 11 equal columns. How many rows of stickers does Stephanie have?	Yes	No	Yes, although unrealistic	Linguistic Distractor-unclear referent
2	How many cookies did I eat?	There were 34 cookies on a baking sheet. I ate some. Now there are only 32 cookies on the baking sheet. If I arranged the cookies equally into 8 columns, how many cookies would be in each row?	No	Yes	Yes, as two separate one-step problems	None
3	How many flowers does Jenny give to Carl?	Jenny has 10 flowers and gives some to Carl. Carl arranges his flowers into 3 columns. How many rows of flowers does he have?	Yes	Yes	No	Numerical distractor-not enough information
4	How many cupcakes did Darcie give to Joseline?	Darcie has 5 cupcakes, she gave some of the cupcakes to Josseline. Now Darcie has 3 cupcakes. Josseline arranged 6 of her cupcakes creating each column from the cupcakes Darcie gave her. How many rows of cupcakes did Josseline arranged them in?	Yes	Yes	Yes	Linguistic distractor-Inference required
5	How many tiles did Jack take?	Jack's mom had 24 tiles she wanted to lay out. Jack wanted to help so he took some tiles leaving his mom with 12 tiles. If Jack laid out his tiles into equal rows with 4 tiles in each row, how many rows of tiles did he lay out?	Yes	Yes	Yes	None

Case 4 represents PSTs' posed two-step problems with the requirement of the hidden question, alignment of the hidden and written questions, but numerical/linguistic distractors. Case 4 posed problems are solvable, however, the linguistic distractors in the problem interfere with the clarity of the problem. In this case, the problem solver must make the inference that Josseline had four cupcakes before Darcie gave her cupcakes to make sense of the array of cupcakes using the cupcakes from Darcie as columns. Last, Case 5 represents two-step problems with the requirement of the hidden question, alignment of the hidden and written questions, and no numerical/linguistic distractors, which represents a clearly posed two-step problems.

Conclusions

Research has shown that engaging teachers in problem posing is a worthwhile tool for learning how to teach mathematics (Cai et al., 2020; Calabrese et al., 2024). Based on our findings, we propose that to pose clearly written two-step problems, the following criteria must be met: requirement of the hidden question, alignment of the information provided to the questions, and absence of numerical and linguistic distractors. Educators can use these findings as guidelines for posing contextually rich word problems that are still accessible from a mathematical and linguistic perspective.

Our study contributes to problem posing literature by providing tools for defining and recognizing PSTs misconceptions with two-step problem posing. Despite the difficulty of multi-step word problems (Verschaffel et al., 2000), there is a dearth of research on two-step problem posing compared to one-step for PSTs. Our analysis focused on two-step problem posing given a structured task; however, evaluating PSTs' two-step problem posing misconceptions given an unstructured or semi-structured task is a future direction of research to further investigate PSTs' understanding of multi-step word problems.

We share the teaching simulation as one approach to providing formative feedback in teacher preparation and consider the ways in which teacher candidates (TCs) take up the feedback in subsequent simulations. We hypothesize that TCs' uptake depends on the connections between their own resources, the focus of the feedback provided, and the context of subsequent teaching.

Keywords: Instructional Activities and Practices, Preservice Teacher Education, Teacher Educators, Elementary School Education.

Beginning teachers who are "committed to supporting the mathematical success of each and every student" (Association of Mathematics Teacher Educators [AMTE], 2017) integrate strong content knowledge for teaching, skill with high-leverage teaching practices, adherence to professional ethical obligations, and commitments to equitable teaching and learning, alongside tools for learning and growing as professionals across their teaching careers (Davis & Boerst, 2014) into their teaching. For teacher educators (TEs), this implies designing opportunities for teacher candidates (TCs) to develop integrated knowledge and skills in ways that support TCs to build their capacity for reflection and improvement. We share teaching simulations as one approach to providing such opportunities with immediate feedback and we consider the ways in which TCs take up the feedback to demonstrate growth in their mathematics teaching practice.

Theoretical Framework

At the foundation of our work, we view teaching as involving the interactions between and among teachers, students, and the content situated inside of the school environment (Cohen et al., 2003; Lampert, 2001). We view teaching *mathematics teaching* as involving interactions between and among the TE, the TCs, and mathematics instruction, the content of teacher education (Ball et al., 2009; Ghousseini & Sleep, 2011; Shaughnessy et al., 2022). This implies that learning occurs through supported engagement in teaching, with opportunities to improve.

In this context, formative assessment allows TCs to demonstrate the integration of content knowledge for teaching, high-leverage teaching practices, and commitments to equitable teaching and learning This provides the TE with a snapshot of the TC's current knowledge and skill that can be the basis for providing feedback and additional learning opportunities that can foster subsequent improvement. Wiliam (2010) posited that the utility of formative assessments is measured by the extent to which they allow the demonstration of knowledge and skill paired with the extent to which they support decisions about subsequent work. This is the goal of formative assessment in teacher preparation—to elicit information about TCs' practice and to provide feedback and learning opportunities that impact their future practice.

Our work is situated at the intersection of this interactive view of learning to teach and formative assessment. Simulations are used as contexts to practice and demonstrate capabilities with teaching practice. Simulations are approximations of practice (Grossman et al., 2009) that place authentic demands on a TC while controlling the complexity of the work. Simulations allow the TE to control the mathematical content that the TC encounters, the strategies and thinking represented by students, and the teaching moves necessary to accomplish the goals of the simulation (Shaughnessy & Boerst, 2018a). We use simulations in formative cycles, allowing feedback to TCs to be taken up in subsequent simulations.

These simulations focus on two practices that are essential to the daily work of teaching, eliciting and interpreting student thinking (National Council of Teachers of Mathematics, 2014). Put simply, eliciting student thinking focuses on making students' ideas available through asking questions and posing tasks, and interpreting student thinking entails making sense of the information gathered to drive subsequent instructional decisions (Shaughnessy & Boerst, 2018b).

The TC's engagement in a teaching simulation cycle has four parts. First, the TC examines a piece of student work and plans questions to ask the student to learn about their process and understanding of the mathematics. Second, the TC has five minutes to interact with a simulated student to elicit the student's thinking. The simulated student is a live actor trained to use a set of response guidelines that specify the student's process and understanding of the ideas underlying the process. These guidelines include general guidance and specific responses to anticipated questions (see Shaughnessy & Boerst, 2018a). Third, the TE interviews the TC to learn about their interpretations of the student's thinking and their own understanding of the mathematics. Throughout the simulation and interview, the TE uses an observational tool to capture key aspects of the performance. Fourth, the TE engages the TC in a feedback conversation. Our approach allows us to gather evidence of a TC's knowledge and skills in nine performance areas (Shaughnessy et al., 2025) through an observational tool that is tied to feedback suggestions that the TE can use. We sought to explore whether and how feedback was taken up by TCs in a subsequent simulation involving the same teaching practices but differing mathematics content.

Methods

As part of ongoing work with TEs and TCs at two universities, we are supporting TEs in using the simulations with their TCs and learning about how TCs take up the feedback. We had 37 TCs engage in a pair of back-to-back simulation cycles with their TE (see the student work in Figure 1). TCs were given 5 minutes to consider the feedback and then engaged in the second simulation. After both cycles, we interviewed each TC to learn about their understanding of the feedback that was provided and their perception of and reasoning about the extent to which they did or did not take up the feedback. The simulations, feedback conversations, and interviews were video recorded. We analyzed the feedback conversations to identify the feedback as well as the interviews to identify the TCs' understanding of the feedback and why it was or why it was not taken up. To understand the corresponding uptake, the research team applied an observational tool to each simulation performance (see Shaughnessy & Boerst, 2018a).

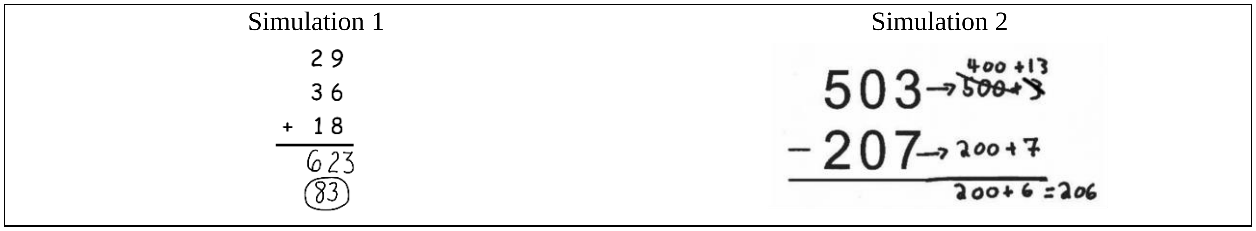

Figure 1: Student Work for Simulation 1 and Simulation 2

How Might a Teacher Candidate Take Up Formative Feedback?

In the first simulation (~3 minutes), a TC, Kendall, began by focusing on where the student had started and why. Kendall then pressed the student on what they had done in the ones place. The student shared how they generated the “23” in 6-2-3. Next, Kendall asked why the student had not carried. The student reiterated that using their approach, they write the answers below the column (and that they do not carry). Kendall then asked the student what would happen if they did carry. Kendall complimented the student on starting with the ones, which was immediately corrected by the student (who had started with the tens). Kendall then (incorrectly) stated that the student needed to start with the ones and asked about the reasonableness of the answer. By the end of the interaction, the student had stated that the answer was reasonable.

As Kendall interacted with the student, her TE used the observational tool to keep track of the sorts of moves she made. The tool revealed that Kendall did not learn about the student’s full process. Further, Kendall did not ask about the student’s understanding of why the 6 and the 2 can be combined, which is crucial given the student’s process. Additionally, the TE noted that Kendall was directing the student to use a different process.

The TE engaged in a 7-minute conversation with Kendall, sharing three main pieces of feedback, which Kendall later described accurately. First, the TE named the importance of learning about the student’s full method and shared that one strategy is rewriting the problem and asking the student to solve it again and to talk aloud as they solve it. Second, the TE suggested that Kendall ask probing questions focused on the student’s understanding. Third, the TE suggested that Kendall stay open to learning about the student’s process rather than imposing her own method to solve the problem or assuming that there is one right approach. Kendall had 5 minutes to consider the feedback and continue to plan for eliciting the second student’s thinking.

For the second simulation (~5 minutes), Kendall began by asking the student to re-solve the problem. She then asked questions about the student’s steps, and after the student talked about the process of the trade, she pressed on where the 10 added to the 3 came from. After getting the student to talk about why they hadn’t crossed out anything in the subtrahend, Kendall returned to probing the student’s understanding of what they were adding to the “3.” The student stated they had taken 100 from the 500 and only added 10 of that 100 to the ones place. The student also expressed that the number (the minuend) is supposed to be “the same” after a trade. Kendall pressed around the reasonableness of the answer and the student stated the answer was not reasonable. Kendall asked about other approaches and the student acknowledged that it was their first time solving a problem “without tens.”

Looking at the uptake of the feedback, first, we see that, as suggested by the TE, Kendall had the student re-solve to support knowing about the entirety of the student’s method. However, Kendall did not have the student talk while reworking the problem. Second, Kendall took up the

TE's suggestion to ask probing questions by pressing on the student's understanding of core ideas. Third, the TE suggested that Kendall stay open to learning about the student's process, which was evident as Kendall did not encourage the student to solve the problem another way.

Contrasting Case: Lack of Feedback Uptake

We next turn to a case in which a TC, Sammie, did not appear to be taking up the feedback provided by her TE focused on probing understanding and posing a follow up problem.

Probing Understanding

In the first simulation, Sammie asked a question about the value of the 6-2-3. Sammie did not ask the student about their understanding of the combining of the 6 (tens) and 2 (tens). Sammie received feedback focused on asking questions to probe the student's understanding. The TE said, "Do you remember how we've been talking about different kinds of questions we ask kids and following up with the whys? That's what I want you to practice doing and continuing to do." In the second simulation, Sammie asked why the student added the minuend and subtrahend together, and the student responded that they "subtracted," but Sammie asked no questions focused on the student's understanding of core ideas. When interviewed by a research team member about how she had taken up the feedback provided by her TE, Sammie said she had heard the feedback and tried to use it but forgot what the student said and filled in her own thinking, noting that she had tried to probe the student's understanding but used the wrong operation. Later, Sammie said, "I think if I had worked with the same style of problem, I think I would've be able to get it right." Thus, Sammie noted that the differences in the approaches used by the two students factored into her ability to probe the student's thinking in the moment.

Posing a Follow Up Problem

As part of the first simulation, Sammie was asked in the follow-up interview to identify a problem that could be posed to the student to confirm their process and understanding. Sammie carefully identified a task and talked through her reasoning. In the feedback, the TE highlighted the care with which Sammie selected the numbers and named that posing another problem can be a useful strategy. In the second simulation, Sammie did not pose an additional problem to the student. Later, she said, "I was like, I don't know what problem I would give this child."

Uptake of Feedback

We note that it is challenging to ask about understanding in a context where there is a wrong answer or an unfamiliar algorithm and that the problem solved was a special case that surfaced a challenge that would not typically arise. Even though the feedback given by the TE could have been applied, Sammie may have needed additional support in learning about the sorts of understanding questions that could be useful in this particular mathematical situation, how to ask those questions in a situation where the answer is incorrect, and how to manage other complexities of interacting with the student in this context. Similarly, Sammie may have needed additional support to think about generating and using a follow up problem in this context.

Discussion

Across the broader data set, TCs varied in their ability or willingness to utilize the feedback provided by their TE. We hypothesize that TCs' uptake depends on the connections between their own resources, the feedback provided, and the context of subsequent teaching. We conceptualize resources as the combination of content knowledge for teaching, skill with high-leverage teaching practices, and orientations to teaching and learning that TCs bring to the work of mathematics teaching. In terms of the feedback, we are examining both the content (e.g., asking questions about student's understanding of core ideas) and the nature of guidance (reminding the TC about something already known, convincing the TC about the importance of something, and/or teaching the TC something new to try or think about). Given that the TC's teaching is influenced by the simulation context in which it occurs, we are considering the demands implied by particular mathematics content (invented/standard process, correct/incorrect answers) and particular characteristics of the student's thinking (degrees of procedural fluency and components of conceptual understanding) designed into the simulation.

We describe how a teaching simulation cycle focused on eliciting and interpreting student thinking in elementary mathematics can reveal important aspects of a teacher candidate's (TC's) knowledge and skill with eight performance areas relevant to more equitable mathematics teaching. Appraising a TC's knowledge and skill with respect to these performance areas is intended to support formative feedback that is actionable in subsequent teaching.

Keywords: Instructional Activities and Practices; Preservice Teacher Education

Formative assessment of teaching practice allows TCs to demonstrate the integration of content knowledge for teaching, high-leverage teaching practices, adherence to ethical obligations, and commitments to equitable teaching and learning, providing the TE with a snapshot of the TC's current knowledge and skill. We situate our work at the intersection of an interactive view of learning to teach (Ball et al., 2009) and formative assessment, a critical component of teacher preparation (Association of Mathematics Teacher Educators [AMTE], 2017). We use teaching simulations to provide interactive contexts to practice and demonstrate skill with mathematics teaching practice inside of formative assessment cycles that offer opportunities for feedback and improvement. Simulations are approximations of practice (Grossman et al., 2009) that place authentic demands on a TC while purposefully controlling the complexity of the work to allow TCs to encounter appropriate cognitive and practical demands on their budding teaching skills. Teaching simulations can provide early, frequent, and substantive formative assessment opportunities that are embedded in the doing of teaching. Specifically, we focus on the teaching practices of eliciting and interpreting student thinking. These practices are crucial for advancing more equitable mathematics instruction because they facilitate teachers' connection with – and attention to – the children they teach. In this paper, we describe how our teaching simulation cycle provides opportunities for TCs' to demonstrate their knowledge and skills with important facets that comprise the work of eliciting and interpreting student thinking and provide opportunities for TEs to observe such knowledge and skill in action. In turn, the observation provides the basis for formative feedback.

Our Teaching Simulation Cycle

Our simulation situation utilizes a piece of student work (see Figure 1) and a live actor (referred to as the simulated student) trained to use a set of response guidelines that specify the student's process and the student's understanding of the ideas underlying the process. These response guidelines include general guidance and specific responses to anticipated questions (see Shaughnessy & Boerst, 2018). As the TC interacts with the student's work and simulated student, the TE uses an observational tool to capture key aspects of those interactions.

The TC’s engagement in a teaching simulation cycle begins with the TC examining a piece of student work and planning questions to ask the student to learn about their process and understanding of the mathematics. Second, the TC has five minutes to interact with the simulated student to elicit the student’s thinking. Third, the TE interviews the TC to learn about their interpretations of the student’s thinking and their own understanding of the mathematics underlying the student’s process. Fourth, the TE engages the TC in a feedback conversation.

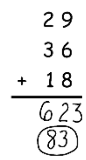

Figure 1: Sample Student Work

For over a decade, we have been designing, using, refining, and studying the use of these teaching simulations with our own preservice teachers. In the context of our current project, we are working with three TEs in different regions of the United States to develop tools and routines that support the using of the teaching simulations to provide formative feedback to TCs on their eliciting of student thinking.

Nurturing More Equitable Mathematics Teaching

Our approach allows us to gather evidence of a TC’s knowledge and skills with respect to eight performance areas that comprise the complex work of eliciting and interpreting student thinking, including why each area matters for nurturing more equitable mathematics instruction (see Shaughnessy et al., 2025 for an overview of how we conceptualize the articulation of performance areas within a more complex teaching practice for the purposes of teacher education). Next, we define each of these performance areas. We include a rationale for focusing on it and describe how the teaching simulation cycle enables us to learn about the knowledge and skills of TCs in that area.

Eliciting the Student’s Process for Solving the Math Problem

Elements of a student’s process may be evident in a student’s written work. However, when teachers look at a student’s written work, they often need to elicit more information about the process because the entire process is not visible in the written work. For example, in the student work shown in Figure 1, it is not clear how the student went from 6-2-3 to 83. Additionally, a teacher might make assumptions that do not correspond with what the student did. For example, TCs may assume that the student added the ones before the tens. This student starts with the tens. By asking about the entirety of the process, TCs can check these assumptions that could otherwise lead to mischaracterization of the student’s thinking and misdirect subsequent teaching. By looking at the interaction between the simulated student and the TC and which steps of the process the TC has the student talk about or otherwise show, we can gather evidence of a TC’s skills in eliciting a student’s process.

Kosko, K. W., Caniglia, J., Courtney, S., Zolfaghari, M., & Morris, G. A., (2024). *Proceedings of the forty-sixth annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Kent State University.

Interpreting the Student’s Process for Solving the Math Problem

Interpreting a student's process is important because sometimes an initial hypothesis and/or in-the-moment interpretation is incorrect. This may be more likely to happen when a student and teacher have different preferences for which process to apply when solving the problem. Inaccurate claims about a student's process and subsequent actions to "correct" or intervene when it is not necessary can be counterproductive to a student's learning. In the follow-up interview, we gather evidence about how the TC interprets the student’s process by having the TC share the student’s process in their own words and apply the process to a new mathematics problem.

Probing the Student’s Understanding

Understandings are crucial to using and recalling a process and a basis for subsequent instructional steps. Teachers need to know a student's reasoning because sensemaking is foundational to doing and learning mathematics. Probing understanding is also a way for teachers to show students that they value the student’s reasoning, not just their process and answer. We can gather evidence of a TC's skills in probing student understanding by looking at the interaction between the simulated student and the TC and the questions the TC asks to uncover the student's understanding of the process they are sharing. We can also gather evidence of the extent to which they probe student understanding when a student’s answer is correct. This is critical because in many classrooms, incorrect answers are interrogated (and assumed to reflect a lack of understanding), and correct answers are affirmed with an assumption of “student understanding.”

Teacher Interpretation Aspects of the Student’s Understanding

Being able to notice and name the understandings that students share and identify corresponding evidence of those understandings is important for leveraging the resources students bring and considering the next instructional steps. In the context of the follow-up interview, we ask the TC to share what was learned about what the student understands about their process and the mathematical ideas underlying that process. By leaving the question open, our simulation allows us to learn what understandings TCs notice and name without support. As a complement to self-identification of student understandings, we also directly ask TCs about pivotal parts of the mathematical processes they encounter in the simulation. Teachers need to know about students’ understanding of these components. These are places where notation or conventions may play an important, but implicit, role in the process. Teachers need to learn about these understandings to leverage students' resources when considering the next instructional steps. When teachers make claims about these understandings, it is crucial that they use evidence to support and check interpretations. This guards against misinterpretations that can arise when the teacher speculates or makes assumptions about what the student understands without information from the student. Misinterpretations of a student's understanding can lead to unnecessary intervention or lack of intervention when one is warranted. In the follow-up interview, we gather information about this by asking the TC to share what they learned about the student’s understanding of pivotal parts of their process and the associated evidence gathered that supports those interpretations.

Attending to the Student’s Thinking

When teachers actively use what a student says and writes as the basis for their next questions, teachers are likely to learn more about the student's process and understanding. It also conveys to students that their ideas are valuable. Helping students to see the value in their own ideas is a core part of building or shifting students' conceptions of what it means to do mathematics. We gather evidence of a TC's skills in this area by examining the interaction with the simulated student and seeing whether there is evidence that the TC is taking up ideas that the student has shared verbally (through revoicing and/or posing questions connected to ideas that have been shared). We can also see whether the TC is attending to written representations of the student's thinking and asking specific questions about what the student has written.

Applying Mathematical Knowledge for Teaching

Teachers use their mathematical knowledge in special ways, such as generating a follow-up problem that supports understanding the student's process. The appropriateness and accuracy of a teacher's communication with the student is important for ensuring the student can access the ideas and preventing misconceptions that language or representations can sometimes create. Through the interaction with the simulated student, we can sometimes gather evidence of a TC's mathematical knowledge for teaching by observing them pose an additional mathematical problem to the student, but this does not always happen. To gather evidence of such knowledge from all TCs, the follow-up interview involves asking the TC to generate a problem that could be posed to the student to confirm the student's process and understanding. We ask the TC why they selected the problem to learn about the features of the problem to which they are attending.

Using Mathematical Knowledge and Skills

Students can share processes for solving problems that are unknown to teachers. Teachers need to be able to use their own mathematical skills to analyze whether a strategy is mathematically sound and how it relates to other mathematical ideas. Determining the extent to which a student's strategy "works" across cases (generalizing) is key for determining the next instructional steps, including helping students see themselves as doers of mathematics. Teachers also need to be able to use mathematical knowledge precisely and with integrity and determine whether answers to problems are mathematically valid. Within the interaction with the simulated student and the interview, we can gather evidence of a TC's use of mathematical language and representations with integrity. We also ask the TC about the correctness of the student's answer and to generalize how the student's process would work across problems.

Conveying Respect for the Student as a Mathematical Thinker and Learner

Equitable mathematics instruction reveals and builds on student sense-making. Critiquing a student's strategy before seeking to understand it or redirecting a student toward a strategy they did not use can communicate to the student that their process is wrong or undesirable and that doing mathematics means deferring to a privileged process, often the algorithms traditionally taught in US schools. Within the interaction with the simulated student and the follow-up interview, TCs can demonstrate skills respecting the student as a mathematical thinker and learner by focusing on the student's process (and understanding of that process) in the interaction and describing and interpreting that process in the follow-up interview.

Discussion

We view the ability to make facets of equitable mathematics instruction concretely visible, doable, and improvable in the work of teaching as a central driver of the design and implementation of the simulation approximation of practice. This paper illustrates how a teaching simulation cycle focused on eliciting student thinking can reveal TCs' knowledge and skill in eight performance domains relevant to eliciting and interpreting student thinking. In our current work, we are using these teaching simulation cycles to provide formative feedback to TCs about their teaching and to understand the ways in which they are able to take up their feedback in a second teaching simulation cycle that immediately follows the first cycle.

TEACHER CANDIDATES' MATHEMATICS ANXIETY AND EFFICACY BELIEFS

Jessie C. Store
Alma College
storejc@alma.edu

Josephine Theut
Our Lady of Victory Catholic School
jtheut@olvnorthville.net

This study examines mathematics anxiety in preservice teachers, their efficacy beliefs regarding mathematics, and the relationship between these factors. The sample includes 50 preservice teachers at various stages of their undergraduate education. Data were collected using the revised Math Anxiety Rating Scale and Teacher Belief Survey. Descriptive statistics revealed high anxiety related to mathematics assessments and moderate anxiety in learning and performance experiences. Preservice teachers generally held a problem-solving view of mathematics and were neutral about the instrumentalist view.

Keywords: Teacher Beliefs

Mathematics anxiety, defined as "feelings of tension and anxiety that interfere with the manipulation of numbers and the solving of mathematical problems in a wide variety of ordinary life and academic situations" (Richardson & Suinn, 1972, p. 551), is more complex than just test anxiety or general anxiety. Hembree's (1990) meta-analysis of 151 studies found a correlation of .52 between mathematics anxiety and test anxiety but attributed 63% of mathematics anxiety to other sources like mathematics learning and homework. Additionally, Hembree identified mathematics anxiety as a learned condition, more behavioral than cognitive.

Teacher efficacy is perceived as teachers' beliefs in their ability to influence student learning (Guskey & Passaro, 1994, p. 628). Mathematics teacher efficacy includes different belief systems on how students learn. Ernest (1989, as cited in Beswick, 2005) explored three views of mathematics: instrumentalist, platonist, and problem-solving. The instrumentalist view focuses on performance and content, the platonist view emphasizes understanding and constructing knowledge, and the problem-solving view is learner-focused, believing in learning through exploration. Van de Walle et al. (2019) promote a problem-solving approach called "teaching through problem solving" where students learn mathematics through exploring real contexts.

Studies show varying relationships between mathematics anxiety and mathematical beliefs. Beswick (2005) found secondary teachers rarely held an exclusive problem-solving view. Hughes (2016) found elementary teachers leaned towards problem-solving views, with high anxiety corresponding to instrumentalist beliefs and low anxiety to problem-solving beliefs. Haciomeroglu (2013) found that preservice teachers with stronger constructivist mathematical beliefs felt less anxious. However, Uysal and Dede (2016) found no significant correlation between anxiety and beliefs in Turkish preservice teachers. Despite differing findings, many studies indicate a lean towards problem-solving views in mathematics teaching (Hughes et al., 2019; Uysal & Dede, 2016).

Literature reviewed has established that high mathematics anxiety for teachers may have consequences on mathematics learners' anxiety. Literature has also shown the relationship between teachers' anxiety, beliefs, and instructional practices. Investigating preservice teachers' mathematics anxiety and the experiences that are associated with the most anxiety can reveal formative feedback for effective teacher education. Preservice teachers' espoused beliefs about the teaching of mathematics can predict their future instructional practices, giving teacher educators learner-centered tools for teacher education. Furthermore, exploring the possible correlation between mathematics anxiety and espoused beliefs about teaching may show factors that affect beliefs and anxiety, and consequently teaching practices. Thus, the objectives of this paper will answer the following questions:

1. What is the nature and level of mathematics anxiety of preservice teachers?
2. What is the nature and level of preservice teachers' espoused beliefs about the teaching of mathematics?
3. Is there a significant correlation between mathematics anxiety and espoused beliefs about the teaching of mathematics?

Methodology

Preservice teachers were conveniently sampled from one college in the Midwest, consisting of 50 participants at varying stages of their undergraduate education, from first year to senior year, including both elementary and secondary preservice teachers. Participants completed a survey comprised of two valid and reliable instruments: The Mathematics Anxiety Rating Scale-Revised (MARS-R, Plake & Parker, 1982) and the Teacher Belief Survey (TBS, Beswick, 2005). The MARS-R includes 24 items on a 5-point Likert scale from 0 (low anxiety) to 4 (high anxiety), while the TBS uses a 5-point scale where 1 represents strongly disagree and 5 represents strongly agree, with high scores indicating a stronger alignment to the problem-solving view and lower scores aligning with an instrumentalist view on mathematics teaching and learning. Descriptive statistics were explored to summarize efficacy beliefs and anxiety.

Results

Nature and Level of Mathematics Anxiety of Preservice Teachers

The total ratings for MARS-R scores range from 0 to 96, representing no to high mathematics anxiety. In the current study, preservice teachers' MARS-R scores ranged from 13 to 86, with an average score of 50.62, slightly over the moderate stress level. The scores have an interquartile range of 41.5 to 60.25, indicating a symmetric distribution, with the lower 25% of scores between 17 and 41 and the top 25% between 60.25 and 86. Mathematics tests and assessments, particularly final exams and pop quizzes, have higher associated anxiety than other categories, with average ratings of 3.62 and 3.58, respectively (see Table 1). Preparing for a test and waiting for test results have lower anxiety ratings. Mathematics performance experiences, such as reading chemistry formulas and working on abstract problems, also induce moderate anxiety.

The anxiety related to mathematics learning experiences, like having difficult homework due and signing up for a statistics course, is moderate, with an aggregate average of 1.913. Experiences with less mathematics interaction, such as buying a textbook or thinking about mathematics, result in lower anxiety ratings, showing that participants feel less anxiety in such scenarios compared to other categories. Notably, the experience with the least amount of anxiety attributed to it is watching a teacher work on an algebraic equation on the board, with an average rating of 1.48. Overall, mathematics performance does not have as much anxiety attributed to it as the mathematics assessment category.

Table 1
Averages and Standard Deviations of Mathematics Assessment Experiences

Questionnaire Item	Average	Standard Deviation
Thinking about an upcoming mathematics test one day before	3.04	1.009
Taking an examination (quiz) in a mathematics course	3.02	1.116
Being given a "pop" quiz in mathematics class	3.58	0.731
Taking an examination (final) in mathematics class	3.62	0.725
Getting ready to study for a mathematics test	2.4	1.05
Waiting to get a mathematics test returned in which you expected to do well	2.52	1.111

Efficacy Beliefs about Teaching Mathematics

The problem-solving view of the mathematics subset of TBS has a highest possible score of 70, while the instrumentalist subset has a highest possible score of 50. Based on Brechin-Harrison's (2008) method of calculating TBS subset scoring ranges, the scoring ranges for each level of agreement are reported in Table 2. The TBS subscale scores provide insight into preservice teachers' efficacy beliefs. The problem-solving view of mathematics has a mean score of 55.44, indicating that participants generally agree with this view. In contrast, the instrumentalist view has a mean score of 33.56, showing that participants on average neither agree nor disagree with it. Ninety-four percent of respondents agreed that "it is important for children to be given opportunities to reflect on and evaluate their own mathematical understanding." Additionally, 90% agreed or strongly agreed with the statement, "a vital task for the teacher is motivating children to solve their own mathematical problems" (mean=4.3), and 84% agreed that "teachers can create, for all children, a non-threatening environment for learning mathematics." However, only 70% agreed with the effectiveness of having students justify mathematical statements (mean=3.94) or allowing a student to struggle with a problem (mean=3.7). Overall, the problem-solving view has many components with which this sample of preservice teachers agrees.

Table 2
Brechin-Harrison's Scoring Range for TBS Subscales

Sub-scale	Level of Agreement	Scale Range
Problem Solving View of Mathematics	Strongly Agree	70.0 - 63.0
	Agree	**62.99 - 49.0**
	Neither	48.99 - 35.0
	Disagree	34.99 - 21.0
	Strongly Disagree	20.99 - 14.0
Instrumentalist View of Mathematics	Strongly Agree	50.0 - 45.0
	Agree	44.99 - 35.0
	Neither	**34.99 - 25.0**
	Disagree	24.99 - 15.0
	Strongly Disagree	14.99 - 10.0

In contrast, the instrumentalist view of mathematics, which preservice teachers had a neutral view on, had statements with averages ranging from 1.48 to 4.46. The most agreed-upon statement was "it is important for teachers to understand the structured way in which mathematics concepts and skills relate to each other," with 92% of participants agreeing (mean=4.46). Interestingly, while 86% agreed that "it is the teacher's responsibility to provide children with clear and concise solution methods for mathematical problems," only 74% believed in an expository style of teaching mathematics. Furthermore, although participants strongly agreed that there is a set amount of mathematics content to be covered at each grade level (mean=4.18) and that mathematics should be taught in a correct sequence (mean=4.2), there was no strong consensus on whether this sequence should come from a textbook (36.73%, mean=2.959). The responses reflected mixed views about the definition of mathematics, with 55.1% agreeing that mathematics is computation (mean=3.571) and 54% agreeing that mathematics is a beautiful, creative, and useful endeavor (mean=3.48). This overlap indicates that some preservice teachers share both problem-solving and instrumentalist views on mathematics.

