The Future Early Mathematics Curriculum Content and Materials

Among Bloom's Four Objects of Change, instructional materials stand out in the current discourse as significantly poised for disruption and evolution by artificial intelligence. The prevalent discussion focuses on AI's tendency towards inaccuracies, colloquially termed as "hallucinations," and the subpar performance of current models in basic mathematical tasks. Concerns have been raised about the potential for such inaccuracies to permeate AI-generated instructional materials. However, these issues are likely to be transient. Substantial progress is being made in the detection and mitigation of hallucinations through strategies that include the careful selection of training data, enhanced detection techniques, and self-correction methods (Huang et al., 2023). In parallel, innovations such as NVIDIA's OpenMathInstruct-1 problem/solution database are poised to significantly improve the mathematical reasoning abilities of models (Shah, 2024).

Assuming that these problems will be solved, it seems best to turn our attention toward applying these models effectively. While large language models in particular are improving at a rapid clip, they are still being trained on general language, and lack the specific expertise for sound, developmentally appropriate mathematics learning pedagogy. In a future where mathematics instructional materials are custom-generated for each student, it is paramount that the AI-enabled generation is trained to emulate best practices in early mathematics instruction.

Even as we innovate in the creation of instructional materials, it becomes crucial to critically evaluate the curricula these materials support. In an era where AI augments human capabilities, the value of memorization and computational skill diminishes in comparison to an individual's aptitude for discerning which problems merit attention. Essential to this competence is the capacity to pose relevant questions and to judiciously evaluate the mathematical soundness of AI-provided solutions. Transitioning from a focus on procedural fluency to fostering critical quantitative reasoning requires an ongoing shift in the educational paradigm. It underscores the importance of nurturing analytical prowess, critical thinking, and the judgment required to effectively navigate an environment increasingly characterized by automated processes and AI-driven outcomes.

The Future Early Mathematics Educator

One of the primary obstacles to delivering quality early childhood mathematics education is the increasing the mathematical content and pedagogical expertise among teachers in this field—especially early childhood educators. Often, educators in early childhood settings are under-trained in mathematics, lacking the depth of knowledge required to effectively teach the subject (Clements & Sarama, 2020). This deficiency is compounded by a widespread phenomenon known as math anxiety—a condition that affects a considerable number of educators, who may then inadvertently transmit this apprehension to their students (Hertz, Beilock, & Levine, 2019). The combination of insufficient training and personal math anxiety among teachers leads to suboptimal instruction in early childhood mathematics. This not only hampers the delivery of high-quality mathematical education but also potentially instills a similar sense of anxiety and aversion to mathematics in young learners, thereby affecting their long-term relationship with the subject (Hertz, Beilock, & Levine, 2019).

It follows, then, that if we expect the teachers of the future to provide students with higher-order math abilities, teachers themselves require further education. The existing literature points to the positive impact that redeveloping teachers' math expertise can have on their ability to teach effectively (Reid & Reid, 2017; Stoddart, Connel, Stofflet, & Peck, 1993) as well as their attitudes toward the subject (Hertz, Beilock, & Levine, 2019). Just as AI can be put to the task of providing instruction and correcting misconceptions in children, it could do the same for their teachers. Such intervention would ensure that teachers are fully equipped to develop their students' mathematical reasoning at the required level of sophistication.

The Future of Family Support for Early Mathematics Learning

In line with recent calls to focus on mathematics teaching and learning in early childhood, the National Council for Teachers of Mathematics issued a call to "strengthen partnerships with families and communities to create a shared vision of deep mathematics learning that is meaningful and relevant to children's lives" (Huinker et al., 2020, p.126). Further to this call, it is important to note that approximately 60% of children in the United States are not enrolled in any kind of pre-primary school (NCES, 2022). For these children, their primary early learning environment is the home, where parents and caregivers—who may or may not have the knowledge needed to effectively support their children's early math learning—are their first teachers. Without more equitable beginnings, it is difficult to ensure that *every* child will have access to the best start in mathematics.

Children who begin kindergarten with the needed prior mathematics knowledge are more ready to learn, more likely to master key early math competencies, and as a result go on to later success in mathematics in school (Claessens & Engel, 2013; Duncan et al., 2007). In addition, children who experience enriching home mathematics environments, filled with warm and nurturing parent-child shared math activities, are more likely to begin school ready to learn math (Blevins-Knabe, 2016). However, many parents report not knowing how to support their children's early math development, or for those children enrolled in preschool or pre-K, parents may prefer to rely on the teacher to foster the math learning of the child (Author, Date; Clements & Sarama, 2020).

For the most part, parents and families want to be involved and want to help their children to prepare to successfully learn math, but they need support (Author, Date). Adults often have deficiencies in their own math understanding, which can lead to math anxiety that they can easily transmit to their children (Hertz, Beilock, & Levine, 2019). As with teachers, AI can be a tool for addressing these deficiencies, providing personalized instruction on both math concepts themselves and the ways in which children develop understanding of those concepts. AI can also serve as a thought partner, helping caregivers to devise games and activities that ambiently incorporate math into family time in a way that is engaging and productive for all involved. AI-enabled chatbots can be designed to simply answer parent questions about what, how, and why to expose children to key math competencies, using carefully vetted databases of information that can replace parents' current "go to"--You Tube (Author, Date). When involving the family, the objective is less to turn caregivers into math teachers, but rather to support them in the raising of confident and capable math learners.

Conclusion

The future of mathematics education in uncertain times requires new paradigms, fresh perspectives, and the ability (and willingness) to leverage new tools and methods to tackle long-standing challenges. This includes, among other measures, a proactive focus on increasing the quality and accessibility of early childhood mathematics education as a means of ensuring that disparities do not have a chance to develop in the first place. An ecosystems approach that seeks to address the child, the instructional materials, the educator and the family has been shown in the research to be greater than the sum of its parts (Bloom, 1984; Authors, Date). Ecosystems intentionally designed to leverage artificial intelligence may be an effective means of impacting each of these objects of change, fostering personalization and building capacity to prepare students to reason mathematically. Envisioning the future of mathematics education in uncertain times is a call to action—an invitation to reimagine our approaches, rethink our priorities, and redouble our efforts to ensure that every student has the opportunity to succeed in mathematics.

Keywords: Technology, Curriculum, Rational Numbers & Proportional Reasoning

Machine learning techniques focus on how computers acquire new information. Typically, artificial intelligence used in mathematics education focuses on intelligent tutoring systems, profiling and prediction, and adaptive systems and personalization (Hwang & Tu, 2021). We propose an alternative use of machine learning techniques to train and optimize a model that gives feedback on student strategies, deploying it as a real-time, interactive feature of the digital curriculum platform. In this poster, we report on the development of the proportional reasoning rubric using students' inscription data—log files and any digital student work saved in the digital platform. The set of curriculum materials embedded in the digital collaborative platform we discuss is the middle grades problem-based curriculum, *Connected Mathematics4* (CMP; The Connected Mathematics Project, 2023; Phillips et al., in production). Given the emphasis of the CMP curriculum on fostering student thinking (Choppin et al., 2015), the rubric is thoughtfully designed to adapt to the diverse array of proportional reasoning strategies that may emerge from students' log files.

To develop the rubric, we examined the research literature on proportional reasoning strategies (e.g., Ben-Chaim, Fey, Fitzgerald, Benedetto, & Miller, 1998) and investigated student work already in the digital collaborative platform. The development of the rubric was based on two critical aspects. First, the rubric could be used across the different units in which proportional reasoning appears throughout the year. Second, the information for each criterion generated from machine learning is useful for teachers, such as aiding teachers in structuring whole-class discussions based on students' strategies. Our final rubric focuses on three criteria: (a) student approach (e.g., part-to-part, or part-to-whole), (b) mathematical representation (e.g., text, drawing, equation, or table), and (c) solution strategy (e.g., unit rates, common parts/wholes, or building up).

Our next steps include applying the rubric to code students’ digital work to train the machine learning model. We also created a new annotation feature to elicit more information on students’ strategies. We are testing a new digital interface that allows students and teachers to sort student digital work based on human and machine learning applications of the rubric criterion.

USING AI TO DEVELOP PRE-SERVICE TEACHERS' LESSON PLANNING SKILLS

Michael Todd Edwards
Miami University
Edwardm2@miamioh.edu

Michael Meagher
Brooklyn College – CUNY
mmeagher@brooklyn.cuny.edu

Asli Özgün-Koca
Wayne State University
aokoca@wayne.edu

We propose a study that aims to utilize ChatGPT to foster and develop the lesson planning skills of pre-service elementary teachers. The goal of the study is to show that pre-service teachers can interact with ChatGPT in a way that takes their initial drafts of mathematics lesson plans and, through working with peers and ChatGPT feedback loops, design improved lesson plans that are more inquiry-based and student-centered.

Keywords: Technology, Preservice Teacher Education, Elementary School Education

Introduction

The use of technology in math education has evolved significantly, from simple calculators to sophisticated online tools. When a new tool is introduced, it is often initially met with doubt, but eventually recognized for its value in teaching and learning. For example, scientific calculators and computer algebra systems were initially questioned but have since proven their worth in classrooms, supported by research that endorses their positive impact on mathematical understanding and student attitudes toward learning (see e.g., Chorney, 2021; Yohannes & Chen, 2021). Major stakeholders such as The National Council of Teachers of Mathematics (NCTM) have asserted that "It is essential that teachers and students have regular access to technologies that support and advance mathematical sense making, reasoning, problem solving, and communication" (NCTM, 2015, p.1). Indeed, a considerable body of research supports the idea that advanced digital technologies can support learning in general (Borokhovski et al., 2020) and mathematics concepts in particular (Hoyles, 2018; Yohannes & Chen, 2021) as well as having positive effects on students' attitude to learning (Fabian et al., 2018).

Artificial Intelligence (AI), particularly through tools like ChatGPT, represents the latest advancement in this continuum. This study aims to use Large Language Models (LLMs) to enhance the lesson planning abilities of pre-service PreK-5 math teachers. By utilizing LLMs to improve existing lessons or create new ones, our research seeks to achieve several objectives: enhance teachers' proficiency in creating effective lesson prompts (prompt engineering), foster a critical approach to evaluating AI-generated teaching materials, and enhance overall lesson planning skills through critical analyses of teaching materials.

Recognizing the inevitability of AI tools in educational settings, we aim to equip pre-service teachers with the confidence and know-how to harness these technologies for the benefit of students in their future classrooms. We see LLMs not just as tools, but as collaborative partners with unique strengths and limitations, aiming to prepare teachers for a future where technology and pedagogy intersect more seamlessly.

Literature review and relationship to research

Lesson planning is pivotal in teaching, with research highlighting challenges encountered by teachers, especially novices, in crafting effective plans. Cevikbas, König, & Rothland (2023) emphasize that while initial teacher education and professional development can enhance lesson planning competence, teachers often require support in areas such as understanding student thinking and leveraging innovative pedagogies. Collaborative methods such as communities of practice (Wenger, 1999) and lesson study groups (Fernandez, 2002) offer valuable frameworks for enriching lesson planning through shared knowledge and a research-based approach.

The advent of ChatGPT (OpenAI, 2023) introduces a novel resource for lesson planning, though empirical studies on its efficacy are still emerging. Rogeaux & Sharp (2023) note that with appropriate prompts, ChatGPT's output can rival the lesson plans of pre-service teachers, suggesting AI's potential to streamline the lesson planning process. Additionally, practitioner accounts (Schulten, 2023; Mok, 2023) and emerging platforms like Eduaide advocate for ChatGPT's role in enhancing productivity and offering personalized support in education.

This study aims to explore the utilization of ChatGPT and similar LLMs in lesson plan development among pre-service PreK-5 mathematics teachers, with a focus on improving candidates' prompt engineering skills, critical usage of LLMs, and overall lesson planning proficiency. Specifically, we investigate the following research question: *What is the impact on pre-service teachers' understanding of the role of AI in designing, revising, and evaluating lesson plans for mathematics instruction of deploying ChatGPT in the design of lesson plans?*

Methods and Methodologies

Setting and Participants

The study encompasses prospective elementary school teachers enrolled in a mathematics teaching methods course (ED 3XX), focusing on the integration of LLMs for planning (and implementing) mathematics lessons. In this study, we leverage AI to enhance collaboration, synthesize ideas, and communicate concepts in a natural language.

The ED 3XX course is divided into three modules, each designed to deepen the participants' lesson planning skills with an emphasis on inclusion, student engagement, and the effective use of technology. Each module spans three weeks, incorporating activities that guide pre-service teachers from initial lesson plan analysis to AI-assisted revision and critique. The modules are structured as follows:

Module 1: Introduction to lesson plan analysis and revision through a blend of classroom activities and homework assignments. This includes analyzing a sample lesson enacted by the instructor, with candidates critiquing it and engaging with ChatGPT for improvements.

Module 2: Similar in structure to Module 1 but focuses on commercially-produced curricula enacted by small groups of candidates, encouraging collaborative lesson planning and AI-assisted revision.

Module 3: Builds on the previous modules with an initial lesson generated using ChatGPT from initial ideas gleaned during students' field work, challenging students to refine the AI-generated lesson further.

Data Collection and Evaluation

The following course assignments have been constructed, in part, to help answer our research question. Students complete versions of these assignments in each of the three modules:

Pre-Teaching Analysis (PreTA): This tool is used before teaching a lesson, where candidates assess a lesson plan based on eight criteria such as learning objectives alignment, lesson detail, and engagement strategies. It includes a rubric and prompts for candidates to anticipate the lesson's strengths and areas for improvement.

Post-Teaching Analysis (PostTA): Conducted after teaching, this reflective tool prompts candidates to evaluate the lesson's execution against their initial analysis and expectations. It focuses on what went well, surprises encountered, and how the lesson could be improved based on the actual teaching experience.

Prompt Effect Worksheet (PEW): This worksheet documents the interaction with AI tools during the lesson revision process. Candidates note down specific prompts used, the AI-generated responses, and provide a critical analysis of how these interactions influenced the lesson plan's revision. It serves as a record of candidates' engagement with AI in refining educational materials.

In addition, candidates complete questionnaires at the beginning and end of the study.

Lesson Planning Questionnaire: Administered at the course's start and end, this questionnaire gauges candidates' perspectives on effective lesson planning, their experience with LLMs, and reflections on AI's role in lesson planning. It aims to capture shifts in candidates' understanding and attitudes towards AI-assisted lesson planning.

Data Analysis

Our analysis employs a multi-tiered approach. Initially, we compare the initial and final lesson plans in each module, focusing on qualitative differences highlighted by candidates regarding lesson strengths and weaknesses. This involves a direct assessment of the improvements attributed to AI assistance. We also look for differences in plans across the three modules. For instance, *do candidates focus more attention on lesson differentiation in later modules? As they gain experience in PreK-5 classrooms during the field component of the course, do they incorporate these experiences and understandings into prompts they provide to LLMs?*

Adding to this, we propose an innovative qualitative analysis by loading all Prompt Effect Worksheets (PEWs) into a ChatGPT interface. This will allow us to systematically evaluate how closely the AI-guided discussions center around eight key quality indicators of a lesson plan identified in the PreTA. Such an analysis not only quantifies AI's focus on critical lesson plan components but also highlights areas for further pedagogical development in AI interactions.

Further, open coding and the constant comparative method (Glaser & Strauss, 1967) will be used to analyze improvements suggested across all modules, developing a codebook that reflects emerging themes such as standards alignment and effective AI prompts. This codebook will then guide the analysis of final reflections and follow-up interviews, providing a comprehensive view of the AI's impact on pre-service teachers' lesson planning skills and their understanding of AI's role in education.

This layered analysis strategy aims to answer our central research question, exploring the depth of ChatGPT's influence on the pedagogical process and its potential to enrich lesson planning in mathematics education.

Preliminary Results

The initial phase of our study has revealed insightful trends regarding pre-service teachers' lesson planning approaches before and after interaction with AI tools. The initial phase of our study has illuminated the nuanced journey of pre-service teachers integrating AI into lesson planning. Five key themes emerged from their reflections:

Specificity in AI Interaction: Pre-service teachers learned the value of specificity when interacting with AI, noting that detailed prompts yielded more relevant and useful responses. A student observed, "I became more and more specific with my requests...the AI does not respond very well to vague or large overarching questions."

AI as a Resource for Inclusive and Engaging Activities: Many appreciated AI for generating diverse and engaging activities, acknowledging, "It created different activities...inclusive and engaging for all my students, that I may not have thought of on my own." Notably, one student remarked, "ChatGPT helped me see beyond the standard curriculum, offering fresh angles on engagement." This echoes Cevikbas et al.'s (2023) findings on the potential of training to elevate teacher competence in lesson planning, particularly through technological integration. Feedback underscored AI's role in surmounting common planning challenges, particularly in diversifying engagement tactics and addressing varied learning styles. Notably, one participant reflected, "AI opened new avenues for differentiation I hadn't considered, making my plans more inclusive."

Overcoming Initial Hesitance: Despite initial hesitance, the practical utility of AI in revising lesson plans was acknowledged, with reflections such as, "I was hesitant about using AI...but when I started the process...it truly wasn't that bad." Engagement with AI tools marked a pivotal shift, resulting in more innovative approaches and a broader perspective on inclusivity.

AI's Role in Enhancing Lesson Content: Teachers found AI particularly helpful in refining lesson content and structure, making lessons more interesting and accessible. "For almost every prompt that I gave AI, I was able to find...suggestions to be extremely helpful."

Learning to Leverage AI for Detailed Revisions: The process revealed that AI's effectiveness increased with detailed, focused prompts, leading to significant improvements in lesson plans. "The AI's responses gave me details and content that was much needed...I learned to include specifics on what I specifically wanted revised," a teacher reflected.

Anticipations for Modules 2 and 3

As we progress, we anticipate a deeper exploration of AI's capacity to enrich lesson planning in Modules 2 and 3. In Module 2, with candidates leading lessons from the Investigations curriculum (TERC, 1998), we expect an enhanced application of AI in real-world teaching scenarios, reflecting on Rogeaux & Sharp's (2023) insights on AI-generated plans related to real-world experiences. Module 3 promises further exploration into AI-initiated lesson plans, where we foresee candidates critiquing and refining ChatGPT-generated content, potentially redefining the boundaries of traditional and AI-assisted teaching methodologies, resonating with Schulten (2023) and Mok (2023)'s advocacy for AI as a transformative tool in lesson planning.

Relationship to Conference Theme

This study directly addresses PMENA 2024's theme by exploring how AI, specifically ChatGPT, can be integrated into mathematics education to navigate and adapt to the changing educational landscape. Through examining pre-service teachers' engagement with AI in lesson planning, our research contributes to envisioning the future of mathematics education amidst uncertainties, highlighting the potential of AI to support innovative teaching strategies and enhance educational outcomes.

DEVELOPING AN AUGMENTED REALITY SYSTEM FOR EMBODIED LEARNING OF VOLUME MEASUREMENT

DESARROLLANDO UN SISTEMA DE REALIDAD AUMENTADA PARA EL APRENDIZAJE INCORPORADO EN MATEMÁTICAS

Volume measurement requires children to develop skills in the coordination of three dimensions, the mental structuring of space, and flexible volumetric reasoning. However, students often face difficulty in these areas. Augmented reality (AR) technology holds promise as a solution to this problem as it can create an environment that introduces a computer-generated layer into the visual environment of the user. In this paper, we introduce an AR smartphone application, MeoGeo, that we developed. This application enables students to use their perceptuomotor actions as pedagogical resources in forming a concept of volume. By employing a multimodal analysis of an elementary student's embodied interaction with this app, we revealed the moments that a student enacts volume measurement of a 3D object. This study suggests that coordinating perception and action in an AR-enabled environment can facilitate mathematical cognition.

Keywords: Technology and Learning Environment Design, Geometry and Measurement, Student Learning and Related Factors

Purpose of the Study

This Brief Research Report aims to demonstrate the potential of an augmented reality (AR) system as an embodied learning technology. AR allows users to augment their view of the real world with computer-generated information. In this paper, we illustrate the embodied repertoire of behavior of an elementary student in learning volume measurement, guided by AR smartphone application, *MeoGeo*, which was developed by the authors of this paper.

Children often struggle with volume measurement, as it requires coordination of three dimensions (3D; Battista & Clements, 1996). Previous research revealed four mental schemes of volume identified by young children: packing, building, filling, and comparing (see Van Dine, 2014; Curry & Outred, 2015). Each scheme can bring particular misconceptions to children. For example, children who use the packing approach (i.e., quantifying the space within a 3D container by iterating unit cubes) tend to miscount only visible faces (Ben-Haim et al., 1985; Panorkou, 2019). In general, mentally organizing the space and imposing structure for volume measurement can be challenging for children, and a carefully designed manipulative can be helpful (Ferrara & Mammana, 2014).

In this study, we introduce *MeoGeo.* This smartphone application was designed for children to *bodily* coordinate 3D models using virtual arrays of unit cubes in their everyday environment in real-time. For example, children can move their body (pre-symbolic register) in alignment with the virtual three axes of object. This experience constitutes situated action where mathematics meanings can arise (Varela, Thompson & Rosch, 1991; Morgan & Abrahamson, 2016). We extend literature on the positive impact of dynamic virtual manipulatives on volume learning (Panorkou, 2019; Rupnow, 2022) to the AR-incorporated embodied learning environment.

Given the increasing popularity of immersive technology across every sector of life, this study aims to report design principles of AR-enabled mathematics learning environments that emphasize pre-symbolic experience for children. We hypothesize that a student's coordination of action with *MeoGeo* can mobilize reasoning with respect to their concept of volume. Our research question asks, "What forms of volumetric reasoning can develop as a result of a child's guided engagement in/with an AR-enabled learning environment?"

Theoretical Framework

Our work is rooted in the theory of embodied cognition and sociocultural theory. Embodied cognition posits that cognitive processes are rooted in the body's interaction with the world, including perceptuomotor coordination and the spatial system (Wilson, 2002). With this framework, this study can analyze how students utilize their body with AR technology (Abrahamson, 2020; Walkington, 2023). Additionally, we also utilize recent scholarship that marries embodied cognition with sociocultural theory to study human-technology interaction (Danish, 2020; Kaptelinin & Nardi, 2017). This approach enables an analysis of the mutually constitutive role of a student within an AR system-applied learning environment (*MeoGeo*).

The Design Study as Mode of Inquiry

We conducted a design-based study with eight students in grades 2-6 to examine how the forms of volumetric reasonings emerge within the context of our AR system (Cobb et al., 2003). The students participated in a seven-week-long mathematics program in New England, with weekly sessions featuring a one-hour-long AR activity session. For this pilot study, we focused on Greg (pseudonym), as he demonstrated motor skills in operating an iPad. Greg showed limited understanding of volume before using the app. To address our research question, Greg was asked to explore how many virtual cubes make up real-objects of his interest. He chose to measure the air-conditioner (AC) (See Figure 1). Two data sources were used: screen recordings of the app and video recordings from an iPad placed in the classroom. These recordings captured Greg's verbal and non-verbal actions. We employed a microanalytic investigation to capture the evidence of how and why *MeoGeo* may help learning of volume (Erikson, 1992). We reviewed the video recordings and identified the forms of interactions linked to the features of the app (e.g, half-transparent virtual unit cubes) using the MAET framework focusing on a user's body position, gaze, and body movement (Walkington, 2023). Below, we illuminate three excerpts that show the moments of interaction between Greg and *MeoGeo*.

Results

Volume as Coordination of 3D

What if children could structure 3D models using virtual unit cubes that visualize hidden portions of shapes and navigate around to experience them in a real world (3D)? Simply observing a physical cube does not enhance children's mental coordination of 3D objects (Battista & Clements, 1996). The utilization of dynamic geometric software, such as *GeoGebra*, can assist students in coordinating 3D representations of volume, but it relies on a fixed computer screen (Rupnow, 2022). *MeoGeo* synchronizes the dimension of the object studied (3D) with the environment in which a child explores it (3D). Excerpt 1 demonstrates a student actively coordinating the 3D of an object, aided by *MeoGeo*. Greg, to measure the height of AC, adjusted his body positioning up and down (Excerpt 1.01). To ensure that the height of the unit cubes was the same as AC, he sat down to align his eye position with AC (Excerpt 1.02). He then moved on to measure the width (Excerpt 1.03), followed by examining the length of AC from another angle (Excerpt 1.04). He moved his body as if there were *x*, *y*, and *z* axes in space, aligning his body with these axes. When children employ volume as a packing or building method, they limit focus to visible faces (Van Dine, 2014). However, Greg's bodily maneuver, enhanced with the transparency of virtual unit cubes projected onto the AC, served to demonstrate the pedagogical utility of an AR environment in reasoning 3D properties.

Table 1: Excerpt 1. Greg's spatial structuring of virtual unit cubes

01	Greg:	Hmm. And then, stack it! ***(Fig. 1**: Greg stands up and places the iPad face down)*	 **Fig. 1**
02	Greg:	So, this. *(**Fig. 2**: Greg sits down, moves the iPad to change the camera angles, and then stacks up one more cube on the first column*)	 **Fig. 2**
03	Greg:	Yep. Let's go. Yeah! It's perfect. *(Greg taps iPad to add another column of virtual unit cubes.*)	 **Fig. 3**
04	Greg:	I think there is another [column to stack up for width.] I can't quite decide. *(**Fig. 3**: Greg stands up and moves beside AC)*	

Volume as Unit Structuring Scheme

Children's flexible coordination of units and composite units (such as rows) can aid in volume reasoning, which later helps in the construction of volumetric calculation algorithms (Clements & Sarama, 2021; Rupnow, 2022). To emphasize the unit structuring scheme, we designed an app where children can build virtual unit cubes without gaps or overlaps, a mistake often made by children (Curry & Outhred, 2005). Drawing on gestalt psychology of continuity, we assumed children are more likely to create a row, column, or layer with cubes rather than randomly placing them. This design choice aimed to encourage students to flexibly manipulate units, units of units, and units of units of units for volumetric reasoning. Excerpt 2 shows evidence that children intuitively and bodily explored these unit construction schemes. Greg stacked up three layers with three cubes per row (Excerpt 2.01). Subsequently, he walked around the object to measure the length. He added three more columns (Excerpts 2.02-2.03).

Table 2: Excerpt 2. Greg's interaction with *MeoGeo* in real time

01 Greg: I think there is another [column to stack up for width.] I can't quite decide. *(Greg stands up and moves beside the AC)* 02 Greg: Ugh. Is this… Hoo.. Uhm. *(Greg* stacks up another column. ***Fig. 4****: Greg stands up and walks far away from the AC*) 03 Greg: How is it doing that? Alright. This one [column]. I figured it out. *(Greg* walks back closer to the AC. ***Fig. 5****: he stacks up three more columns, steps back, pauses, and observes his virtual cubes*)	 **Fig. 4**	 **Fig. 5**

Flexible use of multiple reasoning approaches to volume

A previous study found that children were likely to choose one volumetric reasoning strategy (e.g., packing) for a volumetric measurement problem (Vasilyeva et al., 2013). In contrast, our data shows Greg employed three interrelated reasoning strategies for volume. Greg stacks up virtual cubes *next* to the AC, which shows the volume as building approach (see Fig. 6). Then, he compared the size (comparing) using an allocentric frame of reference (Iachini et al., 2023). Then, Greg tried to 'fill' the virtual unit cubes, with the AC (Fig. 7). Although the filling strategy is often observed when measuring the volume of fluid (Van Dine, 2014), the affordances of AR, combining the digital and physical world, made the filling strategy available. It was also interesting that Greg used the AC (the object being measured) as the measuring unit itself. This finding shows that the use of AR can bring flexible volumetric reasoning strategies.

Table 3: Excerpt 3. Greg engaging in various reasoning strategies with *MeoGeo*

01 Greg: (***Fig. 6****: Greg stacks up another virtual layer. He inserts his foot into the cubes. He circles around the AC and walks farther from it and come back where he stood.)* 02 Greg: (***Fig 7.*** *Greg* grabs the AC and then put inside virtual cubes.) 03 Greg: I am done.	 **Fig. 6**	 **Fig. 7**

Discussion and Conclusions

This study examined video recordings of a fifth grader's embodied interaction with *MeoGeo*. This coincides with the increasing popularity of immersive technology featured in the 2024 PME-NA conference theme. We tested our hypothesis that a student's coordination of action (body position, gaze, body movement) mobilized reasoning about volume by (a) coordinating 3D, (b) exploring unit structuring, and (c) flexibly employing three approaches on volume. As a pilot study, this research is limited to the interaction of only one student. However, it highlights the spontaneous and non-deterministic meaning-making process of a student performing volume measurements within an AR-enabled immersive setting. The virtual arrays of unit cubes, structured with no gaps and overlaps, seemed beneficial for students to arrive at reasonings of volume. We believe our study would be beneficial for educators and designers to attend to such design principles that value students' pre-symbolic register of the body in teaching abstract math concepts.

Pre-service Teachers' Decision-Making Process to Use Technology For Early Algebraic Thinking

Alysia Goyer
Stockton University
Alysia.goyer@stockton.edu

Teruni Lamberg
University of Nevada, Reno
Terunil@unr.edu

Technology is becoming increasingly integrated into many K-12 education classrooms. This study documents pre-service teachers' decision making in utilizing technology to support algebraic thinking for elementary students. A design research study was conducted where pre-service students designed and taught lessons to elementary students. The findings revealed that pre-service teachers intentionally considered the student perspective of their technology selections. Findings were categorized by purpose in for mathematical thinking and role of technology using the PICRAT Framework (Kimmons, 2018) However, selecting the right tool to specifically support early algebra content was more challenging. Implications for integrating technology into a mathematics methods courses to support pre-service teachers' TPACK knowledge are discussed.

Keywords: Pre-service Teacher Education, Technology,

Introduction

Technology has become a normative instructional practice (Horne & Staker, 2011; US Department of Education 2004, 2010). It has been used flexibly as a tool to support mathematical thinking (Romberg & Kaput, 1999; Warren et al., 2016). This requires pre-service teachers to develop technological, pedagogical, and content knowledge (TPACK) (Mishra & Koehler, 2006). While the development of TPACK knowledge for pre-service teachers has been established (Graham et al., 2012). There is little research on pre-service teachers' rationale, anticipated use, or attitudes about technology (Hughes et al., 2020). This paper presents findings from a whole class teaching experiment conducted in a pre-service methods course, specifically focusing on pre-service teachers' technology decision-making processes as they developed and taught lessons on early algebraic thinking to individual elementary students.

Review of Literature

To effectively incorporate technology to support student learning of algebraic thinking, pre-service teachers must develop knowledge in their content (early algebraic thinking), instructional practices, and technology tools. Early algebraic thinking has been well-defined (Blanton, 2008; Carraher & Schliemann, 2018; Kieran, 2018) and emphasizes numeracy, characteristics, and properties of numbers and their arithmetic operations with or without the formal use of symbolic algebraic notation.

Selecting the right technology for teaching math content is challenging. When working with educational math applications for teaching, there is a need for pre-service teachers to be aware of the learning theories within the apps to better align the app use with specific learning objectives or outcomes (Larkin, 2013; Dubé et al., 2020; Kay & Kwak, 2018a, 2018 b). Overall, pre-service teachers primarily select and use technology from a teacher-centered and directed approach (Hughes et al., 2020; Hu & Yelland, 2017). Therefore, it is important for pre-service teachers not to use technology as a quick add-on for their classrooms, but rather to use it in conjunction with research-based practices that support technology for student learning (Bai, 2019; Lai, 2018) for the teaching and learning of mathematics. There is a need to distinguish between the purpose in per-service teachers' use of technology and technology use by the student in order to support early algebraic thinking. This gap in knowledge leaves pre-service teachers with little guidance on how to select or sequence technology tools within their algebraic lessons. Therefore, we investigated: *What do elementary pre-service teachers consider when integrating technology to support early algebraic thinking?*

Methodology

A whole class teaching experiment was conducted in a math methods course in a Western state. Twenty-two K-8 pre-service teachers (N=22) participated in the study for nine weeks. The course integrated content knowledge and pedagogical content knowledge and intentionally integrated instructional technologies. To provide an authentic lesson planning experience, the pre-service teachers were provided a practicum experience where they had to tutor individual students within the methods course. A design research approach (Barab & Squire, 2016; Collins et al., 2016) was used to design and deliver the lessons. The course duration was 9 weeks and was designed to incorporate technology throughout the course using TPACK Knowledge Progression (Chai et al. 2010). The purpose of technology selections was framed using the PICRAT Framework (Kimmons, 2018). The goal was to support pre-service teachers in developing lesson plans to support the learning of algebraic thinking by integrating technology. Additionally, the course incorporated early algebraic thinking (Early Algebra Progression (LEAP) Blanton et al. (2020) and a lesson planning framework (Lamberg, 2019)

The data collected included field notes, audio transcripts, and two lesson plan assignments that required pre-service teachers to support elementary students' algebraic thinking by integrating technology into the lesson. The first assignment was given in Week 5 as an online discussion. The pre-service teachers were given a lesson plan introducing multiplication in this assignment. They were asked to find or create a technology that they could use to support students' early algebraic thinking. The second assignment was given in Week 8, reflecting on the pre-service teachers' lesson sequence with their elementary students. In their reflection, they were asked to describe a specific aspect of students' algebraic thinking they noticed and justify the technology that could be used in their instructional sequence to support their learning objectives. The data was analyzed using (Corbin & Strauss, 1990). Constant comparative method for whole class discussions. Deductive coding was used to distinguish between arithmetic thinking (Radford, 2018) and algebraic thinking (Kaput, 2008).

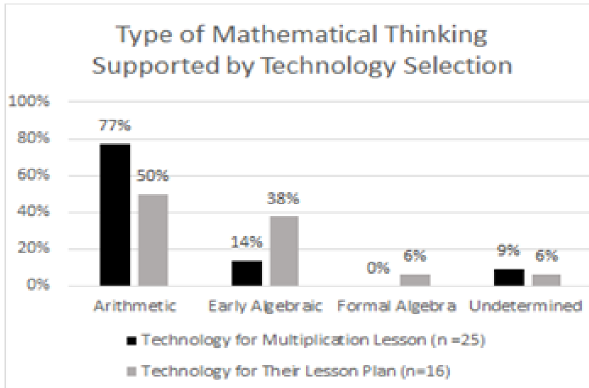
The technology use was also coded for themes using the PICRAT framework by Kimmons (2018) which addresses the student relationship with technology and the teacher's use of technology. To determine the purpose for technology and integration within lesson planning, codes were created inductively using descriptive coding (Saldaña & Omasta, 2018; Saldaña, 2021) .

Results

Selected Technologies Primarily Support Arithmetic Thinking

Pre-service teachers initially selected technologies related to arithmetic concepts, focusing on the operations being done. In the first task of selecting mathematics technology for a lesson plan on multiplication, 100% of participants identified a technology that aligned with the mathematical learning objective in both assignments. The pre-service teachers primarily selected arithmetic technologies to support students' arithmetic (operational thinking). Figure 1 summarizes the types of mathematical thinking supported by the technology selected in each lesson task.

Figure 1: Type of Mathematical Thinking Supported by Technology Selection

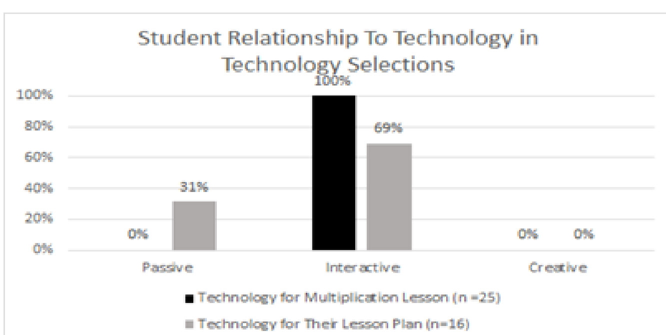


However, the second lesson planning task increased early algebraic thinking and formal algebra. Pre-service teachers identified technology uses that supported generalization, relational thinking, or additive or multiplicative properties. Algebraic thinking could be further distinguished as supporting early algebraic thinking or formal algebraic thinking.

Selected Technologies for Math Lesson Plans Were Passive & Interactive

Coding schemes were created according to PICRAT Framework (Kimmons, 2018), technologies were coded according to student relationship to technology and teacher's use of technology. In both lesson planning tasks 100% of technology selections were chosen based on the student's relationship with technology. Within those tasks, they were further distinguished by passive, interactive and creative technologies. Overall, the pre-service teachers selected three types of technology for both tasks: games or digital manipulatives (interactive) and videos (passive). For both assignments creative technologies were not selected. Figure 2 summarizes the percentage of pre-service teachers who selected each type.

Figure 2: Student Relationship to Technology in Technology Selections



Creative & Teachers' Use of Technologies Emerge

In small grade level groups were asked to create a poster about how they think of technology during lesson planning. While interactive and passive technologies still appeared, creative and a teachers' perspective of technology emerged. Not only do the pre-service teachers describe technologies for supporting math instruction, but they make connections to the lesson planning sequence and provide justifications for technology selection.

Discussion

Initially, pre-service teachers only primarily selected interactive activities to support specific mathematics objectives. However, collectively, in a group discussion, it was revealed that pre-service teachers are aware of and can differentiate between the purposes of passive, interactive, and creative activities for non-content-specific generalized instructional activities. This study differs from Hughes et al. (2020) in showing that pre-service teachers primarily selected technologies that were from the students' perspective but were also aware of the difference in technology for students and teachers' use. Overall, this supports the PICRAT framework (Kimmons, 2018) and continues to validate Kimmons et al. (2020) in utilizing PICRAT within pre-service methods courses to distinguish between student and teacher use of technology. Furthermore, incorporating technology into the lesson planning framework (Lamberg, 2019) goes a step further by linking technology as an intentional decision embedded within the instructional sequence. As technology becomes an instructional norm for teaching, methods courses must support content and pedagogical knowledge and technological pedagogical content (TPACK) knowledge. This study highlights how the pre-service teachers' technology decision-making does not occur within a single lesson but how TPACK knowledge is developed in smaller lessons throughout the course. As technology cannot simply be an add-on to K-12 education, it cannot be a one-time supplement to pre-established learning goals in mathematics methods courses.

TEACHER BELIEFS ABOUT COMPUTER SCIENCE INTEGRATION IN SECONDARY MATHEMATICS CLASSROOMS

Rebekah Hanak
University of Missouri Columbia
rrhd2b@missouri.edu

Samuel Otten
University of Missouri Columbia
ottensa@missouri.edu

Keywords: Computing and Coding, Integrated STEM / STEAM, Teacher Beliefs, Technology

This study explores high school mathematics teachers' beliefs about integrating computer science (CS) content into mathematics curricula. Beliefs are defined as teachers' convictions about the value and efficacy of CS integration. The objectives are to examine (1) teachers' perceptions of the benefits and challenges of CS integration in mathematics classrooms and (2) teachers' beliefs regarding the impact of CS integration on student engagement, problem-solving skills, agency, identity, and access to future opportunities. With thirty US state legislatures mandating the inclusion of at least one CS course (e.g., Missouri General Assembly, 2022) and only 41% of small high schools offering standalone CS courses (Code.org et al., 2023), there is a pressing need to explore innovative alternatives for CS integration within existing core classes (e.g., Missouri Department of Elementary and Secondary Education, 2023).

This study draws on Expectancy-Value Theory (Eccles, 1983) and constructionism (Papert, 1980) to explore integrating CS content into high school mathematics curricula. Expectancy-Value Theory provides a lens to examine teachers' motivations and perceived barriers to incorporating CS content, while constructionism grounds this study in the view that students learn most effectively through active engagement in creating and designing tangible projects. The principles of constructionism advocate for a mathematics education that fosters ownership, agency, and relevance through personally meaningful projects that resonate with students' cultures, values, and societal contexts (Papert, 1980). CS integration aligns with these principles, positioning learners as active creators and designers who use technology to explore, experiment, and construct, thereby deepening their mathematical understanding.

The methodological approach for this study centers on qualitative inquiry through semi-structured interviews with participants identified through a targeted data request to the Missouri Department of Elementary and Secondary Education (DESE) and subsequently emailed for recruitment. The sample included five educators meeting the dual certification criteria for teaching high school mathematics and computer science. Interviews were recorded via Zoom, with thematic analysis applied to the transcribed content. Initial codes were developed from the research questions and theoretical frameworks. Coauthors met to discuss and reconcile coding variances to ensure the coding process's reliability and validity.

Teachers expressed enthusiasm for integrating CS into mathematics curricula, citing benefits such as enhanced student engagement and its potential to foster a positive identity in students as learners of mathematics. However, they also highlighted barriers like limited resources and insufficient training. Teachers emphasized the value of hands-on, project-based learning, noting that students engage more deeply with mathematics when seeing practical applications through CS projects. They believed this integration could empower students from underrepresented demographics by exposing them to CS within a core subject, thus broadening their career aspirations and reducing the gender gap in computing fields. Implications include targeted support for smaller schools through grants and professional development programs and advocating for innovative and resource-aware curriculum approaches.

ILLUSTRATED STORY PROBLEMS: PROSPECTIVE TEACHERS' MATHEMATICALLY PEDAGOGICAL USAGE OF TEXT-TO-IMAGE GENERATIVE ARTIFICIAL INTELLIGENCE

Hamilton L. Hardison

Keywords: Preservice Teacher Education, Technology, Artificial Intelligence, Adobe Firefly.

Artificial intelligence (AI) has quickly become a prominent discussion topic in academia, including within the field of mathematics education (Kaplan-Rakowski et al., 2023). In broad strokes, AI refers to machines that simulate aspects of human thinking, and generative AI refers to AI capable of producing new content (e.g., text, images, music, etc.) based on particular user-specified input (Pavlik, 2023). Professional organizations have begun to enter the AI conversation in the form of recommendations, position statements, or calls for manuscripts on the topic; for example, a recent NCTM President's Message challenged mathematics educators "to learn how to integrate [AI] into [their] instruction and into our profession" (Dykema, 2023). At this point, exactly how mathematics educators should productively do this remains a largely open question, especially with respect to AI that generates non-text output.

In this poster, we consider the ways in which prospective elementary and middle-grades teachers (PTs) intentionally used Adobe Firefly—a text-to-image generative AI—toward mathematically pedagogical ends. In a semester-long mathematics content course on number and operation, 50 PTs were introduced to Adobe Firefly and were directed to use it for selected assignments. Here, we report on PTs' responses to one assignment, which involved: (a) writing a story problem that could be used to support elementary students' understanding of addition and subtraction, (b) using Adobe Firefly to produce an image with countable items matching those in their story problem, and (c) writing 4–8 sentences to explain why they designed their image the way they did, specifically focusing on features they deemed important for supporting students' mathematical thinking. On this assignment, PTs were also encouraged to attempt multiple prompts to find a satisfactory image; additionally, PTs were encouraged to use Firefly's generative editing features to further refine their image (e.g., by using additional rounds of generation to insert or remove objects from a previously generated image).

In the poster, we share examples of the problems, prompts, and images that PTs submitted for this assignment. We present a thematic analysis (Braun & Clarke, 2006) of the features PTs considered in designing their images to support students' mathematical thinking as well as generative edits they reported making to Firefly's initial image outputs. Additionally, we offer a brief analysis of PTs' story problems in terms the Cognitively Guided Instruction problem types (Carpenter et al., 2014) and consider the features PTs considered in conjunction with problem types. We close the poster by (a) considering the affordances and challenges (from PT and instructor perspectives) in using Adobe Firefly for mathematically pedagogical purposes, (b) offering other examples of ways we have used text-to-image AIs in our courses for prospective mathematics teachers, and (c) providing some questions and directions that might be explored in future research endeavors.

Keywords: Technology; Assessment; Algebra and Algebraic Thinking

Online homework systems are widely used in the instruction of college algebra at the post-secondary level (e.g., Boyce & O'Halloran, 2020; Hauk & Segall, 2005). The immediate feedback and variety of tutorial supports in these systems provide an opportunity for students' autonomy in their learning (Boyce & O'Halloran, 2020), encourage students to correct their mistakes (Affouf & Walsh, 2007), and participate in a cycle of learning of attempt-feedback-reattempt (Brewer, 2009). Studies from middle to post-secondary school indicate that students prefer to complete online assignments, which provide a source of motivation (Hauk & Segall, 2005; Ostrom & Heffernan, 2014). One no-cost system, ASSISTments (www.assistments.org) has been used in large quasi-experimental studies at the middle and high school level (Murphy et al., 2020; Singh et al, 2011). Research on the use thereof to support student learning and the use of formative feedback in instruction in middle-school and secondary classrooms is very promising (e.g., Feng et al., 2014; Kehrer et al., 2013; Kelly et al., 2013; Koedinger et al., 2010; Mendicino et al., 2009). Three of these studies provided insight into the effectiveness of "Best so far" supports, namely video hints vs. text hints (Ostrow et al., 2014), worked examples vs. hints (Shrestha et al., 2009), and single vs. multiple template questions (Jiang et al., 2020) and showed positive learning gains for students with these supports. Given this promise, we proposed adapting ASSISTments for use at the undergraduate level.

This research study conducted at two southeastern universities over two years aims to replicate the three aforementioned studies using ASSISTments in college algebra courses. The goal of this study is to determine whether the use of ASSISTments at the college level leads to similar gains in mathematics learning and analogous changes in pedagogical practices as reported in younger grades. Using the E-TRIALS platform, action-level data will be collected from individual students at the universities and combined with administrative data. Preliminary results on the use and effect of support within ASSISTments will be reported.

An understanding of the efficacy of different support can provide insights into the impacts of the design, implementation of education materials, and pedagogical practices. This speaks to research in the areas of learning sciences and technology, and mathematics education. Further, examining how college students use within-problem supports compared to younger students could help understand how mathematics learning changes chronologically. Finally, we can report average effect sizes on performance disaggregated by student characteristics to ensure findings do not inadvertently harm underrepresented groups in college mathematics courses, which was a component missing in many of the prior studies at the K-12 level.

HIGH SCHOOL STUDENTS LEARNING DYNAMIC GEOMETRY ON AN IPAD VERSUS IN AUGMENTED REALITY

Jonathan Hunnicutt	Julianna Washington	Candace Walkington
Southern Methodist University	Southern Methodist University	Southern Methodist University
jdhunnicutt@smu.edu	jcwashington@smu.edu	cwalkington@smu.edu

Keywords: Technology, Geometry and Spatial Reasoning, Reasoning and Proof

Augmented Reality (AR) technologies allow for holograms to be layered over the real-world, "augmenting" human vision by overlaying illustrations onto 3D space. Contemporary AR systems allow students to interact with virtual objects using their bodies. This capitalizes on embodied views of the nature of cognition (Lakoff & Núñez, 2000; Nathan, 2021), which posit that all conceptual knowledge is understood and experienced through the body and is action-based in nature. Meta-analyses are numerous and estimate the effects of AR in educational interventions to be anywhere from d=0.64 (Garzón & Acevedo, 2019), to g=0.65-0.75 (Chang et al., 2022). However, less is known about the impact of AR holograms in math education specifically. Here we explore the question: What affordances does AR in a collaborative environment have for the future of mathematics education in uncertain times? We conducted a study where 120 high school students were randomly assigned in pairs to the AR treatment condition which used the Hololens2 or to the control condition of the iPad. Using the same Dynamic Geometry Software (DGS; Hollebrands, 2007), subjects were asked to collaboratively explore, evaluate, and justify their reasoning about six geometry conjectures (e.g., alternate interior angles are congruent; Figure 1). Half of the conjectures were about two-dimensional objects (e.g., triangle), and half were about three-dimensional objects (e.g., pyramid).

Figure 1. iPad Condition (left) versus HoloLens condition (right)

Data were analyzed in R using a multilevel cross classified logistic regression. Subjects with the iPad evaluating 2D conjectures performed better than both subjects with iPads evaluating 3D conjectures and subjects with HoloLens evaluating 2D and 3D conjectures (log-odds $\beta = 2.04$, SE = .062, $p < .001$). This effect was moderated by scores on a spatial reasoning test, which assessed ability to mentally rotate 2D and 3D objects (log-odds $\beta = 1.3$, SE = .45, $p = .004$). A simple linear mediation analysis suggests that students manipulating the geometric objects while evaluating the conjecture mediated 22% of the effect subject performance in iPad 2D vs. HoloLens 3D (mediation $\beta = 0.027$, SE = 0.012, $p = .024$, total effect $\beta = 0.118$, SE = 0.045, p =

.008). These results show important factors that impact AR's effectiveness for mathematics learning – including dimensionality, spatial ability, and types of interactions.

RE-IMAGINING CLASSROOM TOOLS: MODELING MATHEMATICS IN MICROPROGRAMMING ENVIRONMENTS

Amber Jackson
Louisiana State University
ajac241@lsu.edu

Fernando Alegre
Louisiana State University
falegre@lsu.edu

Juana Moreno
Louisiana State University
moreno@lsu.edu

This paper presents an initiative aimed at integrating tailor-made micro-programming environments (MPEs) into middle school mathematics education to foster student learning and enhance computational thinking skills. We examine the effectiveness of MPEs in engaging students in computational thinking, aligning with mathematical practice standards, and usability in promoting interdisciplinary connections between mathematics and computing in the middle school setting. Findings suggest MPEs can advance computational thinking skills and enrich lesson alignment with educational standards. Most participants indicated approval of integrating MPEs into middle school classrooms.

Keywords: Mathematical Representations, Computing and Coding, Computational Thinking

In pedagogy-centered mathematics classrooms, educators encourage students to articulate and demonstrate their mathematical thinking through various representations, including diagrams, graphs, and verbal explanations. Incorporating MPE tools for mathematical modeling can enhance modeling effectiveness while exposing students to computer science. The idea of using programming to help students learn mathematics and science has a long history (Papert, 1980; Mayer, 2004; Hickmott et al., 2018), but few studies (Benton et al., 2017; Calao et al., 2015) explore learning key mathematical ideas through computing (Schanzer et al., 2015; Bråting & Kilhamn, 2021). Programming languages are excellent for externalizing and manipulating thought processes (diSessa, 2001; Schaffer & Kaput, 1998). While paper and pencil modeling or physical manipulatives are typically used to externalize thoughts, programming requires students to use explicit commands for each step in the problem-solving process. This approach can aid students in correcting their thinking and help teachers recognize misconceptions. General-purpose programming languages, or even tools such as spreadsheets, may be too unconfined to be effective for students and require prerequisite knowledge. Our design allows teachers to limit features, tailoring the MPE to the specific purpose of the activity. Through survey analysis, we assess MPEs' ability to engage learners in computational thinking, align with math practice standards, and overall usefulness in the middle school classroom. Findings suggest MPEs advance computational skills, align lessons to standards, garner general approval for classroom integration, and feature intuitive elements requiring minimal learning time, necessitating no expertise from teachers to implement.

Theoretical Framework

This study is grounded in Constructivism, which posits that learners construct their understanding and knowledge through experiences and reflection (Piaget, 1972). Constructivism highlights the importance of learners being active in their learning process, engaging in meaningful tasks (Vygotsky, 1978). The MPE embodies the constructivist approach by providing hands-on, experiential learning in computing. The MPE allows students to visualize and model their step-by-step problem-solving processes, making their understanding and misunderstandings visible. When the program does not perform as intended, students quickly realize mistakes, enabling immediate feedback and correction through debugging, a key aspect of learning in programming (Papert, 1980).

With the intentionality to bridge the gap between computer science and mathematics, the aim of the MPEs in this study is to create a constructivist environment that develops computational thinking and enhances student engagement in the Standards for Mathematical Practice (SMP):

- SMP1 “Make sense of Problems and Persevere in Solving them.”
- SMP2 “Reason Abstractly and Quantitatively.”
- SMP3 “Construct Arguments and Critique the Reasoning of Others,”
- SMP4 “Model with Mathematics.”
- SMP5 “Use appropriate tools strategically.”
- SMP6 “Attend to Precision.”
- SMP7 “Find and make use of structure.”
- SMP8 “Find and make use of repeated reasoning.”

MPE Modeling

Our MPE offers diverse strategies for solving mathematical problems. Consider the example: "A seventh-grade class needs 5 leaves daily to feed 2 caterpillars. How many leaves would the students need daily for 12 caterpillars?" Various mathematical strategies can be represented through operations performed on ratio tables. Teachers can limit available blocks to encourage specific strategies or provide options for students. Figure 1 illustrates four typical strategies, showcasing features of the MPE and its evolution of reasoning from concrete to abstract.

Explicit Copies: Manual Additive reasoning	**Repeat Block:** Automated Repeated Addition	**Avoiding Magic Numbers:** Multiplication by a scale factor, using only starting values	**Abstract Reasoning:** Generalized to calculate with any starting values.

Figure 1: MPE block-code is shown above, with the corresponding output table below.

Research Methodology and Design

This study addresses the following research questions:

- RQ1. Do micro-programming environments (MPEs) facilitate and enhance participant engagement in computational thinking skills?
- RQ2. Does integration of MPEs support the alignment with and application of mathematical practice standards in the context of middle school mathematics?
- RQ3. What are the perceptions of pre-service teachers on the usefulness and challenges of integrating MPEs into mathematics education?
- RQ4. Is the MPE tool intuitive enough for participants to make sense of the tool without teacher expertise?

This study employed a mixed-methods research design, combining qualitative and quantitative approaches to explore the effectiveness of integrating micro-programming environments (MPEs) into middle school mathematics education. The qualitative approach allowed for an in-depth understanding of participants' experiences and perceptions regarding the use of MPEs, while quantitative data were collected through surveys to supplement the qualitative findings.

As a preliminary to the in-class implementation detailed in publications to come, this trial was run on college students enrolled in a pre-service teacher program. The participants in this mixed-methods study were eleven pre-service teachers who engaged in a self-guided activity using the MPE. Among the participants, 2 (18%) were males and 9 (82%) were females. In terms of racial demographics, 7 (64%) identified as White, 3 (27%) as Black/African, and 1 (9%) as Asian/Vietnamese. The participants had diverse academic backgrounds, with 8 participants majoring in Biology, and one each studying Math, Physics, and Chemistry.

Data were collected through self-reported surveys administered after the MPE activity. The surveys assessed participants' educational backgrounds, experiences with the MPE tool, perceptions of computational thinking, and the usefulness of the MPE in middle school classrooms. Qualitative data analysis was conducted to identify themes and patterns in participants' responses. Thematic analysis was employed to categorize and interpret qualitative data related to participants' experiences, perceptions, and feedback on the integration of MPEs. Quantitative data from the surveys were analyzed using descriptive statistics to provide additional insights into participants' demographics and perceptions.

Analytical Results

RQ1: Computational Thinking

Survey responses revealed significant insights into participants' perceptions of computational thinking. Participants reported an increase in engagement with computational thinking skills during the MPE activity to 82%, compared to 49% in their previous education experiences. Comments included: “This activity developed my computational thinking skills well because I had to think about what I was doing and it helped me develop skills for computer thinking and problem-solving,” and “It really forced me to think about the meaning behind simple arithmetic.”

RQ2: Alignment to Standards for Mathematical Practice

Participants rated the MPE lessons' alignment with the standards for mathematical practice (SMP) on a scale of 0 (no alignment) to 5 (full alignment). The results showed that participants reported full alignment (5/5) with SMP1 "Make sense of Problems and Persevere in Solving them" and SMP3 "Construct Arguments and Critique the Reasoning of Others." The average alignment rating for the other standards was 4 out of 5, indicating near full alignment. Researchers observed that participants engaged more in discussions and debates when using the MPE (SMP4, SMP5), which required precision commands (SMP6, SMP7), than when modeling their thinking on paper. Quotes from the lesson include: "We can't get there from here," and "Yours is more efficient, but mine more clearly shows my thinking. In this format, the table can be used repeatedly for different numbers of days and different numbers of caterpillars."

RQ3: Usefulness of the MPE

Participants rated the usefulness of the MPE on a scale of 0 to 5. Analysis showed that 73% of participants considered the tool generally useful (rating of 3 or higher) in a middle school setting. Comments included: "I think that tools like this would be useful for introducing coding concepts for use in problem solving," and "For students that struggle to solve stepwise problems, this could be a useful tool to outline their thinking. Middle school is a good age to develop these skills." Thematic analysis revealed that participants appreciated the hands-on and experimental nature of the MPE activity, which made their thought processes visible. Some initially struggled with block coding but found it easier once they understood the process. Comments included: "The restriction of having to show every single step forced us to figure out how to solve every step using the program." Participants who rated the MPE "low" (0-1) reported 80% less PBL in their middle school experiences than those who rated it "high" (4-5), and half as much PBL as those who rated it "moderate" (2-3). This suggests that participants with less exposure to similar challenges in their own education found the tool less suitable for middle school settings, while those with more exposure found the tool more suitable. One participant commented: "I don't think I've done project based learning in my entire K-12 schooling, especially in math."

RQ4: Intuitive Design

Although students initially engaged in a productive struggle, all 11 participants were able to quickly deduce the mechanics of the tool without prior knowledge, teacher guidance, or intervention. One participant commented: "It took a while to model my step-by-step process on the block coding, but once I did, it was easy to see the process visually."

Conclusion

This study underscores the potential of Micro Programming Environments (MPEs) to transform middle school mathematics education by fostering computational thinking and aligning with mathematical practice standards. The integration of MPEs facilitates an active, constructivist learning environment where students can model and visualize their problem-solving processes, receiving immediate feedback and opportunities for correction through debugging. Participants reported significant engagement in computational thinking skills and observed near-full alignment with the Standards for Mathematical Practice.

The findings suggest that MPEs are effective tools for enhancing mathematical modeling and computational thinking skills among middle school students. Most participants indicated a positive reception towards integrating MPEs into classrooms, highlighting the tool's usefulness and ease of adoption without requiring extensive teacher expertise. This study contributes to the growing body of research advocating for the integration of computational tools in education, suggesting that MPEs can enrich the learning experience and bridge the gap between mathematics and computer science.

ENHANCING SECONDARY PROSPECTIVE TEACHER'S EQUITABLE PRACTICE THROUGH TECHNOLOGY INTEGRATION

Maral Karimi

University of Central Florida
farshid.safi@ucf.edu

Keywords: Technology, Pre-Service Teacher Education, Mathematics Teaching, Assessment, TPACK,

Research efforts have demonstrated that pre-service teachers (PSTs) often encounter challenges in interpreting students' mathematical thinking and conceptual understanding when technology-enhanced math tasks are involved (McCulloch et al., 2023; Smith et al., 2017; Yeo & Webel, 2019). The practice of teachers noticing students' mathematical thinking often involves three key components: attending to students' strategies, interpreting their conceptual understandings, and determining appropriate responses (McCulloch et al., 2023). PSTs can describe students' interactions with technology but they have challenges in finding sufficient evidence to connect these interactions with students' mathematical thinking (McCulloch et al., 2023; Smith et al., 2017; Yeo & Webel, 2019) which influences how they interpret students' conceptual understanding of the mathematical ideas embedded in the technology-enhanced task (McCulloch et al., 2023). The Association of Mathematics Teacher Educators (2017) Standards for the Preparation of Teachers of Mathematics notes the importance of teachers being proficient with tools and technology designed to support mathematical reasoning and sense-making. The primary question explore here involves the ways in which the integration of technology enhances future mathematics teachers' ability to draw insights about students' learning processes.

In an undergraduate Methods in Secondary School Mathematics course, we identified this common challenge among pre-service teachers. To address this challenge, we adopted a research-based approach to develop curriculum materials, integrating two theoretical frameworks: the TPACK framework (Technology Pedagogical Content Knowledge) and TQE process (Tasks, Questions, and Evidence). In each module, initially, pre-service teachers, based on the TPACK framework, learn about ways to recognize different types of technology in serving different purposes by considering technology choice, curriculum goals, and pedagogical content knowledge (Mishra & Koehler, 2006). Then, we asked them to engage with a technology-enhanced math task as learners by using technology tools: Desmos and GeoGebra. In this step, based on the TQE process, they involved responding to questions and interacting with peers in small group discussions through using technology. This active involvement allows PSTs to anticipate student thinking and understand the learning process more comprehensively. Following this approach, PSTs observed the ways that using technology and implementing the TQE process generate various evidence for formative assessment (Nolan et al., 2016), while also integrating individual learning and small group discussions to explore mathematical concepts deeply. Finally, we asked the teacher candidates to analyze other groups' work and engage in discourse in whole class discussion. As PSTs continue using the TPACK framework and TQE process within technology-based learning during the course, they gather more evidence to connect students' engagement with technology to the students' mathematical understanding. This knowledge enables them to provide personalized instruction and consistent feedback to address the needs of all learners through the use of technology (Black & Wiliam, 2009; Black & Wiliam, 2018; Neumann et al., 2021).

THE IMPACT OF VIRTUAL REALITY TO SUPPORT STUDENT UNDERSTANDING OF POWERS OF TEN

David Kirkland
University of Nevada, Reno
davidkirkland@unr.edu

Teruni Lamberg
University of Nevada, Reno
terunil@unr.edu

Keywords: Number Concepts and Proportional Reasoning, Teaching Practice and Classroom Activity, Technology and Learning Environment Design, Algebraic Thinking

This study examined how virtual reality (VR) supports students' understanding and visualization of the nanoscale. A 90-minute VR session allowed students to explore the human hand and zoom inside the hand to see cells, blood vessels, and even individual molecules. Students were in control of the simulation and could look around and explore what was happening

Methods

This study had eleven participants: students aged eleven to fourteen, seven identifying as female, and three as male. This camp was conducted at a mid-sized Western university. The camp focused on nanotechnology. The culminating design project asked students to create the largest soda geyser possible based on what was learned throughout the camp. Even after multiple activities students still struggled to visualize the nanoscale. Therefore, a design decision was made to utilize virtual reality to allow students to explore the nanoscale.

Findings

The VR gave students a concrete understanding of the nanoscale and allowed students to bridge the gap between macroscopic and nanoscale scales. After the VR session, students could discuss and understand how materials react at the nanoscale. In the post-activity discussion, students understood just how small nano is and the scale at which the nanoworld exists.

Discussion

Virtual reality allowed students to develop a concrete understanding of powers of 10. Students were able to use proportional reasoning to scale down to the nanoscale. This aligns with the work of Lamon (2020), where students were able to reason up and down to the appropriate scale. This is evident through how students talked and thought about the nanoscale and how they could use this knowledge to ultimately solve a design problem (creating the tallest soda geyser they could). The VR session provided students with an embodied cognitive perspective. Students engaged in graspable math and playful learning in a virtual learning environment (Abraham et al., 2020). The virtual reality simulation provided a real-world context inside the hand. It was an open-ended environment where students could flexibly explore things they found interesting to make sense of size and scale. Further research is needed to explore the use of virtual reality to support math learning.

UTILIZING CONJECTURE MAPPING TO DESIGN A DIGITAL TASK FOR DEVELOPING PRODUCTIVE GRAPHING MEANINGS

Claudine Margolis
University of Michigan
czmars@umich.edu

Teo Paoletti
University of Delaware
teop@udel.edu

Allison Olshefke-Clark
University of Delaware
aolshefk@udel.edu

In this preliminary theoretical paper, we describe our use of conjecture mapping (Sandoval, 2014) to guide the design of a digital task sequence to support 6th graders' meanings for points as a simultaneous representation of the amount-ness of two quantities. The conjecture map ultimately serves as a theoretical framework with testable conjectures about how the design of the digital task sequence might promote the intended learning outcomes.

Keywords: Design Experiments, Technology, Mathematical Representations

Graph construction and interpretation are critical skills for advanced mathematics coursework and consumption of popular media (Glazer, 2011). Despite the importance of graphs in K-12 mathematics and science curricula (CCSS; NGSS), research indicates that students struggle with graph construction and interpretation well into their post-secondary studies (e.g., Carlson et al., 2002; Glazer, 2011). One explanation for students' challenges with graphing is that they develop meanings for graphs that are useful initially but are limited as they advance through the mathematics curriculum (e.g., understanding points as a set of directions for how far to move over and up from the origin; Frank, 2016). We posit that one way to address this challenge is to support students in developing more productive meanings for graphs when they first encounter graphs in the curriculum. A promising approach to understanding graphs is emergent graphical shape thinking (EGST; Moore & Thompson, 2015). In this theoretical report, we describe our effort to design a task sequence that supports 6th grade students (11-12 years old) in developing EGST. This task design effort was undertaken between rounds of a design-based research study (Cobb et al., 2003), and we utilized conjecture mapping (Sandoval, 2014) to guide our design toward the dual goals of developing theory about how the design of the learning environment functions and about how the development of productive graphing meanings occurs.

Background

Within a multi-year design-based research study (Cobb et al., 2003), we have been working to develop an instructional sequence that supports 6th grade students in developing EGST. We conducted multiple rounds of small group teaching experiments (Steffe & Thompson, 2000) in which pairs of students worked through our task sequences. The ultimate learning goal we intended to support was students' development of EGST.

EGST entails conceiving of a graph as a record of covarying quantities (Moore & Thompson, 2015) which can be created by imagining the trace of a point moving through the coordinate plane such that the motion of the point is constrained by the relationship between situational quantities. As such, developing EGST requires attention to students' quantitative reasoning within situations and graphs. Quantities are conceptual entities grounded in an individual's conception of a situation. "A person is thinking of a quantity when he or she conceives a quality of an object in such a way that this conception entails the quality's measurability" (Thompson, 1994, p. 7). An attribute of a situation is measurable to an individual if they can conceive of a process for measurement that results in an amount and a unit (or the anticipation of a unit). The situation in which a person constructs quantities can be a graph (e.g., constructing vertical distance above the horizontal axis as an attribute of a point) or some experientially real context (Gravemeijer & Doorman, 1999; e.g., constructing weight and habitat temperature for animals at the zoo). Although engaging in EGST entails conceiving of varying quantities, in this report we detail an effort to support students in what we conjecture is a prerequisite meaning for graphs as representing relationships between static quantities.

Informed by Paoletti et al.'s (2023) LIT for developing EGST with advanced 8th graders, our high-level conjecture is that repeated occasions to draw explicit connections between meanings for situational quantities (situational quantitative reasoning; SQR) and meanings for graphical quantities (graphical quantitative reasoning; GQR) is critical for students' developing EGST. Given space constraints in this report, we focus on the first level of SQR and GQR. Denoted as SQR1 below, students must first construct quantities in a situation and conceive of the quantities as being able to take particular amounts in the situation. GQR1 entails considering the length of a magnitude bar as representing a static amount (i.e., constructing the quantity of length). Bridging SQR1 and GQR1 (SQR1↔GQR1) entails considering a magnitude bar as representing the static amount-ness (Stevens & Moore, 2017) of a situational quantity.

We developed the Zoo Task sequence to provide students with opportunities to reason about points as a simultaneous representation of the amount-ness of two situational quantities. However, retrospective analysis from our first two rounds of teaching experiments that used the task indicated that students needed more (or different) opportunities to bridge SQR and GQR. We decided to redesign the Zoo Task sequence to meet this need and took up conjecture mapping (Sandoval, 2014) as a strategy for redesigning the task in ways that would enable us to test and refine our conjectures about the task design and process of developing SQR and GQR. Conjecture mapping attends to the dual goals of design-based research by differentiating between theories about the design of the learning environment and theories about the process of learning. Conjecture maps depict the ways researchers anticipate the design of the learning environment supporting learners in engaging in observable processes as well as conjectures about how engagement with those observable processes results in the desired learning outcomes. Our initial conjecture map is in Figure 1.

The Zoo Task

We describe the opening sequence (screens 2-5) of the Zoo Task to ground descriptions of the conjecture map in the next section. Due to space constraints, we only report on the opening sequence of the task which we designed to support students' SQR1, GQR1, and SQR1↔GQR1. To support the reader, we provide a link to the opening activity sequence so that the digital interactions we describe here can be experienced as we designed them (https://bit.ly/ZooTaskPMENA). On Screen 2 (Figure 1a), students are prompted to weigh three mystery animals at the zoo and record their weight. Students can weigh each animal by dragging it to a scale and pressing the 'Weigh It' button. In response to those actions, the scale depresses with a bounce (imagine a heavy object being placed on a spring-loaded plate) and the weight of the animal is represented with numbers and a magnitude bar. Students then record the animal's weight by dragging a point to construct a vertical magnitude bar with a numeric readout. On Screen 3 (Figure 1b), students are prompted to order five animals from lightest to heaviest given five vertical magnitude bars. Three of the magnitude bars are copied over from their construction on Screen 2 and include a numeric readout, but the other two magnitude bars represent the weight of new animals and do not have numeric readouts. When students select an order and press the ‘Check It’ button, the vertical magnitude bars are dynamically rearranged to reflect the student’s selection and evaluative feedback (a green checkmark) appears next to the animal names in the list if they are in the correct location within the list. Screens 4 and 5 follow a similar design but with opportunities to measure habitat temperature by dragging a temperature probe into each enclosure and then recording values on horizontal magnitude bars.

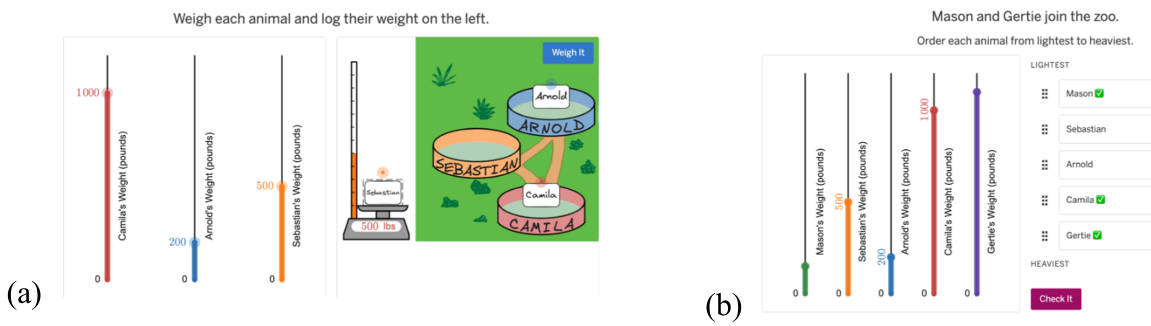

Figure 1: (a) Screen 2, and (b) Screen 3 of the redesigned Zoo Task.

An Initial Conjecture Map for the Redesigned Zoo Task

Recall, our high-level conjecture is that repeated occasions to draw explicit connections between meanings for situational quantities (SQR) and meanings for graphical quantities (GQR) is critical for development toward EGST. To test that conjecture, we need students to (1) develop SQR, (2) develop GQR, and (3) bridge SQR and GQR meanings. Due to space constraints, we report on the opening sequence of the zoo task that we intend to support students in developing the first level of SQR, the first level of GQR, and bridging between those two meanings.

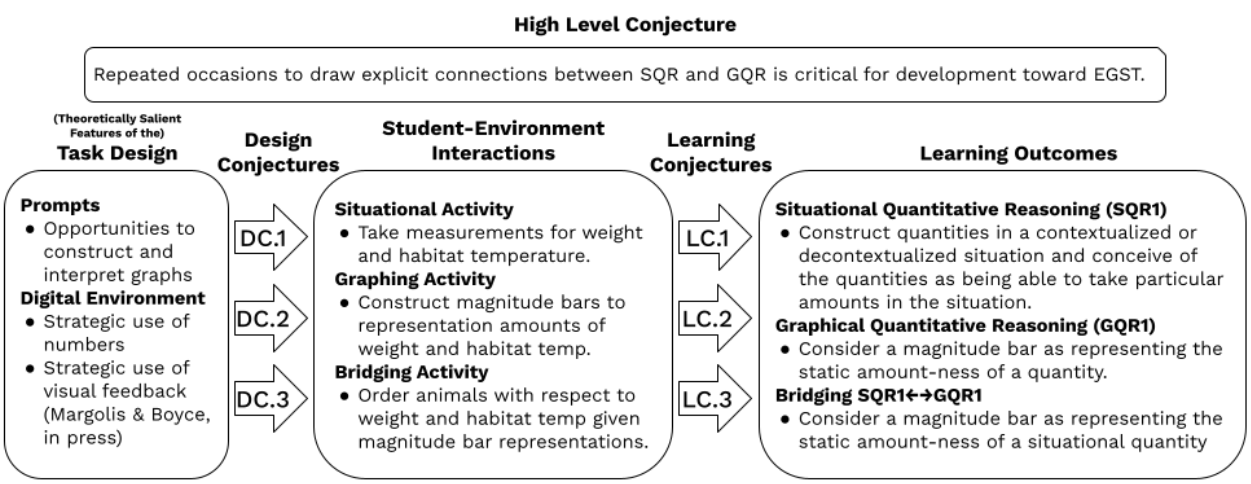

Figure 2: An initial conjecture map to guide the redesign of the Zoo Task.

To support SQR1, we theorized that directly measuring weight and habitat temperature for several animals supports students in conceiving of an attribute of the animals (i.e., heaviness;

hotness) as being measurable (i.e., having an amount and a unit) (LC1; see Figure 2). To support GQR1, we theorized that constructing magnitude bar representations to record particular values would support students in understanding that the length of a magnitude bar represents an amount-ness (e.g., longer bar = larger amount) (LC2). Furthermore, using the magnitude bars to represent particular amounts of weight and habitat temperature derived through direct measurement can help students bridge SQR1⟷GQR1 (LC2). Lastly, we theorized that ordering animals with respect to a situational quantity (weight or habitat temperature) when provided with information about those quantities via magnitude bar representations would support SQR1⟷GQR1 because students would have to set a goal related to the situation (e.g., determine which animal weighs the least) and then use information from the graphical representation to achieve that goal (e.g., which magnitude bar is the shortest) (LC3).

The observable interactions between student and digital environment that are necessary for testing these learning conjectures are listed in the middle column of the conjecture map. Students need to (1) directly measure the weight and habitat temperature of several animals (toward LC1), (2) construct magnitude bar representations of particular weight and habitat temperature amounts (toward LC2), and (3) interpret magnitude bar representations to order animals with respect to weight and habitat temperature (toward LC3).

Next, we developed design conjectures that link the theoretically salient aspects of the task design to the production of desired student-environment interactions. Our goal was for this activity to be a stand-alone digital activity, so we wanted students to be able to directly measure the weight and habitat temperature of zoo animals *within* the digital environment. We theorized that we could design student-environment interactions that emulate direct measurement by coordinating available actions (i.e., drag to the scale and click 'Weigh It') and visual feedback (i.e., "bouncing" on the scale) (DC1). To support students in constructing magnitude bar representations of particular amounts of weight and habitat temperature, we theorized that strategic use of numbers could support students in linking the result of direct measurement in the situation with their understanding of magnitude bars as representing amounts (DC2). The reification of this design conjecture can be seen in Figure 1a where the 500 pounds can be seen as the dynamic label on the magnitude bar representing Sebastian's weight as well as the result of measuring Sebastian's weight on the scale. Our final design conjecture is that strategic use of numbers and strategic use of visual feedback (Margolis & Boyce, in press) can support students in utilizing magnitude bar representations to order animals with respect to weight and habitat temperature (D3). Specifically, when we prompt students to order animals (Screens 3 and 5; Figure 1b), they can view the magnitude bars with numeric readouts for the three animals that they measured on Screens 2 and 4 but are not provided with numbers for the two new animals. We anticipate that this strategic use of numbers will result in students' reasoning about the bars' lengths rather than reasoning about the relationship between values. After students select an order and press the 'Check It' button, the magnitude bars dynamically rearrange to reflect the order of their list. When a student has the animals out of order (as in Figure 1b), we anticipate that the reordered magnitude bars will be useful for reasoning about the necessary adjustments.

Discussion & Future Work

We posit that conjecture mapping is a useful tool for studying the complex links between task design and mathematics learning. Our initial conjecture map serves as a preliminary theoretical framework with testable conjectures about how to design digital tasks that support 6th grade students in developing SQR1, GQR1, and SQR1↔GQR1. Future work can focus on empirically verifying the design and learning conjectures from this conjecture map. Additional work can focus on whether and how the development of SQR, GQR, and SQR↔GQR support the development of EGST. Such research could lead to the development of curricular materials that alleviate student struggles with graph construction and interpretation important for their future in advanced coursework and as critical citizens.

This study examines the preparation of prospective teachers (PSTs) in teaching secondary mathematics with technology. It compares the assessment of PSTs' preparedness using two constructs: Vision of High-Quality Mathematics Instruction with Technology (VHQMIw/T) and Technological Pedagogical Content Knowledge (TPACK). To unpack this, we explore the journey of Avery, a prospective secondary teacher, within the context of Teaching Secondary Mathematics with Technology course. The study finds that while TPACK focuses on technological integration, VHQMIw/T may offer a more comprehensive understanding of PSTs' preparedness, especially in envisioning instructional practices with technology. The authors recommend using both constructs to assess PSTs' preparedness effectively.

Keywords: Instructional Vision, Preservice Teacher Education, Technology

The field of mathematics education has long agreed on the importance of secondary mathematics teachers being prepared to support students' learning of mathematics using technology that supports students' mathematical reasoning and sense making (ISTE, 2000, 2017; AMTE, 2017, 2022; NCTM, 2014, 2023). However, assessing the development of prospective mathematics teachers (PSTs) toward this goal is difficult (e.g., Abbitt, 2011). Researchers have called for the use of PSTs' instructional vision (Hammerness, 2001) to assess the development of their pedagogical practices during teacher preparation programs (Fieman-Nemser, 2001; Arbaugh et al., 2021). Munter (2014) described instructional vision as "ways of seeing the world that encompass horizons not yet reached" (p. 587). While instructional vision has been shown to be a helpful construct to assess PSTs' preparedness to teach mathematics (e.g., Arbaugh et al., 2021; Walkowiak, et al., 2015), to date there is scant research on the use of instructional vision to assess PSTs preparedness to teach mathematics with technology. Rather, the most common way of assessing PSTs' preparedness to teach with technology is through attending to the development of their specialized knowledge for teaching mathematics with technology referred to as technological pedagogical content knowledge (TPACK; Mishra & Koehler, 2006). The purpose of this paper is to compare and contrast what we can learn about PSTs' preparation to teach secondary mathematics with technology through attending to these two constructs, vision of high-quality mathematics instruction with technology (VHQMIw/T) and TPACK.

Theoretical Frameworks

Our approach to preparing PSTs to teach mathematics with math action technologies (MAT: Dick & Hollebrands, 2011) suggests two different ways of framing, and assessing, their development, 1) attending to the development of their VHQMIw/T or 2) attending to the development of their TPACK. We describe both theoretical approaches in the sections that follow.