Correlation Between Mathematics Anxiety and Efficacy Beliefs

When comparing each participant's efficacy belief statements to their MARS scores, there was no significant correlation between the two variables. The statement with the strongest correlation, -0.298, "Knowing how to solve a mathematics problem is as important as getting the correct solution," is still considered very weak. The correlations of the other efficacy statements to their MARS scores were also very weak, ranging from -0.3 to +0.139. This indicates no significant relationship between the participants' mathematics anxiety scores and their efficacy beliefs. Despite the lack of strong correlations between specific items in the Teacher Belief Survey and the Mathematics Anxiety Rating Scale scores, there is a significant correlation between the TBS subscale scores and the MARS-R scores. The instrumentalist view on mathematics has a correlation of 0.734 with the MARS scores, and the problem-solving view has a correlation of 0.839. This indicates a substantial relationship between mathematics anxiety and holding either an instrumentalist or problem-solving view on mathematics, with higher anxiety corresponding to higher alignment with these views.

Discussion and Conclusion

Mathematics anxiety has been linked to various negative impacts on learners (Kargar et al., 2010; Wang et al., 2015), including the performance of students taught by anxious teachers (Beilock et al., 2010; Schaeffer et al., 2020). In this study, elementary and secondary preservice teachers demonstrated moderate levels of mathematics anxiety, differing from previous studies reporting both high and low anxiety levels (Juanita & Budayasa, 2020; Patkin & Greenstein, 2020). Preservice teachers generally aligned with the problem-solving view in mathematics teaching, which has positive implications for student learning outcomes (Behlol et al., 2018). However, despite overall agreement with problem-solving principles, many preservice teachers hesitated to let students struggle with mathematics problems, a crucial aspect of this teaching approach. Additional training may be beneficial to help preservice teachers embrace productive struggle in the classroom. Interestingly, our study found no clear association between mathematics anxiety and specific teaching views, contradicting prior research (Hughes, 2016; Haciomeroglu, 2013).

Limitations include the small sample size from a single institution, lack of disaggregated data for mathematics teaching endorsement seekers, and failure to distinguish between elementary and secondary education majors. Future research should address these limitations to provide deeper insights into preservice teachers' anxiety and teaching beliefs. Nonetheless, our findings offer valuable insights for modifying preservice teacher instruction to alleviate mathematics anxiety, particularly regarding assessments, and reinforce problem-solving pedagogies.

The PrimeD Framework and its Phases

The abbreviation PrimeD stands for Professional Development: Research, Implementation and Evaluation and is a preservice teachers professional development framework as defined in Rakes et al. (2017) and Saderholm et al. (2017). This framework has four phases phase I (Design and Development), phase II (Implementation), phase III (Evaluation) to IV (Research) as illustrated in Figure 1. These phases are dynamic, follow a feedback loop structure (as indicated by arrows in figure 1) and "continuously" build on each other. Together they offer a flexible structure that supports systemic and individual changes and builds leadership and professionalism in preservice teacher candidates.

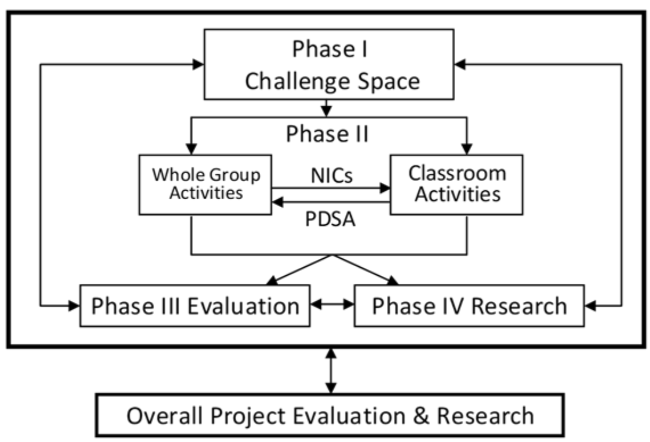

Figure 1. Diagram of PrimeD Phases Interactions with External Evaluation

In Phase I, a common vision is developed, contextual issues are considered, and a plan of action is formed (including goals, outcomes, strategies, and assessments) which drives downstream activity (Bryk, et al., 2015). The Challenge Space from Phase I serves as an overall dynamic monitor to guide the implementation, evaluation, and research phases (indicated by the arrows in figure 1). Phase I is accomplished by preservice teacher ~~candidates~~ along with the project PIs. The next phase is the highly active Phase II where Phase I is implemented in the form of classroom Implementation and Whole Group Engagement (WGE). In other words, NICs and PDSA cycles drive this phase either towards Phase III and IV or back to Phase I. Phase II is accomplished by PIs, preservice teachers, their mentors, program alumni and the Co-PIs of the local and non-local sites.

Figure 2 displays the structure of an observation sequence for the first round of NIC meetings

Kosko, K. W., Caniglia, J., Courtney, S., Zolfaghari, M., & Morris, G. A., (2024). *Proceedings of the forty-sixth annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Kent State University.

occurring at all four university sites. Each co-PI (solid vertical arrows) observed the NIC meeting at their site. They also observed a NIC meeting at one of the other sites (dashed diagonal arrows). The Lead evaluator observed the NIC meetings at all four sites. This structure ensures three observations for every NIC meeting. The data from each observation form is then entered in a spreadsheet, graphed and analyzed. The results are then discussed at the following evaluation and implementation team meetings. This structure is repeated three times each semester.

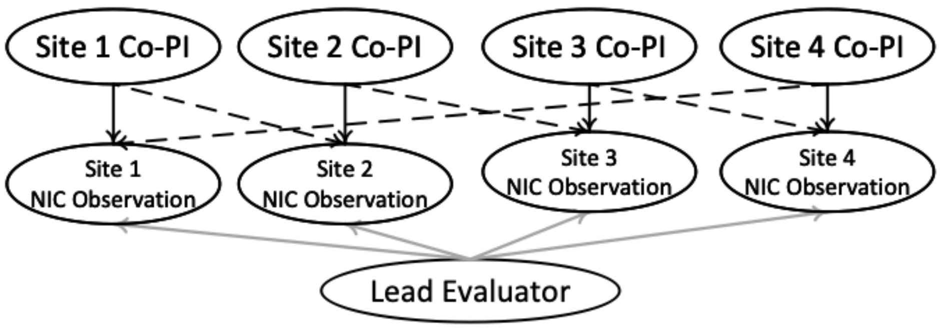

Figure 2: NIC Meeting Observation Structure

Phase III, Evaluation, focuses on the notion that members of a profession participate in establishing what strategies best meet the needs of their student populations. This phase is executed by the preservice teacher and the PIs. Similarly Phase IV emphasizes that it should be common practice that members of a profession participate in generating professional knowledge associated with their practice. The overall project evaluation that differs from the evaluation Phase and is illustrated below the larger rectangle in the Figure 1, should attend to these components as well as other implementation activities. Phases III and IV are interchangeable in their order and can be acknowledged together or individually.

Description of the Evaluation Design

The implementation design includes both evaluation and research components (Figure 1), so the evaluation for this project needed to address that entire structure, that is consist of the project's implementation as well as their evaluation and research efforts within it. Therefore, the research questions are presented in two categories.

Evaluation Questions about the Implementation

- EQI 1: Did the Implementation connect to PrimeD consistently?
- EQI 1a: Was the challenge space vision and design embraced by all participants?
- EQI 1b: Did participants address evaluation and research in their lesson development?
- EQI 2: Did the Implementation team gather sufficient data to answer their research questions?

Research Questions about the Evaluation

- RQE 1: Did the formative evaluation design provide timely and useful data?

- RQE 2: Did the summative evaluation design capture the implementation and impact of the PD?
- RQE 3: To what degree was the evaluation design efficient?

This design builds in multiple collaborative observations which are compared and discussed after the event to calibrate observations and share outcomes as a fundamental part of the process.

Research Questions about the Evaluation Design

- RQ4: Did the evaluation design capture the implementation? Did it provide timely and useful data?
- RQ5: Was the evaluation design efficient?
- RQ6: Was the evaluation design effective; Did it capture the impact of the PD?
-

Results

The project reported improved communication and participation among stakeholders and improved teacher candidate pedagogical content knowledge to engage in research-based teaching strategies for EQI 1. For EQI 2 in the NIC meetings, participants agreed upon innovations to implement in the classroom and evidence to collect regarding the innovation's effectiveness. Participants shared adjustments made to their innovation strategy. Their results directed the conversations and guided further refinements within and across sites. Mentors, supervisors, alumni, and faculty were positioned as a collaborative support team. Finally, the challenge space continued to be discussed at team meetings throughout the project with an explicit focus on converging foci across institutions. Implementation strategies were explored and discussed in detail with a focus on how to maintain coherence across institutions while honoring the necessary contextual differences and aligned with the project vision which addressed EQI 2.

Conclusion

The need for "non-normal" evaluative mechanisms that are adaptive, open to challenges, highly collaborative and participant-centered is urgent, and even more so now, after the COVID-19 period. The PrimeD framework has helped to address some important issues: How collaboration and sense of community benefits all, how to be both structured and flexible in evaluation tasks; How to share formative evaluation results in a timely manner; and how to blend evaluation and implementation in clear and useful ways.

As evaluators, we need to rethink how "professional teachers" are developed. More study is needed to determine what guides change in practice and how that change is key to learning. We need to know how to see the widening gaps that "normal" evaluation in education can create and when "post-normal" evaluation is required (Schwandt (2019). We did learn that PrimeD framework can support "non-normal" evaluation. In today's complex teaching environment, non-normal evaluation will be critical for understanding PD structures and results.

The structure of the PrimeD evaluation team had a number of advantages such as:

1. Open observations (completed observations and recordings were available to all team members as soon as they were completed),
2. A local team member (site PI or Co-PI) was able to share and discuss results within their local team,
3. The non-local team member (the PI or Co-PI at another institution) was able to share new ideas and results with their own team,
4. Local PIs could review the observation results which guided their work and innovations.
5. The PI's (and all team members) could and often did attend regularly scheduled implementation and evaluation meetings in which evaluation results were discussed,
6. Including site Co-PIs as part of the evaluation team reduced the cost of the evaluation and improved the observation reliability,
7. The site PIs or Co-PIs became familiar with the work at all the project sites through the observations and evaluation alignment meetings promoting additional collaboration throughout the project and,
8. Being on the evaluation team provided additional leadership opportunities for site PIs or Co-PIs.

A CUSTOM MIXED-REALITY SIMULATION DESIGN: MINIMIZING TEACHER BIASES IN MATHEMATICAL DISCUSSION PRACTICES

Keywords: Preservice teacher Education, Teacher Knowledge, Classroom Discourse

Mixed-Reality Simulations (MRSs), blending real and virtual environments, provide a low-risk environment (Dieker et al., 2014; Piro & O'Callaghan, 2019) to rehearse core teaching practices (Jacobs & Spangler, 2017). Grant and Ferguson (2021) designed a Mursion™ custom simulation to support pre-service teachers' (PTs) mathematics discussion practice. PTs had opportunities to facilitate a discussion of provided student solutions (e.g., drawing, repeated subtraction, creating table) to a mathematics task: "Harry the Dog Problem" (Grant & Ferguson, 2021), where Harry the dog is waiting in a line of 23 dogs to be washed. When a dog is washed, Harry sneaks ahead of two dogs. How many dogs will be washed before Harry?

In this context, PTs encouraged students to share, attend to, repeat, and critique each other's work. However, they less frequently focused on students' mathematical potentials (Kocabas et al., 2024). PTs attend to learner identities (Drake, 2006; Rubel et al., 2022) participation (Dunning, 2022), influencing PTs' discussion moves (Kocabas et al., 2023). We designed MRS to support PTs to attend to the mathematical potential of student solutions by creating PODSim, a new MRS application unlike Mursion™ (Grant & Ferguson, 2021). PODSim features gender ambiguous rainbow avatars and the ability to compare mathematics work (Table 1a & 1b) to encourage PTs to have increased focus on the mathematics. Further, we revised the solutions using virtual number lines to create opportunities for PTs to engage with avatar learners understanding of solutions that enacted the problem using repeated jumps and distances. We hypothesize that PODSim MRS microteaching environment (Grossman et al., 2009; Ledger et al., 2019) will support PTs' foci on mathematics equity and interaction in discussion practices.

Our revised solutions within PODSim foregrounds student work, removes race and ethnicity and positions PTs to directly encounter avatar students' mathematics solutions created using virtual number line models (see Table 1c & 1d). The PTs were expected to use solutions to investigate avatars' mathematical thinking by facilitating discussion that elicits avatar student reasoning, sense making, and ways of knowing to enhance mathematical understanding (Graeber, 1999; Jacobs & Spangler, 2017; Smith & Stein, 2018).

SECONDARY PRESERVICE TEACHERS ENGAGING MULTILINGUAL LEARNERS IN MATHEMATICS LEARNING

Parastoo Zareie
University of Kentucky
Pza226@uky.edu

As the number of Multilingual Learner (ML) students attending public schools rises, so does the demand for those who can teach them. To address the gaps between theory and practice (Ball, 2000) in professional development (PD) programs, PrimeD (Professional Development, Research, IMplementation, and Evaluation) framework has been proposed which has four phases of Design, Implementation, Evaluation, and Research. The cyclic nature of PrimeD provides a coherent structure to PD activities. The purpose of my study is to examine possible benefits of PrimeD on secondary Mathematics PreService Teachers (MPST) reflecting on their instructional practices that engage ML students.

Introduction

Today, Multilingual Learner (ML) students are the fastest-growing student population group attending public schools nationwide (National Education Association https://www.nea.org/). By 2025, 1 out of four students in the US are estimated to be an ML. With regard to mathematics learning, the achievement gap at different levels between ML and non-ML students has long been recognized. As the number of MLs attending public schools continues to rise so does the demand for those who can teach these students effectively. Based on data from the National Center for Education Statistics (NCES, 2017), the ratio of educators who are dedicated to addressing the needs of this growing population of students is substantially low.

Among the reasons experts mention for the existence of shortage of trained mathematics teachers who are familiar with ML students' needs is lack of robust educator training. Although teacher preparation programs are considered as one of the most important and effective ways to improve the knowledge and skills of STEM teachers and to enhance their performance, research shows that such programs often do not benefit participating teachers in general. To address the gaps between subject matter knowledge and pedagogy while teachers need to be equipped with both to be able to teach their students well (Ball, 2000), a professional development (PD) framework, called PrimeD (Professional Development, Research, IMplementation, and Evaluation), has recently been proposed. PrimeD organizes PD into four phases of Design, Implementation, Evaluation, and Research, which work in a cyclic nature and occur iteratively throughout the program. A key feature of PrimeD that appears to help preservice teacher make stronger connections between field experiences and theories learned in their coursework, as recommended by Gainsburg (2012), is the use of Networked Improvement Communities (NICs) (Bryk, Gomez, & Grunow, 2011; Martin & Gobstein, 2015) to cycle between classroom implementation and whole group engagement in PD sessions.

PrimeD Professional Development Framework

In 2017, Saderholm et al. proposed a Professional Development Framework called PrimeD (**P**rofessional **D**evelopment: **R**esearch, **IM**plementation and **E**valuation) which consists of four phases that are arranged into categories of: Design, Implementation, Evaluation, and Research (Figure 1).

PrimeD first phase (Design and Development) is fundamental in the success of the PD as it focuses on bringing together all stakeholders to agree on a common vision, define the target outcomes, discuss the most critical challenges to reaching those targets, and subsequently develop strategies to overcome them.

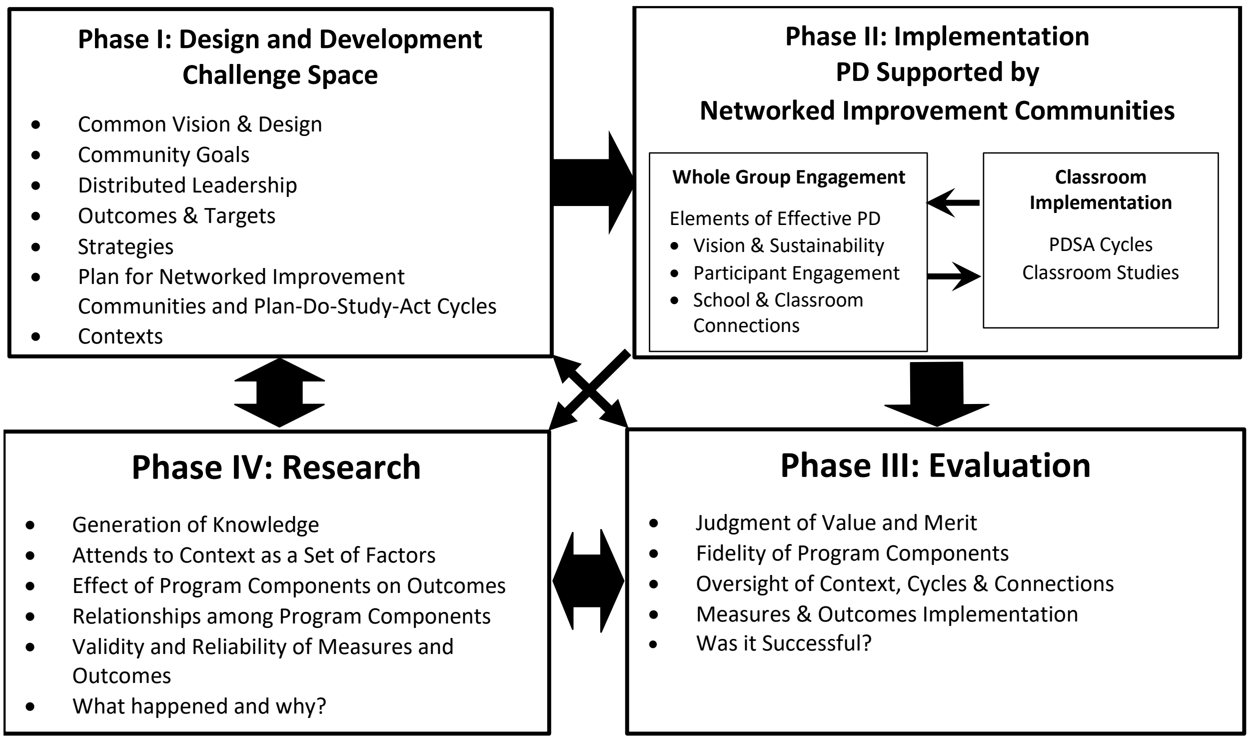

Figure 1: Condensed Model of PrimeD Framework (Saderholm et al., 2017).

The second phase of PrimeD (Implementation), starts with the "whole group engagement" followed by "classroom implementation", both of which are supported through Networked Improvement Communities (NIC). In this phase, the participating teachers will use effective PD elements (planned in the design phase) to come up with strategies that target specific aspects of their teaching through the Plan, Do, Study, Act (PDSA) cycles. The PDSA cycle is an iterative method used for systematic and continued improvement of a process.

The next phase involves evaluation of phases I & II, which should be performed using both formative and summative assessments.

The last phase of PrimeD, called Research, is focused on asking questions that would help better understand "what happened during the PD processes and why", or help "gain insight into effectiveness (or lack of) certain approaches", etc. So, inherently, this phase is closely related to and in constant interaction with other phases.

Methodology

Research Design

I have employed a convergent mixed-methods research design for my study. The design has a single phase of separate quantitative and qualitative data collection and analysis followed by merging and comparing quantitative and qualitative results to see if they confirm or disconfirm the findings (Creswell & Creswell, 2018).

Participants

The participants of my study were chosen by convenience sampling from a mixture of more than eighty-three female, male, and non-binary MPSTs across four institutions (Institutions 1-4) in three Eastern and Southeastern states in the US during the first three years of the program (2020-23). At all four institutions, quantitative data was collected by requiring PrimeD participants to submit two lesson videos (Pre and Post) from the beginning and the end of their student-teaching semester. A teacher evaluation instrument called MCOP^2 (Gleason et al, 2017) was used to code and quantify MPSTs' lesson videos. Excluding the incomplete data, I had access to MCOP^2 scores of sixty-one lesson video pairs. By conducting semi structured interviews with eight MPSTs from Institution 3 and Institution 4, I was able to collect qualitative data.

Analytic Strategy

I used Thematic Analysis (Maguire & Delahunt, 2017) to analyze the interview transcripts and Wilcoxon and t-test to analyze the MCOP^2 scores of MPSTs' recorded Pre and Post videos. The focus of my study is on the nine indicators within MCOP^2 Student Engagement subscale that are presented in Table 1.

Table 1: MCOP^2 Student Engagement Subscale Indicators (Gleason et al., 2017).

Indicator 1	Students engaged in exploration/investigation/problem solving.
Indicator 2	Students used a variety of means (models, drawings, graphs, concrete materials) to represent concepts.
Indicator 3	Students were engaged in mathematical activities.
Indicator 4	Students critically assessed mathematical strategies.
Indicator 5	Students persevered in problem solving.
Indicator 12	There were a high proportion of students talking related to mathematics.
Indicator 13	There was a climate of respect for what others had to say.
Indicator 14	In general, the teacher provided wait-time.
Indicator 15	Students were involved in the communication of their ideas to others (peer-to-peer).

Findings

Table 2 shows that based on the available three-year data from Institution 2, Institution 3, and Institution 4, on average, Institution 3 has the largest percentage of participating MPSTs who improved their observed practices associated with MCOP^2 indicator 1 (investigation and problem solving), indicator 2 (using variety of means to represent concepts), indicator 4 (assessing mathematical concepts critically), indicator 5 (perseverance in problem solving), indicator 12 (mathematical discourse), indicator 13 (creating climate of respect), and indicator 14 (providing wait time). Similarly, on average, Institution 2 has the largest percentage (47%) of participating MPSTs who improved the form of student engagement that is measured by MCOP^2 indicator 3 (mathematical activities in their classrooms). By comparison, Institution 4, on average, has the largest percentage (56%) of participating MPSTs who improved on MCOP^2 indicator 15 (peer-to-peer communication of ideas).

In harmony with the results of Institution3 quantitative data analysis, the emergent themes (Table 3) from interviews conducted with Institution 3 participants focus more on the impacts of offering wait time, mutual respect, and strategies that were implemented in their classroom as PDSA cycles that could increase mathematical discourse. Similarly, the themes emerged from Institution 4 qualitative data are more focused on peer-to-peer communication of ideas which confirm the quantitative results. This answers the first Research Question.

To answer the second Research Question, I only relied on the qualitative data analysis results because the MCOP^2 instrument did not collect any data from teachers' reflections on their practices or with regard to ML students. The results of qualitative data analysis indicate that participating in PrimeD project has made the teachers become more reflective on their practices as they implement interventions, collect data, and study the data within the PDSA cycles. The themes presented in Table 3 that are associated with ML students are results of such reflection.

Table 2: Percentage of MPSTs' who improved scores of each MCOP^2 indicator (highest values shown in bold).

MCOP^2	Institution 2				Institution 3				Institution 4			
	Y1	Y2	Y3	Avg.	Y1	Y2	Y3	Avg.	Y1	Y2	Y3	Avg.
Indicator 1	43	20	40	34	64	38	75	**59**	17	33	33	28
Indicator 2	29	50	40	40	64	50	50	**55**	50	33	17	33

Indicator 15	57	30	40	42	73	38	25	45	67	50	50	**56**

Table 3: Themes emerged from MPSTs' Interview.

Student Engagement Themes	**Participants Frequency**
Higher with activities and real-world problems	3
Having a sense of belonging increases engagement	3
Higher with varying activities	2
Building relationship with students increases engagement	2
Providing wait time increases engagement	2
Impact of PrimeD Themes	
Importance of collaboration	5
Getting new ideas from other participants	4
Introduced different forms of engagement	3
Helped teachers reflect on their practices	2
Receiving valuable feedback from other participants	2
Helped increase engagement	2
Focused on conceptual mathematics learning	2
MPSTs' Reflection on their Instructions Themes	
Building teacher-student relationships help increase math learning	4
Peer support increases participation and math learning	4
MLs engage more in activities within small groups or individually with teacher	4
Less for MLs because verbal communication is a barrier	4
Providing wait time helps MLs participate	3
Looping MLs in conversations helps them participate	2
Building relationships helps MLs' learning	2
Giving a prompt helps MLs get started	1

Keywords: rural, middle grades, professional learning, teacher leader, university specialist

The Rural Action Network for Growth and Engagement in Grades 6-8 Mathematics (RANGE Math) project is a teacher-researcher alliance for rural middle grades mathematics teachers and teacher-leaders, supported by experienced teacher educators with expertise in job-embedded professional development and school-based research. RANGE studies two models for expanding a successful local professional learning project to a large group of rural teachers in [Blind]. The project will investigate teachers' implementation of Explicit Attention to Concepts (EAC) and Students' Opportunities to Struggle (SOS), two clusters of instructional practices with robust research evidence for increasing students' mathematics achievement (Hiebert & Grouws, 2007).

RANGE tests two models for large-scale professional development with rural teachers of mathematics by attending to the unique funds of knowledge and challenges in rural schools. The project scaffolds teachers' improvement efforts with job-embedded cycles of content-focused professional development and structured action research. The research design includes balanced random assignment of N = 90 rural teacher-participants to either online professional development with university-based specialists (Condition 1) or in-person professional development with a local teacher-leader (Condition 2), accompanied by controls for the quality of professional development, cycles of data-informed instructional improvement, and data collection protocols. Condition 2 includes a teacher-leader program that will build capacity of local teachers to lead instructional improvement, with both conditions benefiting from expert facilitators and a team of researchers offering measurement and analysis infrastructure to assist in data interpretation. A sequential mixed methods research design addresses student and teacher outcomes in the network, allowing for statistical estimates of shifts in teachers' knowledge, beliefs, and instructional practices, as well as growth in students' mathematics achievement and classroom engagement. Importantly, the study will build much needed evidence on the relative benefits of online and in-person models of professional development at scale with rural mathematics teachers.

The purpose of the poster is to share the project design, intentions, and future directions to spur conversation about what it means to provide professional learning opportunities and research said opportunities in rural contexts. This project will improve scientific knowledge of STEM teaching by adding to scholarly understanding of: (a) effective mathematics instruction in the middle grades, (b) the adoption of EAC and SOS in rural settings, and (c) conditions that support rural mathematics teachers' professional development.

We explored the videos used to provide professional learning opportunities for coaches taking part in video clubs as part of a three-part professional development project. In year one, professional development facilitators selected the videos, while in the second year of professional development, the coach participants selected videos. We explored the rationale that coaches provided for the selection of their video clips. Findings indicated that coaches selected video clips that included content directly aligned with content-focused coaching, highlighted the practices of coaching, and included content that the selector deemed important for others to notice. We provide implications for those designing video clubs for coaches, as well as teachers, as the findings may be applicable when considering video selection beyond coach video clubs.

Keywords: Professional Development, Teacher Noticing

Video Clubs in Research

Researchers have repeatedly shown that video is a powerful tool for teacher education (Brophy, 2003; Coles, 2019; Christ et al., 2017; Gaudin & Chaliès, 2015; Santagata et al., 2021; Seidel et al., 2013). Of the many uses of video to support teachers, video clubs have been shown to be beneficial in improving teacher learning (van Es & Sherin, 2008; 2010). van Es and Sherin (2008) describe video clubs as the gathering of a group of teachers who "meet to watch and discuss excerpts of videotapes of their instruction" (p. 244). Video clubs have most commonly centered on mathematics or science content (Luna & Sherin, 2017), with the intent to develop teachers' pedagogical development (Kang & van Es, 2019; Luna & Sherin, 2017). Walkoe (2015) notes that the purpose of video clubs is to support teachers to "attend to and reason" about particular content within a video, a purpose mirroring that of professional noticing (e.g., Jacobs et al., 2010; König et al., 2022; van Es & Sherin, 2008)(p. 525). In fact, many video clubs have been intentionally designed to support teacher noticing (e.g., Mitchell & Ariemma-Marin, 2015; van Es & Sherin, 2010; Wallin & Amador, 2019). Researchers have found that what is noticed in the videos in video clubs is consequential for teacher learning opportunities (Borko et al., 2008; Gaudin & Chaliès, 2015; Walkoe, 2015). Given the repeated use of video clubs for teacher learning (Coles, 2019; van Es and Sherin, 2010), and knowing the affordances of the process for learning (Beisiegel et al., 2017; Borko et al., 2008; van Es et al., 2014), we designed and implemented a video club structure for mathematics teacher educators' learning. Situated in a mathematics education context, our video club was designed to help mathematics coaches improve their ability to: (a) facilitate productive planning and debriefing conversations with teachers, (b) notice the impact of their coaching practices on teachers' thinking and instruction, and (c) use evidence from what they notice to make decisions about their coaching practices. The specific focus of the video clubs was to support coaches to notice critical events (see Amador et al., under review) of one-on-one coaching cycles (see Kochmanski & Cobb, 2022).

We designed and implemented the video clubs for a mathematics coaching context because we conjectured that the structure would support coach learning, just as video clubs have supported teacher learning (van Es and Sherin, 2010). However, before studying the outcomes of video club implementation in a coaching context, we considered it important to better understand the design of video clubs, as specific for a coaching context, as a way to delve into the nuances of how the professional learning opportunity was designed. As a result, we worked to answer the following research question: What rationale do coaches provide for how they select clips for video coaching clubs?

Theoretical Framework and Related Literature

We theoretically frame this work with the research literature on noticing. The concept that noticing what is important in educational settings and making decisions based on the interpretation of what is attended to is consequential to learning opportunities (Jacobs et al., 2010; van Es & Sherin, 2008). While the importance of noticing for mathematics educators has gained attention in literature, and researchers have come to recognize the value of noticing (Sherin et al., 2011; van Es & Sherin, 2002, 2021), research on noticing in coaching contexts is limited (Amador et al., 2024). As a result, we frame the video club video selection by considering the opportunities to notice (see Stockero et al., 2017) available in a coaching context.

The coaching approach utilized in our investigation is centered on content-focused coaching (West & Cameron, 2013), differing from instructional coaching or cognitive coaching methods. Content-focused coaching is characterized by its emphasis on disciplinary content during coaching discussions; coaching sessions should delve into the mathematical aspects of the lesson, how these mathematical concepts are incorporated into the task design, and which instructional strategies promote or enhance mathematical comprehension (Callard et al., 2022). The novelty in our professional development initiative was the adaptation of a traditional face-to-face mathematics coaching model into a fully online, video-based coaching model (Amador et al., 2021).

Method

Twenty-three coaches participated in selecting videos as part of video clubs in which they took part during a larger three-part two-year professional development project designed to support coaches of mathematics. The other two professional learning components included an online course and one-on-one content-focused coaching in which a mentor coach (those with more experience who were part of our professional development team) supported the efforts of coach participants (individuals coaching in a school or school district in mathematics).

In the video club structure, four to six coaches met regularly to discuss elements of video of coaching interactions between a classroom mathematics teacher and a coach. These meetings typically lasted from 90-120 minutes and included two focal videos for the coach participants to watch. Prior to the video club meetings, a member of the team selected video clips for participants to watch during the video club. It is the rationale for this selection to which we focus attention. To collect data on the rationale for their selected videos, coaches were asked verbally and in writing to provide an explanation for the video that they selected. Verbal interactions were audio recorded and transcribed verbatim. To analyze data, four members of our research team created a coding scheme that included categories for: (a) content-focused coaching aspects, (b) coach support of the teacher, (c) teacher practices/knowledge, (d) coaching practices, and (e) video coaching club context. Within each of these broad five categories, the codebook had subcategories that further defined various reasons. To code data, all four researchers coded each rationale response with as many codes as were apparent in the data. The team of four then met to reconcile any discrepancies in the coding and arrived at final counts for the rationales coming from each of the 23 coaches. We then calculated frequency counts to arrive at an overall description of the rationale.

Results and Discussion

Analysis of the data reveals three main trends that indicate that participants selected video clips that: (a) included content directly aligned with content-focused coaching, (b) highlighted the practices of coaching, and (c) included content that the coach selecting deemed important for others to notice. The following provides an overview of the findings, and then each trend is described.

Table 1 shows the breakdown of the overall rationale reasons provided. Recall that in some cases, participants provided more than one reason for a particular decision about (König et al., 2022) video choice.

Table 1: Percent in Each Category Provided as Rationale

Content-Focused Coaching Aspects	Coach Supports Teacher's	Teacher Practices/ Knowledge	Coaching Practices	Video Coaching Context	Total
38.61%	5.94%	15.84%	31.68%	7.92%	100%

Content-focused coaching practices were a main reason participants gave for selecting particular video clips to show during the video club. Within this overarching category, participants said they selected their video clips because they: focused on mathematics learning goals, demonstrated the use of instructional practice goals, provided an example of the structure of the lesson design, showed how to talk about anticipating student strategies, examined evidence of student thinking, illustrated the launching of a lesson or task, demonstrated debrief conversation structure, showed the coach doing the mathematics with the teacher, or illuminated collaboration or co-learning. The following is an excerpt of an example of the rationale one coach provided that was coded for aspects of content-focused coaching:

> Yeah, so the first clip is us talking about […] coaching—if you look at the lesson planning document at the bottom there's the debrief coaching cycle. I was just showing her that and letting her know that I was going to use that in the post discussion. That was my own goals. That first section is me setting my goals and making them apparent to her. I don't know, I chose that for that reason. Then the second section, that's kind of long, is her setting some of her goals. I cut out the part for setting content goals, but we focused on her setting the math practice goals. That's why I chose the first one is just highlighted our conversations around goals. That was my number one reason for choosing it.

In this example, the coach explicitly states that the selection was centered on goals, mathematics practice and content goals, which are both aspects associated with content-focused coaching.

Coaching practices were another main theme for why particular clips were selected. Coaching practices that were commonly coded included language related to: the five practices for orchestrating discussion (Stein et al., 2008), mathematics content development, engagement in related professional learning, and lesson content. In the following excerpt, the coach provided rationale related to the five practices, a key component related to coaching:

> As a district we are working on that five practices book […] Every time we do anything with PD, and I work with Arnold, it's always that—what's the goal of the lesson? What's the goal of the teacher? That focus has been there. When I went back and saw the lesson, I'm like, "Woo-hoo, it is in there." I was celebrating that yes, even—because when I did this with her, she's first year teacher too. Being excited that this is being ingrained in her right from the beginning. I guess that's why I picked it.

In this example, the focus is clearly on coaching a teacher to implement the five practices, a theme that was common among participants, with nearly 32% of the reasons given for video selection related to coaching practices.

Finally, a cross cutting theme that was not coded for directly with the codebook but was presented through thematic analysis was that of noticing (i.e., van Es & Sherin, 2008)—coaches selected videos that included content that they thought was important for others to notice. In the verbal description of her rationale for clip selection, Coach Riess shared her rationale behind the clips she chose for her first video coaching club was to include crucial aspects of content-focused coaching. To focus their time during the video club, Reiss narrowed in on learning goals and anticipating student strategies. She stated,

> We felt that those were really important and different to content focused coaching, where you might not see those aspects in other types of coaching, such as cognitive coaching or instructional coaching or student-centered coaching. That was how we kind of chose the topics of our video coaching club. When I went to go look for a clip that showed me having a discussion around learning goals, I first looked for a clip where that was really evident and clear and wasn't chopped up by different conversations that kind of came in and out of that discussion around learning goals. The one I settled on is a clip that, in it, the teacher had provided me with two learning goals for the task, as she had written those learning goals. When I read the learning goals, I felt that one of them really did not match what the task was asking students to do. I knew that the teacher might not have internalized the content as well as I would like. That was one thing I noticed. I also noticed there was other content in the task she had chosen that wasn't encompassed in her learning goals. Those were two things that I thought were interesting as I had looked at the learning goals she provided and the conversation we had.

This example shows that Riess had ideas in mind of what she wanted coach participants to notice in the video club, and she identified a video that contained what she was hoping others would notice during the video club.

These findings illuminate the reasons that specific clips were selected for the video clubs. As researchers have noted, the purpose of video clubs is to support educators to attend to and reason about particular events (Walkoe, 2015). Knowing what events are selected and why provides important information for both researchers and professional development providers, as the videos that are shown are consequential to the possible learning outcomes and can be a powerful tool for educator learning (Brophy, 2003; Coles, 2019; Christ et al., 2017; Gaudin & Chaliès, 2015; Santagata et al., 2021; Seidel et al., 2013). We encourage researchers and professional development providers to be cognizant of video choice during their projects and to maintain awareness of the rationale for video clip selection as the selection evidenced in this research directly related to the coaches' opportunity to notice and learn.

Video-based professional development (PD) supports teacher learning through grounding discussions in representations of practice. We consider PD where teachers, not the facilitator, were responsible for choosing video clips and generating a focal question. Using a framework for pedagogically productive talk, we investigate what contributes to productive video-based discussions. By analyzing two discussions held back-to-back, we unpack how the same group of teachers engaged in more and less pedagogically productive talk. This research has implications for understanding the features that contribute to productive video discussions in PD.

Keywords: Professional Development, Pedagogically Productive Talk, Video-based PD

Video-based professional development (PD) supports mathematics teacher learning through grounding discussions in representations of practice (e.g., Borko et al., 2008; Karsenty & Arcavi, 2017; Santagata, 2009; van Es & Sherin, 2008). In these PD designs, teachers typically view and discuss videos related to a professional learning goal, such as noticing student thinking or facilitating mathematical problem solving. Choosing video clips and focal questions is critical, intentional work for facilitators (Borko et al., 2014; Sherin et al., 2009), as is norm-setting (Borko et al., 2011). Through norm-setting, video selection, and focal question development, the facilitator has great agency to shape teachers' learning opportunities.

However, ceding some of the decision-making from facilitators to teachers may provide teachers more agency in choosing the focus of their learning. Recent research has begun to explore the learning opportunities available when teachers select video clips (Richards et al., 2021). Similarly, we posit that choosing the focal question for discussing a video clip may offer learning opportunities for teachers. Because clip and focal question selection are crucial for supporting teachers' learning in video-based PD, researchers need to investigate the nature of the discussions when they are guided by teacher-selected video and questions.

Pedagogically productive talk in PD consists of "talk that is productive for the development of participants' adaptive expertise and professional judgment" (Lefstein, Vedder-Weiss, et al., 2020, p. 362). This definition is based on Lefstein and colleagues' practical experience and their review of the growing body of literature surrounding teachers' discourse (Lefstein, Louie, et al., 2020). We seek to understand the features of pedagogically productive talk within a video-based PD context where the focal question and video are both chosen by the teachers, rather than by the facilitator. We ask: How do two video-based discussions, where teachers chose both the focal question and the video clip, unfold to produce different kinds of pedagogically productive talk?

Methods

Our research took place in a two-year PD program for early-career secondary mathematics teachers. Designed to promote equitable mathematics instruction (Cohen & Lotan, 2014), the PD included a two-week institute each summer, followed by virtual coaching sessions during the school year. We focused on small group coaching sessions, in which teachers shared videos of their own lessons and discussed emergent issues regarding their practice. For each small-group session, all teachers contributed a video clip, which the other group members viewed and commented on in advance. There were 22 teachers, divided into seven groups, that met three times per year. This resulted in 41 recorded sessions, containing 127 video discussions. Each session had the same structure, led by the same facilitator. Following norm-setting, the groups discussed each teacher's video (20-25 min per video). For each video, first, the video-sharing teacher described the context of the clip and addressed contextual questions (5 min). Second, the facilitator invited each person, beginning with the video-sharer, to name strengths of the video (5-10 min). Third, the facilitator prompted the video-sharer to name a question emerging from the video, which the group then discussed (10-15 min). Following all video discussions, the meeting concluded with the facilitator asking each teacher to name next steps in their practice.

Using a video discussion as the unit of analysis, we wrote memos following the framework for pedagogically productive talk (Lefstein, Vedder-Weiss, et al., 2020). We operationalized the framework using our data to generate indicators, non-examples, and guiding questions. Table 1 briefly presents the six features of the framework and a summary of our guiding questions for analysis. Additionally, we assigned a score for each feature to indicate if it was minimally (0), partially (1), or fully (2) present in each discussion (maximum of 12 for each discussion). Based on these scores, we identified pairs of video discussions that took place in the same session and had different levels of productivity. From five pairs with scores differing by eight or more, we chose one pair for comparison using the analytic memos, video recordings, and transcripts.

Table 1: Features of Pedagogically Productive Talk (Lefstein, Vedder-Weiss, et al., 2020)

Criteria	Summary of guiding questions for analysis
Focused on problems of practice	Is the discussion focused on a clearly articulated problem of practice that is rooted in issues the video sharer has faced in teaching?
Involves pedagogical reasoning	Do speakers offer different ideas, hypotheses, affordances, or constraints related to the problem of practice alongside reasoning?
Anchored in rich representations	To what extent do speakers refer to specific events, words, actions, or moments in the video and use them as evidence during the discussion?
Multivoiced	To what extent are different perspectives offered? How are these attended to, acknowledged, questioned, connected to, and built on?
Includes generative orientations	To what extent do the participants demonstrate orientations toward the problem of practice that are in line with the PD goals and values?
Combines support and critique	Do participants create a collegial and supportive space for sharing? To what extent do they offer critical questions or considerations?

Findings

We present a detailed analysis of two discussions from one coaching session during the first year of the PD. The group consisted of teachers Diego, Rebecca, and Sadie, and facilitator Garima (all names are pseudonyms). The meeting was the group's second of the year. Diego volunteered to discuss his video clip, from a review lesson, first. We found that the discussion of Diego's video scored 2 (present) in all six rubric categories, the highest possible score. The group then discussed Rebecca's video, focused on a novel participation structure Rebecca had tried. This discussion scored 1 (partially present) in the categories of problems of practice and generative orientations, and 0 (minimally present) in all other categories, yielding a total score of 2. This large divergence of scores between two discussions during the same session with the same participants enabled us to interrogate what features of the PD supported productive talk and what features inhibited it. We describe the differences in pedagogically productive talk for each video discussion, focusing on each rubric category individually.

Problems of Practice

The questions Diego posed to the group to frame their conversation were, "At this moment, how could I have gotten more information about what they [the students] do and don't know? What kind of moves could I have done?" These questions focused directly on a problem of practice, how to elicit and understand students' thinking, that is an ongoing concern for teachers across contexts (e.g., Sleep & Boerst, 2012). The questions were explicitly tied to an event in the video and were generalizable and resonated with other teachers. The focus on eliciting and interpreting student thinking was evident throughout the discussion and across contributions from all participants. Rebecca posed the questions, "When you walk around the room and listen to groups, how do you decide when to intervene and what to say? How do I decide when I'm making a useful comment and when I'm interrupting the flow?" While the questions named the problem of practice—when and how should a teacher intervene in groupwork, the question was disconnected from Rebecca's video. This made it difficult for the group to analyze classroom events and justify future courses of action.

Pedagogical Reasoning

During the discussion of Diego's video, teachers engaged in thought experiments (Munson et al., 2021) and reconsidered previous practices. Rebecca, referencing a specific moment from the video, suggested using brainstorming. Sadie extended that thinking, wondering what the goals of that brainstorming might be. Curiosity about classroom events was prevalent, and all participants supported their suggestions with explicit reasoning. In contrast, during the discussion of Rebecca's video, each person gave Rebecca tips and tricks for deciding when to intervene with student groups. These tips and tricks were not linked to specific evidence from the video clip, or necessarily supported with pedagogical reasoning.

Rich Representations

When discussing Diego's video, participants referred to specific moments of the video to gain information and understanding regarding classroom events. They also used the video to create an imagined alternative story, considering how possible actions and interventions could influence outcomes. In contrast, when discussing Rebecca's video, there was only one significant reference to the video, which was offered by the facilitator and not further explored by the group.

Multivoiced

All participants shared ideas during both discussions. However, there were differences in the degree to which participants took up responses and built on ideas. During Diego's video discussion, all participants attended to the ideas shared by others, frequently reflecting on how their suggestions would provide opportunities to deepen connections and student engagement. Conversely, during Rebecca's video discussion, ideas were rarely attended to by any participants. This resulted in a parallel sharing of ideas without dialogism.

Generative Orientations

From the beginning of the discussion of Diego's video, the group showed a generative orientation toward students, problems of practice, and teaching. Diego praised his students' use of classroom resources. Others in the group readily responded to Diego's question, demonstrating a generative orientation toward the problem of practice. At the end of the conversation, Diego indicated that he was planning to try new practices based on suggestions from the group. During the discussion of Rebecca's video, the group demonstrated generative orientations toward students, yet they did not show a generative orientation toward the problem of practice. For example, Rebecca did not identify specific areas for improvement in her activity structure, and the group did not engage deeply with any suggestions for future practice.

Support and Critique

In the discussion of strengths and highlights of Diego's video, the group offered specific examples of the students' mathematical knowledge, their capacity to share their thinking, and the dialogic nature of the discussion. Building from this, Diego positioned himself as open to critique and seeing his practice in new ways. Participants validated his question as shared and thought critically about new ways he could learn about his students' thinking in the moment. In the discussion of Rebecca's video, the strengths identified were largely couched in politeness and were general, including the students' "energy" and Rebecca's risk-taking for trying a new activity structure. Little support was offered to Rebecca in the rest of the discussion, which stayed at a general level about the pedagogical decisions in each participant's own classroom rather than the events and pedagogical decisions in Rebecca's video.

Discussion

Despite similarities in these discussions, including the same participants in the same meeting, the discussions reflected different levels of productive talk. What may have contributed to the differences in how these discussions unfolded? We conjecture that there are three underlying factors distinguishing these discussions. Two factors reaffirm findings in prior literature: video clip selection and focal question selection are pivotal (Borko et al., 2014; Sherin et al., 2009). We found that teachers can select productive video clips for discussion, and with support, they can craft fruitful focal questions. Yet, granting teachers this agency and responsibility comes with certain risks: in response to Rebecca's video clip, participants contributed less pedagogical reasoning and the discussion remained more general. Further, Rebecca's focal question was not directly linked to the video and thus limited engagement with that evidence. This risk does not mean that facilitators must control video clip and focal question selection, only that it is important to note that there is variability in how teachers take up this responsibility.

The third underlying feature that influenced the productivity of these conversations is the degree to which teachers attended to and took up one another's ideas. The presence of *teacher uptake* in Diego's discussion fueled a dialogic discussion in which multivoicedness, critique and support, pedagogical reasoning, and a generative orientation to professional learning and the problem of practice were prominent. Diego repeatedly took up and considered aloud his colleagues' ideas, revising his thinking about the problem of practice he presented. Other participants similarly built on one another's ideas, posed questions, and offered pedagogical reasoning. This orientation, to take seriously other's contributions and be open to revising thinking about one's own practice, was a key lever for productivity in discussing Diego's video and which the discussion of Rebecca's video notably lacked. We argue that the notion of teacher uptake in professional discussions and its connections to other, well-established features of pedagogically productive talk is an area in need of further attention by the field.

CONSIDERING CONTEXT IN THE AVAILABILITY OF SECONDARY MATHEMATICS TEACHERS' PROFESSIONAL LEARNING OPPORTUNITIES

Kelly L. Boles
University of Tennessee, Knoxville

Harviel Arcilla
Stanford University
karcilla@stanford.edu

Keywords: Teacher Knowledge

Context is a critical consideration in teacher professional learning. When queried about formal professional development (PD), many teachers report dissatisfaction, often citing contextual agnosticism, and, thus, irrelevance (Boston Consulting Group, 2014). In informal learning spaces, teachers are generally freer to exercise choice toward more contextually relevant learning opportunities and resources. Regardless of formal or informal settings, the need for professional learning to be context-specific is not new (Borko et al., 2010; Desimone 2009). In fact, efforts to contextualize formal PD are ongoing (i.e., Fairman et al., 2023), with much work in this area attending to the ways professional learning opportunities can and should embrace specific classroom contexts. Relatedly, this pilot work considers how mathematics teachers' course and geographic context shape their accessed set of professional learning opportunities. We pursue the following questions: *What resources characterize the professional learning opportunities accessed by advanced secondary mathematics teachers? To what extent, if any, do the learning resources vary by mathematics subject and geographic context?*

Data for this study were collected via an online survey distributed through various teacher social media groups and discussion boards, with quotas observed for both the mathematics course taught and school district geographic locale (as defined by the National Center of Education Statistics (NCES) locale codes— *city, suburban, town, and rural*). Survey participants (*N*=14) for this pilot work were U.S. public high school teachers who taught an Advanced Placement® (AP®) mathematics course. The survey instrument had two primary parts, including both qualitative and quantitative questions, asking respondents to first select the learning resources they used for content-based professional learning within their AP® course, and second, to identify where the resources were accessed. Survey responses are currently being analyzed using mixed-methods geospatial analysis (Yoon & Lubienski, 2017). Follow-up interviews with selected survey participants are also in the process of being collected, transcribed, and analyzed for the purpose of further elucidating survey responses.

Early findings reveal that mathematics teachers reported a range of resources (Min = 1, Max = 12) supporting their professional learning, with most resources (53.3%) being digital. Non-digital resources were primarily accessed at home or at school. Locally accessed resources, outside of school and home, included professional learning communities, friends, teacher colleagues, university-affiliated learning opportunities, district-sponsored professional development, trainings facilitated by a local/regional educational cooperative, and national/statewide professional conferences. Despite an equal number of AP® Calculus AB and AP® Statistics respondents, AP® Calculus AB teachers reported more non-digital, locally accessible resources, particularly university-related and local/regional cooperative opportunities. Teachers in rural districts reported little access and the least travel to school-external, in-person learning opportunities. These findings suggest potential inequities in accessed professional learning opportunities across content *and* context. Further inquiry is warranted to understand the mechanisms by which mathematics content and geographic context shape professional learning.

Experiential learning represents a shift in K-12 education that requires teachers to change the ways that they engage students. We created a professional development experience in which teachers learned about the entrepreneurial-based design challenges we developed (Authors, 2019) and practiced implementing teacher check-ins with students participating in our summer camp. In this paper, we conduct a case study to explore how three teachers used teacher discourse moves during their teacher check-ins. We found three types of teacher-student interactions: (a) positioning students as experts, (b) co-designing with students, and (c) pushing students towards an outcome. These findings suggest that teacher professional development for experiential learning should intentionally support teachers in learning how to employ the moves during teacher check-ins in ways that elevate student expertise and advance their thinking.

Keywords: Professional Development, Problem-Based Learning, Classroom Discourse

Experiential learning provides opportunities for K-12 students to work collaboratively and across disciplines to create innovative, actionable, and empathetic solutions (Hashim et al., 2019). Experiential learning represents a transformative approach to education (Slavich & Zimbardo, 2012; Yardley et al., 2012), challenging traditional pedagogical norms by prioritizing hands-on, inquiry-based learning experiences. There are many varieties of experiential learning approaches, ranging from problem-based learning to community-based learning (Haigler & Owens, 2018). Teachers play a pivotal part of experiential learning by adopting diverse roles, from facilitators to co-designers (Grossman et al., 2019; Haigler & Owens, 2018). As teachers navigate experiential learning environments, understanding the nuances of teacher-student interactions becomes imperative for optimizing instructional practices and fostering meaningful learning experiences.

The Design & Pitch (D&P) Challenges in STEM project (Confrey et al., 2019) is an experiential learning curriculum that draws on project-based learning (Krajcik & Blumenfeld, 2006), entrepreneurial-based learning (Lackeus, 2015), and design-based learning (Mehalik et al., 2008) to situate mathematics learning within entrepreneurial pitch competitions. In this paper we report how teacher discourse moves (TDMs; Herbel-Eisenmann et al., 2013) are leveraged when teachers practice facilitating experiential learning during a PD on D&P.

Literature Review

Teacher Facilitation of Student Autonomy

Learning environments that employ these experiential pedagogies are built on a culture of student-centered practices (Haigler & Owens, 2018), where students are provided with autonomy to ideate and create, meaning that each group is often thinking about different topics (Lee & Hannafin, 2016; Wilson et al., 2015). A teacher in this situation needs to check-in with students regularly to assess, support, and facilitate their progress (Grossman et al., 2019; Lee & Hannafin, 2016). This requires teachers to have a deep understanding of the learning goals (Grossman et al., 2019), a willingness to allow students to assume autonomy and authority (Langer-Osuna, 2011), and the flexibility to facilitate student thinking relating to a wide variety of ideas and solutions (Haigler & Owens, 2018; Krajcik & Blumenfeld, 2006).

When managing student-centered classrooms with varying ideas and approaches, Herbel-Eisenmann et al. (2013) found that teachers could effectively facilitate student learning through what they refer to as TDMs. Strategies like these are often used to facilitate whole group discussions (Herbel-Eisenmann et al., 2013; Smith & Stein, 2011), but they can also provide a way for teachers to purposefully engage students in conversations during teacher check-ins in experiential learning environments.

Professional Development

One way that teachers learn to use new curricular resources, especially those based in novel pedagogies, is through professional development (PD; Dingman et al., 2021). For PDs centered on learning about a new curriculum, regardless of format, McDuffie and Mather (2009) suggest first engaging teachers in an experience where they are positioned as the student. Then it is important to shift teachers back to the teacher perspective after thinking as a student, so they can reflect on how their experience informs their approaches to teaching with the resource (Dingman et al., 2021; McDuffie & Mather, 2009). An experiential way to do this is by having teachers approximate the practice of facilitating aspects of the curriculum in conditions that are less complex than a real classroom (Schutz et al., 2018). Approximations of practice allow PD participants to engage with how a novel curriculum might look in a classroom (Schutz et al., 2018), since it may be quite different from their traditional teaching practice.

This study explored how teachers leveraged TDMs while checking in with students during a PD on a novel curricular framework. This research is guided by the following question: *How do teachers approximating the practice of a teacher check-in use TDMs to support, or hinder, amplifying student expertise?*

Methods

The data for this paper was part of a larger study that focused on the design and study of a high school mathematics entrepreneurial curriculum and its associated PD, henceforth referred to as D&P.

Context and Participants

The D&P PD, in which the data was collected, lasted one week, and was held at the same time as a D&P student summer camp. In the first 2.5 days participants acted as students to experience one of the D&P challenges alongside the summer camp students, and then the final 2.5 days the participants acted as teachers during the summer camp. During the D&P PD teachers engaged in teacher check-ins in multiple ways. To experience facilitation moves through the student perspective, teachers experienced multiple teacher check-ins as learners. Teachers also had a chance to debrief their experiences as learners with PD facilitators. Additionally, teachers were given a document that outlined questions to consider asking during teacher check-ins.

Five teachers attended the PD experience. Three were high school teachers, one science and two mathematics, and two were elementary teachers. The two mathematics teachers were new to teaching and the other three teachers were veterans. The two elementary teachers were not able to experience the entire PD therefore their data was excluded from this analysis.

Data Collection and Analysis

All aspects of the summer camp and PD were video recorded. For this paper the videos of interest were the periods in which the teachers were checking-in with student groups. Thus, the video data was reduced to these 20 to 30 minute clips for data analysis. The check-in videos were memoed by the first author, from which a content log with brief summaries of each video was created. Considering each video's memo and the content log, the research team selected one video per teacher participant that was representative of their understanding of teacher check-ins. After reducing the data to three videos, transcripts were created and were coded using a TDMs framework (Herbel-Eisenmann et al., 2013). Additionally, the transcripts were analyzed for the breakdown of teacher talk time versus student talk time (Hennesey et al., 2023).

Results

Preliminary analysis of three teacher check-in videos surfaced three types of teacher-student interaction: (a) positioning students as experts, (b) co-designing with students, and (c) pushing students towards an outcome.

Positioning Students as Experts

When the teacher check-ins began, each teacher spent time orienting themselves to the students' ideas in relation to the D&P challenge. Teachers typically did this through the TDMs of assessing student thinking and revoicing (Herbel-Eisenmann et al, 2013). While all of the teachers had periods of positioning students as experts of their ideas, Teacher B exemplified this interaction type. She employed the TDM of waiting (Herbel-Eisenmann et al, 2013) throughout the interaction, as indicated by the short listening cues she provided to students such as "Yeah," "Okay," and "Nice." The students engaging with Teacher B also had the highest amount of talk time, sharing their ideas and work for almost 60% of the time, in contrast to the 25% of time that students talked during the interaction with Teacher A and almost 50% of the time that they talked with Teacher C.

Teacher C also used the TDMs of inviting participation and orienting to student work (Herbel-Eisenmann et al, 2013) to position students as experts. One instance of this was when she said, "Student S is taking what y'all have mapped out and she is tracing over it in color on the map to show the two routes? What are you doing?," which shows both moves. She first elevated what Student S was currently working on (orienting the other students in the group to that work) and then she invited another student in the group to share what they were working on. These two moves together grounded group interactions in student ideas while facilitating collaboration amongst group members.

Co-Designing with Students

As teachers used the TDM of advancing student thinking (Herbel-Eisenmann et al, 2013) towards the challenge goal, they would sometimes become co-designers with the students, acting as a group member during teacher check-ins. During these co-designing periods, teachers worked to advance student thinking through grounding conversations in student ideas. Teacher A did this when creating a map prototype by directing the students to pull up the technology tool for mapping on one computer and then having everyone (including the teacher) gather around that screen to work together. The co-designing interaction is exemplified in this set of quotes:

> Student: Uh, you could just uh add the whatever it's called, the bottom left corner there, no farther down, yep, like then you can like add them along the route, just like plan it out and then you can hit how long to measure it.
>
> Teacher A: So I guess drop a pin where that thing is. And then you have to find [High School Name]. Or whatever, maybe the movie theater.

Both the student and the teacher are figuring out the technology and which decisions to make together to advance towards the goal of prototyping a mapping app.

Pushing Students Toward an Outcome

The other way the teachers attempted to advance student thinking (Herbel-Eisenmann et al., 2013) was to push students in a specific direction based on their understanding of the student ideas in relation to the challenge goals. This tended to frustrate and constrain students, rather than advance them. For instance, Teacher C was trying to advance the students' thinking to be broader:

> What do you think would happen for your users if instead of giving them a very narrow trip from Dominos to the [location of the camp],...what if you expanded it, say from [close-by town] to the [location of the camp]?

The students became frustrated with her pushes because they felt she was disregarding the work they had already done as well as suggesting that they were not doing the correct task.

Discussion and Conclusion

Within a PD focused on supporting teachers to adopt an experiential learning curriculum, teacher participants had multiple opportunities to engage in teacher check-ins–a critical component of experiential learning (Lee & Hannafin, 2016; Grossman et al., 2019; Wilson et al., 2015). When teacher participants had the opportunity to approximate the practice (Schutz et al., 2018) of teacher check-ins three teacher-student interactions emerged. As they engaged as teachers during the second half of the PD, the teachers naturally employed many TDMs (Herbel-Eisenmann et al., 2013) during teacher check-ins, which led to two beneficial teacher-student interactions (positioning students as experts and co-designing with students) and one concerning teacher-student interaction (pushing students towards an outcome). Our analysis highlights an area of focus for experiential learning PD, the importance of how to facilitate moving towards the goal of the activity while staying grounded in the student ideas. While the literature shows the importance of the teacher engaging with groups during experiential learning to move them towards a learning goal (Grossman et al., 2019), our findings show negative student reactions during these moments. Thus, during these teacher check-ins while teachers are engaging with students around their ideas (a beneficial interaction), teachers must employ TDMs that both support the advancement towards the learning goal while continuing to position students as experts. If teachers push too hard to advance towards the learning goal, as shown above, students will begin to become complacent and lose connection to their idea, thus diminishing their expertise.

Therefore, based on our preliminary analysis, we suggest that experiential learning PD should intentionally support teachers in learning how to leverage TDMs (Herbel-Eisenmann et al., 2011) to engage students as experts while advancing them towards learning goals. This intentionality can be built into debrief sessions that support engaging in the curriculum as a learner (Dingman et al., 2021; McDuffie & Mather, 2009), or side-by-side coaching (Munson, 2018) during teacher check-in approximations of practice.

GAUGING PROFESSIONAL GROWTH: MOVING BEYOND BINARY ASSESSMENTS BY EXAMINING TEACHERS' PRACTICAL ARGUMENTS IN SIMULATIONS PRACTICE

Amanda Brown	Pat Herbst	Gil Schwarts
University of Michigan	University of Michigan	Weizmann Institute of Science
amilewsk@umich.edu	pgherbst@umich.edu	gil.schwarts@weizmann.ac.il

Building on the critique of binary frameworks and the need for a nuanced understanding of instructional practices, we offer a methodological approach for gauging teachers' professional growth through a simulation designed to support secondary mathematics teachers in facilitating problem-based lesson discussions. This paper explores data from a pilot online teaching simulation which, by design, avoids feedback reliant on binary labels for instructional practices. The study analyzes responses from ten prospective teachers in a simulation that supplements Milewski & Strickland's (2020) functional framework for responding with subject-generic and subject-specific categories. Our findings demonstrate the viability of this approach in revealing shifts in participants' awareness of the linguistic functions underlying their responding moves.

Keywords: Research Methods, Problem-Based Learning, Professional Development, Classroom Discourse

Mathematics education scholars emphasize the importance of moving beyond narrow perspectives on 'good' teaching to effectively support teachers' professional growth (Chazan & Ball, 1999; Horn et al., 2022). This shift recognizes that framing teaching within binaries such as 'good/bad' flattens the complexities of effective instruction, neglecting the dynamic adaptations required for responsive teaching (Biesta, 2007). Scholars oppose binary frameworks, acknowledging subjectivity and contesting conceptions of teaching framed in such terms (Berliner, 2005; Fenstemacher & Richardson, 2005).

In response, innovative pedagogies guide teachers beyond a singular vision of instructional quality, emphasizing inquiry, practical arguments, and feedback as catalysts for professional growth (Horn et al., 2022; Fenstemacher & Richardson, 1993; Fernandez et al., 2020). However, this raises a methodological question: *How can we assess the potential of professional development programs to support teacher professional growth if those programs do not put forth explicit goals for teachers' instructional practice?* This paper introduces an innovative approach to the practice of responding to students' contributions by developing a measure that does not rely on categorizing specific moves according to binaries.

To illustrate, we delve into data from a pilot online teaching simulation for supporting secondary mathematics teachers in the critical decision-making involved in facilitating problem-based discussions. Participants engage as teacher avatars, making critical decisions (e.g., selecting, sequencing, responding) in simulated discussions. Aligning with the aforementioned calls, we designed the simulation to avoid feedback categorizing participants' moves as more or less 'desirable.' Post-simulation, we grappled with the question of how to assess whether and how teachers were growing in their interactions within the simulation. It felt incongruent to develop a measure relying on a singular perspective of teachers' increased use of 'desirable' practices. How then can we effectively evaluate teachers' professional growth within this innovative and flexible framework of design?

Theoretical Framework

Teachers' discursive moves have often been seen through overly prescriptive lenses. Chazan and Ball (1999) criticized anti-telling rhetoric as too simplistic and agnostic to context, urging the field to move past proscriptions forbidding certain discursive moves. While research has progressed beyond slogans like 'Don't tell' (Ellis et al., 2019; Franke et al., 2009; Michaels & O'Connor, 2015), quick translations from research to practice without context consideration remain common. This is exemplified by reports on the wide-scale dissemination of the Five Talk Moves (Chapin et al., 2009) into diverse professional settings:

> Our focus on the "talk moves" did not always seem to work. While some teachers easily picked them up, other teachers, particularly those less experienced, seemed to find them difficult … using them "robotically." For example, the revoicing move would be used when there was no reason to revoice: a student might state a fact, clearly: "seven is a prime number" and the teacher would query "So you're saying seven is a prime number? Is that what you're saying?" to puzzled looks. Teachers would ask "Who agrees and who disagrees?" in a perfunctory manner, not following up on the reasons. Or "Who can repeat what she said?" when the original utterance was neither complex nor particularly useful for furthering the topic. (p. 117; Michaels & O'Connor, 2019).