VHQMIw/Tech

Instructional vision is a discourse that teachers (including PSTs) "employ to characterize the kind of ideal classroom practice to which they aspire but have not yet necessarily mastered" (Munter & Wilhelm, 2021, p. 343). As such, one's instructional vision is an expression of their appropriation of the principles, frameworks, and ideas about teaching and learning that they have encountered through their personal and professional learning experiences (Munter & Wilhelm, 2021). Munter (2014) described a specific vision of mathematics instruction deemed "high-quality" that is aligned with the literature on effective mathematics instruction, guiding frameworks in mathematics education (e.g., NCTM, 2014) and data collected from the Middle School Mathematics and the Institutional Setting of Teaching project (Cobb & Smith, 2008). As our work is in the context of using MATs, we refer to discourse about high-quality mathematics instruction that incorporates MATs in ways that are aligned with the literature on effective teaching with technology one's VHQMIw/T.

Like Munter's VHQMI, researchers have long characterized successful technology integration with a specific vision toward "constructivist, student-centered technology use" that includes "active and collaborative learning through authentic problem solving and knowledge construction" (Kopcha et al., 2020 p. 730). In fact, Kopcha et al. (2020) point out that many of the frameworks used to describe technology integration characterize student-centered approaches as high-quality. Thus, when considering a VHQMIw/T in the context of using MATs, the only real difference from Munter's VHQMI should be in the type of task used during instruction.

To operationalize how closely one's vision is aligned with the specific VHQMI described in the literature, Munter (2014) created three interrelated rubrics: *role of teacher, classroom discourse,* and *mathematical tasks*. Each dimension has its own 5-point rubric indicating a trajectory of VHQMI with 4 as the highest and 0 as the lowest. We extensively adapted the *mathematics tasks* rubric since the curriculum materials used in our work focused specifically on the use of tasks that include MATs. On the adapted VHQMIw/T *technology-enhanced mathematics task* rubric the descriptions are parallel to Munter's. A score of 0 or 1 indicates that the PST does not envision using a MAT and either "does not view tasks as a manipulatable features of classroom instruction" (0) or "emphasizes tech tasks that provide students with an opportunity to practice a procedure before applying it conceptually to a problem" (1). To score a 2 or higher it must be clear that a MAT is being used in the task. A score of 2 emphasizes "'reform'-oriented aspects of MAT tasks [e.g., "explore," "higher-order"] without elaborating on their function in terms of learning mathematics—often more about motivation/engagement", 3 emphasizes "MAT tasks with multiple solution paths, potential for complex thinking/problem-solving, but no emphasis on generalization, connections btw strategies/representations, etc.", and a score of 4 is characterized by an emphasis on MAT use in ways "that have the potential to engage students in 'doing mathematics' Munter (2014, p. 633)".

TPACK

Researchers in teacher education have built upon Shulman's (1986) notions of teachers' pedagogical content knowledge (PCK). Grossman (1989, 1990), Even (1990), and Hill et al. (2008) drew upon ideas of PCK and further delineated specific constructs for mathematics within PCK. However, none of this work considered the knowledge that comes with teaching mathematics with technology. In 2005, Niess adapted Grossman's (1989, 1990) components of PCK to take technology into consideration and referred to technology-enhanced PCK. In 2006, Mishra and Koehler identified such knowledge as TPACK. The TPACK framework describes the type of knowledge teachers need to understand how to use technology effectively to teach specific subject matter. In 2013, Neiss identified four components of TPACK with detailed descriptors and claimed they provide insight for "developing a transformed knowledge [of] (TPACK)" (p. 196). These four components: "(1) an overarching conception of what it means to teach a particular subject integrating technology in the learning; (2) knowledge of instructional strategies and representations for teaching particular topics with technology; (3) knowledge of students' understandings, thinking, and learning with technology in a particular subject; and (4) knowledge of curriculum and curriculum materials that integrate technology with learning in the subject area" (Neiss, 2005, p. 511) capture the skills teachers need to develop TPACK.

Many strategies have been used to assess TPACK including teacher interviews, team planning and classroom observations, self-reported surveys, open-ended questionnaires, and performance-assessment instruments (Mouza et al., 2014). Studies that use validated instruments to assess performance-assessments or artifacts of teaching have proven quite useful (e.g., Harris et al., 2010; Hofer et al., 2011; Lyublinskaya & Tournaki, 2012) in providing a glimpse into teachers' TPACK applied in their classrooms. Lyublinskaya and colleagues used the four levels as a guide to develop a validated TPACK Levels Rubric (Lyublinskaya & Tournak, 2012; Lyublinskaya & Kaplon-Schilis, 2022) used to code teachers' technology-enhanced teaching artifacts (e.g., lesson plans) for evidence of their TPACK.

Lyublinskaya and Tournak's (2012) rubrics include five levels of TPACK development (1-Recognizing, 2-Accepting, 3-Adapting, 4-Exploring and 5-Advancing) which are applied to each of Neiss' (2009, 2013) four components of TPACK. At the lowest level, 1-Recognizing, teachers use technology as a motivational tool, not to support students' mathematical thinking and are focused on rote practice. At level 2-Accepting, the use of technology is instructor led and focused on teacher delivery of information often mirroring traditional textbook material. For the middle level 3-Adapting, teachers begin to use technology as a source of student inquiry to support students' mathematical thinking under direct teacher guidance and without opportunity for student reflection; math action technologies may or may not be used at this level. At level 4-Exploring, students become the primary driver of explorative technology making full use of math action tools within the technology, however the teacher "still guides the students to see the meaningful consequences of those actions" (Lyublinskaya & Tournak, 2012). At the highest level, 5-Advancing, students are provided opportunities to explore, make conjectures, reflect and develop their own conceptual understanding of mathematical concepts.

Methods

This is an instrumental case study (Stake, 1995) of a single PST, Avery, who participated in a course titled *Teaching Secondary Mathematics with Technology*. Avery was a mathematics major and secondary mathematics education minor. This was the first mathematics specific methods course. The course was designed using principles of practice-based teacher education (Grossman et al., 2009), used curriculum materials from the Preparing to Teach Mathematics with Technology – Examining Student Pracices project [PTMT-ESP], and the course text was *Exploring Math with Technology: Practices for Secondary Teachers* (McCulloch & Lovett, 2024). Throughout the course Avery had many opportunities to engage in high-quality technology-enhanced math tasks as a learner, to analyze the design of these tasks, to analyze video of students and teachers engaged with these tasks, to create technology-enhanced math tasks, and to plan lessons that incorporate technology-enhanced math tasks. Through these experiences, Avery was developing both their VHQMIw/T and their TPACK. Avery was selected as the case for this study because they scored high on both VHQMIw/T and TPACK at the end of the semester, we hoped this similarity would provide insight to what we can learn about a PSTs' preparedness from these two different perspectives. As such, we aim to answer the following research question: What are the similarities and differences in what we can learn about PSTs' preparation to teach mathematics with technology-enhanced mathematics tasks by attending to their VHQMIw/T and their TPACK?

For the purposes of this study, we are focusing on artifacts from the end of the semester to understand Avery's preparation to teach secondary mathematics with technology at that point in time. This includes his description of his VHQMIw/T and a technology-enhanced math task that he created along with its accompanying lesson plan. The data sources and our analysis of them are described in the sections that follow.

TPACK: Data Source and Data Analysis

All PSTs enrolled in the *Teaching Secondary Mathematics with Technology* course along with Avery, were asked to design a technology task and an accompanying lesson plan. In a prior lesson PSTs had engaged in a sequence of approximations of practice related to a Desmos Activity designed to introduce amplitude, midline, and period of the sine function (tinyurl.com/IntroSine). This included anticipating student thinking, noticing student thinking, scripting whole class discussion, and analyzing video of the classroom teacher as she monitored small groups and facilitated a whole class discussion. At the end of this sequence the PSTs were assigned to design a follow up lesson. They had the option to create a task and lesson that either a) provides an opportunity for the students *to further develop* their understanding of amplitude, midline, and period related to sine functions and their graphs, or b) provides an opportunity for her students *to apply* their knowledge of amplitude, midline, and period to a real context through modeling, or c) an investigative task intended *to introduce* phase shift to go along with amplitude, midline, and period. For this assignment, Avery chose option c.

To analyze the tasks and accompanying lesson plans, we used the TPACK Levels Rubric (Lyublinskaya & Tournak, 2012; Lyublinskaya & Kaplon-Schilis, 2022) to capture the PSTs' TPACK levels across the four dimensions: overarching conception, knowledge of student understanding, knowledge of curriculum, instructional strategies. Each dimension has its own 5-point rubric indicating a growth trajectory of TPACK with 5 as the highest and 1 as the lowest. All tasks and accompanying implementation plans were coded by four researchers and then discrepancies were discussed until consensus was reached across the four coders. A composite score was computed (i.e., the sum of the four dimensions).

VHQMIw/T: Data Sources and Data Analysis

Similarly, all PSTs enrolled in the course with Avery responded to a vision prompt adapted from Munter (2014): If you were asked to observe a technology-using math teacher's classroom for one or more lessons, what would you look for to decide whether the mathematics instruction (including the use of technology) was high quality? In your response make sure you describe what you would expect to see/hear from the teacher, students, and mathematical tasks during your observations.

To analyze the PSTs' vision statements, we used our adapted version of Munter's VHQMI rubrics. These rubrics include 3 interrelated dimensions: role of teacher, discourse, and technology-enhanced math tasks. Each rubric indicates alignment with a research informed VHQMIw/T with 4 being the highest, 0 the lowest, and N/A indicating the dimension was not included in the PSTs' vision statement. Like the TPACK analysis, all vision statements were coded by four researchers and then discrepancies were discussed until consensus was reached across the four coders.

Findings

Avery's scores for both VHQMIw/T and TPACK are found in Table 1. Based on the analysis of their vision statement and lesson plan artifacts, Avery would be described as having a VHQMIw/T that is aligned with the literature on effective teaching and learning with technology and TPACK that is aligned with the advancing level of technology integration. In what follows we unpack what we learn from these rubric scores about Avery's preparedness to teach mathematics with technology-enhanced tasks. We begin with VHQMIw/T, then TPACK, and finally we compare and contrast the two.

VHQMIw/T Rubric Scores (max: 4)		TPACK Rubric Scores (max: 5)	
Role of Teacher	4	Overarching conception	5
Discourse	4	Knowledge of student understanding	5
Tech-enhanced math task	4	Instructional strategies	4
		Knowledge of curriculum	5
Composite Score	4	Composite Score	4.75

Table 1: Avery's TPACK and VHQMIw/T Rubric Scores

Avery's VHQMIw/T

When responding to the VHQMIw/T prompt, Avery began by clearly stating their overarching VHQMIw/T and then went on to describe how to achieve that vision. Avery articulated their VHQMIw/T as,

> A high quality, equitable math instruction with technology would include the following: students exploring the mathematics with dynamic math technology, each student/group working with the technology equally, and a lesson designed to incorporate the student's understandings and work into a discussion that furthers the whole-class understanding around the mathematics topic.

In terms of the *role of the teacher*, Avery expanded on this statement by describing that when students are working on a task, a teacher's role is to "ask students assessing questions that help the teacher see students' understanding then ask advancing questions that lead students to a more developed understanding." Avery envisions that an instructor "guides and facilitates, occasionally may need to step in to reach the necessary daily goals, but should almost never directly explain a topic in full without student input." Avery scored a 4 on the *role of the teacher* rubric since they described the teacher's role as more than just a facilitator. By describing that the teacher "should almost never directly explain a topic in full without student input" it is clear that Avery's vision is the teacher as a more knowledgeable other.

With respect to *discourse* Avery also wrote that their VHQMIw/T includes a "full-class discussion around understanding the mathematics." Avery expanded on this stating that "an instructor should facilitate a discussion on the topics using the students' work. This is done through carefully cultivating the responses and ordering them for discussion." Avery went on to explain that a teacher "should lead the discussion by having open-ended questions posed to them that allow them to identify, compare, contrast, and critique the responses." Avery provides concrete images of students learning from each other. Therefore, Avery scored a 4 on the *classroom discourse* rubric.

Finally, with respect to t*echnology-enhanced tasks*, Avery noted that students should explore mathematics and expanded this idea noting that a high-quality technology-enhanced math task "must be dynamic, it must allow students to explore and notice facts and relationships about the topics being presented." Here Avery focused on connections between the mathematical ideas and described a task that would align with "doing mathematics" (Smith & Stein, 1998), therefore Avery scored a 4 on this rubric.

Avery's TPACK

For three of the four components of TPACK – *overarching conception, knowledge of student understanding,* and *instructional strategies* – Avery scored at the advancing level (5). With regard to their *overarching conception*, Avery's lesson plan included a high-cognitive demand (Smith & Stein, 1998), technology-enhanced task built in Desmos Activity Builder. The task focused on developing students' understanding of phase shift and provided opportunities for inquiry and reflection. For example, Avery's task asked students to explore the relationship between the parameters of the sine function when a new parameter was added. Students were then asked to write down what they notice when examining the slider for *h*. This example demonstrates the connection to conceptual understanding through both inquiry and reflection that was seen throughout the task.

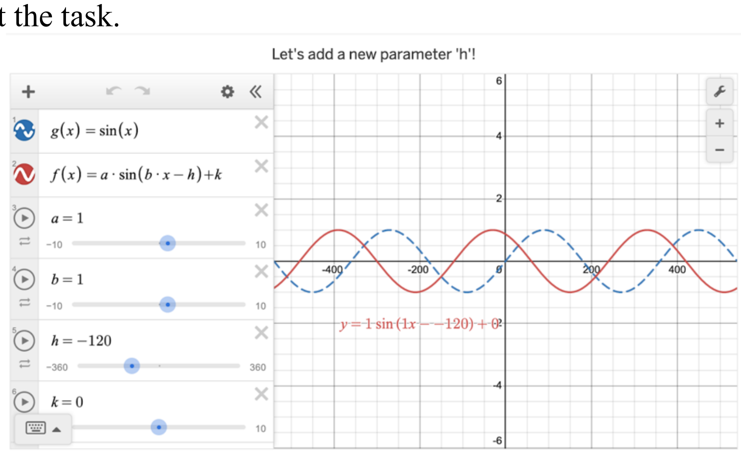

Figure 1: Students could explore the phase shift of the function using sliders

Within *knowledge of student understanding,* Avery's advanced rating of 5 was evident in Avery's task that relied on students taking mathematical actions (using sliders in Desmos) to examine the impact of *h* and *b*, see the consequences of their mathematical actions, and draw conclusions about phase shift (i.e., phase shift = *h/b*) based on these consequences. The lesson plan included how Avery planned to use the resulting student thinking to facilitate discussions and make connections across multiple representations, allowing student thinking to drive the direction of the lesson. For example, Avery included,

> After students have completed the activity, I plan to facilitate a whole class discussion on phase shift. I will ask students to share their noticing looking for…
> - An informal description of how the h slider alters the graph (horizontally shifts)
> - A description of the term phase shift
> - An informal description of the relationship between the slider and phase shift
> - A precisely described mathematical relationship between h, b, and phase shift (direct with h-h/b)

I want to make sure students connect the horizontal shift with phase shift and understand their slight differences…

Avery's advanced rating (i.e., score of 5) for *instructional strategies* was due to the use of sliders within the mathematical task that provided students with an inductive strategy that effectively supported students' exploration of phase shift and included prompts to promote reflection and sense making/reasoning.

With respect to the remaining component, *knowledge of curriculum*, Avery demonstrated an exploring level related to TPACK (i.e., score of 4). This was evidenced in how effectively the task was aligned to the learning and performance goals included in the lesson plan, and how the task provided students an alternative way to explore the mathematical topic (i.e, alternative to using paper and pencil methods) and expand on the mathematical ideas they build with respect to amplitude, midline, and period in the prior lesson through their exploration of the function. Avery's lesson did not score a 5 on the *knowledge of curriculum* rubric because the task did not make connections outside of the curriculum or challenge the traditional curriculum to have students learn different topics.

Comparing and Contrasting Avery's VHQMIw/T and TPACK

Both the VHQMIw/T and TPACK rubric scores suggest that Avery is well-prepared to teach mathematics with technology. What we are curious about is what we learn about Avery's preparation from each of these measures. We begin with the more commonly used construct, TPACK.

Since Avery was in a class focused on teaching mathematics with technology and the lesson planning assignment at the end of the semester required the inclusion of a technology-enhanced task that included a MAT, as long as they created a lesson that met the requirements of the assignment his TPACK rubric scores were going to all be 3, 4 or 5, leaving little room for variability. The TPACK rubrics highlight that Avery is well-prepared to design a high-cognitive demand technology-enhanced task, aligned with learning goals, that provides ways for students to interact with the mathematical objects and prompts them to both explore and reflect. However, we know less about how Avery plans for students and teachers to interact with each other when engaging with the task. The *knowledge of student understanding* and *instructional strategies* rubrics do indicate that the teacher plans to facilitate students' use of the technology in ways that lead to deep understanding of mathematics, and that they will use both deductive and inductive strategies to do so. So there is a sense from the rubric scores that Avery will carefully facilitate the implementation of the technology-enhanced task and resulting whole-class discussion, but this does not provide insight to how Avery's hypothetical students will interact with each other's ideas.

In contrast, the VHQMIw/T rubrics provide insight to not only what Avery envisions a high-quality technology-enhanced math task to be, but also provides further details for how Avery envisions the teacher and students' interacting around such a task. The *technology-enhanced mathematics task* rubric indicates that Avery designed a task that uses a MAT and is of high-cognitive demand, to score a 4 on this rubric they also had to explain how such a task would support student learning (i.e., function view). This additional explanation is not captured in the TPACK rubric. The *role of the teacher* rubric score indicates that Avery envisions the teachers' role as a more knowledgeable other who is proactively supporting students' learning through anticipating student thinking as part of the lesson planning process and then during the lesson, using student work to drive whole class discussions around the important mathematical concepts and connections. Thus, Avery is not only planning to use deductive and inductive strategies as indicated in the TPACK rubrics, but is going to leverage the students' thinking to drive the deepening of their understanding. Finally, the *discourse* rubric indicates that Avery envisions students' learning from each other, with the mathematical discourse often being student initiated and students talking to each other, not solely through the teacher. None of the TPACK rubrics capture the nature of the planned discourse.

Discussion and Conclusion

Comparing and contrasting VHQMIw/T and TPACK using Avery's work at the end of a course focused on preparing PSTs to teach secondary mathematics with technology does reveal some differences in what we can learn about PSTs' preparedness using these two constructs. The most striking finding is that the TPACK rubrics do not capture the nature of planned discourse, including how one envisions the role of the teacher during small group and whole class instruction. The VHQMIw/T *role of teacher* and *discourse* rubrics do capture these important aspects of mathematics instruction. In their review of technology-enhanced pedagogy in teacher learning, Zinger et al. (2017) called for less attention to PSTs' use of technological tools and more attention on the role of the teacher in using those tools to address problems of practice. Our findings suggest that VHQMIw/T might be a helpful framing for researchers taking on that work.

PSTs often do not have field experiences in courses in which they are learning to teach mathematics with technology (McCulloch et al., 2021), making assessing TPACK based on their practice difficult. With this in mind, rather than attending to their enacted instruction, researchers have called for attending to PSTs' instructional vision as an indication of their developmental progress during teacher preparation programs (e.g., Feiman-Nemser, 2001), noting that changes in instructional vision often occur before changes in practice (e.g., Munter, 2014). Our findings suggest that the VHQMIw/T rubrics do provide insight into how PSTs envision the design of technology-enhanced mathematics tasks – the main focus of the TPACK rubrics – while also providing insight to how they hope to one day facilitate students' working on such a task.

Based on the findings in this study, we would ultimately recommend using both the VHQMIw/T and TPACK constructs to understand PSTs' preparedness to teach mathematics with technology. However, assessing TPACK as a pre-test is difficult to do when PSTs have yet to be introduced to teaching mathematics with technology (i.e., it is unfair to ask them to design a technology-enhanced mathematics task and accompanying lesson plan when they have not yet been taught how to do so), yet VHQMIw/T can provide insight to what they aspire. It is not uncommon for researchers to use self-reported TPACK measures like self-efficacy or beliefs as pre/post measures alongside TPACK as post measures (e.g., Akapame et al., 2019). We recommend attending to instructional vision over other self-reported measures as the latter "suggest a relatively static set of decontextualized ontological commitments" and "vision is intended to communicate a more dynamic view of the future" (p. 587). To further compare these two constructs, future work following PSTs into the field to study how their VHQMIw/T informs their practice and whether or not their practice aligns with their VHQMIw/T and enacted TPACK would be useful.

INSIGHTS FROM A CASE STUDY OF AI-INTEGRATION IN UNDERGRADUATE MATHEMATICS

Nirmala Naresh
University of North Texas
Nirmala.naresh@unt.edu

Ellen Li
University of North Texas
ellenli@my.unt.edu

Keywords: Undergraduate Education, Computational Thinking, Technology, Modeling.

AI's influence in mathematics education is growing rapidly with the expansion of new technologies and AI tools. Researchers argue that a deeper study of AI's role in mathematics classrooms is needed to unlock the full potential that technology offers (e.g., Aleven et al., 2023; Gattupalli et al., 2023; Aljarrah & Towers, 2022). In this paper, we share preliminary findings from a study exploring the impact of the AI-powered guide, Khanmigo, on undergraduate students' mathematical learning. Participants completed four tasks drawn from the History of Mathematics (Katz, 1988) and four focused on mathematical modeling (Erbas et al., 2016).

Methods

We chose a case study methodology (Stake, 2000), investigating individual cases (undergraduate students) to address the overall research goal. In this poster, we present findings related to one student's (second author, Li) interactions with Khanmigo specific to this task: *At their last concert, Oscar & the O's sold 2200 tickets for $32 each. The promoter believes that a $1 decrease in the price of a ticket will attract 50 more listeners. Oscar points out that charging $1 more per ticket is just as likely to drive away 50 people. The promoter wants your help to determine the ticket price that will bring in the most money.* Data collected and analyzed include Li's individual response to the task, solution based on her interaction with Khanmigo, and reflections on the task engagement with the AI-tool. Li used the tool for brainstorming ideas, generating suggestions, and seeking clarification on challenging concepts.

Li's engagement with the AI tool is characterized by a progressive exploration of generalized topics related to optimization. Her prompts to the tool evolve gradually, becoming more refined based on the responses received. Khanmigo plays a pivotal role in shaping the conversation's direction by posing questions that prompt Li's thinking and assess her current understanding. An example of this is when the tool inquires, "Do you know what a 'constraint' is in this context?" and follows up with, "Can you think of a situation where you might have a constraint?" The subsequent clarification and the query, "Does that make sense?" demonstrates the tool's role in gauging Li's mathematical understanding. This interactive dynamic underscore the AI tool's function not only as a source of information but also as a supportive tool facilitating hands-on problem-solving and conceptual understanding. However, there was a specific instance when Khanmigo failed to catch the Li's mathematical mistake until she pointed it out. In a classroom setting, this oversight can mislead the learner into thinking that their answer (and thought process) is correct, when in reality, it is incorrect. This hinders the learning process and is counterproductive rather than facilitating. Khanmigo's inability to present graphs and other drawings presents another challenge.

In summary, the above findings demonstrate how an AI tool can be effectively used as a collaborator in the learning process. While Khanmigo has the potential to serve as both an amplifier and reorganizer (Pea, 1985), using it cautiously as a reorganizer proves to be the most effective approach to leverage its AI capabilities, considering the potential modification of Li's thinking processes in this context.

Recent recommendations from national organizations on advancing mathematics education underscore the necessity of integrating artificial intelligence (AI) in the classroom for empowering students. It is necessary to move past the question of "Why use AI" and focus on "How to use AI", "What tools are conducive for AI learning", and "When to use these tools". This shift is necessary for developing a broader and a deeper understanding of the use of AI in mathematics classrooms. In this paper, we feature key findings from a longitudinal case study aimed to explore, understand, and analyze the interactions unfolding between undergraduate teacher education students and an AI tool (ChatGPT) during their engagement with mathematics modeling tasks. We highlight specific findings related to a specific modeling task and describe key aspects of learner-AI engagement.

Keywords: Undergraduate Education, Computational Thinking, Technology, Modeling, Geometry and Spatial Reasoning.

With the rise of new technologies and AI tools, the influence of AI in mathematics education is growing, leading to a current debate within the educational community about if and how AI should be integrated within mathematics education (Kovács et al., 2022, p. 23). AI tools have the potential to transform how learners engage with mathematical tasks (Hwang et al., 2020); however, this requires a comprehensive understanding of AI's nuances and its effective integration within existing curricular and pedagogical frameworks and finding ways to support teachers and learners in the effective and responsible use of AI tools (Celik et al., 2022; Hwang & Tu, 2021). The authors are engaged in a longitudinal research project, aimed to explore the role of AI use in mathematical classrooms, specifically focused on how prospective mathematics teachers (PMTs) engage with AI as 'learners' of mathematics. The primary objective of this research is to explore, understand, and analyze the interactions unfolding between learners and AI tools as they engage with cognitively demanding mathematical tasks. This paper particularly discusses the interactions between learners (PMTs) and Chat Generative Pretrained Transformer (chatGPT) during their engagement with a mathematics modeling task.

Our working definition of AI is that it is a network of "computational systems that simulate human intelligence in machines to reason, learn, and act on complex tasks" (Copur-Gencturk et al., 2023, p.4). ChatGPT, a natural language processing model, has been found to have the potential to assist with both the teaching and learning of mathematics. Teachers use it for various purposes such as lesson planning, student assessments, and providing feedback (Crust, 2023; Firat, 2023; Wardat et al., 2023). Moreover, the chatbot can support learners in generating explanations, answering queries, and engaging in interactive problem-solving related to mathematics (Guo et al., 2023).

Proponents of activity theory (e.g., Vygotsky 1978; Leontiev, 1978) emphasize the central role tools play in mediating human activity. The theory highlights the notion that the relationship between the subject and object is mediated through a tool. Using Activity Theory to investigate learner engagement with AI involves analyzing how the tool-mediated relationship between the subject and the object influences the learning process. In the present context, the subject is the learner, the object is the AI technology, and the mediating tool is the specific AI application (e.g., a chatbot) used for learning. The term "tool-mediated" suggests that tools, whether physical or intellectual, act as facilitators in the relationship between the learner, mathematics, and technology highlighting the importance of these tools in mathematics classrooms.

Methodology

We use a case study methodology (Stake, 2000; Yin, 1994), specifically, an instrumental case study approach to address the research goal. We intend to shed light on a particular phenomenon: the nature of learners' interactions with chatGPT as they engage with a mathematical modeling task. By investigating individual cases (learners), we seek to show how the phenomenon itself could be described, and hence an instrumental case study is appropriate. In this paper, we focus on a subset of data collected for the longitudinal case study.

The geographical context is a large south-western university in the United States. The study setting is a mathematics course for middle school and secondary PMTs - Advanced mathematics from a secondary perspective. Fifteen PMTs engaged with middle school and high school-level topics, including algebra, geometry, and calculus. Within this course, the first two authors developed a course project to explore AI's role in mathematics learning. PMTs completed various activities, beginning with a survey aimed at gathering their initial impressions on the topic. Following this, they researched AI tools applicable to mathematical contexts and completed three mathematics modeling tasks outside of regular class hours. In this paper, we present data specific to the following task (Figure 1).

A company that produces canned food needs short-term storage to store the cylinder-shaped can it produces. The company wants to do this with the least possible cost. Each of the right circular cylinders can be kept 10 cm in radius and 30 cm in height. The company plans to store 175 cans for 2 months. There are 3 different sizes of storage cabinets that the company can store. The rental costs are shown in Table 1 according to the dimensions of base of the storage cabinets, each of which is 100 cm high.

Table 1. Size of the storage cabinets and costs

Width (cm)	Length (cm)	Rental Cost per Month ($)
110	110	100
110	220	150
110	330	200

a. If you were the company owner, in what way(s) would you use which storage cabinet to minimize the cost?
b. The company may need to store different numbers of cans in future production. For this, would it be appropriate for the company to always use the same type of storage cabinets? What do you suggest? Why?
Please note that keeping the cans in an upright position is important for the safety of the storage.

Figure 1: The Mathematical Task (Erbas et al., 2016)

Data collected and analyzed include PMTs' responses to the task, documented interactions with the AI tool, and their reflections on task engagement. Emphasizing inclusivity and ease of use, we allowed learners to self-select the AI tool. During their AI interactions, PMTs were advised to a) use prompts for brainstorming instead of directly seeking answers and b) encouraged to independently solve problems first before collaborating with the AI tool for alternate solutions. The first and the second authors independently read and coded PMTs' interactions with the AI tool, cross-checking their findings. Elsewhere, we have presented a framework that represent levels of learner engagement with AI from foundational recall to creative exploration of mathematical ideas (Naresh et al., 2024). In this paper, we provide a brief synopsis of one case Manu (a pseudonym) – as an illustrative example that highlights a creative level of engagement with AI.

Results

Manu took a distinctive approach by prompting AI to create a recommended table of variables essential for solving the task. After transcribing the AI-generated variables onto the board, Manu analyzed the information, generating initial ideas for solving the task (Figure 2).

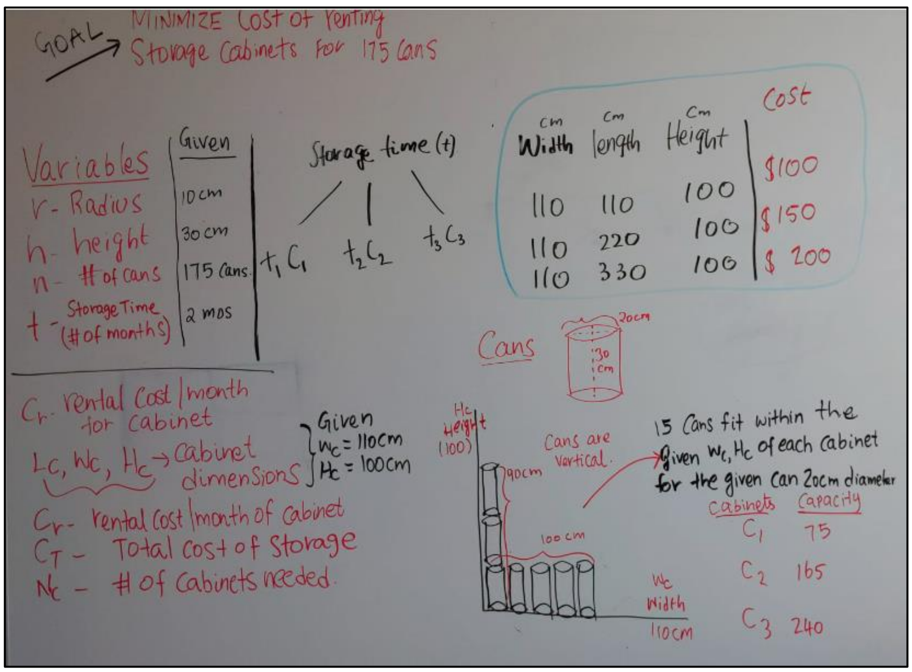

Figure 2: An Overview of Manu's Solution Process

Manu used multiple representations in the solution strategy, illustrating how each can would be positioned and stacked in the storage unit. Using the table, Manu calculated the number of cans each storage unit could accommodate. Next, Manu inquired about an alternative way to model the situation for determining the most cost-effective storage unit, specifically prompting the chatbot to "*act like the college professor and to provide guidance rather than a straightforward answer*". The bot responded with suggestions, including formulating equations to express the volume of a single can and the volume of the storage unit. Manu, recognizing the rigid dimension of the cans, opted for a "Guess and Check method". She calculated the cost associated with using a single storage unit multiple times (e.g., using unit 1 three times costing $300/month) or a combination of multiple units (such as units 1 and 2 together costing $250/month), ultimately choosing storage unit 3 as the most cost-effective option.

Transitioning to modeling for varying number of cans, Manu recognized the problem as an optimization challenge and proposed a simple function to the chatbot. Manu received a set of instructions and identified the following guidance as the most helpful: "*Ensure Minimization: Confirm that the objective is framed as a minimization problem. The goal is to typically minimize the total cost, so the objective function should reflect this"*. Further advancing the inquiry, Manu prompted the chatbot to write code in MATLAB (a programming and numeric computing platform) using the optimization toolbox to mathematically model the situation. After an interactive conversation with chatGPT, debugging the generated code, and testing it in MATLAB, Manu successfully developed a code that recommends the least costly option for storing any number of cans. Reflecting on the practical implications, Manu highlighted the potential real-life application of the code, envisioning a program that allows customers to input the number of cans and receive cost-effective storage recommendations.

Discussion

Manu's engagement surpassed immediate problem-solving by extending into the generalization of mathematical concepts and processes, yielding additional outputs. To further discuss the dynamics between the subject, object and the mediating tool, we turn to Activity Theory. Manu's thoughtful consideration of various solution approaches indicates an activity where understanding the task and exploring potential solution pathways take precedence over immediate task completion. Manu's engagement involves a broader exploration of the task's context before narrowing down to specific mathematical ideas. The progression from a general understanding of the task to a focused engagement with mathematical content suggests a dynamic interplay between the learner, the AI tool, and the evolving understanding of the task. These nuanced engagements highlight the varied depth and creativity in interactions with the AI, offering insights into the potential for more thorough and constructive engagements.

Conclusion

Our findings have significant implications for teaching and research, indicating potential lines of inquiry for further exploration. For teaching, we noted that the AI tool enhances dynamic learning but requires proactive engagement from learners, and incorrect answers or self-corrections necessitate caution for those with varying mathematical understanding. Additionally, the use of AI outside the classroom limits the instructor's ability to monitor adherence to guidelines, with some learners treating the AI as a tutor rather than a collaborator. This highlights the need to further explore AI integration methods, classroom dynamics, pre-AI engagement, and the instructor's role (NCTM, 2024). In our research, we recognize the need to examine how learners interact with AI across various content domains and problem types. Investigating the instructor's role can add new dimensions to our study, providing further insights. Conducting semi-structured interviews will help us understand learners' thought processes and metacognitive factors. Additionally, examining the experiences of prospective teachers with AI tools can offer insights into AI's role in future classrooms.

HOW ARTIFICAL INTELLIGENT TOOLS USE IN MATHEMATICS EDUCATION MEET OR FALL SHORT OF ESTABLISHED EQUITY (IDENTITY) DEFINTIONS: THE CASE OF PHOTOMATH

Emmanuel Nti-Asante
Florida International University
entia001@fiu.edu

Research (Eubanks, 2018; Holstein & Doroudi, 2022) offers insights into how the use of AI tools can exacerbate or ameliorate historical issues such as inequities experienced by non-dominant groups, particularly in Artificial Intelligence Education (AIED). Despite the National Council of Teachers of Mathematics [NCTM] (2024) call for such research in Mathematics Education, few studies exist. Findings from a deductive analysis of video transcripts (Powell et al., 2003) from three comparative case studies conducted over three months in rural, multilingual, technologically constrained, low socio-economic community and school settings in Ghana contribute to this research. As shown in Figure 1, these findings offer insights into how AI tools used for teaching and learning mathematics either meet or fall short of established definitions of equity, particularly concerning students' identity (Gutierrez, 2007). As AI tools in AIEd often exacerbates existing inequities concerning language identity by being trained primarily on mainstream dialects (Holstein & Doroudi, 2022), so are they in mathematics education. Contrary to the lack of flexible customization in AI tools in AIEd, which worsens existing one-size-fits-all pedagogies (Nye, 2014), AI tools in mathematics education explainability's mitigate this. These findings involve five high school students, five parents with two being francophone speakers, a mathematics and AI researcher who integrated the free mobile version of PhotoMath for differential calculus.

Figure 1: AI Tools in Mathematics Education Meeting or Falling Short of Established Equity (Identity) Definitions

Established equity (Identity) definitions in Mathematics Education	AI Tools Meeting Established equity (Identity) definitions in Mathematics Education	AI Tools Falling short of Established equity (Identity) definitions in Mathematics Education
1. Students engage in mathematical tasks according to their preferences, including algorithms and strategies to solve problems (Gutierrez, 2007; Myers, 2014). 2. Students maintain and draw upon cultural and linguistic capacity during mathematics	1. Students had the autonomy to select their preferred Photomath explanability such as step-by-step solution, promoting inclusivity and accommodating diverse learning styles. 2. In the out of school context, Francophone parents actively engaged with teachers and students, utilizing Photomath's French	Photomath support is limited to mainstream dialects such as Spanish, French, and English, commonly taught in Ghanaian schools. This restriction excludes Ghanaian dialects, restricting students' ability to connect with mathematics through their linguistic repertoire and hindering teachers' capacity to adapt to local contexts.

learning (Gutierrez, 2007).	interface to support students learning.

ENHANCING TRANSPARENCY AND INTEGRATION: EXPLORING PHOTOMATH'S EXPLAINABLE FEATURES IN MATHEMATICS EDUCATION

Emmanuel Nti-Asante
Florida International University
enti001@fiu.edu

The integration of Artificial Intelligence (AI) tools in mathematics education is growing, but many tools lack transparency in their outputs. Updated versions of AI tools such as Photomath have incorporated explainable features to improve user comprehension. This paper offers insights into Photomath's explainable features under two areas: technique and practice related. Technique-related comprises the descriptions of available explainable while practice-related covers how they impact users. Findings from the video transcript of a three-month project integrating Photomath into a differential calculus curriculum show that its explainable, such as the embedded dictionary, can impact teachers' mathematics curriculum decisions, amplify equitable mathematics practices, develop students' mathematics communication skills, and provide insights into algorithmic bias, depending on the teacher's instrumental orchestration.

Keywords: Technology, Instructional Vision, Instructional Activities and Practices, Instructional Leadership

Introduction

Fey (1989) identified key areas, including connections to Computer Science and Mathematics Curricula, Artificial Intelligence, and Machine Tutors, as focal points for research into integrating technological tools within mathematics education. In 21st-century Mathematics Education, there is a significant shift towards leveraging Artificial Intelligence (AI) tools (Engelbrecht & Borba, 2023; Lagrange et al., 2023; Richard et al., 2023). These are the newest additions to the digital and analogue tools for teaching and learning mathematics, designed to learn and function based on data that simulates human thought processes. The book titled "Mathematics Education in the Age of Artificial Intelligence: How Artificial Intelligence can Serve Mathematical Human Learning” by Richard et al., (2023) outlines three key areas of focus within this transition: encompassing the process of creating AI in mathematics, examining the integration of AI in learning and investigating the role of AI in optimizing current and future learning based on insights from empirical research.

This paper focuses on the second and the third focal point: the integration of photomath explainable features in the teaching and learning of mathematics and how they can enhance certain teaching practices. Photomath is an AI tool designed to recognize, extract, and solve handwritten as well as printed text mathematical problems using computer vision technology. Photomath's explainable features mainly consist of alterable and non-alterable interfaces, including step-by-step solutions, embedded mathematical dictionaries, variants of mathematical formulas, and approaches to tailor a specific generated solution to offer users an explanation for its output. Among the array of AI tools in mathematics education, Photomath is emphasized for two reasons. Firstly, due to its widespread adoption, with over 220 million downloads worldwide, addressing 2.2 billion problems monthly, and being utilized by over 1 million teachers (Photomath, 2023). Secondly, due to its updated features such as explainability’s aimed at overcoming some of its documented challenges.

In the second section of the paper, a snapshot of the literature documenting challenges with the integration of AI tools such as Photomath for teaching and learning is presented. The third section continues with an insight into the updated features in Photomath aimed at mitigating some of these challenges. The fourth section explores how mathematics educators can instrumentally orchestrate some of these updated features to inform important mathematical practices.

Challenges with the Integration of AI Tools for Teaching and Learning

An artificially intelligent (AI) tool is a software or hardware application that simulates and performs tasks or functions typically associated with human intelligence, such as learning, problem-solving, perception, and decision-making (Zawacki-Richter et al., 2019). Frequently, users remain unaware of the explainability (the extent of understanding regarding how the AI-based system produces specific outcomes) (ISO, 2020). Consequently, scholars argue that this lack of transparency in AI tools renders complex mathematical concepts seemingly irrelevant for students (Newman, 2014). Despite ChatGPT's advanced capabilities as a chatbot model trained on the large language model Generative Pretrained Transformer (GPT), enabling it to handle a broad variety of text-based requests through vast volumes of data (Azaria et al., 2023; Lund, 2022), Bliss (2023) observed its lack of transparency. She stated that that while AI assisted tools such as the large language model Generative Pretrained Transformer (ChatGPT) can aid in delivering information to learners, it cannot think for them or facilitate genuine learning. Bliss expressed concern that students often rely on AI as a quick solution for instant answers, rather than engaging in critical thinking or retaining knowledge, even as educators strive to foster interest and skill acquisition in various subjects. Her concerns are rooted in the premise that human intelligence is innate, developing naturally as we interact with others, contemplate the world, and strive to enhance our connection to it.

In mathematics education, Webel and Otten (2015) discuss concerns regarding the utilization of the Photomath app, noting that "In conceptual problems, Photomath can assist only with computations; it cannot generalize the patterns" (p. 370). They propose potential responses, including banning access, restricting access, or considering a different division of labor. Capinding (2023), citing Muslimah et al. (2023) and Latham (2020), suggests that students may struggle to grasp essential concepts when learning mathematics via Photomath since it provides opaque generated answers instead of the pen-and-paper approach where students engage in manual and transparent calculations. This could lead to an insufficient foundation for future learning, as some may opt for convenience by relying solely on Photomath (Capinding, 2023, p.3). In their 2024 position statement on AI, the National Council of Teachers in Mathematics [NCTM] highlighted concerns about bias in AI tools' training data, which sometimes can lead to amplifying existing inequities faced by non-dominant groups. For instance, in our use of Photomath for differential calculus, we found that Photomath support is limited to mainstream dialects such as Spanish, French, and English, commonly taught in Ghanaian schools (Nti-Asante, 2024). This exclusion of Ghanaian dialects reinforced existing challenges in the study context, where students are restricted from connecting with mathematics through their linguistic repertoire, perpetuating known challenges faced by multilingual students.

Mitigating Challenges with AI Tools for Teaching and Learning

To address challenges associated with AI integration, researchers, policymakers and AI tool making companies have outlined possible approaches. Cox (2020) advocates for educators to cease adversarial engagement with available technology, urging instead an acceptance of its presence and the exploration of ways to leverage it for students' benefit. In line with this, the NCTM advises educators to develop assessments that diminish reliance on computation while fostering problem-solving skills. They stated this approach positions students to critically engage with AI-generated outputs, aiding in the identification of potential biases.

Recognizing the significance of these challenges, AI tool developers such as Photomath have taken proactive steps to ameliorate them. They have introduced updated features, including alterable and inalterable explainable features, aimed at providing users with comprehensive explanations for generated outputs. Due to the profound insights offered by explainability's in tackling challenges faced by users of AI tools, there has been extensive research on the techniques and practices associated with them (Wang et al., 2023). According to Wang and colleagues, technique-related research provides users with an understanding of the various explainability's integrated into a specific AI system and its applications, while practice-related research primarily focuses on evaluating the impact of AI-powered tools' explanations on users. In the subsequent sections, I explore both the techniques and practice aspects of Photomath's explainability's to inform research in the mathematics education community.

Technique Aspect of Photomaths Explainability

The integration of explainability in AI corresponds to teachers' authentic provision of explanations regarding students' task performance, improvement suggestions, self-monitoring prompts, and affect-level comments (Hattie & Timperley, 2007). Khosravi et al., 2022 categorized AI technique related explainability into two main criteria: global approaches vs. local approaches and self-explanatory models vs. post-hoc explanations.

These explanations, generally fall under User-Alterable and Inalterable. User-alterable explainability features empower users to customize and interact with explanations based on their specific needs, while inalterable explainability delivers fixed, predefined explanations by the AI tool that users cannot modify. Photomath incorporates various types of inalterable explainability to enhance user understanding and trust in its system. Global explanations provide users with an overall approach and methodology used by Photomath when solving mathematical problems, contributing to a more comprehensive understanding of its workings. This is evident in Photomath's step-by-step solutions and math concepts tutorials. Self-explainable features offer clear and understandable explanations for their decisions and actions without requiring additional external explanations. These features are exemplified by Photomath's AI-generated explanations and hints for each problem, as well as its proprietary Animated Tutorials, which utilize AI audio voiceover paired with video explanations. Post hoc explanations are provided after the Photomath system has made a decision or taken an action, aiming to clarify and justify its behavior. Users can see this in Photomath's aftermath problem-specific explanations and error analysis, which offer opportunities to delve deeper into the solution process with additional "how" and "why" tips provided. Photomath's alterable explainability focuses on local explanations, which explain how the system works with different inputs and explores alternative solutions to demonstrate how changes affect specific decisions or predictions for inputs or instances. This includes integrating interactive elements, such as buttons and settings, allowing users to select their preferred type of representation for a solution, choose the languages to present their solutions, and explore animated, step-by-step instructions to solve equations—a visually engaging method for learning. The smart calculator feature enables users to input or modify scanned equations via an intuitive math keyboard to experiment with alterations, gaining a more profound comprehension of mathematical problems. Photomath also utilizes graphs to illustrate equations, enabling exploration of graph details like the root, domain, and interpretation of equation solutions. Moreover, Photomath employs Knowledge Graph Embeddings (KGE) models to map and relate mathematical concepts to real-world applications, such as students' home languages. Users can access the embedded Math Dictionary to learn the correct terminology, meaning, and translation by tapping on highlighted vocabulary terms. Photomath also detects mathematical word problems and translates them into equations and other mathematical representations.

Practice Aspect of Photomaths Explainability

Existing practice-related research on AI tools' explainability primarily focuses on their potential to offer explanations for their outputs and how that impacts users' trust in these outputs (Brdnik et al., 2023; Wang et al., 2023). Beyond fostering trust in AI tools, explainability offers opportunities for teachers to orchestrate these tools to address or enhance existing challenges and opportunities in the teaching and learning process. Instrumental orchestration (Drijvers et al., 2010; Trouche, 2004), as used here, refers to the teacher's intentional and systematic organization and use of the various explainable features of an AI tool in a given mathematical task situation, enabling students to develop intertwined technical knowledge about the AI explainability and their mathematical affordances.

Drijvers and colleagues (2010) describe three ways in which teachers' instrumental orchestration can be observed: didactical configuration, exploitation mode, and didactical performance. In terms of AI explainability, didactical configuration includes teachers' decisions on how to set up the classroom environment to integrate AI explainability into mathematics teaching and learning. This can involve various setups, such as whether to use computers, cameras, mobile phones, or the free or paid version of the software. Exploitation mode refers to the hypothetical decisions a teacher makes regarding the potential ways to utilize AI explainability and the related mathematical knowledge and skills to be developed by students. Lastly, didactical performance encompasses the teacher's operationalization of the planned teaching, including the questions posed to achieve the intended use of the AI explainability, handling unexpected inputs from students or the explainability that diverge from the intended purposes of teaching, and navigating these challenges effectively. In the following sections, I use the transcript of a teacher's orchestration of the embedded mathematical dictionary of Photomath as part of our three-month Photomath-infused differential calculus project to demonstrate which mathematical practices were amplified for each type of orchestration.

Methods

Research Design

This study is a revelatory case study (Yin, 2009), revealing the mathematical practices that get amplified through teachers' orchestration of Photomath's explainability features, such as the embedded mathematical dictionary.

Study Context and Participants

The transcript is from one teaching episode purposefully selected from twelve episodes involving five high school students, five parents (two of whom are francophone speakers), a mathematics educator, and an AI researcher. They integrated the free mobile version of

Photomath for teaching and learning differential calculus and geometry. This project was conducted over three months in rural, multilingual, technologically constrained, low socio-economic settings in Ghana. An episode comprises the intended purpose of teaching. The selected transcript was chosen because its purpose was to plan and teach differential calculus by integrating Photomath's embedded dictionary.

Data Collection

Data were collected through video, audio, field notes, and student artifacts, including screenshots from Photomath emailed to the teacher and researcher. The teaching and learning activities for each episode in the project followed a three-part lesson plan: before, during, and after. In the "before" stage, the teacher, accompanied by the researcher, describes his objectives and the supporting resources in place to achieve these objectives. In the "during" stage, students join the teacher and researcher, and the teacher executes his teaching plan. In the "after" stage, the teacher and students meet with the researcher in groups and individually to describe their experiences, including the opportunities and challenges they faced with Photomath and how the teacher intends to address these in subsequent teaching sessions.

Data Analysis

The transcript of the selected episode was generated using an AI tool and reread to correct errors. The generated transcript was then segmented according to the three-part lesson plan: before, during, and after teaching. The three forms of teacher orchestration were used as an analytical lens to analyze the respective transcript segments and describe what transpired. Inductive reading of this description provides insights into which existing practice-related frameworks in mathematics education are amplified by the teacher's orchestration. Specifically, didactical configuration and exploitation mode were used as deductive analytical lenses for the "before teaching" segments of the transcripts. Didactical performance was used as a deductive analytical lens for both the "during" and "after" segments of the transcripts. Components of the transcript are presented based on Powell et al. (2003) description of the composition of a transcript: names, quotes, activities, and time.

Findings

Table 1: Transcript of the Before Teaching

Time on Transcript	Quotes	Deductive code	Inductive Codes/Amplified Mathematical Practice
00:00:30	**Researcher:** Mr. Austin, can you explain what the objective is for class today? **Mr. Austin:** I will integrate the photomath mathematics register into the teaching and learning process today. **Researcher:** How will you do that? **Mr. Austin:** As you know, we currently have the free	**Deductive Configuration**	

00:05:00	version so we will not have a complete use of it. If we subscribe to it, Photomath will highlight the mathematical terminologies in the sentence for students to click on to have the meaning. Currently students can only see the highlighted text but will not be able to click on for the meaning to show. **Researcher:** Oh! Then what is the worth of use? **Mr.: Austin:** I have a plan. We have mathematics dictionary in the library though I have not added it to my lesson plan before. Because of this inconvenience from our current use of photomaths, I have brought some for each students use. **Researcher:** How will they use photomaths along with mathematics dictionary?		
	Mr. Austin: The goal is for students to create mathematics diary which will be their mathematics vocabulary bank. They will each have a book where they will have four columns; highlighted math word from photomath, the related symbol, the sentence, and meaning the highlighted word they will generate from the mathematics dictionary.	**Exploitation mode**	**Equitable Access to Technology (Guitierrez, 2007; Meyers, 2012)**
00:10:00	**Researcher:** This seems rich. Yet how and when will they use this mathematics diary? **Mr. Austin:** Since we use the photomath as a guide, but each student thoroughly discusses their output for justification, I will ensure that they use the words, its meaning and symbols in the right context during their explanation. Also, I will do a weekly collection of students diary for verification and assessment. Lastly, I will allow students to construct their own word problems in differential Calculus and		**Development of Students Mathematical communication skills (**Brenner, 1998; Herbel-Eisenmann et al. 2015) **Teaching activity design for students to become aware of**

	highlight the vocabularies, to compare with what photomath output. **Researcher:** Okay, let us roll it to see the outcome.	**algorithmic bias (NCTM, 2024)**

As shown in Table 1, before the teaching, Mr. Austin explained that his goal is to see how the students will use the photomaths embedded mathematics dictionary during the differential calculus session. However, the challenge is that students can only see the highlighted mathematics register in the text but will not be able to click on it to see the meaning. This is because as of this time on the project we were using the free version. We needed to subscribe to the paid version in order to access the meaning of the highlighted mathematical register. To allow students to have this benefit, he brought to the class mathematics dictionaries from the school library. He stated that the students will develop a mathematics diary where they will develop a mathematics vocabulary bank. To do this, they will pick the mathematical registers photomaths highlights from the text, find its meaning from the mathematics dictionary, create four columned table with headings: differential calculus register, meaning, symbol and embedded mathematics word problem to record. He expects them to do this for the project until we get sponsors to help us access the paid version. When asked where how he will see the students use these mathematical diary, Mr. Austin stated that he will ensure that the students provide explanations to photomaths generated outputs while using these mathematical registers and also provide verbal and symbolic explanations to these registers. Mr. Austin also suggested that he will have students generate their own word problems for differential calculus and underline the mathematical registers in them. Then, they will submit these problems to Photomath to see which mathematical registers it highlights and check if they align with the students' identifications. Table 2 presents just a snapshot from the during the teaching transcript, which was deducted as the Didactical performance. Due to space the after the teaching transcript is not presented.

These efforts by Mr. Austins show how his instrumental orchestration of the photomath explainable offer opportunities for amplifying existing mathematical practices such as equity, mathematics literacy, algorithmic verifications, and mathematical communication skills. Although Mr. Austin had not previously incorporated a mathematics dictionary into his teaching, his desire to provide students with access to the latest educational technology despite constraints motivated him to leverage the mathematics dictionary from the library. This highlights how a teacher's orchestration of Photomath’s explainable features can influence curriculum decisions, including what resources to integrate or exclude. As shown in Table 2, Mr. Austin's approach to engaging students in justifying their Photomath-generated outputs by explaining the vocabulary and symbolic representations facilitates their comprehension and application of mathematical language and symbolism. This demonstrates how Photomath’s explainable features can enhance existing mathematical practices, such as students’ communication skills in mathematics (Brenner, 1998). Furthermore, by orchestrating Photomath’s explainable features to enhance students’ mathematical communication, Mr. Austin reinforces the teaching practice of developing mathematical literacy as an integral part of the learning process. Regarding the amplification of equity in mathematics education, Mr. Austin's use of up-to-date AI (Myers, 2014), support for learning outside of class hours, and the creation of a conducive classroom environment and participation (Gutierrez, 2007) characterize equitable access. Additionally, facilitating communication with mathematics empowers students. Lastly, his efforts to have students verify mathematical registers before using Photomath demonstrate his commitment to educating students about algorithmic bias, a practice advocated by the NCTM for incorporation into teaching and assessment practices.

Table 2: Transcript of During the Teaching Deducted as the Didactical Performance

Time	Quotes	Students screenshot
00:30:00	**Mr. Austin:** Before you justify the methods for your solution, what are some of the vocabularies you generated? Show it on the photomath. **Elvis:** For this problem, because I wanted my solution to be in the L'hopital's method, photomath highlighted terms such as indeterminate limits and L'Hopital's rule. So, I documented them and also used the mathematics dictionary to find their definitions. L'hopital's rule, which is a method of evaluating limits of indeterminate form using differentiation of one variable approach. **Mr. Austin:** That is good to know. However, let me see on photomath. **Elvis:** Here is the screenshot I took. **Mr. Austin:** Faustina, what are some of the Mathematical registers you also generated. **Mr. Austin:** Coming back to you Elvis, what is the symbolic representation you had for those two registers?	**Elvis's Screenshot** 00:45:00	**Elvis:** The indeterminate limits are represented by two different symbols 0/0 or ∞/∞. There is no one specific symbol for the L'Hopital's rule but it involves the connected processes of Lim (x → c) [f(x) / g(x)] = Lim (x → c) [f'(x) / g'(x)] where f'(x) and g'(x) represent the derivatives of f(x) and g(x) respectively. **Mr. Austin:** How about you Faustina.	

Conclusion

The evolving landscape of digital and analogue technologies within mathematics education, notably with the integration of artificially intelligent systems, presents challenges concerning the assurance of transparency in their utilization. While developers continuously enhance these tools with explainable features, a notable lacuna exists in scholarly inquiry providing mathematics educators with comprehensive insights into these updates and their pedagogical implications. This paper examines Photomath's explainable features and their pedagogical impact, urging thoughtful orchestration by educators for optimal educational benefits.

TEACHERS' COLLABORATIVE REFLECTIONS AND PLANNING ON USING DIGITAL AND NON-DIGITAL RESOURCES

Sunyoung Park
Michigan State University
sunpark@msu.edu

Alden J. Edson
Michigan State University
edsona@msu.edu

This study investigates how two middle school teachers of mathematics reflected on and planned for the use of a digital collaborative platform embedded with a problem-based curriculum. As digital resources can help teachers enact mathematics problems that are responsive to the needs of their students, more empirical work is needed to understand and inform relevant teaching practices that leverage evidence of student thinking (Pepin et al., 2017). Drawing on a documentational approach to didactics (Gueudet & Trouche, 2009), we examine the influences of collaborative reflections on teachers' decisions about the use of digital resources. Our preliminary findings show that based on their reflective conversation, teachers considered the affordances and constraints of both digital and non-digital resources in their planning. Our findings suggest collaborative reflections help teachers critically examine digital resources.

Keywords: Technology, Instructional Activities and Practices, Curriculum, Problem-Based Learning

Rationale and Purpose

A critical teaching practice in student-centered, inquiry-oriented classrooms is for teachers to elicit evidence of student thinking and connect with prior understanding (Jacobs et al., 2010; Kazemi & Franke, 2004; NCTM, 2014). Given the power and potential of digital technologies, a growing number of studies are examining the important relationship between teachers and their use of digital resources (Gueudet et al., 2012; Remillard et al., 2009; Geiger et al., 2023). Yet, more empirical research is needed to understand the factors influencing teachers' decisions to integrate technology into mathematics classrooms (McCulloch et al., 2018). Further, the potentialities of using digital resources are amplified when students and teachers use digital curriculum materials or digital platform systems that are designed and developed around student thinking in problem-based classrooms (Edson & Phillips, 2021). This study examines how teachers reflect on their individual use of digital or non-digital resources on the same problems.

Theoretical Perspectives

The notion of the teacher has shifted from teachers as curriculum implementers to teachers as enactors, and more recently, to teachers as instructional designers who make decisions on how to use curriculum materials (e.g., Jones & Pepin, 2016; Remillard et al., 2009). This study takes the perspective of teachers as instructional designers who interact with resources to achieve their instructional goals (Brown, 2009). As the scope of curriculum resources expands to include digital materials such as digital textbooks or interactive online platforms (Pepin et al., 2017; Remillard, 2016), how teachers appropriate and transform resources plays a critical role in their teaching work (Adler, 2000).

In our study, we draw on the documentational approach to didactics (Gueudet & Trouche, 2009), which centers the selection, planning, and enactment of resources (i.e., digital, non-digital) "at the core of teachers' professional activity and professional development" (p. 199).

The documentational approach to didactics emphasizes the dual nature of teachers' interactions with resources. When teachers shape a given artifact to achieve goals (*instrumentalization*), the affordances and constraints of the artifact influence teachers' usage of the artifact (*instrumentation*). As teachers develop schemes of how to use resources in their classroom context, their decisions are influenced by both explicit learning goals and implicit beliefs and knowledge from their teaching experiences (*operational invariants*). Over time, teachers develop documents and resource systems that entail both a set of resources and the utilization schemes of how to enact the resources (Gueudet, 2019; Ruthven, 2019).

We also draw on the perspective that discussions with other teachers are part of resources, highlighting the importance of collective documentation work among teaching colleagues (e.g., Gueudet, 2019; Gueudet & Trouche, 2009, 2012; Gueudet et al., 2016). Drawing from the perspective of understanding individual teacher learning within the context of collective practices (e.g., Lave & Wenger, 1991; Wenger,1998), the documentational approach to didactics provides insights into the influence of collaborative reflections and planning on individual teachers' development of resource system. Given the limited evidence of how teachers navigate the affordances and constraints of resources and how teachers orchestrate them (Pepin et al., 2017; Rezat et al., 2021), this study seeks to understand how teachers extend their perceptions of digital curriculum resources and incorporate them into their teaching practices.

Methods

This study is guided by the following question: How do individual teachers select, adapt, enact, and reflect on the use of resources in classrooms where there is readily access to both digital and non-digital resources? We situate the study within a larger design-based research project that focuses on developing a digital collaborative platform embedded with a problem-based middle school mathematics curriculum (Edson & Phillips, 2021). This platform contains various tools for digital inscriptions, such as texts, graphs, tables, drawings, and images. Also, students and teachers can access and co-opt others' digital work in real-time.

Our study focuses on two teachers, Ms. Evans and Ms. Foster, who teach seventh-grade mathematics at the same school in the Midwestern suburban area. Both teachers have more than ten years of teaching experience with a problem-based curriculum, *Connected Mathematics* (CMP; The Connected Mathematics Project, Phillips et al., in press). They have been using the developed digital platform for several years. During their daily planning meetings, they used to select problems together to utilize the digital platform. In this study, they were asked to enact the curriculum in two different learning environments—digital or paper-and-pencil. This paper focuses on two problems from one geometry unit. For Problem 1.3, Ms. Evans made use of the digital platform, and Ms. Foster did the print curriculum. For Problem 3.1, the type of resources is reversed. Ms. Foster used the digital resources, and Ms. Evans did the non-digital resources.

Teachers' collective planning meetings and their individual reflection interviews after each problem were video recorded and transcribed. Secondary data sources included classroom video recordings, researchers' field notes during classroom observations, teachers' weekly reflection survey responses, and classroom documents generated by the teachers and their students (digital and non-digital). The data analysis was guided by the reflective investigation to study teachers' documentation work (Gueudet et al., 2012). First, we identified how teachers perceived the affordances and constraints of digital and non-digital resources and how they would incorporate those resources into their teaching (*documentation work*). Then, we coded what influenced the teachers to develop their utilization schemes of resources (*operational invariants*). After applying descriptive codes to each teacher's data, we looked for patterns, similarities, and differences in the codes between the two teachers' cases.

Preliminary Findings

Our analysis revealed that after their conversations about teaching the same problem, (a) teachers considered the benefits and limitations of using both digital and non-digital resources in association with students' development of mathematical ideas, and (b) teachers changed their planning on future problems in order to integrate digital affordances.

Seeing Both Sides: Drawing From Each Other's Reflections

When asked to select between digital and non-digital resources, Ms. Foster indicated it would make no difference in student learning experience. It was because she believed that "seventh graders are visual learners" and hands-on activities help visualization. For Problem 1.3, she had her students use patty papers to trace shapes and compare them with other shapes to explore the similarities. After having a reflective conversation with Ms. Evans, however, she recognized the differences in student engagement and understanding in different learning environments. While she appreciated how the hands-on manipulatives' color format helped her students see the corresponding sides, Ms. Foster was "rethinking" the limitations of patty papers compared to the affordances of digital manipulatives. In other words, while maintaining her belief in visualization (*operational invariant*), she could develop a scheme of using digital resources for the same problem. Her rethinking was influenced by Ms. Evan's reflection. Ms. Evans shared how her students explored various approaches using digital tools (Figure 1), whereas most of Ms. Foster's students took the same approach by which they measured the lengths of hypotenuses. Ms. Foster claimed that using patty papers was more challenging to connect with mathematical ideas during the whole-class discussions compared to using digital manipulatives:

> The connections that I heard, Ms. Evans talked about today, was when they could actually go into the platform, make copies of the original, and play with the copies in the new image to where they could actually formulate a conclusion about the corresponding sides, corresponding angles, and even the area. [It is] because my kids didn't, we didn't even talk about the area, whereas Ms. Evans said some of her kids actually picked up on the area. […] Now that I'm talking about this and reflecting, I think, timewise, the digital platform allows us a shorter amount of time but a deeper sense of questioning and understanding.

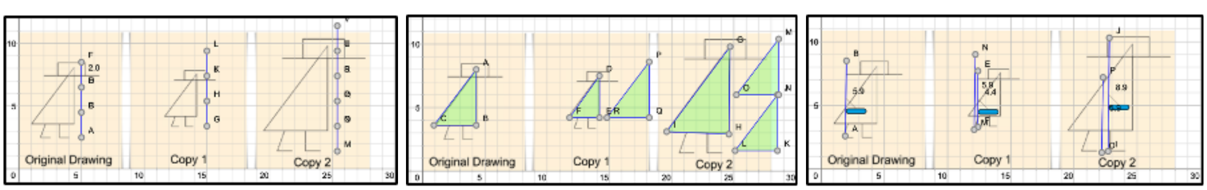

Figure 1: Students' Different Strategies Used on the Digital Platform

Although teachers used one format for each problem, either digital or non-digital resources, they drew on each other's different experiences and considered both resource types to better help students "actually see" embedded mathematical ideas and their conversations "go deeper." After teaching Problem 3.1 on the digital platform, Ms. Foster imagined the possible limitations of

Kosko, K. W., Caniglia, J., Courtney, S., Zolfaghari, M., & Morris, G. A., (2024). *Proceedings of the forty-sixth annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Kent State University.

using patty paper. She continued to say, “It’s an aha moment for me because I used to be the queen of paper-and-pencil” who always used patty paper for these two problems.

Looking Ahead: Adapting Plans for Future Problems

Teachers adapted their plans for the same problem to integrate digital affordances. This means that teachers revised their documents as they perceived that digital manipulatives could help students focus on exploring mathematical ideas (*operational invariant*). For example, after teaching Problem 3.1 using patty paper, Ms. Evans claimed it took longer for students to work on the problem because her class did not have sufficient time to facilitate as deep conversations about scale factors as Ms. Foster’s class. Ms. Evans further pointed out students’ tracing was not accurate enough to examine scale factors, because she learned that from the digital representations, Ms. Foster’s students saw underlying mathematics “right away.” After this conversation, Ms. Evans planned to discard patty papers during her next class, and instead, she provided each group with a set of plastic shapes. She hoped students would struggle less with drawing and focus more on the relationships with scale factors. At the end of the day, however, Ms. Evans said that using plastic shapes was no better than patty paper for seeing the patterns. She noticed that most students stopped drawing after making a shape twice as big. With digital tools, she imagined students would easily have duplicated shapes to stack them into larger shapes more than twice. Thus, Ms. Evans wanted to revisit the same problem using the digital platform:

> I’ll just make some different shapes […] and then have them try and rep-tile it [because] some of them are still not sure about the scale factor. [In the platform,] they’re still looking at how many shapes versus side lengths, so I think that will help with connecting that a little bit better for them. […] Getting to do it again in a slightly different format will help solidify it.

For both problems, teachers compared the benefits and limitations of digital and non-digital resources and concluded that the digital platform would be more beneficial for student learning. Interestingly, they mentioned that if they had to teach these problems in a paper-and-pencil environment, they would prepare multiple pre-cut shapes so students could skip the drawing step and focus on manipulating shapes to explore mathematical ideas. That is, teachers changed the scheme of using hands-on manipulatives to remove unnecessary distractions and help focus on deepening mathematical understanding, inspired by the digital affordances they observed.

Discussion and Conclusions

This study provides empirical evidence of how teachers shifted from using non-digital, hands-on manipulatives toward using digital resources. This shift was based on collaborative reflections about student understandings of the key mathematical ideas. The teachers developed operational invariants that digital resources help students focus on visualizing their thinking more efficiently than hands-on manipulatives. Such belief will influence the ways teachers consider digital affordances and represent their resource systems (Ruthven, 2019).

Findings from the study pose important implications as teachers select, adapt, and use digital and non-digital resources in their mathematics classrooms. First, we provide evidence that teachers can utilize co-planning meetings to share the different affordances of resources for the same problems that inform how to use technology in supporting student learning (McCulloch et al., 2018). As our preliminary findings focused on the two teachers’ cases, further research should investigate the impact of collaborative reflections compared to individual reflections. Second, we provide evidence that digital features in the platform prompted teachers to re-examine the benefits and challenges of using digital resources (Geiger et al., 2023). As our preliminary findings were specific to geometry problems involving patty paper, further research is needed, e.g., How do teachers develop resource systems regarding their use of digital/non-digital resources in problem-based classrooms?

A SYNTHESIS ON THE INTEGRATION OF COMPUTER TECHNOLOGY IN GEOMETRY CLASSES

FNU Pujiyanto
Western Michigan University
Fnu.pujiyanto@wmich.edu

Jane-Jane Lo
Western Michigan University
jane-jane.lo@wmich.edu

This synthesis examines recent research from 2016-2022 on integrating computer technology (CT), specifically as exploratory environments, into geometry education across grade levels. Searches were conducted using Google Scholar and ERIC with relevant keywords. Inclusion criteria focused on peer-reviewed empirical studies combining geometry education and exploratory CT environments. Out of 338 initial search results, 64 articles met the criteria. Key findings show the number of studies increased substantially in recent years, with a peak of 14 studies in 2022. The predominant computer technology used was GeoGebra, followed by Geometer's Sketchpad and emerging Augmented Reality/Virtual Reality. Studies overall found positive effects of CT integrations on test scores, problem solving, spatial skills, conceptual understanding, and attitudes. Furthermore, CT facilitated students' exploration, visualization, conjecture generation, justification, and comprehension.

Keywords: Technology, Geometry and Spatial Reasoning.

Historically, geometry has not been valued as highly as algebra (Nirode, 2013), and research shows that many students struggle with learning geometry concepts and developing proficiency in geometric thinking (Sinclair et al., 2017). The use of computer technology (CT), especially dynamic geometry software (DGS), has been proposed as an effective approach to enhance geometry teaching and learning since it offers interactive diagrams and visualization features that provide students with the opportunity to dynamically construct, manipulate, and analyze geometric shapes and measurements (e.g., Hollebrands & Okumuş, 2018; Sherman & Cayton, 2015; Sinclair & Moss, 2012).

Sinclair et al. (2017) provided a systematic overview of research on geometry education, including studies on the use of technology in geometry classrooms up to 2016. They discussed many ways that computer technology has impacted the teaching and learning of geometry. The use of technology in geometry education has accelerated rapidly in recent years due to the COVID-19 pandemic (Bellamy, 2021; Borba, 2021). This study aims to expand the work done by Sinclair et al. (2017) with the following specific questions: 1) What are the trends of peer-reviewed journal articles focused on the use of computer technology in exploratory environments with a focus on geometry education during the last seven years (2016-2022)? 2) What kinds of computer technology are they using in these studies, and what are the main findings?

In this study, we restrict computer technology (CT) to software rather than hardware. Exploratory environment is one of the four uses of CT in classroom (Li & Ma, 2010; Lou et al. 2001; Means, 1994). This focus on exploratory environments aligns with constructivist learning theories that emphasize students constructing their own knowledge through active exploration and discovery-based learning (Lou et al., 2001). By examining the current role and impact of technology, this research will inform our vision for the future of geometry education.

Methodology

This synthesis examines peer-reviewed journal articles on the use of computer technology in geometry teaching and learning that were published between 2016-2022. The search was conducted using academic databases including Google Scholar and ERIC keywords related to technology, dynamic geometry software, geometry education, learning, and teaching. The initial pool from the search was screened based on criteria in Table 1, resulting in 64 out of 338 articles (18.95%) meeting the inclusion criteria. These articles are indicated with an asterisk (*) in the reference list, or you can click this link for the complete reference list of these 64 studies.

Data analysis involved categorizing the selected articles based on year published, type of computer technology (CT), geometry topics, participants' grade level, findings, and methodology (qualitative or quantitative for most CTs). A spreadsheet program was used to determine frequencies and percentages for each category.

Table 1: Inclusion and Exclusion Criteria

Criterion	Inclusion	Exclusion
Type	Full peer-reviewed journals	Non-peer-reviewed journals, book chapters, books, preliminary reports, short papers, brief reports
Topics	Studies focused geometry and computer technology (CT) integration	Studies focused on non-geometry topics, geometry without technology, technology integration in non-geometry topics
Type of CT	Exploratory environments	CT other than exploratory environments (e.g., tutors or tutorials, communication media, tools)
Populations	Research on technology integration in geometry classes at all levels, including stakeholders (e.g., in-service teachers)	Non-human subject research on geometry and technology even if in an educational context (e.g., meta-analyses, bibliographic studies, syntheses)
Language	Studies written in English	Studies in other languages

Results

The trends of peer-reviewed journal articles

Our analysis shows that the number of peer-reviewed articles meeting the criteria increased consistently from 2016 to 2020, peaking at 14 articles in 2022. In terms of grade levels, the most common participant groups across the research on technology integration in geometry education were at the K-12 levels (38 studies, 59.4%), with the most at grades 6-8 (19 studies, 29.7%). About the same number of studies focused on high school (11 studies, 17.2%) and elementary school (9 studies, 12.5%) levels. Approximately a third of the studies focused on participants in teacher education, with most of them (17 studies, 26.6%) on preservice teachers (PSTs) and a handful on in-service teachers (6 studies, 9.4%). Only 3 studies focused on higher education participants (non-teacher education).

In terms of the trend of geometrical topics, this study found that 70.3% of the reviewed studies focused on 2D geometry only, 18.8% focused on 3D geometry only, while 7 studies focused on both 2D and 3D geometry. Using the primary geometry context as the basis for coding, the majority of the studies (34 studies, 53.1%) focused on the classifications, properties, and relationships of a variety of 2D or 3D shapes, for example, studies that required participants to construct or identify the properties of 2D shapes, focus on parallel and perpendicular lines and angles, and on congruence and similarities of triangles. Eleven studies (17.2%) focused on measurement concepts such as area, perimeter, surface area, and volumes. Nine studies (14.1%) focused on a variety of transformation concepts. Three studies focused on proof, and seven studies (10.9%) focused on a variety of other concepts such as limits or analytic geometry.

The types of computer technology and what are the main findings

This study found that the predominant computer technology (CT) used from 2016 to 2022 that met our search criteria was GeoGebra, with 42 out of the 64 studies (65.63%) either using it as a standalone CT or along with other CTs such as GSP, Desmos, and tools for video, animation, and games. GeoGebra was also incorporated into web-based learning platforms, such as Virtual Math Team, or as an app in AR headsets, such as GeoGebra AR.

The quantitative studies that incorporated GeoGebra found that participants who received GeoGebra interventions demonstrated positive improvements compared to control groups on test scores, problem-solving skills, self-efficacy and self-regulated learning, conceptual understanding of geometry, and spatial geometry skills. Some studies showed that teaching with GeoGebra statistically improved preservice teachers' and in-service teachers' creative thinking skills, spatial visualization skills, creative thinking skills, and in-service teachers' beliefs in using GeoGebra in their teaching instructions. Whereas the qualitative studies found that the dragging feature in GeoGebra helped participants see static figures as movable ones, helping their understanding by enabling exploration of geometrical objects and seeing/justifying relations. Additionally, some studies found that using dynamic geometry activities with GeoGebra helped students progress in their van Hiele levels from basic visual recognition of shapes to a more advanced understanding of geometrical properties and relationships between shapes. Furthermore, some studies found that GeoGebra helped preservice teachers (PSTs) understand geometry proofs and expanded their technological pedagogical knowledge, inspiring the integration of similar activities into their teaching. A study on student opinions of technology-integrated lessons (Dikkartın Övez & Kıyıcı, 2018) found positive attitudes about math being more attractive, entertaining, allowing them to discover without memorizing, making information memorable, and increasing participation.

The second most used CT was Geometer's Sketchpad (GSP), with 10 out of the 64 selected articles using this tool, either standalone or along with other CTs like GeoGebra. We found that the experimental groups whose participants received GSP interventions obtained significantly better test scores or achievements compared to control groups. Some studies found that GSP integration improved students' attitudes toward math, such as self-confidence and curiosity to actively explore geometry concepts. In-service teachers also had positive views on GSP's usefulness for pedagogy (Huang et al., 2020) and its potential as a part of the learning process rather than merely as a tool (Zambak & Tyminski, 2017).

Studies incorporating Augmented Reality (AR) and/or Virtual Reality (VR) have grown in recent years, particularly from 2020 to 2022. The CTs or software used in these studies were Unity software, GeoGebra, Geometry and Quiver, Zappar - HP Reveal, and Neotrie VR. Out of the 64 selected articles, there were five studies that used AR and/or VR. Like the other CTs, quantitative studies using AR/VR found that experimental groups receiving AR/VR interventions obtained significantly better test scores or achievements compared to control groups. Some studies (Elsayed & Al-Najrani, 2021; Flores-Bascuñana et al., 2020; Moral-Sánchez et al., 2022) found that students learning with AR were more motivated in mathematics, although Sarkar et al. (2020) found no significant motivation difference between individual and collaborative AR.

Four of the 64 selected articles focused on Cabri. Similar to other CTs, a quantitative study found that the experimental group receiving Cabri interventions had significantly better scores than the control group (Chang et al., 2016). Meanwhile, qualitative studies on incorporating Cabri showed that students actively explored geometry concepts through guided discovery (Selman & Tapan-Broutin, 2018) and improved their conceptual understanding and confidence with geometry after using Cabri (Gülburnu, 2022). Additionally, Cabri Geometry's dragging feature allowed students to test and refine constructions (Kepceoglu, 2018). Cabri also provided an enjoyable, exploratory learning environment (Gülburnu, 2022).

Other CTs such as Google SketchUp, Scratch, Minecraft, Desmos, and Microworld saw more limited implementation. Google SketchUp was found to improve students' van Hiele levels (MdYunus et al., 2019) and spatial visualization skills relating to rotating, viewing, transforming, and mentally manipulating 3D objects and shapes (Abdullah et al., 2022). Setyawan et al. (2018) found that while Desmos helped students and teachers understand concepts, Scratch helped students understand concepts like coordinates, movement, rotation, and angles (Calder, 2019). A Scratch-based game improved student achievement and computational thinking (Acar & DiKkartin Övez, 2022). Minecraft activities promoted pedagogical content knowledge and experience with game-based math instruction (Kim & Park, 2018).

Discussion

Our analysis yielded 64 studies meeting our strict criteria from an initial pool of 338 search results. This substantial number aligns with the findings of Çavuş and Deniz's (2022) meta-analysis, which identified a similar rise in research examining technology's impact on math and geometry achievement (2000-2016). The trend suggests a growing interest in integrating technology into geometry education which might be partially influenced by the COVID-19 pandemic, which forced many teachers to adopt online learning methods (Borba, 2021; Bellamy, 2021). Further supporting this trend, the most common computer technology used was GeoGebra, followed by GSP, AR/VR, and Cabri which is consistent with the results in Abidin et al.'s (2018) study that the commonly used CT during 2009 to 2017 research articles was GeoGebra and GSP, further suggests continued stability in the use of GeoGebra and GSP for geometry instruction.

Studies consistently demonstrated that experimental groups using CT interventions outperformed control groups on students' scores, problem-solving, spatial skills, conceptual understanding, etc. Like this result, other studies related to article syntheses on technology related to mathematics classes (e.g., Abidin et al., 2018; Çavuş & DeniZ, 2022; Ondes, 2021) also found that the participants who received technology-assisted interventions outperformed the participants who did not receive the technology. Similar to Abidin et al. (2018), this study also found that CTs improved participants' attitudes, confidence, motivation, curiosity, and technology integration skills, possibly due to the dragging feature that enables the participants to visualize static geometry figures more dynamically, which facilitates exploration of geometrical objects and relation noticing (Sinclair et al. (2017).