These perfunctory uses of talk moves echo the kind of lessons learned by educational researchers in the earlier standards reform movements (e.g., Cohen, 1990). Like their earlier predecessors (i.e., lists of standards), lists of moves, when presented and prescribed as a solution for the problems of practice, tend to overpromise and underdeliver, distorting practice while projecting an unwarranted authority.

The observations outlined by Chapin help to illustrate Berliner's (2004) description of the developmental progression of teachers. Berliner categorizes teachers as novices and advanced beginners, noting that novices often see teaching in terms of absolutes, while advanced beginners begin to recognize and respond to the nuanced contexts of teaching situations. The struggles with using talk moves robotically can be seen as characteristic of novice teachers, who are still developing their ability to adapt their practices to different contexts.

To support teachers to move away from these kinds of robotic performance, it is crucial to support them in gaining better "understanding of and reasoning about practice" which requires both "a language capable of finer distinctions and a stance aimed less at evaluation" (p. 9, Chazan & Ball, 1999). Milewski & Strickland (2020) offer a framework categorizing responding moves into functional categories without evaluating them as more or less "productive." Their framework categories responding moves into two layers of independent functional categories (i.e., Response vs. Rejoinder, Support vs. Confront vs. Invite) which can be composed into the following six functional categories for teachers' responding moves:

- **Supporting-response:** curtail the interaction while supporting the contribution
- **Confronting-response:** curtail the interaction while confronting the contribution
- **Invitational-response:** curtail the interaction while inviting other students to respond to the contribution

- **Supporting-rejoinder:** prolong the interaction while supporting the contribution
- **Confronting-rejoinder:** prolong the interaction while confronting the contribution
- **Invitational-rejoinder:** prolong the interaction while inviting other students to respond to the contribution

More recently, we have been exploring an additional layer—subject-generic and subject-specific moves. By **subject-generic** we refer to responding moves that can be used across a variety of content areas and courses without adaptation (e.g., What do others think); while **subject-specific** refers to responding moves that do make adaptations to various instructional situations (e.g., What do others think about the way he constructed the center of that circle?).

When developing the simulations, we wondered whether gaining a greater understanding for the functional categorization of discursive moves would improve teachers' practical reasoning about the practice of responding. Furthermore, we wondered how such shifts might play a role in shaping teachers' instructional choices. To investigate, we needed to develop measures that moved beyond a categorization of teachers' moves into evaluative binaries and toward measures that attend to the shifts in the kind of practical reasoning teachers' use when providing an account for their decisions. In the background section, we provide more details about the simulation, paying particular focus to the ways we provided opportunities for users to both simulate and receive feedback on the practice of responding to students' mathematical contributions. In the methods section, we describe the measures we developed for assessing the potential of that simulation for supporting teachers' professional growth—that we define as participants gaining a better understanding of the functional role of discursive moves they elect to when responding to student contributions (e.g., when using a rejoinder, they indicate they do so because they want to prolong the discussion of an idea). In short, we describe methods used to pursue the following lines of inquiry: *How does a functional approach to responding, featuring a measure that avoids categorizing instructional moves according to evaluative binary contribute to assessing changes in instructional practices when responding to students' mathematical contributions within the context of an online teaching simulation? Additionally, what insights can be gleaned concerning the alignment of participants' justifications with the underlying linguistic theories embedded in the designed feedback during the responding intervention?*

Background

This paper is part of ongoing efforts to develop and evaluate online simulations supporting secondary mathematics teachers in facilitating problem-based lessons. We created four simulations around the Tangent Segments Problem, which asks students to find a circle tangent to two intersecting lines, culminating in the Tangent Segments Theorem[1]. Each simulation immerses teachers in the complexities of fostering discussions on students' work. Two simulations cover the entire lesson, while two focus on specific phases, offering 'soft' feedback.

The ***Responding to student work*** simulation, a targeted intervention, aimed to impact teachers' reasoning about responding. In this simulation, users encounter:

- 4 storyboarded scenarios with student sharing work publicly (see Figure 1a),

[1] The Tangent Segments Theorem states that two intersecting lines are tangent to a circle if and only if the points of tangency are equidistant from the point of intersection of the lines

- A panel of 18 possible responding moves with differing underlying functions, requiring users to indicate at least one they like or dislike,
    - The underlying functions of the moves are as follows: 9 Responses, 9 Rejoinders; among which 6 Support, 6 Confront, and 6 Invite; and among which 12 are Subject-specific and 6 are Subject-generic.
- 3 prompts for participants to articulate their goals for handling each student contribution, followed by a curated subset of moves that fulfill their goals (see Figure 1b).
- The original panel of choices of 18 responding moves is finally provided without delineation and participants are asked to choose a way to respond, which they can edit.

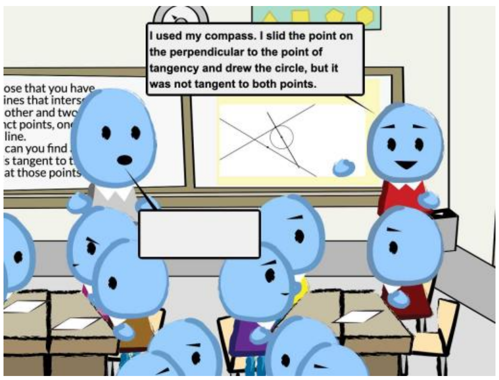

Figure 1a. A scenario embedded in the *Responding to student work* simulation

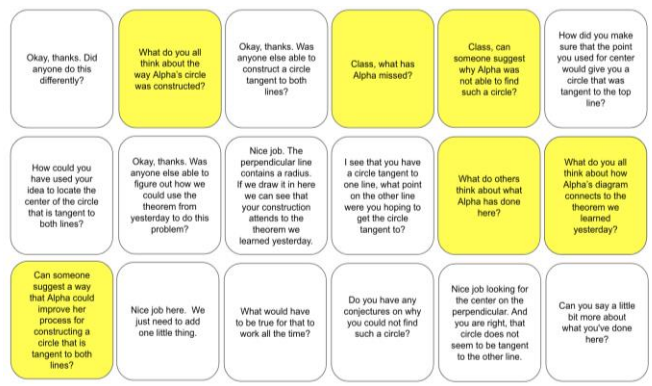

Figure 1b. A panel of 18 possible responding moves, after user expresses a preference for having the class respond, as opposed to responding themselves

Users first select at least one move from the panel that they like or dislike. The second, third, and fourth interactions with the panel provide curated moves based on users' goals (see Figure 1b). This curation is driven by 3 prompts where users indicate (1) whether they prefer to respond themselves or ask the class to respond, (2) whether they prefer to prolong or curtail the discussion, and (3) whether they prefer to support or confront the student's ideas. The fifth interaction asks users to select a single move closest to their preferred response, with the option to revise. These questions along with the curate moves offer participants explicit guidance on linguistic distinctions from the Milewski/Strickland framework but deliberately omitted explicit attention to subject-specific and subject-generic distinctions to investigate the varied impact of feedback on functional distinctions.

The ***Teaching the lesson with student participation*** simulation, serving as a pre-post assessment, presented 12 opportunities for participant responses to students' contributions. Participants shared responses to students' contributions and their reasons for those responses in open-ended boxes. We compared pre-post responses to assess our approach's potential for insights into changes resulting from the ***Responding to student work*** simulation.

Methods and Analysis

The analyzed sample consists of responses collected during the integration of simulations into a Western University methods course in Fall 2023. Our focus is on 10 prospective teachers who completed all simulations (4 males, 6 females; 8 White, 2 BIPOC). These simulations were undertaken individually as homework assignments in the initial half of the methods course, with data collection confined to their simulation performance and subsequent reflective assignments. This study delves into prospective teachers' responses in the pre- and post-assessment, where they engaged in a virtual teaching exercise for a full lesson.

We examined the alignment between the responding moves participants chose and their justifications. We analyzed responses to *"How would you like to respond to the contribution made by…"* (prompt 1) to discern shifts in types of responding moves. For these responses, we used the Milewski/Strickland (2020) framework along with newly added distinctions of subject-generic and subject-specific moves. To further assess the simulation's potential in aiding teachers' understanding of the function of different responding moves, we introduced an additional measure. We sought evidence in participants' responses to follow-up prompts: *"What do you anticipate could happen next?"* (prompt 2) and *"Please explain why you chose to respond to…in the way you did and at this moment (Optional)"* (prompt 3). In our analysis, we looked for participants' recognition of the function of their responding move from prompt 1, ensuring alignment with the functional categorization.

For example, one participant responded to prompt 1 with, *"Why would the compass being smaller make the circle fit better? How would we be sure that it still hit the line and didn't get too small?"* This was coded as a subject-specific confronting-rejoinder move. For prompts 2 and 3, the participant said, "*More discussion about what we need to know about the points. The compass size isn't the problem here it's the location of the two points and that's what I want the conversation to skew towards.*" This was coded as *matching* for subject-specific and linguistic functions because it anticipated a discussion about the location of the points and aligned with the rejoinder and confronting categories by anticipating a prolonged interaction in which the participant desired some problematizing regarding the location of the two points.

Table 1 presents additional coded responses to illustrate our methodological approach. While most responses were coded as matches or non-matches, some instances proved less straightforward. Occasionally, participants did not explicitly address one or more functional categories in their reactions to prompts 2 and 3. In such cases, the data was marked as non-explicit, and this did not count towards the total justifications. We report on shifts in teachers' responding practices and their inclination to provide anticipations and justifications that align with the theories underlying the simulation's design in the findings section.

Table 1: Sample coding for prompts 1, 2, and 3 in the pre- and post-assessments

Prompt 1 Responses	Coding for Prompt 1 Responses	Prompts 2 & 3 Responses	Coding for Prompt 2/3 Responses	Final Code

ask what the class thinks about what was said.	Rejoinder Invite Generic	I would guess because the two circles are both close there would be a majority agreeance [sic] but some might say that it is fine as long as the circle is tangent to the point. I prefer to let the class think about these ideas rather than I giving [sic] them all the answers.	Match rejoinder Match invite Non match generic	Match linguistic Non-Match subject specific
I agree, Iota made some good progress. What do you notice from their work that makes you say that?	Rejoinder Support Generic	I anticipate the student will talk about the arc. I want to hear more and have a contribution from that student deeper than a "good job" while also assessing the student's understanding in the moment.	Match rejoinder Match support Non match generic	Match linguistic Non-Match subject specific
That's great work, Omicron! That angle bisector ensures that our circle's center is equidistant from both sides, so it "fits" inside.	Response Support Subject Specific	I anticipate the class will have more comments maybe on the distance of the points not being equal. I want to ensure Omicron feels validated especially after the comment from their classmate and that the class understands the value of Omicron's contribution.	Non match Response Match support Match SS	Non-Match linguistic Match subject specific
Mu had a similar drawing to Nu, but I like the incorporation of the angle bisector and perpendicular line.	Response Support Subject Specific	I anticipate they will realize they need to edit their picture so the circle is smaller and "fits better."	Match Response Non match support Match SS	Non-Match linguistic

Results

Our methodological approach reveals the potential of simulations to support a multifaceted view of teachers' professional growth. The first six rows of Table 2 demonstrate discernible shifts in participants' instructional moves before and after the intervention. In the pre-assessment, participants employed few rejoinders (29%), which increased to 62% in the post-assessment. Similarly, there was a shift towards supportive moves, with fewer supportive moves used in the pre-assessment (32%) compared to a majority in the post-assessment (67%). Additionally, the use of invitational moves increased from 10% to 16%.

To illustrate these shifts, we share pre-post data from one of the participants, whom we will call Max Zimmerman. The first time through the simulator, Max responded to one of the student contributions with a closed confront, saying,

> *"I would talk about how this is a great start and using perpendicular lines is a good way to think about it. I would then agree with the class and say you cannot just move points so it isn't quite there, but it is getting close."*

In his final time through the simulator, Max responded to one of the student contributions with an open invitation, saying,

> *"I would ask if anyone notices anything about how the circle is made using the points as we have seen examples where the initial point given appears to not work."*

The comparison between Max's pre and post simulation responses to students' contributions illustrates how participants evolved from using more closed and confronting discursive moves to more open and collaborative ones.

Apart from these shifts, we also report there was no substantial change in participants' use of subject-specific moves. Recall, we did not distinguish these moves in terms of more and less productive and even now, we would be hard pressed to make any claims indicating whether these shifts represent improved practice, as our focus is not on changing teachers' behavior, but rather changing teachers' ability to offer more reasonable justifications for their practices.

The analysis of participants' justifications presents a more nuanced picture. While participants did not offer more coherent justifications related to the subject-specific nature of their responding moves, they showed a marked increase in awareness of the linguistic functions of their responding moves. None of the participants' pre-assessment responses aligned with their move in terms of both linguistic functions (rejoinder/response, support/confront/invite), while 71% of post-assessment responses aligned with both functions. Furthermore, 24% of responses had no matches for either function in the pre-assessment, contrasting with 0% of responses in the post-assessment responses had no matches.

To illustrate what this trend looked like in the data, we return to participant Max. Recall, in his first time through the simulator, Max used a closed confront to respond to a student contribution. He justified that decision by stating, *"Encouraging students is always a good idea."* This suggests that Max did not quite understand the ways that his responding move was likely to be interpreted as confronting, rather than supporting, the student's contribution. He offered a second justification by saying, *"Maybe there is a question or two about why using perpendicular lines will help."* Again, at this point, Max seems to not yet understand that because he elected to use an evaluative move, the subsequent interaction about the student's contribution is more likely to be curtailed, rather than prolonged.

In his final time through the simulator, recall Max responded to a student contribution with an open invitation. This time, he offered a more realistic anticipation of that decision stating, *"Hopefully some students begin to notice the pattern that a and b must be the same distance"* and *"Because I think they showed they know what to do and a slight understanding of where these points need to be in order for them to work"*. Unlike the justifications he offered in the first time through the simulation, this time, Max demonstrates an accurate anticipation that his move will lead to students taking the next discursive moves and will do so in a way that promotes a prolonged discussion of the original contribution.

The nuanced shift in participants' justifications underscores the complexity in participants' justifications for their responding moves, highlighting the intricate nature of linguistic functions in the context of the simulation. To be clear, we consider the shift in matched justifications, rather than the shift in types of teachers' responses, to be a more reasonable indicator of professional growth. This approach avoids making value-laden judgments about which responses are good or bad and instead focuses on whether teachers can offer justifications for their decisions that align with the expected outcomes of their chosen actions.

Table 2: Changes in subject-specific moves and justifications across the pre-post assessment (n=sets of responses to prompts 1-3)

		Pre (n=67)	Post (n=61)
Types of Moves	Subject-specific	52 (79%)	49 (79%)
	Response	48 (72%)	22 (36%)
	Rejoinder	19 (29%)	39 (62%)
	Support	21 (31%)	36 (59%)
	Confront	40 (60%)	15 (25%)
	Invite	6 (9%)	10 (16%)
Types of explicit justifications	Matched on Subject-Specific	38 (60%)	34 (53%)
	Unmatched on Subject-Specific	5 (7%)	5 (8%)
	Matched on linguistic functions	0 (0%)	44 (72%)
	Unmatched on linguistic functions	67 (100%)	17 (29%)

Conclusions

The two outcomes concerning participants' ability to align their justifications with the moves they crafted were as expected. We anticipated that given the explicit feedback provided to them on these functions, participants would enhance their proficiency in offering justifications aligning with the linguistic function of their responding moves. Conversely, the absence of shifts in the participants' propensity to provide justifications matching the subject-specific nature of responding moves was predictable since participants did not receive feedback on these aspects.

The results indicating shifts in the function of participants' instructional moves were surprising, as the intervention did not guide preferred responding moves. Nevertheless, these shifts are intriguing, and we contemplate whether similar results would emerge with a larger sample of teachers. The illustration of the evolution in Max's decision making and justifications for his discursive moves demonstrates the potential of the simulator for enhancing teachers' professional growth. Replicating this study on a larger scale with consistent results could strongly support Chazan and Ball's (1999) hypothesis, emphasizing the importance of "a language capable of finer distinctions and a stance aimed less at evaluation" to support teacher inquiry and professional growth. Future research will explore this avenue using the simulation to collect data from a national sample of teachers and employing the outlined methods to investigate whether the simulations help practicing teachers make their responding moves more purposeful.

READING METHODOLOGICAL CONTOURS IN MATHEMATICS EDUCATION RESEARCH: THE CASE OF NARRATIVE INQUIRY

Susan O. Cannon
University of Georgia
cannonso@uga.edu

Christopher H. Dubbs
East Stroudsburg University
cdubbs@esu.edu

In this paper, we begin by mapping major methodological contours in mathematics education research before delving into one methodology: narrative inquiry. We trace the use of narrative inquiry within the disciplinary boundaries of mathematics education noting significantly that it has been underutilized relative to other educational research fields. In order to highlight the potential of the methodology, we share two cases of its use outside disciplinary boundaries. In the first case, 'analysis of narratives' is used to complicate and contextualize mathematics teacher beliefs. In the second case, 'narrative analysis' is used to co-construct voices representing a spectrum of teacher responses to mathematics curriculum reform.

Keywords: Research methods, systemic change, teacher beliefs

Research in mathematics education has a history of maintaining conventional research methodologies and theories; being borne out of the fields of mathematics and psychology (Kilpatrick, 2020) may impact this tendency. When the field has begun to embrace new ways of doing mathematics education research or exploring different ideas as to what might count as mathematics education research (MER) there has been pushback. For example, in a 2010 *Journal for Research in Mathematics Education* (JRME) editorial, Heid asked "Where's the Math (in mathematics education research)?" She contended that the articles published in JRME should have mathematics as an "essential component rather than being a backdrop for another area of inquiry" (p. 103), and her perception was that many submissions had gone astray of this focus. In a later JRME editorial, "A Future Vision of Mathematics Education Research: Blurring the Boundaries of Research and Practice to Address Teachers' Problems," Cai and colleagues (2017) outline a future where MERs and teachers work together to develop, implement, and refine mathematics tasks prior to placing them in a professional knowledge repository: their vision of bridging the theory-to-practice gap endorsed lesson study as a methodology. While this vision indeed bridges theory and practice, it significantly narrows what counts as MER and forecloses many alternative approaches. While we agree with Heid that mathematics should be central, we also ask, "Where is the research (in mathematics education research)?" While mathematics education researchers (MERs) need to center diverse concepts and ideas *within mathematics*, we find it also important for MERs to explore and consider multiple and diverse educational research *methodologies*. Then, complementing Cai's vision for the future of lesson study, we invite mathematics education researchers to consider another methodology to bridge the theory-to-practice gap, another methodology less used than lesson study: narrative inquiry. Our vision for MER is one in which diverse research methodologies, with narrative inquiry (NI) as one example, broaden 'what counts' as MER, what is studied within mathematics, and approaches to research. The following research questions guide our inquiry:

1. How have narrative research methodologies been used in mathematics education research in the last 50 years?

2. In what ways does the narrative inquiry that is being done in MER vary across publication outlets?
3. What unique insights or benefits might narrative inquiry offer to MER?

To answer the first two research questions, we use a combination of (i) reading the *Mathematics Education Atlas* maps (Dubbs, 2021) for the JRME, *Educational Studies in Mathematics (*ESM*)*, and *For the Learning of Mathematics (*FLM*)* and (ii) systematic literature review. The findings of these two analyses together, then, describe the uptake of narrative research methods across time (RQ1) and across publication outlets (RQ2). The details of our analysis and findings are elaborated in the sections that follow. In the discussion, we address RQ3 by elaborating Chapman's (2020) contention that "the field of mathematics education could benefit from more attention to narrative as a way of knowing and narrative analysis" (p. 25). We turn next to an explicit discussion of our theoretical framing and research method before presenting our findings and recommendations.

Theoretical Framing: Discourses and Knowledge Production

Discourses are the taken for-granted narratives which structure our communal understanding of the field. Parks and Schmeichel (2012) argued that the dominant discourses of MER made it difficult to, not only publish research on race and ethnicity in dominant MER journals, but to even think of race and ethnicity together with mathematics education. In a similar way, discourses about MER make it near-impossible to consider MER from a narrative perspective. Thus, as Parks and Schmeichel described the impossibility of considering race and ethnicity in MER, here, we describe the discourses that establish which methods are thought easily and which methods are impossible to be thought. In total, then, these discourses not only have the effect of foreclosing certain research foci (e.g., race and ethnicity) but also certain research methods (e.g., NI).

While our larger project investigates the uptake of the five approaches to qualitative inquiry outlined in Creswell's (2013) *Qualitative Inquiry and Research Design: Choosing among Five Approaches*, in this paper we focus on the specific case of narrative inquiry. As the title suggests, Creswell presented five approaches within qualitative inquiry and, for each, named whose work he relied on to structure each approach: narrative research (c.f., Clandinin & Connolly, 2000; Pinegar & Daynes, 2007; Polkinghorne, 1995), phenomenological research (c.f., Moustakas, 1994; van Manen 1990), grounded theory research (c.f., Corbin and Strauss, 2007; Glaser & Strauss, 1967; Strauss & Corbin, 1990, 1998), ethnographic research (c.f., Van Maanen, 1988; Wocott, 2008), and case study research (c.f., Stake, 2005; Yin, 2009;).

We chose narrative inquiry as our focus because narrative inquiry asks the researcher to come alongside their participants to create more complex and nuanced understandings: this resonates with the future envisioned in 2017 by the JRME editorials. Further, Chapman (2008, 2020) and others (Beattie, 2006; Huber, 2013; Milner, 2007) have established the utility of NI in teacher education both as a research methodology and as a pedagogical tool. As we will show, while narrative inquiry methodology was tentatively being accepted in the 'top-tier' MER journals, it was being utilized more widely outside of MER and had long been an accepted methodology in literacy research. *The Handbook of Reading Research* (Kamil et al., 2001) included an entire chapter dedicated to narrative methods (Alverman, 2001). Subsequently, in 2007, the top journal of qualitative research, *Qualitative Inquiry*, dedicated a special issue (*13*:4) to narrative methods. In addition, *Educational Researcher* composed a special issue (*38*:8) in 2009 and the *Journal of*

Educational Research followed in 2010 (*103*:2). Narrative methods have been clearly established within the field of educational research and its subfields despite MER's relatively slow uptake.

Narrative Inquiry as a Way of Knowing

> Narrative is a scheme by means of which human beings give meaning to their experience of temporality and personal actions... [Narrative] provides a framework for understanding the past events of one's life and for planning future actions. It is the primary scheme by means of which human existence is rendered meaningful. (Polkinghorne, 1988, p. 11).

As indicated by Creswell, Polkinghorne (1988, 1995) is a name often associated with narrative inquiry (NI) as a research method. Within MER writ large and mathematics teacher education in particular, Chapman (2008, 2020)–building on the work of Polkinghorne and Clandinin and Connelly (2000)–is centrally positioned when discussing NI. The purpose of this section is to *briefly* introduce NI as a research method; for a more detailed discussion, we refer the reader to Chapman's (2008) "Narratives in Mathematics Teacher Education," Clandinin and Connelly (2000), and Kim (2016).

For Polkinghorne (1988), narrative is a primary scheme for making meaning of life experiences. Chapman (2008) described five ways that those researchers who accept Polkinghorne's premise have used narratives and NI education research: (i) as a research method, (ii) as a means of collecting data, (iii) as an object of analysis, (iv) as a tool in professional development or teacher education, and (v) as a basis for reflective thinking. Later, Chapman (2020) classified these five ways into the two categories of NI identified by Polkinghorne (1995): narrative analysis (the first way) and analysis of narratives (ways two through five).

Using these two perspectives as a frame, then, our present analysis seeks to understand the ways that NI has been taken up in MER. Those MERs that have taken up NI as a research method will have explicitly named NI as their method and/or cited NI methodologists (e.g., Polkinghorne, Connelly & Clandinin, or Chapman).

Research Method: Mathematics Education Atlas and Systematic Literature Review

Our review of NI literature within MER consisted of two complementary approaches: the Mathematics Education Atlas (henceforth, the Atlas; Dubbs, 2021) and systematic literature review. The Atlas includes a complete mapping of published research and citation relationships in the JRME (1970-2019), ESM (2010-2016), and FLM (2010-2017). We used the database to quickly identify which published articles in these journals cited NI as a method. Since the Atlas' records are limited to these journals and end with research in the late 2010s, we complement the map data with a systematic review of NI published in other research journals (and in ESM since 2017 and in FLM since 2016). Together these approaches comprise a breadth of MER published within disciplinary journals (i.e., JRME, ESM, and FLM). In addition, we highlight two cases from non-mathematics education research journals.

We used the Atlas to identify those articles that cite Clandinin, Connelly, Polkinghorne, and other authors that have developed the theoretical basis for NI as a methodology. In total, our reading of the maps returned one relevant article within the JRME (Wager, 2014), two relevant articles within ESM (Foote & Bartell, 2011; Nardi, 2016), and no relevant articles from FLM. Our definition of *relevance* was 'articles that named and used NI as a method.' For example, other authors (e.g., Remillard & Bryans, 2004) cited Clandinin and Connelly's work on 'teacher as curriculum maker' but did not undertake NI as a research method. We exhaustively discuss the identified articles in the findings section.

Due to the temporal cutoffs of the Atlas maps, we complement our reading of the maps with a systematic literature review (Petticrew & Roberts, 2008). Since our interest is in capturing research that is explicit in naming NI as a method, we searched for articles that cited Clandinin, Connelly, Polkinghorne, and/or Chapman within JRME for articles since 2020, ESM for articles pre-2010 and post-2017, and FLM for articles pre-2010 and post-2016. This systematic search returned no additional articles from JRME, one pre-2010 article in ESM (Lloyd, 2006), and one post-2016 article in FLM (Chapman, 2020). Together with the results from the maps, four of these articles will be discussed in our Findings section related to RQ1. We chose not to separately discuss Chapman's article since it is about NI as a research method instead of an article using NI as a method; instead, we include insights from Chapman through this article to emphasize our affinities with and departures from Chapman's work.

Finally, we chose two articles published outside the disciplinary mathematics education journals that are representative of the two categories identified by Chapman and Polkinghorne: 'analysis of narrative' and 'narrative analysis.' Drake and Sherin's (2006) article in *Curriculum Inquiry* was chosen to represent the first category while Martinie and colleagues (2016) article in *Journal of Educational Research* represents the second. Together, these articles provide the evidence to answer RQ2. We turn now to our detailed discussion of our findings.

Findings

As mentioned above, our use of the Atlas maps and systematic review together returned four articles from the high-quality, disciplinary MER journals included in this review: Foote and Bartell (2011), Lloyd (2006), Nardi (2016), and Wager (2014). This dearth of research evidence, as elaborated in the next subsection, upholds the discursive construction (Parks & Schmeichel, 2012) of NI as an impossible method for undertaking MER. The systematic search of ERIC and Google Scholar, however, shows that NI is indeed a possible method for undertaking MER and we discuss the representative articles next (i.e., Drake & Sherin, 2006; Martinie et al., 2016).

An Impossible Method, Little Uptake within Disciplinary Boundaries

Here, we revisit our research questions and explicitly elaborate our findings in the context of MER and its potential futures. As Parks and Schmeichel (2012) argued, the persistence of particular ideas and relative neglect of others makes it easy to think of particular theories and methods (e.g., lesson study) while others remain difficult to consider (i.e., NI). Indeed, only 15 articles within the three maps–11 within the JRME 2010s map and 4 within ESM–cite primary NI sources. In contrast to both JRME and ESM, in the FLM map, there are no articles that cite Polkinghorne, Clandinin and Connelly, or other authors that have developed NI as a method.

Narrative inquiry as method in JRME. In the JRME maps, there are no articles that cite Polkinghorne while ten articles cite Clandinin and Connelly. Of these ten, nine articles (ranging from 1989 to 2015) cite Clandinin and Connelly's work on 'teacher as curriculum maker' (e.g., 1986, 1992): Averill et al. (2009); Brown et al. (2009); Fraivillig et al. (1999); Gresalfi & Cobb (2011); Huntley (2009); Leinhardt (1989); Oonk & Verloop (2015); Remillard & Bryans (2004); Tarr et al. (2008). The singular article to use NI as a method is Wager's (2014) "Noticing Children's Participation: Insights Into Teacher Positionality Toward Equitable Mathematics Pedagogy"; this article will be discussed in detail shortly.

It is notable, as Creswell explicitly named Clandinin and Connelly as qualitative researchers, that only one article in this group named their study as qualitative research. Tarr (2008) reported their research as a "quasi-experimental design" that "employed both qualitative and quantitative methods" (p. 252). They explained that the qualitative methods were used to 'characterize' curriculum implementation and support the relationships between curriculum, teaching, and learning outcomes ascertained by the hierarchical linear modeling methodology. The first example of a citation that referred to narrative was Oonk and colleagues (2015) in which they explained, "practical knowledge often develops from stories of teaching practice, it is considered to have a narrative character (Clandinin & Connelly, 1996; Lin, 2002)" (p. 561). While we were looking for the influence that Clandinin and Connelly had on the use of NI as a method in MER, we theorize that their work on teachers as active creators of curriculum in these manuscripts helped to shift the positioning of teachers as enactors of fixed curricula to actors who bring stories and experiences that interact and influence curriculum and curricular decision making. This recentering of teachers and their experiences as important to the ways that curriculum is enacted, in our view, laid the groundwork for the entry of NI into the field.

Wager (2014), the only article to explicitly use narrative as a method, looked to the theory of "*identity in practice* (Holland et al, 1998)" (p. 313) in her study of teacher noticing. She describes her use of the theory to "understand how lived experiences shape identity development" (p. 317) including how narratives and discourses position us relative to ourselves and others. Wager acknowledges the importance of teachers' lived experiences and created narratives to "identify a storyline and position the teachers relative to equitable mathematics pedagogy" (p. 319). In her methods section, Wager described her research as an "empirical study" that used "qualitative and, to a lesser extent, quantitative methods to examine narrative data to uncover teachers' actions as evidence of noticing participation" (p. 320). Wager cited Clandinin and Connelly (2000) when describing the "initial narratives" (p. 325) that she wrote to describe the teachers' equity experiences and perspectives. She described these narratives as "inelegant, brief descriptions that were another source of data" (p. 325). Here we see Wager moving from 'narrative analysis' to 'analysis of narratives.' Further based on additional data, Wager refined the narratives to "incorporate the comments made in their reflections" to provide "a snapshot of my interpretation of the teachers' identity… based on the stories they shared (Wortham, 2001)" (p. 325). She then analyzed the narratives to consider the storylines of teacher noticing. While Wager cited Clandinin and Connelly's (2000) seminal *Narrative Inquiry: Experience and Story in Qualitative Research* and used their methods, Wager did not explicitly name her methodology as NI.

Narrative inquiry as method in ESM. In the ESM map, there are no articles that cite Polkinghorne and only four articles that cite Clandinin and Connelly: Darragh (2016); Foote & Bartell (2011); Nardi (2016); and Zazkis & Koichu (2015). Of these, Darragh's review of identity research cited Clandinin and Connelly in reference to the concept of identity and Zazkis and Koichu (2015) undertook a duoethnography that cited Clandinin and Connelly cursorily as an example of the "diverse narrative approaches in qualitative research" (p. 164). The two articles by Foote and Bartell (2011) and Nardi (2016), together with the article by Lloyd (2006), undertook NI as a method and are discussed now.