Abidin et al.'s (2018) found that the incorporation of AR/VR not only improved students' achievement but also their attitudes towards using the technology. However, our study only identified AR/VR use in middle grades and for pre-service teachers (PSTs). This highlights a gap in research, particularly at the elementary level, where the exploratory features of AR/VR could significantly benefit spatial understanding in 3D geometry. Additionally, there is an emergence of

AI tools like ChatGPT or PhotoMath that are changing how students learn math. The future of math education may involve more knowledge construction using immersive exploratory technologies and productively leveraging AI tools.

Acknowledgements

We would like to express our gratitude to Constant Segbefia for his assistance with the initial search and to our fellow graduate students in the Geometry Curriculum course at Western Michigan University whose insightful feedback strengthened this study.

Keywords: Technology, Curriculum, Problem-Based Learning, Classroom Discourse

Technology use in mathematics classrooms can be isolating, dehumanizing, and detrimental to collaboration by encouraging students to withdraw from other people and from society, causing a breakdown in the student-teacher relationship, jeopardizing human values, and over standardizing education (Nissenbaum & Walker, 1998). In these uncertain times, using technology should support the future of mathematics education, which includes *collaboration*, "a joint production of ideas, where students offer their thoughts, attend and respond to each other's ideas and generate shared meaning or understanding through their joint efforts" (Staples, 2007, p. 162). The use of technology in teaching and learning mathematics continues to expand, as it can provide more accessibility, instantaneous feedback, and multiple representations (e.g., Clark-Wilson et al., 2020; Edson & Phillips, 2021; Powell et al., 2018). In this poster, drawing from larger design-based research, we report on the design characteristics of a digital curriculum platform that supports small-group and whole-class collaborative discussions.

When working in small groups, it is essential that students make sense of mathematics, building on each other's thinking. Our digital platform allows students to share work with their groupmates in real time through a "four-up" view that displays all group members' workspaces at once. Sparrows (student proportional reasoning arrows) allow students to explicitly connect and annotate relationships among different representations. Digital messages can be sent from a teacher to individuals and groups to advance student thinking. Teachers can collaborate with colleagues around student work as they plan and use student work for whole-class discussions.

During whole-class discussions, students' various strategies to solve problems are shared to unpack embedded mathematics. In the digital platform, teachers can quickly display different student strategies using a group view or the gallery walk feature. Also, teachers can create a digital document to collect student work and record class discussions, then make it available to all students. The learning logs allow students to reflect on the problem and accumulate their work and ideas over time. Moving forward, we continue to elicit teacher feedback on the features and explore professional development to both support teachers' implementation and discuss what features can be added or changed to enhance small-group and whole-class discussions.

This study investigates the interactions between informal educators and adolescents during math walk activities at an art museum. "Math walks" are activities where students notice and wonder about mathematics in the world around them, often creating their own "math walk stops" where they ask and answer mathematical questions. Drawing upon theories of informal math learning, scaffolding, and problem-posing, our research aims to enhance understanding of math walk implementation. Through video content, interaction analysis and artifact analysis of participants' iPad photos, we explore students' mathematical learning processes and the role of adult facilitators in guiding these activities. Results from a three-day summer camp are given, and findings offer implications for designing effective informal math education programs and fostering meaningful student engagement with mathematics in real-world contexts.

Keywords: Informal Education, Integrated STEM / STEAM, Middle School Education

Research Purpose and Question

Investigating interactions between informal educators and adolescents in informal learning settings provides valuable insights into students' perceptions of mathematics. "Math walks," or "math trails," a method linking mathematics to real-world occurrences, can foster meaningful dialogues in community-based settings (English et al., 2010; Fesakis et al., 2018; Wang & Walkington., 2023). During math walks, learners critically assess their surroundings with their "math lenses," observing both mathematical and non-mathematical elements, generating and addressing their own questions (Wang & Walkington, 2023). However, the role of informal educators in guiding learners through this process remains underexplored (Sager et al., 2023).

This study explores how informal educators facilitate connections between school math and real-world math during math walk activities at a downtown art museum. Focusing on scaffolding techniques and student-created math walk stops, we aim to address gaps in the literature on informal math learning, where research has documented the challenges that learners have while making connections between school math and real-world math (e.g., Inoue, 2005; Lave & Wenger, 1991; Masingila et al., 1996). Insights from our case study of six students shed light on student-educator interactions and problem-posing processes, with implications for informal math education. Our research questions are: (1) How do student and facilitator interactions unfold during math walk activities as educators employ scaffolding techniques? (2) What are the characteristics of, and problem-posing processes leading to, student-created math walk stops? Next, we present our theoretical framework, methodology, findings, and conclude with a discussion on future research implications.

Theoretical Framework

Students' ability to describe mathematics can be explicit or implicit (Kaur et al., 2013). Explicit forms often involve the use of standard mathematical terminology. Whereas implicit forms involve understanding and using mathematics without explicitly describing it as such, often embedded within real-world contexts, like those found in informal settings, and are influenced by factors such as prior knowledge and cultural background (Kaur et al., 2013). To this end, we draw upon *informal math learning*, *scaffolding*, and *problem-posing* in our study.

Firstly, *informal math learning* research has examined how people use math in their everyday lives and in careers (e.g., Nunes et al., 1993; Walkington et al., 2014). More recent empirical studies on learning math within informal settings has helped to understand program effects on achievement outcomes (e.g., grades, GPA, test scores) in school mathematics (Lauer, et al., 2006; Lynch et al., 2023). Although place-based mathematics education in informal learning environments is gaining increasing interest (Mokros, 2006), research on this topic remains limited (Pattison et al., 2017). They go on to explain that visitors in place-based settings are often unaware of their engagement with mathematics, and that promising mathematical thinking and social interactions around mathematics can emerge in informal spaces (Pattison et al., 2017).

Secondly, *scaffolding* describes the guidance and support a teacher (or knowledgeable adult) provides a student during problem solving activity in a particular learning context (Dingman et al., 2019), namely in the context of adult-child interactions (Stone, 1998). This is to center the students' learning and reasoning through a process of "the adult 'controlling' those elements of the task that are initially beyond the learner's capacity, thus permitting him to concentrate upon and complete only those elements that are within his range of competence" (Wood et al., 1976, p. 90). From their work, we employ four of the six primary scaffolding strategies in our methodology and in our findings: (1) *Recruitment:* the instructor elicits the student's interest in the problem and highlights the requirements of the task. (2) *Direction maintenance:* the instructor keeps the student in pursuit of a specific objective. (3) *Marking critical features:* the instructor highlights or emphasizes the relevancy of certain features of the task. (4) *Frustration control:* the instructor reduces stress from working the problem (Wood et al., 1976, p. 98).

Thirdly*, problem posing* in mathematics education involves teachers and students (re)formulating or expressing new mathematics problems within a specific context, as described by Cai et al. (2023). These tasks require students to generate or shape new problems based on real-life mathematical situations, which include both contextual situations and prompts (Cai, 2022; Cai & Hwang, 2023). Contextual situations provide problem posers with necessary data to craft their problems, while prompts guide students in problem posing tasks (Cai et al., 2023). Creating math walk stops is a problem-posing task with the potential to enhance students' interest in and understanding of mathematics. Studies by Walkington and Bernacki (2014) and Wang and Walkington (2023) highlight the challenges students face in problem posing due to the need for prior math knowledge and familiarity with "school math" norms. Problem posing research offers opportunities to enrich the informal math literature by transcending the constraints of formal "school math." Next, we present methods for data collection and analysis.

Methods

Background Context

This study highlights findings from the second year of the MathExplorer project, a research practice partnership (RPP) connecting a university in the southwestern United States, a STEM-oriented nonprofit, and nine informal learning sites. We partnered with informal educators at a local art museum ("Art Museum") to conduct a three-day summer camp. Students from the local community participated, alongside five researchers and supervising professor from the university and the director of the STEM-based nonprofit. The Museum Teacher who led the camp was trained on the app, scaffolding strategies, and problem-posing techniques by the research team.

Student participants used the app to explore real-world objects that they encountered during their math walks at the Art Museum. Accompanied by a facilitator, they gained an understanding of and proficiency in applying mathematical concepts while engaging with objects. During the camp, participants explored selected art pieces each day with the facilitators. They watched previously recorded videos embedded in the App, discussing math concepts related to the informal learning space. Afterward, they freely explored the museum to create their own math walk stops about things they noticed and wondered about in their environment (Sager et al., 2023). At the end of the day, they convened for whole group discussions, sharing their photos and math question(s). On the final day, students presented their math walk stops to the group.

Research Participants

The student participant group was diverse, and relevant demographic information including anonymized pseudonyms is summarized in Table 1.

Table 1: Camp Participants

Name (Pseudonym)	Grade	Race/Ethnicity	Gender
Astrophel Seven (505)	8th	Hispanic/African American	Male
Hamal Slope (201)	3rd	White/African American	Male
Apollo Osmium (202)	4th	White	Male
Zania Copper (203)	6th	African American	Female
Zenith Bit (204)	5th	African American	Female
Daniah Roentgenium (506)	5th	African American and Other (not specified)	Female

Data Collection

We collected video and artifact data while observing students and teachers during the Art Museum's three-day summer camp. Students were divided into partner groups, each paired with at least one adult from either the research team or the Art Museum. Each group was provided with a tablet containing the MathExplorer app. Researchers recorded video footage of each small group using handheld recording devices, resulting in twelve videos totaling 340 minutes of footage. Additionally, we retrieved photos of various artifacts from each participant's iPad, some of which were annotated with markings and included posed questions and answers. All collected data was stored in a shared Box folder, organized by data source type (video, image), group number, and date to facilitate the subsequent analysis.

Data Analysis

This study focuses on three main forms of collected data: demographic surveys, small group video recordings, and walk stop screenshots taken from students' iPads. Transcripts and content logs of videos were manually created by the researchers (Jordan & Henderson, 1995). Eighteen math walk stops were created and shared by camp participants over the three days. Following an iterative process informed by the data analysis spiral (Creswell & Poth, 2018), the authors engaged in systematic reading, viewing, and memoing of data, followed by collaborative meetings to categorize and recategorize codes (Saldana, 2021). Further, the authors rewatched videos, read content logs, and revisited transcripts. We used an inductive process to identify various types of interactions between the adults and students. After two rounds of inductive coding, we categorized interactions by the four scaffolding strategies (Wood et al., 1976). Codes were labeled with a schema (theme-interaction category-type), seen in Table 2 under Findings.

Artifact analysis involved a comprehensive review of student-created walk stops from iPad photos to address the second research question. Authors employed an inductive process to identify walk stop types, categorizing them into explicit and implicit mathematics themes using a "problem-posing-type" schema. Subcodes were generated where necessary to denote specific aspects of the walk stops. A decision was made collectively to classify codes as "explicit school mathematics," "implicit mathematics," or "unrelated" discussed later in detail.

Triangulation involved comparing student-selected walk stops with facilitator-student interactions to understand engagement leading up to each walk stop creation. The process included systematic comparison and integration of data sources to ensure coherence and reliability in the analysis. By using triangulation strategies, our data analysis methods offer a transparent framework for analyzing collected data and generating meaningful insights.

Findings

We present our findings for the qualitative case study by looking at each research question separately. The number of instances we observed for each code is provided in Table 2.

Table 2: Codebook from Interaction Analysis and Artifact Analysis

Code	Definition	Coded As	Example	Count
Scaffolding: Recruitment	Instructor elicits student's interest in problem and highlights requirements of task	Probing (prior knowledge)	"You mean Zeus?"	24
		Probing (connection)	"You think it's interesting? What makes it interesting?"	52

Scaffolding: Direction Maintenance	Instructor keeps student in pursuit of a specific objective	Probing (directive)	"So, remember…at each stop there's gonna be a little video for you to watch…and then there'll be some questions that they ask…"	32
Scaffolding: Marking Critical Features	Instructor highlights or emphasizes relevancy of certain features of the task	Probing (mathematical)	"How can we find the diameter of the eye?	48
Scaffolding: Frustration Control	Instructor reduces stress from working the problem	Probing (redirect)	"It's art."	2
Problem Posing: Explicit School Mathematics	Student explicitly uses school mathematical terms	Measurement, Count, Patterns, and Shapes	"…it was about finding a symmetrical ah a little symmetrical with the white and black arrows."	31
Problem Posing: Implicit Mathematics	Student poses questions about aesthetic elements without using explicit school math terms	Design, Functionality, Artist Motivation	"Q: My question is why is it so colorful and how was it made??"	9
Problem Posing: Unrelated	Student poses questions of situational interest, but not of mathematical interest	Unrelated	"Q: If she sad."	1

RQ1. How do student and facilitator interactions unfold during math walk activities in informal learning settings as educators employ scaffolding techniques?

In addressing Research Question 1, we observed facilitators employing four of the six traditional scaffolding methods (Wood et al., 1976).

Recruitment. Facilitators elicited students' interests as learners observed artworks, sometimes probing students by accessing their *prior knowledge* or making *personal connections*. For instance, Figure 1 illustrates a facilitator-student exchange employing both recruitment strategies. Green highlights indicate scaffolding coded as "probing-prior knowledge" and yellow highlights indicate scaffolding coded as "probing-connection." In this example, and others, the facilitator is eliciting student's interest in the art (situational context) to foster the prompting portion of the problem posing task, as summarized next.

11:37	202	"Can I take more than one picture?"
11:39	Researcher A	"Mmm, hmm."
11:41	202	"Just in the orange?"
11:43	Researcher A	"Would you like to walk around just a little bit more? (pauses for 8 sec) Oh, that's a good picture!"
11:55	202	"What's this?" (taking picture with iPad)
12:10	Researcher A	"202, what do you like about this?"
12:12	202	"It looks like a magician's hat."
12:15	Researcher A	"Okay. What else does it remind you of?"
12:17	202	"Umm, a magician's hat!"
12:22	Researcher A	"What do you notice about it?"
12:25	202	"It looks like a mouth and two eyes."
12:27	Researcher A	"Yeah, okay. (pauses for 3 sec) Do you think it's beautiful?"
12:34	202	"I think it's interesting."
12:36	Researcher A	"You think it's interesting. What makes it interesting?"
12:38	202	"Umm, the thing-a-ma-bob at the top and the thing-a-ma-bob at the bottom. (points to different parts of the object)

Figure 1: Photo-transcription of Museum Teacher Scaffolding by Recruitment

Direction Maintenance. Our analysis also shows facilitators employing direction maintenance techniques (coded as "probing-directive"), to keep students focused on the task of posing mathematical questions. This involved providing explicit directives related to the task, ranging from simple reminders to more descriptive instructions, as exemplified in a transcript excerpt where facilitators guide students through the task step-by-step beginning with the Museum Teacher:

> We can also spread out so we're not like all clustered together to make listening to it a little more easily…Please don't leave the orange area over here…So, you're gonna watch the video, and then you're going to formulate questions and answer the questions. Okay?...

Researcher A, then builds with further instructions to assist a nearby student with using the App's embedded voice recorder:

> You're gonna click on 'record answer' to answer the question that it asks you in the box. (student listens to question) So, what are some math questions you could ask here? (student records herself but has trouble hearing her recording) Can you hear yourself?...Do you want to try again? (student tries again)…Do you have any other questions that you need to answer? Think about another question. You can go look at it if you need to so that you can notice some things. They can be any math questions that you're thinking.

Researcher C, overhearing the adult-student exchange, interjects, "Or any…It doesn't have to be math, just any question you have about this place." This dialogue example is rich with scaffolding techniques that moved students along in the problem posing task including self and group management, technical support, and clarifying the task.

Marking Critical Features. At times, facilitators marked critical features of the artwork, highlighting or emphasizing emphasized the relevancy of certain features of the task. For example, Student 202 is drawn to a large indigenous artifact (shown in Figure 2) stating, “The eyes are really big (30:43).”

Figure 2: Photo Example of Marking Critical Features Taken from Video

Researcher A acknowledges, and then draws attention to the eyes to highlight and emphasize their relevance to the problem posing task, “Okay. Do you see anything on the eyes?” This scaffolding made way for Student 202 to formulate and then pose his question, “I've got a question…What is the diameter of the eye?” It is important to note that scaffolding is also used to mitigate student frustration when seeking mathematical connections with diverse artforms.

Frustration Control. Additionally, facilitators employed frustration control techniques to mitigate student frustrations and maintain focus on mathematical learning. During one session, Student 202 deemed a particular exhibit as inappropriate for kids because it contained nudity. Then, Student 201 agreed how he hoped “nobody makes a walk stop about the naked people”. Researcher A replied, “It’s art,” and Researcher H reinforced, “It is art.” However, the students carried on about “it’d be creepy,” and if there was one it wouldn’t be “for kids.” Researcher A steered the conversation back to mathematical inquiry with a definitive, “All right.”

In addition to facilitator strategies, students described specific characteristics of and the problem-posing process that led to their math walk stops, further enriching our understanding of student-facilitator interactions during math walk activities.

RQ2. What are the characteristics of, and problem-posing processes that lead to, student-created math walk stops?

Students described mathematics in both explicit (coded as “problem-posing-explicit school mathematics-type”) and in implicit ways (coded as “problem-posing-implicit mathematics-type”); “type” refers to more specific characteristics or problem posing processes observed in our analysis. Figures 3a-d illustrate select mathematical examples captured during artifact analysis, categorized by subcodes – *measurement*, *count*, *patterns,* or *shapes*.

Explicit School Mathematics. These codes corresponded closely with the questions students posed during the camp and with their accompanying iPad photos. Firstly, *measurement* questions often pertained to length, such as “how long” (see Figure 3a). Secondly, students inquired about quantities, or *count,* exemplified by questions like, “How many carvings in this photo?” (see Figure 3b). Next, *patterns* revealed students’ describing identified patterns within artworks, posing questions like “How many patterns are there?” (see Figure 3c). Lastly, s*hapes* refer to named or drawn geometric shapes, mostly circles and triangles, as seen in Figure 3d. These explicit school mathematics connections were pronounced during our analysis; however, we also found some implicit mathematical connections as well.

Implicit Mathematics. In contrast, some students described mathematics implicitly, focusing on artistic aspects, namely the object's *design* or *functionality* and the *artist's motivation*. Such descriptions reflect students' ability to see applied mathematical principles in art (Figures 3e-g). For instance, Student 505 questioned the materials used to *design* a clock (Figure 3e), while Student 203 expressed curiosity about an object's usage (Figure 3f), exemplifying *functionality*. Also, Student 204 inquired about an *artist's motivation* for color choices and sewing techniques (Figure 3g). Nine photos fell under this theme, illustrating students' intriguing observations of mathematical applications in art through aesthetic.

Unrelated. Lastly, a student's inquiry about a painting's emotional content (Figure 5d), without any explicit or implicit mathematical connections, highlights the diversity of student responses and interests during the math walk activities.

Our findings present a plethora of observations that underscore the multifaceted nature of student problem posing during math walks. Next, we discuss their significance related to the literature and implications for informal math education.

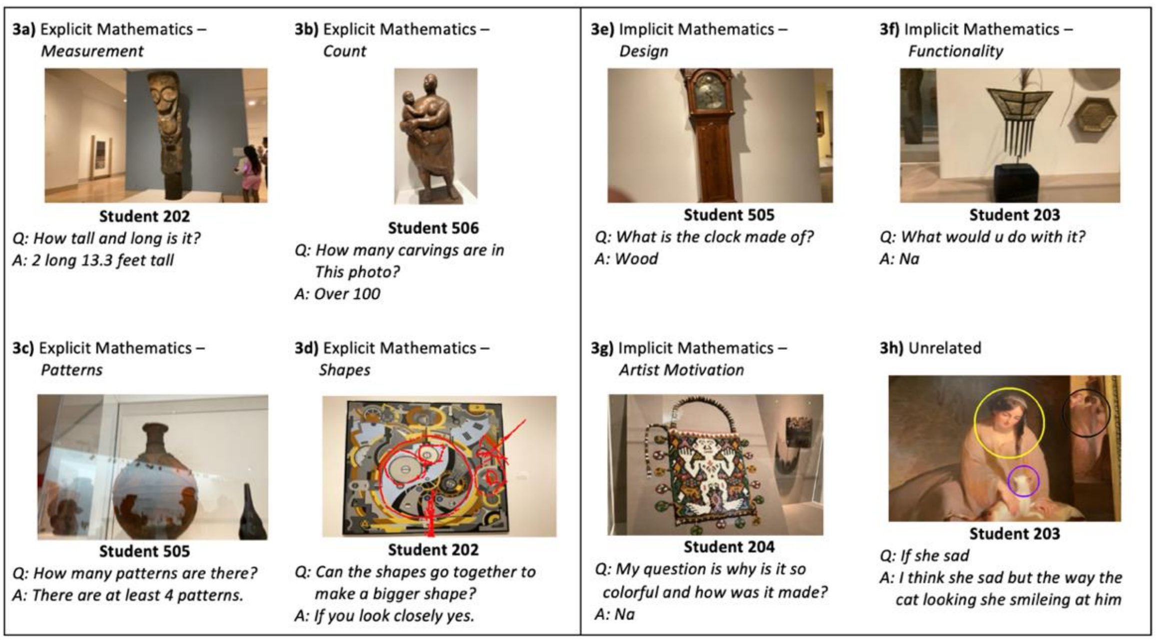

Figure 3: Problem Posing Student Examples (by Codes)

Discussion and Conclusion

While math walks have been identified as an important informal mathematics learning activity, little research has examined how student-facilitator interactions unfold during math walks. Having students generate their own noticings and wonderings from their surroundings is a challenging process, as it involves creativity and the ability to see mathematics as an expansive and situated domain for looking at the world. Here, we show how facilitators can use scaffolding processes like recruitment, direction maintenance, marking critical features, and applying frustration control to make these activities more feasible and rewarding for students, while still allowing students to maintain their independent voice. This offers important guidance for how informal educators can be best trained or prepared to implement math walks – by rehearsing, watching videos of, and discussing these scaffolding strategies.

We also show the kinds of math walk stops students created at an art museum, highlighting the explicit and implicit mathematics they noticed. One striking finding from this study was that the students' walk stops in Figure 3 was quite simple and un-nuanced compared to the rich conversations students had ***while creating*** these math walk stops. Thus, the math walk stops themselves are not the most important demonstration of or product of students' learning from math walks – instead, it is the mathematical discussions that students and facilitators have leading up to the submission of the formal walk stop that best show students' transformations.

AN ESTIMATION GAME TO PROMOTE SECONDARY STUDENTS' CLIMATE CHANGE UNDERSTANDING USING DATA AND VISUALIZATIONS

kei.lester@my.utsa.edu

Data and data visualizations have the potential to shift learners' attitudes and conceptions about controversial science topics. However, many people, particularly secondary students, struggle to make scientific meaning from data. This design-based research project aimed to support data literacy and science learning by developing an online estimation game to support secondary students' understanding of climate change with data and data visualizations. Over the course of three design iterations, we interviewed 12 racially diverse secondary students and documented the design of a climate change number estimation game. Inductive coding analysis illustrated dimensions of students' (a) estimation strategies employed (e.g., drawing from prior knowledge, mental computation, wildly guessing), and (b) emotions experienced while estimating climate change numbers (e.g., emotions about climate change vs. about performance).

Keywords: data literacy; design-based research; numerical estimation; secondary education

Scientific data visualizations—such as maps, charts, and graphs—can communicate critical socioscientific information to the public (Allen, 2018; Harold et al., 2016). However, many people lack the quantitative reasoning skills needed to interpret these visualizations (Börner, et al., 2016; Peters et al., 2006; Thacker & Sinatra, 2019). Secondary students, in particular, struggle with number magnitudes using conventional number line representations (Doyle, 2015; Vamvakoussi & Vosniadou, 2004; 2007; 2010; Wilensky, 1991). This magnitude knowledge predicts math and science achievement (Booth & Siegler, 2006; Sasanguie et al., 2012; Siegler & Booth, 2004; Siegler et al., 2012), and students' inability to use visual representations to compare rational numbers can lead to misinterpretations of science topics (Siegler, 2016).

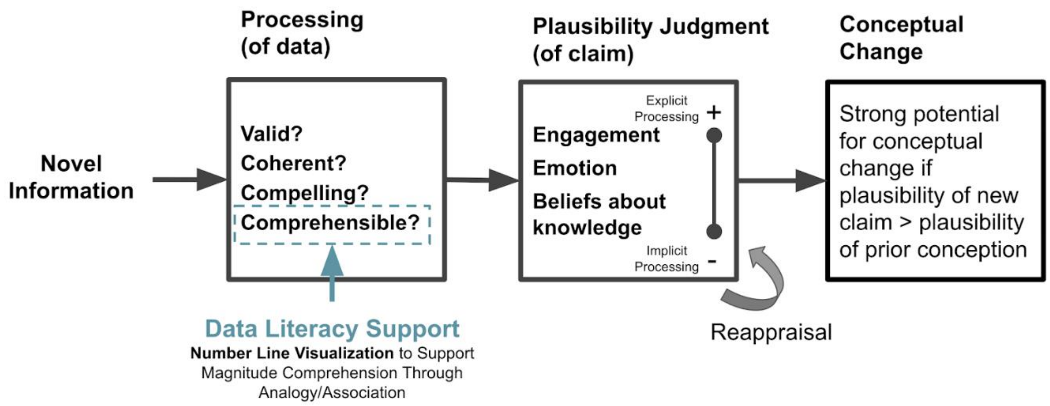
A relevant topic relying on quantitative evidence is climate change. National science standards require students to understand quantities, tables, and graphs related to human-induced climate change (NGSS, 2013). However, students have serious misconceptions about climate change (Dawson & Carson, 2013; McNeil & Vaughn, 2012). There is a need for learning contexts that support climate change understanding and data literacy. Several approaches, such as micro-interventions with surprising numbers about climate change, support learning (Ranney & Clark, 2016; Thacker & Sinatra, 2022), though evidence thus far uses undergraduate samples.

The current project developed an intervention to shift secondary students' climate change misconceptions by leveraging data visualization skills and documenting design choices for integrated STEM learning. The intervention used number line visualizations to support data literacy and climate change learning and investigated estimation strategies students used therein.

Theoretical Framework

To explain how novel data and data visualizations might help shift scientific misconceptions, we integrate theories of conceptual change and numerical development. *Conceptual Change* involves restructuring conceptions to align with scientific consensus (Dole & Sinatra, 1998). The Plausibility Judgments for Conceptual Change (PJCC) model (Lombardi et al., 2016) posits that novel information can shift conceptions if it is *comprehensible*, *coherent*, *compelling*, and *valid*. More explicit plausibility judgments—which are influenced by motivation, engagement, and emotion—increase the likelihood of conceptual change (see Figure 1 for a summary).

Figure 1.
Conceptual Change Process Model



Empirical research shows that novel data can inspire conceptual change about climate change. Estimating climate change numbers before presenting the true values can reduce undergraduates' misconceptions (Thacker & Sinatra, 2022; Thacker, 2023). Further, instruction on data-literacy skills can enhance knowledge gains (Thacker, 2023; Thacker et al., 2024). However, no research thus far has tested this approach with secondary students nor assessed the benefits of supplementing the experience with data visualizations.

Data visualizations can support understanding of scientific quantities and developing of numerical knowledge. Siegler's (2016) *Integrated Theory of Numerical Development* posits that people develop an accurate understanding of number magnitudes and their relationships as they connect numbers (e.g., representing rising global temperatures) to the things that those numbers refer to (e.g., global climate change). Such connections between numbers and their referents happen through processes of analogy and association, as facilitated by conventional representations and visualizations. The linear number line is central to representing real numbers and helps students compare magnitudes and understand abstract concepts (Van De Walle et al., 2013). This can support math and science learning, retention, and engagement (Gunderson et al., 2012; Schwartz & Heiser, 2006; Siegler, 2016; Saxe et al., 2013; Stevens & Hall, 1998).

The current research concentrates on the design of an online intervention presenting secondary students with novel climate change data. The study investigates using number line visualizations to enhance student comprehension of climate change data, math and science learning, and identifies strategies students employ that support this learning. Namely, we ask:

1. *How can a learning intervention be developed to leverage number line estimation skills for the learning of climate change science among secondary students?*
2. *What numerical estimation strategies do students employ when estimating climate change numbers? And how do they respond when presented with the true value?*

Methods

To answer our research questions, we used a design-based research (DBR) methodology (Anderson & Shattuck, 2012; Hoadley & Campos, 2022) to guide the design of an online intervention that we call the "Estimation Game." Typical of DBR, the design, implementation, and revision occurred over several iterations (Bakker, 2019; Cobb et al., 2003).

We revised an existing online estimation game (Thacker et al., 2024), where undergraduate students estimated 12 climate change numbers before being shown the scientifically accepted number. Half of the prompts included given benchmark values (e.g., "hints") that learners could arithmetically manipulate to estimate unknown values. After estimating each value, a pop-up window would appear displaying the true number, accuracy feedback (one to five "gold stars"), an explanation of the climate change number to help students contextualize the quantity in terms of students' prior knowledge, and links to sources of the information to improve credibility.

For this study, we aimed to modify this design to improve data comprehensibility and engagement. Modifications included (a) personalized feedback via a number line visualization to help students compare their estimates with the true value, (b) revised text that is more suitable for secondary students, and (c) a revised look-and-feel to be more game-like. This work resulted in an online, open-source estimation game for secondary students with number line visualization feedback (ianthacker.com/design.html). For a related quantitative study, see Thacker (in press).

Participants and Procedure. The intervention design, implementation, and revision occurred over three iterations. We conducted 12 one-on-one "think-aloud" interviews (Desimone & Le Floch, 2004) via Zoom with a diverse sample of secondary students (grades 7-12) from a southern U.S. metropolitan area. Students identified as female (50%), male (50%), Hispanic (60%), White (58%), two or more races (33%), and Black (8%). Each iteration included pretests, engagement with the game, posttests, and a demographics questionnaire.

Survey Materials. Students completed measures of climate change knowledge and plausibility at pretest and posttest. The knowledge measure assessed the scientific consensus on climate change using a five-point agreement scale (Lombardi et al., 2013). The plausibility perceptions measure assessed endorsements related to human-induced climate change using a seven-point scale (Lombardi et al., 2012).

Analysis. Qualitative analysis occurred in four waves: three after each design iteration and a fourth after all data was collected. Interviews were transcribed and analyzed. Interviewers wrote analytical memos based on open analyses of each transcript, and conclusions informed modifications to the Estimation Game. After three iterations, recordings were open-coded for student thinking dimensions (Corbin & Strauss, 2004; Saldaña, 2021). Themes centered around students' quantitative reasoning strategies and emotions experienced during the game.

Findings

Survey results showed growth from pretest to posttest. At pretest, students had an average knowledge score of 2.4 of 5 and plausibility perception score of 4.87 of 7. Posttest scores improved to 2.91 of 5 for knowledge and 5.08 of 7 for plausibility.

RQ1: Design of an Open-Access Data Estimation Game with Number Line Visualizations

Three design iterations informed several game modifications. The first design iteration redeployed the central design features of the original intervention created by Thacker et al. (2024). We asked participants to estimate 12 climate change numbers. After making each estimate, a pop-up window would display the actual value along with accuracy feedback (one to five gold stars), an explanation of the true value, and links to sources of the information. At the end, a summary page provided an overview of all estimated items and accuracy ratings.

Four key improvements were introduced on top of the original design prior to the first round of interviews. First, we modified the accuracy feedback to also present students with a linear number line visualization illustrating each estimate alongside the true value to facilitate comparisons between the two and boost comprehension. Second, we adjusted the procedure for calculating accuracy feedback to present students with gold stars indicating order of magnitude error rather than absolute error, which is a more generous assessment of estimation accuracy and has been used in similar research (Bröder et al., 2022). Third, to make the intervention more "game-like" we modified the progress bar to include an earth icon, the summary page to provide students with a "final score" indicating the sum of their accuracy ratings, and we updated the "look and feel" of the web app to include more color and animation.

RQ2: How Students Responded to the Intervention

Inductive coding revealed themes in students' estimation strategies and emotional responses. Estimation strategies included drawing from prior knowledge, mental computation, and wild guesses. Emotional responses varied from relief, sadness, and surprise about climate change information to excitement or disappointment about their performance. A summary of related results are presented in Table 1.

Table 1. *Summary of Themes Related to Student Reactions to the Estimation Game*

Dimension	Sub-Dimension	# of Students	Example Excerpts from Student Interviews
Theme 1: Strategies for Estimating Climate Change Quantities			
Prior Knowledge	Educational	1	I was in geography and I saw a picture from 2009 to 2020, and it raised by a lot, so I'll say, say 65 inch increase.
	Personal	7	It's really cold right now… so [I'll estimate] maybe like 7
	Prior item	6	I'm going to use the same answer that I used in my first question.
	Vague	11	I remember hearing somewhere… it was 30.
Mental Computati-on Applied to a Given Value	Extrapolation	10	[Reading hint] Global sea levels rose by 1 inch between [1900 and 1920] that's not a lot…. But [now] it's more… like 5 or 6.
	Arithmetic	9	I would just say 12. I'm just going to multiply by four.
	Unspecified	4	I think it's gone down [compared to what was given in the hint]
	Rounding	1	So we'll round the 53 to 50…
Wild Guess	Wild Guess	12	I'd say four. Wild guess
Theme 2: Emotional Response to New Information			
Emotions (about climate change)	Relief	5	I'm glad that more countries are [committing to climate action] than I thought.
	Sadness	8	Geez [glaciers are melting], well that's sad.
	Surprise	8	I am very surprised and happy about it too. Huh. That is a nice surprise to know that I am very wrong.
Emotions (about	Excitement	6	Amazing job. I was so close. *claps* Look at that. It was 151%. Yay, I got five stars!

performance)	Disappointment	5	Seriously? 5 billion times, I got one star. That's my lowest score. That's really sad.

Contributions

We sought to design an Estimation Game and explore the strategies that diverse secondary students use when estimating climate change data. The intervention, guided by theories of conceptual change and numerical development, reduced climate change misconceptions and increased climate change plausibility perceptions. We found that, as students estimated numbers, they tended to draw from their prior knowledge and/or employ mental computation strategies, supporting the idea that estimating real-world quantities may provide opportunities for students to coordinate their magnitude knowledge and prior knowledge in such a way that is mutually beneficial (Siegler, 2016). Future research might explore relationships between estimation strategies and emotional responses and their impact on STEM-integrated learning.

MATHEMATICAL REASONING AND GESTURES IN GEOMETRY WITH AUGMENTED REALITY

Julianna Washington

Candace Walkington
Southern Methodist University
cwalkington@smu.edu

Recent developments in Augmented Reality (AR) headset technologies have allowed for users to see and manipulate the same 3D hologram at the same time, allowing for collaborative, embodied interactions using gestures and actions. Three-dimensional geometry has traditionally been taught largely through 2D projections of 3D figures on pages or screens, thus dynamic holograms open new opportunities for understanding and extending mathematical cognition. In the present study, we examine multimodal interactions for high school students with either joint 3D holograms or without holograms while exploring geometric conjectures. We examine cases in which changing modalities is associated with changes in reasoning and conclude that holograms have important tradeoffs for embodied mathematical reasoning.

Keywords: Mathematical Processes and Practices, Technology and Learning Environment Design, Geometry and Measurement.

Objectives and Purpose

For many secondary students, formal geometric concepts can be hard to grasp. The abstract way in which geometric figures and concepts are presented in "school math" can create challenges for obtaining deep understanding (Ubi et al., 2018). Grounded representations like gestures and manipulatives can help make more concepts more accessible through connections to prior knowledge and real-world experiences (Cook & Goldin-Meadow, 2006; Demitriadou et al., 2020; Goldin-Meadow, 2005; Nathan et al., 2014; Pier et al., 2019; Walkington et al., 2019). In this inherently *embodied* perspective, learning and practicing mathematics by using the body grounds the concepts through perceptual and motor systems resulting from simulated and performed actions (Abrahamson et al, 2020; Wilson, 2002). The framework of embodied cognition has major affordances for improving the accessibility of these concepts that are presented like amodal mathematical operations that have little connection to the real world, social systems, and physical bodies that sparked the ideas and principles behind them (e.g., Lakoff & Núñez, 2000). Previous literature in the field suggests that embodied learning technologies like augmented reality (AR) can have a positive impact on motivation, learning experience, and understanding (Jabar et al., 2022).

In the present study, we sought to investigate the effect of AR goggles on students' geometric reasoning within the context of mathematical learning. Recent advances in AR goggles have allowed three-dimensional (3D) holograms to be projected in the real-world scene in front of students wearing the goggles, with these holograms controlled through intuitive hand gestures (Walkington et al., 2023). Even more significantly, students can engage with these holograms collaboratively, seeing their partners and the room around them, with each able to manipulate the holograms and see the effects of others' manipulations (Washington & Walkington, Accepted). Here we investigate 28 high school students using AR goggles in pairs to explore geometric conjectures and describe the possibilities this modality offers for sense-making, reasoning, and access to mathematical ideas through bodily and perceptual actions. In this study we sought to answer the following research question: What is the effect of Augmented Reality (AR) on high school students' geometric understanding and reasoning compared to without the use of AR?

Theoretical Framework: Collaborative Embodiment and Gesture

The integration of AR technologies in mathematics education holds significant potential, particularly when viewed through the lens of embodied cognition and gestures. Research shows the critical role of AR in fostering embodied cognition, emphasizing the integration of motion, gesture, and meaningful movement to enhance comprehension (Walkington et al., 2021; Bujak et al., 2013). Embodied cognition, rooted in motor behavior, posits that cognitive processes involve active engagement of the physical body within the learning environment (Schneegans & Schöner, 2008). AR, with its interactive capabilities, immerses learners in virtual surroundings, requiring active physical engagement through gestures and manipulation. Gestures, defined as hand or arm movements used to communicate or explore mathematical ideas (McNeill, 1992), play a crucial role. Research (Alibali, 2005; Goldin-Meadow, 2010) highlights the significance of bodily action in learning (Washington & Walkington, Accepted), suggesting that gestures enhance knowledge structure creation in long-term memory compared to verbalization alone (Cook et al., 2008).

Embodied learning, within an enactivist framework, considers cognition as a result of dynamic interaction with the environment (Gallagher & Lindgren, 2015). AR, as noted by Bujak et al. (2013), encourages the creation of embodied representations, facilitating spatiotemporal alignment and a more meaningful learning environment. The ability to dynamically interact with virtual geometric shapes, observe real-time changes, and manipulate objects in AR provides profound affordances for deeper understanding (Washington & Walkington, Accepted). Studies (Price et al., 2020) suggest that immersive AR environments fill gaps in comprehension for mathematical concepts by allowing learners to use their bodies as tangible resources (Washington & Walkington, Accepted). This aligns with the idea that sensorimotor experiences and meaningful movement enhance geometry and spatial learning (Leitão et al., 2014; Özçakır & Çakıroğlu, 2022). Incorporating technology into education, especially AR, scaffolds reasoning and student capabilities, fostering a better assessment of mathematical understanding and knowledge growth. The literature also emphasizes the importance of interactive AR technologies that go beyond passive engagement (Walkington et al., 2023; Washington et al., Accepted;). Theoretical frameworks centered on gestures and embodied learning highlight how AR enhances sense-making, problem-solving, and collaborative learning. Dynamic gestures in AR, coupled with its immersive nature, make mathematical concepts more concrete and visually comprehensible (Bujak et al., 2013; Dunleavy et al., 2009; Tomaschko & Hohenwarter, 2019).

However, while extant literature provides compelling evidence for the benefits of AR in education, there is a gap in research on the possibilities offered by AR holograms for embodiment and gesture. A comparative study of students exploring geometry conjectures with and without AR goggles projecting 3D holograms seeks to uncover the affordances and limitations of AR technologies for embodied collaboration. This investigation delves into the changes in reasoning, encompassing speech, gestures, actions on objects, and whole-body movements in a distributed cognitive system with multiple learners. Through this analysis, the study aims to contribute insights into the potential of AR holograms in enhancing embodied learning and collaborative problem-solving in mathematics education.

Methods of Inquiry

Participants included 28 high school students enrolled in an enrichment program at a local university intended to support high school students likely to become first-generation college students. Twenty-three of the participants were female and 5 were male; 12 identified as African American, 14 as Hispanic, 1 as White, and 1 as Other Race/Ethnicity. They ranged from freshman to seniors, with an average age of 16.04 years. Only 2 students had not yet taken high school Geometry. Participants were asked to reason about 6 of 8 geometric conjectures about different shapes (see Table 1) in pairs, without AR goggles on. Then they put on the Microsoft HoloLens 2 AR goggles and justified 3-4 of the conjectures a second time. They used an app on the Microsoft HoloLens 2 AR goggles developed by GeoGebra (Hohenwarter & Fuchs, 2004), which rendered the shapes as 3D holograms, with the ability for the researcher to toggle different features (e.g., add a plane intersecting the circle or add a cylinder inscribing a cone). All simulations can be viewed at: https://sites.google.com/view/flatlandxr/home.

Table 1: Sample Conjectures Students Were Asked to Reason About and Explain

2D Simulation	Example Conjecture	Simulation Photo	3D Simulation	Example Conjecture	Simulation Photo
Parallel Lines	If two parallel lines are cut by a third line, the pairs of corresponding angles are congruent.		Sphere	A plane can only intersect a sphere at zero, one, or infinite points.	
Triangle	The sum of the lengths of any two sides of a triangle must be greater than the length of the remaining side.		Cylinder	Given a cylinder with radius r and height h, the cylinder can be unrolled to include a rectangle with length h and width 2**π**r.	Parallelogram	Consecutive angles in a parallelogram add up to 180 degrees.		Prism	If the length, width, and height of a cube are each doubled, then the volume increases by a factor of 8.	
Circle	The perpendicular bisector of any chord always goes through the center of the circle.		Cone	The volume of a cone is one-third the volume of a cylinder with the same base and height.	
The feed from each students' goggles was recorded, and camcorders also recorded the room. Videos were transcribed and entered into NVivo. A coding scheme was determined that focused on the nature of the mathematical reasoning, including gestures, collaborative talk moves, actions on virtual objects (i.e., holograms), and whole-body movements (e.g., walking around a triangle). Reasoning was coded as students showing multimodal evidence they understood key mathematical *insights* related to the geometry conjecture (Nathan et al., 2021; Zhang et al., 2016). For example, for the triangle conjecture, a key insight the students can have is that if the sum of the lengths was greater, the triangle will not be able to close. The key criterion for an insight is that it must extend what was explicitly given in the conjecture text, and that it must be consistent with the actual properties and interactions of Euclidean shapes. Insights can occur across modality, and insights communicated by speech were not privileged. Responses were coded as to whether they included mathematical insights when solving each conjecture without the goggles versus on a subsequent attempt with the goggles. Cases where the students did have key mathematical insights both without the goggles and with the goggles were coded as "Insight Stay," and cases where students did not have key mathematical insights without the goggles and then with the goggles were coded as "No Insight Stay." More interestingly, cases where students did not have key insights without the goggles but had key insights with the goggles were coded as "New Insight" and cases where the students had key insights without the goggles that they discarded with the goggles were coded as "Discarded Insight." We first counted all instances of these 4 categories, and then used multimodal analysis (Walkington et al., 2023; McNeill, 1992; Alibali & Nathan, 2012) to analyze one representative instance of each case.

Results

The dynamic nature of the holograms and their 3D nature seemed to have some powerful affordances for mathematical reasoning and embodied collaboration by either changing a student's mind when they were able to see the shape in front of them as a hologram or reaffirming their initial reasoning in both negative and positive ways. See Table 2 for the reasoning counts of changes or stays in reasoning broken down by conjecture.

Table 2: Reasoning Insight Changes or Lack of Changes by Conjecture

	Insight Stay	No Insight Stay	New Insight	Discarded Insight	N/A	Total
Triangle	6	9	4	1	0	20
Circle	3	0	1	1	3	8
Parallelogram	3	4	2	1	0	10
Parallel Lines	6	2	10	3	1	22
Sphere	7	3	4	7	1	22
Cube	0	2	1	1	0	4
Cylinder	2	3	5	1	1	12
Cone	4	1	3	2	0	10
Total	32	24	29	17	6	108

Some students were able to use the holograms and their associated embodied resources and motions to reason more effectively or reaffirm prior reasoning. Figure 1 demonstrates such instances of "Insight Stay" and "New Insight." Figure 1 shows students discussing the parallel lines conjecture from Table 1 using collaborative speech, actions on objects, and gesture. In Figure 1, we see S107 and S108 use dynamic gestures (P1-P3 – moving their hands diagonally to show the angle and vertically parallel to show the parallel lines) without the goggles to explain reasoning. We coded this as **Insight** for S107 as he talked about the intersecting line not effecting the corresponding angles as they would be congruent for both parallel lines (Line 4, P1). We coded S108 as **No Insight** because she references the length of the parallel lines being the reason the corresponding angles are congruent (Line 5, P2-P3). They then moved to the AR goggles portion where having access to the 3D shape seemed to give the students novel insights, and we see them using the shape manipulation to change the perspective they have on the parallel lines to help with sense-making. The dynamic nature of the hologram, combined with its scale (i.e., students were immersed in large-scale parallel lines together) seemed to allow for effective forms of collaborative multimodal communication to occur. We also see S107 using dynamic gestures to reference the path of the parallel lines and the intersecting line (Line 8, P6) and collaborative actions to dynamically modify their parallel lines (P4 and P7). We coded this as **Insight** for S107 and S108, making this an **Insight Stay** for S107 and **New Insight** for S108. As seen in Table 2, this conjecture had the second highest number of Insight Stays (6) and the highest number of New Insights (10) by over double compared to the next conjecture (4). Thus, the immersive, dynamic parallel lines seemed to be powerful as a hologram, leading to reaffirmed and new mathematical insights.

(S107 and S108 start in Verbal discussion of the parallel lines conjecture)

1. 107: I would say it's true.
2. 108: Yeah true.
3. 107: Because if it were to be a parallel line, it doesn't matter what angle or what type of pass the third line takes, it is always going be congruent to your…or, well the corresponding angle is gonna always be congruent because they're always hitting the same type of angle, the line is going to be the same type of angle for both of the lines.

(S107 gestures hand up and down diagonally to show the line angle of intersection to the parallel lines – P1)

4. 108: Same as him, and then since they're parallel, they are never going to stop, they are just going to keep on going straight, no matter the angle.

(S108 gestures hands vertically parallel to show the parallel lines and then moves them upwards to show them as continually parallel – P2 and P3)

(S107 and S108 move to the HoloLens discussion of the parallel lines conjecture)

(S107 moves the angles of the parallel lines – P4)

5. 107: Wait can you show the image again? *(P5)* Okay. Yeah, they're both still similar. Because they still go through the same trajectories and angles that the third one has which leads to it still having the same effect on both.

(S107 gestures his hand back and forth to show the trajectory of the parallel lines – P6)

6. 108: I was about to say, right now I was trying to move the parallel lines and they stayed the same even if I move the middle line.

(S108 moves all three manipulatives, changing the distance and angles between the parallel lines, and the angle of the intersecting line– P7)

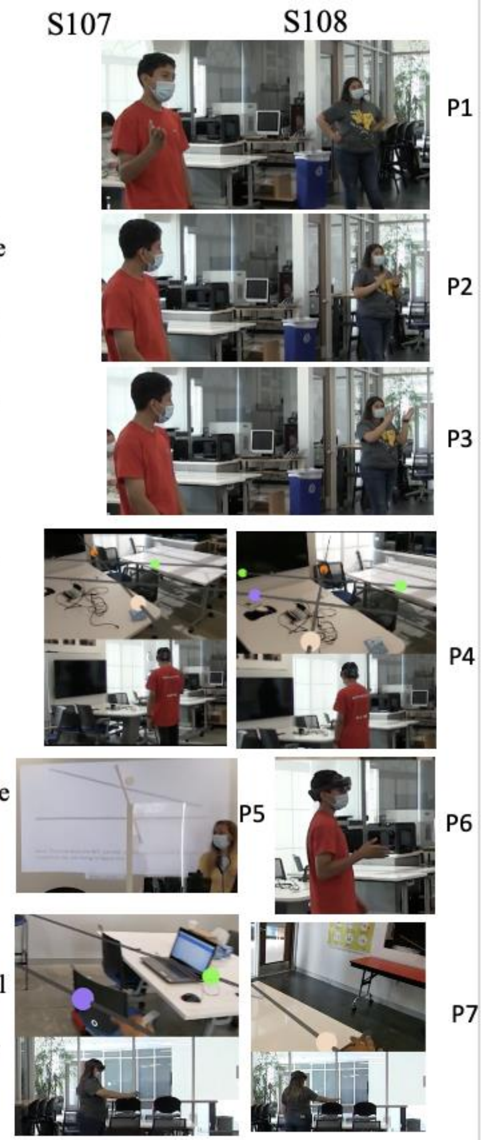

Figure 1: Insight Stay and New Insight: Reasoning about Parallel Lines Conjecture

In Figure 2, we see a case of "No Insight Stay." In this transcript without the goggles, S123 uses representative gesture (P1and P4) that represents two vertically parallel lines, and in P2-3 one arm vertical to show a 90-degree angle and one arm horizontal to show a 180-degree angle. They also use dynamic gestures (P5 – moving his hands back and forth in parallel lines). We coded this as **No Insight** as he talked about the angle and direction to which the sets of parallel lines in the parallelogram were having an effect (Line 2-4 and 9). They then moved to the AR goggles portion where seeing the 3D shape did not seem to give the students novel insights, despite them using the shape manipulation to change the perspective they have on the parallelogram. Despite S124 making a relevant observation in Line 12 (P7), the students cannot see how the angles can equal 180-degrees. In Lines 15-18, S123 and S124 add two sets of angles and explain that neither add to 180-degrees and use pointing gestures (P8-P10 – pointing at the angles) and collaborative actions to dynamically modify their parallelogram (P6) to show their thinking. We coded this as **No Insight Stay**. As seen in Table 2, No Insight Stays were the most common (4) within this conjecture.

(S123 and S124 start in Verbal discussion of the parallelogram conjecture)
1. 123: If parallel lines go straight, they don't touch.
(S123 gestures to represent vertical parallel lines with his arms – P1)
2. 123: The line depends where they really are. Cuz I mean if it goes up it's 90 degrees. But regular straight line is 180 degrees.
(S123 gestures to show a vertical line representing a 90• angle, then gestures a flat horizontal line to represent a line with a 180• angle – P2)
3. 123: So, it kinda depends where the lines are pretty much going.
(S123 gestures both arms vertically parallel and then horizontally parallel – P3)
4. 124: So false?
5. 123: Yeah, I'm guessing false here.
6. 123: So, if they both go up, then maybe they can add up to 180. Depending, cause they're going go up so they're pretty much going to add up to 90•.
(S123 gestures vertical parallel lines three times, once moving his arms up and down two times, then gestures one hand horizontal and one vertical to create a 90• angle – P4)
7. 123: But if they goes sideways you want to slide down the bottom with 180 degrees. So pretty much if you add those up, they will equal 360 degrees, not 180.
(S123 gestures hands left to right horizontally parallel crossing each other to represent the parallel lines, then gestures with both forearms to create a long horizontal line – P5)

(S123 and S124 move to the HoloLens discussion of the parallelogram conjecture)
(S123 and S124 move the shape changing the size and creating different angles – P6)
8. 123: Consecutive angles are angles inside the shape that are next to each other. So next as in parallel or like right next to each other as in...?
9. 124: Yeah, as in top and bottom or left and right, I think that's what it means.
(S124 gestures to the left corner and right corner to show these angles are top and bottom or equivalently left and right that are consecutive angles – P7)
10. 123: So, it said it's always equals to 180. Okay, then it says consecutive angles so its two angles so I'm guessing its 121 plus 121, that doesn't equal 180.
(S123 points at the bottom right angle that is 121• and the top left angle that is 121• – P8)
11. 124: Because it already passed 180.
12. 123: Yeah, 58 and 58, but it doesn't equal to 180. Do we make it smaller to see if it's still to the point where it's about to be...
(S123 points at the bottom left angle that is 58• and the top right angle that is 58• – P9)
13. 123: Make it smaller. If I make it smaller the angles get bigger depending on which side. This one is one... There, it's there. It's smaller but the angle is 126 and this one is 126 and these two angles top and bottom...wait is that left or right?
(S123 gestures to point at two angles and then point to the remaining two angles – P10)
14. 123: False.
15. 124: False.
16. 123: Since it depends on really the angles but even the angles are beyond the point where they can make it to 180 together.
(S123 gestures to point at the angles)

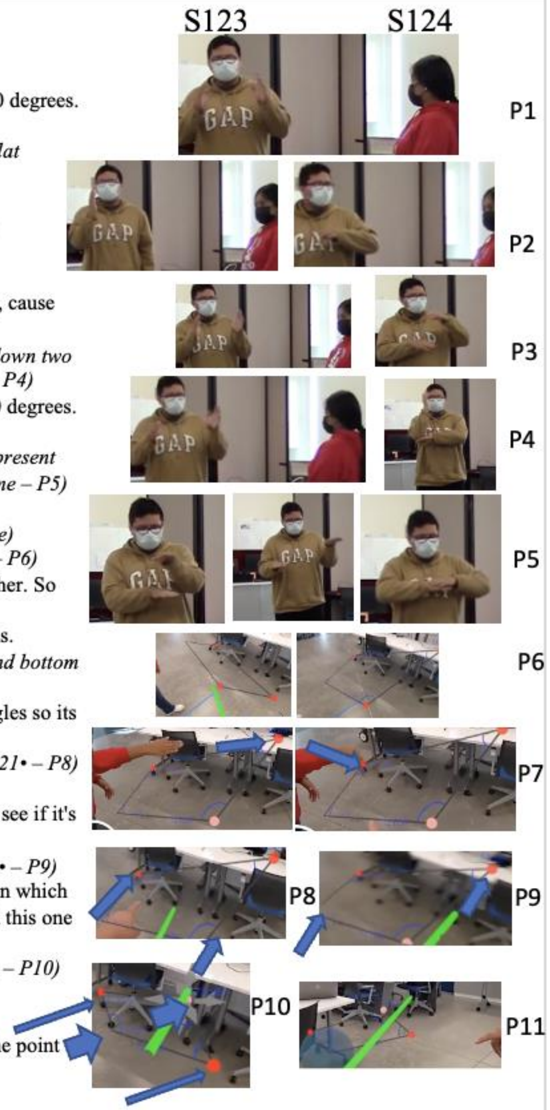

Figure 2: No Insight Stay: Reasoning About the Parallelogram Conjecture

In Figure 3, we see the "Discarded Insight" case where a pair attempts to prove the sphere conjecture. Without the goggles, we see S111 use representational gestures (P1 and P3 – creating an intersection and a sphere with her hands), dynamic gestures (P4 – moving her hand forward to show a cut or moving intersection) and pointing gestures (P3 – pointing at a single point on the imaginary sphere) to explain her reasoning. We coded this as **Insight** as she communicated having an infinite piece of paper and the places that would intersect the sphere (Line 6-7). They then moved to the AR goggles portion where having access to the 3D shape seemed to give the students novel insights, and in the video, we see them using the shape manipulation to change the perspective they have on the sphere to help with sense-making. We see them using pointing gestures to reference places on the sphere and collaborative actions to dynamically modify their sphere, all while engaging in collaborative talk moves. However, despite this strong start (Lines 11-14, P6), they did not see how zero points of intersection was possible with the hologram now present (Lines 16-20). We coded this as **Discarded Insight**. As seen in Table 2, the sphere conjecture had the highest number of Discarded Insights (7) amongst conjectures; thus, the hologram was not functioning for students' math reasoning in the way we had intended.

(S111 and S112 start in Verbal discussion of the sphere conjecture)

1. 111: So, hmm it may be true. Well, I don't know about it being zero. Think it's true?

(S111 gestures one hand flat and another on top gesturing "intersection," then creates a representation of a sphere with her hands – P1)

2. 112: Yeah. I think it's true.
3. 111: Yeah, I think it's true.
4. 111: Umm, I don't know, if you get an actual sphere and a piece of paper but think of it as an infinite piece of paper, and you place the sphere on the piece of paper, it could intersect it that one point.

(S111 gestures her hands outwards, then points to the bottom "one point" she referenced, then creates a sphere with her hands – P2 and P3)

5. But if you take the piece of paper and intersect it through the whole sphere, that is more than one point. That is basically like half the circle or the diameter of it. I am probably thinking too much but that is how it infinite points, so, that's why I said it's true.

(S111 gestures one hand flat and moves it forward to represent the paper "intersecting" through the sphere, then points her finger and moves it in the air drawing a circle – P4)

(S111 and S112 move to the HoloLens discussion of the sphere conjecture)

(S111 and S112 make the sphere bigger and smaller – P5)

6. 111: So, this is the plane and the circle, okay maybe not zero points. I mean it is intersecting it so...okay wait where is the point?
7. 112: I think it's true because it can literally intersect anywhere, so I think it's true.
8. 111: Well, it does say at zero, one, or infinite points so it's including zero, oh crap wait. Well, it's not really intersecting at zero points, so to say. Because it's intersecting it right here and right here. Ummm...

(S111 point to the left side and the right side of the sphere – P6)

9. 111: Okay. Yeah, I mean it still intersects at at least one point. I wouldn't say zero points.
10. CW: Alright so you don't think zero points is possible.
11. 111: No, well if it's intersecting it, it's intersecting at one point, yeah so, I think that's false.
12. 112: Well now that she said zero points, it's kind of making me think about it. But I don't know because I get the one but I also kind of don't get the zero. So, I'll go with false.

(S112 makes the sphere bigger and smaller – P7)

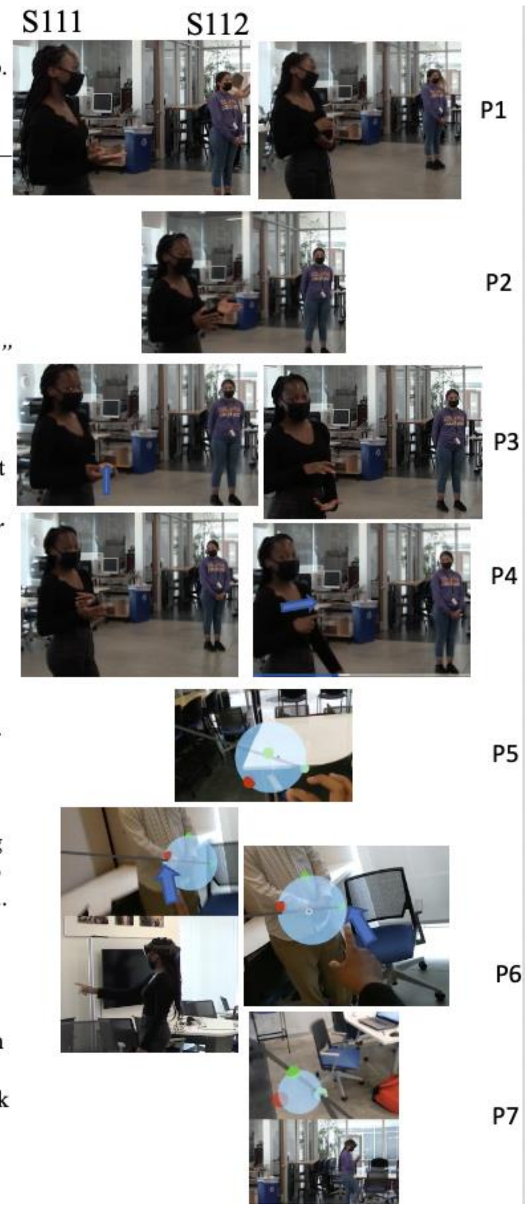

Figure 3: Discarded Insight: Reasoning About the Sphere Conjecture

Discussion

This study has several implications. The first is that AR environments can change, support, or reinforce students understanding, beliefs, or thought processes in their sense-making of geometric objects, in some situations. Students can use these technologies effectively to support in creating meaning to illustrate students' "knowledge" (Bujak et al., 2013; Jabar et al., 2022; Tomaschko & Hohenwarter, 2019; Washington & Walkington, Accepted). AR can also be an effective tool that helps clear up misconceptions or errors in mathematical reasoning with 'physical' manipulatives and visuals to aid in this process (Price et al., 2020; Jabar et al., 2022). However, some students who use the technologies could have trouble with altering their reasoning to be consistent with mathematical insights about how figures and shapes work in Euclidean space. This could come from not using the technology effectively, forgetting to use the technology, or trouble seeing the mathematics in the hologram, which could reinforce students' original reasoning. Another idea is that AR holograms may be more impactful and appropriate for concepts that are inherently three-dimensional, as these objects and our simulations leverage profound affordances; however, our data does support their effectiveness for some 2D objects like parallel lines cut by a transversal. Finally, AR allows students to interact with and explore objects in novel and nontypical ways (Bujak et al., 2013; Dunleavy et al., 2009; Walkington et al., 2023; Washington et al., Accepted; Washington & Walkington, Accepted). However, if you bring more traditional "school" tasks into an AR environment, students' reasoning and attempts at meaning-making could be restricted. In our context, each simulation could use more time for exploration of properties of a figure, rather than confronting a specific conjecture immediately. Future study alternatives we are exploring is to scaffold students by having them work up to making and proving or disproving conjectures after familiarizing themselves with the movements of the figures. Tasks in an AR environment become particularly meaningful if they come from students and their embodied, gestured, collaborative experiences (Walkington et al., 2019; Washington & Walkington, Accepted).

xzy73@psu.edu

Jiexin Gan
Pennsylvania State University
jfg5970@psu.edu

This study aimed to examine the quality of the GeoGebra applets for fraction division by attending to the conceptualizations, representations, and cognitive actions prevalent in these digital resources. The results reveal that a majority of the existing applets conceptualize fraction division as measurement while other conceptualizations of fraction division are underrepresented. Among the various representations used, the length model in the form of fraction bar and area model are the predominant choices, with the number line representation being notably less prominent. The results from this study also show that although most applets attempt to visualize the process of fraction division, there are limited opportunities in most applets for users to enact mental actions associated with fraction division, such as partitioning, unitizing, iterating, and disembedding. These results not only increase our understanding of the affordances and limitations of existing applets for fraction division so that we can become more intentional in our choice of them but also inform the design of new applets that support students' development of a rich and robust understanding of fraction division.

Keywords: Rational Numbers, Technology, Mathematical Representations

A robust understanding of fractional concepts not only extends students' understanding of numbers but also is foundational for learning more advanced mathematical content areas and everyday quantitative reasoning. Research has shown that understanding fractions is predictive of students' long-term success in mathematics (NMAP, 2008; Booth & Newton, 2012; Siegler et al., 2012). Despite its importance, researchers have documented challenges in understanding fraction concepts among students in both elementary and secondary schools (e.g., Pitkethly & Hunting, 1996; Siegler & Pyke, 2013). This is especially the case for fraction division, where the literature indicates that students and even prospective mathematics teachers often struggle to create and use representations appropriately, overgeneralize properties of operations with natural numbers to fractions, interpret division primarily using a primitive partitive model of division, and tend to absorb only mechanical procedure like the invert-and-multiply algorithm and thus create "bugs" in computing division expressions (e.g., Tirosh, 2000; Lo & Luo, 2012; Adu-Gyamfi et al., 2019). In other words, the lack of conceptual understanding and representation fluency of fraction division has been identified as a major issue for learning fraction division.

The past few decades have seen the rise of a large repertoire of mathematics-specific technological tools, which can support teachers and students in visualizing, displaying, acting upon, observing, and validating mathematics relationships (Heid & Blume, 2008). By including dynamic and/or interactive representations, these digital tools have the potential to provide students with new ways to conceive and represent mathematics ideas, which are likely to support their development of conceptual understanding and representation fluency of mathematical concepts. In the domain of fractions, evidence suggests that the use of digital technology can provide opportunities for students to work with/on fractions in interactive and dynamic ways, which are likely to support the development of robust understandings of fractional concepts and their operations (e.g., Steffe & Olive, 2002; Poon, 2018; Anat et al., 2020; Yeo & Webel, 2024). Meanwhile, researchers have pointed out that the design of tool-based tasks can embody different conceptualizations and representations of a mathematical idea (Leung & Bolite-Frant, 2015). The use of different conceptualizations and representations in the design of tool-based tasks might impact not only what mathematical ideas are learned but also how they are learned. Therefore, it is important to analyze how mathematical ideas are conceptualized and represented in different tool-based tasks and resources. This is particularly true for concepts like fraction division, which are not only difficult to teach and learn conceptually but also open to multiple conceptualizations and representations.

As an interactive geometry, algebra, statistics, and calculus application that can run on multiple platforms (e.g., desktops, tablets, and online), GeoGebra is developed for learning and teaching mathematics from primary school to university level. The GeoGebra website hosts more than one million free activities, simulations, exercises, lessons, and games for mathematics and science. A significant number of these GeoGebra applets are created for students to learn fraction division. Given that GeoGebra is a community of millions of students and teachers who are potential users of these applets, it is important to examine the conceptualizations and representations of fraction division in these applets.

Literature Review and Conceptual Grounding

Conceptualizations of Fraction Division

The literature has described diverse conceptualizations of fraction division, including , division as partition, division as the determination of a unit rate, division as measurement and division as the inverse operation of multiplication (Sinicrope et al., 2002; Gregg & Gregg, 2007; Lamon, 2012; Adu-Gyamfi et al., 2019). When interpreting *fraction division as partition*, fraction division is perceived as the process of equally sharing a given quantity (dividend) between a given number (divisor) of groups in order to determine the amount in each group. Note that the conceptualization of fraction division as partition is efficient only in situations where the divisor is a whole number. When interpreting *fraction division as the determination of a unit rate*, the focus is not on the action of equally sharing but rather on the size of one unit. Under this conceptualization, $\frac{a}{b} \div \frac{c}{d}$ is interpreted as $\frac{a}{b}$ of one unit of quantity A corresponds to $\frac{c}{d}$ of one unit of quantity B, and the result of $\frac{a}{b} \div \frac{c}{d}$ represents the amount of quantity A in relation to one unit of quantity B. Therefore, $\frac{a}{b} \div \frac{c}{d} = \left(\frac{a}{b} \div c\right) \div \frac{1}{d} = \left(\frac{a}{b} \times \frac{1}{c}\right) \times d = \frac{a}{b} \times \frac{d}{c}$, in which $\frac{a}{b} \div c$ represents only $\frac{1}{d}$ of a unit and multiplying the quantity by d will get the whole unit. It is worth noting that this conceptualization of fraction division makes use of the partition interpretation of fraction division (i.e., $\frac{a}{b} \div c = \frac{a}{b} \times \frac{1}{c}$) and proportional reasoning. When interpreting *fraction division as measurement*, $\frac{a}{b} \div \frac{c}{d}$ is conceptualized as the number of times that the quantity $\frac{c}{d}$ can go into $\frac{a}{b}$. In other words, $\frac{c}{d}$ is considered as a unit of measure for $\frac{a}{b}$. This conceptualization of fraction division can lead to the common denominator algorithm for fraction division: $\frac{a}{b} \div \frac{c}{d} = \frac{a \times d}{b \times d} \div \frac{b \times c}{b \times d} = ad \div bc$. In this algorithm, the divisor and the dividend are first expressed as fractions with like denominators, and the numerators are then divided to compare the fractions multiplicatively. As *the inverse operation of fraction multiplication*, a fraction division acts as an inverse function to that of fraction multiplication, mapping some set onto another set. More specifically, the original amount (product in multiplication, dividend in division) is multiplied by the denominator and divided by the numerator. This conceptualization of fraction division revolves around actions such as shrinking and enlarging, compressing and expanding, or simply multiplying and dividing.

Mental Actions Associated with Fraction Division

Mental actions constitute the key component of mental schemes. Mental actions, such as unitizing, partitioning, disembedding, iterating, and splitting are essential when working with fractions and their operations (Steffe & Olive, 2009). *Unitizing* is a mental action that treats an object or collection of objects as a unit, or a whole. Unitizing is essential for understanding fraction division because understanding fraction division demands the ability to visualize reference units, to move between the original unit and the intermediate unit, and to interpret a symbol or operation in terms of those units. *Partitioning* is the mental action of dividing a unit, or a whole, into equal parts. Equal-sized parts are fundamental to partitioning and to constructing the part-whole conception of fractions. *Disembedding* is the mental action of imaginatively pulling out a fraction from a whole while keeping the whole intact. The part-whole conception of fraction relies on mental actions of partitioning and disembedding, with which students can project n equal parts in a continuous whole (partitioning) and pull out m of those parts without losing track of their containment within the whole (disembedding), resulting in the fraction $\frac{m}{n}$. *Iterating* is the mental action of repeating a part to produce identical copies of it. The part can be a unit fraction or a non-unit fraction. Iteration helps children conceive of a whole as a multiple of a same-size unit, which draws their attention to the number of times a unit fraction fits within the whole. *Splitting* is the simultaneous composition of partitioning and iterating. Students who can perform the splitting operation recognize that partitioning and iterating are inverse to each other. They can split an unpartitioned piece of a larger or smaller whole to re-create the whole. These mental actions are vital for developing a robust understanding of fraction concepts and their operations, including fraction division.

Dick (2008) proposed a method of evaluating digital tools and resources for their pedagogical, mathematical, and cognitive fidelity, claiming that high levels of fidelity in these areas are necessary for a significant impact on student learning. The notion of cognitive fidelity indicates that digital tools and resources for mathematics teaching and learning should reflect students' cognitive actions with an emphasis on illuminating mathematical thinking processes rather than simply arriving at the final results. A GeoGebra applet with high cognitive fidelity for fraction division should not only demonstrate but also enable its users to enact the mental actions associated with fraction division. Given the importance of mental actions such as unitizing, partitioning, iterating, and disembedding in different conceptualizations of fraction division, it is important to assess how well GeoGebra applets support these mental actions.

Representations of Fraction Division

It has been agreed that mathematical objects such as fractions cannot be directly perceived or observed with instruments, and access to mathematical objects is bound to the use of a system of semiotic representations that allow them to be designated (Goldin, 1998; Duval, 2006). In the mathematical domain of fraction division, representations that model the process of division may include but are not limited to set models (i.e., the whole is understood to be a set of objects and subsets of the whole consist of fractional parts, such as pictures of familiar objects and dots), area models (i.e., fractions are represented as parts of an area or region of a shape, such as circles, rectangles, and grids), length models (i.e., a fraction is identified as being a particular distance from the "start" of the whole, such as fraction bars and number lines), numerals, and algebraic symbols. These representations have been used to model the different conceptualizations of fraction and fraction division. Research shows that specific representations and models of fraction concepts and operations do have their strengths and limitations. For instance, concrete set models may be well-suited to illustrate part-whole concepts but may not be appropriate for helping children understand fractions as numbers with specific magnitudes (Cramer & Wyberg, 2009). Circle representations can illustrate both the part-whole relationship and the meaning of the relative sizes of fractions (Cramer & Wyberg, 2009), but they are less helpful in supporting the conceptualizations of fractions beyond equal partitioning and tend to support additive thinking rather than multiplicative thinking needed for understanding fractions (Moss, 2005). Number lines help students see fractions as not only parts of a whole or parts of a set but also a part of distance. Many studies have argued the superiority of the number line over other representations of fractions (e.g., Sidney et al., 2019; Hamdan, & Gunderson, 2017). However, compared with other visual representations, the number line is more abstract and cognitively demanding because students have to coordinate symbolic information and visual cues in order to bring meaning to this model since the number line uses symbols to convey part of its meaning. Therefore, it is important to use multiple representations in teaching and learning fractions and their operations. To support students in developing a rich and robust understanding of fraction division, it is important to provide with them the opportunity to work with fraction division constructs (e.g., partition unit, referent units, and whole) via mental actions on representations (e.g., unitizing, partitioning, disembedding, iterating, and splitting) and reflective abstraction on those actions, to utilize multiple representations of the same fraction division conceptualization to observe isomorphic transformations between representations and to utilize multiple representations of the different conceptualizations of fraction division.

Research Questions

Informed by the literature on fraction division, this study was guided by the following questions:

1. What conceptualizations of fraction division are used in the GeoGebra applets for fraction division?
2. What representations are used in the GeoGebra applets for fraction division?
3. What cognitive actions are supported by the GeoGebra applets for fraction division?
4.

Methodology

Data Collection

GeoGebra applets for fraction division were collected from two different sources. First, on August 21, 2023, the keywords "fraction division" and "dividing fractions" were typed into the built-in search engine provided by the GeoGebra community resources cloud service (https://www.geogebra.org/materials), which resulted in 156 and 44 outputs, respectively. Data Miner (https://dataminer.io), which is a Google Chrome Extension and Edge Browser Extension that helps its users crawl and scrape data from web pages and export the data into a CSV file or

Excel spreadsheet, was used to collect the names and URLs of the GeoGebra applets. After combining the results from the two searches, 11 files were first removed due to identical URLs. Second, a set of GeoGebra applets for fraction division was identified from a larger raw data set of GeoGebra applets for fractions that aimed to be used to investigate the conceptualizations and representations of fraction concepts and their operations in the existing resources on the GeoGebra website. The GeoGebra fraction applets in the larger data set were collected in two different ways. First, the keyword "fraction" was typed into the built-in search engine provided by the GeoGebra community resources cloud service. Second, fraction applets were also identified through the organization chart on the GeoGebra (https://www.geogebra.org/t/fraction). 1054 GeoGebra applets were left in the larger data set after initial data cleaning, of which 84 GeoGebra applets were likely about fraction division as their names included the word "division". After combining the results from the two sources, 57 files were first removed due to identical URLs. Among the remaining 216 files with unique URLs, 20 applets were in languages other than English, 75 applets were not on fraction division (e.g., modeling division $a \div b$ as a fraction, where a and b are both integers), 61 applets were duplicates of an existing applet with a different URL, and 4 applets were incomplete. This data cleaning process resulted in 56 unique GeoGebra applets for fraction division, of which 43 applets demonstrate fraction division and 13 applets generate practicing problems on fraction division. This study focused on the 43 applets.

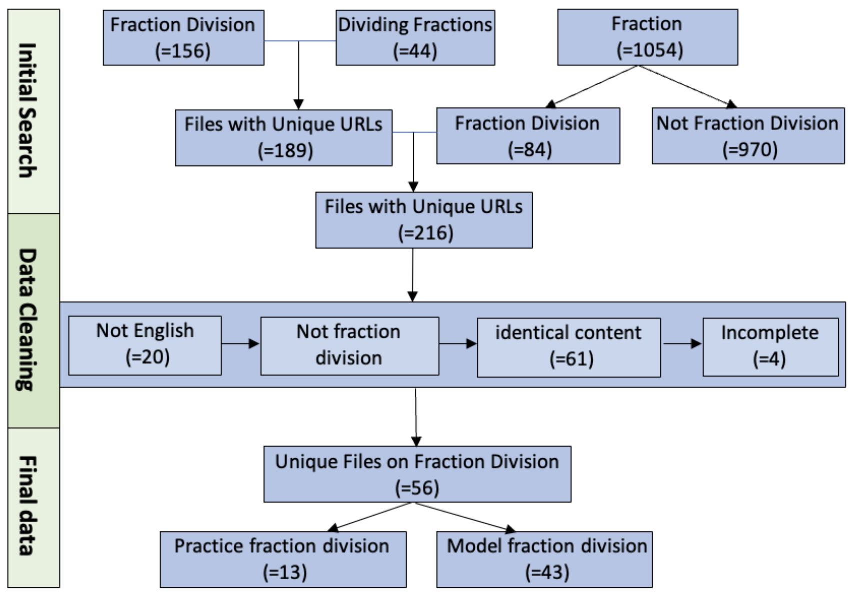

Figure 1: Data Collection and Cleaning Process

Data Analysis

When analyzing each applet, we considered the conceptualization of fraction division that the applet was based upon, the representation that was used in the applets, and the cognitive actions associated with fraction division that the applet could support. We also considered the type of fraction division being modeled, as it can influence the conceptualization used. The types of fraction division include a fraction divided by a whole number $\left(\frac{a}{b} \div n\right)$, a whole number divided by a fraction $\left(n \div \frac{a}{b}\right)$, and a fraction divided by a fraction $\left(\frac{a}{b} \div \frac{c}{d}\right)$. A fraction in an applet could be either a proper or an improper fraction. The conceptualizations of fraction division include fraction division as measurement, fraction division as partitioning, fraction division as the determination of unit rate, and fraction division as operator. The types of representations that could be used in an applet include fraction bar and number line in the length model, rectangle and circle in the area model, numerical representation, and algebraic representation. When coding cognitive actions supported by an applet, we considered the affordance of the applet in supporting the following actions, namely, changing the dividend/divisor fraction, unitizing, partitioning, iterating, and disembedding. We differentiated between the affordance of demonstrating the actions and the affordance of enacting the actions. We believe that such distinction is important because an applet might use a particular representation to visualize the process of fraction division without allowing its users to enact the action in the applet. Each applet was coded by the two authors. There was a high inter-rater reliability between the two authors. Disagreements in codes were resolved through discussion.

Results

Conceptualizations of Fraction Division in the GeoGebra Applets

As shown in Figure 2a, among the 43 applets, 28 were found to model "a fraction divided by a fraction" $\left(\frac{a}{b} \div \frac{c}{d}\right)$, 10 modeled "a whole number divided by a fraction" $\left(n \div \frac{a}{b}\right)$, and the remaining 5 applets modeled "a fraction divided by a whole number" $\left(\frac{a}{b} \div n\right)$. As shown in Figure 2b, among the 43 GeoGebra applets designed to model fraction division, 67% (31) of applets adopt the conceptualization of fraction division as measurement. The remaining conceptualizations are distributed fairly evenly, with 9% (4) applets framing fraction division as a determination of unit rate, 11% (5) as partitioning, and 13% (6) as the inverse operation of multiplication. There are a small number of applets (n=3) that integrate two conceptualizations.

Figure 3: Representations Used in the GeoGebra Applets for Fraction Division

Representations of Fraction Division in the GeoGebra Applets

Regarding the representations employed, a notable number of applets use the length model (n=19) and the area model (n=19) to convey their respective conceptualizations of fraction division. Among the 19 applets using the length model, only one utilizes the number line model, while the remaining 18 applets use a fraction bar model. In the case of the area model, 10 applets use a rectangular area model, while the remaining 9 applets opt for a circular area model. 5 out of the 43 applets provide numerical or algebraic procedural explanation without incorporating any visual representations.