Lloyd (2006) demonstrated the potential of analysis of narratives as a way "to offer a window into preservice teachers' ideas and sense-making about certain mathematics classroom events"

(p. 81) and to initiate change in practice and thinking. In Lloyd's study, preservice teachers were invited to write fictional stories about mathematics classrooms in a methods course by taking up two opposing perspectives on a response to reform. The purpose was to encourage PSTs to imagine situations in the role of a teacher versus more familiar roles as student or observer. The teachers' stories offered "a wealth of information about their individual identities and classroom experiences" (p. 58) and served as "powerful catalysts for change and development" (p. 59). The researchers theorized that the fictional accounts in particular were catalysts for change because they explicitly asked the teachers to create images of themselves and others outside of their actual experiences. The teachers' fictional accounts were analyzed structurally and thematically. This study highlighted the potential of the use of NI both as a pedagogical tool and a research tool to identify preservice teachers' views and anticipate specific responses to common classroom dilemmas.

In a study exploring the narratives pre- and post-doctoral emergent scholars produced regarding their positionality on equity and diversity, Foote and Bartell (2011), explicitly named "two main forms of gathering stories and then analyzing them within a narrative framework" (p. 49). The first form, in which researchers live alongside participants to gather stories of lived experience, aligns with Polkinghorne's narrative analysis while the second, in which stories are gathered from participants "and the narrative data is analyzed for common themes, metaphors, plotlines, and so on to identify general themes or concepts" (Clandinin, 2007, p. xv, as cited in Foote & Bartell, 2011), aligned with Polkinghorne's analysis of narratives. It is within the latter, the analysis of narratives that Foote and Bartell situated their work. They undertook 26 life-story interviews, "semi-structured interviews designed to elicit accounts of the life stories that the participants felt had influenced their interest both in issues of equity and diversity and in mathematics teaching and learning…[probing] for experiences that may have happened during different periods of the life cycle such as in childhood, young adulthood, and the present time" (p. 51). Through this work, Foote & Bartell found three themes within the narratives–"'othering experiences,' 'bearing witness experiences,' and 'orienting experiences'" (p. 52)–that influenced emergent scholars' choice to engage in equity-focused research. These researchers, however, also identified two tensions that the emergent scholars described in their narratives: "(a) a tension between research seemingly more focused on mathematics or research seemingly more focused on equity, and (b) a tension between research grappling with complex and important theoretical issues and urgent, practice-based considerations" (p. 52). The way these researchers gathered their data narratives and the nature of their findings firmly places the work within the paradigm of 'analysis of narratives.' In this analysis, the researchers provided important findings that "[make] visible how the life experiences of some early career mathematics education scholars impact the stance they bring to their research and, in so doing, reaffirms arguments that socio-cultural perspectives of learning are important for mathematics education research" (p. 65). Furthermore, Foote and Bartell's focus on emergent scholars extended Lloyd's work to show that, in addition to serving as a research tool to identify preservice teachers' views and common classroom dilemmas, NI can be employed to identify emergent scholars' views and common research dilemmas.

Nardi's (2015) work with narrative fits within the broad concept of narrative analysis. Nardi justified the use of re-storying, a process of constructing a "story from the original data (Ollerenshaw & Creswell, 2002, p. 330)" (p. 363) that "assimilates the multiplicity of voices (researchers' and research participants' as well as amongst the participants themselves) without suppressing or eliminating this multiplicity" (p. 364). Nardi's project included interviewing mathematicians and creating narrative accounts that were co-constructed from transcripts of multiple mathematicians and mathematics education researchers to provide insight into university mathematics pedagogy. She argued that the stories she created are a "potent communicative tool which can be deployed by two communities—mathematics and mathematics education research—which often find communication challenging" (p. 364). The stories Nardi wrote provided a common language to discuss teaching and learning between the two communities. She described this method as communicating the *substance* of the research knowledge in *forms* that are amenable to both communities. The use of narrative allowed her to produce a "new form of knowledge about mathematical pedagogy co-constructed by members of two often separated communities …relocated to a novel *third space* which welcomes *non-deficit, non-prescriptive, context-specific, example-centered* and *mathematically focused* discourses" (p. 373-374). Thus, Nardi extended NI beyond *understanding* preservice teachers' (e.g., Lloyd, 2006) and emergent scholars' (e.g., Foote & Bartell, 2011) views and provided a powerful example of the ways that NI can open up other possibilities on *knowing*, on knowledge production (co-constructed multiplicative accounts), and communication across fields/communities (mathematics and MER).

A Possible Method, Differences in NI Uptake outside Disciplinary Boundaries (RQ2)

While NI has had slow uptake within the MER disciplinary journals, there has been MER that employed NI published in educational research journals outside the disciplinary boundaries. In this section, we present two examples of this research to explicate the potential of NI as methodology and to further emphasize the distinction between Polkinghorne's (1995) analysis of narratives and narrative analysis.

Case 1: Analysis of narrative. Drake and Sherin (2006) used NI to explore two teachers' responses to reform-oriented mathematics curriculum. The authors justified their use of narrative inquiry because it "allows for a contextualized and integrated understanding of teachers' beliefs, knowledge, and prior experiences" (p. 157). Drake and Sherin came to believe that understanding the teachers' narratives in relation to their experiences as learners and teachers of mathematics provided clarity to teachers' choices in implementing the curriculum. They stated that "narratives of identity both guide the actions of individuals and frame their interpretations of new information" (p. 158). While Drake and Sherin relied on narratives and specifically math story interviews, they did not employ narrative methodology writ large. Like Sfard and Prusak (2005) before them, they relied on narrative as a way to think about identity. The inclusion of narratives (past and present) in considering teachers' decisions about reform complicates both what teachers say about the reform and *who* a researcher believes the teacher *is*. As Drake and Sharin (2006) explained, narrative inquiry "allows for an understanding of teachers' beliefs not as isolated statements, but as interrelated ideas rooted in teachers' identities-their stories of themselves as learners and teachers" (p. 158). Drake and Sherin (2006) included narrative in the theoretical framing of their article-more than in the methodology. Within the methodology, they named 'mathematics story interviews' drawing on McAdams' (1993) life story interviews. They deemed their method of NI "different from and, in particular, more structured than, many other examples of narrative inquiry (Clandinin & Connelly, 2000)" (p. 162). Drake and Sherin's work with narrative falls into the first of Polkinghorne's (1995) two categories, they analyzed the mathematics life stories and coded to teacher beliefs within the stories. Drake and Sherin justified their use of NI because it allowed them to better understand the teachers' adaptation of curriculum by first considering "their identities as learners and teachers of mathematics, as revealed their mathematics stories" (p. 164). They concluded their manuscript with a recommendation for future research that connects "teachers' narrative mathematics identities using alternative methodologies" that are "more unstructured" (p. 184). Martinie et al. (2016) provides an example of a less structured NI methodology.

Case 2 Narrative analysis. Like Drake and Sherin (2006), Martinie et al. (2016) employed narrative methods to understand mathematics teachers' response to reform. Unlike Drake and Sherin, however, in this case, Martinie and colleagues went beyond 'analysis of narrative' methods and acknowledged narrative *methodology* in general, and 'narrative analysis' in particular, as an "important part of the education research landscape…[that] problematizes the positivist nature of knowledge as the objective and unitary way of knowing" (p. 659). They explained that narrative researchers use stories to "interrogate" and "reshape" (p. 659) dominant views and position their approach as being "alongside." In the decade between Drake and Sherin and Martinie et al., narrative methodologies were more broadly explicated and employed. While *analysis of narratives* was used by Drake and Sherin, Maritinie et al. employed *narrative analysis* to both understand math teachers' experience with common core implementation and to synthesize those experiences using narrative analysis that mingles the voices of the participants and "synthesize[s] the fragmented data and (re)construct[s] them into a coherent story rather than separating them into different categories" (p. 660). The mingling of voices provides confidentiality and "attends to the ethical stance of narrative inquirers while interweaving our ontological, ethical commitments (Clandinin & Murphey, 2009)" (p. 660). In this case, the researchers created four voices that represented the teachers' various responses to adopting the reform (hardcore adopter, anxious adopter, cautious adopter, critical adopter). Rather than providing themes of teachers' responses to mathematics curriculum reform siloed into a monologue, this methodology presented four distinct voices that provided valuable insights into various stakeholders and resisted shutting down oppositional voices as less important forms of knowledge. With these four voices acknowledged, researchers, policymakers, and educational leaders can better address concerns, criticisms, and reservations to enact important change in mathematics education.

Discussion

By mapping the methodological contours of the field of mathematics education across time, we establish what has been done. We then use this sketch to emphasize the ways that this landscape and its boundaries limit what is seen as legitimate within the field, what is seen as proper methodologically and theoretically. To wit, we disrupt the present notion that 'much progress has been made in the adoption of diverse qualitative perspectives in mathematics education research' and imagine a more expansive future by making explicit the call to adopt NI methods. In response to our third research question, What might narrative inquiry offer mathematics education research?, we note the movement in the field of MER due to the positioning of teachers as creators of curriculum when Clandinin and Connelly's work was first taken up, we then point to how analysis of narratives allowed MERs to complicate and contextualize teacher beliefs (Drake & Sherin, 2006) and how narrative analysis created a third space for communication between mathematicians and MERs (Nardi, 2015) and 'voices' that represent a range of responses to mandated curriculum reform so that MERs might better understand how to work with teachers to enact change in mathematics education (Maritinie et al. 2016). In many ways, our findings echo those of Geller, Hernández, and Chapman (2013): "[narrative was] used mainly as a conveyer of teachers' knowledge and experiences and not as a narrative research methodology (which was what was proposed by Clandinin and Connelly, 2000)." We close by reflecting on the overall lack of specificity we found in discussions of methodological work within the MER that we reviewed. We encourage mathematics education researchers to be more methodologically (and theoretically) adventurous and to carefully describe and cite their methodological sources.

This study examines the efficacy of two types of instructional strategies - Explicit Attention to Concepts and Student Opportunity to Struggle - for improving middle grades mathematics achievement. We worked with 100 grades 6-8 mathematics teachers, providing professional development on implementing the strategies in their local contexts, then partnering to conduct a large-scale cluster crossover study on two ways of sequencing the strategies, Struggle First vs. Concepts First. Compared to a business-as-usual control group, we found positive effects of both types of instructional sequences on students' mathematics achievement, with greater positive effects for Concepts First than Struggle First. Interestingly, many teachers reported shifts in their beliefs about the strategies. The results highlight the potential for targeted professional development to support teachers' adaptation and use of mathematics instructional practices.

Keywords: Professional Development

Keeping in mind the tensions mathematics teachers face in their instructional choices (Stahnke et al, 2016), we conducted a research study with 6-8 mathematics teachers to study the effects of attempting to adapt new instructional strategies on students' mathematics achievement.

Background

The Explicit Attention to Concepts (EAC) and Student Opportunity to Struggle (SOS) framework focuses on two primary instructional strategies for enhancing mathematics education as articulated by Hiebert & Grouws (2007). Through a synthesis of research indicating positive effects across study design, teaching formats, and contexts, Hiebert and Grouws identified these clusters of instructional practices as supportive of students' conceptual understanding. Stein and colleagues (2017) built upon this work by operationalizing the measurement of the EAC and SOS constructs in teaching practice and examining their relationship to students' skill efficiency and conceptual understanding. Their observational study found that teaching practices with both high EAC and high SOS tended to have the largest estimated effects on students' skill efficiency and conceptual understanding, followed by in order by high EAC-low SOS practices, high SOS-low EAC, and low EAC-low SOS practices. That research, as well as studies that focus on similar constructs (Fennema & Romberg, 1999; Kapur, 2014; Loehr et al., 2014; Schwartz et al., 2011), has demonstrated positive effects of EAC and SOS instruction on students' math achievement. Nonetheless, there are questions about supporting teachers' implementation of EAC and SOS, including how EAC and SOS practices may differentially influence student learning, effective ways to order instructional practices aligned to EAC and SOS (c.f., Schwartz et al., 2011), and how the practices are taken up by teachers.

The 3-year *Researching the Order of Teaching* (ROOT) project, a $3 million research project sponsored by the National Science Foundation (Award No. 1907840) was designed to address some of the open questions about EAC and SOS in the context of middle grades mathematics settings. The ROOT project started in fall of 2019 with the recruitment of 100 Grade 6-8 mathematics teachers from 34 schools within 22 school districts in the western United States. Initially, the professional development activities were designed to engage participating teachers in exploring ways to adapt and implement EAC and SOS as instructional practices in their classrooms (Hughes et al., 2023).

A distinctive feature of the project was our objective to foster idea-sharing and provide support for implementation, without pushing for strict adherence to the researchers' interpretations of the EAC and SOS instructional practices. We view teachers as key stakeholders, experts in their local contexts, and co-producers of knowledge (Kieran et al., 2012). We included activities such as interacting with colleagues around the practice guide as a boundary object (Crawford et al, 2022), planning and implementing a small sequence of lessons, and reflecting on features of the strategies to support teachers' development of personalized routines and practices that fit their preferences, curriculum, and local context. The research questions were:

1. Strategy Efficacy: What are the effects (if any) on student math achievement when teachers are asked to enact EAC and SOS instructional strategies?
2. Sequencing Efficacy: What are the effects (if any) on student math achievement when teachers are asked to enact "Struggle First" or "Concepts First" instructional strategies?
3. Teacher Beliefs: After attempting both Struggle First and Concepts First instructional strategies, which strategies did teachers perceive to be most effective for promoting students' math achievement?

Methods

We recruited 100 grades 6-8 mathematics teachers to participate in the project, of which 99 completed the initial baseline data collection. The teachers all worked in public schools in a single western U.S. state, spread across 34 schools in 22 school districts. Nearly all worked in brick-and-mortar schools, though one teacher worked for a virtual public charter school. Teachers' mathematics instruction often spanned multiple grades (49 taught Grade 6, 44 taught Grade 7, and 44 taught Grade 8) and courses (37 taught one course, 48 taught two courses, and 12 taught three or more courses). The teachers worked in a variety of school settings, both in terms of students' socio-economic status (mean eligibility for federal free or reduced school lunch was 58%, SD = 21%) and locale type (31% rural, 69% suburban or small city). Teachers' demographics indicated substantial variability in mathematics teaching experience (mean = 9.8 years, SD = 7.4, Range = 1 to 32), and they primarily self-identified as female (77%) and white (96%). Educational attainment among the teachers was typically a bachelor's degree (57%), though 40% held a master's degree, and 2% held an Ed.S.

As an optional professional development activity for middle grades teachers, we planned for 20% attrition annually (expected n = 100 teachers in year 1, 80 in year 2, 64 in year 3). A global pandemic began disrupting participating schools during the spring of year 1, causing a shift to primarily remote activities during year 2 and increased attrition as teachers responded to their local crisis contexts. By year 3, the schools had primarily returned to in-person instruction (often with masks) and N = 58 teachers completed the planned research activities. We analyzed teacher-level factors (e.g., grade levels, district types, years of prior experience) to look for indications of differential attrition during the pandemic disruptions, but found no significant evidence of divergence from random attrition.

Research Design

In year 3 we partnered with teachers to implement a cluster crossover research design in which the teachers were divided randomly into two groups – Concepts First and Struggle First during the summer prior to the study. We randomized the assignment of teachers to conditions at the school level to ensure teachers could collaboratively plan with teachers in their building, with students clustered within their teachers. There were 28 teachers in the initial Concepts First group and 30 teachers in the initial Struggle First group. During the fall, the Concepts First group was asked to start each lesson with EAC instructional practices followed by SOS instructional practices, while the Struggle First group was asked to start their lesson with SOS instructional practices followed by EAC instructional practices. In the spring, the groups 'crossed-over', with each group of teachers asked to follow the other groups' sequencing instructions from the fall.

The professional development during years 1 and 2 of the project involved familiarizing teachers with EAC and SOS, as well as supporting their implementation of these practices in their classroom through a summer institute, online modules, and small-scale teaching studies each fall and spring with in-school support from dedicated math instructional specialists. The teaching studies were typically 2-3 weeks in length and focused on whether a particular EAC/SOS strategy was practically useful for supporting student learning. The design and implementation of the instructional unit was supported by one of three full-time instructional specialists working on the project who were directly assigned to the teachers by school. The level of support provided during the crossover study was dependent on teachers' request for support, with an average of $M = 21$ interactions (Range = 11 to 31) with specialists per teacher for an average duration of $M = 31$ hours (Range = 12 to 49).

Data Collection & Analysis

The primary data source was the state mathematics assessment data system, which was developed by a multi-state consortium for use in Grades 3 to 10. Nearly all students completed the exam each spring, which we used as pre and post scores. An interim comprehensive exam was administered during the winter between the "cross-over" of instructional strategies to obtain mid-year scores. We used demographic data for all students in the districts to generate a group of students from participating districts with non-participating teachers using a genetic algorithm to select a balanced sample of a control group with a similar demographic profile along key variables (district, grade level, sex, special-education status, and pre score). The final subsamples included $n_1 = 2202$ students in the Concepts First in fall arm, $n_2 = 1941$ students in the Struggle First in fall arm, and $n_3 = 4246$ students in the control group. The sample was approximately balanced by grade level (Grade 6 = 32%, Grade 7 = 35%, Grade 8 = 33%), with students' primarily reported as White (67%) or Hispanic/Latino (30%). Approximately, 10% of students met Special Education criteria and 11% were identified as English language learners. Demographic distributions were within 1% across the 3 subsamples.

For the two research questions about student achievement, we applied standard procedures for (ordinary least squares) multiple linear regression modeling. The outcome variable was students' gains during periods of instructional intervention, with pre-identified explanatory variables obtained from prior observational studies of student achievement, including students' grade level, study condition, race, and special education status. This included technical verification of model assumptions (e.g., independence, homoscedasticity, non-multicollinearity, omission of outliers, normal residuals) and summary reporting of model characteristics. The primary purpose of the regression models was estimates of effect sizes, relying on the crossover research design for claims of causal effects. For the third question, we visualized teachers' responses to brief survey questions during the final weeks of the crossover study about their pre and post beliefs regarding the relative effectiveness of the Concepts First and Struggle First.

Results

To assess Question 1, we applied multiple linear regression on the outcome variable of students' annual mathematics achievement, with explanatory variables of categorical grade level (6, 7, or 8), binary study condition (control or EAC/SOS), binary race (White or non-White), and binary Special Education eligibility (no or yes). This resulted in a significant model, $F(5, 7379) = 25.68$, $p < .01$, $R^2 = .02$. All of the explanatory variables had statistically significant coefficients, including the intercept = 4.3 ($t = .14$, $p = .03$), grade 7 = 13.6 ($t = 7.04$, $p < .01$), grade 8 = 5.5 ($t = 2.8$, $p = .01$), White = 6.7 ($t = 4.0$, $p < .01$), special education = -17.32 ($t = -6.1$, $p < .01$), and EAC/SOS condition = 7.0, ($t = 4.5$, $p < .01$). The coefficients indicate absolute differences in average annual achievement across the explanatory variables while holding all other variables at baseline levels (listed first above). In particular, holding all other variables at baseline, the model suggests students of teachers participating in the EAC/SOS study had 7.0 points (95% CI = 3.4 to 10.1) greater average mathematics achievement than comparable students of teachers engaged in business-as-usual instruction. For relative comparison, the average estimated effects of grade levels were 13.6 and 5.5 points (for Grades 7 & 8 versus Grade 6, respectively).

To assess Question 2, we applied multiple linear regression on the outcome variable of students' semesterly mathematics achievement, with explanatory variables of categorical grade level (6, 7, or 8), study condition (control, Struggle First, Concepts First), binary race (White or non-White), and binary Special Education eligibility (no or yes). This resulted in a significant model, $F(7, 10389) = 66.25$, $p < .01$, $R^2 = .04$. With the exception of White (estimate = 2.7, $t = 1.9$, $p = .06$), all the explanatory variables in the model had statistically significant coefficients, including the intercept = -15.0 ($t = -7.6$, $p < .01$), grade 7 = 9.9 ($t = 6.0$, $p < .01$), grade 8 = 4.2 ($t = 2.5$, $p = .01$), Spring semester = 27.4 ($t = 20.0$, $p < .01$), special education = -5.8 ($t = -2.4$, $p = .02$), Concepts First = 8.9, ($t = 5.6$, $p < .01$), and Struggle First = 4.5 ($t = 2.7$, $p = .01$). Similar to the other regression analysis, the estimated coefficients indicate absolute differences in average semesterly student achievement across the explanatory variables while holding all other variables at baseline levels. In particular, holding all other variables at baseline, the model suggests students of teachers attempting to enact Concepts First teaching had 8.9 points (95% CI = 5.6 to 12.2) greater average mathematics achievement per semester than comparable students of teachers engaged in business-as-usual instruction. This is approximately twice the estimated effect of Struggle First teaching, which was 4.5 points (95% CI = 1.2 to 7.8) per semester.

For Question 3, during the last few weeks of the crossover study, teachers reported their beliefs about the relative effectiveness of Struggle First and Concepts First. Responses suggested teachers' experiences led many to shift in their beliefs about which way of sequencing EAC/SOS instruction was more effective. For instance, 24 of the teachers reported shifting from believing Concepts First was more effective to believing Struggle First was more effective, compared to only 5 teachers who reported the reverse type of shift from Struggle First to Concepts First.

Conclusions

Overall, the findings support professional development structures that recognize the complex systems within which teachers are teaching, and that providing professional development around well-research strategies and providing autonomy around important aspects of implementation can result in increased student achievement.

MANAGING PEDAGOGICAL DILEMMAS IN A CONTENT FOCUSED COACHING CONVERSATION

Jeffrey Choppin
University of Rochester
jchoppin@warner.rochester.edu

Julie Amador
University of Idaho
jamador@uidaho.edu

We explored pedagogical dilemmas in a content focused coaching conversation. We explored how a coach managed the dual obligations of producing viable lesson artifacts while also advancing teacher thinking with respect to content and pedagogical knowledge. We termed these as instrumental and learning orientations, respectively. We describe a representative case selected from a larger sample to characterize: (a) the presence of these orientations, (b) the purposes each orientation served, and (c) how the orientations functioned in tandem. The results show that the coach found strategic moments to advance teacher thinking while fulfilling the instrumental obligation of producing lesson artifacts.

Keywords: In-service teacher education; teacher educators; professional development

Educators face the perpetual tension of conveying conventional disciplinary knowledge to learners while simultaneously eliciting and building from learners' idiosyncratic ways of thinking (Lampert, 1985). While these tensions have typically been explained in terms of teachers and students, there is a parallel to the work of teacher educators whose goal it is to help teachers understand content or pedagogy. We situate an exploration of these tensions in the context of content focused coaching (CFC) (West & Cameron, 2013). An important goal in content focused coaching is to support teachers' development of their content and pedagogical content knowledge (Ball et al., 2008), a goal that may be in tension with more instrumental goals of producing a set of viable lesson artifacts for the teacher to implement in an upcoming lesson. We frame this tension in terms of pedagogical dilemmas, which Windschitl (2002) describes as navigating between "honoring students' attempts to think for themselves while remaining faithful to accepted disciplinary ideas" (p. 133). We translate the notion of pedagogical dilemmas of teachers to those of coaches, a parallelism termed *lifting* (e.g., Prediger et al., 2022) in which experiences from teaching are applied to the facilitation of professional development, including coaching. We posit that the knowledge required to teach is a form of disciplinary knowledge, involving both content and pedagogical knowledge (cf. Ball et al., 2008; Shulman, 1986), and that coaching is intended to develop those forms of knowledge.

Content Focused Coaching

The coaching model employed in our study was CFC (West & Cameron, 2013), which stands in contrast to instructional coaching or cognitive coaching. CFC is distinguished by its focus on disciplinary content in the coaching conversations; coaching sessions focus on the mathematics of the lesson, how that mathematics is addressed in the task design, student thinking that might emerge during the lesson, and what kinds of instructional moves facilitate or advance mathematical understandings (Callard et al., 2022). The innovation in our professional development project was the translation of a face-to-face model of mathematics coaching to a fully online, video-based coaching model (Amador et al., 2021).

Orientations in Coaching Conversations

We characterize pedagogical dilemmas in coaching in terms of two orientations: *learning* and *instrumental*. A learning orientation involves a focus on advancing teacher thinking with respect to mathematical content, student reasoning around that content, and pedagogical strategies that promote student thinking. An instrumental orientation involves a focus on generating a set of tangible artifacts around the lesson, including a well-defined learning goal, a high-quality mathematical task, and a set of anticipated student strategies (West & Staub, 2003). With respect to the presence of these orientations, we posed the following research questions: How were instrumental and learning orientations evident in a planning conversation as part of content-focused coaching cycles, what purposes did each serve in the conversation, and how did they function in tandem?

Methods

We selected a representative coaching conversation from a larger set of 28 conversations, ten of which we analyzed for pedagogical dilemmas in a broader study (Choppin et al., in review). For reasons of space, we restrict analysis in this paper to one planning conversation. The focal coaching conversation involved a teaching team of two teachers, named Larson and Walters, and a coach, named Reiss.

For this paper, we analyzed the planning conversations for the presence of instrumental and learning orientations. An instrumental orientation related to the obligation to produce viable lesson artifacts by the end of the planning conversation, while a learning orientation related to the coach's desire to advance the teacher's content and pedagogical content knowledge. In terms of distinguishing between instrumental and learning orientations in the coaching transcripts, we coded a coach turn instrumentally oriented if: (a) the coach suggested revising the mathematical goal or task without an accompanying explanation, (b) elicited details of a task or student strategy, or (c) described student strategies or mathematical task without explaining connections to the mathematical goals of the lesson. We coded a coach turn as learning oriented if: (a) the coach pressed the teacher to explain the rationale for their choice of goal or task, (b) explained a goal or task in ways that connected to broader mathematical or pedagogical ideas, or (c) explained how a student strategy indicated understanding of a mathematics concept. The key distinction between the two categories was the presence of an explanation or a press for an explanation; explanations entail a connection between two related topics (e.g., between an interpretation and evidence, between a representation and the idea it is intended to convey, between student thinking and the mathematical goal). We interpreted explanations or press for explanations as evidence of the coach's intent to advance the teacher's content or pedagogical content knowledge.

Results

We selected a case to explore the distinctions between the two orientations and how the interweaving of the two characterized the coaching conversation. The teachers (Larson/Walters) sent Reiss a task they had adapted from an online source but communicated to Reiss that they wanted to revise the task. The task required students to generate a graph and function from a table of values, generate a table from a verbal rule, and match multiple representations. Reiss explained that during the planning meeting "we ended up greatly modifying the task … it was very skills-based [and we transformed it to focus on] the relationship between the three different representations." Our analysis revealed three phases in the planning meeting. We characterized the first and last phases as instrumentally oriented and we characterized the middle phase as learning oriented.

Phase One. In the initial phase the teachers provided multiple goals: Larson stated, "They would be able to see the relationships between the coordinates, to be able to write the rules, and be able to articulate how you get the coordinates just based on the rules." The teachers had indicated to Reiss that they had revised the task in advance of the planning meeting to include a series of input / output tables, from which they hoped students would be able to generate rules. Walters explained that the students "have multiple tables with X and Y coordinates and coordinate pairs [to] figure out what the rule might be for those particular tables." Larson added that the rules would be "adding three to X and … adding six to X or something like that." We characterized this phase as instrumentally oriented because the focus was on generating detailed descriptions of the mathematical goal and task. In the second phase, Reiss sought to clarify how students would engage with the task and if the current formulation of the task presented sufficient opportunities for sensemaking, described below.

Phase Two. Reiss initiated this phase with a suggested revision to the task that was more open than the one the teachers had presented, stating "would there be a way to give them … a bunch of tables, and have a bunch of rules and have a bunch of graphs to see if they could match them." Reiss also suggested leaving some blank spaces on the bottom of the table to have students generate their own points. Reiss asked, "Where do you think kids will struggle if you were to give them a set of graphs, a set of tables, and a set of rules? Where do you think they're going to struggle with that?" Larson responded that students might struggle to identify coordinates, to which Reiss responded by explaining that students struggle with identifying coordinates that do not correspond to points visible on the graph. Reiss elaborated on the suggestion to add blank spaces on the table, stating "I think if you left spaces on the table where they had to add in some additional points" so that students would understand that "all those points are still falling on this line." Reiss explained that leaving blanks on the table and matching rules with tables would open up the task and provide more opportunities for students to make connections.

We characterized this phase as learning oriented because Reiss pressed the teachers to explain why they thought that the task would support students to identify coordinates and to make rules from a table. In this phase, Reiss made suggestions about the task and explained how those suggestions would support students to make sense of the mathematical goals of the lesson. The pressing and explaining by Reiss pushed the teachers to provide their justifications for the task and how it addressed the mathematical goal.

Phase Three. The third phase of the conversation focused on finalizing the task features and the summary discussion. Reiss suggested an extension to the matching activity in case some students completed it too quickly. Reiss made this suggestion without explaining how it would support students to make sense of mathematical concepts, so we characterized it as an instrumentally oriented move. Though we characterized this phase as instrumentally oriented, there were moments when Reiss provided additional explanations of how students might struggle with generating points on the line and rules, why her suggestions for revising the task provided opportunities for student sense making, and how to support the students in their efforts. Reiss pushed the teachers to consider how leaving a blank space provided opportunities for sensemaking that a more scaffolded approach would not. We characterized the last part of this phase as instrumental because it primarily focused on logistical details of the summary discussion.

Discussion

Reiss used the first phase (characterized as instrumentally oriented) to clarify the mathematical goal and the task. In the second phase (characterized as learning oriented), Reiss pushed the teachers to consider connections to the big mathematical idea embedded in the task and goals, and to revise the task in ways that supported student sensemaking of the mathematical goals. The third phase (characterized as instrumentally oriented) was focused on finalizing key details of the task and to organize the summary discussion of the lesson.

The analysis shows how the orientations served distinct but complementary purposes. Reiss leveraged an instrumental orientation – making specific suggestions to revise the task – with a learning orientation, explaining why these suggestions would enhance students' sensemaking opportunities. Reiss balanced the obligation of pushing the teachers to expand their understanding of mathematical and pedagogical ideas with the obligation to produce viable lesson artifacts by the end of the conversation. The dynamic between the orientations allowed Reiss to honor the teachers' ideas and their need to produce a viable and well-defined lesson plan with her own desire to advance the teachers' understanding of mathematical content and pedagogical principles.

Regarding the pedagogical challenges coaches face, the findings illustrate how Reiss managed the tension between instrumental goals (e.g., crafting instructional materials for teachers to use in a lesson) and learning goals (e.g., eliciting and advancing teachers' cognitive processes regarding mathematical content, ambitious pedagogy, task design, and student cognition) (Harbour et al., 2021; Russell et al., 2020; West & Staub, 2003). Reiss ensured that Larson/Walters established a clear mathematical goal, a key component to develop teachers' pedagogical content knowledge (Ball et al., 2008). Simultaneously, Reiss leveraged the development of the goal and task to stimulate teacher thinking by prompting them to articulate their thoughts and providing explanations that underscored aspects of the task that afforded connections to significant mathematical concepts. We hypothesize that an excessive focus on instrumental goals might have limited teachers' cognitive expansion, while an excessive emphasis on learning goals could have hindered the creation of high-quality instructional materials for an upcoming lesson.

The three phases showed how the interweaving of the two orientations is an essential feature of coaching conversations. Each orientation was strategically employed in the planning conversation. These phases illustrate Reiss' awareness of the conflicting obligations and opportunities to stimulate teachers' cognitive processes. In summary, Riess coached in a way that navigated pedagogical dilemmas by leveraging the production of viable artifacts as opportunities to stimulate teacher thinking at strategic junctures, providing opportunities for teachers to develop their pedagogical content knowledge.

We argue that the actions of Reiss, to balance pedagogical dilemmas between the instrumental phase and learning phase, all within one coaching planning meeting illuminate coach actions parallel to those of an effective teacher as they would balance teaching phases. The case shows a situation parallel to a teacher's work to hone students' attempts to think for themselves (Windschitl, 2002). At the coach level, this principle was lifted (e.g., Prediger et al., 2022) as Reiss honed the teachers' attempts to think for themselves in the process of planning a mathematics lesson. Building from these findings, the following provides implications for coaching and research on coaching.