A cross-analysis of the use of conceptualizations and representations reveals several noteworthy patterns. The use of the length model is preferred in the conceptualizations of fraction division as measurement and fraction division as the determination of unit rate. Specifically, among the 31 applets that use the measurement interpretation, the length model is used in 17 instances (16 use fraction bar, and 1 uses number line), followed by 12 instances of area models (6 rectangular, 6 circular). However, in contrast to that, all 5 applets that conceptualize fraction division as partition exclusively use the area model, with 3 instances of the rectangular area model and 2 instances of the circular area model. When fraction division is interpreted as an operator, although the length model is not used in any of the 6 applets, there is no distinct preference identified in the use of the other three representations.

Cognitive Actions Supported by the GeoGebra Applets

The analysis of cognitive actions supported by the GeoGebra applets for fraction division reveals a predominant reliance on passive demonstration rather than interactive user engagement. As shown in Figure 4, among the analyzed applets, 70% (30) applets showcase the action of partitioning, providing a visual representation of the fraction division process without allowing users to execute the partitioning action. Similarly, 42% (18) applets demonstrate the action of unitizing, while 32% (14) applets and 5% (2) applets illustrate the process of iterating and disembedding, respectively. Out of the 43 applets, 74% (32) applets allow users to change the values of the divisor and/or dividend. However, this prominence of fraction modification is counterbalanced by the limited incorporation of interactive features that support students' enactment of cognitive actions associated with fraction operations. More specifically, only 11.6% (5) applets allow their users to iterate a fraction, only 2.3% (1) applet allows its users to partition a fraction, and only 2.3% (1) applet allows its users to enact the action of disembedding. None of the applets allow the users to enact the action of unitizing.

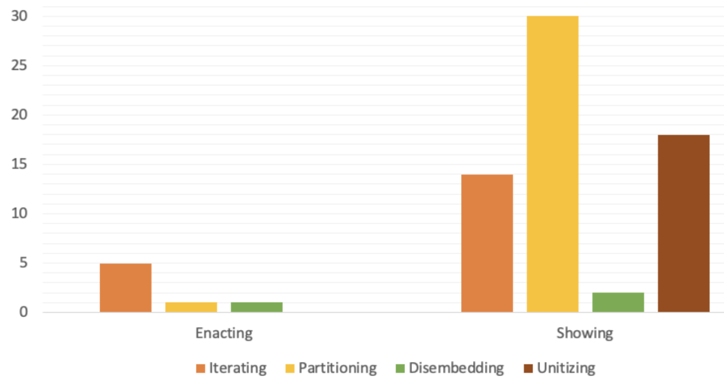

Figure 4: Cognitive Actions Supported by the GeoGebra Applets for Fraction Division

Discussion and Conclusion

Although dynamic mathematical software programs such as *GeoGebra* make it easy for their users to create and share digital applets with interactive and dynamic features, the quality of these applets is less clear. This study aimed to examine the quality of the *GeoGebra* applets for fraction division by attending to the conceptualizations, representations, and cognitive actions prevalent in these digital resources. The results offer valuable insights into the features of the GeoGebra applets for fraction division, which could inform the choices and design of GeoGebra applets for fraction division. This type of content-specific analysis of GeoGebra applets is important because it moves beyond the dynamic and interactive features of digital applets and focuses on what they actually can or cannot afford and how they can be improved in terms of supporting the teaching and learning of fraction division.

One noteworthy observation is the underutilization of the number line in the GeoGebra applets for fraction division, despite its advocated superiority in various studies (Sidney, Thompson, & Rivera, 2019; Hamdan & Gunderson, 2017). While the number line is argued to align well with the measurement conceptualization of fraction division, its scarcity in the analyzed applets suggests a gap in its integration. This might be due to the contradictory facts that the number line is more abstract and cognitively demanding as compared to other visual representations, yet fraction division is usually taught to young students in Grade 5. This also indicates that educators and applet designers may still need to fully explore how the number line can be used to support different conceptualizations of fraction division. Future design of GeoGebra applets for fraction division may consider utilizing the number line to model different conceptualizations of fraction division.

Furthermore, the findings illustrate the popularity of the use of length model (i.e., fraction bar) to represent the measurement interpretation of fraction division and the use of area model (both circular and rectangular representations) to represent partition interpretation of fraction division. This may be partially attributed to the common representations that are typically associated with different conceptions of fraction. While area models such as circles and rectangles are often used to highlight the action of equal partitioning, length models such as fraction bar and the number line are often used to underline the action of iterating. Since the partition interpretation does not necessitate the cognitive action of “iterating”, there is no specific need to use a length model, as an area model is more than enough to enable the cognitive actions of “partitioning” and “unitizing”.

It is evident from the findings that the conceptualization of fraction division as measurement is more prominent than the other conceptualizations. This might be partially attributed to the promotion of measurement conception of fraction by the mathematics education research community and curriculum standards. There is no doubt that the conceptualization of fraction division as measurement can support students in developing a conceptual understanding of fraction division and the common denominator algorithm for fraction division, which might make more sense for many students than the invert-and-multiply algorithm for fraction division (Van de Walle, Karp, & Bay-Williams, 2022). However, the dominance of measurement interpretation of fraction division in the analyzed applets also raises concerns about the underrepresentation of other conceptualizations of fraction division. Working with different conceptualizations of fraction division enables students to not only develop a rich and robust understanding of fraction division but also connect fraction division with other mathematical ideas. For instance, developing an understanding of fraction division as the determination of unit rate not only allows students to see how fraction division as partition can be extended to a fraction divided by a fraction but also provides them with an opportunity to use and deepen their understanding of ratio and proportional reasoning. Therefore, the design and choice of GeoGebra applets for fraction division should provide students with opportunities to learn multiple conceptualizations of fraction division to foster a rich and robust understanding of it.

Despite GeoGebra's functionality and affordability to support the design of high cognitive fidelity applets, the results from this study show that most existing open-access GeoGebra applets for fraction division fail to leverage this potential. That is, many provide their users the opportunity to visualize the process of fraction division but not the opportunity to enact the mental actions associated with fraction division. This might be attributed to the emphasis on visualization and teacher-centered use of technology, in which students are positioned to listen and watch digital information rather than actively act on mathematical objects on the screen. Future design might consider enhancing the cognitive fidelity of the GeoGebra applets for fraction division by enabling students to enact essential mental actions associated with fraction division.

This study reports on a part of a broader research project on enhancing preservice elementary mathematics teachers' understanding of number theory concepts in AI-integrated independent learning sessions. Exit interviews were conducted with participants to understand their perceptions of using an AI-powered guide (Khanmigo) in their mathematics learning experiences. Findings suggest that preservice teachers found AI to be beneficial in helping them understand mathematical problems better, providing personalized learning opportunities, and promoting open sharing of questions and challenges. They also faced challenges with AI such as confusing responses and AI's limitations in getting to know individual learners.

Keywords: Preservice Teacher Education, Artificial Intelligence, Technology

Research on the role of AI in mathematics teacher preparation is in its nascent stage. Emerging research has demonstrated that the integration of AI in mathematics education can provide opportunities for cultivating a deeper understanding of mathematical concepts and situating mathematics in meaningful contexts (Aleven et al., 2023; Gattupalli et al., 2023). AI-powered guides are recognized for their potential to boost students' mathematical learning and thinking skills (Hwang & Tu, 2021). Despite the potential benefits, little progress has been made in exploring ways to support teachers and learners in the effective and responsible use of AI tools (Celik et al., 2022; Hwang et al., 2020; Hwang & Tu, 2021). Moving forward, there's a critical need to delve into various aspects of AI's role in mathematics education, including creating innovative and personalized learning environments, understanding the impact of AI on learning experiences, and evaluating the effectiveness of AI through theoretical perspectives (Balacheff, 2023; Hwang et al., 2020; NCTM, 2024).

In our commitment to fostering meaningful student engagement with AI in mathematics classrooms, we recognize the pivotal role of teacher education. Future teachers must grasp the significance of AI and engage with it meaningfully and productively (Hwang et al., 2020; McGrath et al., 2023; NCTM 2024). Consequently, it is the responsibility of mathematics teacher educators to devise innovative instructional approaches into teacher education courses, to model the integration of AI into productive mathematics learning environments. In this paper, we present an initiative where an AI-powered guide, Khanmigo (https://www.khanmigo.ai), was integrated into five teaching modules in content courses for preservice elementary mathematics teachers (PEMTs). As part of a broader research project investigating the impact of teaching modules on PEMTs' understanding of basic number theory concepts, this paper is focused on findings related to this research question: How do PEMTS describe their experiences with an AI-powered guide during independent learning sessions (ILS) focusing on number theory concepts?

Methods

Interviews were used to gain an in-depth understanding (Brenner, 2012) of PEMT's perspectives on their experiences as they interacted with Khanmigo in AI-integrated content course. An ILS refers to a period within class time in which the PEMTs worked collaboratively in small groups, utilizing Khanmigo to explore number-theory concepts and solve open-ended problems. Students engaged in discussions without direct instruction from the mathematics teacher educator who played a supportive role when needed.

We selected Khanmigo to enhance mathematical discourse through personalized tutoring and interactive learning (Kshetri, 2023) during each ILS. Utilizing GPT-4, Khanmigo's chatbot simulates a tutor who facilitates conversations ad provides constructive feedback to the learner rather than providing direct answers (Ofgang, 2023).

Research Context

The study was conducted at a university in the midwestern United States during Fall 2022 in a Fundamental Mathematical Concepts for Elementary Teachers course. Participants were 26 PEMTs who engaged in five 75-minute AI-integrated ILS. The sessions were centered around the following concepts: prime and composite numbers, divisibility rules, prime factorization, greatest common denominator (GCD), and least common multiple (LCM). The instructor (third author) created a set of open-ended problems for each concept and modeled how PEMTs could use Khanmigo (used interchangeably with AI in this paper) to engage with the problems. During each session, the instructor guided and provided support to the PEMTs when they faced difficulties while utilizing AI to solve problems and/or comprehend number theory concepts. The PEMTs used Khanmigo's tutor mode to solve the problems and explore number theory concepts while also participating in discussions with their peers.

Data Collection and Analysis

Data collected for the broader study included observations and screen recordings, content-based pre and post-tests, and end-of-semester exit interviews. In this paper, we will focus on the analysis of the exit interviews conducted with three volunteer PEMTs from different small groups. A 30 to 45 minutes individual interview was conducted with each PEMT to gain an in-depth understanding of the PEMTs' perspectives on the perceived benefits and challenges of the use of AI to solve number theory problems. Interview data were analyzed in three phases. First, interviews were transcribed to identify the text segments (DiCicco-Bloom & Crabtree, 2006) in which the PEMTs' shared benefits and challenges during their use of Khanmigo. We engaged in an open-coding process to identify the patterns in the data to develop themes and categories. The first author coded all text segments, and the second author independently coded a third of randomly selected text segments. Then, these researchers discussed the disagreements in coding until they reached a consensus. The agreement rate was found to be 86%.

Findings

We classified our interpretations of PEMTs' perspectives on Khanmigo using two themes, benefits and challenges. Within the classification of benefits of AI use, we identified three benefits and two challenges as described in the sections below.

An AI Tutor Supports the Problem-solving Process

PEMTs shared that the AI tool supported their engagement with the problems by a) helping them to understand the problems by breaking the problem into steps (n = 2), b) allowing them to elicit meaning of the mathematical concepts and words used (n = 3) and c) exploring multiple solution approaches (n = 2). For instance, PEMT1 shared how Khanmigo helped her understand story problems and elicit the meaning of mathematical concepts: "I really liked about AI is that you can input story problems. And some problems can be hard to dissect, kind of what it's asking, especially when you are unfamiliar with those terms."

Two PEMTs emphasized how AI supported them to elicit and explore multiple solutions for the problem assigned in the course. For instance, PEMT2 stated:

> …to find the least common multiple of, say, like nine and six, and …sometimes it would already give you two ways to do it. But then if you asked, is there another way to find this out? Is there a simpler way? What does this mean? Then it would explain that to you more.

An AI Tutor Supports Individualized Learning

Participant describe the benefits of Khanmigo in structuring self-paced learning and attending to individual learning needs. All PEMTs highlighted the challenges a teacher faces in larger size classrooms of moving beyond direct instruction to support diverse learning needs. They emphasized how AI could foster more differentiated instruction. PEMT3 describe the how she could work at her own pace.

> In a normal classroom, you usually are given those strategies right off the bat, for me, I was able to ask for one strategy at a time from the AI. It was a slower process. And it was really nice for me to be able to learn and figure out each strategy before moving on to the next.

PEMT2 extended this idea about self-paced learning as she reflected on the increased opportunities to learn because the interactions focused on her level of knowledge and curiosity.

> In the AI class, It wasn't me teaching myself, but it was definitely more me centered in a classroom of 20-30 students. It is challenging for it to really be geared towards one student specifically. With the AI, I was able to breeze past what was simple, what came easy, what I already knew, and then spend more time on what was confusing. And what I didn't know.

An AI Tutor Responds to Student Struggles and Questions

All PEMTs indicated that they felt comfortable sharing their struggles and questions with the AI tutor. For instance, PEMT3 stated:

> We felt a little more on our own, at least I did [using AI]. But I liked that aspect of it because I have some social anxiety and it's hard for me to ask questions in front of a whole class sometimes. So being able to just ask a computer and it tells me step by step that was something that was great for me at least.

PEMT1 pointed out that the individualized interactions with AI significantly improved her comfort in asking questions: "Whereas with the AI, it's between you and the computer. I feel like you get more out of it, because you can ask questions on every problem and not feel ashamed and not be worried." This benefit supported PEMTs in engaging in positive and productive struggle with mathematics concepts

An AI Tutor Produces Confusing Responses

Although the conversational nature of AI was a benefit to PEMTs in fostering productive struggle, the PEMTs felt that the occasional lack of clarity in the responses created a challenge in using AI. Two PEMTs' stated that sometimes AI produced mathematically confusing responses. For instance, PEMT3 stated:

> …And so we finished and we got a different answer. And then, we saw that AI had gotten something very off. And so all we did was we typed in what we thought was wrong. And we did it. I'm not quite sure how AI ended up getting the right answer. So that was something *interesting*, but also a struggle almost.

PEMT3 noted how their group reacted to this discrepancy between their solutions and the AI tutor's solution. They questioned the AI tutor's solution instead of accepting it as correct, but they also felt the need to seek out the instructor's support in trying to resolve the discrepancy.

The AI Tutor Doesn't Know Students' Learning Preferences

Although all PEMTs shared how AI could support individualized learning experiences, PEMT1 and PEMT3 highlighted the challenge of interacting with an AI tutor as a non-human. Unlike a classroom teacher, the AI-tutor is not able to respond to individual students' learning preferences and building relationships with students in a mathematics classroom. For instance, PEMT3 stated:

> There's definitely the human interaction portion where you can build that relationship with your professor, they know your learning style. So, it's a lot easier for them to explain things right away. And then with AI, there's still a learning process. They don't know you. So, it's harder for them to help out, get it, get through the process of figuring out the problem.

Discussion and Conclusion

The results suggest that the PEMTs perceived both benefits and challenges for their mathematical thinking in AI-integrated ILS. PEMTs highlighted the benefits of using an AI tutor to assist in the problem-solving process. They helped students grasp the meaning of mathematical concepts and words used in the problems while encouraging students to explore multiple problem-solving strategies. PEMTs noted that AI acted as a supportive and non-judgmental resource, providing a more comfortable environment for seeking assistance compared to asking questions in a whole class setting.

The results also highlight the challenges that PEMTs experienced during engagement with the AI tutor. The benefits that they described suggest that PEMTs valued a humanistic responsiveness in their AI expert tutor that could enhance their learning and their mathematical confidence. These perceived benefits became challenges because at times the PEMTs felt the need to question the reliability of the AI's answers. They struggled to accept that they might have a better solution and sought reassurance or explanation from their instructor. They also felt challenged by the lack of humanistic responsiveness in an AI tutor who could not understand their unique learning preferences build sustained relationships with them. The PEMTs compensated for these challenges by actively seeking support from their instructors and collaborating with peers. The PEMT's perceived benefits should motivate continued exploration of the individualized content learning opportunities that AI integration can create, while the PEMT's perceived challenges highlights the need for students and teachers to understand that the

AI tutor is neither perfect or human. As NCTM (2024) position statement on AI and mathematics education, the need for high-quality pedagogy to support AI integration is an important implication of this study and an area for further research.

Optimizing the use of AI in developing PEMT's mathematical knowledge requires collaborative efforts between educators and AI developers. Such partnerships can ensure that the tools and platforms align with the needs of PEMTs and provide meaningful support in their learning. In our further work, we plan to design AI-integrated sessions that focus on other mathematical topics and investigate how they impact both PEMTs perception of learning and instructor decision-making.

Facilitating productive struggle is an essential aspect of teaching that is responsive to students' thinking and develops deep and meaningful understandings of mathematics. Researchers, teacher educators, and teachers would all benefit from being able to draw on a common definition for the term "productive struggle" and a common understanding of the teaching practices needed to facilitate it. This working group will bring researchers and educators together to investigate what we know about facilitating productive struggle and draw on the expertise in the room to move our individual and collective understanding and practice forward.

Keywords: Research Methods, Instructional Activities and Practices, Preservice Teacher Education, Teacher Educators

Over the past 15 years, the term *productive struggle* has become commonplace in mathematics teaching and teacher education. Both the National Council of Teachers of Mathematics (NCTM, 2014) and the Association of Mathematics Teacher Educators (AMTE, 2017) identify providing students with opportunities to engage in productive struggle as a key component of effective mathematics teaching and learning. However, a preliminary systematic review of how researchers define the term productive struggle leaves many unanswered questions about what productive struggle actually entails (Kamlue & Van Zoest, 2024). This new working group seeks to develop a shared, consensus definition of productive struggle and a related conceptual framework that can be utilized to support research and opportunities for students to experience productive struggle in learning mathematics in the classroom.

Theoretical Background

Several seminal writings influence how we perceive and use the term productive struggle in our different contexts. Here, we highlight three seminal works. First, Hiebert and Grouws (2007) define *struggle* as follows, "students expend effort in order to make sense of mathematics, to figure something out that is not immediately apparent" (p. 387). Several researchers (e.g., DiNapoli & Miller, 2022; Warshauer, 2015) use Hiebert and Grouws' (2007) definition of struggle as their definition of productive struggle in their studies. Second, NCTM (2014) frames struggle as involving, "opportunities for delving more deeply into understanding the mathematical structure of problems and relationships among mathematical ideas, instead of simply seeking correct solutions" (p. 48). This framing continues to inform educators', teacher educators', and researchers' understandings of productive struggle (e.g., Edwards, 2018; Warshauer et al., 2021). Third, practitioners and researchers often invoke the first Standard for

Mathematical Practice: *Make sense of problems and persevere in solving them* (National Governors Association Center for Best Practices & Council of Chief State School Officers, 2010) when speaking of struggle.

As we seek to illustrate here, there is great variety regarding how the field has described and conceived of productive struggle (e.g., expend effort, delve deeply, perseverance). This lack of consensus and common language presents a challenge to those who research productive struggle, those who teach how to facilitate productive struggle, and those seeking to create opportunities for their students to experience productive struggle.

Structure of the Sessions

The purpose of this working group is to bring together researchers and teacher educators to examine existing and new conceptualizations of productive struggle. This work is crucial for the mathematics education community, as the current lack of consensus regarding the use of the term productive struggle presents a host of issues, including the inability to: (a) compare findings across studies and build on each other's work precisely, (b) determine when productive struggle occurs, and (c) effectively model how teachers can support productive struggle. Each session will be focused on a different aspect of productive struggle research and classroom practice.

Session 1: Developing a Consensus Understanding of Productive Struggle

Our goal for this session is to co-develop a shared definition of *productive struggle* and a theoretical underpinning of the term. We will first present how productive struggle has been defined by researchers, teacher educators, in-service teachers, and preservice teachers, and what theoretical frameworks they attended to in their contexts (Hiebert & Grouws, 2007; Jarry-Shore & Anantharajan, 2024; Warshauer, 2015). We will surface unanswered questions from working group participants and ask them to situate and relate their use and understandings of the term to existing literature in order to move our understanding of the term forward.

Session 2: Analyzing Classroom Videos

For this session, working group participants will be asked to apply the conceptualization of productive struggle developed in Session 1 to attend to and interpret instances of struggle in classroom video (Jacobs et al., 2010). Specifically, participants will view a collection of three 5-minute video-clips that display struggle of different forms. Video-clips will portray students solving problems individually and in collaborative groups so that we can assess the usability and applicability of our collective conceptualization of productive struggle to varied problem-solving contexts. The work during this session will be iterative, with participants revisiting and refining ideas between each video viewing, with the goal of drafting a more comprehensive and refined conceptualization of productive struggle.

Session 3: Facilitating Productive Struggle

In the third session we will shift to thinking about how to operationalize the co-constructed conceptual framework developed in sessions 1 and 2 for research, PK-16 classroom practice, and teacher education/professional development. We will attend to two questions. First, how can we use the framework(s) we have developed in our practice to (a) more effectively engage students in productive struggle and (b) teach educators to facilitate productive struggle? Second, how can we use the framework(s) we have developed in our research to more effectively study productive struggle and its facilitation. For both questions, we will focus on assessing the usability of the framework and the benefits and challenges of having such a framework.

USE OF CHILDREN'S LITERATURE IN MATHEMATICS TEACHING AND LEARNING

Mahtob Aqazade
Illinois State University
maqaza1@ilstu.edu

Laura Bofferding
Purdue University
lbofferd@purdue.edu

In this new initiative working group, our goals are to explore and share our experiences of teaching and learning mathematics using children's mathematics and build a community for future collaborations. Over three days, drawing from the mathematical exploration lens, we will engage the participants in open notice and wonder reads, focused math lens reads, and idea investigations with different children's literature, discuss the challenges and benefits of mathematizing children's literature with elementary students and elementary prospective teachers, and initiate the conversation for follow-up activities at future PME-NA conferences.

Keywords: Elementary Childhood Education, Instructional Activities and Practices

Using children's literature to teach and learn mathematics provides a context for problem-solving, creates mathematical investigation and reasoning opportunities, and supports deeper conceptual understanding (e.g., Young et al., 2018). The research has supported the benefits of using children's literature to teach mathematics to significantly increase mathematical learning, interest, and engagement in mathematical discourse. Within this body of research, the focus has been primarily on early childhood education (e.g., Elia et al., 2010; Monroe & Young, 2018; Hassinger-Das et al., 2015; Hong, 1996; Jennings et., 1992; van den Heuvel-Panhuizen et al., 2016; van den Heuvel-Panhuizen & van den Boogard, 2008). While envisioning the future of elementary mathematics education as mathematics teacher educators and researchers, it is essential to facilitate the teaching and learning of mathematics by moving beyond the boundaries of mathematics education. At the boundaries of mathematics and literacy education, our goals of this new initiative working group are to (a) share our experiences of using children's literature in mathematics teaching and learning with elementary students and elementary preservice teachers, (b) engage in mathematical explorations using children's literature, and (c) build a community of scholars and educators for future research collaboration to develop research-based resources for preservice and in-service teachers.

Theoretical Background

One of the key recommendations for mathematics instruction described in *Catalyzing Change* is that "Each and every child should develop deep mathematical understanding as confident and capable learners; understand and critique the world through mathematics; and experience the wonder, joy, and beauty of mathematics" (Huinker et al., 2020, p. 11). Using children's literature in mathematics provides opportunities to follow this recommendation. Hintz and Smith (2022) provide a framework for thinking about three types of explorations with children's literature (whether the literature has an explicit or implicit mathematical focus). The *open notice and wonder reads* are an initial exploration that focus on promoting wonder, joy, and beauty in mathematics. First, in an open notice and wonder read, teachers invite students to notice and wonder about what they are hearing and seeing in a story. This process helps students develop a common background of the story's content and begin to think about how the story could be enhanced by viewing it through a mathematical lens. Second, the *focused math lens reads* involve revisiting the notice and wonders, considering which of the students' ideas might be helpful to pursue mathematically, and then inviting students to think about the story from a mathematical lens (Hintz & Smith, 2022). Third, the *idea investigations* involve extending mathematical explorations beyond the book, helping them understand their broader world through similar mathematics. These mathematical explorations with children's literature provide opportunities for students to engage in mathematical problem-posing and open-ended problem-solving (Cai et al., 2015; Warden, 2022).

Several factors play a role in how mathematical explorations with children's literature unfold. One factor is the type of book used: mathematical-focused, general fiction, or nonfiction. A second factor is the people involved: teacher, preservice teacher, and students. A third factor is the mode of sharing the book: electronic (or multimedia) or physical. A better understanding of how mathematical explorations emerge from situations with different combinations of these factors is important for understanding mathematics instruction using children's literature.

Focus and Organization of the Working Group

This working group focuses on understanding the benefits and practices of using children's literature in mathematics teaching and learning. We organize the working group by sharing our experiences of using children's literature in mathematics teaching and learning; learning about different approaches, challenges, and benefits of mathematizing children's literature; and forming a community to build upon our learnings throughout the conference.

Plans for Participants' Active Engagement

Day 1. We first will share our plans for the three days, introduce the theoretical background around mathematical explorations with children's literature (Hintz & Smith, 2022), and provide research evidence supporting the benefits of using children's literature in mathematics teaching and learning. Second, we will ask the participants to share their interests in this working group and their experiences using children's literature in teaching and learning mathematics. Third, by drawing from the theoretical background, we will engage the participants in an open notice and wonder read of two books, one with an explicit mathematical focus (e.g., *Lion's Share* by McElligott, 2009) and one with an implicit mathematical focus (e.g., *Two of Everything* by Hong, 1993). Fourth, the participants will brainstorm ways of using and doing research around this mathematical exploration.

Day 2. We will start the second day by reviewing the first day. Then, in small groups, we will invite the participants to mathematically explore and categorize books (e.g., concept, explicit or implicit mathematical focus, grade level). Groups will select one book and problem-pose around one page to develop a problem-solving situation (Cai et al., 2015; Warden, 2022) and connect these to the types of mathematical explorations from our theoretical background (Hintz & Smith, 2022). Finally, we will share future opportunities for research and teaching in using children's literature to teach and learn mathematics within teacher education programs.

Day 3. Reflecting and building on the last two days, we will brainstorm about the future directions of this working group for follow-up activities at future PME-NA conferences. We will aim to focus on the use of children's literature in mathematics content and method courses for prospective elementary teachers. We will invite participants to share their insights and expertise around challenges prospective elementary teachers and teacher educators might encounter. We will wrap up the last day by taking a survey of participants to document their learning throughout this working group and their interests in future collaboration.

During and since the 2023 PME-NA Annual Conference the working group has carried out many ongoing activities with the goals of creating community and producing scholarship in relation to our group's interests in statistics and data science education. During the conference, issues of environmental justice/sustainability and social justice were two major common interests of participants. Though both themes are clearly linked, discussions of social justice do not always include conversations about environmental justice. We then broke into two groups based on these interests to discuss current work we might have related to the topic or ideas for future work. These groups have continued to meet and have discussions throughout the year and will continue into the 2024 conference. We additionally had a group of interested participants publish an article in Mathematics Teacher: Learning and Teaching PK-12 based on a gap in the literature identified by the group.

Keywords: Data Analysis and Statistics, Sustainability, Social Justice

The 2023 conference marks the fifth PME-NA conference that our working group has met. Each year has been more productive than the last, with growing momentum and membership over the years. The working group began at the 2019 conference where we explored a recently published framework for meaningful statistical learning environments (Ben-Zvi et al., 2018), trying to start conversations about different aspects of design. Then, in the 2020 conference, we focused on considering statistics education across boundaries with collaboration between scholars in the US and Mexico with the sessions held in Spanish and English. In 2021, we began to consider how data science education might play a role in statistics education and the mathematics curriculum. In 2022, we took seriously the growing interest and movement toward incorporating data science education into K-12 schools (Education Development Center, 2015; Lee et al., 2022) and focused on data investigations as a vehicle for addressing the broad data literacy needs of people today rather than considering statistics and data science education as fields. The working group has grown in size year after year and has increasingly taken on an explicit focus on using data investigations to explore issues of justice.

Overview of the Working Group Activities

Coming into the 2023 PME-NA conference, we had two main goals for the working groups 1) sustaining the ongoing cross-institutional collaboration to develop frameworks and resources for supporting mathematics educators in facilitating data investigations and 2) advancing our discussions on designing data investigations with an eye towards taking action to promote socially and environmentally just outcomes. We recognize context is at the core of data investigations, which are driven by a problem. We view data investigation as a vehicle to make sense of and act upon issues of social and environmental justice around the world. Based on the role of context in teaching and learning with data, we organized this working group into three themes: the context of mathematics teacher preparation, the context of cross-disciplinary work, and the context of research and collaboration. Across the three days of the working group sessions, we moved from making connections between interested participants to making explicit plans for action after the conference. In the sections that follow, we discuss in further detail the activities during each day of the conference followed by a discussion of our activities since the conference.

Day 1: Overview of Statistics and Data Science Education

Following a round of introductions, the initial day started with a reexamination of pivotal questions central to our working group discussions. Six questions were placed onto large Post-it papers and a digital Jamboard, facilitating remote participants to collaboratively brainstorm and share their insights in smaller groups. Subsequently, a whole group discussion ensued to collectively analyze the generated ideas. This conversation aimed to discern overarching themes of interest, resulting in the identification of three prominent themes: (1) the use of social and environmental justice as key contexts for data investigations, (2) the exploration of interdisciplinary collaborations within K-12 teacher education, and (3) the integration of statistics education and data science within the realm of mathematics education.

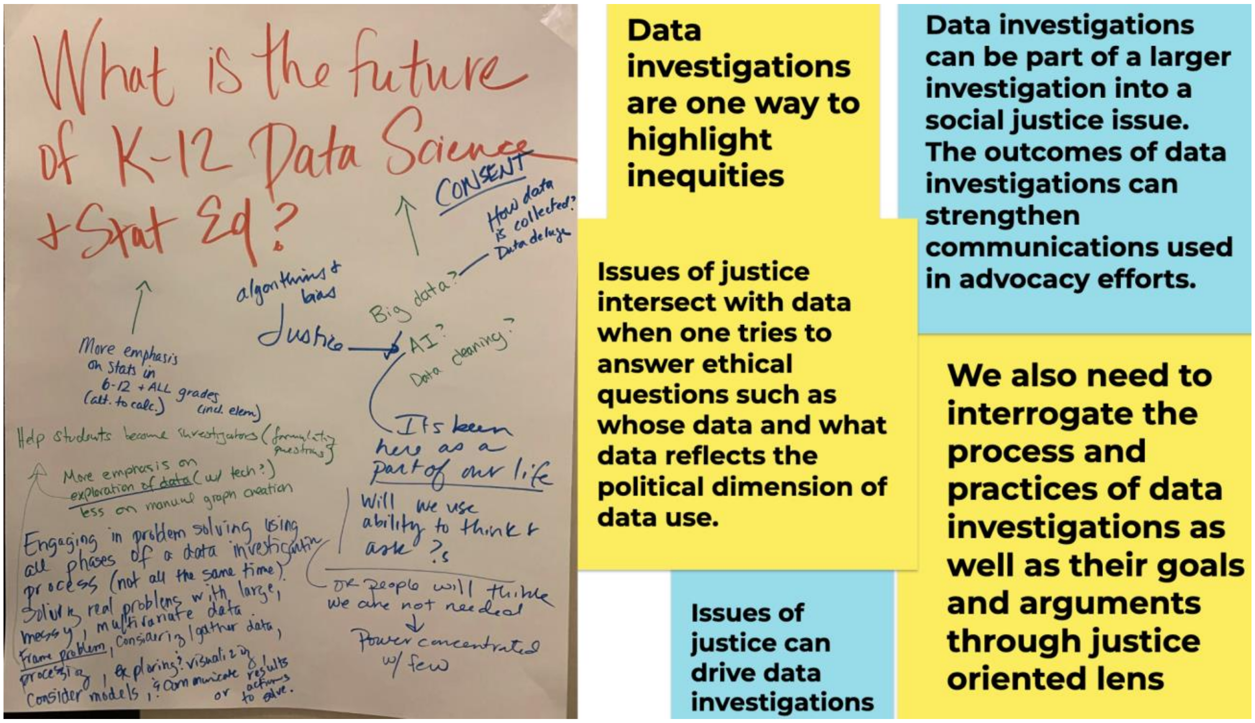

Figure 1: Sample Responses by Participants

In our conversations, we noted the increasing significance of K-12 statistics and data science education and a notable shift towards the recent development of computing and artificial intelligence (AI), leading to an anticipated larger role in K-12 education. AI integration in education, exemplified by tools like ChatGPT, prompts a need for thoughtful adaptation in teaching and evaluating processes. Anticipated challenges include the need to strike a balance between data literacy and traditional learning pathways within the K-12 mathematics curriculum, considerations of data ethics, and addressing algorithmic biases. Additionally, we acknowledged the varied interpretations of the term “data science,” which at times was perceived more as a "buzzword" associated solely with working on large datasets (Donoho, 2017). It is crucial to recognize that applying computing and programming to data investigation is a significant aspect of data science.

All participants expressed a heightened interest in investigating social and environmental justice as a promising approach to teaching and learning with data investigations. Data investigations, which can play a pivotal role in illuminating social inequities and issues of justice, can be a means to critically examine the ethical considerations inherent in the use of data science and AI through a justice-oriented lens. The intersection between data investigations and justice-oriented inquiries can amplify the significance of each other and contribute to deepening participation in civic engagement that attends to societal and environmental challenges. These types of inquiry gain particular relevance in the context of data-driven decision-making, where considerations of justice play a key role.

Day 2: Lessons from Prior Collaborations and Designing New Collaborations

The second working group session began with a report from Smucker on a publication that was initiated during the previous working group in 2022. During that working group, a group of participants wanted to pursue connecting the 5 Practices Framework (Smith & Stein, 2018) to statistical investigations. This sub-group met throughout the first half of 2023, which led to a manuscript submitted to *Mathematics Teacher: Learning and Teaching PK-12*. During the conference, the manuscript was returned with minor revision requests. The manuscript has now been published as a Front and Center article in the journal (Smucker et al., 2024). The group discussed the benefits of this collaboration and the potential for future publications coming out of this working group. Weiland then reported on possible pathways of pursuing a special issue on statistics or data science education in multiple journals in the field. Working group members could participate in different ways, such as guest editors and manuscript authors. Multiple participants indicated an interest in this, with some participants willing to take on editorial responsibilities. This work could begin in 2024-2025.

The rest of the session was spent considering the themes that had come up during the gallery walk on Day 1 to determine which area(s) the group might want to focus on further. The working group organizers had grouped the ideas from Day 1 into the following categories: cross-discipline data investigations, social justice and data science/statistics education (specifically issues of ethics and power), environmental justice in data science/statistics education, and supporting practicing and prospective K-12 teachers to prepare students to make sense of data in today's world. Based on the interests of those in attendance, the larger group was divided into two subgroups to continue discussing the next steps, with one group focused on social justice and the other on environmental justice in statistics and data science education. It was determined that these two subgroups would continue their conversations on Day 3.

Day 3: Planning for Year-Long Collaborations

First, the social justice subgroup planned for a year-long collaboration, building on the diversity of experiences working with social justice topics within the subgroup. The initial part of the discussion was too broad, leaving the group undecided on whether the focus should be on working with students or teachers and at which grade levels. The group also noted that the relevance and appropriateness of certain social issues varied across different grade levels, although some topics remained pertinent across all ages. Issues such as immigration, gender differences, diversity, and climate change were among those that captured our attention.

Subsequently, the discussion shifted towards the characteristics of datasets. Questions such as the following emerged: What variables could facilitate discussions on such social issues (e.g., school discipline)? What types of data could be collected? While existing databases could be valuable, we pondered if there were ways for students to gather relevant data related to social justice. Fernandes, who was working on a research project related to social justice, also described his work with a database of car stops and school discipline ("Statistical Investigations of Systemic Racism", 2023). More questions than answers arose during the discussion, indicating the need to extend our work beyond the conference. Consequently, we decided to continue our conversations throughout the year.

Second, the discussion of the environmental justice group began by sharing their past and ongoing projects or research studies related to environmental data and classroom connections. Subsequently, the group engaged in a discussion about integrating environmental justice and science into various content areas, emphasizing the incorporation of mathematics, science, and social studies. The primary challenge identified was providing students with opportunities to delve into authentic research in environmental justice and science. In addressing topics like climate change, for example, there are challenges with going beyond having students merely feel hopeless; it requires balancing negative with positive affective developments without overwhelming students with large-scale climate data.

Our discussion then shifted to questions regarding the means to enhance K-12 students' data literacy skills. How can working with environmental data be integrated in elementary and pre-service elementary education across disciplines? This integration could manifest through citizen science projects that are locally relevant to students' communities. What are useful tools for data exploration, analysis, and visualization? An example we discussed was the free Common Online Data Analysis Platform (CODAP; Concord Consortium, 2023) and its incorporation of NOAA data. Members of this group planned to continue these discussions beyond the scope of the conference and are committed to identifying goals for future collaboration regarding the integration of authentic environmental data into schools.

Post-Conference Working Group Activities

Social Investigation Group

The group focused on connections between data science education and social justice and has met several times since the conference to refine our focus and consider potential projects for collaboration. At our first meeting in November, we discussed some of the ideas that came up during our sessions at the conference, including how we might connect to existing projects in K-12 data science education and teacher preparation like Data Science 4 Everyone ("Data Science 4 Everyone", 2023), Introduction to Data Science materials from UCLA ("Introduction to Data Science", 2022), ProCivicStat materials, ("ProCivicStat", n.d.) and the ESTEEM project (ESTEEM, 2024), along with Fernandes and Weiland's work on creating data science modules around the contexts of traffic stops and school discipline using real data which was previously mentioned. In particular, projects that might support teachers in states with standards and pathways specific to data science (e.g. Georgia, Oregon, North Carolina, Virginia) seemed like one place where there might be space for a contribution from this group. There was also a discussion on how the group might serve different purposes for various individuals, with some looking for collaboration partners while others may be interested in learning more about what others are currently doing in their research and teaching.

At the January meeting, there was a shift towards thinking about how to encourage mathematics and social studies teachers to collaborate at the intersection of data science and social justice topics. Those who have been working to implement data investigations with prospective and practicing teachers involving issues of social justice noted the challenge in finding mathematics teachers and teacher educators who feel comfortable both facilitating a data investigation and having a productive discussion in these contexts. A cross-curricular collaboration with social studies educators might help resolve this issue. Mathematics teachers can provide expertise in facilitating data investigations, and social studies teachers can serve as experts in the contexts and navigating conversations around sensitive topics. The group built a consensus that this would be a productive idea to pursue further, but they also agreed that additional meetings were needed to determine what exactly this project might look like. Ideas for future discussion included applying for a grant to create professional development that could bring mathematics and social studies teachers together, along with using and adapting existing resources mentioned above. The importance of connecting data science and statistics to more than mathematics classrooms was highlighted in a recent *Passport to Potential: Exploring Data Literacy Worldwide* webcast that included the President of the National Council of Social Studies Education along with members of the Global Partnership for Sustainable Development Data (Data Science 4 Everyone, 2023). We plan to continue meeting on a monthly basis to refine this focus further.

Environmental Investigation Group

The group met once soon after the conference to further develop the collaboration on examining teaching and learning with environmental data. The first meeting was organized as a "data session," in which members brought data (either research data gathered from their own research projects or datasets that are relevant to environmental justice) to formulate collaborative research ideas to contribute to the common environmental justice goal. Three members showcased data from their individual projects or professional development programs (e.g., MODULE(S2), n.d.). One member showed data collected from an interview study, in which participants were asked to estimate climate-related numerical values. Another member shared student work, which led to a discussion on how the task could be modified for the next iteration. Additionally, we highlighted potential data sources, such as the USDA website featuring a Food Access Research Atlas (USDA, 2024) and the CDC website featuring a National Environmental Public Health Tracking resource (CDC, 2024) for future consideration. The aim was to build on existing research projects and collectively explore collaborative studies that the group could undertake. The group is determining the next steps for the collaboration.

In going into our sixth year as a working group, our aims are to build off of previous work of the group and look to new productive avenues of scholarship. In particular, based on ongoing conversations of people who met during the 2023 PMENA conference, we seek to find ways of forming interdisciplinary collaborations to support the teaching and learning of statistics and data science through data investigations in meaningful contexts drawing from the contextual knowledge of experts from other fields such as social studies education and science education. We hope to begin work on a grant proposal to pursue funding for ideas developed and refined during the conference to support the ongoing work of the working group. We also invite new members who are interested in exploring issues around teaching and learning with data investigations.

Keywords: statistics education, data science education, data investigation

As our working group continued the effort to identify ways to bring existing recommendations for teaching statistics and data science, such as GAISE II, and NCTM Principles and Standards (Bargagliotti et al., 2020; NCTM, 2000) to the variety of K-12 education settings, we built a consensus that one of the key considerations is facilitating and supporting interdisciplinary teaching and learning. Mathematics teachers are often bound to teach mathematical aspects of statistical thinking, which often overlook students' meaningful engagement with the context while teaching and learning statistics and data science. This issue is exacerbated by a confluence of complex factors including standardized testing, limited teacher learning opportunities, and resources. Whereas, science, social studies, and career and technical education bring abundant opportunities to explore authentic issues with real data that are situated in disciplinary contexts and closely aligned with students' civic lives and professional trajectories. Therefore, we suggest that statistics and data science education researchers need to look beyond K-12 mathematics classrooms and investigate feasible and sustainable approaches to position statistics and data science education as a critical interdisciplinary link between mathematics and other multiple subject areas. Initiating these interdisciplinary efforts and designing mechanisms for collaborations are the primary goals of this year's working group.

Theoretical Background

We draw from two key discussions in the field to inform this year's working group: the interdisciplinarity of statistics and data science and the known challenges with supporting teachers in teaching them. First, as Cobb and Moore (1997) described, statistics is a methodological discipline in service of other fields, such as medicine, science, and sociology. Data science, by building on its foundation of computing, mathematics, and statistics, offers powerful modeling tools in a variety of disciplinary contexts. Though there are multiple views on what data science specifically entails, its fluid boundaries allow us to look beyond what has been considered as computing, statistics, and mathematics when we think of teaching and learning with data investigation (e.g., digital humanities). The utility of data science is well reflected in numerous data science programs and initiatives in higher education institutions, drawing students from across colleges and majors who want to investigate their topics of interest with data.

Second, the literature also presents known challenges associated with supporting teachers in fully leveraging these emerging understandings of data investigation in the classroom. These challenges include supporting teachers in facilitating data investigation (Bargagliotti et al., 2020), their development of statistical knowledge for teaching (Groth, 2013; Lovett & Lee, 2017) and the knowledge needed to adapt the use of technology to teach with data (Lee & Hollebrands, 2008). Some scholars reported promising approaches to professional development for teachers to address these challenges (e.g., Suazo et al., 2015), but the professional development that did not work as intended often remains unreported, which obscures existing challenges in preparing and supporting teachers to teach with data investigation.

Informed by these discussions in the field, our working group plans to explore key challenges that are faced when teacher educators work to bring data investigations into mathematics classrooms and other subject areas, such as science and social studies. We aim to develop collaborative projects and funding proposals that can address some of the identified challenges based on the diverse expertise and experiences represented in the group.

Organization of Working Group Activities

The working group activities are organized in a way that the participants can briefly recap the ongoing progress in collaboration. This would allow the newly participating members to see the history of the group and also welcome them to existing collaborative efforts. Also through our collaboration, we learned that securing grant funding would substantially propel the ongoing collaborations. Based on the rich experience of grant writing by multiple members in our working group, we will progress by identifying key challenges, organizing resources and expertise, and developing a plan for proposal development.

At PME-NA 2023 in Reno, NV, the Conceptualizing the Role of Technology in Equitable Mathematics Classrooms (now referred to as TechQuity) working group met for the first time. While in Reno, we invited scholars of all backgrounds to contribute their voices to our new working group with the goal being to engage in conversation and plan research agendas centered on exploring how technology can promote equitable classrooms. The group has been able to sustain a dedicated group of members that have been meeting regularly online since the end of PME-NA 2023. In this report, we summarize the history of the TechQuity group, some insights gained through our work, and share some plans for the future of the working group.

Keywords: Technology; Equity, Inclusion, and Diversity

Our PME-NA working group focuses on the importance of using technology in equitable ways to advance our field of teaching and learning mathematics and preparing mathematics teachers. Two recent position statements from the National Council of Teachers of Mathematics (NCTM, 2023) and the Association of Mathematics Teacher Educators (AMTE, 2022) emphasize the importance of equitable integration of technology for mathematics learning. An urgent challenge in our time is the need to advance equity in mathematics education, particularly for those who have been historically marginalized. Technology is ubiquitous in our society and innovative technologies are showing promise in the teaching and learning of mathematics.

Building on research in mathematics education focused on equity and technology, our TechQuity working group draws on several theoretical frameworks including Gutiérrez's (2009) dominant and critical axis of equity. We are working on evaluating the role technology has on the dominant axis in promoting and increasing the mathematics achievement and participation of each and every student as well as the role technology has on the critical axis in promoting identity and power. In addition, as we work to bridge these two areas of interest (i.e., technology and equity), we build on transformative ways technology: offers student-centered learning experiences for exploration, discovery, collaboration and facilitating discourse (McCulloch & Lovett, 2024); advances equitable teaching practices (Suh et al., 2022); provides access to rigorous mathematics that connect to society (Byun et al., 2023); and allows for ease of differentiation and useful formative assessment to support teaching and learning (Barlow et al., 2020).

History of the Working Group

This group began through conversations at the PME-NA 2022 conference after a presentation on leveraging mathematical action technology to develop a sociopolitical disposition. During this conversation, some of the founding members of the group discussed the idea of engaging in more equity-centered work in conjunction with technology use in mathematics education. Given PME-NA's history of successful working groups, we felt starting a new working group was the best avenue to help us connect with others who have similar interests and move this work forward. Thus, at the beginning of 2023, we met to determine the goals, possible outcomes, and structure of the meeting times for the working group. Initially, our goals were (a) "[To] lay the groundwork for a research program dedicated to better understanding how technology can be used as a tool to support equity in mathematics education"; and (b) "bolster existing technology-centered frameworks with considerations of equity from various dimensions" (Witt et al., 2023). With these goals in mind, we planned to engage the participants in our sessions as shown in Table 1.

Table 1: PME-NA 2023 Plan for Engagement

	Activities	Next Steps
Session One	1. Introduction and goals 2. Our work around technology and equity 3. Questions and small group discussions about technology and equity frameworks	Come to session two prepared to share how/what other frameworks may inform your work
Session Two	1. Small group discussions about which frameworks we should consider 2. Group debrief to share current stances on how technology can support equity	Think about what subgroups would be useful to examine various perspectives on equity
Session Three	1. Form subgroups and plan 2. Subgroup share-out 3. Reflections and future work plan	Implement subgroup plan and prepare to share subgroup work next year

Overall, we felt these three sessions were a success in reaching a broad range of mathematics education researchers. We were pleased with the turnout to the group during our first session in Reno, NV (approximately 20-25 people), and we were encouraged to see many returning faces on days two and three. Below we share more about what transpired during the PME-NA 2023 conference, the progress we have made since the close of the conference, and what we plan to do next.

2023 Conference Activities

Before the Conference

Prior to the PME-NA 2023 conference, we asked the conference organizers to share an interest form with potential conference attendees so that we could gather information about who might attend. In this interest form, we asked them what goals they have in relation to the group, which sessions they plan to attend, and to share frameworks or constructs related to technology and equity in mathematics education that they were familiar with, including a place for them to share relevant files (i.e., screenshots of diagrams or frameworks, articles, etc.). While only two people completed the interest form before attending the conference, we used the information they shared as we designed the facilitation plan for each session.

Day One

We began our time together at PME-NA 2023 with the founding members briefly sharing about our work and how we came together to form the working group. We also asked participants to introduce themselves and share why they were interested in this working group. From there, we transitioned into six groups to do a card sort activity examining 17 technology-centered and nine equity-centered frameworks that are used in mathematics education research. The frameworks were all mixed together and participants were not informed from which category each framework originated. We asked the participants to read each framework card and consider how the framework might support mathematics teacher educators (MTEs) and/or prospective mathematics teachers (PMTs). In groups, participants were asked to organize the frameworks into categories of their choice and provide a title for each grouping explaining their sorting criteria. During this time, participants worked together to find connections between and common themes across frameworks to identify and describe their groupings. Figure 1 shows two groups in action. At the end of the card sort activity, we asked each group to share their process for sorting the frameworks, their final categories, what they noticed, and how they felt this could help us articulate where we are within mathematics education in relation to these ideas.

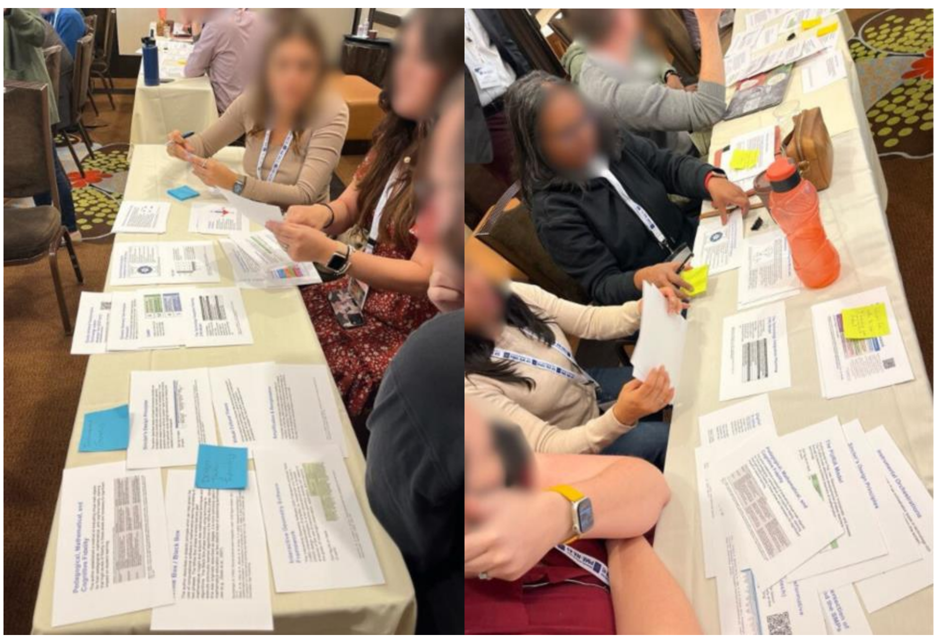

Figure 1: Participants working in groups on framework card sort

Most groups seemed to initially separate the frameworks into two broad categories of equity and technology. This result was not surprising given our working group's focus on finding ways these areas of work may intersect. In other words, it seemed from the card sort activity that the participants, much like us, struggled to make connections across the two sets of frameworks.

And, within the technology category, some groups created subcategories similar to the categories McCulloch et al. (2021) identified when examining technology frameworks MTEs use in preparing secondary PMTs. For example, some groups included a subcategory related to the McCulloch et al.'s (2021) design and evaluation of technology tools and tasks with groupings titled "evaluation," "design tasks & technology," and "task design and evaluation".

While the results of the sorting activity described above were what one might expect, other categories emerged as conversations continued within groups about how we might bridge technology-centered and equity-centered frameworks. These discussions included considering if the intersection of these two ideas should be about the teacher's use of technology in equitable ways, the teacher and student interactions with technology, or how the students are perceiving the use of technology. One group furthered the discussion by considering if we needed to distinguish between macro and micro theories of equitable technology use. Still, some other groups had collections of frameworks labeled "don't know yet" or "IDK", indicating there are more conversations needed to work out a description of this category or determine where these frameworks fit within other existing groupings. Most notably, however, we found that there seemed to be a collection of categories across the groups that might all fall under the same theme of "pedagogy". For example, four groups had categories named "teacher and teaching focus", "pedagogy", and "teaching practices" (Figure 2 shows three of these groupings). It was interesting to see that although the ways that the groups sorted the cards were not identical, there were some common ways in which the participants were thinking about these frameworks as they engaged in conversation. We were encouraged when we noticed that within some of these groupings, both technology-centered and equity-centered frameworks appeared, as this captured the essence of an important goal and theme of the group: finding intersections between teaching mathematics with an equity focus and teaching mathematics with technology.

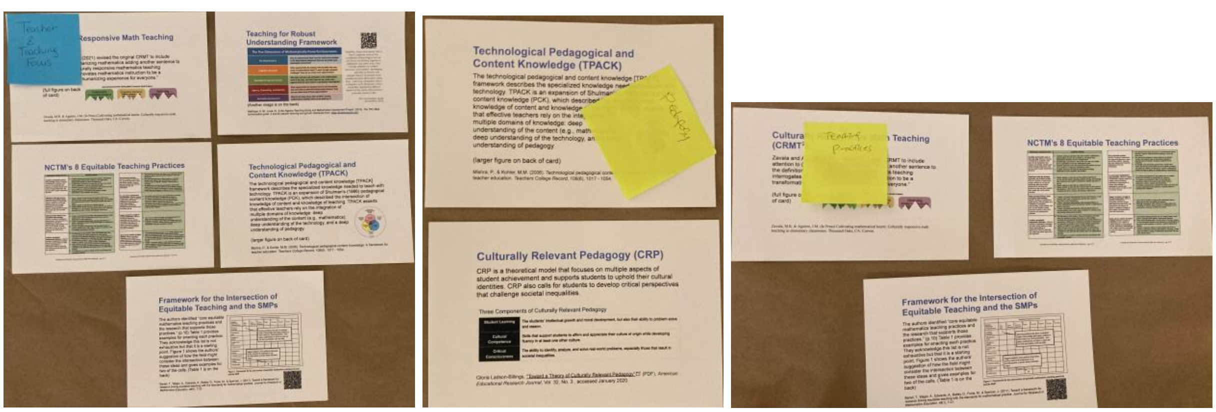

Figure 2: Pedagogy-related categories

We ended our first session asking participants to complete the interest survey that we had distributed prior to the conference so we could better gauge what aspects of technology use and equity participants were familiar with and collect their contact information. We also asked them to complete some homework by reading through position statements related to technology and equity from two national organizations in mathematics education, NCTM (2023) and AMTE

(2023). We asked that they come to the second session prepared to share what resonated with them from these statements. Finally, we asked all participants to share their reflections from the first session via a Padlet. The Padlet contained the following prompts: “What are you hoping will come out of this working group?” and “Do you have any particularly illustrative examples of how you or how you’ve seen technology used to support equity?”.

Day one team debrief. Shortly after the first session, the founding members of the working group met to debrief and adjust our plans for the next working session. Here, we briefly discussed how the day one session went and what the participants shared in the interest survey and Padlet. We used this information to guide the small group discussions for day two.

At this debrief, we reviewed the 16 new responses to the interest survey. Across both the technology-centered frameworks and equity-centered frameworks questions, there was a lot of variety in what the participants shared. For example, three participants indicated that they did not know any frameworks or constructs related to teaching and learning mathematics with technology, while at least one participant from the survey indicated that they were familiar with the following technology-related frameworks and constructs: constructionism, microworlds, situated abstractions, instrumental genesis, instrumental orchestration, semiotic mediation, theory of semiotic register, TPACK, SAMR model, embodied cognition, and new materialism. From this list, two important things stood out to us: 1) some of the frameworks and constructs are technology-specific (e.g., TPACK, SAMR model), while others are not technology-specific (e.g., constructionism, semiotic mediation), and 2) some of the frameworks and constructs they shared are more general, while others are more specific in that they target particular aspects of technology use in mathematics teaching and learning. We found these ideas particularly interesting as they indicated there is much variability in the way the participants are thinking about the use of technology in mathematics education and that there may be multiple areas of interest that emerge from the group depending on one’s view of technology use in mathematics teaching and learning. In terms of equity-related frameworks and constructs in mathematics teaching and learning, half of the respondents indicated that they did not know of any, while others included frameworks such as critical theory, teaching mathematics for social justice, critical race pedagogy, equity pedagogy, black critical theory, culturally responsive teaching, funds of knowledge, Gutiérrez’s four dimensions of equity, rehumanizing mathematics, Watson’s care framework, and neurodiversity. Finally, our analysis of the survey responses about the participants’ goals for attending the working group fell across three main ideas: 1) integrating equity focused goals and impacts into research on teaching and learning with technology, 2) connecting existing technology- and equity-related frameworks on mathematics learning and learning, and 3) looking for future research collaboration on issues related to equity and technology use in mathematics teaching and learning.

We also took a few minutes to review the responses to the Padlet reflection questions. From the six responses to the question: “What are you hoping will come out of this working group?”, two stated they would like to see a framework bridging equity and technology in math education that can be used for research and teacher preparation, two indicated they want to broaden their knowledge in understanding of technology and equity, one expressed interest in seeing a balance between technology and equity in instruction, and one stated they wanted to find research partners to explore topics of equity and technology use. The second Padlet question about providing examples of technology used to support equity only elicited two responses, both of which were general descriptions. Yet, we agreed that the ideas shared within these responses would be a nice addition to the day two discussions, and hopefully by asking the question within the session, we might learn more about how others are using technology in equitable ways.

Day Two

At the start of our second working group session, we asked participants to share what resonated with them from the NCTM (2023) and AMTE (2022) position statements using Jamboard slides for each statement or declaration. We intentionally built in time to allow participants to review the statements if needed and discuss in small groups what they noticed and wondered about. This led to a whole group discussion about each statement or declaration where we asked participants to share to what extent their work aligned with the statement and any other ideas that stood out from the Jamboard. During this time, participants also pointed out that one important idea not captured in these statements is guidance for how mathematics teachers or teacher educators might design tasks that promote these ideas. Conversations like these about possible ways to equip educators led us into a nice transition to share what the founding team learned in their debrief of the day one activities.

We used participants' responses about their reasons for joining the working group from verbal communications on day one and from the interest survey to generate a word cloud to help us visualize overall themes in why we as a group came together (Figure 3). From this word cloud, it was evident that participants aimed to learn about, collaborate on, bridge (i.e., make connections across technology and equity), design around, and conduct research to better understand how we can support equitable technology use in mathematics teaching and learning.

Figure 3: Word cloud illustrating participants' reasons for joining the working group

Then, building from the responses to the second question from the day one Padlet (i.e., provide examples of technology used to support equity), we felt it was important to allow time for participants to share more about their own work and interests. Following these conversations, we then brainstormed possible subgroups that would be of interest to participants. We left day two with the charge of identifying which subgroup you might want to be part of and any relevant research questions or ideas you may have.

Day two team debrief. After the day two working group session, the lead team met to debrief and determine how to structure the conversation for day three. We were encouraged by the amount of participants that returned on day two from day one and how willing everyone was to share about their own work and ideas. We agreed that there are many avenues that we can pursue together to move this work forward and that the conversation on day three needed to center around determining subgroups and possible products that may result from our work.

Day Three

On day three, we began by revisiting the list of possible subgroups identified on day two. We then engaged in conversations about what we are excited about exploring to help us narrow down where to start as many of us had numerous interests from the original subgroup list. Our discussions led to the creation of two subgroups, the Frameworks subgroup and the Task Design and Implementation subgroup. We then spent the remainder of the session determining potential products from each subgroup as well as establishing how we would remain in contact and continue working between conferences. We ended this last working group session with a plan for each group to meet within the next month and establish a regular meeting schedule. We also agreed to maintain a working group website where participants could find the most up to date information about the working group.

After the Conference

In the three months following the close of PME-NA 2023, the subgroups met separately multiple times, for a total of nine times across both groups. A few organizers led these sessions and recorded ideas in a running meeting notes document. At each first post-conference meeting, each subgroup initiated a process of having participants share literature through a Google form that then populated a folder with the relevant literature. This collection of literature helped inform how each group began to conceptualize their next steps. Additionally, one of the organizers, who is a member of both subgroups, has been maintaining our website (https://bit.ly/TechQuity) and distributing email updates to each group about the other group's work and progress.

Subgroup Activities and Artifacts as of February 2024

Frameworks subgroup. The Frameworks subgroup aims to examine a variety of frameworks on equity and on technology and develop a framework on equitable technology integration for mathematics education. At the first meeting, the group created a Google form to enrich the pool of frameworks that were used in the card sort. Through this form, we aim to gather more equity frameworks, technology frameworks, and search for any frameworks that bridge the two. At the same time, we initiated discussions on what a framework on equitable technology integration would focus on, what we refer to as the TechQuity Framework. At our next meeting, we began to conceptualize the TechQuity Framework. Figure 4 illustrates these initial conversations.

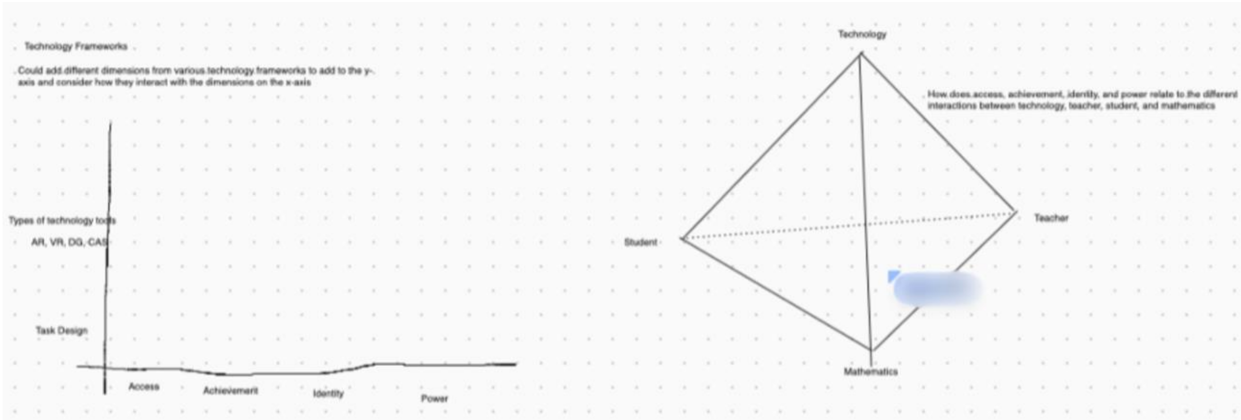

Figure 4: Diagrams of our conceptualizations of the TechQuity Framework

The diagram on the left shows our initial attempt to visualize the intersection of technology and equity as a graph. On the y-axis, we placed task design principles and the types of technology tools one might use while the x-axis focused on Gutiérrez's (2009) four dimensions of framing equity, namely Access, Achievement, Identity, and Power. Based on this diagram, we asked questions such as "How can technology help build student identity? How can it support the student voice? How can technology support access to resources and mathematics?" We also discussed what we mean by "access": access to high quality tasks with technology, a tool's accessibility, or access to diverse populations of learners.

These conversations led to the creation of the diagram on the right. In this conceptualization as a didactic tetrahedron (Hollebrands, 2016), the framework would model interactions between the students, the teacher, the technology, and the mathematics. Our current endeavor is to examine how each of these interactions may be framed and described in terms of Gutiérrez's (2009) four dimensions. We plan to expand upon these ideas between now and the next conference; our goal is to share the first draft of the framework with the 2024 participants.

Task design and implementation subgroup. The Task Design and Implementation subgroup began their work by also using a Google form to gather documents. Specifically, participants used this form to upload tasks that they felt were either (a) centered technology but had potential to be reframed from an equity lens, or (b) centered on some component of equitable teaching and had potential for being productively used with technology. As this subgroup met to discuss how technology can enhance mathematics curriculum and bring equity to the forefront, we began to highlight the many ways MTEs were engaged in integrating Artificial Intelligence (AI) into their curricular tasks and lesson development. Thus, it quickly became apparent after a few meetings, that many participants in this group had a budding interest in exploring the role of AI in mathematics education. As such, the subgroup decided to move forward by shifting our focus to the role of AI for creating equitable mathematics tasks. Subsequent conversations have also considered the role of AI for building equitable mathematics classrooms more broadly, including the ways AI can be used for assessment and as tools for instruction. Our discussions led to the realization that we need funding to bring various stakeholders together. We have since been in communication with NSF program officers about where our ideas might best fit.

Between now and the 2024 conference, we plan to continue these conversations. At the upcoming conference, we will share what we have learned and determine how to proceed.

Next Steps

Expanding on our prior efforts, the working group sessions in 2024 will delve into the following five agendas. First, we will focus on the development of the TechQuity framework, a framework that bridges theories in technology and equity and describes the relationships between mathematics, technology, students, and teachers (Figure 4). Second, we will delve deeper into an examination of the role of AI in promoting equitable mathematics instruction and the ways that various stakeholders might contribute to this. Third, we will continue our conversations around task design by exploring existing literature on mathematical tasks using technology for students in grades K-12 and seeking new mathematical tasks that are designed to enhance equity in teaching and learning mathematics. Fourth, we will grow our dissemination and networking efforts by expanding our website to serve as a hub for collecting resources for the equitable use of technology in mathematics for a larger audience and identifying ways to broaden participation in our professional community (e.g., newsletter). Lastly, we will continue to seek grant opportunities for technology use in mathematics education, particularly in the realm of artificial intelligence, such as applying for an AI workshop conference grant.

Acknowledgments

Work sustaining this group was supported in part by NSF grant 2222018. We'd also like to thank Charity Cayton, Jon Davis, and Matthew Mauntel for their continued support and participation in some activities regarding this working group.

This working group focuses on integrating mathematics with translanguaging literacy to support emergent bilingual students and strives to gain a better understanding of how translanguaging practices and critical literacy can support the mathematical learning of emergent bilingual students. Participants will be encouraged to share current work supporting emergent bilingual students, network with other mathematics education researchers interested in integrating mathematics and literacy and establish new collaborations and research partnerships.

Keywords: Elementary School Education; Equity, Inclusion, and Diversity; Culturally Relevant Pedagogy; Curriculum

With the recent calls to consider how mathematics and literacy can coalesce to provide connected learning in both domains (NCTE & NCTM, 2024), this working group would be a new initiative taking up that call to consider how mathematics and literacy can be integrated, and in particular to support teaching and learning for emergent bilingual (EB) students. In the initiation of this group, we hope to be able to provide space and networking for scholars interested in connecting mathematics and literacy, drawing on translanguaging literacy and translanguaging practices. Our overarching aim is to explore opportunities for collaboration and exchange of ideas, to ultimately support the mathematical learning of EB students.

Theoretical Background

Decades of research have been dedicated to understanding mathematics teaching and learning of EB students. Many studies emphasize the importance of maintaining robust mathematical learning opportunities alongside language development and suggest that engaging in rich tasks can actually enhance language proficiency (de Araujo et al., 2018; Poza, 2019). Yet, for EB students in dual-language education (DLE) programs the learning opportunities often depend on what language mathematics is taught and assessed in (Author, 2023), given that DLE programs often lack clear directives as both federal and state levels regarding the distribution of instructional time between language and content areas (Boyle et al., 2015). As these DLE programs continue to expand, understanding how the separation of language shapes EB students' mathematical learning becomes crucial. Maldonado Rodriguez & Krause (2020) caution against strict separation of language as a means to improve language proficiency, and instead advocate for embracing translanguaging as an "empowering and critical act" that encourages EB students to convey their mathematical thinking utilizing both languages (p. 21).

Other researchers have additionally advocated for leveraging EB students' cultural backgrounds as valuable resources (Moschkovich, 2022 de Araujo et al., 2018). In his framework for teaching mathematics for social justice, Gutstein (2006) pushes us to create learning opportunities for students to "[read] and [write] the world with mathematics" (p. 23). Within the landscape of literacy, Critical Literacy scholars suggest that "any issues that capture learners' interest, based on their experiences…can and should be used as a text to build a curriculum that has significance in their lives" (Vasquez et al., 2019, p. 301). At the core of critical literacy lies the importance of centering students' lived experiences to build on meaningful texts that address power, inequality and social justice, emphasizing the students' role as agents of change. Critical literacy fosters personal connections where students can interrogate the status quo, encouraging them to look beyond themselves. This is critical to EB students as they gain voice and make meaningful personal connections to mathematical texts.

Structure of Workshop

Expanding on these theoretical foundations across research in mathematics, translanguaging, and critical literacy to support EB students, this working group will focus on sharing current research across these topics to cultivate further development in this burgeoning area of study. In the following sections, we outline our approach to engage participants throughout the three days of the working group sessions.

Day 1: We will focus on introductions and providing opportunities for participants to share their interests in the group, their current/ongoing research, and what they would like to be able to accomplish throughout the three days. Participants will be asked to share research experience (or interest) in supporting emergent bilingual students' mathematical learning. Participants will be encouraged to begin identifying intersections for possible collaborations. current work integrating mathematics with translanguaging literacy. Contributing researchers will each help guide discussion at different groups/tables and document common themes to support establishing smaller working groups for the remaining two days.

Day 2: Contributing researchers (Author1, Author2, and Author4) will lead a short presentation (20 minutes) on rationale for the new working group. Presentation will focus on theoretical underpinnings of research and methodologies that have focused on supporting translanguaging practices of EB students in both mathematical and literacy contexts. Participants will then establish smaller groups interested in either collaborating on a manuscript or proposing a new project. Groups will begin developing ideas for their proposed research projects and outlining their proposed manuscripts.

Day 3: Participants will continue developing ideas for proposed projects and manuscripts. Groups will also develop a working plan to move continue moving forward their projects or manuscripts after the conference. We will also design and schedule follow-up activities that will include setting optional virtual monthly meetings for all participants to support their ongoing work.

This report summarizes the collaborative work and discussions from the third meeting of the working group on Mathematics Curriculum Recommendations for Elementary Teacher Preparation at PME-NA 45. Specifically, we share details from our meetings at the PME-NA conference in Reno, NV, as well as updates about all working group endeavors after the conference. We also share specific accomplishments and updates from each of the eight research subgroups of the working group, and our overall plans for the future of the working group. Across this report, we emphasize how we will continue to welcome and actively involve new members to our working group across North America.

Keywords: Preservice Teacher Education, Teacher Educators, Mathematical Knowledge for Teaching, Elementary School Education

The Mathematics Curriculum Recommendations for Elementary Teacher Preparation (MCRETP) working group entered Phase III of its long-term plan during the PME-NA 45 conference in Reno, NV in 2023. This phase centers on the research subgroups of MCRETP, specifically designing and supporting each other in conducting small-scale research studies that could address questions relevant to producing a research-based set of recommendations for elementary teacher preparation programs. The organizers of the working group created structures during PME-NA 45 for the MCRETP research subgroups to meet, brainstorm, collaborate, and share information about these small-scale research studies. Furthermore, the organizers welcomed several new members to the MCRETP working group at PME-NA 45, and meaningfully involved them in the work of the research subgroups.

In this report, we will summarize the outcome of our meetings at PME-NA 45 in Reno, NV. Next, we will describe post-conference activities that have helped our MCRETP working group continue to make progress. Then, we will review the eight research subgroups and describe each subgroup's work and accomplishments at PME-NA 45 and beyond. We will end this report with our revised long-term plan for the working group and discuss what questions we hope to address in the future.

We continue to emphasize that the MCRETP working group welcomes new participants to join at any time. We are especially interested in new members from North American countries outside of the United States, in an effort to better represent the diverse nationalities and perspectives of the whole PME-NA community. New members of our working group can expect to be involved immediately, either in being supported in conducting their own original research in a subgroup(s), joining an existing research team in a subgroup(s), and/or by being a non-researcher in a subgroup(s) and finding ways to support the endeavors of the group. We encourage anyone interested in joining the MCRETP working group to reach out to the working group organizers and/or research subgroup leader(s) to learn how they can get involved.

Our Meeting at PME-NA 45

Day 1

On Day 1 of the PME-NA 45 conference, MCRETP organizers aimed to orient everyone to the working group and to the research subgroups of the working group. We welcomed several new members to the working group, so we began Day 1 by restating our overarching goals, reviewing what we've accomplished so far, and previewing our long-term plan.

We explained that the overarching goal of the working group is to develop research-based, specific, and usable recommendations for the curriculum of elementary mathematics teacher preparation. We reviewed the past work of the MCRETP working group, which included understanding the concerns about elementary teacher preparation (Phase I in 2021) and designing research studies that could inform curricular recommendations (Phase II in 2022). Then, we previewed the present and future work of the working group, which included conducting these research studies and disseminating and synthesizing the findings (Phase III in 2023-2024), drafting research-based curricular recommendations (Phase IV in 2025), and drafting and submitting a grant proposal for a larger-scale, multi-site research study on the curricular recommendations (Phase V in 2026).

We also introduced and explained each research subgroup of the MCRETP working group. These subgroups included (in no particular order): (1) Literature Review and Critique of Current Recommendations, (2) Survey of Current Program Structures and Local Requirements, (3) Preparation Program Alumni Survey and Interviews, (4) Selection of Topics in Content Courses, (5) Pedagogical Practices, Tasks, and Thinking-Oriented Approaches in Content Courses, (6) Pedagogical Practices in Methods Courses, (7) Integration of Content and Methods Courses, and (8) Field Experiences and Clinical Work. Each subgroup leader(s) described their subgroup and its goals, research, and frameworks that guide their vision, and any progress that has been made toward achieving these goals. These descriptions helped reorient working group members to these eight areas of research, as well as introduce new members of the working group to potential subgroups they could join. Details about these research subgroups, their goals, and their up-to-date progress can be found in the Updates About Our Research Subgroups section below.

Day 1 ended with time for new members of the working group to visit with different subgroups and decide on the research subgroups they would like to join. Also, MCRETP organizers used this time to collect updated contact information from all working group members, as well as to preview the goals for Days 2 and 3. In all, Day 1 was a productive meeting because it reconnected members of the working group to the MCRETP goals and progress, and also meaningfully involved new members of the working group with research subgroup(s) of their interest.

Days 2 and 3

On Day 2 of the PME-NA 45 conference, each research subgroup convened and engaged in discussion. Subgroup members were prompted to share issues related to the mission of the subgroup that were salient in their current institutional context. Subgroup members were also invited to share details about a small-scale study they were planning to conduct or had already started conducting. The main purpose of these subgroup convenings was for subgroup members to gather feedback about these in-progress, small-scale research studies. Moreover, as more subgroup members shared about their in-progress research studies, subgroups could start to hypothesize about how findings from these studies might complement one another and to work together to test some hypotheses important to the subgroups' research agendas. Near the end of Day 2, about half of the subgroups shared summaries of their conversations with the entire working group and sought feedback. Members of the working group asked questions of each presenting subgroup and provided suggestions to support the development or progress of the study presented.

On Day 3 of the PME-NA 45 conference, subgroups continued to convene and engage in discussions, similarly to Day 2. Subgroups that had not yet shared about their conversations with the entire working group were given time to do so and collect more feedback. Each subgroup was also encouraged to start to make plans about how to keep their subgroup active and connected post-conference. The goal of the MCRETP organizers was for each member of the working group to leave PME-NA 45 with concrete steps for conducting research (or collaborating in such research) that will support our eventual curricular recommendations. Subgroup leaders used this time to start planning follow-up meetings and check-ins with their subgroup members. Days 2 and 3 proved to be valuable meetings because not only did all working group members have an opportunity to share their voices and visions, each research subgroup was able to make practical plans to stay connected with their collaborators after the conference. Next, we describe some of our post-conference activities that have helped our MCRETP working group continue to make progress after PME-NA 45.

Post-Conference Activities

Between November 2023 and February 2024, we have done the following:

1. Each research subgroup convened (some several times), via Zoom, to provide updates about research endeavors and to continue to get support and feedback from each other.
2. The leader/co-leaders of each research subgroup contributed information about their subgroup's progress to inform this report.
3. The MCRETP working group organizers met to discuss the overall progress of research subgroups. Using these updates, this team met to plan how to make PME-NA 46 as productive as possible.

Next, we review the eight research subgroups and describe each subgroup's work and accomplishments to date. See the author list of this report for contact information for each group leader/co-leader.

Updates About Our Research Subgroups

Literature Review and Critique of Current Recommendations

Group co-leaders: Nicole Wessman-Enzinger, Dana Olanoff, Kim Johnson, Jennifer Tobias, and Neet Priya Bajwa

This subgroup has two main aims. First, we are compiling and analyzing existing recommendations for the mathematical preparation of teachers. Using established criteria (e.g., the number of mathematical content/methods courses, specific content/methods recommendations, course delivery recommendations), this group is analyzing recommendations from groups including the Conference Board of Mathematics Sciences (CBMS), the Association of Mathematics Teacher Educators (AMTE), the National Council of Teachers of Mathematics (NCTM), and the National Council on Teacher Quality (NCTQ). We plan to articulate the ways that these recommendations align (and do not align) with each other. Second, we will use this analysis and synthesis to create a literature review of work related to these recommendations. We know from research (e.g., Garner et al., 2023; Masingila & Olanoff, 2022) that the majority of teacher preparation programs are not meeting the current recommendations. Our hope is that the work from this subgroup will help us to create a set of practical recommendations related to the existing work that programs would more likely be able to implement.

Survey of Current Program Structures and Local Requirements

Group co-leaders: Tuyin An and Dan Clark

The purpose of this research subgroup is to understand how elementary teacher preparation programs are structured across the nation, focusing on models of mathematical content and pedagogy integration, as well as how programs address social-justice-related topics. Since we presented our project idea to explore the structure of elementary teacher preparation programs at the 2023 PME-NA working group meeting, three colleagues have joined our sub-group. We shared similar interests in the policy, design, and structure of teacher preparation programs. We established our goal as a cross-institutional team: applying for an NSF IUSE grant to fund the development of our project. Our working group worked diligently throughout Fall and Winter 2023 and early Spring 2024. We set up weekly and bi-weekly working objectives and supported each other in conquering these challenging tasks: project design, application material preparation, external evaluator collaboration, and cross-institutional budgeting. We successfully submitted our grant proposal in January 2024. The title of our project is "Fostering Cross-Institutional Communication and Partnerships in Mathematics Teacher Preparation Programs." The total request amount is $396,828 over two project years.