FACILITATING VIDEO COACHING CLUBS

We explored the facilitation of video coaching clubs to provide professional learning opportunities for coaches taking part in video clubs as part of a three-part professional development project. We lifted a facilitation framework (van Es et al., 2014) from a video-based teaching context to a video-based coaching context to better understand how the facilitators of video coaching clubs drew out contributions from coach participants while simultaneously leveraging their own insights as productive tools to advance the conversation. We further explored how facilitation practices changed over the course of two years. We found that facilitators increased their contributions when the videos came from the participants. The facilitators used the videos to reinforce the principles of content-focused-coaching, to model how to reflect on videos of coaching, and to conjecture about broader issues in coaching.

Keywords: rural, middle grades, professional learning, ambitious teaching, video clubs.

We studied discourse moves of facilitators of video clubs that were designed to support the professional learning of mathematics coaches. Our video coaching clubs consisted of groups of four to five coaches who met regularly to collectively view and analyze videos of coaching practice, similar in structure to video clubs that have been used with teachers (Gaudin & Chalies, 2015; van Es & Sherin, 2008). While there has been considerable literature on the facilitation of video clubs for teachers (cf. van Es et al, 2014; Coles, 2019), there has not been a parallel focus on video clubs for mathematics coaches. Karsenty et al. (2023) define a facilitator as “a professional who manages the PD activities, sets norms for interactions, supports teachers’ exchange of experiences and insights, monitors the discussion, and works with teachers toward the goals set for the PD” (p. 28).

We note the complexities of extracting practices from nested activities to new layers of practices (e.g., nesting and lifting [Prediger et al., 2019]) to analyze the practices of facilitators of teacher educators). We studied the practices of the video club facilitators by adapting the Framework for Facilitation of Video-Based discussions, developed by van Es et al. (2014). This framework includes broad categories such as *orienting group to the video analysis task*, *sustaining an inquiry stance*, *maintaining a focus on the video and the mathematics*, and *supporting group collaboration*, that include specific facilitation moves (e.g., launching, countering, etc.) The literature on video clubs for teachers shows that these clubs provide opportunities for teachers to develop their capacities to attend to how their actions supported student thinking. In turn, we hoped to show how the Video Coaching Clubs–given the name because mathematics coaches are the participants, not teachers–would support coaches to attend to how their actions impacted teacher’s learning. The premise of a mathematics education video club is to create an environment for a group of educators to develop evidence-based reasoning as the basis of teacher growth (van Es & Sherin, 2008); our intent was that video coaching clubs would foster a context for coaches to develop evidence-based reasoning as the basis for coach growth. We answered the following research question: How did the facilitator draw out contributions from the coach participants while simultaneously leveraging their own insights as productive tools to advance the conversation? How did facilitation practices change over the course of four video coaching clubs?

Design Principles for our Video Coaching Clubs

We based our video club design on several principles. First, we wanted our coach participants to draw on videos of coaching to support their evidence-based noticing of relevant coaching incidents; this follows the principle of lifting (Prediger et al., 2019) principles from teacher video clubs to that of coach video clubs.

We also drew from the notion of unpacking content related to teachers' planning practices to serve as a basis for the coaching episodes around which we wanted the coach participants to reflect. In other parts of our project we utilized content-focused-coaching [CFC] (West & Staub, 2013) as the model of coaching we emphasized; CFC is intended to develop teachers' content knowledge and pedagogical content knowledge. Content-focused coaches typically engage teachers in a three-part coaching cycle in which a coach and teacher collaboratively plan, teach, and reflect upon a mathematics lesson (West & Cameron, 2013). The planning phase of the coaching cycle is an opportunity to support teachers to develop new planning practices, while the debriefing phase is an opportunity to help teachers reflect on the ways students engage with mathematics (e.g., Witherspoon et al., 2021). Thus CFC-based planning and debriefing practices were the focus of the coaching episodes coach participants viewed..

Third, we followed the lead of van Es et al. (2014) and Coles (2019) in designing for high quality or productive discussions, which are characterized by four primary purposes for facilitation: orienting the group to the video analysis task, sustaining an inquiry stance, maintaining a focus on the video and the mathematics, and supporting group collaboration (the same key components of the van Es et al. (2014) facilitation model). Our model was intended to manage the tension between providing adequate scaffolding without being too prescriptive (Coles, 2019; Elliot et al., 2009).

Study Context

The Video Coaching Clubs are one of three components of fully online professional learning intervention designed to support mathematics coaches to engage in CFC. Coach participants from rural districts participated in an online course, online video coaching clubs, and one-on-one video-based coaching cycles with a Mentor Coach. Each video club met eight times over two years for approximately two hours each time; in the first year (first four clubs) the facilitator presented a video clip of their own coaching; these clips were chosen as examples, not exemplars of coaching moments, intended to initiate an inquiry into coaching, not an evaluation of the coach or the teacher (Borko et al., 2011). In the second year, each coach participant, rather than the facilitator, presented a video as the basis of group reflection. To facilitate evidence-based reasoning, the coach participants were asked to follow a see-think-wonder sequence for each relevant moment they noticed in the video, meaning they responded to prompts asking: What did you see? What did you think? What did you wonder?. These responses were written independently; these reflections became the basis of the public reflection that followed via dialogue as part of the video coaching club.

Methods

Data Collection

We analyzed transcripts from three groups of coaches who each met eight times, for a total of 24 Video Coaching Clubs. The clubs were all part of the first cohort of our project; consequently, all of the facilitators were new to the roles and to video coaching clubs. The Video Coaching Clubs were conducted via zoom and recorded; these sessions were then professionally transcribed and entered into spreadsheets for analysis.

Data Analysis

We adapted the coding framework from van Es et al. (2014) that was focused on teachers reflecting videos of mathematics lessons. The categories from that framework described the facilitator role of the Video Coaching Clubs in regard to high quality discussions and thus largely aligned with our purposes. However, we made a couple of adaptations to the framework to capture the extent to which the intellectual contributions drew from the facilitator or the participants. We were interested in capturing the ways in which the facilitator drew out contributions from the coach participants while simultaneously leveraging their own insights as productive tools to advance the conversation.

The practices from the Van Es et al. (2014) were: *orienting the group to the video analysis task*, *sustaining an inquiry stance*, *maintaining a focus on the video and the mathematics*, and *supporting group collaboration*. We largely kept the first and fourth roles, but incorporated the second and third into two newly defined practices. Both new categories, *focusing on contributions of participants* and *facilitator interjecting their thinking*, incorporated aspects of an inquiry stance and evidence-based reasoning while allowing us to explore how intellectual authority played out in the clubs. For example, in the category of *focusing on contributions of participants,* the codes *probing participant reasoning*, *paraphrasing*, *lifting up*, and *summarizing and connecting* function to make explicit the reasoning of the participants' reflections on the videos; these promote an inquiry stance. In the *facilitator interjecting their thinking* category, the codes offering an explanation and questioning/wondering focus on the reasoning of the coach, while the code *highlighting / providing evidence* mark moves where the coach focused on the video and the mathematics. See Table 1 for a list of categories, codes, and definitions.

Category	Code	Definition
Orienting to the video club norms and activities	Setting norms / expectations	Setting cultural norms for participating, such as how to formulate disagreements
	Explaining Video Coaching Club activity and directions	Providing details of the activity and how it will be structured
	Contextualizing clip	Provide additional information about the coaching context and mathematics lesson
Focusing on contributions of participants	Prompting participant ideas	Pose general prompts to elicit participant ideas
	Probing participant reasoning	Prompt participants to explain their reasoning and/or elaborate on their ideas
	Paraphrasing	Restate and revoice to ensure common understanding of an idea

	Lifting Up	Identify an important idea that a participant raised in the discussion for further discussion
	Summarizing and Connecting	Make connections between ideas raised in the discussion
Facilitator interjecting their thinking	Offering an explanation	Provide an interpretation of an event, interaction, or mathematical idea, from a stance of inquiry
	Highlighting / providing evidence	Direct attention to noteworthy coaching or teaching moves in the videos
	Questioning/wondering	Coach poses a hypothetical question or wonders about possible alternative actions.
Orchestrating discussion	Distributing participation	Invite participants to share different ideas who have not already participated in a discussion thread. Use in cases where the instructor calls out names to ensure everyone has participated.
	Validating participant ideas	Confirm and support participant contribution

Table 1: Categories, Codes, and Definitions in the Framework

Results

The summaries for each category yielded some consistencies across the facilitators. The facilitators spent roughly one third of their turns orienting the coach participants to the VCCs, with percentages decreasing from the first year to the second for each facilitator. The following quote from Reiss in VCC1 is an orienting move that illustrates how the coaches framed the clubs:

> We've come up with three goals that we're really working towards in these video coaching clubs. The first one is to grow in our ability to make sense of coaching moves and teacher thinking by noticing and naming interesting moments in a planning conversation. Then we also want to work on growing our personal capacity to facilitate content focused coaching planning conversations with teachers. We're going to continue to grow our collaborative community of coaches through rich conversations about authentic coaching moments. (Reiss, VCC1)

Roughly a fifth of the facilitator turns *focused attention on the contributions of the coach participants*; about half of those were *prompting participant ideas* and the other half a combination of the other four codes in that category. Roughly one in six facilitator moves involved *facilitator interjecting their thinking*, though the percentages in this category increased from the first year to the second year, which we explore below. Table 2 displays the overall percentages across both years of the VCCs.

Code Category	Lowrey	Reiss	Whilton
Orienting	32.2	43.5	32.7
Focusing on contributions of participants	20.4	23.0	18.9
Facilitator interjecting their thinking	15.5	13.9	16.1
Orchestrating	20.2	9.7	14.7

Table 2: Results across Categories for Both Years

We noted a number of trends when comparing the first year (the four VCCs where the facilitator presented a video of their own coaching) with the second year (the last four VCCs where the video was from one of the coach participants). These trends offer insights into the nature of VCC facilitation and into the impact of the selection of videos in terms of the conduct of the VCCs. We focus on four codes where we noted differences across the two years of the VCCs, three of which are in the *facilitator interjecting their thinking* category. Three of these codes showed increases across the two years while one did not. We will provide examples of facilitation moves for each of these codes to provide insights into facilitation and why facilitation changed when the source of the videos changed. We first note that the code *setting norms and expectations* decreased for Lowrey and Reiss across the two sets of VCCs from around 7% of facilitator turns to around 1.5%; this can be explained in part because by the second year of VCCs the norms and expectations would already be established. We note this to illustrate that there were some expected changes across the two years, first because the norms of the community had already been established and because the facilitator was no longer presenting their own video. See Table 3 to see the codes and the percentages across the two years.

Code Category	Lowrey VCC1-VCC4	Lowrey VCC5-VCC8	Reiss VCC1-VCC4	Reiss VCC5-VCC8	Whilton VCC1-VCC4	Whilton VCC5-VCC8
Paraphrasing	5.5	1.5	3.3	2.9	4.4	1.8
Offering an explanation	7.6	10.1	3.0	10.3	6.1	11.1
Highlighting / providing evidence	0.5	4.6	0.3	4.9	1.7	3.6
Questioning/wondering	2.2	6.1	0.00	13.2	2.2	9.3

Table 3: Percentage of Facilitator Moves for Selected Codes

The four codes we focus on below showed notable changes across the two years, with *paraphrasing* being the only one of the four that decreased. Here is an example from Lowrey:

> I guess what I'm hearing is that there were—you bumped into some kids that just having that understanding of fractions that we can cut things up and we can still share them and be able to use all of them and share them equally and what that might mean. Then this idea of cutting 'em all into fourths and is that going to give me the same amount as if I had a whole brownie? If I had four of those fourths, would that give me a whole brownie? (Lowey, VCC1)

Here, Lowrey emphasizes the mathematical explanation provided by a participant in a detailed way. This example and others of paraphrasing largely served the purpose of "facilitator modelling the kinds of discourse or social and discussion norms desired in a group" (Coles, 2019, p. 11). Similar to the decline in the norms and expectations code, the incidences of this code likely declined because the norms and expectations were more established in Year 2.

The *highlighting / providing* code increased in part because the facilitator in year two followed the same see-think-wonder sequence to reflect on the video as the other non-presenting participants. For example, Whilton referenced a moment in participant Rice's coaching video:

> One thing, too, from a coaching move that I noticed, I felt like the—I felt like the teacher's explanation in response to the coach's question was … just a broad statement. Then Rice followed up with a very specific, though. "Well, I heard a student say"—she named a very specific moment. (Whilton, VCC7)

This differed a bit from the first year, where the highlighting revealed new insights into a coaching session the facilitator had conducted:

> Just like Stevens said, I didn't even catch the why. The part I caught from the teacher in that same moment though was she said, "I would have asked them this because that would have aimed at our third goal," right? Same moment, but then she named the question and then said, "I would have asked that because that would have gotten us towards the third goal." (Whilton, VCC4)

The two codes that had the highest frequency of these four were *offering an explanation* and *questioning/wondering*. These codes represented the most substantial and detailed insights from the facilitator. As represented in the Reiss quote that expressed the goals of the VCCs, the facilitators' goals included supporting the participants to understand the principles of content focused coaching and to make sense of specific instances of coaching with respect to those principles. Below, we include instances of these codes to show how the coaches accomplished these goals and why they were more prevalent in year two.

The first example of *offering an explanation* is from Reiss connecting her interpretation of the video to the process of supporting teachers to identify a mathematical goal:

> I think what was happening was that the coach didn't want to give away too much about what she—I think she may have been trying really hard not to make the goal for her, so she was trying not to give too specific of examples because she wanted the teacher to self-select her goals. (Reiss, VCC 5)

A second example comes from Whilton, who described how the coach was trying to get the teacher to notice what students were doing:

> [was] the coach picking up maybe on this general nature of, "We talked about, and we did this," and the coach was like, "Wait a second. "We" were doing this stuff. What were the

> kids actually saying?" And pushing for that specificity from what were the kids actually saying versus living in this (Whilton, VCC 6)

These examples illustrate how facilitators used moments in the video to raise essential tensions in content focused coaching; in one case it was about providing opportunities for teachers to contribute to lesson planning and in the second it was about supporting teachers to notice students' mathematical thinking. In both cases, the facilitators' explanations animated the coaches' intentions and actions in ways that foregrounded principles of content focused coaching; they were able to leverage a participant's video to make a point that may not have been as poignant had it been their own video.

The first example of *questioning/wondering* is from Reiss in which she wonders about the outcome of the coaching conversation:

> Then I had a lot of wonderings about it. I wondered what might have happened when the teacher actually taught the lesson, if the students were able to actually make connections between the tiles and, again, it seemed like a rote procedure. Were they able to make a connection between the tile and solving equations or was it really just this procedure of I do this, I do this, I put this tile down. (Reiss, VCC 8)

The second is from Whilton as he wonders about a broader coaching principle;

> My wondering, then, as a coach, is maybe, how do we press—again, back to the "all" conversation. What do we do about the kids who are conceptually challenged versus—what are the coaching moves to not let that just be like, "Oh, they struggle"? It very well could've happened. I'm not saying that Rice didn't do it, but it makes me wonder, how, maybe, do we press in the moment for the "all" piece on that? (Whilton, VCC 7)

These wonderings represent the two most common types of wonderings, one in which the wondering about what happened in the subsequent lesson and the other a wondering about coaching in general. The first kind of wondering creates an anticipatory mind frame to support coaches to envision how their coaching impacts teaching, while the second kind of wondering is connected to general issues encountered in coaching and how to address them.

Discussion

This study explored the design and implementation of video clubs for mathematics coaches who are learning about content-focused coaching. We adapted a framework previously used to study facilitation in video coaching clubs for teachers because our design had considerable overlap with that of the framework's authors. We used that framework to study facilitation moves in 24 VCC sessions across three facilitators in order to better understand how facilitation might differ in video clubs for coaches and to understand how the source of the coaching videos impacts facilitation.

We found that the facilitators utilized some of the norming and orchestration moves documented elsewhere, showing that they were principled in adhering to facilitator roles for video clubs. The most interesting findings related to the differences between year one and year two of the VCCs, when the source of the video changed from episodes of the facilitators' coaching to that of the participants' videos. We found that the norming moves decreased while the moves in which the facilitators injected their insights increased. We saw this particularly with moves associated with explanations and with questioning and wondering. We attribute this to opportunities in which the facilitators used the videos to reinforce the principles of content-focused-coaching, to model how to reflect on videos of coaching, to foster anticipatory thinking, and to conjecture about broader issues in coaching.

PLANNING TO RESPOND TO STUDENT-WRITTEN WORK IN PROFESSIONSAL LEARNING COMMUNITIES

Tierra D. Fender
University of North Carolina at Charlotte
mstierrafender@gmail.com

This study examines how a Math 1 Professional Learning Community (PLC) collaboratively plans responses to student thinking on formative assessments. The PLC demonstrates awareness of student adaptability, yet there is potential to more fully embrace diverse student perspectives. While the PLC shares insights, there are opportunities to further integrate student work as class-wide learning opportunities, which could enhance the effectiveness of planning responses. Findings underscore the importance of sustained collaborative learning spaces for educators to continuously improve their ability to respond to student work equitably.

Keywords: teacher noticing, formative assessment, Professional Learning Community

When students express their mathematical thinking, they provide valuable insights for teachers to make informed instructional decisions. Making space for this during the process of learning a topic is considered formative assessment (Wiliam & Black, 1996). The use of formative assessments allows educators to monitor student learning and adapt teaching strategies accordingly (Jacobs et al., 2010; Wiliam & Black, 1996). Although there are many proponents of implementing formative assessments in the classroom (Black & Wiliam, 1998), there is limited research on how teachers go about *planning to respond*. When considering *plans to respond*, research is mostly related to individual feedback (Abdulhamid & Venkat, 2018; Jacobs & Ambrose, 2008; Land et al., 2019) and whole group instruction (Abdulhamid & Venkat, 2018; Dunning, 2023; Leshin, 2023; Stockero et al., 2022), with minimal reference to small group interactions. In the articles that reference small groups, no commentary is made to whether these small groups are heterogeneous or homogeneous (Land et al., 2019; Leshin, 2023). Knowing that there are teaching habits of wanting to fix misconceptions rather than building on students' strengths and various strategies (Cohen & Lotan, 2014; Ladson-Billings, 2009), there is a gap in the research on *planning to respond* equitably for heterogeneous groupings. As research supports the benefits of heterogeneous groups for student learning (Boaler et al., 2000), the same is ideal for adult learning; potential benefits of analyzing student work as a PLC include better understanding of student thinking and structured opportunities to ask questions of colleagues related to student thinking and responsive instruction (Jilk, 2016; Little et al., 2003). This study aims to describe the ways that a PLC collaboratively *plans to respond* to student thinking on a formative assessment item.

Background Literature

Formative assessments inform educators of student understanding, allowing for adaptive teaching, as highlighted by the value of students sharing their reasoning and offering teachers a snapshot into their understanding (Baldinger, 2020). Abdulhamin and Venkat (2021) advocate for formative assessments as they establish a two-way feedback loop between students and teachers. According to Bas-Ader and Carlson (2022), educators' respond more adeptly to student ideas when they strive to comprehend students' thinking while also reflecting on their facilitation.

Dunning (2023) found that teachers might adjust their learning goals to align with student strategies. Thus, formative assessments play a key role in cultivating a dynamic learning atmosphere.

PLCs are pivotal in collectively analyzing written formative assessments, offering educators a collaborative platform to merge expertise and perspectives while examining student work (Jacobs et al., 2010). Jilk (2021) says the benefits of PLCs sharing best practices promotes shared learning and continuous improvement, boosting teachers' collective instructional capabilities. Little et al. (2010) shows that collaborative analysis when looking at student work leads to more consistent and holistic evaluation methods, crucial for meeting diverse student needs. Regular PLC meetings allow teachers to coordinate their instruction, address challenges, and create effective responses to student work, fostering equity and inclusivity in education (Little et al., 2010). Such collaborative effort in PLCs ensures that every student's learning journey is understood and supported, enhancing the overall quality of education.

Theoretical Framework

To frame *planning to respond* to students' written work on formative assessment items, literature on teacher noticing of student thinking is referenced. Jacobs et al. (2010) describes teacher noticing of student thinking as consisting of three interrelated phases: attending, interpreting, and *planning to respond*. In the attending phase, teachers document the specific strategies used by students. During the interpreting phase, teachers evaluate and infer the student's level of understanding based on these strategies. Lastly, in the *planning to respond* phase, teachers evaluate the best ways to react, informed by their evaluation of the student's understanding. Leshin (2023) extended this framework to emphasize what each of the components includes when noticing for equity in students' mathematical thinking. Specifically related to *planning to respond* to student thinking on formative assessments, teachers must leverage trends in student understanding to determine multiple *plans to respond* for the entire class and small groups, highlight elements of student work to share, and showcase student work that can elevate an individual's status (Leshin, 2023).

Methods

This research employs a case study approach (Yin, 2014) to investigate a specific PLC's method of analyzing written formative assessment data.

Participants and Context

The case in this study involves a Math 1 PLC, composed of nine high school educators, that regularly analyze student-written work. Among the PLC are two co-teachers and an Instructional Leader (IL). The IL facilitates PLC meetings and coaches teachers.. All members of the PLC are educators of color. In this session, one member was absent, resulting in a gender-balanced composition.

The PLC meets for one hour twice a week. Analysis of student work occurs twice a month. For this session, each PLC member brought one of their class sets of student work to analyze. This PLC's agenda is based on their prior experiences for analyzing formative assessments; no training for this process was provided. This session included 40 minutes to analyze students' work on a formative assessment task from a unit on systems of linear equations and inequalities (see Figure 1). PLC members sat in pairs for this session.

Here is another riddle:

- The sum of two numbers is less than 2.
- If we subtract the second number from the first, the difference is greater than 1.

What are the two numbers?

1. The riddle can be represented by a system of inequalities. Write an inequality for each statement.
2. These graphs represent the inequalities in the system. Which graph represents which inequality?
3. Name a possible solution to the riddle. Explain or show how you know.

Figure 1: The Formative Assessment Task

Data Collection and Analysis

Data collection took place during one PLC meeting, involving video and audio recordings of the team collaboration while noticing student thinking of written artifacts, detailed field notes to align conversations with student work being referenced, and pictures of completed student work being referenced.

All talk related to noticing student-written work for student thinking and equity during the PLC meeting was transcribed verbatim. The transcripts were then coded using Leshin's (2023) codebook for noticing student thinking and equity (see Table 1). Other artifacts were used to reference the student work that teachers referred to in conversations with peers. Once the data was coded, the presence or absence of data for each *Planning to Respond* subsection of Leshin's (2023) codebook revealed recurring themes representing common practices that supported or provided opportunities for growth in the PLC while equitably noticing student thinking.

Table 1: Leshin (2023) Sub-codes and Descriptions for Planning to Respond

Planning to respond sub-codes	Description
Patterns shape multiple plans to respond	Teacher uses patterns in understanding to shape plans to respond for the whole class and small groups.
Leverage aspect of work for learning	Teacher identifies aspects of work (including mistakes or partial understandings) to share with the class as a learning opportunity.
Highlight exemplars to elevate status	Teacher identifies aspects of work to share with the class to celebrate or elevate a student.

Results

Based on the framework set by Leshin (2023), one component of *planning to respond* was observed, using patterns to shape multiple *plans to respond*. According to Leshin (2023), effectively planning instructional responses involves recognizing and using patterns in student understanding. Teachers in the PLC discussed multiple patterns across student work, including misreading ordered pairs, misreading scale, and misunderstanding inequality symbols. All trends shared were misconceptions. For misunderstanding inequality symbols, a teacher in the PLC identified a recurring pattern where students replace inequality symbols with equality symbols. As a PLC, this misconception was identified as not being unique to current students but was noted as a common issue observed over several years. The teachers decided on different *plans to respond*, some decided to encourage students to reread the question upon completing their work while other teachers decided to have students box the symbol to bring their attention to the mathematical statement. These strategies were aimed at helping students realize the need to revert the placeholder equality symbol back to the correct inequality symbol.

Two aspects of Leshin's (2023) framework did not occur during this PLC session, leveraging aspects of student work for class learning nor highlighting student work to elevate student status. The PLC did not actively use student mistakes or partial understandings as class-wide learning opportunities. Responses to student work were more individualized, with general soft-skill advice like "read the question out loud" or skill tips such as reminding students to replace equality signs with inequality symbols. Leshin (2023) suggests using aspects of correct student work to elevate student status; however, this practice was not observed in this PLC session. There was no discussion nor selection of admirable student work to be shared with the class, indicating a potential area for growth in acknowledging and showcasing student achievements. On the contrary, students were often referred to in terms of evaluating their abilities, "those tend to be the stronger kids," "these kids can do this," and "you have that data and you can kind of see where kids are stronger and weaker."

As the PLC discussed trends and different possible ways to respond, the discussion became multifaceted, addressing immediate next steps as well as longer-term plans for several days ahead. There was a reality for teachers about being at different places with pacing; teachers ranged from being 0-5 lessons apart from each other in the unit. This created a space for a teacher who had already taught subsequent lessons to share their experiences, including decisions made and where students continue to struggle. For one particular activity implemented, the teacher shared that for "a lot of students, you could tell them from the kids who don't know how to solve with the variables being on both sides, that's where they will struggle, so I need to do a big lesson on that." This exchange provided insights for those who had not yet taught these lessons.

Discussion and Conclusion

The PLC's practices while *planning to respond* show an understanding of the need for student adaptability, yet fall short in fully centering diverse student thinking. While there is collaborative sharing of insights, the lack of integrating student work as class-wide learning opportunities (Leshin, 2023) limits the effectiveness of *planning to respond* in a way that supports a space where students have the right to make mistakes, share ideas, and engage in conversations to deepen their learning (Kalinec-Craig, 2017). Determining how to respond to student work become more natural as educators attempt to understand student thinking more often, suggesting that the craft of *planning to respond* can be learned (Baş-Ader & Carlson, 2022). Since *planning to respond* can be learned, sustained collaborative learning spaces for educators can strengthen a teacher's craft of *planning to respond* (Jacobs, 2010; Jilk, 2016; Little et al., 2003). The findings of this study indicate that PLCs need support with respect to equitably *planning to respond* (Leshin, 2023). Future work is needed to design resources and support learning experiences for PLCs with diverse team members with this focus. It is important to note that a limitation to this study is that only one PLC session was observed; a more in-depth understanding over time is needed to capture the full complexity of current practices. Additionally, since this study only focused on *planning to respond*, future work should aim to understand how PLCs' interpreting practices influence their *plans to respond*.

Keywords: In-service teacher education; teacher educators; professional development

Coaching literature is replete with guidance on how coaches can lay the foundation for successful in-person coaching partnerships with mathematics teachers (e.g., Knight, 2007; Killion, 2008). With the increased use of virtual coaching (e.g., Carson et al., 2019; Gregory et al., 2017; Matsumura et al., 2019), amplified by the pandemic, it is less certain how coaches create conditions for productive coaching interactions with teachers in online spaces, which arguably are more impersonal as compared to in-person settings. To address this gap, we sought to answer the question: In an initial conversation with mathematics teachers, how do experienced coaches create conditions for future one-on-one coaching interactions?

We adapted conceptualizations from the medical field regarding how doctors seek to build rapport with their patients (e.g., Roter & Larson, 2002) and contend coaches have three central tasks during initial conversations with mathematics teachers: (1) build social and emotional rapport; (2) discuss professional experiences and goals; (3) communicate expectations for future coaching interactions. Our study aimed to understand the ways in which coaches navigated these three tasks given they require a coach to act, respectively, as fellow human, professional colleague, and knowledgeable authority.

We analyzed one-on-one "Getting to Know You" meetings of 18 coach-teacher dyads, conducted via Zoom, that occurred prior to online coaching cycles. All coaches had multiple years of experience coaching online and all teachers taught grades 4 – 10 mathematics. We coded the talk-turns of the coach, parsed at the sentence level, using specific codes nested within the following broad categories: *social rapport building, emotional rapport building, professional experience*, *professional goals*, *conversational goals and logistics*, and *coaching expectations*. Each broad category corresponded with one of the three central tasks previously described.

Preliminary findings revealed that coaches tended to focus on topics related to *professional experience* but used diverse strategies to infuse *social* and *emotional rapport building* into conversations about professional topics. In doing so, coaches managed the obligations to act as both a professional colleague and fellow human by connecting simultaneously at professional and personal levels. Our study contributes to the growing body of research focused on how coaches engage with teachers and productive coaching practices (e.g., Kochmanski & Cobb, 2023; Gibbons & Cobb, 2016; Witherspoon et al., 2021). Specifically, our findings provide new knowledge about how experienced coaches responded to the complexity of supporting mathematics teachers in one-on-one interactions that occurred in online spaces. This knowledge holds implications for future research and points to practical strategies to support coaches as they seek to support the teaching and learning of mathematics.

EXPLORING TWO TENSIONS IN CONTENT-FOCUSED COACHING PLANNING CONVERSATIONS

We analyzed the planning conversations of two coach-teacher pairs in an online version of content-focused coaching. We used four coaching discourse moves to explore two central tensions in content-focused coaching: the tension between the intellectual authority of the teacher and the coach and the tension between instrumental and learning orientations. We analyzed the coaching conversations by the number and nature of phases, by how authority was distributed across the coaching conversations, and by how the orientations fluctuated throughout the conversations. The analysis revealed that one coaching conversation was more structured in terms of the progression of content and authority; by contrast, the other conversation was more improvisational and free-flowing. We also noted that other factors, such as the teacher's familiarity with the task and the mathematics content, influenced the conversation.

Keywords: In-service teacher education; teacher educators; professional development.

Coaching is a professional learning activity that holds the potential to improve teaching (e.g., Kraft & Hill, 2020) and student learning (e.g., Campbell & Malkus, 2011). Content-focused coaching, a particular model of coaching, has the primary goal of developing teachers' content knowledge and pedagogical content knowledge (Callard et al., 2022; West & Cameron, 2013). Content-focused coaches typically engage teachers in a three-part coaching cycle in which a coach and teacher collaboratively plan, teach, and reflect upon a mathematics lesson. The planning phase of the coaching cycle has drawn considerable attention from the mathematics education research community. This phase is an opportunity for coaches to cultivate new planning habits for teachers, which are necessary for implementing ambitious instructional practices (e.g., Witherspoon et al., 2021).

The discursive behaviors of a coach shape the learning experiences of a teacher (Costa & Garmston, 2016). Thus, realizing the potential of coaching during planning conversations as a mechanism to improve teaching and learning depends upon the coach's ability to skillfully facilitate the interaction. When facilitating planning conversations, content-focused coaches encounter two central challenges. First, coaches must dynamically manage competing roles of acting as a knowledgeable expert and a collegial partner. Coaches often hold a formal role and title that can elevate their position in relation to the teacher (Mosley Wetzel et al., 2017). Furthermore, content-focused mathematics coaches also tend to possess expertise in both content and pedagogy, as this is a prerequisite for the position (West & Cameron, 2013; Witherspoon et al., 2021). Throughout a conversation, content-focused coaches must carefully balance the distribution of intellectual authority as they operate from a potential position of power (e.g., Ippolito, 2010). As a second tension in facilitating planning discussions, coaches must support teacher learning while simultaneously helping a teacher to generate products needed to teach the lesson. Thus, coaches navigate between two orientations: learning and instrumental. When operating with a learning orientation, content-focused coaches strive for outcomes that can transcend the current interactions, such as helping teachers deepen their knowledge of mathematical content and content-specific pedagogy along with cultivating new planning habits (Stein et al., 2022). When operating with an instrumental orientation, content-focused coaches help teachers develop practical products needed to teach the upcoming lesson, such as a detailed lesson plan or list of anticipated student strategies (West & Cameron, 2013).

Existing studies are beginning to examine the ways coaches manage the tension of acting as an expert and colleague (Gillespie et al., 2024; Witherspoon et al., 2021) and holding learning and instrumental orientations (Choppin et al., 2024). However, there is not adequate research that has explored how coaches manage these two tensions in tandem during planning conversations. Specifically, we explored the following research question: How do mathematics coaches manage the two central tensions of (a) distributing intellectual authority between the coach and teacher and (b) holding both instrumental and learning orientations during planning conversations with teachers?