The objectives of the proposed project are two-fold. First, we seek to understand the various programmatic structures that preservice elementary teachers (PT) preparation programs across the nation utilize in the mathematical preparation of their teacher candidates, as well as their perceived needs. Second, we will build an online, cross-institutional platform to foster communication and partnerships among PTs preparation programs regarding the mathematical preparation of their teacher candidates. Through the interactive platform, PT preparation programs would be able to easily find other programs (like or unlike themselves) in order to share resources and collectively optimize their courses and program structures. Having this catalog of resources available in one place would facilitate communication across programs of all types, as well as lessen the financial burden of programs looking to improve themselves. In addition, as more and more participants are involved, the online platform will regularly publish newsletters to keep the community informed. Faculty from all over the country can share their program changes, course redesigns, collaborative projects, related publication news, and other resources through the newsletters. This will all lead to PTs entering the workforce with stronger mathematical preparation.

Preparation Program Alumni Survey and Interviews

Group co-leaders: Dana Olanoff and Nicole Wessman-Enzinger

One of the best ways to determine what should be included in the mathematical preparation of teachers is to ask teachers which aspects of their preparation they find useful in their teaching practice. This subgroup has created a survey which we intend to distribute to recent alumni (within 5 years) of our teacher preparation programs. The survey asks respondents how prepared they felt to teach mathematics as well as to identify aspects of their teacher preparation programs that they felt were impactful to their current practice. We also ask for suggestions for aspects of teacher preparation programs that were missing that respondents wish had been included in their teacher preparation. We plan to distribute the surveys in the Spring of 2024 and to analyze the data in the Summer and Fall of 2024 in the hope of sharing preliminary data analysis with the whole Working Group at PME-NA 46.

Selection of Topics in Content Courses

Group co-leaders: Joseph DiNapoli, Valerie Long, and Jennifer Tobias

This research area investigates the affordances and constraints related to the instructional time spent (or not spent) on specific mathematics topics included in content courses for elementary PTs. Our subgroup is largely motivated by a recent longitudinal research study (Corven et al., 2022) that shows that survey courses, or courses that devote small amounts of high-quality instructional time to many mathematical topics, may have little or no impact on a future teacher's retention or use of knowledge related to those topics. Conversely, this study showed that teachers could more easily and effectively access knowledge related to mathematical topics for which ample high-quality instructional time was spent, years earlier, in their content coursework. This suggests that challenging decisions must be made about which topics to teach in content courses, and which to omit.

At PME-NA 45 in Reno, NV, this subgroup met to continue to support each other in designing and conducting original research to test our hypotheses about instructional time in content courses. We made ample progress during these meetings, including designing studies that we could conduct at our home institutions. For example, one study that is currently underway seeks to investigate the relationship between instructional time and the development of mathematical practices like perseverance in problem-solving: do elementary PTs learn to persevere more with challenging tasks about topics for which more instructional time was spent? Another study that is currently in process concerns the relationship between teaching fewer topics and students' summative assessment outcomes. After PME-NA 45, this subgroup has continued to convene virtually to offer support to those who are interested in designing and conducting their own original research relative to our subgroup's goals. Just recently, an idea for a new study to survey North American programs about their selection process for topics in content courses was born in one of these virtual meetings. In this subgroup, several studies are underway and some are even under review as potential presentations for PME-NA 46 about in-process research.

Pedagogical Practices, Tasks, and Thinking-Oriented Approaches in Content Courses

Group co-leaders: Julien Corven, Jennifer Tobias, and Neet Priya Bajwa

The purpose of this research subgroup is to consider recommendations for how to teach mathematics content within elementary content courses. Although recommendations for what to teach are important, without parallel recommendations for how to teach the content, the recommendations may end up ineffective. Li and Howe (2021) assert that it is critical for teacher preparation programs to focus not just on PTs' knowledge of the mathematical content (a knowledge-oriented approach), but more so on how to apply this knowledge to the craft of teaching by, for example, using such knowledge to understand and base instruction on students' thinking (a thinking-oriented approach). However, Li and Howe (2021) acknowledge that this assertion is their opinion, and they echo a call from Hiebert and Berk (2020) for more research that would support a professional knowledge base for MTEs on thinking-oriented approaches.

Subgroup members are currently planning specific research projects in the content courses they teach to assess the effectiveness of particular pedagogical approaches and tasks. For example, one study underway focuses on how PTs analyze student thinking on student solutions to decimal division tasks through the use of base-10 blocks. Another study evaluates tasks and the effect their modifications have on PTs' understanding of number concepts and operations.

We see this research subgroup's work as supporting our future recommendations by giving examples of how to design, modify, and/or implement tasks to support PTs' development of the mathematics they are to teach in their future careers. An underlying aspect of this is pedagogical practice recommendations for MTEs who can then modify and iterate on these tasks and activities (Hiebert & Morris, 2009). We also anticipate results from our studies will help us develop a repository that includes rationales for instructional decisions and information about how PTs may respond to the activities as a way to support novice MTEs (e.g., Superfine & Pitvorec, 2021; Suppa et al., 2020).

Pedagogical Practices in Methods Courses

Group co-leaders: Valerie Long, Richard Velasco, and Hartono Tjoe

This subgroup has two research aims: (1) to investigate the learning experiences that mathematics teacher educators utilize to help elementary PTs develop a rich understanding of equitable pedagogical practices in mathematics; and (2) to examine elementary PTs' implementations of these practices in their field placements as far as advancing their own students' mathematical thinking and learning. These learning experiences might include integrating culturally sustaining pedagogies, selecting and analyzing mathematics tasks, writing lesson plans, conducting teaching experiments, analyzing videos, examining misconceptions for a topic, etc.

At PME-NA 45 in Reno, NV, subgroup members discussed next steps for the current research project pertaining to PTs' analysis of tasks. These next steps are writing a practicum-based article about how researchers implemented the semester-long project in elementary math methods classes, analyzing data from PTs' evaluations using a class rubric of a low-level place value task, and comparing these results with those from PTs' evaluations using a class rubric for a high-level place value task. Additionally, members discussed applying for seed grants for research projects, starting a literature review of access and equity practices within elementary mathematics methods courses, creating pedagogical tasks grounded in the literature that promote access and equity in mathematics, making recommendations for teacher preparation programs associated with mathematics methods courses, beginning preliminary/pilot work within our own respective elementary mathematics methods courses, and using findings to initiate a NSF grant application. Some recent accomplishments from our group include: (1) a manuscript proposal submission to *Review of Research in Education* (a systematic literature review for culturally sustaining pedagogies in mathematics teacher educator programs, inclusive of elementary teacher programs), and (2) a potential article publication to the *School Science and Mathematics* journal for PTs' analysis of tasks.

Integration of Content and Methods Courses

Group co-leaders: Kristy Litster and Bona Kang

This research area seeks to develop recommendations for integrating pedagogical methods and mathematical content that support and assess PTs' learning. Specifically, it is looking at what MTEs can do in courses to support elementary PTs' ability to develop specialized mathematical content knowledge and pedagogical methods to teach any mathematical standard or grade level. AMTE (2017) noted this is an important area for MTEs as they provide guidance in designing and implementing course structures, assignments, and fundamental methodologies when preparing high-quality elementary mathematics teachers. To support the learning of a diverse student population, PTs should learn to evaluate and reflect on both the content and methods they use in the classroom. Research shows many elementary teacher preparation programs have limited time available due to course and program structures, which constrains MTEs' efforts to help PTs develop deep knowledge of children's mathematical thinking as well as ambitious teaching practices (Berry, 2004; Bertolone-Smith et al., 2023; Cochran-Smith et al., 2015; Saclarides et al., 2022). Integrating content and methodologies through a thinking-oriented approach within mathematical content and methods courses helps mitigate limitations of allotted time in programs to support PTs to build cohesive understandings of both specialized content knowledge and pedagogical practices (Li & Howe, 2021).

During the 2023 calendar year, this research group met monthly to review goals and plan potential collaborative research projects based on goals set at the 2023 AMTE conference in New Orleans, LA. We chose to focus on one of our project ideas: To try out specific strategies to integrate content and methods and assess PTs' content and pedagogical knowledge through qualitative and quantitative outcomes. Specifically, we were able to develop a project to assess these outcomes using a diagnostic interview assignment in content and methods courses across multiple universities. We developed a rubric using the teacher noticing (Jacobs et al., 2010), domains of Mathematical Knowledge for Teaching (Ball et al., 2008), and NCTM's effective mathematical practices (NCTM, 2014), which will be used to evaluate specialized content knowledge and pedagogical knowledge of PTs. We finalized the project idea at the PME-NA 45 conference in Reno, NV, and we will be gathering data during Spring 2024.

Field Experiences and Clinical Work

Group leader: Kim Johnson

At PME-NA 45, this subgroup narrowed our focus on paired field experiences and embarked on research on the benefits of providing this opportunity for PTs during their math methods courses. It is the aim of the methods courses that the PTs should observe mentors that use and implement effective mathematical teaching practices (NCTM, 2014). However, choosing the best mentor teachers for PTs to work with is often problematic given the large number of students enrolled in many programs. As noted in Bullough et al. (2002), using paired placements allows the reduction in the number of mentor teachers required and enables the concentration of effort and energy needed to produce the simultaneous renewal of effective placements. According to previous research (Baker & Milner, 2006, Bullough et al., 2002), paired placements also bring other benefits for PTs such as an increase in confidence and deeper reflection on lessons.

Our subgroup has met monthly since Reno, NV, and is pursuing a research study at University of Missouri to look closely at paired field placements versus individual field placements. This is an opportunity to do a comparison study, as they are piloting both types of placements. Additionally, group members are doing some work on developing planning tools for both in-service teachers and PTs to conduct more meaningful number routines in the classroom as part of professional development for mentor teachers. These lesson planning tools can be used by the PTs as part of the field experiences to help PTs focus on student thinking.

Our Long-Term Plan

The long-term plan for our MCRETP working group consists of five phases. We are currently in Phase III. Our working group, and consequently Phase I, began in 2021 at PME-NA 43 in Philadelphia, PA, with a primary focus on understanding the issues surrounding the preparation of elementary teachers. We entered into Phase II in 2022, at PME-NA 44 in Nashville, TN, with an emphasis on formulating research subgroups and brainstorming research studies aimed at providing insights that could inform our eventual curricular recommendations. As detailed in this report, we entered into Phase III in 2023, at PME-NA 45 in Reno, NV, and have continued this work since the conference. Phase III is designed to encompass two years, 2023 and 2024, as members of the MCRETP working group continue to design, conduct, and synthesize the findings from small-scale research studies that address questions relevant to producing a research-based set of recommendations for elementary teacher preparation programs. We aim to continue our work in Phase III at PME-NA 46 in Cleveland, OH, and in the months following the conference. Each research subgroup will continue to meet periodically, outside of our formal working group meetings at PME-NA conferences, to offer research support and feedback. The full MCRETP working group will also convene periodically, providing a platform for subgroups to share their progress and solicit additional feedback. We anticipate several members of the working group to be able to start disseminating findings from their small-scale studies near the culmination of Phase III. We will encourage working group members to write proposals to present research findings at PME-NA or other relevant professional conferences and to publish reports in other appropriate outlets.

Looking beyond our current work, Phases IV and V are scheduled for 2025 and 2026, respectively, with a primary focus on synthesis and the eventual production of research-based recommendations. In Phase IV, we plan to propose a PME-NA 47 research colloquium, where the research findings from each subgroup of the MCRETP working group will be cohesively presented. This colloquium will serve as a formal platform for synthesizing collective findings and addressing questions about the implications of our work. Simultaneously, we anticipate organizing a special issue of a journal, featuring a synthesis article from each research subgroup and a concluding article discussing the policy implications of the research findings. Moving into Phase V, our initial goal is to publish the special issue prepared during Phase IV. Furthermore, we intend to pursue a grant to host a 2026 conference with the objective of crafting and debating a research-supported set of recommendations for elementary teacher preparation.

In conclusion, our MCRETP working group has formulated a distinct vision focused on creating a research-based set of recommendations for elementary teacher preparation programs. Our time at PME-NA 45 in Reno, NV was exciting and productive, fueling our enthusiasm as we embark on the subsequent phases of our long-term plan. We emphasize one last time our openness to new participants, inviting them to join the MCRETP working group during its current phase, contribute to a research subgroup, and collaborate with us in achieving our long-term goals. Your participation is welcomed as we continue this impactful journey.

cpedging@ncsu.edu

Kenya Lawrence
NC State University
kllawren@ncsu.edu

This group is dedicated to dismantling anti-Blackness in secondary mathematics teacher preparation through the development of critical, research-informed modules for Mathematics Teacher Educators. Our mission is to equip Pre-Service Teachers with knowledge, skills, and dispositions necessary to foster critical consciousness and counter systemic inequities in mathematics education. Leveraging improvement science methods, we aim to create, refine, and share six modules addressing instructor reflexivity, PST beliefs, identity and agency, political and historical context, systemic anti-Blackness, and actionable plans for student liberation. These modules are poised to transform mathematics teaching practices, promoting equity and stimulating interest in STEM among historically marginalized students.

Keywords: Preservice Teacher Education, Equity, Inclusion, and Diversity, & Social Justice

This newly established working group will contribute to ongoing efforts to increase access (Males et. al, 2020) to much needed research-based resources for Mathematics Teacher Educators (MTEs) to engage their pre-service teachers (PSTs) in learning to better serve the students in their diverse classrooms. The primary artifacts of discussion, development, and distribution will focus on six modules. These six modules are rooted in critical pedagogies (Duncan-Andrade & Morrell, 2008; Shor, 2014) to support PSTs in understanding how a) anti-Blackness functions in mathematics education and b) to counter cultural hegemonic practices. In line with Whitehead (2021), we define anti-Blackness as “whiteness and anti-Blackness are discrete, entangled ideologies through which Black people are stripped of their humanity. … [and the] relationship between whiteness and anti-Blackness operates both systemically and interpersonally” (p. 310). Programmatic structures must allow students to commit to a praxis Freire, 1996) reflecting on how anti-Blackness (white supremacy culture) impacts mathematics education and focus on the actions they may have already taken and will continue to take in the future. Through an awareness of anti-Blackness and the agency to challenge white supremacy, PSTs will develop critical consciousness. In mathematics education critical consciousness is related to the context of learning (connections to the real world) and how we see/treat students. Critical consciousness in mathematics education harkens on the importance of connecting mathematics to the socio-political (real) world (Kokka, 2019; Seda & Brown, 2021). However, our prior work shows that MTEs lack resources for doing this work (Males et al., 2020). Therefore, we aim to use improvement science methods (Bryk et al., 2015; Martin et al., 2020) to design and refine a series of modules for use in undergraduate 6-12 mathematics methods courses that address PSTs knowledge, skills, and dispositions to counteract anti-Blackness. The goal of this working group is to create a space for MTEs to collaborate on research and reflect on the harm caused by inaction, in order to sustain action towards dismantling systemic anti-Blackness within mathematics education, fostering a community of praxis that actively engages in the development and implementation of transformative pedagogies and curricula grounded in social justice and equity.

Modules & Session Structure

Recognizing the need for resources that empower MTEs to confront anti-Blackness in educational settings, our working group moves from theory to action. The six modules are designed to deepen PSTs understanding of anti-Blackness in mathematics education and equip them with the practical skills and reflective practices necessary for transformative teaching. PSTs will be encouraged to reflect on their own positions, challenge systemic issues, and develop actionable strategies for change.

The first module, **Instructor Positionality & Reflexivity (Module 0)**, prompts educators to reflect on their beliefs and practices related to anti-Blackness. **Understanding PSTs' Perspectives on Mathematics (Module 1)** encourages PSTs to examine and reflect on their own beliefs about mathematics teaching and learning. **Identity & Agency (Module 2)** explores the influence of personal identities in the learning environment. The fourth module, **Political & Historical Context (Module 3)**, links the history and politics of race to teaching practices. **Anti-Blackness and the System (Module 4)** delve into systemic issues perpetuating inequities and the impact of the culture of white supremacy, while the final module, **Developing a First Year Teacher Action Plan for Student Liberation (Module 5)**, focuses on actionable strategies for PSTs to foster an inclusive and liberating classroom.

Session 1 – Overview and Reflexivity. We will begin by providing an overview of the project and the work completed thus far, including sample data from the first rounds of implementation (30 minutes). We will engage participants in aspects of Module 0 to reflect on our own beliefs and practices as MTEs (30 minutes). The session will close with a whole group discussion on the necessity of developing critical consciousness (30 minutes).

Session 2 - Developing PSTs Critical Consciousness. Day 2 will engage participants in an activity from Module 2 called "Discarding Identities" (30 minutes). Participants will analyze the activity and further explore the modules in small groups (45 minutes). We will close with a whole group discussion on implementation of modules within participant contexts (15 minutes).

Session 3 – Moving Towards Action. Based on day 2 participation, we will dive deeper into the modules and existing data in smaller interest groups (45 minutes). Groups will discuss next steps and movement towards action to inform future PMENA working group meetings (45 minutes).

This new working group will reflect on intersectional equity issues in today's mathematics learning environments and create a resource to expand critical conversations through equity-oriented cases. We plan to engage participants in discussions regarding current uses of case-based instruction to reframe and dismantle violent and ideological views (e.g., racism, sexism, ableism) that diminish and disparage individuals from participating in mathematics settings. As a collective, participants will develop equity-oriented cases specific to mathematics education and establish collaborations to use the newly developed cases in mathematics teacher preparation. This working group aims to provide the community with space to generate a book of cases that will be shared with the mathematics education community.

Keywords: Preservice teacher education; instructional activities and practices; equity, inclusion, and diversity

Standards documents recommend teachers have a repertoire of equitable teaching strategies to be ethical advocates for every student (AMTE, 2017, Standards C.2 and C.4). Teacher education can provide opportunities for preservice teachers (PTs) to learn how social, historical, and institutional contexts influence mathematics teaching and learning, particularly with respect to equity and the various ways to challenge inequities that affect marginalized students' learning experiences. Additionally, PME-NA's Equity Statement (2020) calls for re-conceptualizing pedagogical practice away from deficit ways of knowing and learning to promote a humanized perspective of education that positions all students as capable contributors to mathematics education. In response to these initiatives, mathematics teacher educators (MTEs) use various research-based practices to support PTs' understanding of power and privilege in mathematics education, how to cultivate positive mathematical identities, draw on students' mathematical strengths, and enact ethical practice for advocacy. One such practice is using case-based instruction, which uses stories to explore the complexities of mathematics classrooms to develop a critical lens for teaching (Gorski & Pothini, 2018; Kavanagh, 2020). MTEs continue to develop, use, and share their cases at conferences and through personal connections. However, the sharing is not easily accessed by all in the mathematics education field.

This new working group will create a resource to expand critical conversations through equity-oriented mathematics cases that can be shared widely. The cases will illuminate the mathematical brilliance of all students, focusing on the intersectional identities of oppressed and marginalized students. While this work is not new, as there have been many equity-oriented cases shared at PME-NA, AMTE, and AERA where MTEs report on how PTs responded, including some of our presentations (Gonzalez et al., 2022; Moldavan et al., 2023), the goal of this working group is to leverage the productive critical conversations that have foregrounded the collective work to meet the following goals (1) assist participants in becoming familiar with recent research and resources addressing the benefits of case-based instruction and how cases can be used in mathematics teacher education to help PTs challenge equity issues in K-12 mathematics settings and (2) develop equity-oriented cases specific to mathematics education that can then be implemented in their settings and submitted to a case book.

Theoretical Background

Case-based instruction is widely used as a pedagogical approach to examine authentic, real-life scenarios that can engage teachers in analyzing dilemmas of practice (White et al., 2016). It can be used as a tool for uncovering teachers' deficit noticings and perspectives that can lead to differential student treatment, such as over-punishing Black students, which is a form of systemic violence in mathematics education (Childs & Wooten, 2023; Martin, 2019). While cases can be used to present a complex classroom dilemma situated within discussion questions for individual and group reflections (Gorski & Pothini, 2018; Redman & Redman, 2011), the cases often need to be modified to address the specific needs of mathematics teacher educators using the cases to bridge theory to practice in the teaching and learning of mathematics (Gonzalez et al., 2022). Furthermore, cases are typically organized around specific issues, such as race, gender, or socioeconomic status, and do little to explore the intersectionality of oppressed and marginalized identities that create compounding systems of disadvantage. The field of mathematics education needs a resource of equity-oriented cases that represent mathematics learning and teaching while also highlighting the importance of attending to multiple students' identities.

To frame the equity-oriented cases, we consider Cochran-Smith and Keefe's (2022) definition of strong equity, considering redistribution, recognition, representation, and reframing. MTEs can use equity-oriented cases to explore the power of one's story, which provides entry points to self-reflect and learn from other's experiences. The cases can encourage PTs to critically reflect on particular scenarios to reframe, integrate, and unlearn deficit views of students and transform equitable instructional practices that position all students as capable mathematics learners and doers. Recognizing the need to reframe and dismantle violent and ideological views (e.g., racism, sexism, ableism) that diminish and disparage individuals from participating in mathematics settings can guide the purpose and use of cases, especially cases that present counternarratives to challenge deficit perspectives.

Organization and Presentation Plan

The working group will be organized into three sessions where participants can actively contribute their experiences and expertise to satisfy a deliverable. The first session will welcome participants with an introduction to case-based instruction, an exploration of recent resources, and a discussion about the desired product that the working group will produce. As a collective, we will collaboratively critique existing cases focusing on equity and mathematics spaces. After sharing an example template for writing equity-oriented cases, participants will be tasked with drafting their own case to bring to the next session.

In the second session, participants will work in small groups to provide feedback on their drafted cases. They will collaboratively unpack the intersectional equity issues the cases explore and critically reflect on how the cases were written so as not to perpetuate biases and deficit perspectives. They will then be tasked with coming to the next session with a revised draft with discussion questions that will engage PTs in unpacking the inequities alongside the mathematics content. The last session will provide a space to refine the discussion questions, coordinate implementation plans to use the cases, and note recruitment plans to contribute to the case book.

By the end of the conference, the group will have produced multiple equity-oriented cases that are ready to be used with PTs. Additionally, we intend to continue this work with broader participation from the mathematics education community by including the voices of mathematics teachers, coaches, and school leaders.

Gender research has a long history in mathematics education, whereas sexuality research is a newer research focus in the field. Much of this research has been conducted using a singular lens, that is, strictly focusing on the influence of participants' genders (or sexualities) in their mathematics experiences. However, in recent years, increased focus has been placed on the importance of conducting research with an intersectional lens, with the acknowledgement that experiences within the same identity group (e.g., boys, lesbians) differ due to multiple intersecting identities. Although research has been conducted about the intersections of gender and race in mathematics education, far less attention has been paid to identity aspects that are less (visually) obvious than race, such as socioeconomic status, first-generation college student status, and certain disabilities. In this year's working group, we will explore how to make gender/sexuality research more intersectional, addressing both methodological and theoretical considerations, with special attention to concealable stigmatized identities, which have rarely been explored in gender/sexuality research.

Keywords: Gender; LGBTQIA+; Equity, Inclusion, and Diversity

Mathematics education and mathematics education research are subject to influence from broader societal shifts and government policies. In recent years, there have been numerous bills introduced and passed in North America (French, 2024; Trans Legislation Tracker, n.d.) that have negatively impacted the lived experiences, including the schooling experiences, of LGBTQIA+ students and teachers (Kosciw et al., 2021). Hence, for these groups of individuals, their learning and teaching of mathematics are indeed taking place during uncertain times.

Given these uncertainties, as well as recent societal shifts regarding perceptions of gender and sexuality, it is crucial that we, as mathematics education researchers, acknowledge and honor the complexities of participants' lived experiences through our work. One such topic that has increasing relevance is intersectionality. Coined by Crenshaw (1989), the term *intersectionality* refers to "the intersection of people's identity categories but also the intersection of individual and institutional factors" (Pugach et al., 2019, p. 207). Although some mathematics education research is intersectional, intersectional research is still uncommon in the field and typically only pertains to intersections of gender and race (e.g., Battey et al., 2022; Hsieh et al., 2021). Hence, scholars (e.g., Bullock, 2018; Hall et al., 2024) have called for an increased focus on intersectionality, as well as for intersectional analyses beyond gender and race.

Social (or membership) identities are based on belonging to groups that share those identities, such as gender, sexuality, race, and language (Langer-Osuna & Esmonde, 2017). These identities, especially as they intersect with each other, influence students' experiences in and out of school (Eddy et al., 2015; Ferguson, 2017). Social identities can be conspicuous or concealable (Quinn, 2006). Concealable stigmatized identities (CSIs) are those "that can be hidden from others and that are socially devalued and negatively stereotyped" (Quinn & Earnshaw, 2013, p. 40). Examples include minoritized sexualities, certain health conditions (e.g., mental illness), and low socioeconomic status (Busch et al., 2023). Both hiding and disclosing CSIs can have consequences for people's lives in school and beyond (Quinn & Earnshaw, 2013; Weisz et al., 2016). This relatively neglected research topic is thus a significant area of exploration for mathematics education researchers because mathematics identity is formed by interactions between mathematics learning and social identities (Gresalfi et al., 2019).

History and Goals of the Working Group

Since the Gender and Sexuality Working Group began in 2018, various topics have been explored, including methodologies and theories for conducting inclusive gender and sexuality research. Over the years, the working group has grown, indicating expanding interest in this research area. In last year's working group sessions, participants shared their experiences conducting gender and sexuality research, including discussing how they initially became involved in the field. They expressed that they felt that the working group was a safe space to discuss research challenges that they faced, due to the similar perspectives, goals, and experiences of those in attendance. Participants also shared examples of research successes and pragmatic ideas to support each other's research.

One topic that arose in last year's working group discussions was intersectionality. Participants expressed interest in exploring this topic in more depth in future working group sessions, which is why we selected the topic as this year's focus. Specifically, we plan to use the working group sessions to provide participants with an opportunity to share their experiences and suggestions for conducting intersectional gender and sexuality research, with a focus on CSIs.

This Year's Working Group Sessions

Each session will have a different, but related, focus. Specifically, **Session 1** will have an introductory focus so that participants can become better acquainted with the topics of intersectionality and CSIs, their histories, and their places in gender and sexuality research, via two 10-minute presentations: one about intersectionality and one about CSIs. In the remainder of Session 1, participants will share their experiences conducting intersectional research, particularly research involving CSIs.

Session 2 will begin with a 15-minute presentation in which examples of intersectional research involving CSIs (conducted by other researchers in the field) will be shared. The remainder of Session 2 will be a working session in which participants will be provided with case studies involving sample research questions and will be invited to conceptualize practical ideas for conducting the research using an intersectional lens. Participants will consider the case studies in small groups, and the responses to the case study questions will be shared in a jigsaw format.

In **Session 3**, participants will be asked to form groups based on common areas of interest and will work together to brainstorm potential study designs around these topics. We anticipate that these discussions will lead to future research collaborations among the working group participants.

100-Word Description of the Working Group Sessions

The focus of this year's Gender and Sexuality Working Group is intersectionality. Although some intersectional gender/sexuality research has been conducted, these studies typically only involve gender and race. Hence, in the sessions, we plan to specifically focus on concealable stigmatized identities (e.g., mental health conditions, socioeconomic status), as they are rarely addressed in gender/sexuality research. Participants will share their experiences conducting intersectional gender/sexuality research, particularly research involving concealable stigmatized identities. Participants will also be able to put their understandings into practice, through considering case studies, and will be able to brainstorm future research collaborations with other group members.

COMPLEX CONNECTIONS: REIMAGINING PURE AND APPLIED RESEARCH IN UNITS CONSTRUCTION AND COORDINATION

Amy J. Hackenberg
Indiana University
ahackenb@indiana.edu

The theory of units construction and coordination originally posited a rationale for students' mathematical reasoning with whole numbers; for instance, explaining that students may conceive of 12 as 12 units of one, 1 unit of 12, or 1 unit of 3 groups of 4, among other possibilities. Research has subsequently identified connections between students' construction and coordination of whole number units to fractional units, proportional reasoning, and other mathematical domains. This working group aims to engage mathematics educators in discussion to deepen the field's understanding of units construction and coordination, including pure theoretical research, and research applied in classrooms.

Keywords: Learning Theory, Learning Trajectories and Progressions, Number Concepts and Operations

Background

For the past several years, the Complex Connections working group has met to broaden the research, understanding, and application of units coordination in mathematics education. This work has included discussions around algebraic reasoning, covariational reasoning, combinatorial reasoning, mathematics knowledge for teaching and many other mathematical concepts. The goal each year is to provide an opportunity for researchers to discuss the links between the mathematical concepts and the types of of units constructions and coordinations needed for reasoning. This year, the working group is hoping to move beyond these discussions and look ahead at research we may develop to broaden the understanding of units construction and coordination.

Units coordination is related to student reasoning, particularly multiplicative reasoning, fractional reasoning, algebraic reasoning, covariational reasoning, and combinatorial reasoning (Hackenberg & Lee, 2015; Hackenberg & Tillema, 2009; Norton et al., 2015; Antonides & Battista, 2022; Tillema, 2013, 2018). Units coordination refers to one's ability to construct and operate on composite units made up of sub-units and switch between the multiple units (Norton et al., 2015). For example, in a multiplicative task (e.g., You have 5 towers of cubes, each with 3 cubes, how many cubes do you have altogether?), an individual reasoning multiplicatively could coordinate three different units within the task (composite units – towers, single units – cubes in each tower, and total compilation – total cubes across the 5 towers) (Tzur et al., 2017).

Day 1: The Future of Units Construction and Coordination

Day 1 will have the working group transitioning from what has already been studied to what the future holds in units construction and coordination research. The session will begin with an introduction to provide a framework for the working group's goals and allow for a discussion on the distinctions between applied research versus pure theory research. This will give members the opportunity to consider which direction their future research may take based on their own aspirations and research goals. From there, members will be introduced to a scenario to provide context for further discussion: If we had unlimited funding to study units construction and coordination, what would we, as a community of researchers, want to study, what questions would we want to answer, and what problems would we want to explore? The goal is to provide a possible roadmap of where we want our research to go based on the progress we have already made and what we have left to explore. This discussion will provide members with an opportunity to collaborate with others interested in similar research goals and organize times to meet throughout the conference days and plan future research.

Day 2: Nuances of Units Construction and Coordination

Over the last several years, the working group has come to realize that the nuances of units construction and coordination research vary across researchers and their work in the field. Therefore, the group will spend the second session exploring these nuances and coming to some agreements and commonalities for our research field. These nuances include how we assess units construction and coordination, the stages of units coordination we observe and analyze, and the terminology we use in our research dissemination (i.e., unit vs units; structure; coordination vs. construction, etc.). We will culminate the session by analyzing discrepancies within the units coordination literature through guided prompts provided by the leadership team. The goal is to find a common foundation on which units coordination research can further build.

Day 3:

Day 3 will be a session bookmarked for members to report to the group what they are currently studying in units coordination and providing an opportunity to ask questions and discuss the research currently going on. The session will also include time to plan for the 2025 working group, as well as expectations of working group members over the next year.

Matney et al.'s (2020) Black Hole of mathematics educational research involves an instructional practice that has attained critical gravity in the mathematics teaching field. While practitioner anecdotes and related research suggest the practice's efficacy, there is a lack of rigorous research into the practice itself. Launching from Matney et al.'s example of Number Talks, this new working group will describe and elaborate on the Black Hole metaphor, identify additional possible Black Hole research domains, define parameters for researching and ultimately illuminating Black Holes, and establish future research collaborations.

Keywords: Instructional activities and practices, research methods

In mathematics education, practitioners often take up an instructional practice that intuition tells them will be impactful. This intuition is guided by experience and research related to the practice, but at times school systems use this practice widely without objectively understanding the efficacy of this practice. Furthermore, the practice often evolves into practices bearing the same name while being somewhat different in purpose and substance. This working group seeks to promote a "practice-to-research" focus on scholarship examining the 'Black Holes' surrounding these instructional practices in mathematics classrooms. The authors of this proposal are from various institutions and have connected at various conferences, including PME-NA, over their shared interest in widely used classroom practices that lack a solid foundation of empirical research. This working group seeks to formalize these connections and bring others into the conversation. In doing so, we have the following goals:

- Introduce and discuss the metaphor of Black Holes of research and identify examples.
- Describe constraints to working on research to illuminate a Black Hole.
- Discuss what it means to contribute to research on practices represented as Black Holes of research.
- Develop future work across institutions for systematic investigation of the practices.

Theoretical Background

Matney et al. (2020) labeled the phenomenon described above as a Black Hole of research on instructional practice, meaning an instructional practice that has attained 'critical gravity' in the teaching field, but little to no blind-peer-reviewed research has investigated its efficacy. When a practice resides in a research Black Hole, the Black Hole does not represent empty space; rather, there is 'something' there attracting practitioners, but research has yet to systematically guide or illuminate it. Despite this lack of direct investigation, the Black Hole of research is surrounded by an accretion disk made up of connected knowledge from the results of rigorous research that suggests the practice's validity (Matney et al., 2020).

Matney et al.'s (2020) impetus for developing the metaphor of the Black Hole for instructional practices that lacked a rigorous research base was the practice of Number Talks (e.g., Humphreys & Parker, 2015; Parrish, 2011). Number Talks are said to promote sensemaking and computational fluency (Humphreys & Parker; Parrish). However, while established research on several relevant topics—such as classroom environment, discourse, mental math, number sense, and teacher questioning—suggest the practice's efficacy, Matney et al.'s systematic literature review identified only one study that examined the impacts of the practice itself with K-12 students. Matney et al. asserted that investigation of the practice itself is necessary in order to bridge the gap between research and practice and identify the features of the practice and its implementation that contribute to the practice's impact.

Structure of the Sessions

On **Day 1** of the working group, we will begin with introductions of the participants of the working group and review the goals of the working group (15 minutes). Then, based on his original literature review (Matney et al., 2020), Matney will introduce the Black Hole metaphor and explain its origin (10 minutes). Two research teams will present an overview of their research into the practice that spurred the creation of the Black Hole metaphor, Number Talks (10 minutes each for a total of 20 minutes). One research group investigates in-service teachers' curriculum assemblages with Number Talk resources. The second research group explores when and how preservice teachers use teacher authority in their enacted Number Talks and their related reflections. The remainder of the session (45 minutes) will involve small and whole group brainstorming and discussion of other potential instructional practices that are surrounded by a Black Hole of research. Discussion points will include parameters for what 'counts' as a Black Hole, what sources should be reviewed in order to identify a Black Hole, and what constitutes a lack of systematic research.

On **Day 2**, we will review the items discussed on Day 1 (15 minutes). Three research projects will present overviews of their research on practices they have identified as surrounded by a Black Hole of research (10 minutes each for a total of 30 minutes). One researcher studies pre-service elementary teachers' engagement in open mathematics tasks such as Which One Doesn't Belong? (Danielson, 2016), How Many? (Danielson, 2018), and Notice and Wonder (Fetter, 2021; Ray-Riek, 2013). The second research group investigates in-service teachers' purposes for using Notice and Wonder. A third researcher studies Complex Instruction (Cohen & Lotan, 2014) from its theoretical underpinnings of expectation states theory. In the remaining 45 minutes, in small groups and as a whole group, discussion will address issues such as research questions, populations, data collection, data analysis. We will also discuss what it means to provide evidence of a practice's 'efficacy.' We will discuss challenges inherent in researching in Black Holes such as establishing research in K-12 settings with K-12 students.

Day 3 will focus on establishing joint goals and initiating research collaborations. We plan to have a website to keep a record of our work between and across conference meetings.

For conference program:

Matney et al.'s (2020) Black Hole of mathematics educational research involves an instructional practice that has attained critical gravity in the mathematics teaching field. While practitioner anecdotes and related research suggest the practice's efficacy, there is a lack of rigorous research into the practice itself. Launching from Matney et al.'s example of Number Talks, this new working group will describe and elaborate on the Black Hole metaphor, identify additional possible Black Hole research domains, define parameters for researching and ultimately illuminating Black Holes, and establish future research collaborations.

WORKING GROUP REPORT: CRITICAL DISABILITY STUDIES IN MATHEMATICS EDUCATION

In continuing with past working groups on research at the intersection of disability studies and mathematics education, this working group met at PME-NA 45 to share new developments from group members, to make new connections, and work toward shared goals. Over the course of the three days, we articulated topics and ideas in which to invest our energies, specifically: (a) the development of the Mathematics Education Conference Access Committee, (b) a commitment to supporting the leadership of PME-NA as they work toward increasing accessibility to and at the annual conferences, (c) a plan for a Disability Justice and Mathematics book proposal, and (d) a plan for pursuing grant funding for a Disability Studies in Mathematics Education conference.

Keywords: students with disabilities, special education, equity, inclusion, and diversity

History

Kai Rands and James Sheldon conceptualized and convened this working group, formally from 2016–2018, although other informal meetings occurred before and after these dates. During these early meetings, group members discussed employing different theoretical perspectives within their work, described current projects, and raised critical issues. This core group consisted of faculty, graduate students, disability activists, and classroom teachers and consisted of: Amber Candela, Jessica Hunt, Rachel Lambert, Katie Lewis, Paulo Tan, and Cathery Yeh. The working group convened again in 2022 and 2023 at PME-NA. In between formal meetings, many working group members collaborated to conduct research, write grants, produce manuscripts and books, and engage with the mathematics education, special education, and disability communities.

Work at PME-NA 45

Across the three sessions at PME-NA 45, 27 people participated in our hybrid working group. This hybrid approach allowed access for people to participate and engage in the group who would have otherwise been excluded from an in-person-only working group. The need for a hybrid working group surfaced when group members expressed concerns about COVID-19, travel, in-town transportation, and the difficulty many caregivers face when being away from home for multiple days. Our group discussed the various ways hybrid access allowed for more inclusivity, specifically for disabled, immunocompromised, and otherwise marginalized scholars.

Hybrid access allowed many working group organizers to meet and form collaborations across space before, during, and after the conference. Over the three days we built community, worked in small groups, and planned for next steps beyond the bounds of conference meetings. We created a set of shared documents to capture meeting notes, conversations, and ideas.

Day 1: Community, Connections, and Generating Small Group Topics

Our group started with introductions and sharing access needs. The importance of the invitation to share access needs is discussed by activists and scholars (e.g., Reinholz & Ridgway, 2021; Sins Invalid, 2019). For example, sharing one's access needs might sound like, "I am [name], and I am at [university]. My pronouns are she, her, hers, and it is important that I can get up and stretch; I need to take breaks periodically," or, "My access needs are being met through having the virtual environment." Through these introductions, our group built camaraderie as people identified similar needs and ways to collectively meet various needs. These introductions served as opportunities for group members to identify people with whom they would like to connect based on, for example, their professional role or interests. These introductions were also an inroad for folks to learn about ableism and how professional norms often (unintentionally) impede access. During these introductions, we recorded names and contact information on a shared electronic document so group members could reach out to each other during or after the conference. One access need shared by many participants was having a virtual modality for the working group. Throughout the session, organizers regularly ensured that access needs were met and that communication throughout both modalities was successful and comfortable. This helped create an environment in which those participating virtually were viewed as full and contributing members of the community and spurred a discussion about implicit ableism in the way that virtual participation is often viewed as less legitimate. Several members expressed disappointment that they, and other marginalized scholars, were unable to engage in the remainder of the conference.

We generated a list of topics for members to pursue in a small group; ideas were documented on the shared electronic document. As we generated this list, it became evident that attendees had a range of experiences, background knowledge, and interests. It was clear that attendees, both old and new, were interested in a space to feel intellectually, professionally, and personally seen and heard. Thus, the first meeting organically developed into a space for community and connection.

Day 2: Generating and Planning

Our next meeting afforded the opportunity to enact the value that access is a collective responsibility, thereby moving toward a collaborative actualization of Disability Justice (Piepzna-Samarasinha, 2019). One small concrete example of this occurred as people arrived at the session. Group members immediately began collaboratively rearranging chairs and tables, with members joining in as they arrived, to honor multiple access needs simultaneously, even if those needs were not shared by those doing the rearranging. They did this because increasing access meant we all had a greater understanding of each other's access needs and were thus all able to honor those needs and engage in deeper work.

We had multiple new attendees and so took care to (re)introduce ourselves and conduct an access check-in. We continued generating ideas and raising issues to address in small groups. We asked for volunteers to lead different small groups and then split into those groups to pursue different topics or projects. The groups were: (a) Disability Justice and teacher education, (b) Disability Justice and Mathematics book proposal, (c) addressing and/or responding to the

"Science of Math" website, including international perspectives, (d) accessibility and ableism within mathematics education research spaces, specifically at professional conferences (This group formalized themselves into the Mathematics Education Conference Access Committee.), and (e) conference grant proposal writing to convene educators and disability-led organizations and coalitions.

Day 3: Updates, Strategizing, and Articulating Next Steps

On our final day we shared updates on our work in relation to the "Science of Math" website and heard from group members who were on the PME-NA steering committee. We discussed ideas to push PME-NA to make its conference hybrid and to examine biases and presumptions regarding different approaches to conference engagement (e.g., virtual v. in-person). We also worked towards establishing how the working group community could continue to make progress throughout the year. We assigned leaders to the logistical and intellectual work we wanted to pursue. Then, we planned to (a) update the group's email listserv, (b) publicize speaking engagements and papers generated by group members, (c) we summarized what we had accomplished during this working group and (d) articulated next steps.

Progress Since PME-NA 45

This group maintains regular communication through an established listserv and has continued to work on several collaborative projects since our last meeting. In July 2023, four members of the working group submitted a paper that analyzed the language used on the "Science of Math" website. Since PME-NA 45, this paper has been rejected, revised, and is currently under review.

In October 2023, following the conference, one group member reported that they and other members of the Mathematics Education Conference Access Committee had engaged in ongoing conversations with PME-NA conference organizers, specifically about increasing conference accessibility via a hybrid option. The group member elicited feedback from the working group about priority accessibility concerns and took those concerns to others in conference decision-making roles. This small group continues to meet and advance our position about increased conference accessibility.

In November 2023, three members of the working group elicited ideas for chapters and art works for a proposal to Teachers College Press' Disability, Equity, & Culture series. The editors anticipate submitting a revised prospectus to the publisher in spring 2024.

Actions to Include Participants

To include as many people as possible, we employed several intentional strategies. First, by offering a hybrid option for our working group we signaled to our colleagues and in-person conference attendees that we prioritized enacting our values of inclusivity and access. Further, when people joined the working group on the second or third days of the conference, we took care to pause the work and properly introduce newcomers and orient them to the ongoing work. Beyond the conference, we maintain two different email groups: a PME-NA working group list and a broader listserv for anyone interested in staying connected to information about mathematics education and disability. This provides community, connection, and a recruitment avenue as our group positions PME-NA as a focal site for folks interested in taking up critical questions about mathematics education and disability.

Questions to Address in the Future

Critical questions that our group will continue to address include:

- What do we mean by "critical disability studies in mathematics education"?
- How, if at all, does "critical disability studies" relate to "critical special education"?
- As mathematics educators, how might we continue to engage folks in other disciplines including special education?
- How could this group promote activism and advocacy within and beyond mathematics education?
- What kinds of conversations about disability and mathematics education are happening in international contexts and how can those inform the work of this group?
- What else is needed with respect to addressing disability and other intersectional identities in mathematics education?
- What is the ethos of this group?
- How can we meaningfully engage and mentor doctoral students within mathematics education and between mathematics education and other fields?
- How can we support novice and experienced researchers to work and learn with disabled students, educators, and scholars?
- What role can this working group play in advocating for and actualizing increased conference accessibility, specifically through organizations with an explicit commitment to equity and inclusivity?

Goals and Effort Toward These Goals

"Taking up space as a disabled person is always revolutionary" (Ho, 2020, p. 115).

As we *Envision the Future of Mathematics Education*, the theme of PME-NA 46, that future necessarily includes the voices, perspectives, and experiences of disabled students (and their families), disabled teachers, disabled activists, and disabled scholars. Yet, disability is persistently omitted from research in mathematics education (Lambert & Tan, 2020). Because mathematics education classrooms and content are often used as tools for marginalization, we draw upon critical theories such as Disability Studies in Education, Critical Race Theory, and Disability Critical Race Studies (DisCrit) to offer a justice-oriented vision of mathematics education. PME-NA 46 would represent the group's sixth meeting; therefore, our goals necessarily encompass the continuation of past work as well as the development of new work:

- Create an inclusive and accessible space that centers disability and topics related to mathematics education;
- Anchor our work in the 10 principles of Disability Justice (Sins Invalid, 2019);
- Generate interdisciplinary and cross-institutional collaborations; and
- Leverage the group's collective wisdom to (re)imagine solutions to persistent problems.

Our strategies to meet these goals include:

- Provide a hybrid option for the working group;
- Unpack the 10 principles of Disability Justice (Sins Invalid, 2019);
- Design spaces that prioritize focused, small-group work; and
- Identify small-group leaders who are equipped to facilitate the cross-pollination of ideas.

Beyond this meeting, we anticipate proposing future PME-NA working groups to ensure the sustainability of this community and the work that this community generates.

Theoretical Background

We theorize ableism through Disability Studies in Education (Connor et al., 2008). We seek to disrupt ideologies of "ability" and "normal" (e.g., Annamma et al., 2013; Siebers, 2008) to study the pervasiveness of ableism in education. We apply scholarship on ableism to investigate how this operates in mathematics education (Dolmage, 2017; Price, 2021; Westby, 2021). We draw on the Disability Justice framework, which was developed by disabled queer activists and disabled people of color (Sins Invalid, 2019). We specifically draw upon the 10 principles for disability justice created by Patty Berne and others from Sins Invalid (Sins Invalid, 2019): intersectionality, leadership of the most impacted, anti-capitalist politics, cross-movement solidarity, recognizing wholeness, sustainability, cross-disability solidarity, interdependence, collective access, and collective liberation. Given the harm done to disabled communities, Disability Justice allows researchers to recognize the intersecting legacies of white supremacy, colonial capitalism, gender oppression, and ableism to understand how people are labeled "deviant", "unproductive" and/or "invalid" (Sins Invalid, 2019). Acknowledging that disabled students and communities of color have gifts (Annamma & Morrison, 2018), such as unique mathematical ideas, perspectives, and solutions, challenges the deficit narrative and structures of ableism (Lewis & Lynn, 2018; Yeh, 2023).

Plan for Active Engagement and Working Group Organization

In specific response to the growing size and diversity of our working group members, we have designed a three-session sequence that is both structured and flexible. Group members will have choice in how and with which topics they engage. Small-groups will have the autonomy to define what "meaningful outcomes" mean for small-group members and a timeline by which those outcomes will be achieved; these strategies are designed to promote engagement.

Session 1: Community, Connections, and Co-Designing

Most of this session will be to introduce and orient people to the working group. We will start with introductions and access needs (20min), followed by an update about the group's accomplishments, sharing the goals of the group, and introducing the principles of Disability Justice (30min). We will introduce small-group topics and their leaders and identify any additional small groups that may arise (10min). Small-group topics include, but are not limited to: (1) teacher education (ongoing from 2023); (2) intersectional identities, specifically LGBTQIA+; (3) interdisciplinary work with special education and addressing the "Science of Math" website (ongoing from 2022); (4) advocacy / activism; (5) conference accessibility (ongoing from 2022); (6) international contexts; (7) conference proposal development (e.g., Mathematics Education and Society; ongoing from 2023); (8) theoretical dives into Disability Justice, DisCrit, and Critical Disability Studies; and (9) articulating the working group's ethos. This session will conclude with small-group meetings (30min).

Session 2: Generating and Planning

Most of this session will be working in small groups. We will (re)introduce people and share access needs (15min). We will transition into the small groups identified in Session 1 (55min). We will conclude by coming back to the whole group and sharing out (20min).

Session 3: Articulating Next Steps

Most of this session will be working in small groups. We will begin in small groups (60min). We will come back to the whole group and share out (20min). Finally, we will wrap-up the working group by articulating a plan for ongoing communication and support beyond the conference (10min).

This new working group seeks to produce innovative ways to support the implementation of and research about 'Building Thinking Classrooms' at the university and K-12 levels.

Keywords: Professional Development, Preservice Teacher Education, Classroom Discourse.

Introduction

Since it was first introduced to the mathematics education community, *Building Thinking Classrooms* (BTC) (Liljedahl, 2021) continues to grow in relevance among teachers and teacher educators across North America. We see this growth in regional conferences, professional learning programs, and learning communities across social media platforms. The relevance of this initiative has grown so much that the first annual International Building Thinking Classrooms Conference was held in Indianapolis in 2023.While BTC is a research-based initiative, the resources for teachers are mainly limited to the book and online forums for sharing ideas. For teachers to successfully implement, critique, and supplement these practices, guidance is needed to support their work. Our goal as mathematics teachers and mathematics teacher educators is to study how the practices and their implementation are supporting effective teaching and learning. Our aim is to support teachers to draw on the practices, along with other research-based initiatives that align with increasing student thinking in the classroom, as they make professional decisions in their classroom.

The authors of this working group have engaged in various initiatives centered around BTC. One author has created an Instructional Circle (Author, 2022) to provide personalized and deprivatized feedback to teachers as they implement BTC. There are three stages to implementation of BTC that become more difficult to implement in a classroom (Liljedahl, 2016). The instructional circle is a form of professional learning where teachers can find support from experienced teachers and knowledgeable others about ways they can improve their instructional practices. Another author developed an initiative with a local school district to provide instruction and materials for teachers wanting to implement BTC but lacking the support or materials to be successful. Lastly, one Author's team is engaging in an initiative looking at specific aspects of BTC including task writing and “thin slicing” and how teachers are utilizing them in their implementation of BTC (Frazee & Scharfenberger, 2023).

As mathematics teachers and mathematics teacher educators we feel it is worthwhile to support the implementation of BTCs in a variety of contexts. This instructional practice supports ambitious teaching as defined in *Principles to Actions: Ensuring Mathematical Success for All* (NCTM, 2014). The creators of BTC also understand professional learning principles that state incremental changes to teacher practices are more sustainable long-term than sudden transformational professional developments (Otten et al., 2022).

Goals of the Working Group

The goals of this working group are two-fold. First, we want to serve as a forum for authors and participants to share a variety of research projects centered around *Building Thinking Classrooms* (Liljedahl, 2021). This will inform the conversations about how to create a more effective implementation and support structure for teachers using this instructional practice in both K-12 and university levels. Second, instructional circles (Melville, 2022) will be created for the participants of the working group to form professional learning communities for support around their specific interest with BTC beyond this conference. Specifically, these contexts may include using BTC in math content courses, math methods courses, in-service professional learning, and ways in which research projects can be designed to study various aspects of these settings. We believe that these instructional circles will be a valuable resource as we implement and study the effects of BTC on student learning and teacher education and the growth of mathematics teacher educators.

We expect this working group to continue for multiple years; however, this initial setting will be for the introduction of BTC to some, and reports of what the authors and participants are currently doing. For future iterations of this working group, we hope to develop more concise ideas about the needs, struggles, and benefits of implementing BTC in content courses, method courses, and other professional learning settings.

Organization and Presentation Plan

The first session will start with presentations from the authors about what they are currently doing regarding coaching, implementing, and teaching BTC in methods courses and professional learning contexts. The authors alone have a variety of initiatives around BTC. One example is that BTC is being studied as a vehicle for task assessment and professional learning of teachers around planning (Frazee & Scharfenberger, 2023). has created an Instructional Circle (Melville, 2022) to provide personalized and deprivatized feedback to teachers as they implement BTC. The last initiative studies how BTC is being used in a more traditional professional learning course for teachers who are or would like to implement these instructional strategies.

The second session will include reports from non-author participants about their current initiatives that utilize BTC or that could benefit from using BTC. These participants will volunteer during the first session for this activity. The second session will end with forming break out groups according to participants’ interest in utilizing BTC (i.e., math content classrooms, math methods classrooms, professional learning settings, or researching the effects of BTC in these other contexts).

The third session will continue the breakout groups for the different contexts that participants are interested in utilizing BTC. During these breakout sessions, we plan to help organize the participants into instructional circles to provide support and fresh ideas to implement or study BTC in different settings. This session will also include each group sharing their current ideas and goals with the whole group.

The Embodied Mathematical Imagination and Cognition (EMIC) Research Colloquium offers hands-on activities; technological, curricular, and pedagogical demonstrations; and open spaces for exploration and discussion regarding the embodied nature of mathematics education. We use the PME-NA 46 conference theme "Envisioning the Future of Mathematics Education in Uncertain Times" to invite the community to experience perspectives across multiple institutions and expand notions of mathematical activity, effective teaching, learning, assessment, and learning technology design. We focus on current uses, future prospects, and challenges of virtual and augmented reality (VR/AR) to foster inclusive and effective educational experiences.

Keywords: Cognition; Learning Theory; Teaching; Social Justice; Systemic Change; Technology

Theoretical Background

Virtual and augmented reality (VR/AR) serve an increasingly central role in mathematics education and teacher training (Bock & Dimmel, 2021). As with any such advancement, the research community must contribute to this process of technology transfer and translation based on rigorous methodology and sound theoretically-principled designs for curriculum, instruction, and assessment. However, few studies in AR/VR are informed by a clear theoretical framework (Mikropoulos & Natsis, 2011). VR/AR offers learners unprecedented access to mathematical objects and tools through sensorimotor and collaborative processes that may generate new forms of mathematical inscriptions, even entirely new branches of mathematics (Nathan, 2024). EMIC contributes a compelling framework for the empirical study of embodied interactions (collaborative gesture; multimodal analytics) using VR/AR, the design of future platforms and activities (affordances and constraints), and formative and summative assessments of nonverbal ways of knowing (Abrahamson, 2014; Alibali & Nathan, 2012; Arzarello et al., 2009; De Freitas & Sinclair, 2014; Edwards et al., 2014; Radford, 2009; Walkington et al., 2021) that address the *whole learner*, facilitate the development of diverse learners, and foster inclusive and effective educational experiences (McKinney de Royston, et al., 2020).

A Brief History and Motivation of the EMIC Working Group

The EMIC working group officially started in East Lansing, MI during PME-NA 2015. We have convened annually at PME-NA ever since, organizing events that investigate the embodied nature of mathematics through physical and digital games, arts and crafts, individual and collaborative dance and movement, language, perception, immersive experiences, and more. EMIC members continue to explore new technologies (e.g., Harrison et al., 2018; Walkington et al., 2021) and research methods (e.g., Abrahamson et al., 2021; Closser et al., 2021) that acknowledge and leverage the inherently embodied nature of mathematical cognition. They go beyond scholarly publications and presentations to offer: novel embodied technologies, including some that have gone to scale for classroom use, special education, and emerging bilinguals; teacher learning for instructional uses of gestures; and webinars for teachers and parents. In addition to the authors, the organizers/institutions will include Dr. Teruni Lamberg (UNR), David Kirkland (Clark County School District), and Dr. Candace Walkington (SMU).

VR/AR: Envisioning the Future of Mathematics Education in Uncertain Times

VR/AR technology is rapidly altering the landscape of mathematics education and STEM professional work through immersion and direct, body-based interactions with (holographic) mathematical objects. In 2024, we will organize hands-on activities and group discussions around the proliferation of VR/AR technologies in classroom instruction and research. On **Day 1**, we will do introductions and then give an overview of grounded and embodied mathematical thinking and teaching. We will then talk about published findings on the educational value of VR/AR technology for supporting math learning and teaching and its connection with embodied learning (e.g., Garzón et al., 2020). We will invite participants to engage and observe the use of an example VR system for teaching about powers of ten. We will explain why students often struggle to understand orders of magnitude and reason about very small and very large numbers in domains such as nanotechnology, and demonstrate how VR provides perceptual experiences that can improve their mathematical reasoning. Day 1 will conclude with an open-ended Q&A on the nature of embodiment theory and embodied design principles for VR/AR.

On **Day 2**, organizers will facilitate exploring EMIC accounts of VR/AR in collaborative, embodied math activities. We address research methods for analyzing collaborative embodiment in immersive learning environments and some of the benefits and challenges for implementing these interventions in authentic learning contexts. We will then break into small design groups where participants consider ways VR/AR could be used to explore other topics in mathematics education, and ways of supporting diverse learners with varying physical abilities and linguistic and cultural experiences. We will report these ideas to the whole group, theorizing about the nature of learning in ways that inform research and the design of valid knowledge assessments for a broad range of learners and math topics, which will be chronicled in a shared document.

Day 3 will start with reflections on the design ideas and learning principles generated during Days 1 & 2. We explore ways that VR/AR enables novel forms of mathematical activity by directly interacting with and transforming geometric objects using body movements and perceptual processes. We then consider how VR/AR can support expanded notions of mathematical representations, such as inscribing operations through person- and group-centered actions and perceptions, in contrast with disembodied, formalism-centered, symbolic notations and diagrams. We plan to have a facilitated discussion on why embodiment offers a unique set of theoretical and methodological resources for designing meaningful learning experiences.

Conclusions and Looking Ahead

Embodied learning theory and design principles provide key insights into how perceptually concrete, bodily experiences and collaboration in VR/AR can engage learners across a wide range of topics and grade levels. Movement- and perception-based mathematical activities can reach students who may otherwise feel left out of highly discursive and symbol-based activities. Through EMIC, we aim to foster an engaged community committed to transformative education.

100-word description

VR/AR technology is rapidly altering the landscape of math education and STEM professional work. Embodied approaches to mathematics learning, instruction, design, and assessment offer natural inroads for understanding the challenges and benefits of using VR/AR to engage all learners. Since 2015, the Embodied Mathematical Imagination and Cognition (EMIC) Research Colloquium has organized hands-on, collaborative, and generative activities for experiencing the contributions that embodied mathematics has to offer. During this 3-part research colloquium, participants are invited to experience, reflect on, and design activities for immersive learning experiences using VR/AR across a range of topics to suit all learners across learning settings.

MATHEMATICS CURRICULUM RECOMMENDATIONS FOR ELEMENTARY TEACHER PREPARATION WORKING GROUP: RESEARCH IN PROGRESS

In our third year of meeting at PME-NA, we brainstormed and solidified plans for conducting research studies that would support our future recommendations for how to prepare future elementary teachers to teach mathematics. Our goals for this year are to continue to support such research conducted by working group members, adding new members and studies as appropriate, and to prepare to synthesize and disseminate our research findings.

Keywords: Preservice Teacher Education, Teacher Educators, Mathematical Knowledge for Teaching, Elementary School Education

Elementary teacher preparation in North America is vitally important to ensure a robust mathematics education for elementary students. However, preparation programs for elementary teachers contain large variations in terms of what, how, and how much is taught. Various organizations (e.g., AMTE, 2017; CBMS, 2012; NCEE, 2016) have made recommendations about teacher preparation including the number of credit hours that prospective teachers (PTs) should take as well as what content should be taught, and what types of experiences PTs should have. However, research (e.g., Garner et al., 2023; Masingila et al., 2012) has shown that the majority of teacher preparation programs are not meeting these recommendations. In many programs, it seems that the current recommendations are not feasible, given the other requirements for preparing PTs. The purpose of this working group is to create a set of research-based, specific recommendations for elementary teacher preparation that can be feasibly implemented by teacher education programs. We will do this by providing research-based evidence to stakeholders to show that our claims for the amount of instruction time and specific topics and instructional practices are needed to prepare PTs for their future jobs.

Progress of Current Work

According to Garner et al. (2023), the overwhelming majority of elementary teacher preparation programs in the United States fall short of the number of credit hours in elementary mathematics content and methods recommended by the *Standards for Preparing Teachers of Mathematics* (AMTE, 2017). More specific research-based recommendations of what topics to teach, how much time to spend on each topic, and what pedagogical strategies are effective in teaching these topics will help programs advocate for change at their institutions. Corven et al. (2022) indicate that elementary prospective teachers require 6-8 hours of instructional time to acquire lasting and deep specialized content knowledge (Ball et al., 2008) for key mathematics topics from the elementary curriculum. Whereas Corven et al. (2022) claim this finding underscores the need to limit the number of topics taught in elementary teacher preparation (cf. Walsh et al., 2022), this result further supports the conclusion of Garner et al. (2023) that programs with fewer credit hours than AMTE's (2017) recommendations may not be serving future elementary teachers well. Our working group continues to conduct research that will be useful in providing more specific recommendations for elementary teacher preparation programs.

Organization and Presentation Plan

This will be the fourth year that this working group has met at PME-NA. We have already created a number of subgroups that are undertaking research projects as detailed in our report. At PME-NA 46, we plan to have each research subgroup present their current research plans and research studies in progress during the first two sessions, with time allocated in the first session to orient new members to the working group. After each presentation, the audience will have an opportunity to ask general questions and give feedback. Each day, after the presentations, the subgroups that presented will meet to discuss the feedback and revise their research plans. Members of the working group who are not members of any of the subgroups that presented that day will be asked to serve as "outside reviewers" to a subgroup of their choice to provide additional specific feedback on research plans. This structure will allow new members of the working group time to figure out which subgroup(s) they want to join and be able to contribute meaningfully to subgroup work right away. Additionally, this structure will permit members who are part of two subgroups to meet with both subgroups during the conference.

During the third session, all subgroups will meet for the first part of the session to discuss the concrete next steps for their research plans. We will provide a calendar template to subgroups to help with this planning. In the second half of the third session, we will give each subgroup five minutes to present their plan to the whole group. We will ask subgroups to talk specifically about the potential results they might present at a PME-NA Colloquium in 2025.

Opportunities for New Members to Contribute and Future Plans

New members of the working group should select one or two research subgroups that interest them. They will have opportunities to join these subgroups and contribute meaningfully to the in-progress research plans as a collaborator. We encourage anyone interested in joining the working group to reach out to a subgroup leader before the conference (contact information for the subgroup leaders is in our report) to get added to the email notifications list.

We expect the working group to transition to a Colloquium for PME-NA 47 (2025) to allow the subgroups to present research results. We also encourage researchers who are not members of the working group but who have conducted research related to one of the subgroups to reach out for inclusion in the Colloquium. After the Colloquium, we intend to organize a special issue of a journal or a book to disseminate the results of the working group. We expect to have an introductory article, one article for each subgroup that summarizes and synthesizes their work, and a concluding article that contains policy recommendations and implications of each article. After the journal/book is published, we intend to hold a conference to discuss and debate a draft of the curricular recommendations.

Gender and sexuality research in mathematics education remains a significant focal point for discussions among researchers, educators, and students. During the 2023 Annual Meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education (PME-NA), the working group met to explore our journeys as gender and sexuality researchers, the challenges and supports encountered throughout our endeavors, and the stories told through our research. In this report, we discuss the key activities conducted during the working group sessions at PME-NA 2023, including a presentation about a recent literature in gender and sexuality, as well as two focus group discussions. Furthermore, we delve into how the discussions held during the 2023 working group sessions propelled us toward embracing intersectionality as a central focus for the 2024 working group initiatives.

Keywords: Gender; LGBTQIA+; Equity, Inclusion, and Diversity; Social Justice

History of the Working Group

The Gender and Sexuality Working Group originated from discussions on equity in mathematics education at PME-NA 2017 in Indianapolis and first convened at PME-NA 2018 in Greenville. Since its inception, the working group has met annually at PME-NA to facilitate crucial discussions on gender and sexuality in mathematics education. At these gatherings, we have focused on various research approaches, including theory and data (Przybyla-Kuchek et al., 2022), conceptual and methodological frameworks (Jackson et al., 2021), and data collection (Ataide Pinheiro et al., 2023). The group has been a welcoming and supportive venue for early-career faculty and graduate students, and has provided opportunities for them to share their research, assume leadership roles, and engage with researchers from institutions across the United States, Canada, Brazil, and Australia.

A significant aspect of the working group has been its efforts to broaden participants' perspectives on gender and sexuality research in mathematics education and to support individuals in developing and advancing their work for publication. For instance, the group was pivotal in supporting contributions to the special issue on gender and sexuality in *Mathematics Education Research Journal*, co-edited by Jennifer Hall and Eva Norén (2021). Notably, during PME-NA 2021, the working group organized discussions featuring authors of articles from this special issue, providing a platform for in-depth exploration and debate, facilitated by a designated discussant (Jackson et al., 2021). The Gender and Sexuality Working Group continues to serve as a vital forum for advancing research, fostering collaboration, and promoting inclusivity within gender and sexuality research in mathematics education.

2023 Working Group Sessions and Efforts Made to Include Participants

After several years of engaging in crucial discussions on theory and methodologies in gender and sexuality research, the 2023 Gender and Sexuality Working Group shifted its focus towards exploring the personal narratives and motivations that shape us as gender and sexuality researchers. Specifically, we sought to understand the life stories of researchers in this field, including what led them to develop an interest in this research topic, their experiences navigating research across various academic venues (e.g., faculties of education, departments of mathematics), and how these lived experiences may or may not have influenced their research agendas and the stories that they have told through their research. This exploration encompassed the challenges encountered and the support received in conducting gender and sexuality research.

Next, we provide a detailed overview of the activities that transpired during the PME-NA 2023 Gender and Sexuality Working Group sessions.

Day 1

We began the working group session on Day 1 with introductions of attendees and an open discussion to learn about the types of research that attendees were interested in pursuing in connection to gender and sexuality in mathematics education. After these introductions, we outlined the plans for the working group sessions.

On Day 1, we also had the opportunity to delve deeper into a literature review prepared and presented by one of our 2023 leadership team members, Ana Dias of Central Michigan University. Ana systematically reviewed research methods utilized in previous research articles focusing on gender, sexuality, and mathematics education from 2020 to 2024, using the databases Google Scholar, EBSCO, ERIC, Web of Science, and ProQuest. In her review, Ana drew upon and expanded the dates covered in the review done by Becker and Hall (2023). English, French, Spanish, and Portuguese were the languages used in the review. For this systematic literature review, the types of work that were excluded were thesis and dissertations, conference proceedings, books, opinion pieces, theoretical papers, and reports on lessons and activities; studies in which STEM was treated as a whole (as opposed to those that had separate data about mathematics students, preservice teachers, or in-service teachers); and research articles in which gender or sexuality were used as a variable (as opposed to as a category of analysis). After the exclusion criteria were applied, 31 articles remained for review. Only four studies involved quantitative methodologies (Copur-Gencturk et al., 2021; Teague Tsopgny et al., 2020; Voigt, 2022; Wolff, 2021). The rest were qualitative studies.

Methods used in the qualitative studies were discourse analysis, content analysis, and interviews with drawing solicitation (Gjøvik et al., 2022; Guichot-Reina & De la Torre-Sierra, 2023; Lafay, 2022; Neto & Ataide Pinheiro, 2021); interaction analysis for analyzing video data (Kolovou et al., 2023); semi-structured interviews and coding (Jaremus, 2021; Jaremus et al., 2020); task analysis (Rubel et al., 2022), interventional studies (de Souza Ortolan et al., 2020; Soares et al., 2023); a combination of interviews, focus groups, photo solicitation, and discussion (Hall & Robinson, 2020); narrative inquiry and grounded theory (Kersey & Voigt, 2021); longitudinal mixed methods and national surveys (Barbosa et al., 2021; Hsieh et al., 2021); document analysis and ideology critique (Martins et al., 2021); questionnaires analyzed qualitatively (Guse et al., 2020); feminist post-structural discourse analysis (Przybyla-Kuchek, 2021); doctrinal methodology (Sharma, 2021); and comparative methodologies (Sharma, 2021; Jao et al., 2023). Some of the perspectives from which the studies were conducted were post-structural feminism (Jaremus, 2021; Jaremus et al., 2020; Przybyla-Kuchek, 2021), and decolonization (Barbosa et al., 2021; Soares et al., 2023). This introductory discussion laid the groundwork for subsequent conversations during Days 2 and 3 of the Working Group.

Day 2

Day 2 discussions were focused on stories of how the working group participants became gender and sexuality researchers, and what led us to be interested in researching gender and sexuality in mathematics education. We also discussed the challenges and supports that we have encountered and continue to encounter as gender and sexuality researchers. In our discussions, we aimed to support graduate students and early-career faculty embarking on research in gender and sexuality who may benefit from learning about and learning from obstacles that we have faced, and that they may themselves face. Furthermore, such discussions are beneficial for all scholars as we shared knowledge, skills, and resources that are useful for successfully navigating conducting research in this field.

The discussions on Day 2 were organized as focus group discussions. Therefore, we divided the leadership team and the participants into two groups. The questions discussed on this day by both leadership team members and participants included, but were not limited to:

(a) How did you become interested in gender and sexuality research?
(b) What challenges have you faced while doing gender and sexuality research?
(c) What supports have you encountered while doing gender and sexuality research?
(d) Is there anything else you would like to share about your story?

Some of the themes that arose during these focus group discussions included challenges of conducting this kind of research, including having our voices not be heard in university departments, difficulty obtaining IRB approval, and differences in norms between countries.

Day 3

On the last day of the working group sessions, we engaged participants in focus groups in a similar manner to the ones that we employed on Day 2. The specific discussion questions we used to guide the discussion on Day 3 were:

(a) What stories have you told through your gender and sexuality research? (For those who haven’t had the chance to conduct research in this area yet, what would you like to know before engaging in gender and sexuality research?)
(b) How have your years of experience affected the stories that you have told through gender and sexuality research?
(c) What ways do you envision this working group moving forward as a space to engage in discussions of gender and sexuality in mathematics education?

Some of the topics that emerged from this focus group discussion were the need for better pre-service teacher education regarding these topics, the challenges of teasing out intersectional identities (especially hidden ones), the need to move beyond binaries and normativities, and the increased expectation of researchers sharing their identities with research participants and in publications.

We concluded Day 3 by consolidating our plans for future research discussions using a Jamboard, as shown in Figure 1. During the conversation that followed, we noted that many of the topics suggested on the Jamboard pertained to intersectionality and thus determined that for the 2024 working group sessions, we would focus on a theme related to intersectional identities.

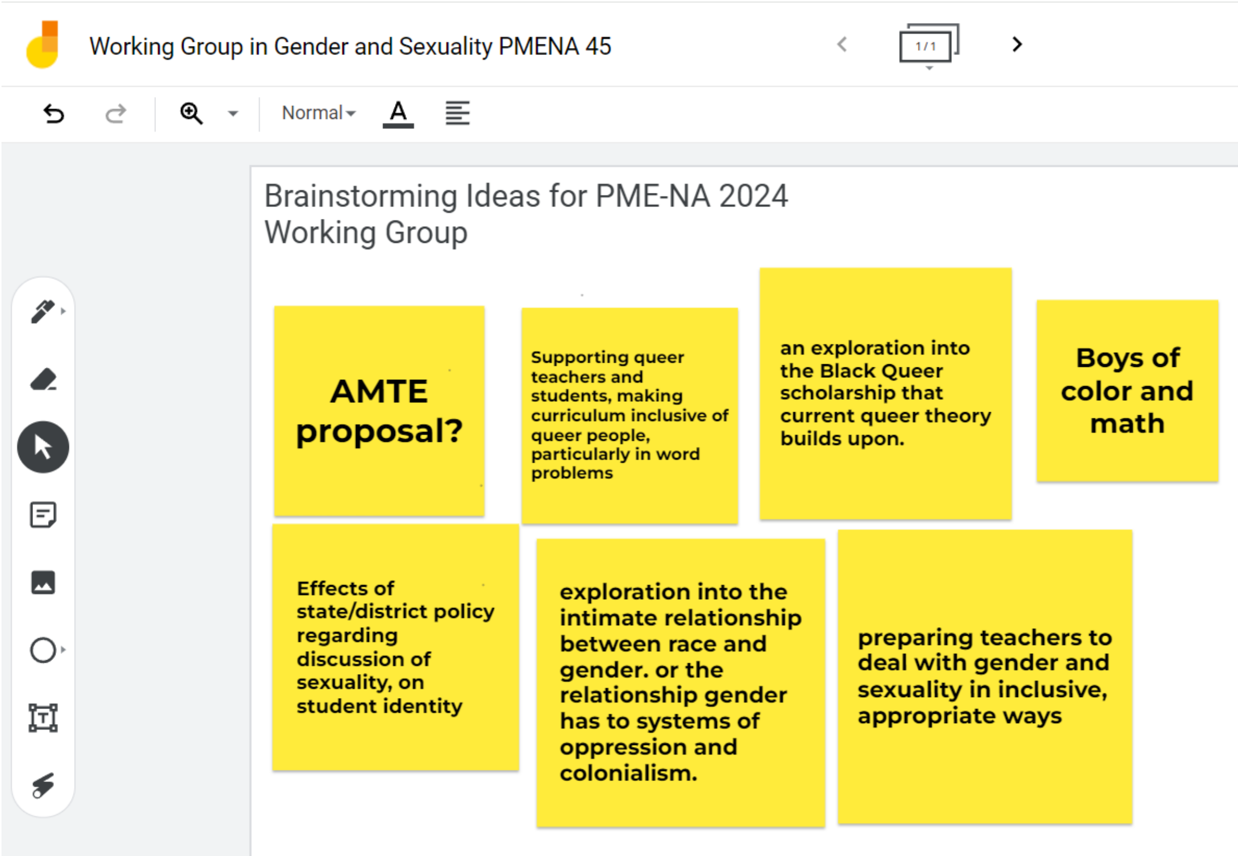

Figure 1: Jamboard Used by Participants During the Day 3 Session

Progress Made From the 2023 Conference to the 2024 Conference

As discussed, the initial design of the PME-NA 2023 Working Group on Gender and Sexuality involved building a repository of why and how individuals become gender and sexuality researchers, the challenges and supports that they have encountered when conducting research in this field, and the stories they have conveyed through their research. We are planning to follow up from the focus of the 2023 working group sessions and investigate possible outlets in which our stories could be shared more publicly (e.g., a special issue of a journal). We are eager to better understand: What motivates scholars to become gender and sexuality researchers? What challenges and supports do gender and sexuality researchers experience along the way? What stories have gender and sexuality researchers told through their research? How do their lived experiences affect the research questions that they choose to pose?

Questions to Address in the Future

As mentioned, one area of interest raised by participants of the 2023 working group was the topic of intersectional identities. Specifically, participants discussed how the multitude of individuals' social identities, in addition to gender and sexuality, could be used to control, oppress, and exclude individuals from mathematics education. Therefore, discussing gender and sexuality without considering race, socioeconomic status, disability, and other identities makes it difficult to have a more holistic discussion about how gender and sexuality impact the teaching and learning of mathematics. Participants demonstrated an interest in further discussions by the working group that bring to the forefront the intersections of race, gender, and sexuality, as well as socioeconomic status, disability, and other identity factors that may be less 'visible' than gender or race. Participants also raised questions regarding (a) the effects of national/state/district policy on discussions of sexuality on student identity, (b) supporting queer teachers and students by making the curriculum inclusive of queer people, and (c) preparing teachers to address gender and sexuality in inclusive, appropriate ways. These questions may be considered and explored in working group sessions at future PME-NA conferences.

Students' aesthetic and affective responses are intertwined and are both central to mathematics learning. This working group will continue the conversation begun in 2022 to investigate the connection between the affective and aesthetic dimensions of mathematics education, and how connecting these dimensions can help us to better understand students' experience with mathematics. The goals of this third meeting of the working group are to explore useful tools and methodologies for studying aesthetics and affect, as related to participants' sharing their research interests.

Keywords: Affect, Emotion, Beliefs, and Attitudes; Curriculum; Instructional Activities and Practices.

Theoretical Background

The relationships between aesthetics and affect (beliefs, engagement, motivation, etc.) for their centrality in understanding students' mathematical experiences and learning is clear (e.g., Cheeseman & Mornane, 2014; DeBellis & Goldin, 2006; Malmivuori, 2001). The purpose of this working group, from Riling et al. (2023), is to investigate "the potential enabled by identifying the shared interests in aesthetics and affect. Our aim is to enable new solutions to a persistent problem [poor student experience in mathematics] that can become possible by bringing together these two domains" (p. 596).

We describe the theoretical foundations for our working group, from our first proposal (Satyam et al., 2022): *Affect* has been defined as all aspects of experience that involve feeling (McLeod, 1988). This ranges from deeply held, long duration constructs such as beliefs, attitudes, math anxiety, and motivation, to shorter-term and in-the-moment feelings such as emotions and engagement (Grootenboer & Marshman, 2016; McLeod, 1992; Middleton et al., 2017). In mathematics, where success versus failure is often visible, students' affective responses can be quite strong (Boaler, 2015) and impactful (Grootenboer & Marshman, 2016; Op 't Eynde et al., 2006).

Yet, similar to how we would also examine a piece of art for explanations for an individual's gasp in a museum, we argue that researchers also need to attend to the nature of the mathematical experience for explanations of how it potentially impacted students (e.g., inspiring a question, enabling predictions and eliciting surprise). We refer to the way a lesson supports the felt impulses that compel (or impede) a student to continue to progress (or not) through an experience as its *aesthetic dimensions* (Dietiker, 2015). Some researchers have recently begun to study the aesthetic potential of mathematical learning environments (e.g., Dietiker, 2016; Sinclair, 2001), learning for example how the design of technological tools can offer surprise and appeal (Sinclair et al., 2009). While still emerging, the field is learning how to design and enact what Sinclair (2001) calls “aesthetically-rich” mathematical experiences, which she describes as those that “enable children to wonder, to notice, to imagine alternatives, to appreciate contingencies and to experience pleasure and pride” (p. 26).

This working group will continue to explore the linkage between affect and aesthetic to tackle multiple dimensions of one of the most significant dilemmas facing mathematics classroom practice today: poor student experiences with mathematics that fuel negative student dispositions. Through our working group design, we plan to bring together graduate students, early career and senior faculty together, to solidify the current state of the field and help form informal and formal connections for future research endeavors.

History of Working Group at PME-NA 2023

The goals of the second meeting of this working group were to bring researchers together to build community through structured but also informal activities, learn about each other’s work through participants sharing, and explore potential writing projects. We met over three days and a mixture of university faculty and graduate students attended.

Day 1: Task as Anchoring Experience

We began with an overview of aesthetics and affect, the purpose of our working group, and a recap of what occurred at the previous (first) meeting of the working group. This was important as we had some returning participants and some new participants joining. We then all engaged in an online task, Parable of the Polygons, as a shared experience through which participants could then have grounded reflection and discussion about their aesthetic and affective reactions. This was successful in new and returning members meeting each other, equalizing their contributions, yet bringing them together on the same page. Participants discussed which aspects of the activity most “drew them in” to explore more and how that related to the aesthetic and affective aspects of their experiences.

The session ended with us collecting their information: research interests, population of interest (students or teachers, grade band, etc.) and what they would like from the working group. We also provided a sign-up for participants to share their work with the whole group the next day.

Day 2: Participants Share Work

On Day 2, we facilitated extended introductions, in which participants shared their research and/or teaching interests that fell under the umbrella of aesthetics and/or affect. We intentionally planned for this to occur after our participants had an experience together first (the previous day), so that participants would have shared language and experiences when learning about each other’s work and interests. The main activity of this session was for participants to share their work for 5-10 minutes. There were seven presenters (including the organizers):

Brady Tyburski: Undergraduate STEM students’ art and artist statements
Megan Selbach-Allen: Caring instruction
Matt Melville: Teacher reactions to deprivitization of practice
Tracy Dobie: Student perceptions of math usefulness
Sandra Hall: Frameworks of aesthetic and affective domains
Leslie Dietiker: Mathematically Captivating Lesson Experiences
Meghan Riling: Types of aesthetic experiences and creativity

Participants shared digital copies of their posters from the current PME-NA and other conferences, as well as artifacts from their research (see Figure 1).

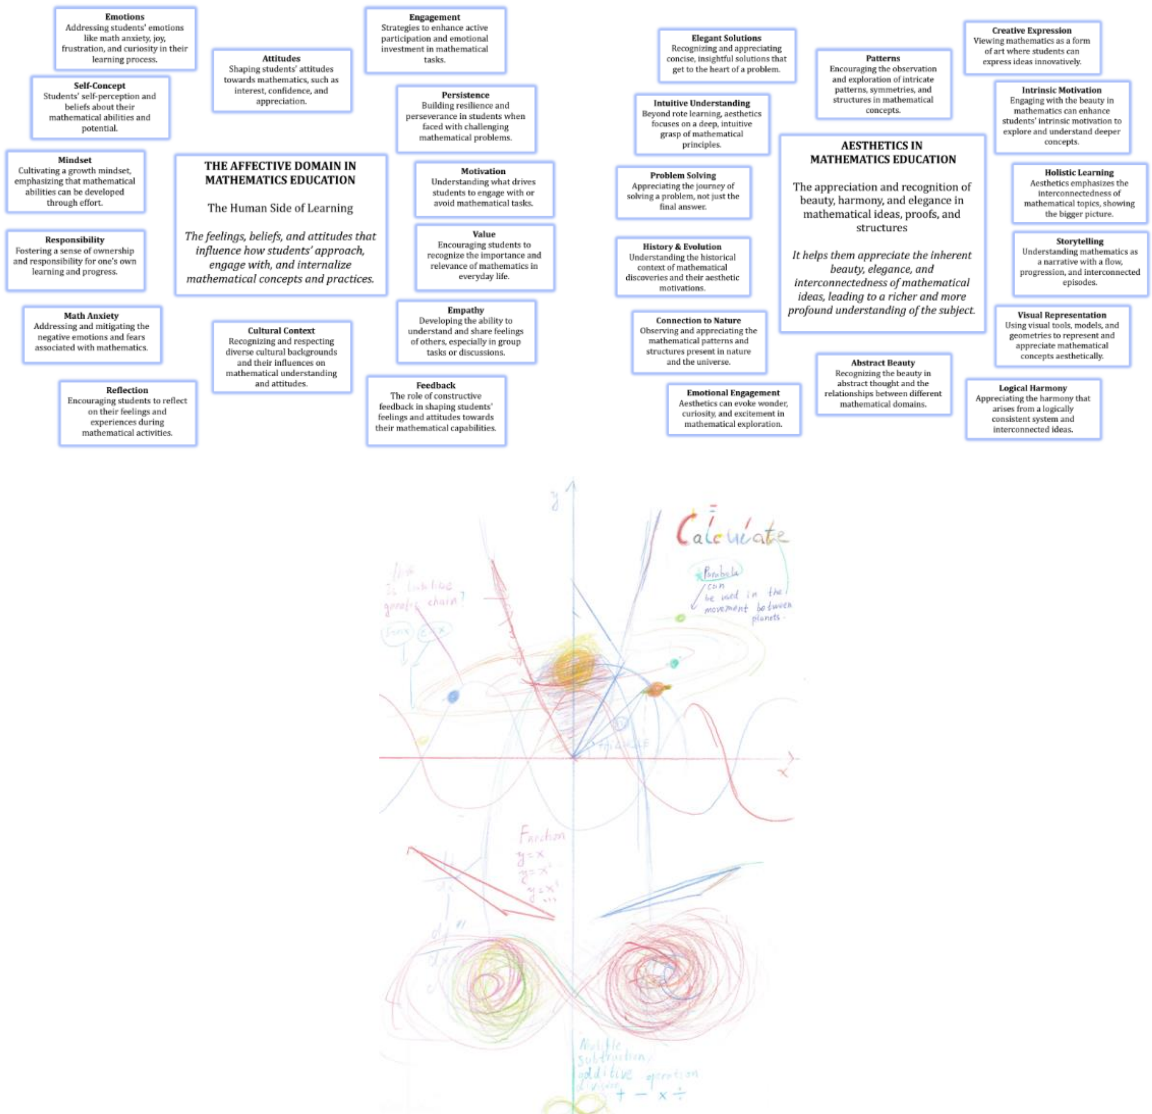

Figure 1. Samples of participants sharing conceptual diagrams and student work. Above: Sandra Hall. Below: Brady Tyburski

At the end, participants reflected with a partner on what they found interesting across the presentations. This served as a wrap-up for Day 2 and as preparation for Day 3.

Day 3: Comparing and Contrasting Conceptualizations

On day three, we worked to bring the group together and set directions for future research collaboration. We finished presentations from Day 2. Then, we did a video analysis: we together watched a classroom video from a 9th grade geometry classroom about midpoint quadrilaterals and posed the following questions. *How can you describe the aesthetic elements of the* *interaction? How can you describe the affective elements of the interaction?* Participants were given a transcript of the video and in groups, recorded their observations and preliminary analysis electronically in google docs. Participants noted constructs such as engagement, affective reactions, relations to Dewian aesthetic, and the overall benefits for how aesthetic and affective aspects created a space in which students could share ideas. The group also pondered the relationships between affect and aesthetic. For example: "Affective as part of the aesthetic - if aesthetic is felt reaction to a stimulus, then the affect is just the felt part. Aesthetic tries to tell the story of what happened and how student felt. Affect zeroes in on the student feelings."

The video analysis served as an example of future work together and a segue into an open discussion about next steps. We provided participants these prompts:

Opportunities for Collaboration: What ideas or projects might you want to work on with a colleague? (Casual/informal)
Group Interaction: What kinds of communication would you be interested in receiving from the group between now and next year?
Connections: What other constructs are you most interested in connecting to aesthetics/affect, and how do you currently see them as being connected?
Questions: What questions related to aesthetics or affect are you wondering about now?
Anything Else: Is there anything else you'd like to share with any of us?

We also shared an outline for a theoretical paper Dr. Dietiker had started, about aesthetics and affect, including possible journal venue and potential inclusion of video analyses.

Next Steps for PME-NA 2024: Session Organization

The goal of this third iteration of the working group will be on exploring useful tools and methodologies for aesthetics and/or affect, by way of participants sharing and talking about their own research and identifying resources to explore together. Given the success of the prior meetings, we will follow a similar structure as before. In particular, we have found that doing a task together on Day 1 to provide a collective, grounded experience provides a solid foundation that is memorable and useful.

Prior to the working group start, we will send out an interest survey for participants' research and/or teaching interests, population, and if they'd be interested in sharing any of their work (published work, data, instruments, etc.).

Day 1: We will start by having participants introduce themselves, share their research and/or teaching interests and experience in aesthetics and affect so far (15 min). We will all engage in an anchoring mathematical activity from an existing research study, aimed toward producing affective and aesthetic reaction (30 min). This will elicit informal conversation among participants, returning and new, centered around a task and focus. We will pair this experience with some research data, such as video, that we will all watch together (30 min). This picks up where Day 3 of our last working group left off: selecting a task from a study and engaging with its data. We'll end with an overview of the goals of this working group and will offer opportunities for participants to share a piece of their work for the next session on Day 2 (15 min).

Day 2: We will provide a short recap of Day 1 for any new participants (10 min). The main activity will be for a few participants who are currently working in the domains of aesthetics and/or affect to share their research. To elicit conversation and interaction, we will split the entire working group into 2-3 groups, so people can both share research within the group (20 min) and pick something else to explore together as a subgroup (40 min). Topics for further exploration may be other constructs, methodologies, or instruments related to the research shared, if applicable. We will then share out collectively what each group discussed and pursued (20 min), as a record of the working group's thinking.

Day 3: We will provide time and space for participants to discuss next steps. Options include: writing short pieces for future conferences or journals such as *For the learning of mathematics*, a conference proposal grant, and/or adapting powerful activities for students based on participants' teaching interests. We will maintain a Google Drive folder, where Google Docs with work that we generate together will be kept as a record after the conference. There will also be a folder for participants to share their relevant published work with the group to facilitate spread of ideas, especially from new scholars.

We plan for future iterations of the working group to be a larger, shared authorship team with participants. Our report would be a compilation of reflections from the participants, and those that agree to share for the report would be listed in the working group as authors.

manjula.joseph@fresno.edu

This continuing working group, Conceptualizing the Role of Technology in Equitable Mathematics Classrooms (TechQuity), plans to extend the ongoing conversation regarding the role of technology in building equitable mathematics classrooms. During PME-NA 2023, the group met for the first time to better understand the intersections between technology- and equity-centered mathematics teaching and learning. While our initial meeting was successful, we found the complexity of the role of technology in equitable mathematics classrooms to be far-reaching. This year we plan to grow our community and enact ideas to build sustainable programs of research dedicated to TechQuity in mathematics education.

Keywords: Technology; Equity, Inclusion, and Diversity

In this second year of meeting, the TechQuity working group will continue to develop opportunities for collaboration through the sharing of our current work in progress and facilitating opportunities to grow this network of mathematics educators dedicated to exploring TechQuity.

While attending to precisely what *equity* means can be a challenge, our current conceptualization of TechQuity centers around examining potential intersections between, Gutiérrez's (2009) four dimensions of equity, namely Access, Achievement, Identity, and Power, and the didactic tetrahedron (Hollebrands, 2017) that models interactions between students, the teacher, technology, and mathematics. This year we plan to continue unpacking what these intersections might look like in research and practice, especially in light of new advancements in technology (e.g., AI). Prior work on this topic (e.g., Suh et al., 2022; Witt, 2022) offers promising starts to promoting TechQuity. For example, Suh et al (2022) present,

> "...dimensions for technology that have transformative potential to enhance access to inquiry based learning, promote positive math identity through authorship and agency, provide formative assessment and differentiation, encourage collective thinking, and amplify mathematical thinking processes" (p. 1564).

Additionally, Witt (2022) argues for the leveraging of mathematical action technology– that is, dynamic interactive digital technology to support student-centered exploration (Dick &

Hollebrands, 2011) to support the development of a sociopolitical disposition in students. While promising, we acknowledge much more work and many more voices are needed to pursue TechQuity.

Throughout the three-day working group sessions at the 2023 PME-NA conference, we set the stage for sustaining two interconnected subgroups. The *Frameworks Subgroup* focuses on creating a framework for equitable technology integration, what we refer to as the TechQuity Framework. The *Task Design and Implementation Subgroup* focuses on the design and implementation of mathematical tasks using technology that promote equitable teaching practices. Additionally, the *Task Design and Implementation Subgroup* decided to pursue further grant opportunities for examining the role of AI use in mathematics education. Our recent discussions in this subgroup have supported calls (e.g., NCTM, 2024) to bring more mathematics educators into the discussion on researching and developing AI for equitable access and outcomes in mathematics education. Ultimately, the most promising outcome of our work together thus far has been the building of a community of mathematics educators who are committed to pursuing more work related to TechQuity.

With these two subgroups meeting regularly, we see this year's working group as a great opportunity to share with the PME-NA community what our group has learned and plans to pursue while also welcoming new members interested in exploring these ideas with us further. Thus, we organize this year's working group around the goals of these two subgroups: 1) *sharing progress and gathering feedback on developing a TechQuity Framework,* 2) *compiling research on the implementation of and development of tasks that support TechQuity*, and 3) *examining ways that AI can support equitable opportunities to learn in mathematics classrooms*. With these three emergent areas of interest, we intend to broaden participation by welcoming current and new members to join us and contribute to these conversations and collaborations.

Table 1 shows our tentative plan for engagement with working group participants; we plan to adjust these plans to accommodate participant interests.

Table 1: 2024 Plan for Engagement

Session	Activities
One	1. Introductions (20 mins)
	2. Updates and discussion of goals (70 mins)
	a. Developing a TechQuity Framework
	b. TechQuity Task Design and Implementation
	c. Equitable Use of AI in Mathematics Classroom
	d. Reflection: "What is TechQuity?" and "What are we missing?"
Two	Identifying emerging subgroups (15 mins)
	Collaborating in subgroups (60 mins)
	Sharing out ideas from the subgroups (15 mins)
Three	1. Planning for future work in subgroups (45 mins)
	2. Sharing of subgroup plans (30 mins)
	3. Planning for dissemination, including website expansion (15 mins)

Our anticipated follow-up activities include: (a) collaborative research and task development, (b) grant writing, (c) continuing to develop a TechQuity Framework, (d) expanding our website to disseminate our work, and (e) growing our community.

The implicit connections between the practices of computational thinking and mathematics have the powerful potential to strengthen students' reasoning about quantitative and spatial relationships. Working group participants will build upon their PME-NA 45 exploration of the synergies between CT and mathematics education to refine directions for collaborative research. We will continue to work toward our overarching goal of providing more equitable access to authentic mathematical problem solving through computing. Discussions will relate participant experiences with computationally-integrated mathematics tools and curriculum to the construction of productive learning environments and problem-solving identities.

Keywords: Computational Thinking, Mathematical Thinking, Teacher Identity, Student Identity

The integration of computational thinking (CT) and mathematics learning (Shute et al., 2017; Weintrop et al., 2016) has the powerful potential to deepen K-16 students' mathematical skills and practices as they seek patterns, create visualizations, make strategic guesses, and experiment systematically (Pei et al., 2018). The natural connections across disciplines can foster students' active engagement in the CT practices of abstraction, decomposition, pattern recognition, and algorithm design as they solve authentic mathematical problems (Gadanidis, 2017, Ng et al., 2023). Ye and colleagues (2023) further describe this disciplinary relationship as an interactive and cyclical process of reasoning mathematically and computationally to generate knowledge. By extending upon constructionist perspectives of computational artifacts as "objects to think with" (Papert, 1980), mathematics educators integrate computational artifacts as dynamic visual representations of mathematical thinking (Dahshan & Galanti, 2024; Cui et al., 2023).

Several directions for potential research were discussed at the inaugural meeting of this working group at PME-NA 45. While all participants were interested in exploring the synergies between CT, mathematics education, and data science education, there was a consensus that an actionable research agenda demanded a narrower focus. This year's working group will draw on the expertise of our current and new participants to focus specifically on the use of CT to enrich K-16 mathematics teaching and learning. We will continue to work toward our overarching goal of more equitable access to authentic mathematical problem solving through computing.

Session Plans and Focus

Session 1 – Are we using mathematics to teach CT or CT to teach mathematics?

In their systematic review on CT-based mathematics instruction and student learning, Ye et al. (2023) highlighted the need for research on curriculum resources and instructional designs aimed at integrating CT into school mathematics beginning from early grades. However, existing research is still in process to unpack what productive integration of CT and mathematics might look like and how the synergies and differences between these disciplines might influence integration. Studies suggest there is a reciprocal relationship between CT and mathematical thinking (Wu & Yang, 2022). Thus, we will explore whether we are using mathematics to teach CT or are we using CT to teach mathematics. To kick-start our inquiry, Ms. Strickland will share her extensive experience in elementary computer science and mathematics integration with a focus on culturally responsive pedagogy and curriculum. Then, small groups based on grade-level interest discuss the overarching questions of session 1.

Session 2 – How have we experienced CT integration in mathematics teaching?

This session will focus on an international, multilevel exploration of existing curricular resources centered on the integration of CT into mathematics education in both the United States and Europe. Participants will contextualize their concepts of interdisciplinary teaching from session 1 as they engage with two presentations. The first presentation focuses on how many European countries have incorporated CT into their mandatory education systems. While some countries, such as England and Poland, have integrated CT skills as part of a separate subject (Bocconi, 2022), the Nordic countries Finland, Sweden, and Norway, have integrated CT and programming into existing subjects, notably in mathematics (Vinnervik & Bungum, 2022). We will discuss a selection of one or two tasks that exemplify aspects of the integration of CT into primary and lower secondary education mathematics. We also will discuss illustrative examples of the opportunities and challenges encountered by teachers when incorporating CT into mathematics. The examples are drawn from a longitudinal evaluation study (Burner et al., 2022).

Unlike the Nordic coordinated integration into school curriculum, there is no unified approach for integrating CT into US postsecondary mathematics classrooms. The second presentation will discuss research on curricular materials integrating computational modeling and linear algebra (Castle, 2022). Participants will critically consider the affordances and constraints of CT integration as described by students, focusing on the power that computation has to potentially disrupt previously held mathematical notions and confront mathematical assumptions. Small groups based on grade-level interest will then discuss the overarching question of session 2 along with potential structural barriers to classroom implementation.

Session 3 – How do we foster learner and teacher identities at the intersection of CT and mathematics education?

The integration of CT into mathematics education necessitates a critical exploration of the potential intertwining of computational identities (e.g., Kafai & Proctor, 2022; Kong & Lai, 2022) and mathematical identities (e.g., Boaler & Greeno, 2000; Graven & Heyd-Metsuyamin, 2019). After primer presentations on both student and teacher identities in CT and mathematics, participants will develop potential theoretical framings for the interaction of computational and mathematical identity. We will consider how identity development can be supported and how it can be interpreted so it becomes an outcome of the learning processes in both K-16 classrooms and teacher education contexts. Specific attention will be given to topics such as avoiding the perpetuation of stereotypes of who belongs in these disciplines and focus on how the integration can bring out positive self and world views for students. We will also explore ways in which mathematics teachers (and mathematics teacher educators) can shape classroom discourse and power dynamics to strengthen CT and mathematics learner identities (Perez, 2018).

Acknowledgments

The first and second authors contributed equally to writing this proposal.

The "Power of Computational Thinking in Mathematics and Data Science Education" working group held its inaugural meeting at PME-NA 45 in Reno, Nevada. The skills and practices of CT can empower teachers to emphasize abstraction, automation, modeling, and simulations as their students investigate relationships in mathematics and data science. The focus of the three sessions was to advance conversations about the integration of CT in mathematics and DS education with aims to launch new collaborations. Our overarching goal of providing more equitable access to authentic mathematical problem solving through guided the design and facilitation of the working group sessions. Participants experienced three CT-integrated data science tasks on Day 1, created working visuals of the synergies across the disciplines on Day 2, and proposed directions for future research on Day 3.

Keywords: Computational Thinking, Computing and Coding, Data Analysis and Statistics, Modeling

A Brief History and Motivation of the Working Group

This working group journey started at the PME-NA 44 conference in Nashville in 2022. During a session focused on computational thinking (CT) in mathematics education, the founding members (Yilmaz et al., 2023a) embarked on a journey, laying the groundwork for this thematic group. Mr. Alegre and Dr. Yilmaz presented on the transformative integration of mathematical thinking (MT) and computational thinking (CT) within the "Cultural Quilts" coding project. They shared how the coding efforts of high school students not only offered valuable insights into mathematical strategies (e.g., defining functions, using geometric transformations) within their code but also served as a means for students to express their cultural identities and values through uniquely personalized quilt designs (Alegre et al., 2022). Dr. Galanti (2022) presented on how elementary teachers in an online graduate-level CT course engaged in mathematical sensemaking using block-based programming. She shared how teachers modified parameters in a Scratch project to explore the dynamic relationship between changing height and changing volume to create a box with maximum volume from a sheet of paper. Teacher's coding artifacts modeled the reciprocal relationship between CT (algorithmic thinking, abstraction, and automation) and MT (pattern seeking and generalization). These two presentations contribute to the growing knowledge base on the integration of CT and mathematics and its potential to deepen learning in both disciplines (e.g., Brady et al., 2021; Goldenberg et al., 2021; Kallia et al., 2021; Weintrop et al. 2016).

Our shared passion for exploring the integration of CT and mathematics extended informal conversations at the PME-NA 44 conference to more format collaborations. Dr. Lawler invited the presenters from the CT session at PME-NA 44 to co-host a mini-symposium at Kennesaw State University supported by the National Science Foundation (https://research.kennesaw.edu/cistemer/culturally-relevant-integration-cs-mathematics.php) This two-day event was attended by over 30 computer science and mathematics education scholars from diverse backgrounds and contexts. They considered ways in which culturally relevant pedagogy might enhance integrated approaches to learning computation and mathematics.

Furthermore, our discussions extended to wonderings about the role of CT in data science education. We draw on several definitions of data science as an overlap of the skills of multiple disciplines including mathematics, business, statistics, and computer science (Lee et al., 2022). Acknowledging that data science requires not only CT but also MT, we were excited to expand our exploration to the synergies among these three disciplinary domains. Dr. Yilmaz envisioned extending these efforts beyond our one-time symposium event. She facilitated our submission of a thematic group proposal for PME-NA 45 by its founding members. This proposal created a "community focused on advanced conversations about synergies between CT in mathematics and data science education with the aim to launch new collaborations" (Yilmaz et al., 2023a, p. 674). Recognizing the importance of CT as a crucial yet underemphasized aspect of K-16 education in an increasingly technological world, this working group aims to challenge the mathematics education community to advance the teaching and learning of CT within both mathematics and data science.

Progress Made Throughout the PME-NA 45 Working Group

Day 1 Progress and Outcomes

Workshop participants collaboratively engaged in three integrated problem-solving tasks. These tasks, all focused on statistical concepts (measures of central tendency), were selected to provide multiple entry points to our discussion of the synergies among CT, MT, and data science without an assumption of prior knowledge. The discussion questions were designed to stimulate conversations about the ways in which the concepts and practices of CT could be integrated in mathematics and data science teaching.

Task 1 was adapted from a set of freely available elementary CT-integrated mathematics modules (Education Development Center, 2021). Participants used an unplugged CT approach (without a computer) to write algorithms to move two bots to calculate the mean and median of a data set (See Figure 1). They considered the following synergistic questions:

- How does CT contribute to the development of the mathematical concepts of mean, median, and spread in this task?
- How does the context of a mathematics task create opportunities to develop CT skills and practices?
- How do the algorithms developed by the students in this task relate to concepts and techniques commonly used in data science?

Task 2 was an adaptation of a plugged YouCubed K-12 Data Science activity (2020). Participants accessed an open-source Common Data Analysis Platform (CODAP) to explore mean, median, and mode for a mammals data set See Figure 2). They considered the following synergistic questions:

- How does data science contribute to the development of the mathematical concepts of mean, median, and spread in this task?
- How does the context of a data science task create opportunities to develop CT skills and practices?
- What shifts do you see in CT skills and practices used when students transition from Task 1 (algorithmic design as problem-solving) to Task 2 (data exploration and visualization as problem-solving)?

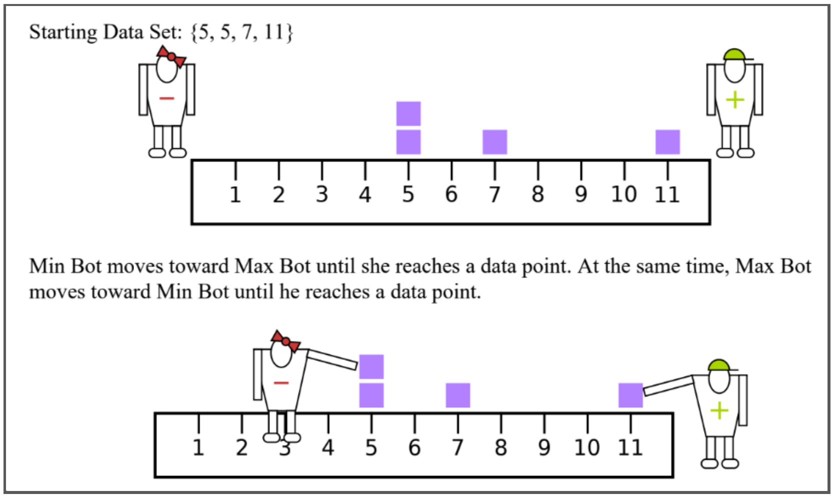

Figure 1: Excerpt from Task 1 - Algorithm Writing to Compute Mean and Median) (Education Development Center, 2021)

Mammals

8	Donk...	Perisso...	40	1.2	187	3	50	land	plants

Figure 2: Excerpt from Task 2 - Using CODAP to Explore Attributes of Mammal Data Set

Task 3 used a simple computer program (Figure 3) to explore the interactions of CT and MT in block-based programming approaches to calculating the mean of a set of numbers. Participants had the opportunity to modify code to compare and contrast two approaches to a statistical calculation: 1) the use of a single variable to accumulate the sum of numbers as they are entered by the user and divided by the number of entries; and 2) the use of a list to first store all entered values before calculating the mean by iterating over a list of numerical entries.

All three of these tasks were intended to highlight abstraction, decomposition, pattern recognition, algorithmic thinking, logical thinking, modeling, and automation as productive aspects of CT within mathematics education (Kallia et al., 2021). The participants were able to draw upon these different problem-solving experiences within a data science context to think about how dynamic computer models and the underlying algorithmic thinking can support generalization and evaluation in problem solving.

Figure 3: Excerpt from Task 3 (Using a Block-based Scratch Computer Program to Calculate Mean)

Day 2 Progress and Outcomes

The three tasks on Day 1 provided a shared experience from which to elicit participants' own teaching and learning experiences with CT, MT, and data science. After examining a series of published visual conceptualizations of relationships between the three disciplines (e.g., Lee et al., 2022; Sneider et al., 2014), the participants worked in small groups to create their own visuals (see Figure 4 for examples). To contextualize these visualizations of disciplinary relationships, Mr. Alegre and Dr. Lawler presented research that challenges us as mathematics education researchers to reflect on whose ways of knowing are valued in CS and mathematics education. Mr. Alegre described a research practice partnership between Louisiana State University and secondary teachers to integrate CS in mathematics. Dr. Lawler shared work in after school programs designed to engage middle grades students in imagination, creativity, reasoning, and discourse through integrated coding and mathematics experiences. These presenters encouraged conversations about the need to draw upon teachers' and students' cultural assets in considering future directions for disciplinary integration.

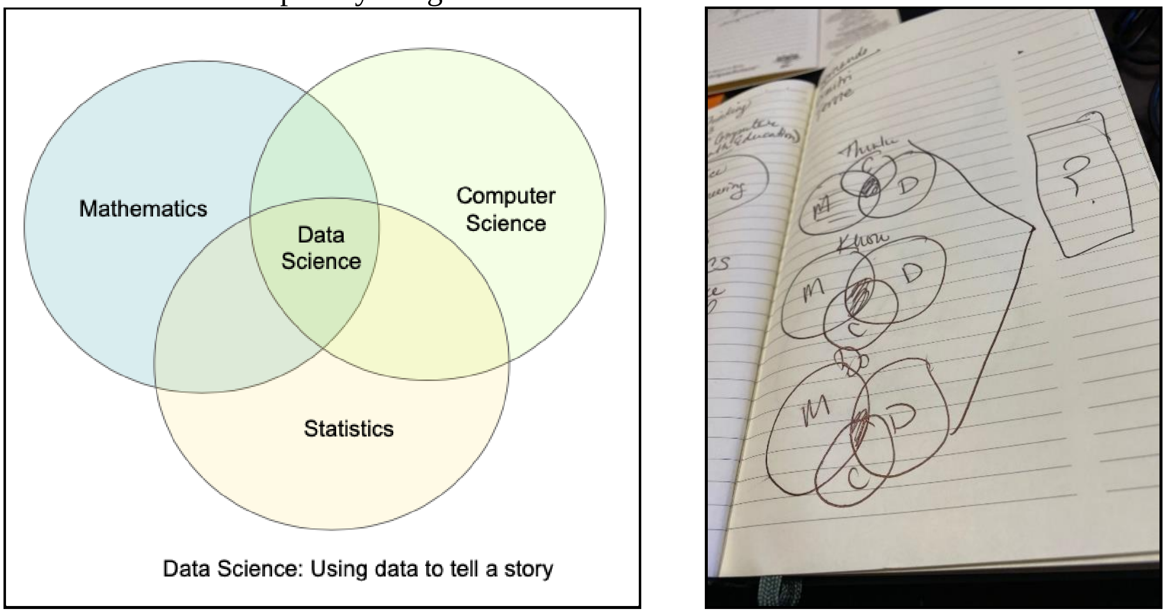

Figure 3: Participant-created visualizations of CT, MT, and Data Science

Day 3 Progress and Outcomes

The final session started with participants' reflection on the visuals created on Day 2 and organic conversation across two main areas: 1) Computational Thinking: Knowing, Doing, Thinking and 2) Equity and Access: Practical Applications of Computation and Mathematics in Schools.

Computational Thinking: Knowing, Doing, Thinking.

The participants delved one of the visuals created on Day 3 (See Figure 3 above). This visual emphasized the three aspects of computational integration as knowing, doing and thinking. They suggest computational knowing could include understanding algorithms and data structures and computational doing could include coding. They argued that both knowing and doing are both essential for CT. They also discussed concrete examples on the misconception that learning to code with an application such as Scratch (a visual block-based programming language) equates to CT. They shared the need for a broader conceptual understanding of what CT encompasses. The participants generated two questions for inquiry and reflection.

- Is computational doing limited to coding, or are there other ways to enact CT?
- What constitutes computational knowing, thinking and how can it be effectively taught and assessed in mathematics and data science education?

Examination of various visuals from Day 1 and Day 2 motivated participants to consider the benefit of creating a unified visual showing the synergies between CT, MT, and data science. They suggested such a visual could support educators, policymakers, and practitioners in conceptualizing the varied approaches to integrating computation in K-16 mathematics and data science education and identifying areas for cross-disciplinary collaborations.

The participants acknowledged the challenges in creating a unified visual. One significant challenge is the establishment of common language and frameworks across disciplines. Each discipline may have its own terminology, methodologies, and epistemologies, making it challenging to develop a shared understanding. For instance, while mathematicians may approach problem-solving through abstraction and proof, computer scientists may focus on algorithms and computational complexity. Bridging these diverse perspectives requires careful negotiation and collaboration among experts from different disciplines. Additionally, the rapid evolution of technology and research methods further complicates efforts to create a unified representation that remains relevant over time.

Equity and Access: Practical Applications of Computation and Mathematics in Schools

The participants discussed how mathematics could serve as a pathway to increase access to computer science and related fields, potentially addressing issues of equity. Unlike elective courses like computer science, which may have prerequisites or limited availability, mathematics is a core subject taught to all students. One of the participants described how some students, particularly those underperforming in traditional subjects like mathematics and English, may be denied access to elective courses like computer science. This lack of access denies them the opportunity to explore practical applications in which they can use both CT and MT. Concrete applications of CT and MT skills, such as pattern making and measurement in fields like interior or fashion design, could improve students' understanding of mathematical concepts. Similarly, engaging students in computational activities rooted in mathematics might not only enhance their computational skills but also deepen their mathematical understanding. By incorporating CT into mathematics, schools can provide students with opportunities to explore real-world problem-solving and creative expression, potentially empowering students who might otherwise struggle with traditional math instruction.

Consideration of future research on equity and access to CT within K-12 mathematics and data science education settings yielded two questions for further inquiry. The first question was “Can students succeed in computer science courses without first meeting traditional grade-level math standards?” This question delves into providing alternative pathways or interventions to support more diversity in engagement with computer science in K-12 settings. The second question was “How can we as mathematics educators promote equitable access to CT in K-12 settings, particularly for students from marginalized backgrounds?” This question underscores the need to address systemic barriers and biases that may hinder students participation in CT programs.

Progress Made Following the October 2023 Working Group

Our working group convened virtually in November 2023 and in January 2024 to continue to discuss directions for research and collaboration at the intersection of CT, MT, and data science. The participants collapsed our working list of 13 researchable topics generated on Day 3 of the October meeting to a set of seven topics for collaborative research (See Table 1). The attendees also considered methodologies to support exploration of these topics. A literature review seemed well aligned with Topic 1, while an investigation of existing curricula seemed to be a productive entry point for Topic 4. Discussions of potential research centered on the stakeholders in disciplinary integration, specifically students and classroom educators. The ways in which students and educators experience the integration of CT and MT was of continuing interest, with multiple theoretical frameworks (e.g. identity, content knowledge and pedagogical content knowledge) and mathematical domains (e.g., geometry, algebra, and number) guiding the conversations.

Our working group has continued its effort to define a near-term collaborative project by reading a 2023 systematic literature review on the integration of CT in K-12 mathematics education with a focus on instruction and learning (Ye et al., 2023). The central question of this literature review was, "How do students' CT and mathematics learning interact when they are involved in CT-based mathematics instruction, and what are the consequences of such interactions?" (p. 13). Participants met virtually in January 2024 to share their key takeaways and their key wonderings based upon their reading. The following questions emerged:

- Ng & Cui (2021) offered the descriptor of "computationally-enhanced mathematics education". Would this description attract more interest in innovating traditional school curriculum with mathematics as a standalone subject?.
- There was no mention of the role that artificial intelligence or machine learning could play in the teaching and learning of CT and MT. Should we expand our focus to these potential integrations?
- Dick and Hollebrands (2011) define a mathematical action technology that can "perform mathematical tasks and/or respond to the user's actions in mathematically defined ways" (p. xii). How does computer programming fit within this definition?
- Dynamic geometry software applications are mathematical action technologies. What CT skills and practices are teachers engaging in with students using dynamic algebra and geometry software applications?

Table 1: Directions for Collaborative MT-CT- Data Science Research

Direction for Collaborative Research	Number of Interested Researchers
Synergies between MT, CT, and Data Science	9
Integration of MT, CT, and Data Science in K-12 Education: Curriculum, Implementation, and Challenges	6

Affordances of Data-Driven Math Curricula	2
Teaching Mathematics, Data Science, and Computer Science Simultaneously	4
STEM Teachers as "Integrators" of computational thinking	3
STEM Parenting Identity	1

Ye et al. (2023) stated that "future research on teacher professional development concerning the emergent competency of CT-based mathematical thinking is indispensable" (p. 24), but research on preservice and practicing teachers was an exclusion criterion for their literature review. We are tentatively working toward a collaborative literature review on preparing pre-service and practicing teachers to integrate CT in mathematics instruction.

Conclusions and Looking Ahead

Based on existing literature that explores the connections between CT and MT (e.g. Brating & Kilham, 2021; Hickmott et al., 2021) , as well as the integration of CT into mathematics as a school subject (e.g., Chan et al., 2023; Rich et al., 2020), our group is motivated to delve deeper into identified gaps, needs and challenges in these studies. Limited empirical studies have explored the synergies between CT and MT (Hickmott et al., 2018). Only a few studies have incorporated the expertise of mathematics educators to explore the integration of CT in mathematics (Hickmott et al., 2018; Kallia et al., 2021).

Another identified gap in the research is evidence of what resources (e.g., knowledge, curricular materials, tools) teachers need to effectively integrate CT into their mathematics teaching (Wu et al., 2021; Yadav et al., 2016) and how to assess teacher CT learning (Galanti & Baker, 2023). These gaps highlight the need for more professional learning opportunities for teachers. However, only a limited number of PD studies (e.g. Ahamed et al., 2010; Hart et al., 2008; Wu et al., 2021; Yilmaz et al., 2023b) have focused on the integration of CT and MT. This indicates a need for more tailored PD initiatives designed through interdisciplinary collaboration of mathematics and CS educators (Dahshan & Galanti, in press; Menekşe, 2015).

Our group is also interested in how the integration of CT in mathematics education and data science education in fostering teacher and student problem-solving identities. By looking across the literature in CT identity (Kong & Lai, 2022) and use of coding to foster creativity in mathematical thinking (Castle, 2023), we seek to understand how CT integration can build an individual sense of self as a “doer” of mathematics or data science.

As we continue engaging in generative inquiry and collaborative research, our thematic group is committed to seeking ways to address these gaps and needs and to broaden interest in this work in the PME-NA community.

This text explores the influence of artificial intelligence (AI) and technology in shaping mathematical work in educational contexts, with a focus on human-machine interaction dynamics. It addresses key aspects such as symbolic and statistical AI, digital artifacts, and the role of hybridization as a technological counterpoint to overcome current limitations. By presenting practical examples, it demonstrates how technology creates new forms of control, necessities, and challenges in mathematics education. Although large language models possess extensive knowledge, their limitations in performing genuine mathematical reasoning remain, highlighting the need for innovative approaches to carry out the new mathematical work.

Introduction

The integration of artificial intelligence (AI) and technology into mathematics education presents both opportunities and challenges in reshaping mathematical work. While the development and application of symbolic and statistical AI, along with digital tools, have become increasingly common in mathematical research, many educators and mathematicians remain hesitant to fully embrace these innovations. This hesitation is partly rooted in a long-standing belief that mathematics is closely intertwined with language—not only as an expression of mathematical thought but as a core component of mathematical activity itself. Is mathematics not a science, and do the mathematical sciences not trace their origins to history, with the expression of writing as a fundamentally human characteristic? Consequently, the notion of delegating this inherently human endeavour to a machine—often perceived as a "black box" with opaque inner workings—sparks concerns about relinquishing control over the mathematical process. Moreover, the concept of reasoning, central to mathematical work, calls for reexamination in this evolving context.

In contrast, the evolving reality of the modern classroom, where students interact daily with powerful digital tools and AI technologies, necessitates a shift in how mathematics is taught. Today's learners, who have grown up in a world increasingly shaped by digital artifacts, are not only familiar with these tools but rely on them as part of their everyday lives. This trend has made it imperative for mathematics education (ME) to adapt to these new technological realities.

However, this adaptation often occurs without a foundation in what might be called instrumented mathematics, or a clear epistemological reference or long-term understanding of the cognitive issues at stake with digital artifacts. This gap makes the theoretical and practical issues surrounding mathematics even more complex.

This paper examines these dynamics by considering the role of AI, particularly through the synergy between symbolic AI and generative models in transforming the nature of mathematical work. It explores how hybridizations, or technological counterpoints—both in the integration of symbolic and statistical AI and in human-AI collaboration—may provide a potential solution to some of the limitations currently faced in the field. By drawing on concepts such as augmented intelligence, idoneity, and the challenges posed by "black box effects," this work seeks to provide a comprehensive understanding of the shifting landscape of the new mathematical work in the context of fast technological advancements.

Our Focus: Traditional and New Mathematical Work

Mathematical Work

Mathematical work refers to the activities, processes, and approaches involved in practising mathematics, whether by students, teachers, or professionals in the field. It encompasses various dimensions, including problem-solving, modelling, demonstrations and reasoning, representations and communication, as well as knowledge, procedures, and attitudes.

In a more formal framework, mathematical work includes reflection on the nature of mathematics itself, on how it evolves, and on how it relates to other disciplines. In the theory of mathematical working space (ThMWS), mathematical work is progressively constructed as a process that bridges epistemological and cognitive aspects through three intertwined genetic developments, identified in the theory as semiotic, instrumental, and discursive genesis (Kuzniak, Montoya, & Richard, 2022). Beyond didactic transposition, the concept of mathematical work stimulates epistemological awareness in educational programs.

New Mathematical Work

The integration of digital artifacts into mathematical activity goes beyond merely facilitating or accelerating tasks; it transforms the nature of mathematical work itself by opening new pathways for problem-solving, exploration, and learning. The human-machine interaction resulting from this integration produces new forms of mathematical activity (Bruillard & Richard, 2024), including the dynamic interplay of representations, automated calculations and reasoning, exploratory conjecture, instant feedback, and the cognitive impact of artifact interactions.

This new mathematical work, shaped by human-digital collaboration, is characterized by automation, dynamic visualization, and interactive feedback. These elements redefine mathematical practices by weaving together semiotic, instrumental, and discursive dimensions—creating a complex "dance of genesis" that brings new depth to learning and problem-solving (Flores Salazar, Gaona, & Richard, 2022).

The effects of this evolving mathematical work are wide-ranging, influencing all aspects of mathematical practice, from problem-solving and modelling to proofs and reasoning. In reasoning, specifically, studies such as Richard, Venant, and Gagnon (2019) show how instrumental proofs and technology-assisted reasoning can already serve as valuable models for future exploration.

Underlying References

Aside from the theory of symbolic mathematical working spaces (ThMWS), our discourse also draws on two main references. First, the book *Mathematics* Education *in the Age of Artificial Intelligence: How Artificial Intelligence Can Serve Mathematical Human Learning* (Richard, Vélez, & Van Vaerenbergh, 2022) underscores the contributions of artificial intelligence to mathematics education, presenting concrete ideas grounded in mathematical work developed through dynamic international collaboration. This book further addresses the evolution of new mathematics in the contemporary world. Its themes and sections explore the creation of AI-enhanced learning environments for mathematics, AI-supported mathematics learning, and the integration of traditional paper-and-pencil techniques with new AI-aided educational working spaces.

The second key reference, the article *Artificial Intelligence and the Didactics of Mathematics: Current Situation and Issues* (Emprin & Richard, 2023), delves into the complex interplay between artificial intelligence (AI) and mathematics education (ME), particularly timely given AI's profound impact on society and the economy. Initially, the article questions the concept of "intelligence" itself, examining its definitions and the biases it may invoke when applied to AI. This foundational exploration paves the way for an analysis of potential links between AI and the didactics of mathematics, illustrated through examples of current projects in the Francophone world that offer insight into actively developed areas. The article then discusses theoretical frameworks in mathematics education and their integration with AI. Finally, it addresses critical questions and challenges that arise from AI usage, presenting promising perspectives for future developments.

Artificial Intelligence (AI)

From Foundations to Collaborative and User-Centric AI Design

The historical and inherent connection between artificial intelligence and the didactics of mathematics is well established. Notably, the foundational references to this relationship were published nearly 30 years ago, with the work *Didactique et intelligence artificielle* (Balacheff, 1994). The previous underlying references by Richard, Vélez, and Van Vaerenbergh (2022), and Emprin and Richard (2023), coincided with the rapid rise of public interest in ChatGPT and generative AI models. Indeed, ChatGPT gained widespread recognition in November 2022, when OpenAI released an accessible version based on the GPT-3.5 model. Its user-friendly interface and advanced conversational capabilities quickly captured the attention of users, media, and businesses alike, generating significant interest in AI applications across various fields. This surge in popularity has often led to a conflation of AI with generative models, overshadowing the foundational contributions of diverse research approaches in the field of AI (as discussed further below). Consequently, these recent publications have become essential references for understanding the challenges of new mathematical work, particularly concerning numerical and symbolic approaches.

Balacheff's (1994) work highlighted advances in AI and their impact on the development of computer environments for human learning. This initial period of enthusiasm was, however, followed by a phase of disillusionment, during which the challenges involved were underestimated. Today, paradoxically, AI appears to be converging once again with didactics by offering approaches focused on solving non-routine problems, even before generative models began attracting significant attention. These approaches integrate phases of learning, modelling, and prediction that evoke both mathematical work and the expertise required to devise solutions. For AI to effectively contribute to academic success and assist teachers in monitoring student progress, any collaboration between a teacher and a tutoring system must involve a well-informed understanding of didactic culture. The tutor must recognize the specific demands of teacher-student knowledge interactions and support these dynamics alongside human reasoning competencies. The system should adapt to human needs, rather than the reverse, to avoid reducing these considerations to mere instrumental issues.

The integration of "machine thinking" and "human thinking" through artificial intelligence requires collaborative input that goes beyond computer scientists alone. Given the fundamental, shared concept that mathematics is pursued through seeking and solving specific problems—and thus continually posing new questions—each problem presents an opportunity to deepen understanding of both mathematics and reality. When students take ownership of this process, problem-solving and modelling provide insights into the nature of learning itself—whether in moments of blockage, overcoming obstacles, or successfully explaining and clarifying complex situations. As AI already proves valuable with traditional techniques (Lagrange, Richard, Vélez, & Van Vaerenbergh, 2023), its potential growth is imaginable through collaborative development involving both didactics and computer engineering, adopting a perspective of new mathematical work. Above all, AI could thrive by incorporating user involvement early in the design process, embracing the principle of "design-in-use" for the learning of mathematics.

Classical Perspectives on AI Research Approaches and Beyond

Artificial intelligence (AI) has long raised fundamental questions about its nature. In his preface titled *AI for the Learning of Mathematics*, Balacheff (2022) explains:

> It would have been good to have a precise and clear definition of Artificial Intelligence (AI) unanimously accepted. Unfortunately, it is not the case today as it was not the case formerly. The common criterion, AI is a property of machines "exhibiting certain behaviours which strikes as intelligent," reminds us that this is a judgement underpinned by a kind of human empathy. Looking closer, it appears that such a judgement assesses both the task which has been achieved by the machine and the way it has been achieved: a behaviour is striking because the task is acknowledged complex and/or the way in which it has been achieved looks smart.

Is it simply a "machine story," a modelled extension of human capabilities, or a human-machine collaboration that can take the form of both partner and adversary? While all three perspectives are possible, it is certain that the idea of collaborative interaction aligns more closely with the concept of mathematical work. Drawing on the classical perspective—and a bit beyond—we will initially explore contemporary issues related to AI in mathematics education.

AI is traditionally divided into two dichotomous approaches, as illustrated by the OECD report (2019) and studies by the Massachusetts Institute of Technology (MIT) (Fig. 1). Generally, symbolic approaches are based on rules and symbols, striving to model human thought through logical processes that generate truth from truth. While powerful for certain tasks, symbolic AI is limited by its inability to handle uncertainty and the complexity of real-world situations. It stands out for the transparency of its decisions due to explicit rules, its precision in logical reasoning, its formal demonstrations, and its resolution of symbolic equations. It is well suited to geometric constructions for exploring properties and performing visual proofs. It is effective in symbolic analysis to solve integrals, derivatives, and limits formally, without numerical approximation. Finally, it is useful in the symbolic treatment of statistical data to model distributions or establish theoretical correlations. However, it remains rigid when faced with new data, requiring manual updates or adaptations. It is difficult to adapt to uncertain data or unexpected variations, and generally, it is less effective at learning from large datasets.

Statistical approaches to AI are based on data analysis to establish correlations and make predictions. They use techniques like machine learning and neural networks, allowing AI to recognize patterns and learn from large datasets. Unlike symbolic AI, statistical AI effectively handles uncertainty and unexpected variations, adapting its models autonomously as new data becomes available. It is particularly effective for predictive tasks, time-series analysis, and pattern recognition in complex data. In mathematics, it excels in the approximate resolution of numerical problems, such as statistical simulations and probabilistic modelling. However, it lacks transparency in its decisions (the "black box" effect) and does not provide formal demonstrations. Its results are often approximations, and despite its flexibility, it may lack precision in contexts requiring rigorous logic or explicit proofs.

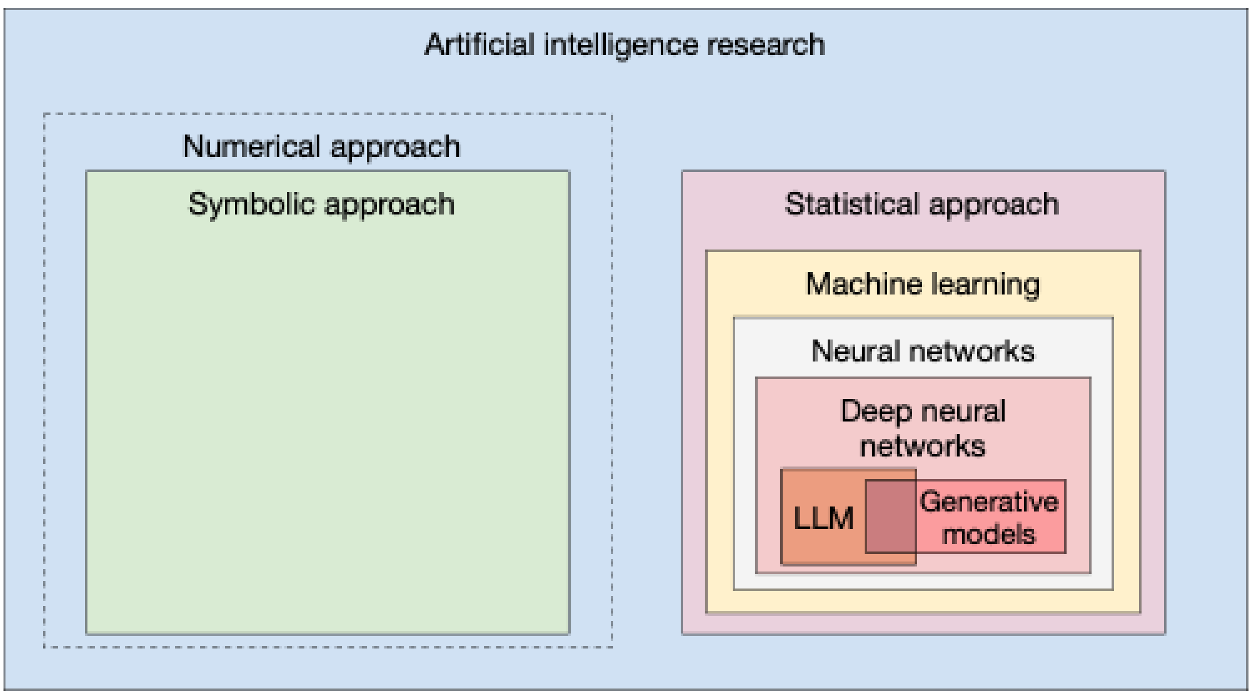

Figure 1: Adaptation of the original diagram in OECD, in which we added the "numerical approach" in dotted lines around the symbolic approach, and the "LLMs" and "generative models" in the deep neural networks.

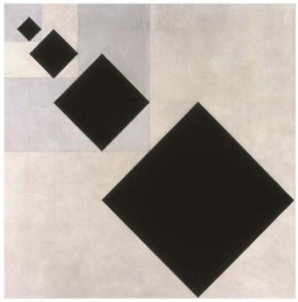
As shown in Fig. 1, while there is no doubt that “LLMs” and “generative models” fall under the category of deep neural networks, it is less certain whether numerical approaches belong to AI for mathematical work. The answer may be yes, as numerical approaches seem essential for AI in mathematics. Indeed, statistical AI and large language models often struggle to achieve the precision needed for rigorous mathematical tasks, making them less suitable for high-level mathematical applications. For example, while symbolic approaches are effective for derivable functions, they fall short when integrating functions without primitives, which limits their scope. Additionally, numerical methods are crucial for solving complex and nonlinear differential equations, expanding the potential applications of AI in mathematics. Thus, without numerical models, AI’s capacity in mathematics is constrained. With them, AI gains a broader, more robust range of applications, making numerical approaches integral to mathematical AI.

Technological Counterpoint

In the title of our presentation, we used the term *hybridization* due to its familiarity. However, we need a term that operates on two levels: first, it should convey the integration of symbolic and statistical AI, representing a novel technological synthesis; second, it should capture the emerging interaction between humans and AI as a complex, cohesive system, like an instrumented human or augmented intelligence. While *hybridization* commonly denotes the crossbreeding of species—as seen in the historical interbreeding between humans and Neanderthals—it might not fully represent our intent in the context of human-AI interaction. Viewing the learner in mathematics as a “cyberborg” similarly implies an identity, we prefer to avoid.

The term *technological synergy* could also be considered, as it suggests a harmonious collaboration where distinct elements combine to create a greater force. However, *synergy* often implies a fusion or productive integration between humans and technology, which does not accurately reflect the nuanced, non-fusional interaction we aim to describe.

Instead, we propose the term *technological counterpoint*. Borrowed from music, counterpoint evokes a contrast or constructive opposition, presenting technology and human intelligence as distinct, parallel perspectives that mutually critique and enrich one another, creating a subtle dynamic tension. For describing human-AI interaction, *counterpoint* captures the idea of two entities acting in concert while preserving their individuality. Similarly, in the case of symbolic and statistical approaches, counterpoint aptly reflects two distinct currents that coexist and enrich the field of AI in a complementary, yet non-blending, manner.

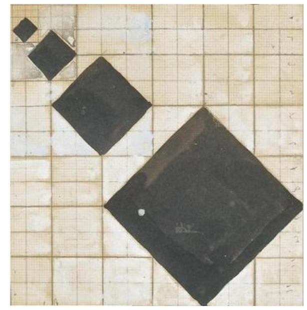


Figure 2: The pinnacle of concrete art is exemplified in *Arithmetic Composition* by Theo van Doesburg (1929–1930). Black, white, and gray squares, repeated with varying dimensions and intervals according to a geometric progression, merge space and time. The artwork is on the left, and its study, on 12 cm graph paper, is on the right.

Human "Hybridization"

To assess how AI influences learners' engagement in problem-solving, we developed an activity that fosters mathematical exploration by incorporating critical thinking and argumentative skills. The study is framed by a historical context: in the late 1920s, Dutch painter, architect, and art theorist Theo van Doesburg created his *Arithmetic Composition* (Fig. 2), at a time when mathematical character evidently took precedence over impressionism. Drawing from the artist's approach, we designed a structured activity focused on exploring mathematical necessity within the artwork. This activity employs a guiding questionnaire and involves trainer interventions in sessions for teachers and researchers in mathematics education. It emphasizes critical reflection, in-depth analysis, and creative problem-solving, while allowing participants freedom in their use of technological tools.

For the design of the activity, we incorporated findings and expertise gained from previous research in teacher training. The first area involves task definition by teachers and the establishment of hypothetical learning progressions within the context of *Arithmetic Composition* (García-Honrado, Clemente, Vanegas, Badillo, & Fortuny, 2018). The second area introduces an instrumented approach using GeoGebra's automated reasoning tools to support the discovery, derivation, and demonstration of mathematical properties (Kovács, Recio, Vélez, 2021). Initial analysis results are presented in García-Honrado, Fortuny-Aymemi, Recio, & Richard (2024), and the complete questionnaire is included in the appendix.

The questionnaire is structured around two exercises, each designed to immerse students in training in distinct aspects of AI-supported mathematical exploration and problem-solving. The first exercise emphasizes qualitative analysis of Theo van Doesburg's *Arithmetic Composition* (Figure 2) by engaging primarily with statistical AI, including advanced generative language models such as ChatGPT (developed by OpenAI) and Gemini (developed by Google DeepMind), alongside conventional tools like Google and Bing search engines. This exercise invites participants to examine the visible regularities and recursive patterns within the artwork, fostering critical observation skills that AI tools can supplement. For instance, students in training are guided to use ChatGPT to generate hypotheses about the mathematical properties embedded in the artwork, then compare these with factual data sourced from Google. This blend of AI tools allows participants to evaluate the distinct contributions of statistical AI and search engines, providing insight into how generative models can support exploratory reasoning within a mathematical and artistic context.

The second exercise shifts focus toward symbolic AI and traditional paper-pencil methods, encouraging participants to analyze the geometric structures in *Arithmetic Composition* through the automated reasoning capabilities of GeoGebra Discovery. As outlined in Figure 1, this exercise exemplifies the symbolic AI approach within the broader AI landscape, enabling the exploration of recursive geometric sequences and Thales' configurations (Exercise 2) using GeoGebra's interactive geometry modules. Students in training are tasked with verifying the alignment of square vertices and investigating proportional relationships, such as the scaling ratios and the positioning of elements in Thales' configurations. These tasks highlight how symbolic AI, unlike statistical AI, provides precise calculations and direct verification of mathematical properties.

The questionnaire embodies a dual "hybrid" approach through a structured *technological counterpoint*, bridging human-AI and symbolic-statistical AI paradigms to enhance mathematical exploration and validation. This approach aligns with the concept of *new mathematical work*, where digital artifacts transform traditional mathematical practices by enabling new forms of engagement. As illustrated in Figure 1, which depicts symbolic, statistical, and generative AI models, students in training are immersed in both the generative, language-based reasoning of models like ChatGPT and Gemini, and precision-oriented symbolic tools such as GeoGebra Discovery. This interplay fosters *augmented intelligence*, whereby human cognitive capacities are amplified through interaction with digital tools, supporting deeper exploration of mathematical concepts and enhanced problem-solving processes. Within this framework, the concept of *idoneity* becomes central (Emprin & Richard, 2023): through iterative questioning, students engage in a recursive adjustment process between their problem-solving intentions and the digital responses provided by AI tools, leading to an evolving alignment between human initiative and the technological affordances of AI. In their written answers, students also reveal the outcomes of their decisions, indicating whether the AI tool served as a partner, an adversary, or introduced new and surprising challenges in the process. This approach not only diversifies problem-solving methods but also cultivates critical thinking and argumentative skills, equipping students with a nuanced understanding of AI's role in mathematical inquiry and fostering an adaptable, optimal integration of AI into pedagogical practices.

Technological "Hybridization"

When examining the intentions of AI system designers, the concept of technological counterpoint highlights the automated integration between symbolic and statistical AI. A notable example is the neurosymbolic approach implemented by OpenAI and Wolfram in ChatGPT. In the following, we aim to compare ChatGPT's standalone performance with that of this type of "hybridized" system.

Let's be clear: when doing mathematics with ChatGPT, it can be misleading. It gives the illusion of performing genuine mathematical work, but this is not truly the case. For example, if we pose the following problem to the system:

Prove that a quadrilateral with three right angles is a rectangle, ChatGPT provides a solution (Fig. 3, left) derived from its training data. When we repeat the question immediately afterward (Fig. 3, right), its response changes because it now uses the prior context (our first question and its solution) as additional contextual input. This creates a form of learning by the system, where contextual inferences help maintain continuity in the conversation.

To prove that a quadrilateral with three right angles is a rectangle, let's use the properties of quadrilaterals and their internal angles.

Step 1: Recall the properties of a quadrilateral's angles

A quadrilateral is a closed figure with four sides, and the sum of its internal angles is always 360°.

Step 2: Hypothesis

Let's assume that quadrilateral $ABCD$ has three right angles:

- $\angle A = 90^\circ$
- $\angle B = 90^\circ$
- $\angle C = 90^\circ$

Step 3: Calculate the missing angle

Since the sum of the angles in a quadrilateral is 360°, the angle $\angle D$ can be calculated as follows:

$$\angle D = 360^\circ - (\angle A + \angle B + \angle C) = 360^\circ - (90^\circ + 90^\circ + 90^\circ) = 90^\circ$$

Thus, $\angle D = 90^\circ$.

Step 4: Conclusion

We have shown that all four angles of the quadrilateral $ABCD$ are 90°. By definition, a quadrilateral with four right angles is a **rectangle**.

Final Conclusion

A quadrilateral with three right angles must be a rectangle because the fourth angle also has to be a right angle to make the sum of the angles 360°.

To demonstrate that a quadrilateral with three right angles is a rectangle, we will proceed with the following steps:

Statement

Consider a quadrilateral $ABCD$ such that angles $\angle A$, $\angle B$, and $\angle C$ are right angles. We need to prove that $ABCD$ is a rectangle.

Proof

1. **Properties of the angles:**
   - By assumption, we know that:
   $$\angle A = 90^\circ, \quad \angle B = 90^\circ, \quad \angle C = 90^\circ.$$
2. **Calculating angle D:**
   - The sum of the angles in a quadrilateral is 360°. Therefore, we can write:
   $$\angle A + \angle B + \angle C + \angle D = 360^\circ.$$
   - Substituting the known values, we get:
   $$90^\circ + 90^\circ + 90^\circ + \angle D = 360^\circ.$$
   - This implies:
   $$270^\circ + \angle D = 360^\circ \quad \Rightarrow \quad \angle D = 360^\circ - 270^\circ = 90^\circ.$$
3. **Conclusion about the angles:**
   - We have shown that:
   $$\angle D = 90^\circ.$$
   - Thus, all angles of the quadrilateral $ABCD$ are right angles.
4. **Properties of the sides:**
   - In a quadrilateral with all right angles, opposite sides are parallel and equal in length. Indeed, by definition, a quadrilateral is a rectangle if and only if it has four right angles and opposite sides that are parallel.
   - Since we have already proven that $ABCD$ has four right angles, we can conclude that $ABCD$ is a rectangle.

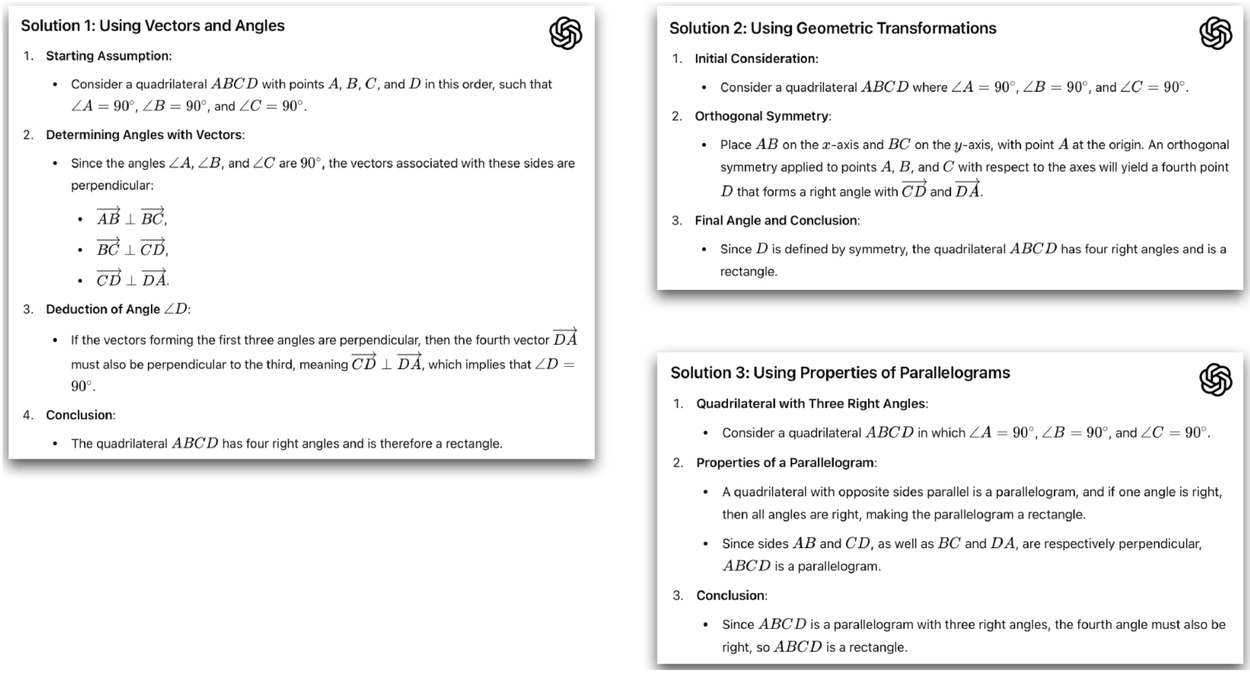
Conclusion

The quadrilateral $ABCD$ with three right angles (and thus four right angles) is a rectangle.

Therefore, we have shown that any quadrilateral with three right angles is necessarily a rectangle.

Figure 3: First and second requests to ChatGPT for the rectangle problem.

Although the problem itself is relatively simple, ChatGPT's responses reveal two key aspects. In the first instance (first request), the solution appears well structured, almost textbook-like, with mathematical elements (angles, the property of the sum of a quadrilateral's angles, the equation to calculate the missing angle, the definition of a rectangle, etc.) and metamathematics elements (initial hypothesis, recall of geometric properties, logical steps in reasoning, "final conclusion" as a general reasoning) that seem appropriate for the problem. However, when the question is repeated (second request), instead of confirming its initial solution or exploring alternatives, ChatGPT adds contextual arguments that, while seems true, are unnecessary. This behaviour resembles the *comportement heuristique* observed in mathematics education research, where students employ heuristic strategies while attempting to solve proof problems (Richard, 2004) or when they "say everything they know" on an exam to gain points. When explicitly asked for three different solutions (Figure 4), ChatGPT generates responses that use vectors and angles, geometric transformations, and parallelogram properties—an impressive variety, but how reliable are these?



Solution 1: Using Vectors and Angles

1. **Starting Assumption:**
   - Consider a quadrilateral $ABCD$ with points A, B, C, and D in this order, such that $\angle A = 90^\circ$, $\angle B = 90^\circ$, and $\angle C = 90^\circ$.
2. **Determining Angles with Vectors:**
   - Since the angles $\angle A$, $\angle B$, and $\angle C$ are 90°, the vectors associated with these sides are perpendicular:
     - $\overrightarrow{AB} \perp \overrightarrow{BC}$,
     - $\overrightarrow{BC} \perp \overrightarrow{CD}$,
     - $\overrightarrow{CD} \perp \overrightarrow{DA}$.
3. **Deduction of Angle $\angle D$:**
   - If the vectors forming the first three angles are perpendicular, then the fourth vector $\overrightarrow{DA}$ must also be perpendicular to the third, meaning $\overrightarrow{CD} \perp \overrightarrow{DA}$, which implies that $\angle D = 90^\circ$.
4. **Conclusion:**
   - The quadrilateral $ABCD$ has four right angles and is therefore a rectangle.

Solution 2: Using Geometric Transformations

1. **Initial Consideration:**
   - Consider a quadrilateral $ABCD$ where $\angle A = 90^\circ$, $\angle B = 90^\circ$, and $\angle C = 90^\circ$.
2. **Orthogonal Symmetry:**
   - Place AB on the x-axis and BC on the y-axis, with point A at the origin. An orthogonal symmetry applied to points A, B, and C with respect to the axes will yield a fourth point D that forms a right angle with $\overrightarrow{CD}$ and $\overrightarrow{DA}$.
3. **Final Angle and Conclusion:**
   - Since D is defined by symmetry, the quadrilateral $ABCD$ has four right angles and is a rectangle.

Solution 3: Using Properties of Parallelograms

1. **Quadrilateral with Three Right Angles:**
   - Consider a quadrilateral $ABCD$ in which $\angle A = 90^\circ$, $\angle B = 90^\circ$, and $\angle C = 90^\circ$.
2. **Properties of a Parallelogram:**
   - A quadrilateral with opposite sides parallel is a parallelogram, and if one angle is right, then all angles are right, making the parallelogram a rectangle.
   - Since sides AB and CD, as well as BC and DA, are respectively perpendicular, $ABCD$ is a parallelogram.
3. **Conclusion:**
   - Since $ABCD$ is a parallelogram with three right angles, the fourth angle must also be right, so $ABCD$ is a rectangle.

Figure 4: Requesting three different solutions from ChatGPT for the rectangle problem.

To understand how ChatGPT "reasons" in mathematical contexts, it becomes evident that it generates solutions based on identifying patterns and utilizing knowledge derived from text data within its training set. Rather than performing calculations or deductive reasoning, ChatGPT combines mathematical rules and examples it has "learned" from text exposure, but it does not employ symbolic engines like like Wolfram Mathematica or Maple for validation or calculation.

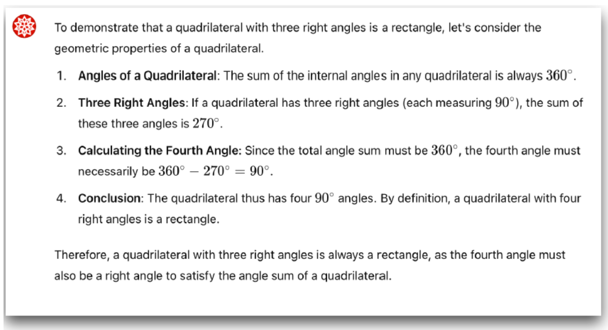
This approach has significant limitations. First, ChatGPT lacks exact calculations and real-time validation, meaning it does not verify each step as a symbolic tool would, which can lead to errors, particularly in complex calculations or advanced logical steps. As a result, ChatGPT's solutions are often plausible but remain unverified, offering logical coherence but risking inaccuracies, especially in complex or ambiguous cases.

A closer look at its inferential processes shows that ChatGPT's "deductive reasoning" is closer to inductive inference, as it primarily relies on pattern recognition to produce responses that are relevant yet unverified. This contrasts with tools like WolframAlpha, GeoGebra Discovery, and other Computer Algebra Systems (CAS) that offer validation mechanisms. WolframAlpha combines CAS functionality with numerical and statistical tools, while GeoGebra Discovery uniquely integrates CAS with automated reasoning for symbolic AI, particularly in geometry. Unlike these tools, ChatGPT alone does not provide a mathematical validation, depending instead on unverified inductive patterns rather than formal, symbolic deduction.

This tendency to make non-deductive deductions or to combine deductive fragments derived from training data in problems that have already been solved poses several problems. By blending different types of rationality, such as those found in experimental sciences versus mathematics, ChatGPT creates a confusion that can lead to significant challenges. For example, induction is useful for identifying invariants, models or conceptualizing categories, but its validation is an experimental matter and generally requires further research or long-term studies to stand the test of time. In other words, induction is not designed to produce necessary truths from established truths, as deductive reasoning does, nor to articulate knowledge that necessarily follows from other knowledge, as is expected in mathematics.

Moreover, when ChatGPT uses abduction, it can generate creative responses and explore potential solutions based on partial information, fostering interaction and opening up avenues of inquiry, while also mitigating the “blank page” effect. However, these abductive responses can be misleading by giving an impression of certainty, when in fact they are merely unverified hypotheses that require additional validation to ensure their accuracy.

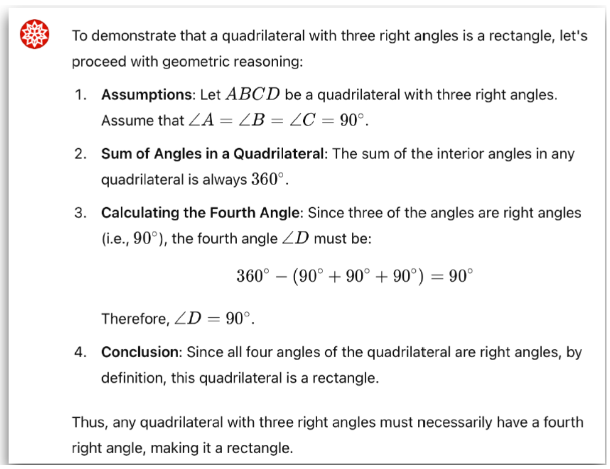
Paradoxically, a deeper understanding of how this AI functions allows us to tackle real problems and engage in an authentic modelling process, thereby moving away from often artificial school exercises. This approach recentres exploration and scientific inquiry—essential elements of learning that align with the natural curiosity of students, especially given the new possibilities offered by digital tools. However, this openness may unsettle inexperienced teachers, who might feel a loss of control over their students’ learning due to the element of uncertainty introduced. Should we then prioritize the student’s curiosity or the teacher’s need for control?



To demonstrate that a quadrilateral with three right angles is a rectangle, let's consider the geometric properties of a quadrilateral.

1. **Angles of a Quadrilateral**: The sum of the internal angles in any quadrilateral is always 360°.
2. **Three Right Angles**: If a quadrilateral has three right angles (each measuring 90°), the sum of these three angles is 270°.
3. **Calculating the Fourth Angle**: Since the total angle sum must be 360°, the fourth angle must necessarily be $360^\circ - 270^\circ = 90^\circ$.
4. **Conclusion**: The quadrilateral thus has four 90° angles. By definition, a quadrilateral with four right angles is a rectangle.

Therefore, a quadrilateral with three right angles is always a rectangle, as the fourth angle must also be a right angle to satisfy the angle sum of a quadrilateral.



To demonstrate that a quadrilateral with three right angles is a rectangle, let's proceed with geometric reasoning:

1. **Assumptions**: Let $ABCD$ be a quadrilateral with three right angles. Assume that $\angle A = \angle B = \angle C = 90^\circ$.
2. **Sum of Angles in a Quadrilateral**: The sum of the interior angles in any quadrilateral is always 360°.
3. **Calculating the Fourth Angle**: Since three of the angles are right angles (i.e., 90°), the fourth angle $\angle D$ must be:

$$360^\circ - (90^\circ + 90^\circ + 90^\circ) = 90^\circ$$

Therefore, $\angle D = 90^\circ$.

4. **Conclusion**: Since all four angles of the quadrilateral are right angles, by definition, this quadrilateral is a rectangle.

Thus, any quadrilateral with three right angles must necessarily have a fourth right angle, making it a rectangle.

Figure 5: Rectangle problem, first and second requests with ChatGPT + Wolfram.

With the neurosymbolic technological counterpoint provided by the integration of ChatGPT and Wolfram, new dynamics emerge in mathematical reasoning and problem-solving (see Fig. 5). This “hybrid” model combines the precision of symbolic AI (Wolfram’s computational engine) with the generative flexibility of ChatGPT’s large language model. However, achieving coherence between these two approaches introduces distinct challenges, especially around communication, interpretation, and validity, where human input plays a central role.

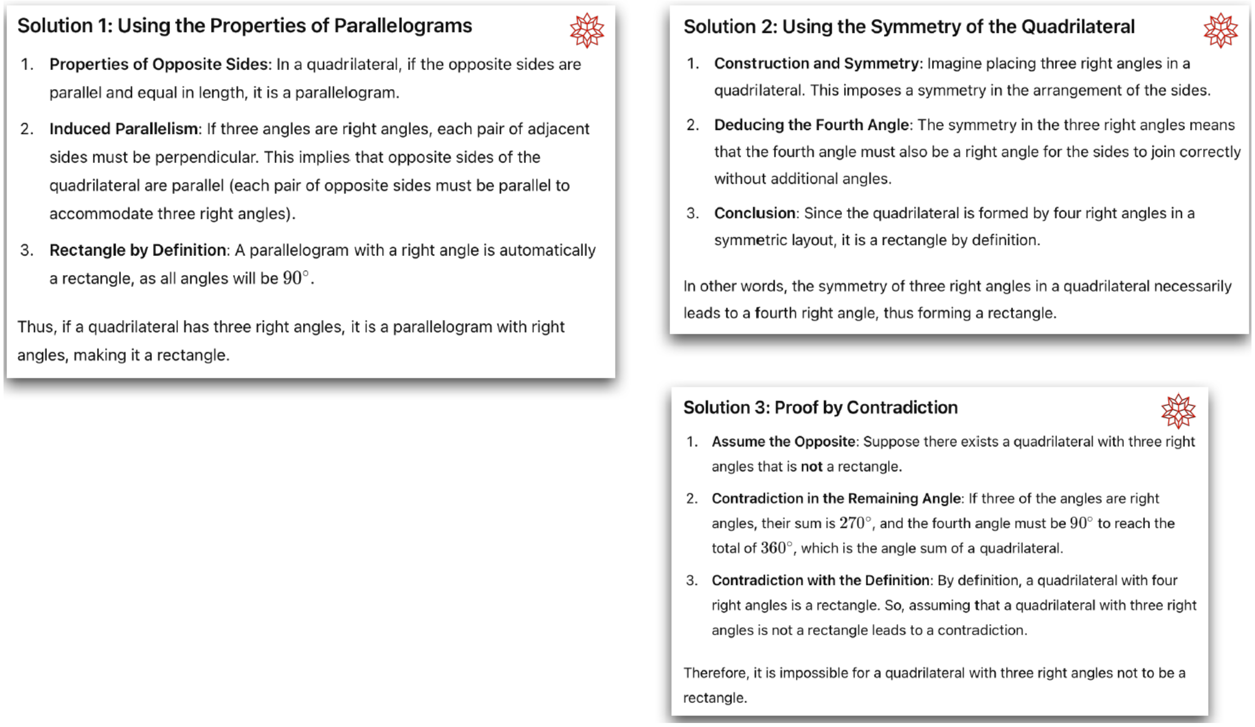
Firstly, effective integration relies heavily on clarity in questioning, where the user’s role is crucial. The phrasing, precision, and structure of the user’s question directly influence ChatGPT’s interpretation and the subsequent instructions it sends to Wolfram. For instance, if a user ambiguously asks for multiple proofs of a geometric property, ChatGPT may interpret this in ways that don’t align with the structured, symbolic expectations of Wolfram’s system. The user, therefore, must provide carefully framed questions, guiding ChatGPT to relay mathematically precise requests to Wolfram, minimizing ambiguity and maximizing alignment between the systems. This is a typical case of the quest for idoneity in which scientific questioning is at the heart of the approach. Secondly, interpretation by ChatGPT introduces another layer where human oversight is beneficial. ChatGPT's pattern recognition generates responses based on linguistic data and probabilistic associations from its training, yet it lacks formal verification for each logical step. Human users must be prepared to guide ChatGPT toward interpretations that are contextually relevant for Wolfram's symbolic processing. For example, while ChatGPT might generate additional contextual information that is linguistically coherent, human oversight can help filter out unnecessary content that doesn't contribute to the mathematical precision required by Wolfram. This interaction requires users to understand potential interpretive gaps and adjust their input for reliable outputs.

Ensuring validity within this neurosymbolic integration hinges on the verification methods designed by developers, but also on human interaction during validation. Wolfram's computational engine provides verified mathematical outputs, yet when combined with ChatGPT's generative responses, unverified elements may arise. Human users play a vital role here, reviewing and assessing the outputs for coherence and accuracy, especially in complex or ambiguous queries. This oversight helps bridge the flexibility of generative responses with the strict validation of symbolic AI, guiding the combined system toward reliable and rigorous outcomes. The integration of ChatGPT and Wolfram offers a powerful tool for mathematical inquiry, blending exploratory reasoning with computational rigour. However, the human role in questioning, interpreting, and validating remains essential to navigate the system's interpretive boundaries and to ensure coherent and accurate outputs.

ChatGPT alone provides a step-by-step solution, including a recall of geometric properties and a progressive reasoning process that makes the solution more "pedagogical." This approach includes metamathematical elements such as the initial hypothesis, the reasoning logic, and a general conclusion, making the reasoning relatively accessible to learners. In fact, this is not necessarily a drawback in itself, especially considering that, in a mathematics classroom, both human argumentative reasoning and deductive reasoning with calculations are typically present. However, as ChatGPT relies solely on probabilistic models, the solution lacks formal validation, introducing a latent uncertainty or a low epistemic value.

With the integration of Wolfram, the solution becomes more concise and benefits from rigorous mathematical validation through symbolic computation. Wolfram enhances the accuracy and reliability of calculations, but the presentation adopts a more demonstrative style, focusing on results rather than intermediate "pedagogical" explanations. Consequently, while this approach is mathematically more precise, it may be less clear for beginner learners who wish to understand each step of the reasoning process.