Theoretical Framework

We identified two central tensions present in content-focused coaching. First, coaches act as both a knowledgeable expert and a collegial partner, which requires coaches to balance intellectual authority through a planning conversation (Gillespie et al., 2024). Intellectual authority refers to whether the coach's or teacher's perspective is privileged at moments in time and relates to how a coach manages the competing roles of acting as expert and colleague. As a second tension, coaches navigate instrumental and learning orientations to support teacher learning while meeting coaching obligations. An instrumental orientation relates to the obligation to produce viable lesson artifacts by the end of the planning conversation, while a learning orientation relates to the coach's desire to advance the teacher's content and pedagogical content knowledge.

To make sense of the ways coaches manage these tensions, we focused on the coaches' discourse moves. We define a discourse move as the way coaches use language within a specific conversational moment to communicate with teachers. In other words, we focused on *how* coaches talked to teachers. Within mathematics education, researchers have analyzed discourse moves to understand how teachers participate in professional learning experiences (e.g., Borko et al., 2008), how facilitators manage discussions in small group settings (e.g., Amador & Carter, 2018; van Es et al., 2014), and how coaches facilitate one-on-one conversations (e.g., Gillespie & Amador, 2024; Witherspoon et al., 2021).

We identified four central coaching discourse moves: *elicit, press, explain, and suggest*. We argue that the coach's use of each move within a conversational moment a) positions either the coach or teacher as the intellectual authority and b) reflects the coach's orientation (learning or instrumental). First, we describe *elicit* and *press* moves, which each position the teacher as the intellectual authority, but reflect different coaching orientations. *Elicit* moves are coaching discourse moves that initiate opportunities for the teacher to share their thinking, making the teacher's thinking about the planned lesson visible to the coach (van Es et al., 2014). *Press* moves also invite the teacher to share their thinking but call for the teacher to elaborate and expand upon previously shared ideas or provide a rationale for why their ideas might be productive (Franke et al., 2009). For example, an *elicit* move could involve the coach asking the teacher to share how they were planning to launch the lesson. A *press* move could involve the coach asking the teacher to explain why they feel their plan to launch the lesson would be effective. With respect to managing the tension between acting as expert and colleague, we consider both *elicit* and *press* moves to position the teacher as the intellectual authority within a conversational moment since both moves invite the teacher to share their thinking or ideas. However, we argue that *elicit* moves reflect an instrumental coaching orientation since teachers are simply asked to report on their existing ideas. In contrast, *press* moves correspond to a coach holding a learning orientation since these moves call on teachers to elaborate on initial thinking, which can support new insights about content or pedagogy (Stein et al., 2022).

Explain and *suggest* are associated with the coach acting as an expert since both moves position the coach as the intellectual authority within a moment in the conversation. In using an *explain* move, a coach shares their interpretation of a mathematical concept or pedagogical principle (van Es et al., 2014). *Suggest* moves involve the coach recommending an action for the teacher to enact (Amador et al., 2024). While explanations and suggestions both position the coach as the intellectual authority, they reflect different coaching orientations. *Suggest* moves relate to an instrumental coaching orientation since the coach is recommending a practical action for the teacher to use when teaching the lesson. *Explain* moves, in contrast, correspond to a learning orientation since the coach is sharing their interpretation of a mathematical concept or teaching principle, which provides opportunities for teachers to deepen their understanding of content and/or pedagogy. Figure 1 visually depicts these four moves in relationship to intellectual authority and orientation.

Coach Orientation	**Instrumental**	Primary Discourse Move: Elicit Description of Move: Coach poses general prompt to elicit teacher ideas. Example: Coach asks teacher how they will launch the lesson.	Primary Discourse Move: Suggest Description of Move: Coach recommends an action for the teacher to enact. Example: Coach tells the teacher how they could launch the lesson.
	Learning	Primary Discourse Move: Press Description of Move: Coach prompts teacher to explain their reasoning and/or elaborate on their ideas. Example: Coach asked teacher why they think their plan for launching the lesson will be effective.	Primary Discourse Move: Explain Description of Move: Coach provides an interpretation of an event, interaction, or mathematical idea. Example: Coach tells the teacher why they think their plan for launching the lesson will be effective.
		Teacher	**Coach**
		Intellectual Authority	

Figure 1: The Four Discourse Moves in Relation to Intellectual Authority and Orientation

Methods

We analyzed two planning conversations involving separate coach-teacher pairs. The conversations took place as part of a larger professional development project that involved three cohorts of teachers; these coaching conversations were part of the third cohort (see Choppin et al., 2021). The two coaches, pseudonyms Reiss and Whilton, were paired, respectively, with middles grades teachers Harris and Jackson. We considered Reiss and Whilton to be mathematics specialists serving as *organization-based mathematics coaches* (e.g., Baker et al., 2022) as they were employed by a professional learning organization external to the participating teachers' schools and districts. Both coaches had coached in at least one of the prior two cohorts and were familiar with the content-focused coaching model employed in the project. All the coaching activities occurred online, with the planning conversations taking place via Zoom.

We recorded the planning conversations and had them professionally transcribed. We then parsed the coaching conversations into stanzas. Each stanza contained at least one coach-teacher interaction as well as text needed to understand the context of that interaction (Saldaña, 2013). Stanzas entailed interactions around a bounded discussion; when the topic shifted, we created a new stanza. Within the stanzas, we coded the coaches' discourse moves at the level of turn using the four codes described in the framework: *elicit*, *explain*, *press*, and *suggest*. Four coders coded each transcript, after which we met to reconcile the codes to ensure consensus.

The transcripts were also coded for the content of each turn, focusing primarily on the following three codes that represented principles of content-focused coaching: mathematical goal; mathematical task; and potential student strategies or misconceptions (e.g., Callard et al., 2022; West & Cameron, 2013). The mathematical goal involved the articulation of the content addressed in the lesson and sometimes the local curriculum standard associated with that content. The mathematical task involved the main problem that would be presented to students during the lesson. Potential student strategies and misconceptions involved likely approaches students would utilize when working on the mathematical task.

We then divided the transcripts into phases consisting of one or more stanzas. Phases were demarcated initially by a change in focus of the discussion (e.g., mathematical goal, mathematical task). Our description of the focus for each phase included the content code and additional details as warranted (e.g., *revising the mathematical task* instead of just *mathematical task*). In some phases, multiple topics were interwoven, so we listed all relevant topics. We then characterized each phase using the categories in the framework. We characterized a phase as *teacher as authority* if most of the coach's discourse moves were either *elicit* or *press* and *coach as authority* if most of the coach's discourse moves were *explain* or *suggest*. Similarly, we characterized a phase as *instrumentally oriented* if most of the coach's discourse moves were *elicit* or *suggest* and as *learning oriented* if most of the coach's discourse moves were *explain* or *press*. There were instances in which the intellectual authority and orientation changed within a stanza, which led us to divide some phases into two. We characterized phases as *mixed* if there were relatively equal amounts of discourse moves associated with each category.

In terms of distinguishing between instrumental and learning orientations in the coaching transcripts, we coded a coach turn instrumentally oriented if: (a) the coach suggested revising the mathematical goal or task without an accompanying explanation, (b) elicited details of a task or student strategy, or (c) described student strategies or mathematical task without explaining connections to the mathematical goals of the lesson. We coded a coach turn as learning oriented if: (a) the coach pressed the teacher to explain the rationale for their choice of goal or task, (b) explained a goal or task in ways that connected to broader mathematical or pedagogical ideas, or (c) explained how a student strategy indicated understanding of a mathematics concept. The key distinction between the two categories was the presence of an explanation or a press for an explanation; explanations entail a connection between two related topics (e.g., between an interpretation and evidence, between a representation and the idea it is intended to convey, between student thinking and the mathematical goal).

Results

The analysis showed how the Reiss-Harris and Whilton-Jackon planning conversations proceeded in quite different ways. The differences were marked by the number and nature of phases, how intellectual authority was distributed across the coaching conversations, and, to a lesser degree, how the orientations fluctuated throughout the conversations. See Figure 2 for a visual summary of the analysis.

The phases in the Reiss-Harris conversation were generally confined to a singular topic (e.g., goal or task) and had a content progression (goal, task, strategies) that was the most common across the larger set of over 30 coaching conversations we analyzed for a larger study. The conversation, however, was unique in the extent to which the coach and teacher discussed the mathematics of the task. The task, informally known as the Locker Problem, can be stated as:

> The first student opens every locker; the second student starts with the second locker and closes every other locker; the third student starts with the third locker and changes the state of that locker and every other third locker; etc. After all the students have gone through, which lockers remain open? (Lappan et al., 2014)

Figure 2. Visual of Authority / Orientation Dynamics Across Coaching Conversations

(Note: The length of the boxes roughly corresponds to the relative lengths of the phases.)

Reiss and Harris engaged in extensive discussion about the mathematics in the task (totaling 10 stanzas), in part because the teacher had not solved the problem in advance of the planning meeting and was not familiar with it, as reported by Reiss. During this discussion, Reiss provided numerous explanations about the mathematics and possible student strategies and pressed the teacher to explain her thinking. For example, Reiss stated:

> First kid goes down and opens everything. Then the second kid, I actually kept, okay, he’s going to change and close 2, 4, 6, 8, and 10. Then I went to the third guy. I tried to see in each state what happened. Then I knew after 10 what would still be open after 10, so I just—I broke it down that way to see if that would help. What I found was after 10, locker 1, locker 4, and locker 9 were still open.

Here, Reiss shared her insights into the mathematics content without giving away the pattern, leaving her openings to subsequently press the teacher about her thinking. The phase in which this took place was characterized as mixed in terms of intellectual authority because Reiss provided explanations but also pressed the teacher to explain her thinking. The phase was characterized as learning oriented due to the consistent presence of explanations and press for explanations. Once the conversation turned to the design of the lesson, Reiss made numerous suggestions related to revising the mathematical goal, the design of the task, and how to enact the task. As Reiss made these suggestions, she explained why they would provide or enhance opportunities for student sensemaking. These phases were characterized as positioning the coach as the authority, as Reiss was the primary contributor, and as mixed in orientation because Reiss suggested ways to finalize the details of the mathematical goal (instrumental) and task while simultaneously explaining how these suggestions would support students' mathematical sensemaking (learning).

In contrast to the Reiss-Harris conversation, the phases in the Whilton-Jackson conversation typically involved multiple topics, with an emphasis on making connections between the topics. For example, the fifth phase of the planning conversation consisted of nine stanzas in which Whilton emphasized connections between the mathematical goal, the task, advancing questions, and student strategies. The phase began with Whilton pressing the teacher to explain what kinds of student strategies would indicate their understanding of the mathematical goal. Whilton then explained the connections between the representations emphasized in the mathematical task and the strategies discussed by the teacher. He also explained the connections between different strategies, and suggested to the teacher about how to respond to one of the strategies they discussed:

> In a sense, once they say, 'Wait. I saw one plus three plus one,' if we just capture that for them, like, 'Hey, I'm just going to write down what you said. You said one plus three plus five. Tell me. What did your brain do on the next one?' I feel like we're still trying to unpack the kids' thinking for them as opposed to implanting thinking for them. At least in my interpretation, I feel like we haven't—I can see where it's a real slippery slope, but I think we're still honoring where kids are, their thought process, and just helping bring clarity. What do you think about that? Do you agree with me?

Whilton explained how the question he suggested could simultaneously advance and validate student thinking, connecting to a broader pedagogical principle of building from student thinking. Whilton then returned to explaining the connections between the visual diagram in the task and a potential strategy but then tied that strategy to the mathematical goal:

> I think then you can hear, 'Oh, they're talking about five and then adding three each time,' … I think we can really listen to what kids have to say and help them, but I like how you just added that … that also really helps bring home that other goal you were talking about, too. Right? That seeing this constant rate of change now. Why is it happening, and where is it coming from?

These examples illustrate how Whilton emphasized connections between the task, the strategies that students might produce, the mathematical goals represented in those strategies, and possible questions to pose to students in response to a given strategy. We characterized this as a single phase because there were inter-connections between the stanzas and the topics throughout the phase. In terms of overall characterization of authority, the phases fluctuated, with a trend from teacher to coach; in much of the conversation, Whilton mixed elicitations and presses with explanations and suggestions. The orientations across phases also fluctuated, with some instrumental phases where Whilton pressed for details around the mathematical goal and student strategies and some learning phases where Whilton explained the reasoning behind strategies or instructional moves or pressed the teacher for explanations. The results show how Whilton nimbly moved between topics and between elicits/presses and explanations/suggestions to establish essential understandings and finalize details of the goal, task, and potential strategies.

Discussion and Implications

The framework and visual representations of our findings provide insights into the evolution of and nuanced differences between two planning conversations with respect to the topic of discussion, distribution of intellectual authority, and coaching orientation. In turn, we illustrated the unique ways two coaches managed the two central tensions of distributing intellectual authority, thus serving as both an expert and colleague, and navigating instrumental and learning orientations during planning conversations with mathematics teachers. The analysis showed a purpose in how the Reiss-Harris conversation evolved; first Reiss wanted the teacher to understand the mathematics before she turned the conversation to the more instrumental discussion around the details of how to enact the mathematical task with students. Furthermore, given the teacher's lack of familiarity with the task and the mathematics, Reiss's emphasis on suggestions and explanations (i.e., positioning herself as the authority) was warranted. The trend toward mixed or learning oriented phases also provides insight into her intention to push the teacher's mathematical and pedagogical understanding while producing viable lesson plan. The Whilton-Jackson coaching conversation was more complex because there was no consistent progression across topics, authority, or orientation. This conversation was more free-flowing and improvisational, with Whilton strategically injecting his perspective, thus assuming intellectual authority temporarily to make opportunistic connections between topics.

Our study offers two primary contributions to the collective knowledge of coaching within the field of mathematics. First, prior studies have attended to the ways coaches continually shift the intellectual authority across coaching conversations (e.g., Gillespie et al., 2024; Russell et al., 2020; Witherspoon, 2021). Through our detailed analysis of the Reiss-Harris and Whilton-Jackson planning conversations, our findings suggest that intellectual authority is intertwined with a coach's orientation and topic of conversations, which are related to underlying contextual features of the coaching cycle. Thus, we contend that the ways in which a coach distributes intellectual authority are associated with multiple factors and caution against making inferences about inherent coaching styles or tendencies from the analysis of a single cycle. For example, the discursive actions of Reiss were likely influenced by the teacher's lack of familiarity with the task and underlying mathematics. Other cases, with differing contexts, might look quite different with respect to intellectual distribution, and in fact, we have noted differences in other analyses of Reiss's coaching.

As a second contribution, prior studies have highlighted the need to better understand the interactional patterns of a coach and teacher (e.g., Saclarides, 2022). In response, researchers such as Gillespie et al. (2024) and Baldinger (2014) have developed methodologies and generated visual representations to depict salient features of coach/teacher interactions. Similarly, our framework and methodology weave together three constructs – intellectual authority, coach orientation, and content – to generate visual representations that afford insight into nuanced ways coaches manage two central tensions in planning discussions.

The findings connect to the conference theme - *envisioning the future of mathematics education in uncertain times* – by highlighting the influence of contextual factors on the nature of coaching conversations and the need for both intentionality, as seen most prominently in the Reiss conversation, and flexibility, as seen in the Whilton conversation, to meet the contingent needs of teachers.

Future Research

The analysis illustrates how the framework provides insights into the nature of coaching conversations. We framed the analysis in terms of two central tensions, one involving intellectual authority and the other involving instrumental or learning orientations; furthermore, we connected these tensions to the content emphasized in phases of coaching conversations. The use of the framework leads us to several new questions about the nature of coaching conversations. First, the analysis revealed that the Reiss-Harris conversation was more structured in terms of the progression of content and was influenced by the teacher's lack of familiarity with the task and the mathematics. By contrast, the analysis showed that the Whilton-Jackson conversation was more improvisational and free-flowing. We encourage future research to consider characterizing coaching conversations according to a structure-improvisation continuum and examine what factors influence how coaching conversations play out.

Second, it is plausible that both conversations were productive in terms of supporting teacher development. We encourage future research to use of our framework and methodology to deconstruct the planning conversations into phases, characterized by content, intellectual authority, and coach orientation, as a first step to understanding how a multi-faceted conversation may support teacher development. Our analysis showed how each phase presented different opportunities for teachers' development; future research should examine how the different coaching orientations and intellectual distribution in a phase of a planning conversation results in changes to teachers' knowledge or their subsequent teaching. Finally, in the discussion section, we cautioned against making inferences about a coach's style or tendencies, given the contextual features of a coaching cycle likely influenced the behaviors of the coach. To better understand coaches' tendencies with respect to distributing intellectual authority and holding differing orientations, we recommend future studies use our framework and methodology to examine multiple coaching cycles from a single coach-teacher pair and coaching cycles that feature a single coach working with different teachers.

EXISTING QUESTIONS AND ANSWERS: A REVIEW OF COACHING LITERATURE WITHIN MATHEMATICS EDUCATION

Adam Hanan
University of Idaho
ahanan@uidaho.edu

Ryan Gillespie
University of Idaho
rgillespie@uidaho.edu

Julie M. Amador
University of Idaho
jamador@uidaho.edu

Keywords: In-Service Teacher Education, Professional Development, Instructional Leadership, Teacher Educators

The term "coach" carries broad and diverse definitions throughout professional development literature within mathematics education. Such differing definitions consider a coach to be a peer observer, one-on-one teacher support, implementation support, or small group professional development facilitator (Baker et al., 2022; Bengo, 2016; Campbell & Griffin, 2017; Kraft et al., 2018; Kraft & Hill, 2020; Russell et al., 2020). While definitions of coaching vary, the primary purpose of coaches in mathematics education does not. Researchers consistently emphasize the *hope* of coaches supporting teachers' learning to positively impact student learning (e.g. Gibbons & Cobb, 2016) through ongoing, active, and content-focused observation and feedback cycles (Desimone & Pak, 2017; Kraft et al., 2018).

Considerate of these diverse definitions, we have identified a need to synthesize existing coaching literature within mathematics education through a systematic review of related literature in order to organize the contributions based on the specific focus of stated research questions. The intent of this poster will be to share the design of our systematic review and the analysis of the literature to formulate an image of how researchers are further developing understandings around coaching in mathematics education. Our review considers the varying definitions of coaching and diverse research on the impact of coaching in mathematics education.

The following research questions guided our review of the literature: (1) What questions are researchers asking to better understand (define, support, promote) coaching in mathematics education? and (2) What frameworks and methodologies are researchers utilizing to better understand (define, support, promote) coaching in mathematics education?

To answer the first research question, we examined 45 research questions from 21 peer-reviewed journal articles published between the years 2013-2023 that focused on coaching in mathematics education. We organized these research questions in four categories based on focal populations: coaches, teachers, school systems, or students. Preliminary analysis revealed that within these categories research questions related to: (1) coaching behaviors, (2) coach learning, (3) teacher outcomes, (4) system outcomes, or (5) student outcomes. To answer the second research question, we recorded the theoretical framing researchers utilized to position their work along with accompanying methodological approaches to understand trends in how researchers have conducted empirical inquires on coaching within mathematics education. Within our emergent categories, we are finding tendencies in literature favoring certain methodological approaches. Further analysis from this systematic review is underway. Our poster will provide an organized synthesis of recent research questions as well as accompanying methods and theoretical perspectives, thus providing the field with greater clarity about research trends on coaching within mathematics education.

This study explores how an instructor designing assignments in an online homework system for a college algebra course considers the development of procedural fluency in connection with conceptual foundations. Findings reveal shifts in the instructor's perspective, highlighting the importance of connecting procedural fluency to conceptual foundations. The study underscores the potential of co-design activities in reshaping instructors' beliefs and instructional practices, offering insights into enhancing mathematics education in college algebra courses.

Keywords: Instructional Activities and Practices; Undergraduate Education; Technology

The instruction of college algebra courses has long been a concern given the barrier it presents for many students (Tunstall, 2018) – both those for whom it acts as a terminal math course and those who need it as a prerequisite for another course within their major. Mathematics education organizations have long called for undergraduate mathematics instructors to support students' deeper engagement with mathematical ideas and habits of reasoning (e.g., NCTM, 1980; AMATYC, 2006; MAA, 2018). This means attending to students' conceptual understanding, procedural fluency, and how the latter builds on the former. In the Mathematical Association of America (MAA) *Instructional Practices Guide* (2018), the authors noted,

> Conceptual understanding involves knowing what to do and why it works, while procedural fluency involves deciding and knowing how to do it…. When students learn procedures in such a way that they are connected to conceptual foundations, they will have more success in using these procedures, will recall them for a longer period of time, and will be able to use these procedures flexibly and effectively in a problem-solving situation. (p. 42)

In undergraduate mathematics courses, like college algebra, there is widespread emphasis on traditional lecture focusing on procedural knowledge, rather than conceptual understanding (e.g., Duffin et al., 2019; Khasawneh et al., 2023; Veith et al., 2023).

College algebra courses are typically quite large, often having well over 50 students enrolled in a single section. In these contexts, web-based homework systems are often used to support students and instructors by providing immediate feedback to both. Research has shown that these systems can make learning more active and adaptive while also focusing on improving conceptual understanding and problem-solving skills (e.g., Porter et al., 2015; Rochelle et. al, 2016; Twigg, 2009). However, there is little research on how instructors might use these systems to improve their practice – especially as it relates to supporting their students in learning procedures in ways that are connected to conceptual foundations. The purpose of this study is to answer the following research question: How does an instructor who is designing the assignments and supports for an online homework system for a college algebra course consider the development of procedural fluency as connected to conceptual foundations?

Context of the Study

This study is in the context of a larger project in which the instructor is leading the co-design of a set of online homework problems – and their supports – for undergraduate college algebra using the online homework system ASSISTments (www.assistments.org). Online homework systems are commonly used in college mathematics courses (e.g., ALEKS (Hagerty et al., 2005), MyMathLab (Duffin et al., 2023), WeBWork (Roth et al., 2008)), in addition to learning management systems that have mechanisms for creating online assignments (e.g., Canvas, Moodle). These programs are similar in that they make assigning homework problems easy, students can resubmit multiple times until their response is deemed correct, and students are given immediate feedback with respect to the correctness of their final answers. However, in addition to this immediate feedback, students also have the ability to access carefully designed supports. What sets ASSISTments apart are the supports that instructors can add at the problem level (up to 3 different supports), rather than just using publisher-supplied supports available to students as they work on assigned problems. Supports can be in the form of videos, worked solutions, or scaffolding hints. While ASSISTments has been used widely at the middle school level (Feng and Heffernan, 2006; Heffernan et al., 2012; Heffernan and Koedinger, 2012), this is the first use of it in undergraduate college algebra meaning that though the platform exists, the problems and supports for those problems needed to be created.

Methods

This is an intrinsic case study (Yin, 2018) of one college algebra instructor, Michael (the third author of this paper), who is also leading the co-design of the college algebra assignments in ASSISTments at a large southeastern university. This unique context provides an opportunity to learn about how Michael is making sense of "building procedural fluency from conceptual understanding" (MAA, 2018, pg. 42) through co-design (Severance et al., 2016).

The data for this study include a series of interviews as well as analysis of artifacts used in the creation of assignments and supports to use in ASSISTments assignments. Michael took part in 6 semi-structured interviews over the course of a year. The interviews were between 30 and 60 minutes long, took place via Zoom, and were recorded. Artifacts include Google documents and sheets in which Michael kept meeting notes and planned the problems he was going to add to an ASSISTments assignment as well as the associated supports. Given that the rest of the local research team is made up of mathematics education researchers, Michael's practice was to ask for their feedback on all supports as well as problems he had labeled as "conceptual" in nature. As such, discussions about these designs occurred in the shared documents using the "comment" features.

Interview transcripts and design artifacts were coded (by the first two authors) for *attending to conceptual foundations*. All of the quotations assigned this code were then read for emerging themes. Throughout this process, the research team would share the emerging findings with Michael to get his feedback and to make sure we were representing his ideas appropriately. Those emerging themes are what we report on in this study.

Preliminary Findings

In what follows, we share three phases of Michael's ongoing development: his stance that conceptual understanding is not a priority, coming to understand what conceptual understanding of a procedure means, and advocating for making connections between procedures and their conceptual foundations.

Conceptual Understanding is Not a Priority

Early in the project, Michael repeatedly noted that attending to the connections between procedures and their conceptual foundations was not a priority for him. This was evident in the design of both the questions he included in the ASSISTments assignments and their associated supports. For example, approximately 6 months prior to the pilot semester, Michael and his team began identifying problems to include in the first ASSISTments assignments. In one of these early meetings, he shared that he knew he needed to include what he referred to as "conceptual problems", but he was not sure what that looks like. He mentioned many times that he was only including this type of problem because he thought he had to due to the goals of the overarching project. He did not think they were a priority because they are not tested on the course common exam. Michael explained, "I don't think I would highly emphasize any feedback that I give for conceptual questions in the current course format for College Algebra. Conceptual questions tend to not be emphasized on the common final." He also shared that "using space on my tests in order to ask the conceptual questions will take that space away from the procedural questions that are going to be on the final."

Coming to Understand What Conceptual Understanding of a Procedure Means

As Michael started to draft what he referred to as "conceptual problems", there is evidence that he felt he was learning what conceptual understanding of a procedure might mean. When he drafted these items, there was a lot of back and forth with the mathematics educators on the team about what makes a question "conceptual". For example, the first draft of a "conceptual question" for a unit on exponents stated, "When can you subtract two exponents?" After some discussion about the fact that the question is simply asking students to identify when they can use a particular procedure, and was missing the conceptual "why", Michael revised the question to, "Provide an example of when subtracting two exponents is appropriate. Explain your reasoning." This revised question is focused on procedural fluency - recognizing when a procedure is appropriate to use - and by asking students to explain their reasoning it is asking for the underlying concept as well.

Figure 1: Sample Supports for an ASSISTments Item

Support Draft 1	Support Draft 2
Similar to the graph of a parabola, the quadratic formula, $x = \frac{-b \pm \sqrt{b^2-4ac}}{2a}$, can determine the solutions to a quadratic equation. The discriminant, b^2-4*ac*, is part of the quadratic formula. The value of the discriminant indicates how many times the parabola intersects the x-axis and how many real solutions a quadratic equation has.	As a reminder, the discriminant, b^2-4*ac*, is the part of the quadratic formula that is under the square root symbol, $x = \frac{-b \pm \sqrt{b^2-4ac}}{2a}$. Given a square root can have two (if > 0), one (if = 0), or no real solutions (if < 0), the value of the discriminant determines how many solutions there are for a quadratic equation.

Kosko, K. W., Caniglia, J., Courtney, S., Zolfaghari, M., & Morris, G. A., (2024). *Proceedings of the forty-sixth annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Kent State University.

If the discriminant is positive, i.e., b^2-4ac > 0, how many solutions does the quadratic equation have?	If the discriminant is positive, i.e., b^2-4ac> 0, how many solutions does the quadratic equation have? Write the answer as a number.

At the same time as he was creating the questions in the assignments, Michael was also creating the supports for those questions. We saw a similar shift in this work. For example, when designing a support for the problem: "Based on the discriminant, state how many real solutions there are to the following quadratic equation: $2x^2 - 6x + 7 = 0$." Michael's first support draft was very procedural, asking students to recall a rule they learned about the discriminant (see the example on the left side of Figure 1). After some back-and-forth discussion with the mathematics educators to identify the foundational concept – that a square root can have one, two, or no real solutions, he revised the support to include the conceptual foundation (Figure 1 right side). Michael later noted that this back and forth was helping him understand what conceptual understanding means in the context of a procedure-heavy course like college algebra.

Advocating Connecting Procedures to their Conceptual Foundations

After a full semester of pilot and design work, there was evidence that Michael not only had a deeper understanding of how to develop procedural fluency from conceptual understanding but also thought it was important. Michael shared that based on his engagement in this design work, he has started to change his practice. He explained, "I started to really think about how I should give an explanation in class…I've gotten better over time, I think my instruction has gotten better." At the same time, there is evidence that Michael has begun to advocate for an emphasis on providing conceptual foundations in the supports for ASSISTments assignments as well. He explained that he reached a point where he thought "those explanations I was giving a class are just so much better than the ones that we were putting into the assignments." This made him realize that,

> If I had to give this to my students, I would want to make sure that they had a support that was the closest thing to what I could provide them if they were actually in person with me…So that's why I started saying that these things need to be better. These things can't just be railroaded through and just kind of shoved down their throats. They actually need to understand what is going on.

Michael is currently redesigning many of the ASSISTments assignments to align with what he now understands about the importance of connecting procedures to their conceptual foundations.

Discussion and Conclusion

The case of Michael provides an interesting example of how engaging in co-design, like designing the ASSISTments assignments and supports, might shift instructors' beliefs about the importance of attending to the conceptual foundations of procedures when developing procedural fluency in a college algebra course. We emphasize the co-design aspect of such work, as it seems as if the interaction with mathematics educators was an important part of Michael's journey. Our results are consistent with research on curricular co-design efforts (e.g., Severence et al., 2016). We recognize that engaging in this kind of design is not something that all instructors get to do, but the findings here suggest it might be helpful to consider ways of possibly engaging them in similar co-design activities. In fact, unlike online homework products that are prepopulated with questions, ASSISTments allows all instructors to add their own questions and supports making such work possible. We are curious about how instructors who engage with the assignments and supports that Michael has created will, or will not, take up his stance on the importance of including the conceptual foundations – consistent with MAA (2018) recommendations – in their own explanations and attention to student responses on conceptual questions within ASSISTments to inform their instruction. This is an area ripe for future research.

SECONDARY MATHEMATICS TEACHERS' JUSTIFICATIONS FOR SEQUENCING STUDENT WORK

This study examines secondary mathematics teachers' justifications for sequencing student work (SW) in relation to the different ways they might sequence SW. Existing research recommends selecting and sequencing SW in a way that creates a coherent mathematical storyline (Smith & Stein, 2011), but there is a lack of empirical evidence on how teachers can develop the expertise needed to enact that (Dunning, 2023). We focused on actions teachers might take when considering how to sequence SW in the context of StoryCircles, a lesson-centered professional development program. We found emerging patterns between teachers' heuristics for sorting SW and the obligations they use to justify those heuristics. In particular, the disciplinary obligation was consistently prioritized, and the individual obligation played a crucial role in justifying teachers' attention to making mathematics accessible by scaffolding SW by complexity.