In summary, ChatGPT alone provides a step-by-step reasoning process that can help learners visualize the logical progression in a mathematical solution. However, in the absence of formal validation, this approach carries the risk of errors and inaccuracies, particularly for more complex problems. ChatGPT with Wolfram, on the other hand, incorporates formal mathematical verification that ensures the rigour of calculations and conclusions, though it may be less detailed in explaining intermediate steps. For situations where mathematical precision is essential, integration with Wolfram offers a more reliable and rigorous solution, and it can serve as a model for correct mathematical reasoning, though it may sometimes require additional work to elaborate the complete reasoning pathway for learners.



Solution 1: Using the Properties of Parallelograms

1. **Properties of Opposite Sides**: In a quadrilateral, if the opposite sides are parallel and equal in length, it is a parallelogram.
2. **Induced Parallelism**: If three angles are right angles, each pair of adjacent sides must be perpendicular. This implies that opposite sides of the quadrilateral are parallel (each pair of opposite sides must be parallel to accommodate three right angles).
3. **Rectangle by Definition**: A parallelogram with a right angle is automatically a rectangle, as all angles will be 90°.

Thus, if a quadrilateral has three right angles, it is a parallelogram with right angles, making it a rectangle.

Solution 2: Using the Symmetry of the Quadrilateral

1. **Construction and Symmetry**: Imagine placing three right angles in a quadrilateral. This imposes a symmetry in the arrangement of the sides.
2. **Deducing the Fourth Angle**: The symmetry in the three right angles means that the fourth angle must also be a right angle for the sides to join correctly without additional angles.
3. **Conclusion**: Since the quadrilateral is formed by four right angles in a symmetric layout, it is a rectangle by definition.

In other words, the symmetry of three right angles in a quadrilateral necessarily leads to a fourth right angle, thus forming a rectangle.

Solution 3: Proof by Contradiction

1. **Assume the Opposite**: Suppose there exists a quadrilateral with three right angles that is **not** a rectangle.
2. **Contradiction in the Remaining Angle**: If three of the angles are right angles, their sum is 270°, and the fourth angle must be 90° to reach the total of 360°, which is the angle sum of a quadrilateral.
3. **Contradiction with the Definition**: By definition, a quadrilateral with four right angles is a rectangle. So, assuming that a quadrilateral with three right angles is not a rectangle leads to a contradiction.

Therefore, it is impossible for a quadrilateral with three right angles not to be a rectangle.

Figure 6: Three solution requests to ChatGPT + Wolfram for the rectangle problem.

Comparing the three solutions proposed by ChatGPT alone (Fig. 4) and by ChatGPT with Wolfram (Fig. 6), we observe notable differences in terms of reasoning depth and diversity of geometric approaches. ChatGPT alone employs several methods, such as the use of angles and the properties of parallelograms, thereby offering solutions that evoke direct methods. In contrast, ChatGPT with Wolfram demonstrates increased rigour by adopting various geometric frameworks, notably moving from synthetic geometry to vector geometry, and by incorporating reductio ad absurdum arguments similar to those found abundantly in the original Elements of Euclid, prior to the introduction of algebraic calculation in subsequent versions. This flexibility in approach and the ability to rigorously validate each step through symbolic calculations confer a higher epistemic value and greater adaptability to the solutions provided by ChatGPT with Wolfram, allowing for a deeper exploration of mathematical concepts and processes while ensuring accuracy.

Inspiring Examples of Technological Counterpoint and AI Classification for ME

AlphaGeometry exemplifies a remarkable case of technological hybridization, showcasing substantial progress in solving geometric theorems. This neurosymbolic system combines a language model trained on synthetic data with a symbolic deduction engine, allowing it to navigate the “infinite space” of possible solution graphs in plane geometry. AlphaGeometry addresses one of the greatest challenges in AI for mathematics: the synthesis of human proof data into machine-verifiable languages, a problem reminiscent of the concept of computational transposition (Balacheff, 1994). With a massive set of 100 million automatically generated theorems, AlphaGeometry produces human-readable proofs and even solves problems at the Olympic level, marking a step toward high-level automated reasoning in a field where rigour is essential (Trinh, Wu, Le, et al., 2024). For comparison, Euclid's *Elements* contains approximately 465 propositions. While these propositions are meaningful condensations derived from human culture, many of AlphaGeometry's properties hold no epistemological value.

Although this example is not directly related to mathematics, it illustrates the resurgence of expert systems fuelled by advancements in generative AI (e.g., Trafton, 2019; Fearn, 2024). Machine translation systems, for instance, exemplify a technological counterpoint where expert systems and generative models work together to interpret and translate content across multiple languages. MIT is currently developing a hybrid architecture that combines symbolic and statistical AI, allowing machines to simulate "reasoning" about complex relationships with less data by integrating perception, language, and reasoning modules for more nuanced interpretations. In truth, the machine only simulates reasoning to some extent; it does not truly reason in the human sense of the term and is incapable of doing so. This hybridization leverages the efficiency of expert models, which provide linguistic precision in specialized fields, alongside the flexibility of generative models, which capture broader contextual nuances. Such architectures apply beyond translation to other areas requiring advanced cognitive functions, where AI can approximate a deeper understanding through a synergy of statistical approaches and symbolic reasoning.

The QED-Tutrix system provides an innovative approach in AI-powered tutoring for mathematical proofs, focusing on enhancing human learning. As described by Font, Gagnon, Leduc, and Richard (2022), QED-Tutrix operates as an intelligent tutoring system, modelling knowledge and reasoning to support learners in understanding mathematical justifications. This kind of AI system plays a vital role in mathematics education by simulating interactive sessions where students can practise proof techniques, gradually mastering the logic and procedural steps necessary for complex problem-solving. Although promising, such systems require ongoing funding, especially in regions like Canada, to reach their full potential and expand their applications in AI-assisted learning.

According to Van Vaerenbergh and Pérez-Suay (2022), AI systems for mathematics education can be classified into four categories: information extractors, reasoning engines, explainers, and data modelling systems. These categories reflect the various ways in which AI supports mathematical learning: information extractors transform raw data into usable mathematical representations, reasoning engines, such as WolframAlpha, solve complex problems, explainer breakdown solutions to facilitate understanding, and data modelling systems personalize learning by analyzing student interactions.

This classification highlights how each type of AI can enhance mathematics education according to specific needs. Reasoning engines provide precise answers, while explainers help make these answers accessible, fostering a deeper understanding. By combining these tools, students strengthen their autonomy and actively engage with mathematical concepts.

This categorization also supports the integration of AI within the technological counterpoint framework, providing teachers with a structured foundation for selecting AI tools that align with learning objectives and student profiles, thereby enriching the educational experience.

Implications and Challenges for the Future

In the era of new mathematical work, it is clear that in-depth studies on technological counterpoint involving human learners are essential. However, the rapid growth of computing and the utilitarian ideology often present in the field of AI developers—who are eager to decide alone on orientations and applications—raise critical questions for mathematics education. This movement risks overlooking the complexity of human learning and the pedagogical dynamics necessary for a thoughtful integration of AI with our students. By prioritizing efficiency and automation over scientific inquiry and the cultivation of critical thinking, we risk creating powerful tools that address learners' educational needs only indirectly, with validity based solely on action itself. The absence of dialogue with researchers in didactics and mathematics education could also lead to AI systems poorly suited to the diversity of learning contexts, thereby limiting their educational impact to narrow usage considerations. Yet, mathematics education plays a central role in AI development, dating back to the rise of cognitive sciences in the 1980s. Enhancing intelligence within the framework of new mathematical work necessarily requires modelling knowledge and reasoning that can be implemented in today's digital tools.

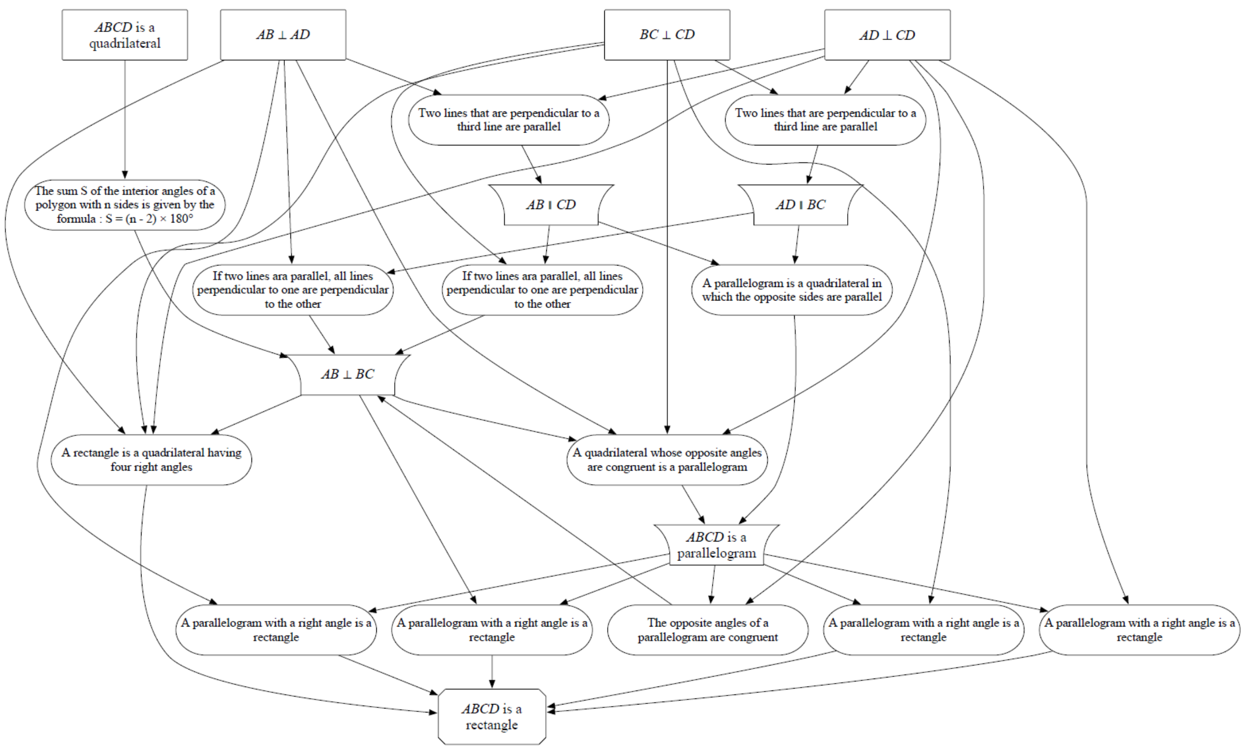


Figure 7: The QED-Tutrix rectangle problem solution graph (Richard, Gagnon, & Fortuny, 2018).

Imagine for a moment that the QED-Tutrix project receives funding and a team of researchers in mathematics education and computer engineering is reassembled. As mentioned in the previous section, QED-Tutrix is an intelligent tutoring system designed to support students in solving complex geometry proof problems. Unlike AlphaGeometry or ChatGPT + Wolfram, QED-Tutrix was created to facilitate students' understanding of geometric reasoning by enabling them to explore, articulate, and validate their problem-solving processes through guided interactions. While reasoning engines can solve mathematical problems and generate correct proofs, they do not necessarily produce results that are accessible to human understanding. Since QED-Tutrix is intended for mathematics education and needs to produce messages when students encounter blocks in the proof-solving process, an approach was required in which each step of the reasoning is known or accessible in some way by the computer system. This is why, at its core, the system models students' thought processes and provides feedback based on an extensive memory of problem-solving steps (Fig. 7), allowing it to guide students out of impasses by suggesting connected problems that enhance understanding without simply providing solutions (Richard, Gagnon, & Fortuny, 2018).

A unique feature of QED-Tutrix is its focus on enhancing mathematical competence by positioning problem-solving as a fundamental skill. Leveraging a comprehensive database of potential solution paths, it aims to simulate a teacher's ability to provide contextually relevant hints and feedback. The system encourages students to analyze and synthesize geometric properties, ultimately empowering them to construct proofs independently. However, QED-Tutrix's development also underscores certain challenges, particularly the need for funding and additional research to expand its capabilities in adaptive learning and AI-supported education.

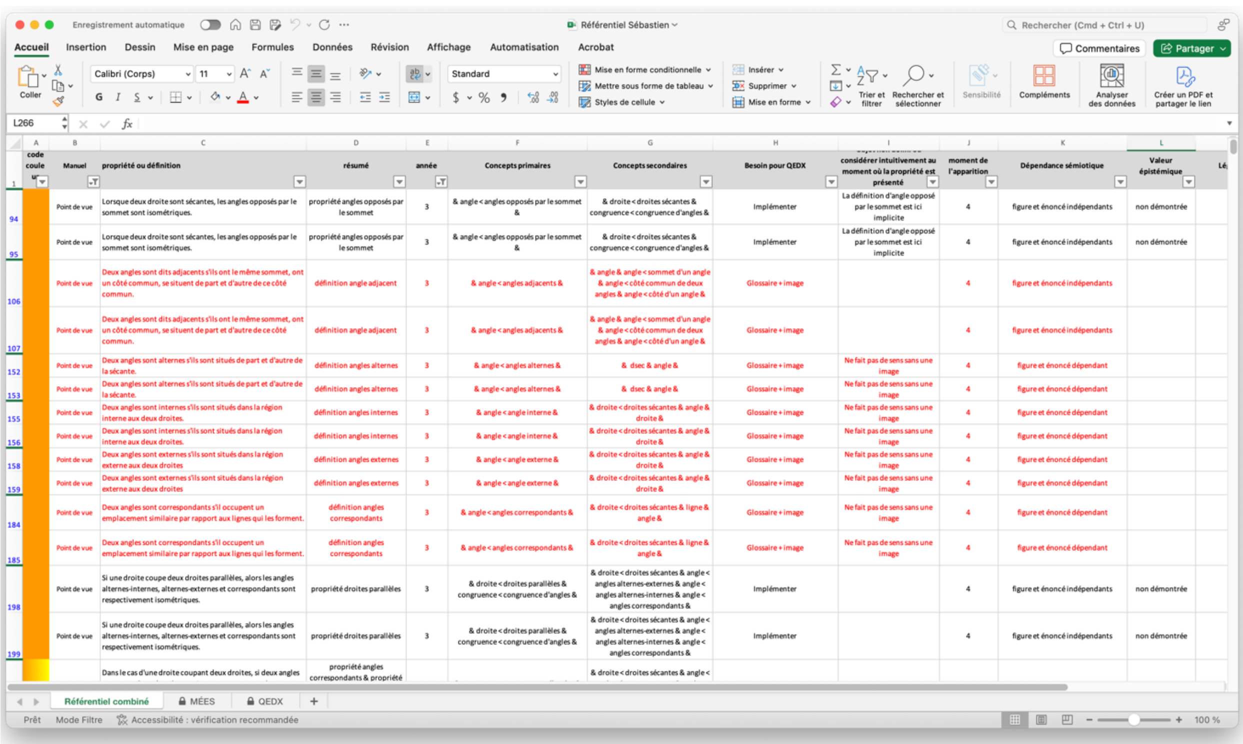

Figure 8: Repository of geometry referential used in Quebec school textbooks and official documents for the creation of a common referential framework for implementation in the QED-Tutrix system (Cyr, 2018).

Looking to the future, QED-Tutrix aims to enrich the pedagogical experience by becoming more adept at identifying student needs and responding with customized prompts and connected problems, thereby fostering an integrated learning environment. Although this approach has not yet been fully implemented, generative models and large language models (LLMs) could provide substantial support. These technologies could not only facilitate human-machine communication but also help the system to accommodate the varied formulations of mathematical properties and definitions encountered in Quebec classrooms and beyond. For example, Cyr (2022) has already documented numerous variations found in official documents and various textbooks, both old and new (Fig. 8). By using AI to identify a representative for each definition or property—acting as a class representative in an internally unified referential—the system can adapt to different learning environments, operating with a streamlined solution graph that respects each classroom's didactic contract. This approach allows QED-Tutrix to preserve unique inferential shortcuts and familiar styles of formulation without compromising rigour.

This methodology is well aligned with the educational objectives of mathematics didactics, aiming to foster a richer, interactive environment where technology and human learning intersect dynamically through projects and purposeful tasks. As a member of the ThEDU community (see below), QED-Tutrix is positioned within a network dedicated to advancing educational technology, particularly in enhancing mathematical reasoning through digital tools, and serves as an intelligent tutoring system for the teaching and learning of mathematical proofs.

The Xena Project, founded by Kevin Buzzard at Imperial College London, introduces mathematicians, particularly undergraduate students, to the use of Lean for formal verification of mathematical proofs. This software is based on the calculus of constructions with inductive types, enabling not only the formalization of deductive reasoning but also the modelling of inductive structures, which are essential in mathematical exploration and discovery. By transforming proofs into a kind of interactive game, it makes each theorem computer-verifiable through the mathlib library, integrating rigorously structured reasoning steps. This approach provides a technological counterpoint to large language models like ChatGPT, which Buzzard compares to students who "know a lot but do not think for themselves." Unlike LLMs, Lean follows a verifiable, step-by-step proof logic, combining the rigour of formal and inductive systems from computer science to enrich mathematical learning and enhance understanding.

ThEDU (Theorem proving and Automated Deduction in Education) is a community dedicated to integrating automated theorem proving and deduction in the field of education (Quaresma, 2022). Its objective is to promote the development and application of systems capable of verifying, proving, and exploring mathematical statements within an educational context. ThEDU supports the creation of educational software that leverages automated proof techniques to enhance learning in mathematics and logic, facilitating students' understanding of proof concepts and rigorous reasoning. The community organizes academic events, such as workshops, to bring together researchers and practitioners around the latest advances in educational AI and proof systems.

In conclusion, while large language models and symbolic AI systems represent significant advancements in computational capability, they are not inherently suited for authentic mathematical work. Despite drawing from an extensive knowledge base, these models lack the structured, autonomous reasoning and control essential for genuine, dialectical mathematical learning—one that actively responds to the learner's questioning and fosters the creation of meaningful knowledge. As we navigate an era of rapid computational evolution, the integration of technological counterpoints, where symbolic and statistical AI work in tandem, offers valuable support but may still fall short of addressing these intrinsic limitations. It is essential that humans act as "chefs d'orchestre" of this technological counterpoint, steering its design and applications to meet specific didactic needs and countering the utilitarian ideologies that often drive AI development. By prioritizing a collaborative, human-centered approach, we can foster a new generation of critical thinkers who not only engage deeply with mathematical concepts but also uphold the primacy of human reasoning in mathematics education.

The illusion of creativity in ChatGPT arises from its ability to establish unexpected connections based on data produced by humans. Novelty, as envisioned in the principle of idoneity, thus becomes an essential reference that influences new mathematical work. It is worth recalling that the concept of idoneity, introduced by Ferdinand Gonseth, proposes an innovative approach in the philosophy of science, particularly for analyzing the relationship between established reference frameworks and the evolution of knowledge. According to Gonseth, these frameworks are not fixed structures; they must be continuously adapted to new experiences and discoveries. Although statistical AI attempts to mimic this adaptive process, it fails to exercise conscious control over these adjustments. Rather than seeking absolute and immutable foundations, we should adopt flexible approaches that allow knowledge to advance in step with ongoing developments. For humans, this implies a "strategy of engagement": an active approach open to uncertainty, in contrast to the often rigid predictive methods, thus valuing adaptability, whether to explore scientific truth or simply to learn how to formulate and solve problems. Understanding the emergence of new ideas, and particularly those with real value, remains complex; yet it is precisely what we must aim for, even as we take into account the contributions and limitations of AI and other technological counterpoints.

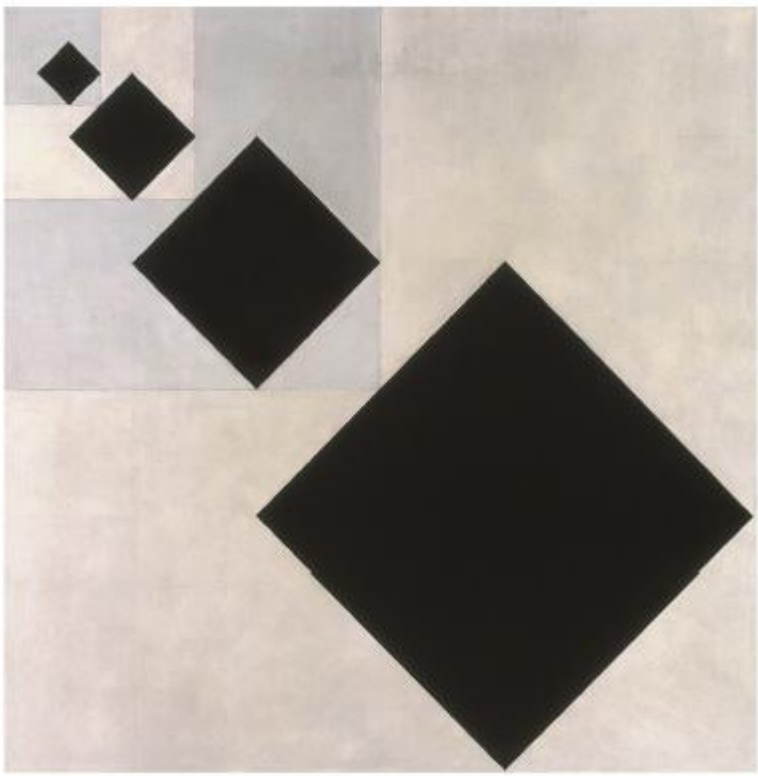
Condensed version of the initial questionnaire.

Mathematical Exploration: Abstract Harmonies in Visual Art

To answer the following questions, you may use the conversational agent ChatGPT or the dynamic mathematics software GéoGébra, at any time, which includes interactive geometry modules and automated reasoning tools.

Exercise 1 *Face-to-Face with Plasticism*

Here is an **image**:



Here is a **problem situation**:

When observing Theo Van Doesburg's Arithmetic Composition (image above), an abstract painting created in 1929-1930 during the neoplasticism period, visible regularities are noticeable. Black, white, and gray squares are arranged with varying dimensions and intervals, evoking a sense of recursion.

Our aim is to understand and explain the mathematical aspects that visually emerge in this artwork before delving into the artist's motivations behind choosing these abstract harmonies.

1. Check if ChatGPT contains information on Theo Van Doesburg's Arithmetic Composition, then compare it with information obtained through a search engine like Google.

2. Describe the visual properties that emerge from Arithmetic Composition. Use ChatGPT for assistance if needed.

3. Share the observed properties of Arithmetic Composition with another team. Compare the methods of direct observation with those using ChatGPT, highlighting the formulation of questions and the responses obtained.

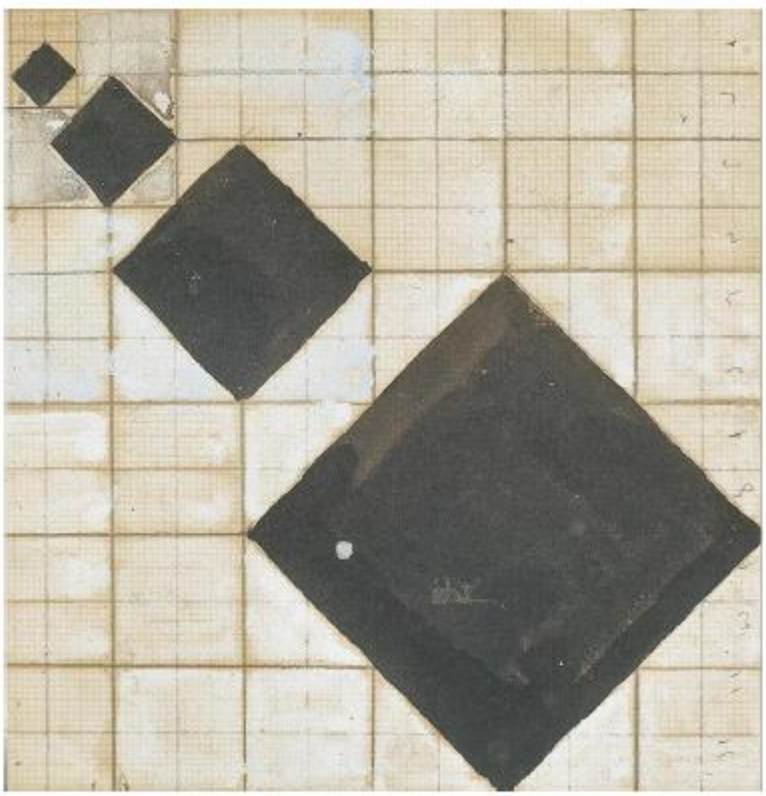
4. Examine if ChatGPT has information from a direct analysis of Theo Van Doesburg's Arithmetic Composition, excluding peripheral data. Explain your approach.

5. Evaluate the usefulness of ChatGPT in its interaction, taking into account its reasoning abilities, its influence on knowledge development, and the advantages and limitations related to its dependence on training data.

6. Explain the significance of the statement, "ChatGPT can make mistakes. Remember to verify important information."

Exercise 2 *Geometric Sequence*

Here is a **sketch**:



Here is the continuation of the **problem situation**:

> It's easy to imagine that creating such a balanced work as Arithmetic Composition required a series of preliminary trials. A sketch, drawn on graph paper and measuring 12 cm per side, has been preserved, though we do not know if it was a draft or a communication tool once the work was completed.

> It's easy to imagine that creating such a balanced work as Arithmetic Composition required a series of preliminary trials. A sketch, drawn on graph paper and measuring 12 cm per side, has been preserved, though we do not know if it was a draft or a communication tool once the work was completed.

1. Are all squares, when taken in pairs, necessarily in a Thales' configuration? Verify this property in general using ChatGPT, and indicate the necessary condition for a Thales' configuration.

2. In the sketch of Arithmetic Composition, it is easy to see that the vertices of the black squares are carefully placed on grid nodes.

- **a)** Why are the "black diamonds" actually squares? Justify your answer.
- **b)** In the file Exercise 2-2b.ggb, points A to H and Z have been fixed on grid nodes. Using the "Relation" tool (on the side), or the command `Relation(a, e)` in the input bar, verify whether the configuration involving Z, [AB], and [EF] constitutes a Thales' configuration, and confirm why this is the case.
- **c)** In the input bar, enter the command `AreParallel(a, e)` and note the result. When compared with previous answers from the "Relation" tool, the software returns "true," "are parallel (evaluated by calculation)," and "are parallel (generally false)." What explains these differences?
- **d)** Calculate the scaling ratios k and ℓ that allow one measurement to be converted into another, specifically "side: AB $\xrightarrow{k}$ EF" and "area: ABCD $\xrightarrow{\ell}$ EFGB".
- **e)** In the previous file, place vertices I(8, 0), J(12, 4), K(8, 8), and L(4, 4) of the large black square, as well as the centers M(4, 8) and N(8, 4) of squares EFGH and IJKL. The lines (MN) and (FL) intersect at point O.
  Calculate the ratio $\frac{OM}{ON}$ and find a significance for point O between the two squares.

3. Looking closely at the paper, we note that the numbers from 1 to 12 are written on the right, suggesting that the author deliberately chose this number. Additionally, using thicker lines, it seems that he grouped the squares on the sheet by "three" to form "┘"shapes, as seen in the artwork itself.

- **a)** Why would a 12 cm grid have been chosen? What purpose might grouping by three serve? Justify your reasoning.
- **b)** Discuss the possibility of extending the construction of black squares indefinitely on the sheet, whether or not this is related to Theo Van Doesburg's grid.

4. We are interested in the largest square that can be inscribed in a triangle.

   a) If 4 points are placed on the sides of a triangle, must at least two points be on the same side? What mathematical property applies in this case?

   b) In Arithmetic Composition, we notice that the large black square is inscribed within half of the grid square. Is this the largest square that can be inscribed in an isosceles right triangle? Demonstrate your reasoning.

Generated by Bing Image Creator.

5. A teacher asserts that for a square inscribed in a triangle with base b and height h, the area of the square is maximal when the side of the square measures $\frac{b \times h}{b + h}$. Is this possible? Prove or refute this assertion using two different methods from the following options:

   i. Discussing the problem with ChatGPT to reach a convergent conclusion;

   ii. Using traditional dynamic geometry through numerical models;

   iii. Utilizing automated reasoning tools or CAS commands;

   iv. A manual approach in the paper and pencil environment, without the use of instrumented mathematical devices (such as ChatGPT, GGB, ART, etc. 🤭) showing through in the written solution 🤔.

RESEARCH AND THE NEW AI TOOLS MEET FACE TO FACE: TAKING ADVANTAGE OF WHAT WE KNOW ABOUT THE LEARNING OF MATHEMATICS

Teresa Rojano
Mathematics Education Department, Cinvestav, México
trojano@cinvestav.mx

This article aims to acknowledge the role played by the findings of mathematics education research in the development of technology learning environments, especially when AI components are incorporated. Reference is made to two examples that illustrate how knowledge of students' mathematical thinking processes enables anticipating critical moments in the understanding of concepts or in the resolution of mathematical tasks. The examples also illustrate how such possibility of anticipation is a fundamental element in didactic designs that include intelligent support for providing pupils with feedback on their performance within the learning environment.

Introduction

After four decades of research in mathematics education, one finds an enormous amount of accumulated knowledge about the nature of the difficulties students face in understanding concepts and developing skills in different areas of mathematics. Access to digital technologies for personal use made some researchers -the undersigned included- consider them as tools to create learning environments. It would be impossible here -in this space- to give a fair accounting of the different programs and devices with which studies and experiments have been carried out for the purpose of delving into the potential of those technologies. Their potential, that is, to help students overcome didactic and epistemological obstacles that make it difficult for them to understand concepts and develop mathematical skills. However, it is worth mentioning that in addition to supporting students in facing such difficulties, programs such as Logo, Scratch, Spreadsheets, Computer Algebra Systems, Dynamic Geometry (in versions of Cabri Géomètre, Geometer Sketchpad and Geogebra) have given rise to didactic designs that encourage exploration, experimentation and different forms of knowledge construction.

In this regard one must acknowledge the role played by the findings of mathematics education research in the development of these didactic designs. Such is the case of studies on generalization processes or on conceptualization by working with different modes of representation of mathematical objects. These studies have led to the use of environments such as Logo and Geogebra (among many others) to realize the approach and verification of didactic hypotheses, as well as to propose their use in the mathematics classroom.

A common denominator of the programs cited is the possibility to provide users with visual and quick feedback on their actions performed on mathematical tasks within the environments. In relatively recent times it has been carried out the development of digital environments"

A research project bearing those characteristics was taken on by a group of academics at the UCL-Knowledge Lab of the University of London, for which the *eXpresser*[1], microworld was developed. In that microworld students are asked to express in different codes the pattern they identify in a given diagrammatic configuration. Through the intelligent system embedded in the environment, natural language prompts are provided to students as they work on a proposed task (Gutiérrez Santos et al., 2012). It is not difficult to imagine how knowledge concerning generalization processes and structure sense, derived from specialized research, could have influenced the design of these interventions with prompts. Similarly, in the project entitled *Intelligent dialogues with tertiary education students*[2], the *Intelligent Dialogues* learning environment was developed with an intelligent support that provides students with feedback in natural language as they perform modeling activities in mathematics and science (Rojano & García-Campos, 2017). In this case, the basis for the design of the feedback/intervention resource was research findings on the difficulties faced by tertiary education students at critical moments in modeling (Molyneux et al., 1999).

Continuing with the theme of intelligent support that includes communication with users in natural language, one cannot ignore the fact that we are now entering a new era arising from progress in development of generative AI chats and expedited access to their use. There is an expectation that with new tools it will be possible to enhance feedback such as those of *eXpresser* and *Intelligent Dialogues.* But in addition to their role in feedback generative AI chats are expected to be used in the creation of increasingly effective assistants or user support guides for learning concepts and solving mathematical tasks and problems. In the design of these assistants, drawing on what is known about the learning of specific mathematics topics is crucial, and it is in this use for design purposes that a meeting between fundamental research in mathematics education and the potential of new AI tools can take place.

The following section uses two examples -taken from the aforementioned projects- to illustrate how knowledge of students' mathematical thinking processes enables (in many cases) anticipating critical moments in the understanding of concepts or in the resolution of mathematical tasks. They also illustrate how such possibility of anticipation is a fundamental component in the development of technology learning environments that include intelligent support for interaction with users, including feedback on their performance within those environments.

Intelligent systems with didactic design based on foundational research

In this section reference is made to two examples of the use of AI systems to encourage students to reflect, analyze and (where necessary) correct or redirect their actions, through

[1] The eXpresser microworld was designed to help students with mathematics generalization processes. Inspired by the robotics and adaptive systems methodology, the MiGen project used a 'layers' approach to develop and assess the intelligent support system for eXpresser.

[2] Intelligent Dialogues with tertiary and university education students is a three-year research project, funded by the National Council of Science and Technology (Conacyt) in Mexico, Reference No. 168620

didactic designs of activities and feedback resources based on findings in mathematics education research.

Example 1. *eXpresser*

Researchers at the UCL-Knowledge Lab, the developers of *eXpresser*, refer to Exploratory Learning Environments (ELEs) as a particular type of computer-based learning environments in which the focus is on learners' exploration of an area of knowledge (Mavrikis et al., 2019). These authors include microworlds in this ELE category, microworlds that are environments developed with a constructionist perspective, characterized by didactic designs based on open-ended tasks aimed mainly at promoting exploration and the construction of conceptual knowledge among students (Healy & Kynigos, 2010). As mentioned in the previous section, the possibility of providing feedback related to learners' actions is a constitutive element of interactive digital environments and ELEs are no exception in that regard. On the contrary, feedback in ELEs and especially in microworlds has distinctive features that distinguish it from the interaction in classical intelligent tutorial systems. Such features are related to the nature and purpose of the tasks designed for the microworlds, which as mentioned above are more about fostering students' exploration, discovery and understanding of concepts, rather than development of operational skills through instructionalist designs (Mavrikis et al., 2019, p.2).

In the *eXpresser* microworld students are asked to build models with mosaics and algebraic rules associated with the models. The suggested strategy is to first construct 'building blocks' (which are perceived as a common piece of the different parts of a given model or diagrammatic configuration) and then repeat these blocks and generate the model with a particular number of constitutive elements and to thus infer/produce a general rule (algebraic formula) that makes it possible to generate a model with *n* elements (Mavrikis et al., 2019). A typical *eXpresser* activity is shown in Figure 1.

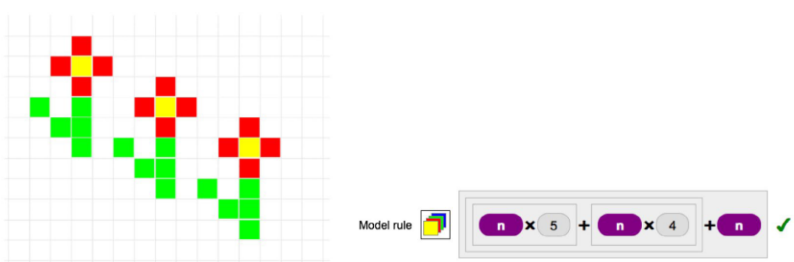

Figure 1: "An example model and rules that students may construct in eXpresser. They can do so by creating "building blocks" to generate the centres of the flowers, the petals and the stalks, which they will then repeat to make the yellow, red, and green patterns. They will be nudged towards deriving general rules for n number of flowers. This is challenging as an "animation" feature applies different random values to the variables used by the student in order to check the generality of their rules." From Mavrikis, et al. (2019, p. 4).

Clearly the construction of such blocks and of the model is a process that involves different stages of generalization, from the perception of the structure of a given pattern and the identification of the common unit that characterizes the structure associated with the pattern as it is perceived, to the steps of expression of that unit and its relation to the diagrammatic configuration in different codes (natural language, diagrammatic, numerical, or algebraic). These processes have been extensively researched, theoretically and empirically, from different perspectives; and the design of the tasks in *eXpresser*, as well as their feedback resources, are based on the results of that research. For example, present in the didactic design of the *eXpresser* tasks are both the well-known fact that the perception of the structure of a pattern is not unique (different individuals may have multiple perceptions of one same configuration), and what Rivera (2010) has pointed out regarding how decisive identification of the unit of repetition is to conceive the structure of the pattern. As already stated, in those tasks students are asked to build blocks that represent the common unit that they identify in the figural representation of the pattern (building blocks strategy).

At the stage of the activity in which the review of and reflection upon the blocks and formulas built by each student or group of students is carried out, by verifying whether their construction (or formula) leads to the reproduction of the given figural pattern, feedback from the environment and/or through the teacher's intervention is usually required. It is at these times of review/reflection that the use of prompts -via questions and suggestions- is crucial for advancing towards the desired generalization. Some of the knowledge concerning the perception and generalization processes of a pattern, underlying the design of the activities that take place in the learning environment, translates into warnings regarding the difficulties that learners may face and they therefore also play an important role in the design of feedback. Geraniou & Mavrikis (2022, p. 134) refer to how thanks to the intelligent support of the MiGen system, of which *eXpresser* is a part, students participating in an experimental study were able to find the minimum number of tiles they could group in a building block and repeat it to form a pattern. This shows the relevance of having supports of this type, of specific and timely intervention, whose design considers both tracking data of student actions while working on a task, as well as knowledge of their learning and comprehension processes in mathematics.

Another recurrent finding in studies on patterns and generalization is the tendency of students to view the relationships in the pattern recursively (and not functionally). This is an obstacle to generalization for case *n* (Stacey, 1989) and therefore it also represents an obstacle to the generation of an algebraic rule associated with the pattern. Hence intervention (of some sort) in this transition to symbolization in order to promote student reflection is also highly relevant. The case of the MiGen project and the intelligent system associated with eXpresser is an example of the usefulness of having knowledge of possible anticipations in student performance in generalization tasks for designing AI resources that allow relevant interventions. But in terms of types of use of such resources as well, the project goes beyond individual adaptive feedback and the article *Intelligent analysis and data visualisation for teacher assistance tools: The case of exploratory learning* (Mavrikis et al. 2019, p.6) describes intelligent support components of the MiGen system that include intelligent Teacher Assistant Tools, and outlines the work that has been done to extend the use of these tools to classroom activity, thus complementing the work of the teacher as facilitator or orchestrator.

Example 2. *Intelligent Dialogues*

The findings of the Anglo-Mexican project *The role of spreadsheets within school-based mathematical practices in science*[3] include the identification of specific moments that were critical for all participating students (tertiary education students) during their performance of modeling activities using spreadsheets. The critical moments in question are: prediction of phenomenon behavior, verification of the prediction and generalization of the model (Molyneux et al., 1999). This finding together with the *Dialogues with Theo* (DiT) program (http://recursostic.education.es/descartes) served as the basis for designing and building the integrated environment *Intelligent Dialogues in Parameterized Modelling Activities*, hereafter referred to as *Intelligent Dialogues.*

Using the DiT program, in the integrated *Intelligent Dialogues* environment it is possible to simultaneously display a dialogue window and a microworld window on the computer screen, both of which are dynamically linked (see Figures 2a and 2b). In that environment students can work on specific modeling tasks in the spreadsheets microworld and dialogue with the system in natural language. Consequently, students receive feedback both in the microworld and in the dialogue window. Figure 2a shows the activity scene *Molecular diffusion in a cell*, by means of a simulation of the phenomenon that consists of considering a simplified cell (in two dimensions) with six compartments. The outer walls are impermeable, although the internal membranes between each two compartments do allow molecules to move from one compartment to another. At time t=0, there are 1,200 molecules in the first compartment. In each time unit the molecules move in the four directions with the same probability. The students are asked to build a spreadsheet model that represents the molecules spreading into the different compartments over time. Figure 2a describes the phenomenon behavior at time t=0 and t=1; Figure 2b shows the questions asked by the system and student answers (dialogue window), as well as the calculations performed by the student (window on the right). The microworld offers students the option of working numerically or with formulae on a spreadsheet (Rojano, 2018, p. 227).

[3] Anglo-Mexican Project developed in collaboration with the Institute of Education of the University of London and the Department of Mathematics Education of the Centre for Research and Advanced Studies (Cinvestav) in Mexico, funded by the Spencer Foundation of Chicago, Ill, Grant No. B-1493.

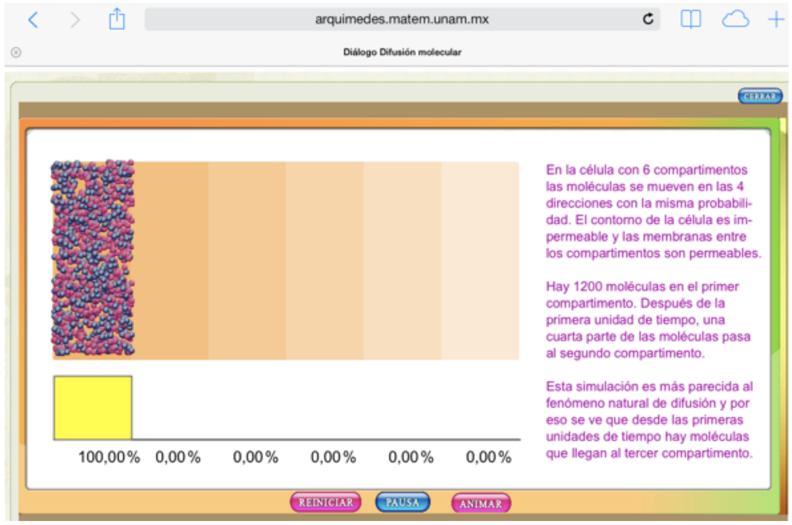

Figure 2a. "Screen with simulation of Molecular diffusion in a cell. From Rojano (2018, p. 227).

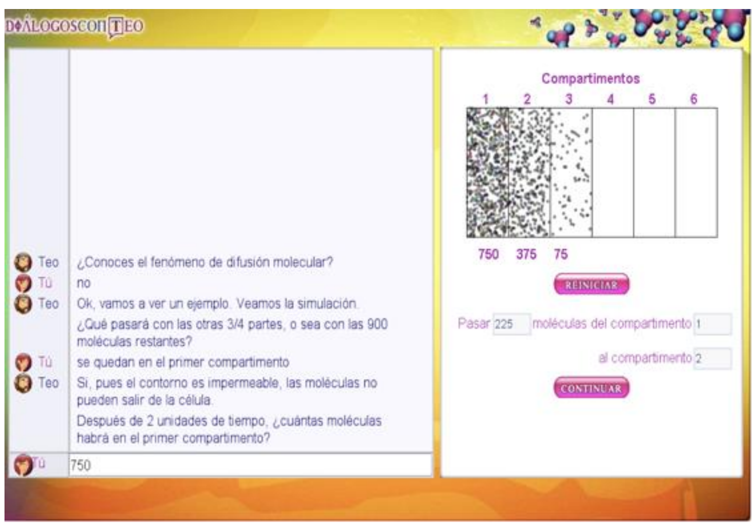

Figure 2b. "Screen with the dialogue (on the left) and the microworld (on the right) windows". From Rojano (2018, p. 227)

For the experimental study associated with this integrated environment, activities were designed considering three stages of the modeling activity: understanding the phenomenon, building the model, and predicting the phenomenon behavior in the long run. In view of the results of the previous study (without the AI layer), the critical moments were anticipated at each of the stages in order to design the feedback in the dialogue window. Figure 3 shows how students are presented with the option of a correct and an incorrect prediction of the long-term behavior of the molecular diffusion to encourage them to reflect on their choice and provide them with hints on how to verify or correct their prediction. Moreover, to support the students in going through the different stages of the modeling activity, open questions, multiple-choice items, suggestions, and prompts were included in the dialogue window, whereas in the microworld window, different mathematical representation systems were used (see Rojano & García-Campos 2017, for the type of activities used and the methodological aspects of the study). The outcomes from the experimental study indicate that the Intelligent Dialogues system responds differently depending on to the type of strategy used by the student, be that spreadsheet-numerical or algebraic (using a formula). It was furthermore observed that the intervention through the intelligent system allowed students to successfully complete the activity. However, in some cases, where students were experiencing great difficulty from the initial stage of the modeling, substantive intervention from the teacher-researcher was necessary (Rojano & García-Campos, 2017, p.29).

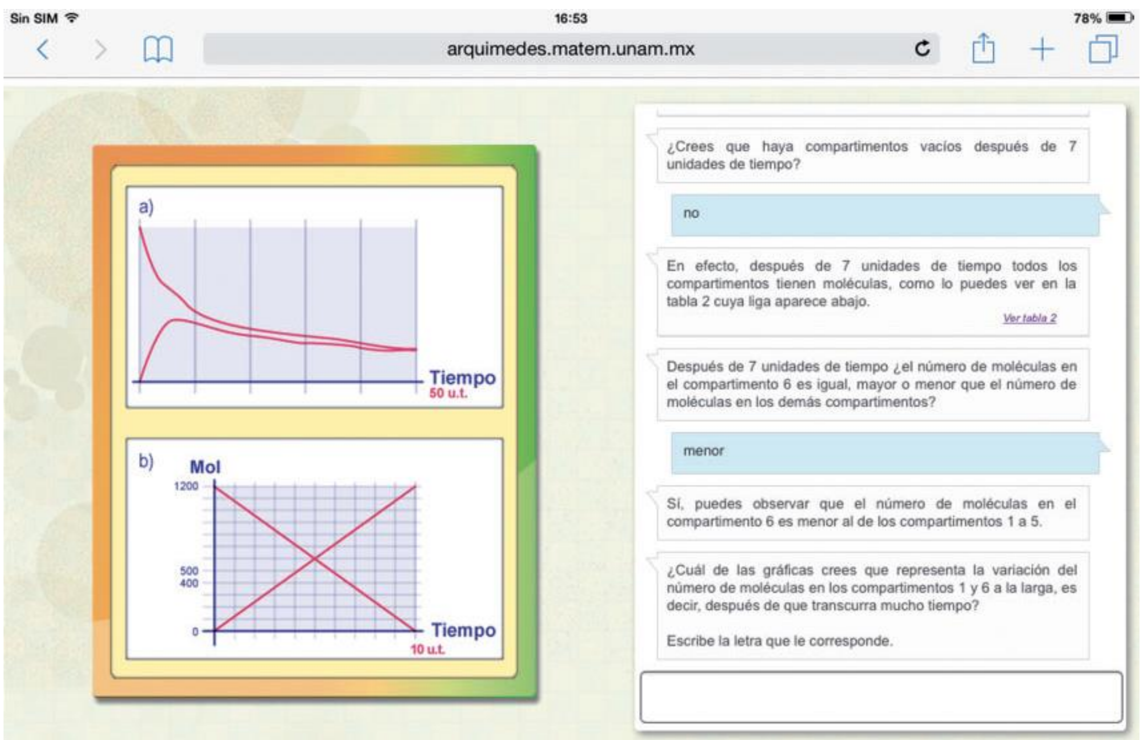

Figure 3: Dialogue and microworld windows. Choosing graphs for compartments 1 and 6. From Rojano, & García (2017, p. 25)

Intelligent Dialogues -inspired by the MiGen project- is another example of integrating an AI component into a microworld, in which natural language is used as a vehicle for interaction with students. Due to the exploratory nature of the activities, both in this environment and in eXpresser, the possibility of dialogue with other students and with the teacher is considered. That is to say, the interaction with natural language goes beyond an individual-intelligent system chat modality. Hence in this type of use of intelligent systems and teamwork, natural language communication plays a key role in the didactic scenario. It is worth noting that in this respect the experiment in empirical studies conducted with both environments confirms the hypothesis formulated by some authors to the effect that interaction through natural language contributes to the improvement of learning achievements, especially when it takes place in a technology environment. That hypothesis is derived from the research conducted by Litman et al (2009), which reports that a higher percentage of content-rich talk is correlated with higher learning gain. To the previous result it should be added that Chi, et al (1994) showed that self-explanation among students significantly improves learning, which reinforces the above-mentioned hypothesis.

From incorporating a feedback system in a microworld to creating AI assistants to foster mathematical thinking: Algebra Structure Sense (ASS) and Expression Machine (*Mex*)

Algebra structure sense (ASS) is the capability to gain awareness of the internal structure of algebraic objects (Rojano, 2022, p. 2). According to an operational definition of that capability, a person has structure sense if he/she: sees an algebraic expression or sentence as an entity, recognizes an algebraic expression or sentence as a previously met structure, divides an entity into sub-structures, recognizes mutual connections between structures, recognizes which manipulation it is possible to perform, and recognize which manipulations it is useful to perform (Hoch & Dreyfus, 2004, page 351). Hoch & Dreyfus used this definition to verify in a study involving 92 16-17 years old pupils whether a subject makes use of ASS when performing an algebraic task. The authors applied the following test:

> Study with 92 16-17 years old pupils. The purpose is to identify students who display structure sense, and if structure sense is affected by the number of sets of brackets (0, 1, 2) and by the placement of the variable (on one side of equation or on both sides of equation). From Hoch & Dreyfus (2004).

A. $1-\frac{1}{n+2}-\left(1-\frac{1}{n+2}\right)=\frac{1}{110}$

B. $\left(1-\frac{1}{n+1}\right)-\left(1-\frac{1}{n+1}\right)=\frac{1}{132}$

C. $1-\frac{1}{n+3}-1+\frac{1}{n+3}=\frac{1}{72}$

X. $\frac{1}{4}-\frac{x}{x-1}-x=5+\left(\frac{1}{4}-\frac{x}{x-1}\right)$

Y. $\left(\frac{1}{4}-\frac{x}{x-1}\right)-x=6+\left(\frac{1}{4}-\frac{x}{x-1}\right)$

Z. $\frac{1}{4}-\frac{x}{x-1}-x=7+\frac{1}{4}-\frac{x}{x-1}$

In the data recorded two essentially different types of strategies were observed. One is based on the use of ASS, which allows students to identify identical compound terms that can cancel each other out and thus obtain the solution of the equation immediately. The other strategy consists of developing the operations called for, (including the elimination of parentheses or looking for a common denominator in rational expressions), which led in several cases to long and complicated processes that did not allow the students to arrive at the solution (Hoch & Dreyfus, 2004).

With another approach to the same topic, in the project *Developing algebra structure sense in a digital interactive environment with an adaptive system*[4], *Mex*, an interactive web environment was created for the purpose of helping students from different educational levels to develop their ASS (Muñoz & Xolocotzin, 2022, pp. 79-84). In that environment, interaction is between the user and a multilevel network of algebraic tasks of varying degrees of complexity, and feedback is based on the user's responses to each task, without the use of a chat. The results of a first study with *MEx* (carried out among subjects with varying mathematical experience and knowledge) show that a group of participants make progress in the development and use of structure sense as they solve tasks along paths entailing different levels of complexity. However, the subjects with a tendency to develop algebraic expressions instead of using structure sense found it difficult to distance themselves from that tendency (Solares & Rojano, 2022 pp 91-104). In such cases the need for intervention to guide students to reflect on their responses and procedures was recognized. As seen in a preceding section, in projects such as *eXpresser* and *Intelligent Dialogues*, this need has been addressed through incorporation of prompts and a dialogue window. But in view of the nature of the cognitive ability involved in recognizing the internal order of algebraic objects (Kirshner, 1989), one option to support ASS development is to use generative AI systems applications to develop assistants.

Knowing more about and exploring the potential of the new tools

The features that distinguish generative AI applications from non-generative or conversational AI applications **(**https://mail.google.com/mail/u/0/?tab=rm&ogbl#inbox) make it possible to think of sophisticated and ambitious usage models, both as interlocutors for students and as teacher assistants in the classroom. Unlike conversational AI based in part on predefined answers or rule-based systems, generative AI can be used to create new content with the use of machine learning algorithms and deep learning to generate outputs. This has led to the creation of ChatGPT and Google Gemini, as well as many other applications **(**https://mail.google.com/mail/u/0/?tab=rm&ogbl#inbox). In a short period of time tools such as these have proven to be very powerful in assisting users with activities in different areas; it is at this point when the question arises as to how reliable and effective they are in the field of mathematics. For the moment, what can be said is that in some cases the applications can give mathematically and didactically correct answers or guidance. However, there are cases in which "their knowledge" of the subject matter is poor or scarce and their intervention can be erratic as a result. In other words, their effectiveness depends to a large extent on the mathematical content in question and the AI application’s ability to perform a particular task or solve a particular problem. The latter was evidenced in a preliminary study, in the framework of an ongoing PhD

[4] *Developing algebra structure sense in a digital interactive environment with an adaptive feedback system* is a Frontiers of Science Project, funded by the Council of Science and Technology in Mexico (Conacyt Ref. 2016-01-2347). The main aim of the project is to prove the feasibility to foster the development of high algebraic competencies in heterogeneous groups of students, using a technology environment that promotes autonomous learning. (https://www.teresarojano.com)

project[5], when a selection of items from the Hoch & Dreyfus questionnaire was used to test the ASS of a set of generative AI applications.

In the doctoral research in reference, the author sought to answer the following questions regarding the generative AI applications: 1) Do they apply ASS to solve the Hoch & Dreyfus items; 2) Can they be taught to apply ASS; 3) How can AI be used to foster development of ASS in subjects? When testing the selected applications, it was found that only some of them make use of ASS when asked to solve one of the equations in the questionnaire; while others develop the algebraic expressions present in the equation, just as some of the participants in the study did with *MEx.* The above answers question 1). The following shows the performance of two of these tools when they are asked to solve the equation $1 - \frac{1}{(n+3)} - 1 + \frac{1}{(n+3)} = \frac{1}{72}$, taken from the Hoch & Dreyfus questionnaire (Nebbia, in process).

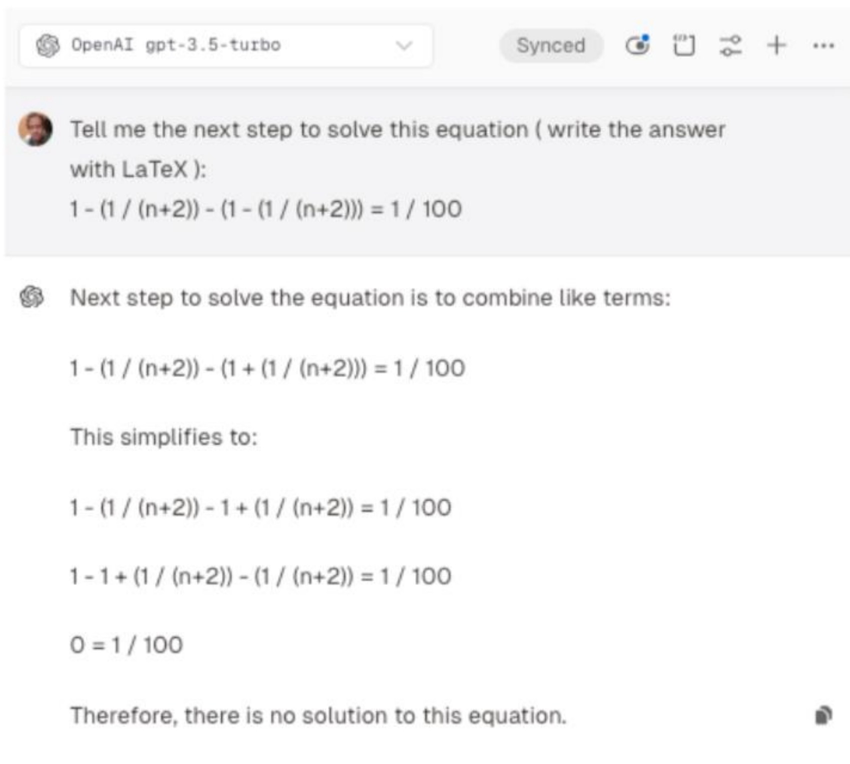

Figure 4b: Example of Open AI GPT 3.5 turbo solving the equation $1 - \frac{1}{(n+3)} - 1 + \frac{1}{(n+3)} = \frac{1}{72}$ (from the Hoch & Dreyfus questionnaire). The AI application used a syntactic rule-based strategy to find the solution (Nebbia, in process).

[5]Nebbia, C. (in process). *Construction of interactive environments for the enhancement of algebra structure sense: Into the world of generative AI tools*. PhD project, Center for Research and Advanced Studies (Cinvestav), IPN, Mexico

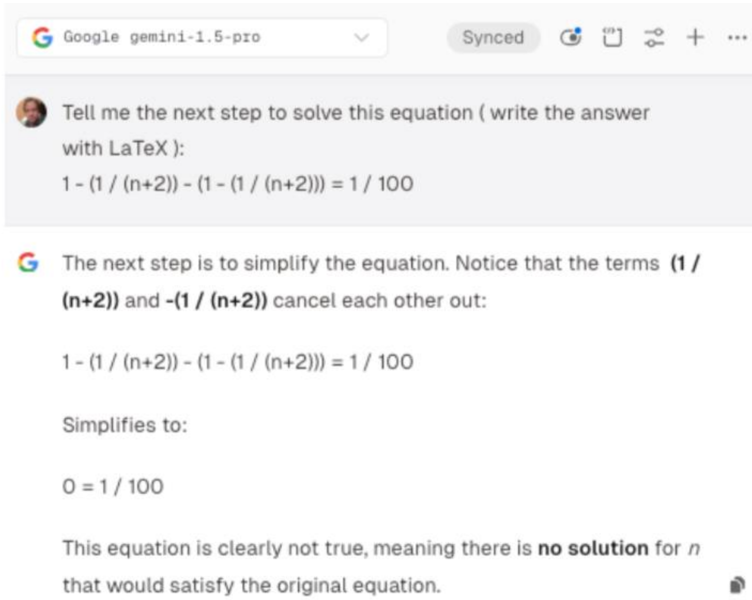

Figure 4b: Example of Google Gemini 1.5 pro solving the equation $1 - \frac{1}{(n+3)} - 1 + \frac{1}{(n+3)} = \frac{1}{72}$ (from the Hoch & Dreyfus questionnaire). The AI application used structure sense to find the solution (Nebbia, in process)

The overall plan of this project entailed choosing generative AI applications that can be used to build an assistant that accompanies students as they solve algebraic tasks designed to promote the use of structure sense. The accompaniment will consist of engaging in a dialogue with the student during the joint resolution (student-assistant) of the tasks, making the student aware of the structural properties that s/he has not perceived and suggesting how to use them to perform the algebraic transformations that lead to the solution.

Final Thoughts

The author aimed to use the examples submitted in this article to emphasize the role of knowledge concerning the mathematical thinking of students in the design and development of technology learning environments. Through empirical studies, the latter environments have shown their potential to foster such thinking among users, both conceptually and in development of mathematical skills and abilities. However, one must acknowledge that matching didactic designs of this type with the dizzying advance of digital technology and AI tools represents an enormous challenge. This is in part because the generation of and access to fundamental research results in mathematics education are slower processes than technological progress. It is also partially due to the fact that widespread access to an expeditious use of the new tools - particularly what we are witnessing today in relation to the use of generative AI applications- favors a great diversity of spontaneous uses in and out of school. The foregoing makes up a very different scenario as compared to what existed in the 90s, when access to use of digital devices and software was very restricted; in many cases the use of technology was barely starting in academia or the workplace. The current context is in many ways very different, and major changes are beginning to be hypothesized both in the ways of teaching and learning, as well as in the manners of conducting educational research in general, and in mathematics education in particular.

Acknowedgements

I want to thank The National Council of Humanities, Science and Technology (CONAHCYT) in Mexico for funding the frontier project Development of higher mathematical capabilities: The role of transformative algebra and technology learning environments, and for the partial support for presentation of this paper at the North American Chapter of the Psychology of Mathematics Education Conference (PME-NA), Cleveland Oh, 2024.

THE IMPLICATIONS OF GENERATIVE ARTIFICIAL INTELLIGENCE FOR MATHEMATICS EDUCATION

Candace Walkington
Department of Teaching and Learning, Southern Methodist University
cwalkington@smu.edu

Generative Artificial Intelligence has become prevalent in discussions of educational technology. These AI models can engage in human-like conversation and generate answers to complex questions in real-time, with education reports accentuating their potential to make teachers' work more efficient and improve student learning. In this paper, I provide a review of the current literature on generative AI in mathematics education, focusing on four areas: generative AI for mathematics problem-solving, generative AI for mathematics tutoring and feedback, generative AI to adapt mathematical tasks, and generative AI to assist mathematics teachers in planning. I then discuss ethical and logistical issues that arise with the application of generative AI in mathematics education, and close with some observations, recommendations, and future directions for the field.

Generative Artificial Intelligence has taken the world by storm since the release of ChatGPT in November of 2022. This release marked an important milestone in the development of conversational Artificial Intelligence agents, driven by ChatGPT's ability to engage in human-like conversation and answer complex questions. Stakeholders immediately began imagining how these tools might be applied to education. It has been nearly two years since ChatGPT's release, and research is rapidly emerging on its implications for education. In this paper, I seek to summarize current trends and issues related to GenAI in mathematics education, since the release of ChatGPT.

Artificial Intelligence (AI), according to the U.S. Department of Education, is "automation based on associations" (Cardona et al., 2023, p.1). Generative AI (GenAI) is a class of AI that is capable of generating new data and outputs by learning patterns from training data. Large Language Models (LLMs) are one type of GenAI that "build sophisticated statistical predictors by identifying patterns in a massive set of human-curated training data" (NCTM, 2023, p. 1). What was so revolutionary about GenAI models like ChatGPT when they were released was the ability of a human user to *respond back* to the AI model and ask it to change elements of its response – this practice is known as *prompting*. This ability gave rise to *prompt engineering,* which is the process of constructing inputs for LLMs to elicit precise, coherent, and pertinent responses (Liu et al., 2021). This process allows users to iteratively refine the kinds of output the LLMs provide, customizing the LLM's work to their needs and context.

The U.S. Department of Education gives many possible benefits of AI in education – from increasing the adaptivity of learning materials to students' needs, to providing teachers support via automated teaching assistants, to better customizing learning resources to meet local demands (Cardona et al., 2023). NCTM's (2023) AI Position Statement further expands on these affordances – describing how GenAI can allow for the quick development of multiple problem versions to illustrate a mathematics concept, can efficiently design engaging, personally relevant questions tailored to individual students' experiences, and can generate rich mathematical explanations that adapt to students' current level of expertise. Both of these reports also detail the incredible risks that GenAI poses – including issues of bias towards marginalized groups, concerns related to privacy and surveillance, and GenAI's tendency to hallucinate and provide incorrect information.

I structure this paper by first discussing affordances and use cases of GenAI in mathematics education in four broad areas – focusing on mathematics problem-solving, mathematics tutoring and feedback, adapting mathematical tasks to learner needs, and supporting mathematics teachers in planning. I then move to discussing important ethical, theoretical, and practical issues to consider when implementing GenAI in education. I close by providing some observations and recommendations for the future of GenAI in mathematics education.

Generative AI for Mathematics Problem-Solving

GenAI programs like ChatGPT can have a wide variety of mathematics problems inputted into them and can not only generate an answer to these problems, but also give a detailed explanation of how to get to that answer. The latest version of the LLM GPT-4 (OpenAI, 2023) integrates computer vision, such that the AI can examine mathematical diagrams in addition to the problem's text. GPT-4 scores 700 out of 800 on the mathematics portion of the SAT (OpenAI, 2023), which is in the 89th percentile. This is an improvement on a score of 590 (70th percentile) that was achieved by GPT-3.5, its predecessor. GPT-4 also scores a 4 out of 5 on the AP Calculus BC exam, while its predecessor scored a 1. GPT-4 scores in the 80th percentile on the GRE Quantitative exam, with its predecessor in the 25th percentile. And while GPT-4o scored only 13% on the qualifying exam for the Math Olympiad, the new GPT-o1 model designed for complex reasoning scored an impressive 83% (OpenAI, 2024), although it is slower and more costly than its alternatives. These results paint an impressive picture of the capability of contemporary LLMs for mathematics problem-solving.

LLMs also seem to have a relatively easy time with typical K-12 mathematics word problems used in open-source curricula. For example, GPT-4 solved and generated explanations for middle school mathematics word problems from ASSISTments with only a 4% error rate in its mathematical explanations (Wang et al., 2024a). Interestingly, none of these errors in explanations were associated with incorrect answers, allowing researchers to conclude that the AI was relatively safe for use with middle school students. Other researchers have used GPT-4 to solve more difficult graduate-level mathematics problems, to test whether GenAI can assist mathematicians in their professional activities (Frieder et al., 2023). They found that while GPT-4 could solve undergraduate mathematics problems, it performed poorly on graduate-level work.

They concluded that GPT-4 can best be leveraged to act as a mathematical search engine and query databases of mathematical objects, rather than as a direct solver of advanced problems. Analyses have also been done into the nature of the mistakes GPT makes when solving mathematical tasks. Typical errors made by GPT-3.5 included using incorrect formulas or methods or unclear question definition, along with calculation errors and misinterpretations of the question being asked (Yen & Hsu, 2023). Mathematics problems that have a high number and diversity of mathematical operations needed to solve them tend to be more difficult for LLMs, as are problems that utilize a conversion of a quantity that requires real-world knowledge (Srivasta & Kochmar, 2024). Math word problems with unfeasible solutions (i.e., the analytical solution is not practical with respect to the real-world context), that contain quantities in them that are not needed to solve the problem, or that involve a comparison between quantities are also more difficult for LLMs (Albornoz-De Luise1 et al., 2024). In addition, holding mathematical features constant, longer and more difficult-to-read word problems are harder for LLMs to solve. One reason why understanding the capability of LLMs to solve mathematics problems is important is because these tools are used by students as a form of assistance. Although for primarily symbolic problems computer algebra systems like Maxima and Wolfram Alpha are more accurate, LLMs offer the advantage of communication using natural language, and can explain different steps for problem solving. Thus, LLMs may be preferred by students over alternatives. Integrating computer algebra systems (Matzakos et al., 2023) or other secondary systems that can check the LLM's calculations (Yen & Hsu, 2023) with LLMs will be an important future direction to improve the reliability of these systems.

There is surprisingly little research on how GenAI can be used effectively by *students* to enhance their learning of mathematics. Barana et al. (2023) gave university students combinatorics problems to solve with the help of GPT-3.5. They found that although GPT-3.5 did not consistently achieve correct answers to the problems, the output given by GPT-3.5 could be leveraged by the students. The students used the output to generate ideas for how to approach the problem, to compare their reasoning with GPT-3.5's reasoning, to solve smaller parts of the problem, and to evaluate and then correct GPT-3.5's solution paths. This is an important example of how LLMs can support higher-level thinking in mathematics. Research has also been done with pre-service mathematics teachers using ChatGPT to help them solve mathematical modelling tasks (Naresh et al., 2024). The researchers highlighted that incorrect answers from the AI could be opportunities for student learning and could launch important mathematical conversations. The teachers also recognized that their students could self-explain the different steps shown by ChatGPT as an opportunity for deeper learning. In sum, more research on how students can effectively partner with LLMs to confront challenging mathematical tasks, like mathematical modeling tasks, is needed.

Generative AI for Mathematics Tutoring and Feedback

Several different online learning platforms have launched GenAI chatbot mathematics tutors, which communicate with students through text chat to assist them with solving mathematical tasks. The most well-known is Khan Academy's Khanmigo (Khan Academy, n.d.), which is free for teachers through a partnership with Microsoft, but has a monthly charge for students, families, and districts. Khan Academy describes how "Unlike other AI tools such as ChatGPT, Khanmigo doesn't just give answers. Instead, with limitless patience, it guides learners to find the answer themselves." Notably, Khanmigo is student-facing with no human directly in the loop – children interact directly with the GenAI conversational agent, relying on Khan Academy's safeguards to prevent inappropriate interactions. Khanmigo acknowledges that it will sometimes make mathematical errors, with a disclaimer at the top of the tutoring screen reading “Khanmigo make mistakes sometimes.”

Results are starting to emerge on the effectiveness of GenAI tutoring. Bastani et al. (2024) conducted a pre-registered RCT that involved nearly 1000 high school students and compared students learning mathematics over a semester with either: (1) GPT-4, (2) GPT-4 with knowledge of correct solutions and student mistakes, as well as instructions to not give students answers, or (3) a control condition where students used books and notes with no access to devices. They found that both versions of GPT-4 improved immediate performance, but that the version that lacked the safeguards actually harmed later exam performance by 17%. Additional analyses suggested that GPT-4 was being used as a crutch by students, and that they were often simply asking it for the answer without a substantial conversation. The enhanced version of GPT-4 with the safeguards did not offer any benefit on the exam over simply studying the text and notes without devices, and its effect trended slightly negative compared to the control group.

As little research exists on GenAI tutors, we can look to research on chatbot tutors that were built predating the rise of contemporary LLMs. A study that compared adults learning mathematics with a chatbot to adults learning with Khan Academy videos did not find significant differences in learning (Grossman et al., 2019), suggesting that the chatbot was generally not effective. However, a math tutoring chatbot for a younger population of elementary students showed some evidence of positive results for engagement and learning above a control condition with no support (Ruan et al., 2020). A follow-up study (Ruan et al., 2024) of elementary students found no differences in overall learning compared to a control condition with no support, but some suggestion of increased learning for students with lower pretest scores in the chatbot condition. At the secondary level, a chatbot implemented in ASSISTments was compared to students simply receiving static hints, and researchers found no differences in learning (Cheng et al., 2024). However, students who had interacted with the chatbot actually had *lower* confidence in their problem-solving, due to potentially becoming reliant on the chatbot’s high degree of assistance.

None of these studies compared chatbots to human tutors, and overall, the evidence base for chatbot tutors does not seem particularly promising. However, we should not discount that many marginalized learners may not have access to human tutoring, and that LLMs’ abilities to communicate in different languages may have important affordances. Butgereit and van Staden (2023) report on an implementation in South Africa of adult learners receiving mathematics tutoring through a version of GPT-4 configured for tutoring interactions. The tutoring was delivered in several different languages, including less-resourced African languages that typically perform less well in LLMs.

Given that there is little research on GenAI chatbots, I next look to research on whether LLMs can give actionable feedback to students on their mathematical problem-solving. In online learning platforms, generating text and images for explanations and hints to be administered when students need assistance can be time-consuming for curriculum developers. As a result, many curriculum developers are looking to LLMs to help with this process. Research suggests that GPT-4 has a tendency to over-identify instances of students making mathematical errors

(Karkarla et al., 2024). Other studies have examined the quality of GPT-generated explanations through ratings of explanation quality. Wang et al. (2024a) asked ten undergraduate mathematics majors to evaluate either explanations for middle school mathematics problems written by GPT-4 or explanations for the same problems previously written by educators. They found that the perceived quality of the explanations was higher for GPT-4 than for teacher-written explanations, potentially because the GPT explanations were seen as having a clearer, step-by-step approach. Prior research had shown that GPT-3's explanations for mathematics problems were rated lower than teacher-generated explanations (Prihar et al., 2023). Research comparing pre-service teachers' reactions to educator-generated hints versus hints generated by GPT-4 found that educator-generated hints were preferred in some cases, as they incorporated visuals, while the LLM-generated hints were preferred in other cases, as they often were more thorough and detailed (Gattupalli et al., 2023a). Other research on GPT-4 suggests that the hints it gives may be too procedurally-focused and are not always written appropriately to support students' reading needs (Gattupalli et al., 2023b). The rated quality of GPT-4-written explanations for middle school mathematics problems can be improved if the LLM integrates previous annotations of the student's work from experts into its reasoning (Wang et al., 2024b). This blending of human and GenAI capabilities may be a promising approach.

Research has also examined the learning implications of AI versus human-generated hints, in addition to preference scores. Pardos and Bhandari (2024) compared GPT-3.5-generated hints for mathematics problems in the OpenStax curriculum to human tutor-generated hints. They found that adult learners had higher learning gains in the GPT condition compared to a control condition with no hints, while the difference between human-generated hints and the control condition did not reach significance. However, they found that 32% of the hints generated by GPT were initially disqualified for inaccuracy, and that this percentage was reduced through the use of an LLM hallucination reduction technique. Overall LLMs seem to be improving in their ability to generate hints and feedback but work still needs to be done on ensuring the hints are accurate, conceptually-focused, and do not lead to over-reliance on the LLM.

Generative AI To Adapt Mathematical Tasks to Learner Needs

GenAI can also be used to adapt learning tasks to meet different learner needs. For example, students often struggle to read the text of mathematics word problems (Walkington et al., 2018), and LLMs have the potential to adapt problems to assist emerging readers. Norberg et al. (2024a) showed that having GPT-4 rewrite middle school mathematics problems to improve their readability resulted in similar effects on student performance as having humans rewrite the problems. They also found that compared to the original problems that had not been rewritten, the problems rewritten for improved readability using GPT-4 could in some cases improve students' mastery rates. Using earlier LLMs, like GPT-3, for the same kind of task resulted in less impressive results, where outputs had more error and noise (Patel et al., 2023).

LLMs can also adapt mathematics problems based on students' interests in popular culture areas like sports or music, or career areas like nursing or engineering – this is often called *context personalization* (Walkington, 2013). GPT-3.5 was used in a research study to rewrite probability and statistics problems to correspond to undergraduates' career interests in areas like pharmacology or economics (Einarsson et al., 2023). The study found that the problems sometimes required revisions due to mathematical issues, and that while some students liked the relevant contexts, others did not like the extra length and complexity the personalized contexts added. However, the authors recognize that better results for accuracy with respect to mathematical issues may have been found with GPT-4. Indeed, another small study where GPT-4 was used to personalize secondary mathematics word problems to correspond to students' interests in areas like TikTok, results showed that GPT did not change the difficulty, intent, or values in the problem (Yadav et al., 2023). In a unique approach to personalization, Hwang et al. (2024) used GPT-3.5 to pose mathematical problems based on camera-captured images of real-world geometric objects, personalizing mathematics problems to objects in the learners' environment. They found that 5th grade students using the system outperformed a control group.

While research shows some effects of personalization and readability on student outcomes, it is also important to examine the perspectives of teachers. An interview study with teachers who taught 8th grade math in urban settings asked about the possibilities of using GenAI to personalize mathematics problems (Walkington and Bainbridge, under review). The study found that teachers felt it would be an effective way to draw upon students' real-world knowledge, activate interest, and allow for sense-making around mathematical problems. One teacher described how "If it's talking about a place, thing, or situation that they're actually familiar with, that they've actually had hands-on experience with, or have seen with their own eyes then, of course, it's gonna be a little bit easier for them to comprehend the problem," while another teacher said, "I think them being able to have a little bit of background knowledge makes word problems a little less scary, sometimes, too, where they feel like they understand it better." However, the teachers had concerns that LLM-generated problems would create greater reading burdens for students, that students still lacked important fundamental math knowledge, and that having different problem versions would translate into additional preparation time for teachers and/or create difficulty when going over problems as a class. One teacher described how "But if they're struggling in math, even giving them what they're interested in, it still may pose a challenge." Overall teachers showed some enthusiasm about the approach, mixed with concern that it would not solve the fundamental issues they were experiencing with their instruction.

Research has also examined partnering students with LLMs to engage in mathematical problem-posing activities (Silver, 1994), as a way to create personalized versions of story situations written by students (e.g., Walkington et al., 2024a). Norberg et al. (2024b) engaged middle school students in authoring their own personalized problems relating to probability and ratios and based on their interests, using GPT-4 to assist students. They found that students preferred more control over the personalization system and found slight increases in students' sense of belonging in mathematics. Zhang et al. (2024) conducted a study of 4–8-year-olds writing math stories while partnering with a GPT-4 agent to support their storytelling. They found that compared to a human partner, the LLM's assistance was actually better in helping students comprehend mathematical definitions, and comparable for supporting mathematics language learning and the generation of quality math stories. However, children interacting with the LLM were less likely to provide substantial responses in the conversation and more likely to give uncertain responses, compared to when interacting with a human.

Another study examined middle school girls posing mathematics story problems with the assistance of GPT-3.5, as part of a project-based unit to create a pitch for a mathematics video game (Walkington et al., 2024b). The study found that the girls used prompting to fine-tune the mathematics story problems for their game and their pitch, and typically gave length and style parameters to the LLM. The girls found that using GPT-3.5 created story problems they felt were fun and engaging, was an efficient process, and that the problems had the potential to increase mathematical understanding. However, further analyses found that the quality of the mathematics story problems, in terms of their realism and correspondence to actual real-world objects and events, was relatively low and problems could contain mathematical errors or inconsistencies. Overall, partnering students with GenAI to accomplish complex mathematical tasks that include problem-posing activities may be an important future direction of GenAI research, if students have an appropriate understanding of the issues involved with using GenAI.

Generative AI To Support Mathematics Teachers in Planning

Research suggests that teachers work an average of 50 hours per week, and that only 49% of this time is in direct interaction with students. The rest of this time involves preparing lessons, giving feedback, doing administrative work, and engaging in professional development (Cardona et al., 2023). There has thus been interest in leveraging GenAI to make teachers more efficient during the 51% of time they are not directly interacting with students. Many tools have arisen that use GenAI to help teachers plan their lessons and accomplish logistical classroom tasks. One of the most well-known tools is MagicSchool (powered by GPT-4, among other models), currently advertised to be used by 2 million educators worldwide (MagicSchool, n.d.). The MagicSchool suite has over 70 AI tools for educators that "help you lesson plan, differentiate, write assessments, write IEPs, communicate clearly, and more." The base version of MagicSchool is currently free for teachers, with more advanced plans having recurring charges. However, there are many other GenAI tools for teachers, with Khanmigo, for instance, having a similar suite of free teacher tools (Khan Academy, n.d.). Gemini for Google Workspace (Google for Education, 2024) has also arisen as a major player in the "GenAI for Teachers" field. Gemini has easy integration with Google tools that are widely used in schools already like Docs, Sheets, Slides, and Gmail, as well as integration with Google's Gemini chatbot.

Research on pre-service and in-service mathematics teachers using MagicSchool (Beauchamp & Walkington, 2024) has examined the use of various tools to make mathematics tasks more relevant to students. This study found that teachers felt the tools had the potential to support students' motivation to learn mathematics and that the tools could increase the efficiency with which the teachers could generate tasks. However, the teachers found the tools limited in their support for English Learners and felt that some of the tasks did not accurately or deeply reflect elements of students' real-world experiences or had mathematical issues. Research has also examined pre-service elementary mathematics teachers using Khanmigo as a support for their mathematics learning related to number theory (Yilmaz et al., 2024). This study found that teachers using Khanmigo appreciated the individualized learning and were comfortable sharing questions and struggles with Khanmigo. However, in some cases they found Khanmigo responses confusing or of questionable reliability and missed the human interaction of someone who gets to know them as students.