Keywords: Lesson-centered Professional Development, Instructional Activities and Practices, Classroom Discourse, Sequencing

Objective

Some years ago, Stein and colleagues (2008) outlined five fundamental practices for orchestrating productive mathematics discussions: anticipating strategies, monitoring strategies, selecting strategies, sequencing strategies, and connecting strategies within whole-class discussions. According to them, the purposeful selection and sequential presentation of student work increases the likelihood of fostering discussions where mathematical understanding is collaboratively constructed by all individuals in the classroom. Furthermore, teachers' attention on the practices of selecting and sequencing supports their efforts to teach in ways that are responsive to students' mathematical thinking. However, "more research needs to be done to compare the value of different sequencing methods" (Smith & Stein, 2011, p. 11) and little is yet known about how teachers reason about the practices of selecting and sequencing students' work (Dunning, 2023). In this paper, we share about an ongoing data collection and analysis effort in which we seek to gain more understanding by sharing data gathered in the context of a lesson-centered professional development, examining the ways that two different groups of secondary mathematics teachers (one set of algebra teachers, one set of geometry teachers) annotated a set of storyboard frames representing written samples of students' mathematical work. In that context, teachers collectively considered how to leverage and expand upon students' mathematical work in the context of a problem-based lesson. Specifically, we ask:

In what ways do existing heuristics for categorizing teachers' practices of sequencing distinguish the set of interactions about sequencing we observed across two groups of StoryCircles teachers? What justifications for selecting and sequencing student work do teachers *make according to the type of sequencing they want to do?*

Theoretical Framework

While the aforementioned scholars have emphasized the importance of the lesson goal in shaping teachers' decisions regarding selecting and sequencing, empirical research suggests that teachers use a variety of ways to think about selecting and sequencing—some of which prioritize other matters as more pressing than the lesson goal (Ayalon & Rubel, 2022; Dunning, 2023). Researchers have suggested a variety of heuristics for selecting and sequencing students' work, including focusing on misconception (Smith et al., 2008) and building on correct strategies by employing the order of complexity heuristic (Meikle, 2016), but the field has yet to understand the differences in the ways that teachers' reasons about those heuristics. Expanding on this prior work, Ayalon and Rubel (2022) recently reviewed the lesson-centered PD literature and reported four distinct heuristics recommended to teachers for selecting and sequencing: (1) privilege variety of ideas, (2) accessibility and participation considerations require scaffolding by complexity, (3) the importance of attending to errors, and (4) any set of solutions yields particular connections and mathematical ideas. The authors also report that associating with these heuristics, especially the order of complexity, reflects a particular perspective on mathematical ability and teachers were more often observed prioritizing accessibility over the effort to develop a coherent sequence in a mathematical storyline. As such, Ayalon and Rubel (2022) suggests needing to find more strategies that integrate these heuristics:

Privileging a variety of ideas, including diverse strategies, creates the basis for the mathematical conversation that ensues (Dunning, 2023) and helps recognize the important mathematical connections within those ideas (Richards & Robertson, 2016). Such comparison of different strategies has been proven beneficial in enhancing students' procedural flexibility and deepening conceptual understanding (Rittle-Johnson et al., 2009). The variety could be based on the representation type (e.g., graphs, formulas), the underlying problem-solving strategy (e.g., drawing a diagram, looking for patterns), or solutions that produce divergent answers (Ayalon & Rubel, 2022). Teachers also consider strategies in terms of mathematical sophistication, recognizing less sophisticated strategies and increasing progression to the most complex (Ayalon & Rubel, 2022; Stein and Smith, 2011). This *scaffolding by complexity* could be based on "criteria like concrete to abstract, specific to general, or most common to unique" (Ayalon & Rubel, 2022, p. 4). By sharing or *attending to errors*, and then discussing the erroneous solution or contrasting it with another solution could help resolve misunderstandings (Rittle-Johnson et al., 2009; Stein et al., 2008). Meikle (2014) notes that teachers often begin with erroneous solutions. Finally, *yielding particular connections and mathematical ideas* has to do with building a mathematically coherent storyline (Smith & Stein, 2011) that aligns with the lesson goal.

We leverage the ideas from Practical Rationality (Herbst & Chazan, 2011, 2020) to argue that teachers' decisions can be accounted for on more than just individual resources, such as skills, knowledge, and beliefs. In particular, there are professional sources of knowledge that teachers draw crucially on, namely recognition of the (1) norms of instructional situations (Herbst, 2012) and (2) professional obligations of teaching mathematics. In prior work, we have described how teachers' recognition of the norms of instructional situations help account for their decisions related to selecting and sequencing student work (Schwarts et al., 2023), such as letting the lesson goal guide their decisions when there was tension with attending to all students. In this paper, we aim to describe ways that teachers' recognition of the professional obligations of mathematics teaching play a role in informing their decisions about sequencing. While a complete description of practical rationality and all of its components are beyond the scope of this paper, we do take a moment to describe more details related to the professional obligations.

To describe what sources of justification are available for a teacher to justify decisions, we build on the idea that teachers' actions relate to the obligations they need to satisfy as teachers in an instructional system (Herbst & Chazan, 2011). These obligations bind the teacher to the environment of the instructional system which impacts their ties with the students and content in an instructional triangle (Cohen et al., 2003). At the same time, obligations provide sources of justification for a teacher's action, just as much as norms of instructional situations do, sometimes even justifying deviations from the norms as well. Herbst and Chazan (2011) propose four professional obligations which demand teachers' attention, namely the professional obligation to attend to: (1) the discipline that the teacher is meant to represent (*Disciplinary Obligation*), (2) the individual students the teacher is meant to serve (*Individual Obligation*), (3) the socio-cultural world of a given society and its customs and values (*Interpersonal Obligation*), and the (4) institution(s) that create official time, space, and sanction for all those relationships to happen (*Institutional Obligation*).

Methods

Context

The context of this study is Story*Circles*, an innovative professional development model where secondary mathematics teachers collaboratively anticipate a problem-based lesson through iterative phases of scripting, visualizing, and arguing about alternatives (Herbst & Milewski, 2018, 2020). Similar to Lesson Study (Lewis, 2009), Story*Circles* engages groups of practitioners (secondary mathematics teachers in this study) to create a lesson through successive iterations. This activity is animated not only by the processes of scripting, visualizing and arguing, but also the problems of practice that the group collectively identifies and shows a willingness to work on as they work out the details of the lesson (see Figure 1). The group's activities are supported by a facilitator who is not simply another group member who suggests possible ideas for the lesson, but instead takes up the role for directing the discussions toward the instructional goal and orienting practitioners toward one another—encouraging participants to share their professional knowledge through the creation of a common artifact. Distinct from Lesson Study, the group is involved in this process virtually and uses storyboards to visualize their practice and receive feedback on it (Milewski et al., 2018).

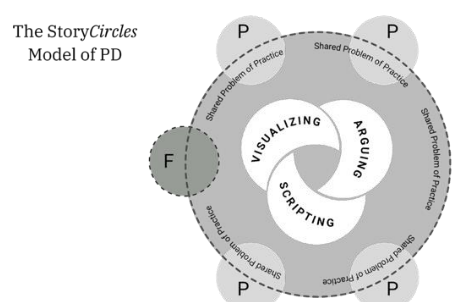

Figure 1: The Story*Circles* Model of PD

The data in this report is drawn from three groups of secondary mathematics teachers (1 Geometry and 1 Algebra) engaged in a six-week long Story*Circles.* All three groups focused on transforming a thinly developed storyboard (which contained only a few key frames) into a fuller representation of the way a lesson could unfold. The geometry group focused on the Tangent Circle Problem and the algebra groups focused on the Walkie-Talkie Difference of Functions Problem. Across these engagements, teachers engaged in asynchronous activities which include the frames for different phases of a lesson: Problem Posed (Phase 1); Getting Your Feet Wet (Phase 2); Whole Class Check-In (Phase 3); Redirecting the Work (Phase 4); Whole Class Discussion (Phase 5); Goal Statement (Phase 6). First, the teachers were expected to review and leave comments on the frames in each phase. Then, they were expected to discuss these frames considering how they could modify and/or use those frames to develop their storyboard.

For the purpose of this analysis, we focus on suggestions secondary mathematics teachers from two groups (1 Geometry and 1 Algebra) made about a set of frames representing the second phase: Getting Your Feet Wet. In these frames, student work (SW) examples are shown from the viewpoint of looking over the shoulder of the student. The frames were provided to give resources for the group of teachers to consider for incorporation into their storyboard (see Figure 2a) and discuss during the synchronous meetings. Across the 15 frames, the student work samples varied in terms of their strategies, correctness, normativity to the instructional situation, serviceability for advancing toward the instructional goal, and their responsiveness to the problem statement (Herbst et al., 2023). In their interactions with these frames, secondary mathematics teachers had the opportunity to delve more deeply into given SW examples to notice the features of SW beyond their correctness. The teachers were expected to consider which ideas they would address in the context of a small group setting and which they would feature as part of the coming whole class interactions which refer to the latter phases. For this reason, while the actions are around the decisions of this phase, the justifications may expand on to the other phases if the teachers felt they were relevant to their decisions in Phase 2.

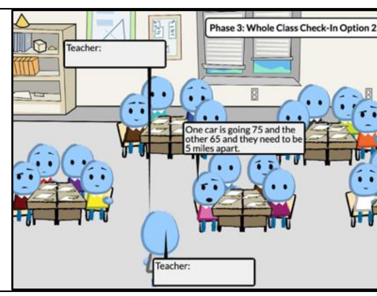
b. A SW from Phase 2: Getting Your Feet Wet



c. A frame of Phase 3: Whole Class Check-in

Figure 2: Examples from different phases of a lesson

Data Sources and Analysis

The data used for this analysis comprise memos and transcripts from synchronous meetings involving two groups of teachers who participated in Story*Circles*. Each group of teachers developed a Geometry or Algebra lesson-centered storyboard over six to seven one-hour synchronous meetings. We identified the specific synchronous meetings from each group where they made the most changes to the storyboard by tracking alterations in their 6 to 7 versions of the storyboard, each created during each of the synchronous meetings.

Table 1: Examples of actions categorized by Ayalon and Rubel's (2022) heuristics

Types of Heuristics	Examples
Privilege variety of ideas	"I like how there's a table, a graph, and an equation."
Accessibility and participation considerations require scaffolding by complexity	"I might start with the work of [student] Epsilon that's at a very basic level. And then maybe go to [students] Delta or Kappa or [Omicron], or Kappa's work to share first, and then, as I progressed through the frames show a more detailed understanding."
Attending to errors	"they [(students whose work was selected)] accounted for the 5 miles, which I don't think any of the other ones had done at that point."

Within the synchronous meeting, our focus was on moments when participants discussed the selection and sequencing of student work. We conducted an analysis of the actions taken by the participants during professional development, employing coding based on Ayalon and Rubel's (2022) framework for guiding teachers in selecting and sequencing students' solutions (see Table 1). Then, we examined the participants' justifications following their actions, drawing on the four professional obligations (Herbst & Chazan, 2011; see Table 2).

Table 2: Examples of justifications based on types of professional obligations

Professional Obligations	Examples
Disciplinary Obligation	"the difference in [Gamma's and Mu's] answers, because they're not wrong. If I did my math right, they're not wrong. They're just representing 2 different things."
Individual Obligation	"the kid that doesn't understand by the time the first thing comes out it's already way over his head. They're checked out, they're done. And so I think it does make a lot of sense to keep it in that order."
Interpersonal Obligation	"because they're both inputting hours. And maybe the kids [can] discuss where that 1.5 differences [are] and what that 1.5 represents."
Institutional Obligation	"I think that we need to be realistic. So how long is, I mean, I don't know of any math teacher that's getting more than an hour of instructional time, do you have? Well, how long is your class?"

Through this analysis, we consider the following questions:

1. How well do Ayalon and Rubel's (2022) heuristics for categorizing teachers' practices of sequencing distinguish the set of interactions about sequencing we observed across two groups of Story*Circles* teachers?

2. What justifications for selecting and sequencing student work do teachers make according to the type of sequencing they want to do?

We found that actions related to selecting and sequencing student work could be classified according to the heuristics described by Ayalon and Rubel (2022). Specifically, we were able to categorize participants' ways of sequencing student work based on the first three categories of action featured in Table 1 as they were more prevalent in our data and easily distinguishable. With more data, we may be able to make use of the fourth heuristic, yielding mathematics connections and ideas.

Results

Across the sets of exchanges about sequencing that we observed, a higher occurrence of the suggestions in those exchanges favored the *variety of ideas* and *attending to errors* heuristics than the *order of complexity* heuristic (see Table 3, number of actions). This could be attributed to our focus on synchronous meetings where most changes were made to the storyboard artifact, and participants began examining individual SW during the "Getting Your Feet Wet" phase. At the same time, focusing on decisions that resulted in the most changes in the artifact lends strength to the actions the participants claimed they wanted to take in sequencing and selecting student work.

Table 3: Relationship between the heuristics argued for and the professional obligations used to support those argument

	Number of Actions	Disciplinary	Individual	Interpersonal	Institutional
Variety of ideas	20	16	1	2	1
Order by complexity	10	5	4	1	0
Attending to error	26	16	8	2	0
Number of justifications:		37	13	5	1

In terms of the justifications made by participants, we found more attention to the disciplinary and individual obligations (see Table 3). Some of the references to the disciplinary obligations were related to the teacher's recognition of the need to sequence work intentionally to build on each other and ensure mathematical correctness (see Table 2, example of disciplinary obligation). Participants also delved into specific mathematical features of student work, such as markings on geometric constructions, providing insights into the students' thinking process and procedure. Individual obligations were also prominent, with a focus on how the individual student who created the work was thinking (see Table 2, example of individual obligation). Another common justification attending to individual obligations involved focusing on students who may be struggling and considering how they might benefit from the student work being potentially shared out. The interpersonal obligation was typically attended to when related to how other students as a whole class might benefit from the student work selected or sequenced and how they might discuss it among themselves (see Table 2, example of interpersonal obligation). Finally, the institutional obligation didn't receive much attention when considering the practices of selecting and sequencing student work. One instance of the institutional obligation was mentioned when participants were attending to time constraints in a typical mathematics class when considering how much variety of student work they would then want (see Table 2, example of institutional obligation).

As we consider the relationship between the types of heuristics participants argued for and the professional obligations used to support those arguments, we generally found that the disciplinary obligation was a consistent priority for participants, regardless of their preferences in selecting and sequencing student work (see Table 3, number of justifications). When using the variety of student work heuristic, participants emphasized conceptual differences among various types. These distinctions were clarified through specific procedures, such as inputting different numbers, and involved prioritizing evidence of students' understanding of the problem over correctness, although the correctness was often considered a distinguishing factor among types of student work. When using the attending to errors heuristic, participants often justified their actions using the disciplinary obligation—providing justifications related to addressing misconceptions and describing specific mathematical features they felt were important for students to learn and for the work to highlight so that there is a progression towards the lesson goal.

In contrast, when using the scaffolding by complexity heuristic, participants often justified their suggestions with the individual obligation—arguing for the importance of understanding how individual students, who completed the work, were thinking and how certain tasks in the earlier sequence would provide opportunities to support struggling students with comprehension. For example, while creating a table might be easier for some, presenting a graph first could offer a visual aid to enhance problem understanding. This reflects Meikle's (2016) general rationale for sequencing solutions, which typically involves the order of complexity heuristic while remaining independent of the mathematical content.

We also acknowledge the important role that the interpersonal obligation played in participants' justifications. References to this obligation involved attending to all students and ensuring that the selected and sequenced student work would contribute to class-wide conversation and all students' learning. This also demonstrates how the participants adhered to the design of the professional development as the latter phases of the storyboard included activities like whole-class discussions, which were observed by the participants in the professional development and connected to initial selection and sequence of student work.

Conclusion

We illustrate a potential relationship between teachers' heuristics for sequencing student work and particular professional obligations. We found that the disciplinary obligation remained a consistent priority for participants, leading to an emphasis on the comparison of strategies, progression of procedures, and learning opportunities by addressing errors. At the same time, the individual obligation was crucial, especially when using the scaffolding by complexity heuristic, as teachers argued for comprehension while maintaining independence from the mathematical content. Purposefully selecting and sequencing strategies and fostering a shared language among teachers to discuss these ideas is an important emphasis in Story*Circles*. This practice of selecting and showcasing a representative solution from each category adds significant value in the eventual whole class discussions (Ayalon & Rubel, 2022). Planning for and leading mathematical discussions is challenging due to its inherent complexity, requiring teachers to notice and interpret students' thinking and make on-the-spot decisions. The attention to heuristics for selecting and sequencing and the extent to which they depend on the professional obligations provides the field with greater opportunities to understand the ways that teachers reason about important instructional practices. Furthermore, providing teachers with opportunities to learn more about why other teachers make the decisions they do has the potential to help support teachers gain greater clarity on their own instructional practices.

One-on-one coaching often involves a coach and teacher meeting to debrief after a lesson. One function of debriefing conversations is to enable coaches and teachers to look back on the lesson and figure out whether the instructional changes the teacher made were in fact improvements. We examined 25 cases in which a mathematics coach and teacher debriefed after a lesson to understand how coaches can support teachers in accomplishing this function. The findings emphasize the importance of mathematics coaches supporting teachers to explicitly link the instructional changes they made with their implications for students' thinking, learning, or engagement. Doing so can enable teachers to see whether the changes they made were improvements. In further clarifying this process of analyzing a prior lesson, we contribute to research examining effective one-on-one coaching interactions.

Researchers have reached a consensus on the types of instructional practices that can support students in attaining rigorous mathematical learning goals, such as those proposed by the Common Core State Standards in Mathematics (National Governors Association, 2010). Often referred to as *ambitious and equitable instructional practices* (Lampert et al., 2011; Lampert et al., 2010; Author & colleague, 2010), these practices include selecting tasks of high cognitive demand (Stein & Lane, 1996), launching tasks in ways that enable all students to begin working on them productively (Jackson et al., 2013), and pressing students to explain their reasoning and make connections between solution strategies during whole-class discussions (Kazemi & Stipek, 2001; Stein et al., 2008). Ambitious and equitable instructional practices differ significantly from typical instruction in most US mathematics classrooms (Hiebert, 2013), and there is substantial evidence that teachers require sustained support if they are to develop such practices (e.g., Author et al., 2018). Many schools and districts are providing the required support by hiring *mathematics coaches* to work directly with mathematics teachers to aid them in developing ambitious and equitable practices (Mudzimiri et al., 2014; Obara, 2010).

Mathematics coaches often work with mathematics teachers by engaging them in one-on-one coaching cycles. One-on-one coaching cycles consist of three phases: a lesson planning phase, in which a coach and teacher collaboratively prepare for a focal; a classroom instruction phase, in which a coach and teacher implemented the focal lesson; and a debriefing phase, in which the coach and teacher collaboratively analyze the impact of focal lesson (West & Staub, 2003). There is evidence that one-on-one coaching cycles can support individual mathematics teachers' development of ambitious and equitable instructional practices *when coaching cycles are facilitated effectively* (Kraft & Hill, 2020; Russell et al., 2020).

Researchers have made progress in understanding what it looks like for coaches to facilitate one-on-one coaching cycles effectively, especially as it relates to planning conversations (Russell et al., 2020; Witherspoon et al., 2020) and the classroom instruction phase (Saclarides &

Munson, 2021). Yet, comparatively less is known about how mathematics coaches can facilitate debriefing conversations effectively. In particular, little is currently known about how coaches can support teachers to look back on a lesson they taught and determine whether any changes they made in their instruction actually enhanced students' learning opportunities. As we note below, making such a determination is a primary function of debriefing. In this report, we clarify how coaches can support teachers in determining whether a change in instruction enhances students' learning opportunities, and is thus an improvement. We do so by examining 25 coaching cycles in which a mathematics coach and teacher debriefed after the lesson.

Literature Review

In recent years, scholars have begun to investigate how coaches can facilitate one-on-one coaching cycles productively, such that they can support teachers' development of ambitious and equitable instructional practices (e.g., Kochmanski & Cobb, 2023a; Munson & Dyer, 2022; Russell et al., 2020; Witherspoon et al., 2021). To date, researchers have predominantly focused on the co-planning phase (Rusell et al., 2020; Witherspoon et al., 2021) and lesson enactment phase of coaching cycles (Munson & Dyer, 2023; Saclarides & Munson, 2021). Far fewer studies have examined how coaches can support teachers' development of ambitious and equitable instructional practices in the debriefing phase of coaching cycles (Saclarides, 2022). That said, there is evidence that debriefing conversations can function in two ways to support teachers' learning (Gillespie et al., 2023; Saclarides, 2022). First, coaches and teachers can look back on a lesson to figure out whether any instructional changes they made enhanced students' learning opportunities (Hinojosa, 2022; Saclarides, 2022), and thus constituted improvements. We refer to this as the *retrospective function* of debriefing. Second, coaches and teachers can collaboratively identify new instructional changes they might make in future lessons (Kochmanski & Cobb, 2023b; Russell et al., 2017; Saclarides, 2022). We refer to this as the *prospective function* of debriefing.

In our prior work (Kochmanski & Cobb, 2023b), we have clarified how coaches and teachers can collaboratively identify the specific instructional changes they might make in future lessons. We found it is important for coaches to first prepare for a debrief by analyzing the lesson and identifying possible potential instructional changes that the teacher might make. Much as anticipated student solutions can inform class discussions, the instructional changes a coach identifies for a teacher ahead of a debrief can inform how the coach supports the teacher in setting improvement goals when debriefing. Further, we found it is essential for coaches to identify instructional changes that are (a) feasible for the teacher to make with the coach's support and (b) likely to immediately enhance students' learning, if attained (Kochmanski & Cobb, 2023b). We consider changes to be feasible when they build directly from a teacher's current practices. Instructional changes are likely to enhance students' learning when they occur in phases of lessons where students' learning first breaks down. To illustrate this latter criterion, consider a lesson in which almost all students could not start the mathematics task because the launch was confusing. In this case, working to improve how the teacher facilitates whole-class discussions would not immediately enhance students' learning because most students are unlikely to benefit from the whole-class discussion if they have not had opportunities to engage themselves in the mathematics task prior to the discussion. In contrast, it would immediately benefit students to make changes in how the teacher launches the task.

While we have made progress in understanding how coaches can support teachers to accomplish the prospective function of debriefing, there is still much left to learn the retrospective function of debriefing conversations. We are unaware of any studies that have closely investigated how coaches can facilitate debriefing conversations in which they support teachers in determining whether the changes they tried out in the lesson enactment phase actually benefited students' learning and were thus improvements in teaching. Given this, we asked the following research question: *How can mathematics coaches support teachers in determining whether the instructional change(s) they made during the lesson benefitted students' learning, and were thus improvements?*

Methods

Study Context

This study occurred in the context of a multi-year research-practice partnership (RPP) between university researchers and district leaders from a large, urban school district in the south-eastern United States. The district comprises 128 total schools, including 74 elementary schools, 30 middle schools, and 24 high schools. It serves over 85,000 students and is highly diverse, with over 100 languages spoken by students. Over 40% of the district's students are classified as economically disadvantaged and just over 20% of students have limited English proficiency. A primary goal of the RPP was to improve the quality of mathematics instruction in the district by training a cadre of middle and secondary mathematics coaches who could work with teachers in their schools. As part of the RPP, researchers and district leaders conducted a coach professional development (PD) design study that aimed to support mathematics coaches in learning to conduct one-on-one coaching cycles effectively with teachers. In the PD design study, researchers and district leaders collaborated to design and implement a sequence of eight 90-minute PD sessions. Because debriefing is a central part of coaching cycles, a significant portion of the PD design study focused on supporting the coaches to prepare for and then facilitate debrief conversations productively, including how coaches can support teachers to determine whether changes in instruction constitute improvements. Consequently, if the PD was successful, we would be able to collect data that would enable us to analyze the types of debrief conversations in which we were interested.

Participants

Fourteen middle school mathematics coaches and one high school mathematics coach participated in the coach PD. All 15 coaches were school-based and all of them were hired from a district-approved pool of applicants who had demonstrated prior success in ambitious mathematics teaching. We purposefully selected seven focal coaches to be representative of the range of coaching experience in the larger group. We collected data on these seven coaches' enactment of coaching cycles with the same teacher after each of the coach PD sessions. All seven focal coaches had more than five years of experience teaching prior to becoming a coach. Four of the seven coaches were novices in their first year of coaching, two of the seven coaches had extensive experience coaching in the district, and one coach had multiple years of coaching experience but was new to coaching in the district. Six of the coaches worked in middle schools, and one of the coaches worked in a high school.

Data Collection

We documented 25 total coaching cycles conducted by the seven focal coaches. For each of the cycles, we collected three types of data relevant to answering our research question. First, we audio recorded the co-planning conversations between the coach and the teacher. Reviewing the audio recordings of the co-planning conversations enabled us to identify the instructional changes the coaches *intended* to make in the lesson. Second, we observed each lesson and wrote structured lesson observation notes. We also collected students' work from the lesson. These data enabled us to see whether the teacher actually made the intended instructional changes, as well as whether those changes appeared to enhance students' learning opportunities. Finally, we audio recorded the debriefing conversations between the coach and teacher. These audio recordings enabled us to see whether and how the coaches and teachers discussed the instructional changes the teachers made in the lesson.

Data Analysis

We conducted two phases of analysis to answer our research question. In the first phase of analysis, we determined whether the coach supported the teacher in accomplishing the retrospective function in each of the 25 coaching cycles. We considered coaches and teachers to have accomplished the retrospective function when the debriefing conversations satisfied two criteria: (1) the coach and teacher concluded whether or not the teacher made an intended instructional change in the lesson and (2) if the teacher made an instructional change, the coach and teacher accurately determined whether or not the change improved students' learning opportunities, and thus constituted an improvement. In phase two, we answered our research question by comparing cycles in which the coach supported the teacher to accomplish the retrospective function with those in which the coach did not.

Phase 1. We first determined whether each debriefing conversation satisfied the first criterion. To do so, we identified the instructional change(s) the coach and teacher *intended* to make in the lesson by analyzing the co-planning conversations for each cycle. We used inductive coding to record the intended instructional changes in a table. We then determined whether the teacher made the instructional change by analyzing the structured lesson observation notes and students' work. Finally, we identified episodes in the debriefing conversations in which the coach and teacher discussed the instructional change. We compared these episodes with our own assessment of the lesson to see whether the coach and teacher accurately determined whether the teacher made the intended instructional change(s).

We next determined whether the debriefing conversations satisfied the second criterion. This took three steps. First, we identified when in each lesson students' learning first broke down (e.g., launch of the task, small group work time, whole-class discussion), if it did at all by analyzing the structured lesson observation notes and students' work from the lesson. Following a process similar to that described in Kochmanski and Cobb (2023b), this involved asking two analytic questions: "Were all students able to work meaningfully on the tasks?" and "Was the range of student strategies in the lesson rich enough to have a productive discussion?" If we answered no to either of the questions, we considered students' learning to have broken down in the launch of the task or in the small group work time prior to the whole-class discussion because the potential for students' learning in the whole-class discussion wasn't there. If we answered yes to the questions, we considered students' learning to have broken down during the whole-class discussion, if it did at all. For example, in one case, the structured lesson observation notes and students' work indicated that almost all students had blank papers during their small group work time, indicating that students' learning opportunities broke down during the launch of the task.

The first two authors analyzed each lesson separately, and then met to reach consensus on when in the lesson students' learning broke down, if it did at all.

In the second step, we compared the instructional change the teacher made with the results of our analysis from step one to determine whether the instructional change improved students' learning opportunities. We considered an instructional change to have improved students' learning opportunities when the change occurred *in* the phase of the lesson in which students' learning first broke down or in a phase *prior to* the break down in students' learning. For example, if our assessment of a lesson indicated that students' learning broke down in the whole-class discussion, and the coach and teacher made a change in how they organized small group work time, then we considered the instructional change to have improved students' learning opportunities. We also considered an instructional change to have improved students' learning if there was no evidence of a break down in students' learning. In the third step, we identified episodes in the debriefing conversations where the coach and teacher discussed whether the instructional change the teacher made was an improvement. We classified debriefing conversations as satisfying the second criterion when our analysis of the instructional change corresponded with the coach's and teacher's conclusions.

Phase 2. As a reminder, in phase 2, we compared cycles in which the coach supported the teacher to accomplish the retrospective function with those in which the coach did not. We first identified episodes in the debriefing conversations in which the coach and teacher discussed the instructional changes the teacher made in the lesson. We then used open coding to characterize coaches' and teachers' justifications for whether and why the instructional change, if made, was an improvement or not. We open coded these episodes because there is limited research examining why coaches and teachers see instructional changes as improvements, and there was thus no available coding scheme that was adequate for our purposes. When appropriate, we adapted language for our open codes from prior research examining one-on-one coaching conversations between coaches and teachers (e.g., Kochmanski & Cobb, 2023b; Russell et al., 2020; Saclarides, 2022). Table 1 shows the codes we used to characterize the justifications. We then compared the justifications in the cases that accomplished the retrospective function with the justifications in the cases that did not.

Table 1: Justification Codes for Debriefing Conversations (Retrospective)

Coach and Teacher Justification	Definition
Coach and/or teacher attributed changes in students' thinking to changes in instruction	Discussed how an instructional change impacted how students reasoned mathematically in the task or explained and justified their reasoning in whole-class or small-group discussions.
Coach and/or teacher attributed changes in students' engagement to changes in instruction	Discussed how an instructional change the teacher made impacted how students engaged in the task or students' apparent confidence in engaging in the task.

Teacher connected an instructional change to opportunity to learn about students' thinking	Discussed how an instructional change impacted their ability to understand how students were thinking about mathematics in the lesson.
Teacher made the intended instructional change	Based determination solely on whether the teacher actually made the intended change in the lesson.
Coach compared the instructional change with vision of effective, high-quality teaching	Coach tells the teacher that the instructional change is an improvement because it marks a shift toward what the coach sees as effective teaching.

Results

We found that coaches supported their partner teachers in accomplishing the retrospective function in 13 of the 25 coaching cycles. In six of the 12 unproductive cycles, the coach and teacher accurately determined whether the teacher made the intended instructional change. However, their assessment of whether that instructional change was an improvement was at odds with our analysis of the lesson. In one of the unproductive cycles, the coach and teacher did not discuss an instructional change in the debriefing conversation. They therefore could not accomplish the retrospective function. In the remaining five cycles, the coach and teacher did not specify an intended change in the co-planning conversation.

To understand how coaches can support teachers in accomplishing the retrospective function of debriefing, and thus answer our research question, we compared the 13 productive cycles with the six cycles in which the coach and teacher's assessment of the instructional change differed from our own. Table 2 shows the frequency of the types of coach and teacher justifications organized by whether the coach supported the teacher in accomplishing the retrospective function. The types of justifications that coaches and teachers gave in the 13 productive cases differed from the corresponding justifications in the six unproductive cases.

Table 2: Frequency of Justification Codes

Type of Justification	Number of cases	
	Accomplished retrospective function	Did not accomplish retrospective function
Coach and/or teacher connected changes in students' thinking to changes in instruction	10	0
Coach and/or teacher connected changes in students' engagement to changes in instruction	2	0
Teacher connected opportunities to learn about students' thinking to changes in instruction	1	0

Teacher made the intended instructional change	0	4
Coach related the instructional change with vision of effective, high-quality teaching	0	2

In each of the 13 cases with productive debriefing conversations, the coach and/or the teacher connected changes in students' thinking, their engagement in the task(s), or opportunities for the teacher to *learn about* students' thinking to the instructional change the teacher had made. In one coaching cycle, for example, the coach and teacher planned to implement a more open-ended task in the lesson. The teacher implemented the task as intended in the lesson. In the debriefing conversation after the lesson, the coach and teacher identified changes in students' thinking, and they attributed the changes to the teacher's decision to implement the more open-ended task. Specifically, the coach and teacher noticed that the students had to figure out their own strategies for solving the task, rather than using a strategy that was hinted at in the task. Consequently, there was a wide range of solution strategies in the small group discussion time on which the teacher could capitalize in the concluding whole class discussion. The coach prompted the teacher to relate these changes in students' strategies to their decision to implement an open-ended task, asking, "What did you think about [the new task]?" In response, the teacher *attributed the changes she noticed in students' thinking* to her selection of the open-ended task. She noted that students in her class usually "figure out something to do with the numbers," and then come up with an answer without explaining why it might make sense. However, with the new task, the teacher observed that her students "actually had to problem solve" and discuss different solution strategies in their small groups. Then, the groups had to draw on their prior mathematics knowledge to settle on an answer. The teacher and the coach agreed that the new task was an improvement because it resulted in enhanced student learning opportunities.

In contrast, in all six cases with unproductive debriefing conversations, the coach and teacher discussed the change in instruction without considering whether the change made a difference for students' learning and/or engagement. In four of the cases, the coach and/or the teacher concluded that making the intended instructional change was a sufficient reason to consider the change as an improvement. In one case, for example, the coach and teacher worked together to ensure the teacher could "make it through" all parts of her lesson plan. In the co-planning conversation, the coach suggested that she and the teacher make a timeline for the lesson and then use a timer to stay "on track". The teacher used the timer successfully in the lesson. In their subsequent debriefing conversation, the coach and teacher agreed that the lesson was an improvement because the teacher stayed on track. While the coach and teacher perceived this change in instruction to be an improvement, our analysis indicated that this change had limited bearing on students' learning opportunities. Instead, we found that the teacher provided minimal support to students during the launch of the task, and as a result, many students left their papers blank during their work time, indicating they struggled to get started on the task. Completing all phases of the lesson therefore had limited impact on students' learning opportunities because students' learning opportunities first broke down early in the lesson during the launch of the task.