Research has also examined pre-service mathematics teachers using ChatGPT for lesson planning (Berryhill et al., 2024; Broutin, 2024; Kwom & Ko, 2024; Naresh et al., 2024). One study found that teachers asked ChatGPT for both mathematical and pedagogical knowledge, that they used ChatGPT as an assistant in developing and organizing lessons, they had ChatGPT simulate possible student responses, and they asked ChatGPT to validate or comment on their ideas relating to teaching (Broutin, 2024). The teachers used continuous prompting to adjust the output and ideas that ChatGPT generated, and they extensively modified the output from ChatGPT to meet their needs. Similarly, a study on pre-service mathematics teachers using ChatGPT highlighted that it can be used to anticipate student misconceptions and approaches to problems, and that ChatGPT can simulate being an age-appropriate student to assist teachers in planning (Naresh et al., 2024). Teachers can also use ChatGPT to generate culturally relevant word problems, with research suggesting that the LLM can be a helpful thought partner through the use of iterative prompting and revision (Berryhill et al., 2024). GPT can further be used to generate mathematics assessment items. Secondary mathematics teachers using GPT-3.5 to generate statistics assessment items felt variably in their desire to actually use the GPT-generated problems (Kwon & Ko, 2024). The teachers appreciated the creativity, efficiency, and specificity of GPT, in addition to its ability to produce anticipated student solutions. However, concerns were raised about GPT's mathematical errors, security and copyright issues, GPT's lack of transparency, its inability to know teachers' students and classrooms, as well as issues with item difficulty and discrimination. Overall, LLMs have some functions that will be useful to teachers in lesson planning, as long as the output can be modified and enhanced by the teachers themselves to best fit their needs.

Issues with the Use of Generative AI in Mathematics Education

A myriad of important ethical issues and concerns arise when applying GenAI technologies to education. Bender et al.'s (2021) groundbreaking paper describes some of these issues, highlighting the environmental and financial cost of increasingly complex and accurate GenAI that require more and more computing power (see also Li et al., 2023). In addition, the training data for GenAI is from large internet datasets that overrepresent people in positions of power in society, that show bias towards the inclusion of marginalized groups, and that include derogatory associations and stereotypes towards these groups (Bender et al., 2021).

Issues with training data may be of particular concern in mathematics education, as common textbooks (including open access textbooks) that GenAI is drawing from have been found to be culturally-biased. An analysis of the top 9 textbooks for 8th grade mathematics on EdReports. found that the majority of the problems in these texts were situated in White, middle-class American culture (Pruitt-Britton & Walkington, 2022). Many of the activities described in the story problems in these texts required wealth or transportation to participate in – such as a story problem about renting a jet-ski or vacationing in the Poconos. The analysis also found problems with specialized non-mathematical language that would be challenging for English Learners. If these are the kinds of data that GenAI is trained from, then GenAI is likely to show these same issues and biases when asked to generate problems.

There are also concerns about LLMs having stereotypical negative associations with the subject matter of mathematics itself, given the commonness of mathematics anxiety and negative reactions to mathematics that are prevalent in society and thus in the LLM's training data. Abramski et al. (2023) studied the associations that GPT-4 makes with the academic subject of mathematics, and the degree to which these associations are negative or positive. They found that 10% of sentiments associated with mathematics were negative for GPT-4, compared to a surprising 50% in GPT-3.5. However, the authors still found that in GPT-4, "Math was associated with frustrating, anxiety, fearful, intimidating, confusing, and struggle. These negative associations were not found in the semantic frame of physics, whose negative associates were related to domain knowledge (e.g., chaos, nuclear)" (p. 15).

When discussing limitations of LLMs, Bender et al. (2021) further describe how, "Text generated by an LLM is not grounded in communicative intent, any model of the world, or any model of the reader's state of mind. It can't have been because the training data never included sharing thoughts with a listener, nor does the machine have the ability to do that" (p. 616). Although these models can generate human-like responses, they are not reasoning or "thinking" in the way humans do. Indeed, the development of mathematics concepts themselves and the development of students' mathematics learning is situated in their individual and collective interactions with the physical world (Nathan, 2022). However, it has been argued that AI systems are "fundamentally incapable of understanding people's embodied interactions in the ways that humans understand them" (Nathan, 2023, p.1). These systems cannot account for forms of human reasoning that are non-verbal and non-pictorial, like gestures and actions.

In addition, in education particularly, there are concerns about the protection of users' inputs into the LLM, including privacy and issues of ownership of intellectual property (Gómez Marchant & Hardison, 2024). When an LLM collects data about young students to better adapt learning materials to student needs, issues of who sees the data and how it is deleted are paramount (Cardona et al., 2023). The rise of LLMs integrated into educational settings may also involve increasing possibilities for surveillance of both students and teachers, as the LLM collects data from multiple sources in order to best adapt instruction and assist teachers.

Further, research on using ChatGPT in mathematics teacher education has shown that ChatGPT can create developmentally inappropriate learning activities and materials that include mathematical mistakes. ChatGPT may create inappropriate materials, such as a middle school mathematics scenario about someone losing 5 pounds per month in a weight loss program (Sawyer & Aga, 2024). LLM-generated problems can also involve haphazard, rather than purposeful, choice of numbers, and LLM's lack of authentic connections to learners' lived experiences can "demonstrate a dangerous surface-level approach to culturally relevant pedagogy" (Gómez Marchant & Hardison, 2024, p. 3).

Indeed, Walkington et al.'s (2024b) study of middle school girls using GPT-3.5 to create mathematics story problems, and Beauchamp and Walkington's (2024) study of teachers using MagicSchool to create relevant learning tasks, found that the problems created by these LLMs often involved surface-level connections to students' experiences. For example, one teacher asked MagicSchool to create a lesson relevant to their students' interest in Mexican-American rapper ThatMexicanOT, and it generated the following: "Students will create a Spotify playlist based on songs by ThatMexicanOT. Each song will be represented by a cylinder-shaped object, and students will calculate the volume and surface area of each cylinder. This activity will show students how real-world math concepts are used in creative ways, like organizing playlists based on their favorite music." Obviously, this scenario is nonsensical, as representing songs as cylinders and calculating their volume and surface area makes little sense. Similar issues were found for student-generated math problems in our study of middle school girls – GPT-3.5 generated the problem "Jack, one of the last five remaining humans, is determined to defeat the robot army by factoring the polynomial expression 2x^2 + 5x - 3, representing the robots' central control system. If Jack successfully factors the polynomial into its linear expressions (Ax + B)(Cx + D), where A, B, C, and D are integers, he can exploit the weaknesses in the robots' programming." This again is a shallow connection between the mathematics concepts and the real-world context.

Image-generating GenAI also exhibit significant bias. For example, Figure 1 shows the output that was generated when DALL-E3 was asked to create "An image of a room of mathematics educators attending the Psychology of Mathematics Education - North America conference in Cleveland, Ohio." The lack of diversity in the image is striking. A study of middle school girls using DALL-E2 reported that the girls recognized bias when the GenAI would generate mainly light-skinned images of humans, despite most of the girls being girls of color (Walkington et al., 2024b). One group of girls in this study described how the pictures of the "landlord" character in their game were consistently generated as older, White men. Gómez Marchant and Hardison (2024) further describe how Adobe Firefly's image-generating AI shows negative racial imagery and incorporates an anti-fatness bias. They asked Adobe Firefly to generate images of a mathematics teacher, and all the images were of White adults. In the mathematics textbook analysis mentioned previously (Pruitt-Britton &Walkington, 2022), it was found that the majority of images of humans in mathematics textbooks were of White, able-bodied people. Given that GenAI is largely trained on these kinds of datasets when generating images for mathematical problems, it is not surprising that the generated images lack diversity.

There is also a lack of guidance in schools about how to handle students using GenAI to complete their assignments. This can lead to disciplinary action that may have disproportionate impact marginalized students, specifically special education students (Laird et al., 2023). There is evidence that English Language Learners and neurodivergent students may be disproportionately targeted by AI detection tools (Gegg-Harrison & Quaterman, 2024). Further, there is evidence that Black students are more likely to be false accused of using GenAI tools to cheat (Madden et al., 2024).

Discussion

NCTM (2023), in their Position Statement on Generative AI, compares GenAI to advances in technology like calculators, search engines, and image-based solving systems like Photomath. They describe how these tools have the potential to reduce an emphasis on computation in mathematics classrooms and increase focus on creative problem-solving. NCTM (2023) also describes how such tools can create positive pressure for teachers and curriculum developers to pose mathematical tasks that are deeper and involve creative thinking and are thus less prone to being solved with LLMs. NCTM further describes how GenAI tools can shift the focus of mathematics instruction from *solving* tasks to both *solving* and *verifying* – an evolutionary change where students must critically examine outputs from LLM and engage in deeper reasoning.

This is a very optimistic and forward-looking account on how GenAI could be used to deliver on its promise to change education. The research that has emerged before and since this Position Statement, however, paints a different picture. There is certainly some important, emerging research happening that leverages GenAI to engage students in rich and meaningful mathematical problem solving – probably far more than is represented in this review, as results may not be published at this early stage. But much of the effort, funding, and emphasis in GenAI in mathematics education is being directed at creating AI chatbots or personalized feedback systems, and then making small incremental enhancements to these systems to more optimally respond to students' errors or assess students' knowledge. This may sound promising, but these technologies are primarily being developed in contexts where students are solving simple, repetitive, skill-based mathematics tasks individually on a screen. Critiques of GenAI chatbots have been harsh, with Meyer (2024) arguing that Khanmigo "regards math as machine-executable code, a numbered list of steps that a machine can execute one at a time with any error bubbling up the stack and identifying the earliest step that produced it" and "regards students as buggy computers whose errors should be identified and corrected as efficiently as possible." As a result, Meyer describes how "The lie that Khanmigo perpetuates here is that 'math is about a huge number of small ideas.'" This then leads to the important question of, what actual, pressing problem in mathematics education is GenAI suited to solve?

A survey in 2023 of why K-12 teachers are not using GenAI found that the most common reason was "I haven't explored these tools because I have other priorities that are more important" (Klein, 2024). This was echoed by one of the teachers in the Walkington and Bainbridge (under review) interview study. An Algebra 1 teacher with 10 years of experience teaching in a district composed of predominantly marginalized learners, when asked about using GenAI to personalize content to his students' interests, described how:

> It could help, you know - anything is better than nothing, but that's not the issue. The issue is the gaps of what they do and what they don't know based on where they are… We're trying to fill gaps like the city does potholes. If you've ever seen the cities do potholes, man, they just put something over it. But if the car hit that hole, maybe 20-30 minutes later, the pothole gonna be right back there next month. Instead of tearing up the street and starting over. And unfortunately, that's kind of what we're trying to do… we need to be able to kinda almost start over instead of trying to fix their gaps, the gaps are turning into canyons and in doing this, we're kind of wasting a year because we ain't fixing what the real issue is.

These kinds of sentiments relating to teachers having to confront bigger issues than GenAI can solve were also echoed by a first-year mathematics teacher teaching in a district composed primarily of marginalized learners, in the Beauchamp and Walkington (2024) study. During a discussion of using MagicSchool in the classroom, this teacher described how:

> It's so hard, because I feel like coming in, the teaching philosophy was "Oh I want to make sure my kids are well-rounded and critical thinkers." But now, since like the district is like "Why are test scores so bad? Why are test scores so bad?" it's like, my curriculum is going to be test questions basically, to prep them… They still tell us that we need to be stretching our kids thinking, but I'm like, we only have so much time. So I feel like because my district really does want to see test scores higher, I feel like my curriculum really is just test questions.

Discussing the possibilities of GenAI with mathematics teachers can be a reminder that these technologies may not be particularly effective for solving the larger problems they face with mathematics instruction every day. The mixed reviews from teachers we see in the studies of

GenAI we reviewed lends further credence to this point. This leads to the question of whether the hype around GenAI in education, and its transformative potential, is indeed justified.

Conclusion

I close by considering how can GenAI give us opportunities to truly transform the nature of mathematics education, in the way that the advent of calculators and dynamic geometry software was transformative. First, the practice of students engaging critically with the output of LLMs, particularly their function to create an endless amount of worked examples with explanations, could be powerful. This may be especially important for learners who speak diverse languages or learners in low-resourced settings where human tutoring is not possible. This approach may be particularly effective for student learning if the LLM makes mathematical mistakes that learners must grapple with and reason about – but as these LLMs rapidly become more advanced, mistakes happening with regularity seems increasingly unlikely, especially for K-12 mathematics content. Second, students using LLMs as a thought partner for problem-posing or mathematical story-telling activities seems like a promising direction from the existing research – story-telling is one practice that this technology excels at, and mathematics instruction is often missing the integration of rich, compelling stories about quantitative and spatial experiences.

Third, image-generating GenAI still has a long way to go to be ethical and useful. However, a promising way they could be leveraged is to automatically create rich visual representations to accompany mathematical tasks. This could also function to reduce costs associated with the development of high-quality open access materials that are freely available to teachers and districts. Fourth, mathematics teachers using GenAI as a thought partner to help them brainstorm and iterate upon lesson ideas, adapted for their context and needs, certainly has potential, especially if these lessons would be free. However, there are a variety of logistical and structural issues that may prevent this from being possible for individual teachers, and teachers will need to be prepared to modify and adapt the output of LLMs to suit their needs. Depending on the amount of time this modification takes, LLMs may not greatly enhance efficiency, and may instead mainly enhance creativity.

Finally, the power of GenAI to support students with mathematics skill practice, particularly in its ability to adapt to student needs, does have real-world value. These skill-based tasks are ultimately the kinds of mathematical scenarios that students will be held accountable for being able to solve in K-12 settings, and students' mathematical fluency can have high-stakes implications inside of school. However, the field of mathematics education needs to look beyond such applications of GenAI and consider how this technology, coupled with other initiatives, can help us solve the pressing problems teachers actually face with mathematics instruction.

Drawing on a math lesson from a kindergarten class, we reflect on the evolution of the field's thinking about teacher noticing. Changes in the prevailing theoretical trends have influenced how we think about teacher noticing. In addition, evolving interests have led to the expansion of teacher noticing in new directions, pushing at the boundaries of the idea, as it was initially posed. Similarly, changes in recording technologies have profoundly impacted how we study and support teacher noticing. In reflecting on these developments, we first trace some of the origins of research on teacher noticing, then discuss the current state of research in the field, and finally share some considerations of next steps.

Dorothy Fields, an experienced kindergarten teacher, was participating in an online course for early elementary teachers on mathematical argumentation (Lomax et al., 2017). As part of the course, Ms. Fields video-recorded her students as they engaged in weekly math activities. She then selected portions of the recordings to share and discuss with her peers. It was the fourth week of the course, and teachers were continuing to explore what their students understood about equality.

Imagine for a moment, you asked a group of kindergarteners if the following equations were true or false (Figure 1). What might they say?

$$7 = 2 + 5$$
$$2 + 5 = 5 + 2$$
$$2 + 5 = 5 - 2$$

Figure 1: True/False Questions

Ms. Fields' students gathered on the rug in the front of the room, and she set up her computer at the back of the class to record their discussion. Ms. Fields projected each equation on the board, one at a time, asking students if it was "true or false" and stating that "I want to hear your thinking."

Students had mixed views about the first equation, with one student noting that 2 + 5 = 7 would be the "regular equation." When discussing the second equation, Timmy claimed that it was true "because 2 plus 5, it equals 7, *and* 5 plus 2 equals 7" and that "5 plus 2 is just reversed from 2 plus 5." Ms. Field's revoiced Timmy's idea for the class, pointing to each side of the equation “So, this side is just the reverse of this side.” Ellen agreed with Timmy because of how “in the last one…it [2 + 5] was the same thing as the first thing [7].”

Miles then brought up the idea of “the wall” which Ms. Fields interpreted to mean the equals sign. Miles explained that “they’re both 7, but it’s actually kind of wrong because (pointing to the 5 + 2)…the 2 should be there and then the 5 would be there,” suggesting that 5 + 2 should be rewritten as 2 + 5. Rose and Nelson argued that the equation was false because “there’s two pluses” and if the final + 2 “was gone then it wouldn’t be true.” Rose also explained that “the minus is in the middle” instead of “next to the 2.” Ms. Fields asked Rose if she meant that “the *equals sign* should be over here [next to the 2]” and Rose agreed.

Ms. Fields next turned to the third equation. Ellen claimed “I think it’s false because that one’s a minus… and that’s one says plus.” Callie then added that “this one is false because this one (pointing to 5 - 2) is 3 and this one (pointing to 5 + 2) is 7.” At one point, Timmy added that it was “extra, extra, extra false.”

What do you “notice” in the students’ thinking? Is the idea of 2 + 5 = 7 being the “regular equation” something you have heard before? What might Timmy mean when he says the third equation is “extra, extra, extra false?” What do you think the teacher notices? Is Ms. Fields cueing into students’ comments about the order of the numbers in the equations? Does she notice that Callie’s claim is about the *sum* and *difference* of the two equations, rather than the *form* of the equations? What is it about Rose, or about what Rose says, that prompts Ms. Fields to wonder if Rose meant that the “equals sign is in the middle?”

Teacher noticing continues to be of strong interest to the mathematics education community. Recent reviews note the wealth of publications on teacher noticing, the diversity of the work, and key shared assumptions (Amador et al., 2021; König et al., 2022; Weyers et al., 2024). More and more there is consensus that *what* teachers notice, and *how* teachers notice, matter for student learning. In addition, research continues to document that learning to notice is, to some extent, teachable — that teachers can learn to notice through teaching, through professional development, and with the use of tools (e.g., Larison et al., 2024; Sherin et al., 2011; van Es et al., 2017).

Yet we believe this is a good moment to reflect on the evolution of the field’s thinking about teacher noticing. As trends have come and gone in the study of teacher learning, noticing has been impacted as well. Changes in the prevailing theoretical trends have been reflected in how we think about teacher noticing. And evolving interests have led to the expansion of teacher noticing in new directions, thus pushing at the boundaries of the idea, as it was initially posed. Similarly, changes in recording technologies have profoundly impacted how we study and support teacher noticing. In what follows, we reflect on these developments, first tracing some of the origins of research on teacher noticing, then discussing the current state of research in the field, and finally by sharing some considerations of next steps.

Theoretical Perspectives on Teacher Noticing

How it started. The idea that teacher noticing is a component of teaching expertise had multiple origins, largely within cognitive traditions characteristic of the time. One line of thinking had its roots in the literature on expertise, which documented that experts in a variety of domains have the ability to see patterns and structure in domain phenomena that are different from those seen by novices. Furthermore, these patterns tend to be particularly useful for the types of tasks that are characteristic of expertise (e.g., Chase & Simon, 1973). In the 1980s, Berliner and colleagues applied these ideas to teaching, showing across a range of studies that expert teachers perceived meaning and substance in various depictions of classroom interactions, while novice teachers struggled to do so and often focused on features of the classroom that are less useful for the work of teaching (Berliner, 1986; Carter et al., 1988). Returning to our example, consider how Ms. Fields' interaction with Rose's idea about "the minus" being "in the middle" might reflect her teaching expertise. In her response, Ms. Fields pursued how Rose was thinking about the organization of the equation and where certain pieces belong rather than Rose's inaccurate use of the term "minus" to refer to the equals sign. As an experienced teacher, we think it is quite possible that Ms. Fields foregrounds Rose's comments about the organization of the equation because that is an aspect of Rose's reasoning that was more relevant to her learning.

Around the same time, Erickson and colleagues investigated what they referred to as "teachers' practical ways of seeing" (Erickson et al., 1986). Central to the cognitive paradigm was viewing teaching as a way of thinking that involved a particular set of specialized knowledge and cognitive processes. Erickson's claim was that to truly understand teaching, one needed to understand how teachers "observed and made practical sense of what happened in their classrooms daily" (Erickson, 2011, p. 19). Erickson explained further that teacher noticing was selective and multidimensional, and at times opportunistic, tied to areas where teachers believed they might act.

Mason (1982, 1987) also explored the construct of teacher noticing in the early 1980s. Mason's approach emphasized the importance of teacher awareness — of teachers paying attention to what and how they see mathematics and mathematics teaching and learning. Mason (2002) referred to this as the "discipline of noticing" to emphasize that effective teaching involved preparing to notice in particular ways, and required sustained effort and energy to successfully do so. In this way, Mason made clear his position that teachers can develop their noticing capabilities.

My own (M. Sherin's) interest in teacher noticing developed in the early 1990s as I worked with colleagues on a project in which teachers watched and reflected on excerpts of classroom videos (Frederiksen et al., 1998; Gamoran, 1994). Goodwin's idea of "professional vision" (Goodwin, 1994) — that members of any professional group develop specialized ways of noticing — guided my work. A key feature of Goodwin's idea is that expert vision is not simply something that individuals acquire, on their own, through repeated practice and experience. It also is partly shaped from their participation in a profession, one with its own technical foundations. To me, then, the idea of professional vision further elevated teacher noticing and did so at a time when professionalizing teaching was an important goal (Firestone, 1993).

All of these lines of work shared the idea that perception was an active process; that is, that teachers direct their attention to significant features of the classroom environment as they engage in teaching. Additionally, these influences emphasized that teacher decision-making is dynamic and dependent in part on what teachers perceive to be taking place in the moments of instruction.

How it's going. Research on teacher noticing has continued to expand and evolve over the past forty years. Much of this work continues to take a cognitive approach, describing the cognitive processes involved as individual teachers notice classroom events. However, over the last decade, increasing attention has been paid to what König et al. (2022)[6] refer to as a socio-cultural perspective of teacher noticing. This perspective aligns with Goodwin's claim that "the ability to see a meaningful event is not a transparent, psychological process, but instead a socially situated activity" (Goodwin, 1994, p. 606). Furthermore, it foregrounds the idea that noticing is not just a social but a cultural activity, and that what a teacher notices is necessarily situated within the larger systems and discourses in which teaching and learning take place, systems that include, but stretch far beyond, the profession of teaching. In an early example of this approach, Levin et al. (2009) highlighted the challenge a teacher faced in consistently attending to student thinking in her classroom given direction from school administrators to focus on classroom management and content coverage, pressures that the school administrators may have felt more acutely given the recent passing of the No Child Left Behind Act (Klein, 2015). Lefstein and Snell (2011) similarly emphasized the political nature of teacher noticing, suggesting that there are often multiple "professional visions" (p. 505), and that teacher noticing is inherently political given that some ideologies are privileged while others are marginalized.

Expanding on such work, a number of recent studies examine the relationship between teacher noticing and cultural, historical, and ideological perspectives (Chen, 2020; Dominguez, 2021; Louie et al., 2021; Scheiner, 2023; Shah & Coles, 2020). These studies illustrate, for example, that dominant discourses in mathematics education position students of color as less capable mathematicians and, therefore, influence teachers' perceptions of "smartness" in student contributions (Louie, 2018). Returning to our example, a socio-cultural perspective would ask us to consider, among other things, ways in which Ms. Field's noticing was influenced by her perceptions of Timmy, Ellen, Miles, and others more broadly, including their status in the classroom community and their broader societally-relevant identities. In short, this perspective emphasizes that what a teacher does and does not notice is shaped by cultural forces, and that research on teacher noticing must consider the broader framings within which noticing takes place, particularly in our efforts to help teachers develop noticing practices that promote equitable and meaningful mathematics learning (Horn & Garner, 2022).

What's next? The developments discussed in the preceding subsection all push on the notion of teacher noticing and in quite reasonable ways. It is certainly a good idea to think of teacher noticing as socially-situated. It also seems certain that a teacher's noticing will be dependent on aspects of their past histories, such as, generally speaking, their cultural and ideological backgrounds (Hand, 2012; Mendoza et al., 2021).

---

[6]König et al. (2022) introduce a total of four perspectives on teacher noticing — cognitive-psychological and socio-cultural, as discussed here, as well as discipline-specific and expertise-related. We would argue that the discipline-specific and expertise-related also take a cognitive approach to the study of teacher noticing. And of course while discussed separately, these perspectives are often interwoven in research.

But it's less clear to us what this should mean for how we think about teacher noticing – how we should theorize about and study it going forward. In the proposals mentioned, there is still something called "noticing" that a teacher does. The proposals add inputs, and they say that what a teacher notices is going to heavily depend on these inputs. The details of the classroom context heavily impact a teacher's noticing. And various inputs throughout a teacher's life impact the noticing that they do in the classroom.

But we should worry whether the developments discussed above require a more fundamental kind of change. Are we doing the equivalent of adding epicycles[7] to a theoretical framework that needs a more thorough rewriting?

Sherin and Star (2011) distinguish multiple possible ways to understand teacher noticing. One of these is noticing as *a cognitive sub-process.* This, loosely speaking, is how noticing was originally understood. A second possibility they discuss is noticing as *an emergent property of the larger cognitive system*. We believe that the above developments suggest the possibility that we should consider a third kind of understanding of teacher noticing: Noticing as *an emergent property of a teacher and a classroom, taken together.*

Let's consider this latter possibility for a moment. If we see noticing as an emergent property of a teacher-classroom system, where do we look to see teacher noticing? How can we say what is "noticed?" One possibility is to simply say that an attribute of the classroom context is noticed if it in some manner impacts a teacher's behavior.

This stance, if adopted, has some intriguing implications for how we might think about teacher noticing going forward. Suppose that Ms. Fields did not react, in any way, to Rose's inaccurate use of the term "minus." If we adopt the emergent perspective on noticing, then we would say that Ms. Fields did not *notice* Rose's use of "minus."

Further, we imagine other teachers may notice differently than Ms. Fields; not all teachers will act the same in a given context. In some manner, a teacher's behavior depends on their past history. A way to accommodate this is to borrow a term from Greeno (1998). We can say that, based on their histories, teachers develop "attunements" - propensities to be impacted by some features of the classroom context.

So, in summary: we might say that teachers develop attunements based on their past histories. In the moment, in part because of these attunements, teachers behave in a manner that depends on some features of the classroom context and not others.

We are not sure we want to argue for this new way of thinking. Our own belief is that it will be productive, going forward, to adopt multiple perspectives. But we do want to make the general point that, given the observations mentioned in the preceding section, we do have to think hard about where to go next. This emerging line of work raises an important question - is it sufficient to add new inputs and dependencies? Certainly, understanding the expansiveness of what captures teachers' attention and why is important. At the same time, it prompts us to ask, how does this work advance our understanding of what constitutes teacher noticing or what

[7]Some early astronomers added epicycles to geocentric models of planetary motion in order to better account for observational data. In these models, the planets move in smaller circles — the epicycles — as they trace their larger orbit around the Earth. The models were complicated, but could make highly accurate predictions.

teacher noticing is? Does it invite us to see noticing in a new light, such as, that noticing is being done and, in the doing, noticing enables new forms of action and social relations? If not, should there still be something called "teacher noticing?"

The Boundaries of Teacher Noticing

How it started. As work in teacher noticing continues to expand and evolve, it is important to carefully consider what we see as the *boundaries* of teacher noticing — that is, what belongs in a theory of teacher noticing. Early work in human perception emphasized the active nature of noticing, which involves both bottom-up and top-down processing (Gibson, 1950). On the one hand, we recognize patterns in available visual information and then apply our knowledge and experiences to make sense of what is seen (think here of walking into an unmarked building, seeing gurneys and people in scrubs, and realizing that you are in a medical center). On the other hand, our knowledge and experiences help us perceive and interpret visual information (think of walking into a medical center and immediately looking for the reception area in order to check in).

In line with such work, initial conceptions of teacher noticing emphasized two key subprocesses: selective attention, or *attending*, reflecting the idea that teaching involves attending to some events while not attending to others, and knowledge-based reasoning, or *interpreting*, reflecting that teaching involves teachers using their knowledge and experiences to make sense of what they observe (Sherin, 2007). Furthermore, attending and interpreting were understood to act in a dynamic manner.

Our decision to include both attending and interpreting in the construct of noticing was not driven by theory alone, as empirical work with teachers illustrated the close connection between these two subprocesses. For example, after viewing the recording of her class, Ms. Fields wrote, "I was not surprised by Timmy's answers because I know he has a solid understanding of the equal sign." In line with Sherin and Star (2011), we believe that Ms. Fields' statement points to something that she noticed about Timmy's comments, but it is not possible to distinguish what she attended to from her interpretation. Nor is it possible to say that these subprocesses operated in some kind of typical chronological fashion (Castro Superfine et al., 2017). It may be that, based on experiences with Timmy during the previous week's activity related to equality, Ms. Fields was primed to attend to Timmy's answers in a certain way. Or it could be that attending to Timmy's comments in class were what convinced her that he had a "solid understanding of the equals sign." Either way, empirical work supports the theoretical claim that "attending and interpreting are inextricably linked" (Castro Superfine et al., 2017, p. 422).

How it's going. Researchers have sought to expand the construct of noticing further by introducing other components. The most widespread of these is related to the introduction of *professional noticing of children's mathematical thinking* by Jacobs et al. (2010). In doing so, Jacobs et al. defined three central processes: (a) attending to children's strategies, (b) interpreting children's mathematical understandings, and (c) deciding how to respond on the basis of children's understandings. They emphasized that "deciding how to respond" is temporally linked to attending and interpreting, and therefore should not be separated. The authors write, "We suggest that… the three component skills of professional noticing of children’s mathematical thinking—attending, interpreting, and deciding how to respond— happen... almost simultaneously, as if constituting a single, integrated teaching move” (Jacobs et al., 2010, p. 173). Blömeke et al. (2015) similarly include decision making as an integrated component of noticing. What might these scholars point to as evidence of Ms. Fields “deciding how to respond”? Perhaps when Ms. Fields followed up with Rose about the placement of the equals sign rather than Rose’s inaccurate use of the term “minus,” Ms. Fields had made a decision based on what she believed about Rose’s thinking — a decision that was not distinct from her attending to and interpreting Rose’s thinking.

Two additional components were introduced in 2021. In their discussion of teacher noticing from a sociopolitical perspective, Louie et al. (2021) positioned *framing* as an important component of noticing. Building on previous studies that explored the relationship between framing and noticing, they chose to “locate framing *within* noticing, as an integral process that both shapes and is shaped by other noticing processes” (p. 97). In doing so, they sought to elevate ways that broader sociopolitical frames, like deficit discourses about students of color or framings of mathematics as “universal, objective, and fixed” (p. 98), are influential in a teacher’s framing in the moment and intimately bound up with processes of attending, interpreting, and (in their framework) responding. How might this idea of framing as connected to noticing be evident in our example? Consider that in the lesson, Ms. Fields probes statements from some of her students, while moving on after the responses of others. Might this indicate that she has a fixed sense of some students’ abilities and is unlikely to notice potential insights in their comments or to believe there is more to what they are thinking that was stated? Thus, what she notices about students’ thinking is connected to her sense of their capabilities as mathematical learners. Alternatively, Ms. Fields may be aware that some of her students seem to have a great deal of authority in the classroom, and so she attends more closely to the thinking of those who do not, in order to ascribe them more agency among their peers. In this case, her noticing about students’ thinking is connected to her beliefs about their positionality among their peers.

Around the same time, van Es and Sherin (2021), revisiting their early work on teacher noticing, introduced a third component to their model of teacher noticing, what they refer to as *shaping* which involves “teachers constructing interactions, in the midst of noticing, to gain access to additional information that further supports their noticing” (p. 23). The idea then, is that teacher noticing involves not only attending to and interpreting what is happening in the classroom, but also actively seeking out, and in some cases creating, information that can be noticed. This component builds from the notion that noticing is active and in addition, that noticing involves interaction with one’s environment. van Es and Sherin discuss shaping specifically in the context of student mathematical thinking. Looking at our example, they might point to Ms. Fields’ question to the class “Does anyone think this is false?” as evidence of shaping. In response to several students having shared their thinking that 7 = 5 + 2 was true, Ms. Fields was creating opportunities to notice students who disagreed. Later in the lesson, Mason responded to the discussion that 2 + 5 = 5 + 2 is true by stating “if you just put the wall on” to which Ms. Fields said "Tell me more about the wall." Again, Ms. Fields was promoting an opportunity to have access to additional information about this idea of "the wall."

What's next? As with our discussion of theoretical perspectives, evolution of the boundaries of a construct like teacher noticing feels natural as the field engages with it. New components can represent progress and refinement. However, new components can also muddy the waters of conceptual and analytical clarity. Here, we consider both sides of the coin in relation to teacher noticing.

Conceptualizing components like *deciding how to respond*, *framing*, and *shaping* as part and parcel of noticing can help to draw our attention to key purposes and facets of the work teachers are doing when they notice classroom events. For instance, as Erickson (2011) discussed, teacher noticing is often tied to aspects of classroom events on which teachers want to act - including *deciding how to respond* as a component of noticing can emphasize this purposeful, selective nature of noticing on the part of teachers. Including *framing* as a subprocess of noticing can intentionally promote the field's attention to the broader contexts in which teachers and classroom interactions operate, especially which culturally dominant frames or counterframes may be in play in acts of noticing. Positioning framing as a component can productively push researchers to consider this in any noticing analysis, not just ones in which relations between framing and noticing are an explicit focus of study.

Yet additional components can also make it challenging to know where teacher noticing starts and stops. Are we headed down a slippery slope in which many acts of teaching fall under the umbrella of noticing (Sherin, 2017)? For instance, engaging in *shaping* in a classroom interaction, in order to create better opportunities for attending to and interpreting student thinking, looks quite similar to revoicing or asking probing questions (Franke et al., 2007). Did we ourselves create this potential slope when we extended noticing beyond attending to interpreting, to also include shaping (van Es & Sherin, 2021)?

In short, we are asking ourselves and wish to ask the field — in what ways and for what purposes is it useful to think of these components as *part of* noticing, versus *entangled with but separate from* noticing? What are the implications for making progress on understanding teachers' practice and thinking writ large? For designing teacher learning environments that cultivate noticing? Can teacher noticing be useful as a construct, if everything is teacher noticing?

Using Video to Support Teacher Noticing

How it started. In the 1960s, video cameras became more portable and less costly, and recording in classrooms as part of teacher education and professional development became increasingly common. One of the earliest uses involved a practice called microteaching in which participants were recorded using a specific teaching skill, then assessed their use of the skill based on the recording. Another approach, interaction analysis, involved the use of an observation instrument that outlined specific student and teacher behaviors to note when viewing a recording of a lesson. Both microteaching and interaction analysis were based on the idea that teaching consisted of a set of observable teacher actions and that there exists a straightforward relationship between those actions and student outcomes (Russ et al., 2016).

By the mid 1980s, the cognitive paradigm had become quite popular in educational research, and research on teaching focused on the mental structures of teachers, including identifying specific categories of knowledge. Recording teachers and classrooms was used as a way for researchers to investigate teachers' thinking, and new approaches to the use of video with teachers were introduced. For instance, in 1994 the National Board for Professional Teaching Standards began to accept applications for certification that included video segments and corresponding teacher reflections (Goldhaber et al., 2004). Around the same time, M. Sherin and colleagues began to work with groups of teachers in *video clubs* in which participants watched and discussed excerpts of videos from their classrooms (Frederiksen et al., 1998).

One of the outstanding questions of the time was what video might help teachers learn. Video cases, for example, were often geared towards the development of teachers' subject matter knowledge or pedagogical content knowledge, though research was mixed on whether such efforts were successful (Sherin, 2004). In contrast, consideration of the affordances of video suggested that video was particularly well-suited to support the development of teacher noticing. In particular, because video provided a permanent record of classroom interactions that could be viewed repeatedly and did not require teachers to respond immediately as is needed when teaching, video came to be viewed as a valuable resource for working with teachers around their noticing capabilities.

How it's going. Over the past 25 years, the use of video to support teacher noticing has received a great deal of attention and innovation. A range of research has documented that video clubs and other video-based professional development can promote the development of teacher noticing as teachers shift in *what* and *how* they notice (Gaudin & Chaliès, 2015). A common focus in this work were efforts designed specifically to help teachers notice students' mathematical thinking (Santagata et al., 2021). Such work demonstrated that reflecting on video of one's teaching enabled both pre-service and in-service teachers to develop productive approaches for attending to and making sense of the ideas that students raise (Kleinknecht & Gröschner, 2016; Seidel et al., 2011; Santagata & Guarino, 2011). Related research looked specifically at how to situate video productively in order to support teachers' learning to notice as well as the role of facilitation in such efforts (González et al, 2016; Seago et al., 2018; van Es et al., 2014). Of interest also was work that explored implications for instruction. Sherin and van Es (2009) and van Es and Sherin (2010), for example, documented that the development of teacher noticing in video clubs did in fact influence teachers' classroom practices, as teachers came to use the noticing strategies developed in the video clubs during instruction.

Research on the use of video to support teacher noticing has also explored the use of various video-based tools in this process. For example, Larison et al. (2024) and Walkoe et al. (2020) describe the use of a video-tagging tool to support teachers' ability to identify and comment on interesting moments of students' mathematical thinking in classroom video excerpts. Others discuss the use of video annotation tools that allow teachers to mark moments of video as associated with particular features of a framework (Suh et al., 2021) or video editing tools that invite teachers to highlight particular moments of a video for themselves and others (Chen & Chan, 2022; Fadde et al., 2009). Another important line of research examined specific features of video clips that promote teacher noticing (Sherin et al., 2009) and in particular, the characterization of “critical events” in which student’s mathematical thinking is particularly salient and therefore can serve as key tools in helping teachers learn to notice (Leathem et al., 2015; Rotem & Ayalon, 2022).

What’s next? For the most part, research on the use of video to support teacher noticing has been based on the idea that teacher learning occurs through review and discussion of video excerpts among teachers. Further, video excerpts for discussion have often been chosen by teacher educators and researchers, rather than teachers themselves. More recently, however, we and others (e.g., Borowiec et al., 2022; Brouwer, 2022; Xiao & Eriksson, 2020) have begun to examine how the acts of self-capturing video in one’s classroom and selecting excerpts to share with others can also be sources of learning to notice for teachers. Sherin and Dyer (2017), for example, document that in preparing to record student mathematical thinking in their classrooms, teachers engage in a kind of *anticipatory noticing* in which they predict in what part of a lesson student mathematical thinking will be visible and what students might say or do at that time. In addition, teachers consider some of the logistics of recording with an eye towards making sure students’ ideas can be seen and heard on the video (Richards et al., 2021). Thus, prior to recording, teachers engage in what Mason (2002) described as preparing to notice. While recording a lesson, teachers also have opportunities to develop their noticing as they identify interesting student mathematical thinking taking place and, in some cases, adjust the lesson in progress in order to provide additional opportunities for student thinking to be visible. Finally, learning to notice can occur as teachers review their videos in an effort to select portions of a lesson to share with others.

Animating some of these opportunities with our example, we focus on Ms. Fields’ initial review of the lesson in an attempt to select a 3-4 minute clip to share with peers in the course. Ms. Fields explained that she was looking for parts “where the thinking [in] the conversation is best,” or what was “interesting or different or surprising.” As she watched the recording on her own, Ms. Fields commented on what she noticed. “That was a good point. It's just reversed.” “So, she's thrown off by the, the set up of the equation.” “Miles changed his thinking here. He wanted it to look like two plus five equals two plus five and then it would be true and then at the end, he realized that it still is the same, which I think is... it's interesting.” In an interview later in the course Ms. Fields explained that sometimes watching the video reminded her of something she had noticed while teaching, while at other times she noticed new aspects of what students shared. In fact at one point she stated “I think this part is better [than] what I remember.”

After viewing the recording Ms. Fields explained that she would go back to “the most interesting moments” and “trim that part” to prepare a 3-4 minute excerpt to share with her peers in the course. As she made the selection for this lesson Ms. Fields explained that she “wanted to capture when she changed it to subtraction.” More generally, she explained that she wanted her recording to “show my colleagues…how [students] approached the numbers andtheir different thinking." Her peers similarly described attending closely to what they considered "more meatier" discussion among students and moments that showed changes in students' thinking.

We believe that this expansion of the use of video for teacher noticing is quite significant. As video equipment becomes smaller and more ubiquitous, teachers can more easily record their classrooms, and we are seeing that doing so can provide novel opportunities for meaningful teacher learning. Further, in our view, these shifts importantly put teachers at the helm of deciding what to elevate and discuss in video as classroom professionals, rather than locating this decision-making primarily or solely with teacher educators or researchers. While we still envision a role for teacher educators and researchers in designing and facilitating video-based programs for teachers, we feel that this represents an important move toward democratizing video-based teacher noticing and learning. Looking forward, we are intrigued by the possibilities of AI for facilitating teachers' selection of video excerpts from their classrooms, while of course cautious of the ethical implications of doing so. Imagine Ms. Fields with a full corpus of video from her kindergarten class asking chatGPT to pull out moments where she said "interesting" in class, or to identify moments where students talked directly to each other. What possibilities might this open up for how the field both theorizes teacher noticing and studies teachers' learning to notice in the future?

Reflecting on the evolution of the construct of teacher noticing and the different ways noticing has contributed to our understanding of teaching, we believe that continuing to question what it means to notice and, therefore, how to study teacher noticing is a worthwhile endeavor. Our snapshot of Dorothy Fields offers a window into the ample and different opportunities for teachers' learning to notice in the context of their recording, selecting, sharing, and reflecting on video of classroom activity. Indeed, we suspect that technological advancements and novel designs for teacher learning will continue to influence research on teacher noticing and how we conceive of and promote teacher noticing.

RESCUING THE BABY: FORMATIVE DIAGNOSTIC ASSESSMENT USING LEARNING TRAJECTORIES[8] [9]

Jere Confrey
North Carolina State University
Distinguished University Professor of Mathematics Education, Emerita
jere_confrey@ncsu.edu

The state of assessment in mathematics education is arguably precarious at this time. Many educators question, if not downright reject, the use of high-stakes tests (Au, 2022). In fact, the climate of anti-testing in mathematics education has reached a point where some doubt the value of measurement itself, as a tool for the improvement of learning, (Zhao, 2020). Others are staunch advocates for the use of formative assessment to stimulate powerful reflective teacher noticing of students' approaches but may overlook that formative assessment practices seldom accrue records of student progress over time—either individually or across groups of students. One might say that the field has thrown out the baby (measurement) with the bathwater (high-stakes assessment). My goal is to rescue the baby, placing it carefully in the category of "assessment for learning", rather than "assessment of learning" (Black & Wiliam, 1998).

In this paper, I introduce the concept of a Learning Trajectory-based Diagnostic Assessment system (LTDA)[10] as an alternative genre of assessment, which combines diagnostically valid with low-stakes characteristics and includes longer term record-keeping. I report on the kinds of contributions to instructional improvement made possible by harnessing and making accessible the rich foundation of research in the learning sciences and describe some emergent dynamics that influence student outcomes. This paper does not review related diagnostic systems but rather shares the story of the design and implementation of a prototype with the potential to improve practice at scale.

Section One: Achievement, Student Voice, and Learning Trajectories

The Current Context

Most readers here are probably familiar with the data from The Nation's Report Card or the National Assessment of Educational Progress (NAEP), which I review as a starting point. The NAEP mathematics scores were trending modestly upward until they plateaued in 2013. From 2019 to 2022, during the pandemic years, there was a steep drop on both the fourth grade and eighth grade assessments (NAEP, 2022a; Figure 1). Of the regionally sampled NAEP test takers, the average scores in low-performing percentiles dropped more precipitously than those of the higher ones (NAEP, 2022b; Figure 2), as can be seen by comparing the decreases for students in the 10th percentile (12%) to the 90th percentile (only 3% decline). The declines during 2020-2022

[8] A shorter version of this paper was presented as a talk at the IES Math Summit, Sept. 2024. This version has been modified and expanded considerably.

[9] I wish to thank Alan Maloney, Meetal Shah, and Erin Krupa for their helpful comments on earlier drafts.

[10] At a 2010 conference (Confrey et al, 2011), the term IDAS (Interactive Diagnostic Assessment System) was introduced. Subsequent work discussed here adds in the use of learning trajectories to create a LTDA.

were even more substantial for Black (13 points) and Hispanic (8 points) students than for White students (5 points) (NAEP 2022a; Figure 3). Some scholars have raised concerns that too much focus is placed on the differences in scores (called "gap gazing" (Gutiérrez, 2008)) and that doing so leads to deficit thinking (Davis & Museus, 2019; Valencia, 1997). As valid and as historically justified as these perspectives are, it is still critical to disaggregate achievement scores; these data are essential for demanding action on inequity in instructional opportunities. We should simultaneously keep in mind that 75% of *all* of our 12th graders have been performing below proficiency since 2005. As Bob Moses reminded us, "As a nation, we stand with bated breath, waiting for public schools to reopen, and for a return to normal, while ignoring that for many 'normal' is not only not good enough, it was never really good." (Moses, 2021).

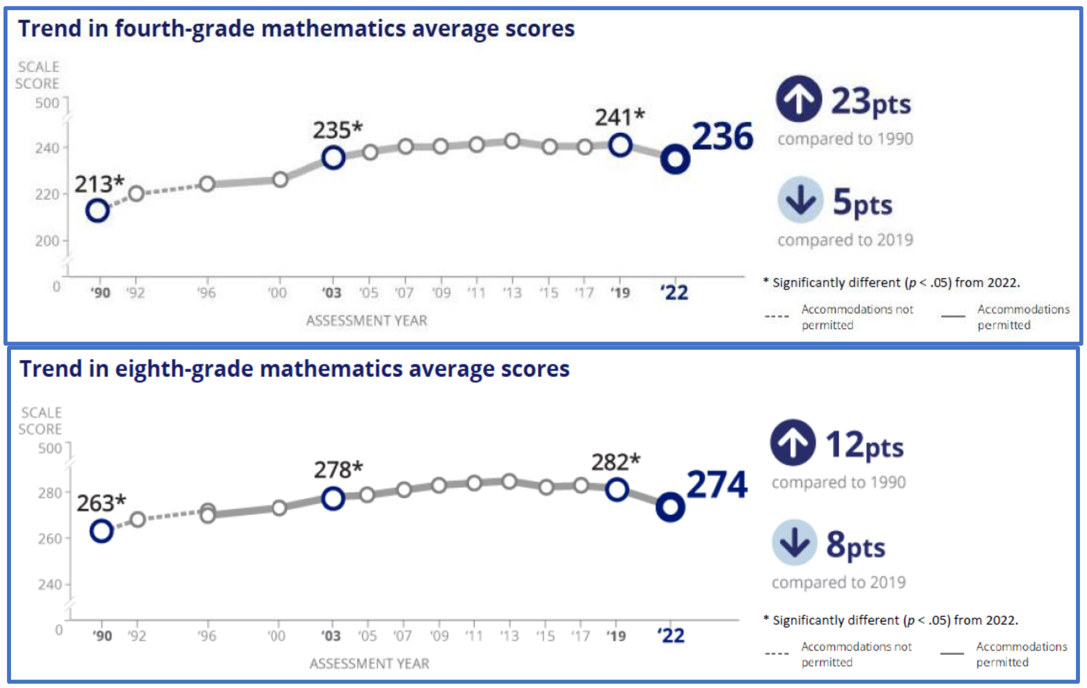

Figure 1: Average math scores trend upward (1990-2013), level off (2014-19), then drop (2019-22) (https://www.nationsreportcard.gov/mathematics/supportive_files/2022_rm_infographic.pdf)

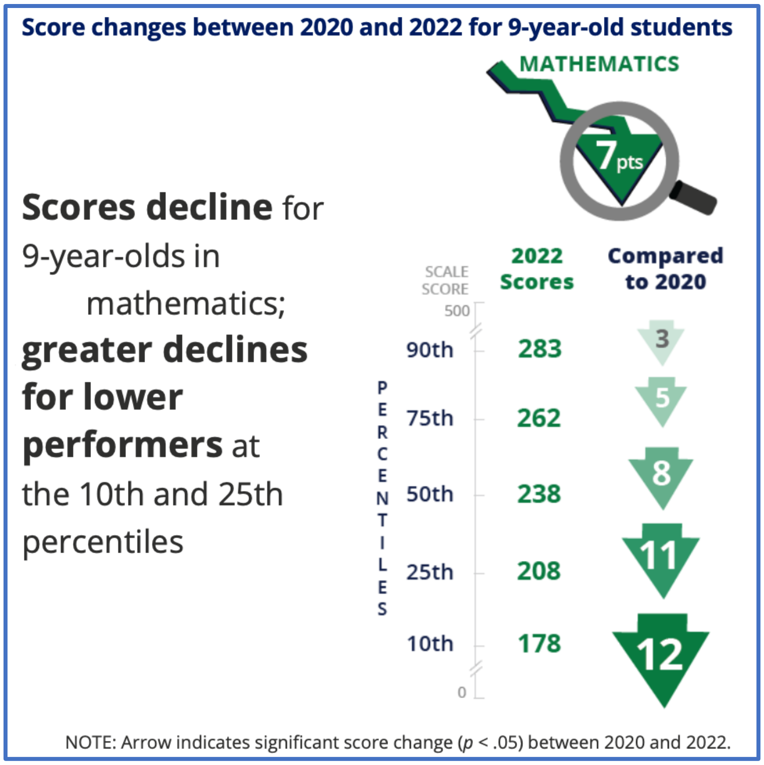

Figure 2: Lower performers' scores dropped more precipitously (https://www.nationsreportcard.gov/highlights/ltt/2022/supporting_files/ltt-2022-age9-infographic.pdf)

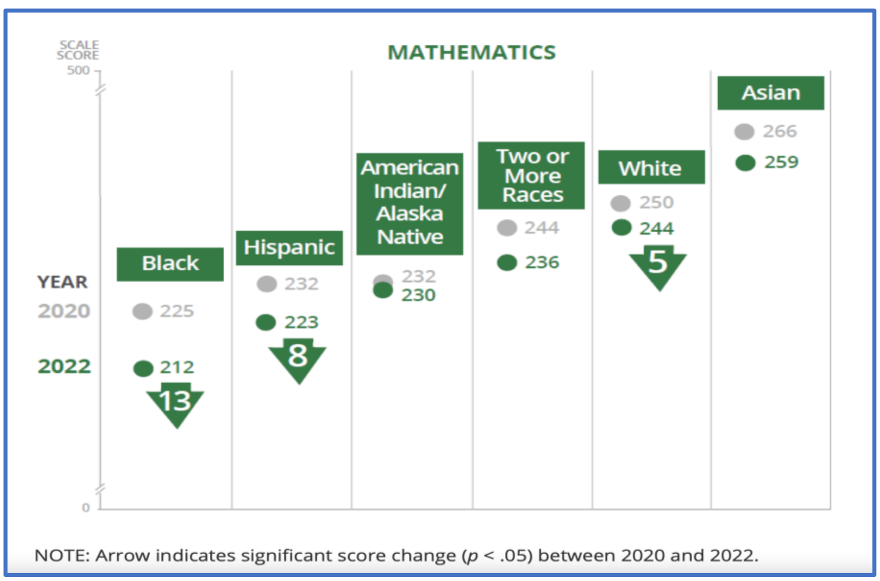

Figure 3: Score reductions are greater for Black and Hispanic students (https://www.nationsreportcard.gov/highlights/ltt/2022/supporting_files/ltt-2022-age9-infographic.pdf)

These data imply massive systemic failure both in policy and in practice. Further, inequitable post-pandemic outcomes were predictable—not as student failure, but as direct evidence of how rapidly learning losses accrue if equitable, adequate resources and supports are withheld (Kane & Reardon, 2023). At this point in our country's history, we should be pursuing a commitment towards solving a nationwide problem; namely, how to achieve quality education as a constitutional right for all citizens (Liu, 2006).

Focusing on Learner's Voice

To generate alternative approaches to improve instruction and outcomes, we need to focus on the learners and their perspectives. I, along with others, have argued repeatedly that students are, ironically, the most underutilized resource in our educational system. I view them as receivers of their education rather than as partners in a journey. In order to describe how to design a more robust approach to assessment and use it to foster instructional improvement, we begin with an admission that, in general, adults are not very good at listening to and seeing learners (Confrey 1991).

To give the reader a sense of what it means to listen to students' mathematical reasoning, I begin with a story. I asked a six-year-old to explain what the digits in the number 314 stood for. Using base 10 blocks, he pulled out 3-100s blocks (flats) and 14 single blocks. His representation (Figure 4a), while correct, was missing the interpretation of the one as a single ten (along with four ones). He saw the digits as representing 300 + 14. As I pondered how to respond to the missing use of ten-stick, he said, "It's like the clock." And he drew two boxes on the paper, as shown in Figure 4b (without adding numbers).

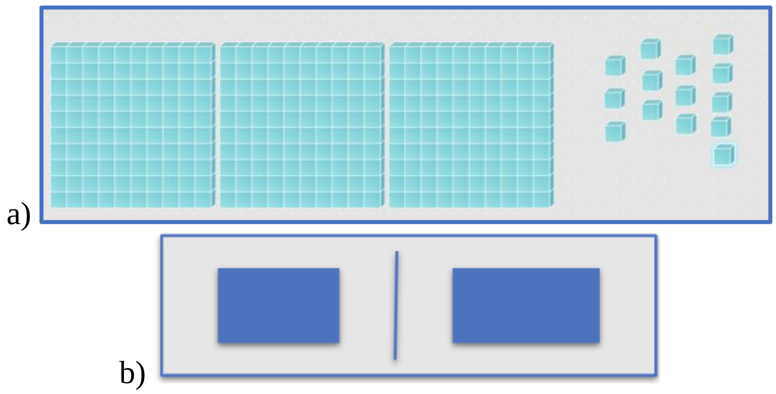

Figure 4: a) Child's representation of the number 314 using Dienes blocks. b) Child's representation of a digital clock display

Now my question is, how would you respond if you were his teacher? Take a second to think about this before reading on.

For the number 314 in our base ten system, each of the digits represents a different unit; hundreds, tens, and ones. This system, associated with counting, operates so that as the number of units reaches ten, the single digit numeral is replaced by a 1 and a zero. The numeral 1 no longer represents a single unit but rather the composite unit 10, consisting of 10 ones, hence it is a system of placement of the digits (hence place) and value of that digit (based on place as ones, tens, hundreds).

Typically, his comment about the clock would either be ignored or corrected, calling his attention only to the need for a ten-stick to represent the fourteen. But if this were how a teacher proceeded, s/he would miss an opportunity to consider how his response sheds light on a particular–and ubiquitous–use of place and value in our culture.

Consider his second representation: two boxes separated by a vertical line. It *does* mirror what one sees on digital clocks. In the case of clocks, the two boxes represent hours and minutes. On a timer (*e.g.,* on a microwave oven), the boxes could represent minutes and seconds. In either case, the numeric values in the boxes or places can exceed 10; they can range to 12 or 24 in the case of the hours, and 1 to 59 for minutes or seconds. The boxes can contain only certain *values*, whose meanings depend on their *placement*. Further, they represent a place value *system*, because there is a relationship between the places that determines the conversion from seconds to minutes or minutes to hours. Thereby one can see that digital timers contain a rudimentary place value system, and one for which his representation of 314 as, for instance, 3 hours and 14 minutes, would be accurate and complete. (And it is also the case that our base ten system of place value is operating *within* each of the places referenced in the clock/timer.)

So, has this child demonstrated an understanding of place value? Note that with his second idea he demonstrates a sound, culturally-situated response to the question of what the digits could represent (time); in doing so, he articulated an understanding of a connection between place and value with his boxes. (If I had asked him about the relative values of the numbers that could be in the two boxes, I could have further assessed the extent of his understanding of a system of exchange or conversion.)

This anecdote and the description of a common response serve several purposes. First, children's inventions should be a basis on which they are made to feel welcome, engaged, and capable in mathematics. However, a common experience of learners is having their ideas under-recognized and undervalued. Children's expressions of ideas, their insights and inventions, frequently and unintentionally, fall on deaf ears, a common occurrence (which I have witnessed in hundreds of classrooms across the country over the course of my career). Alternatively, but no better, children may receive merely superficial encouragement, a kind of pat on the head, when in fact, their idea's validity, vitality, and legitimacy are being overlooked or disregarded. Students' experiences of this kind could even be considered a form of micro-oppression. Over time, for a child to have his or her ideas treated as irrelevant has a deadening effect on a child's eagerness to learn.

Much is asked of teachers. For instance, elementary teachers, who are often weak in or frightened of mathematics, are assigned to teach *all* subjects. What supports are provided for most elementary teachers? Typically, the answer is two meager courses during teacher prep programs around the country. Secondary teacher candidates likewise cannot possibly re-examine all of K-12 mathematics as they complete math and other required coursework. As a result, there is a fair amount of evidence that American teachers are not adequately prepared to recognize children's legitimate alternative competences nor to steer them toward more complete understandings. This requires significant insight and a strong foundation in mathematical reasoning. And few school districts offer professional development with a strong focus on content learning (Scott & Philip 2023).

Ma (2010) conducted a study that compared the ways Chinese and American teachers discuss elementary math content including the topic of place value. Comparing their explanations of place value, she documented that Chinese teachers refer to the relationship among the places in a place value system as “decomposing a unit of higher value” (p. 7). This phrase refers to the fact that each time one switches places, from ones to tens or tens to hundreds and so on, a group of ten of a given unit or value comprises the next unit. In a base ten system, that exchange rate across units is always in the ratio 10:1. In contrast, the digital clock place value system has a variable rate; switching from 60:1 (for seconds to minutes and then minutes to hours) but it switches to 12:1, for an hour to a half day where the clock recycles, or 24:1 if days are recorded. Ma’s study documented that American teachers said little about this underlying mathematical principle, speaking only of the act of “carrying” in addition.

One might hope the Standards will help address these teacher needs. If one examines the relevant standards for place value (Table 1), one sees that they do express what kind of numbers to analyze each year (teens, two-digit, three-digit) and how to represent the digits in terms of bundles of ones, tens, and hundreds. But the Standards provide little insight or guidance into how these composite units are formed, how the key ideas of “place” and “value” are combined and related; nor do they express the idea of a constant or variable “rate of composition/decomposition.”

Table 1: The Common Core Standards for Numbers and Operations in Base Ten for K-2

K.NBT	*1.NBT*	*2.NBT*
Work with numbers 11–19 to gain foundations for place value. *.A.1 Compose and decompose numbers from 11 to 19 into ten ones and some further ones, e.g., by using objects or drawings, and record each composition or decomposition by a drawing or equation (e.g., 18 = 10 +8); understand that these numbers are composed of ten ones and one, two, three, four, five, six, seven, eight, or nine ones.*	*Understand place value.* *.B.2 Understand that the two digits of a two-digit number represent amounts of tens and ones. Understand the following as special cases:* *.a 10 can be thought of as a bundle of ten ones — called a "ten."* *.b The numbers from 11 to 19 are composed of a ten and one, two, three, four, five, six, seven, eight, or nine ones.* *.c The numbers 10, 20, 30, 40, 50, 60, 70, 80, 90 refer to one, two, three, four, five, six, seven, eight, or nine tens (and 0 ones).* *.B.3 Compare two two-digit numbers based on meanings of the tens and ones digits, recording the results of comparisons with the symbols >, =, and <.*	*Understand place value.* *.A.1 Understand that the three digits of a three-digit number represent amounts of hundreds, tens, and ones; e.g., 706 equals 7 hundreds, 0 tens, and 6 ones. Understand the following as special cases:* *.a 100 can be thought of as a bundle of ten tens — called a "hundred."* *.b The numbers 100, 200, 300, 400, 500, 600, 700, 800, 900 refer to one, two, three, four, five, six, seven, eight, or nine hundreds (and 0 tens and 0 ones).* *.B.2 Count within 1000; skip-count by 5s, 10s, and 100s.* *.B.3 Read and write numbers to 1000 using base-ten numerals, number names, and expanded form.* *.B.4 Compare two three-digit numbers based on meanings of the hundreds, tens, and ones digits.*

Realistically it is unreasonable to expect the Standards alone to support a teacher's readiness to recognize and support the range of students' inventions and nascent reasoning. Standards express goals for accomplishment at particular grade levels to allow coordination of topics across grades and set expectations for levels of achievement.

Other resources could be synthesized to help teachers consider student reasoning about place value, specifically the extensive research on "composite units" (Boyce et. al, 2024; Steffe, 1992; Ulrich, 2015). Built within constructivist paradigms, this research documents how students come to create bundles into larger units and how they use these units in place value, skip counting, and multiplication and division. However, to support learner-centered instruction, this type of research from the learning sciences must be synthesized and made accessible to and actionable by teachers. Seldom does this occur.

In this one small story, I have tried to encapsulate how a child's explanation often needs to be recognized and acknowledged as "correct" in relation to his own experiences and ideas, and that these explanations are potentially productive in a shared journey to more sophisticated reasoning. But it also further represents the need for teachers and researchers to use such student explanations as opportunities to reexamine their own understanding of mathematical ideas and meanings.

I formalized the concepts underpinning this story when I developed the notion of a "voice-perspective dialectic" (Confrey, 1998) and it has served as an underlying theme of much of my subsequent work. *Voice* refers to the *learner's* way of making sense of a situation; *perspective* refers to the way the *more experienced listener* (a researcher, teacher, etc.) makes sense of the situation (Figure 5a). The reason it is a *dialectic* is that a listener cannot directly know what the student is perceiving and thinking. Instead, the listener filters the student voice through their own perspective (Figure 5b). When that perspective is formal mathematics training, understanding a child can require the expert to relax, or momentarily ignore, their prior knowledge. In this case (the student's clock idea), a listener need *not* see 14 indivisible blocks as wrongly ignoring the tens place in place value, but as situated in a place value system where the box on the right can range to sixty before conversion (and hence can have two places in the base ten system). It requires one to break set on the "rigor" expected in mathematics, in order to build a bridge from student ideas and towards the connections and distinctions among concepts. As one begins to understand the student voice, another fundamental opportunity emerges: the voice-perspective dialectic reverses and one can employ student voice as a means to reconceptualize one's own perspective (see Figure 5c). The clock example is an illustration of opportunities to apply this dialectic, and eventually reconsider one's own understanding of place value. Learning to recognize student inventions is a bit like seeing fireflies. The first one is difficult to see, but once you do, then you often realize they are all around you, winking on and off. For me, the interactivity of the voice-perspective dialectic in collaboration with learners comprises one of the most profound and satisfying aspects of teaching mathematics.

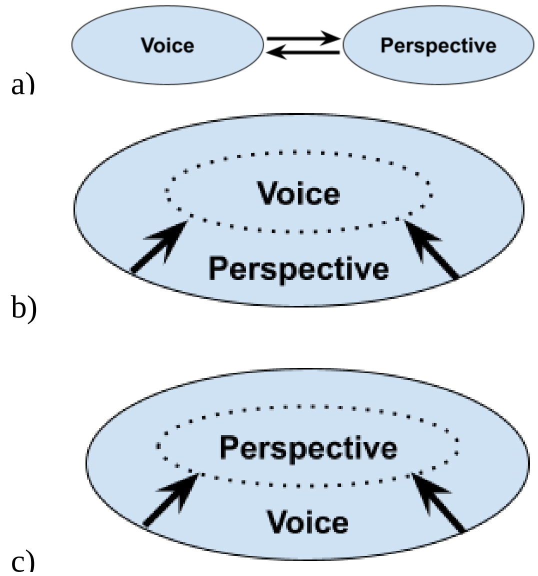

Figure 5: Using the Voice-Perspective Dialectic

The Concept of Learning Trajectories

Developing a learner-centered frame of mind is essential for educators, but it has to be accompanied by informational resources about what is known about patterns in student reasoning. The learning sciences have documented extensive information, concept by concept, about misconceptions, multiple representations, strategies, cases, verbal descriptions, connections to familiar contexts, and predictable approaches of students. Little of this research has been easily available outside of a few systematic efforts such as cognitively guided instruction (CGI) (Carpenter et al., 1996), the Rational Number Project (Behr et al., 1983), and "Turn-On CCMath" (Confrey et al., 2011).

I suggest that learning trajectories offer another resource for organizing relevant research from the learning sciences. In a learner-centered classroom, teachers begin teaching a topic by examining what students already know, often stimulated by posing a provocative task or activity. Depending on the responses, they must figure out how to weave from the students' experiences, conjectures, inventions, or ideas towards an intended learning target. Simon (1995) called these conjectured paths "hypothetical learning trajectories" (HLTs). These HLTs *should* be richly informed by the wealth of research on student thinking, so numerous researchers have proposed actual learning trajectories (LTs) as a systematic way for teachers to access student reasoning patterns as guides to drive instruction (See Confrey, 2019, for one compilation of these.)

The National Research Council (2007) described "learning trajectories" as "successively more sophisticated ways of thinking about a topic that can follow one another as children learn about and investigate a topic" (p. 214). They typically include a domain-specific target and descriptions of the levels of student reasoning. Some researchers include associated instructional tasks by level in LTs, while others, including myself, provide them for illustrative purposes. In my case, this approach allows me to associate a range of tasks with a level and keep curricular materials distinct from the LTs themselves. For this paper, it is important for the reader to recognize the salient points about what LTs are and are not (Table 2). For more detailed reviews of LTs see Anderson et al., 2012; Confrey, 2019; Daro et al, 2011; Lobato & Walter, 2017).

Table 2: Features of Learning Trajectories (from Confrey, 2019)

Learning Trajectories *Are*:	**Learning Trajectories Are *Not*:**
Domain-specific models	General or universal principles
Expected probabilities	Stage theories
Empirically-based models of student thinking	Logico-mathematical deconstructions
Elicited by rich or novel tasks	Derived from typical exercises
Include strategies, reasons, explanations and cases	Sub-goals of the target
Include exploring misconceptions	A means to avoid errors
Ordered by increasing sophistication	Ordered by difficulty
Evolving	Fixed

Although LTs represent domain-specific models of learning, they rely on aspects of "grand" theories of learning. Learning trajectories draw from sociocultural theory and situated cognition in that they are built on students' ideas, and hence demand unearthing and drawing on learners' ideas and experiences. They also draw from the Piagetian tradition of studying cognitive development using as a key concept "genetic epistemology" (Piaget, 1971). It focuses on the movement in thinking, an action of learning that progresses from an initial idea or set of operations, through their extension to new situations or cases, to reach a generalization, or scheme, which is then available for use in future situations. It requires one to think of mathematical ideas in terms of purpose, asking what a mathematical idea allows one to do, recognize, predict, or explain.

For instance, the concept of percents makes the process of comparing ratios more efficient because it standardizes relative size, expressing it as a single comparable number. Instead of comparing ratios of 2/5 and 1/3, one compares 40% to 33.3% (of the same whole). The driving heuristic in mathematics education is for students to realize the beauty of how mathematics can help them make sense of their world in compelling, efficient ways. How can one apply genetic epistemology? Consider asking if two different-sized concert venues, with different numbers of seats and attendees, are equally full—where "full" can be described as the ratio of attendees to seats. Imagine how students might first argue that the one with the *most* attendees is more full. Or that the one with the *fewest* empty seats is more full. And then might consider when the two venues would be considered equally full or empty. And so on.

Genetic epistemology focuses one's attention on the starting ideas and their transformation from operations to schemes through "reflective abstraction" (Piaget, 1977). In this sense, a LT is not simply a list of behaviors to elicit, but a description of increasingly sophisticated ways of reasoning about a phenomenon, with the key concept being how the levels' descriptions scaffold the movement between levels. That said, LTs are not stage theories nor are they logical mathematical deconstructions built using typical exercises. Learning trajectories are probabilistic; different students may be more or less likely to exhibit the behaviors associated with a level when working on a related task. Learning more about the probabilities will require more research, new methods of data collection, larger samples, and careful attention to the cultural background and experience of a diverse set of participants.

I liken the array of ideas explicated at the level of an LT to the multiple paths on a climbing wall (Confrey, McGowan, Shah, et al., 2019, p. 79) but where the target is clear, obstacles are predictable, as are the handholds and footholds. The levels can include strategies and representations, explanations and cases, and they necessarily include *exploring* misconceptions instead of avoiding them. It is very important to note that grain sizes of LT-levels matter. If they're too fine-grained, they can't be readily used to guide instruction, and if they're too broad or coarse-grained, the level of detail is also insufficient to guide instruction.

In summary, low achievement scores on NAEP continue to remind us that large portions (often minority and poor students) of our student population are still underserved by our mathematics education system, and, at the same time, the overall system is faltering. When students are given opportunities to participate in engaging tasks, they offer their own ideas about mathematical concepts, but these ideas are not typically leveraged to revitalize classroom learning. Learning scientists, however, have studied the patterns in student reasoning and identified fruitful pathways, which can be packaged in the form of learning trajectories. These LTs may be a fruitful source of innovation that can be employed to address the system's weaknesses at scale.

Section Two: Introducing a Learning Trajectory-based Diagnostic System, Math-Mapper Features, Partners, and Validation

Designing a Learning Trajectory-based Diagnostic Assessment (LTDA) System called Math-Mapper

Between 2015 and 2022, my research group built a web-based application in which the LTs, associated assessments, and an overarching measurement validation process were described as a prototype of a "Learning Trajectory-based Diagnostic Assessment" (LTDA) system. We sought to accomplish multiple goals. Those included bringing the rich resources of domain-specific knowledge (LTs) from the learning sciences into the classroom. We sought to provide detailed learning feedback to students and teachers: timely, precise, and relevant descriptions of what students already knew *and* what remained to be learned. We hoped our LT- and feedback-oriented approach would support students in considering their own learning and enrich teachers' understanding of both student responses and the underlying mathematical epistemology. Further, if incorporated as designed into classroom routines, this approach could reduce or avoid the disfiguring pressures and drawbacks of high-stakes testing, and, instead, highlight student voice and put it to work in deepening students' agency as learners.

The assumptions underlying this approach included: 1) students are empowered to be more aware of their own progress, and 2) teachers are able to target subsequent instruction to topics needing more (or different) approaches, and plan more effective and efficient ways to meet the personalized individual or group needs of their students. We had two additional goals: creating such a system in partnership with on-going practice to anticipate issues of scale and establishing measurement bona fides for the system in order to document its effects validly and fairly, and include evidence of growth, as movement along the LTs.

In this section of the paper, I describe a range of features and capabilities of our prototype LTDA called Math-Mapper (MM)[11]. I selected one learning trajectory (LT) to illustrate the use of the LTDA. A report validation process is also provided to illustrate how its measurement model shifted in part due to the low-stakes structure of the LTDA design. In a subsequent section, I report on some insights learned from its implementation.

The model for use of the diagnostic assessment evolved over time and came to be referred to as an "agile curriculum framework" (Confrey et. al. 2018). It placed curricular implementation between the two bookends of standards and policies on the one hand and high-stakes testing on the other. The model for diagnostic assessment was specified to coordinate the administration of diagnostic assessments with the curriculum across a department at a grade level. Diagnostic tests were scheduled approximately 2/3 of the way through a curricular topic's designated time allocations (based on pacing guides). MM returns assessment data in real time, so teachers can review data with their students and make individual instructional adjustments. The model also included periodic professional learning communities (PLCs) where one teacher would present and discuss their data and others would report on their data and discuss explanations and approaches. We referred to this as two-cycle feedback (Figure 6).

[11] It is not possible to acknowledge every contributor to MM–however, I do wish to acknowledge a core group who contributed significantly and consistently across nearly the entire project: Meetal Shah, Youngjae Kim, Emily Toutkoushian, Charlene Marchese, Margaret Hennessey, Pedro Larios, and Alan Maloney.

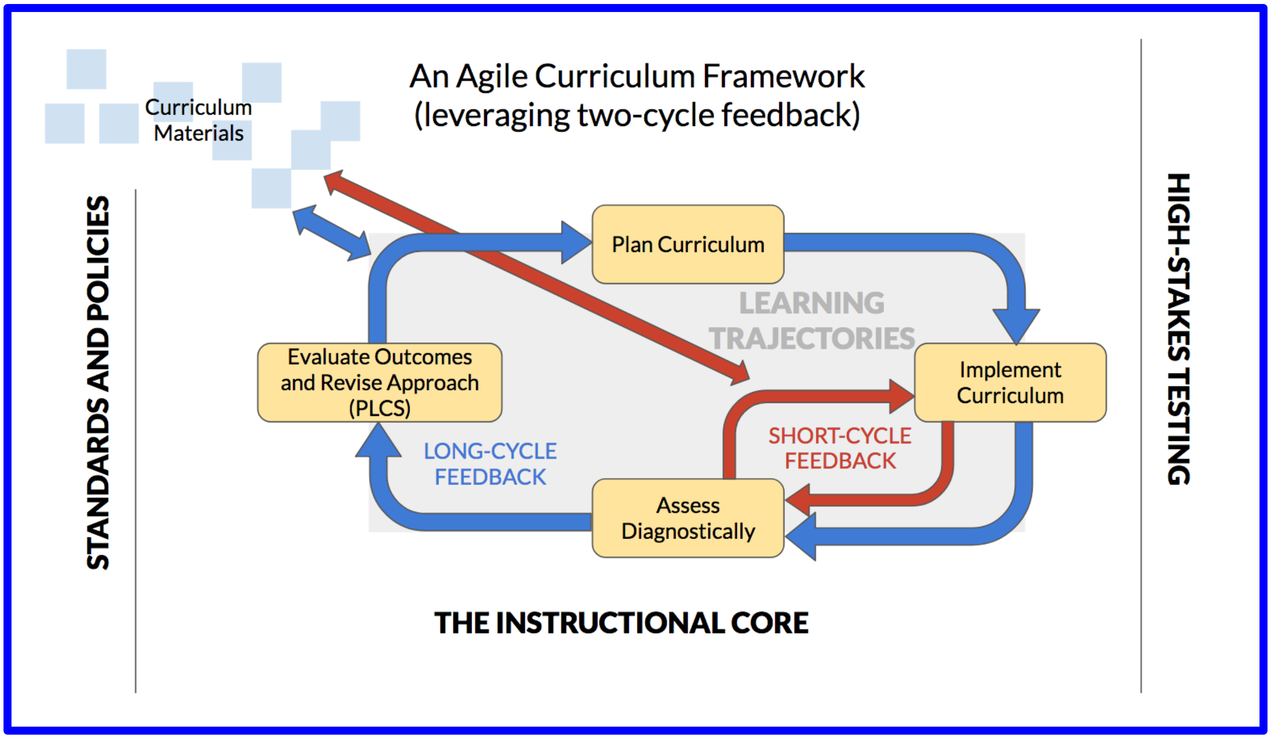

Figure 6: A Two-Cycle Feedback Use in a Diagnostic Formative Assessment System based on LTs (Confrey et al., 2018)

The system consisted of a map of "11 big ideas" to cover all of middle school mathematics including algebra (Figure 7) incorporating 74 individual learning trajectories (called "constructs") organized into a total of 32 "clusters" of topically related constructs. To the degree possible, the LTs were research-based; however, we acknowledge that some topics have a more secure foundation in research than others.

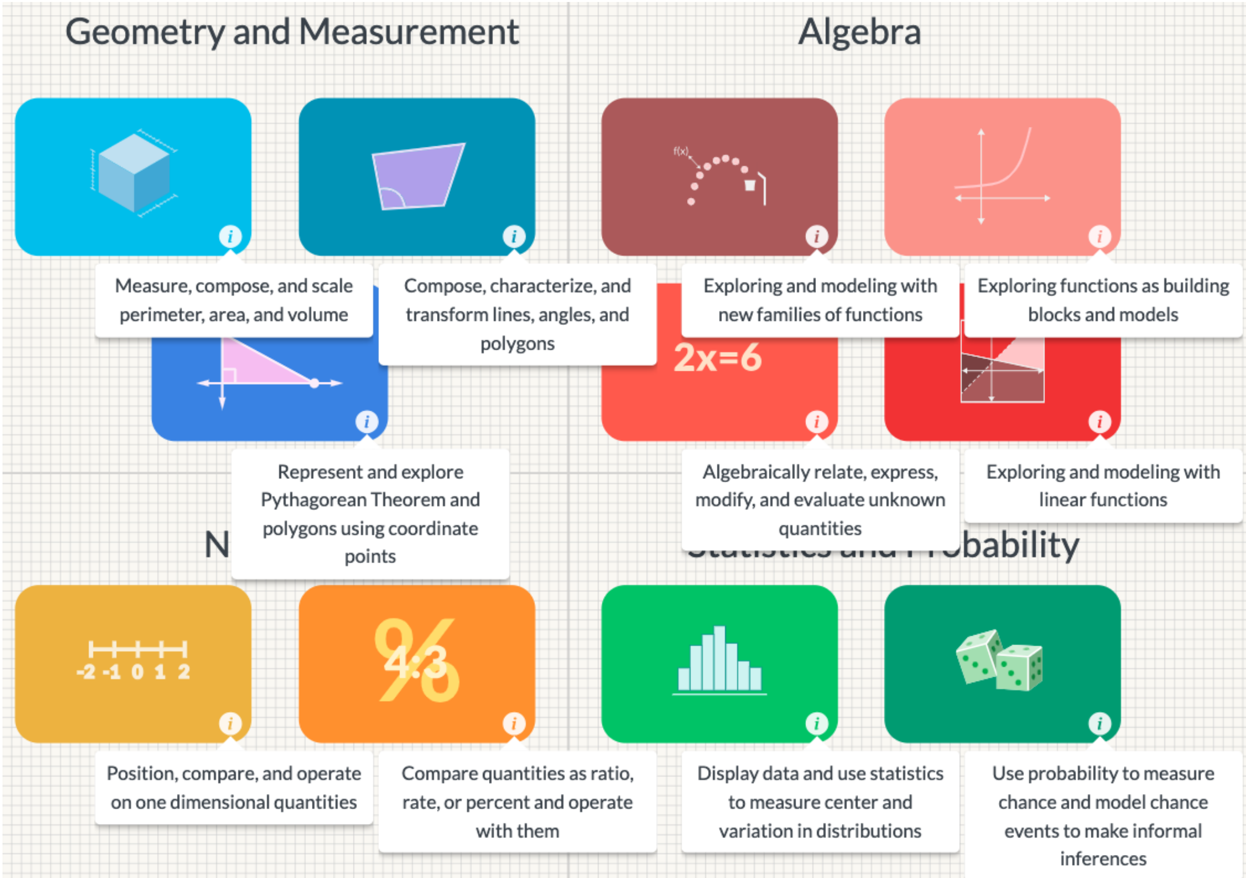

Figure 7: The MM learning map, at top level (i.e. displaying the "big ideas" of the Fields of Geometry and Measurement, Algebra, Number, and Statistics and Probability

In the system, tapping on a construct reveals the associated learning trajectory (Figure 8). The LT levels also include descriptions of related misconceptions (yellow triangles) and their corrected conceptions. Teachers can also access the Common Core Standards related to a LT, or conversely, use a standard to search for its relevant LTs on the map.

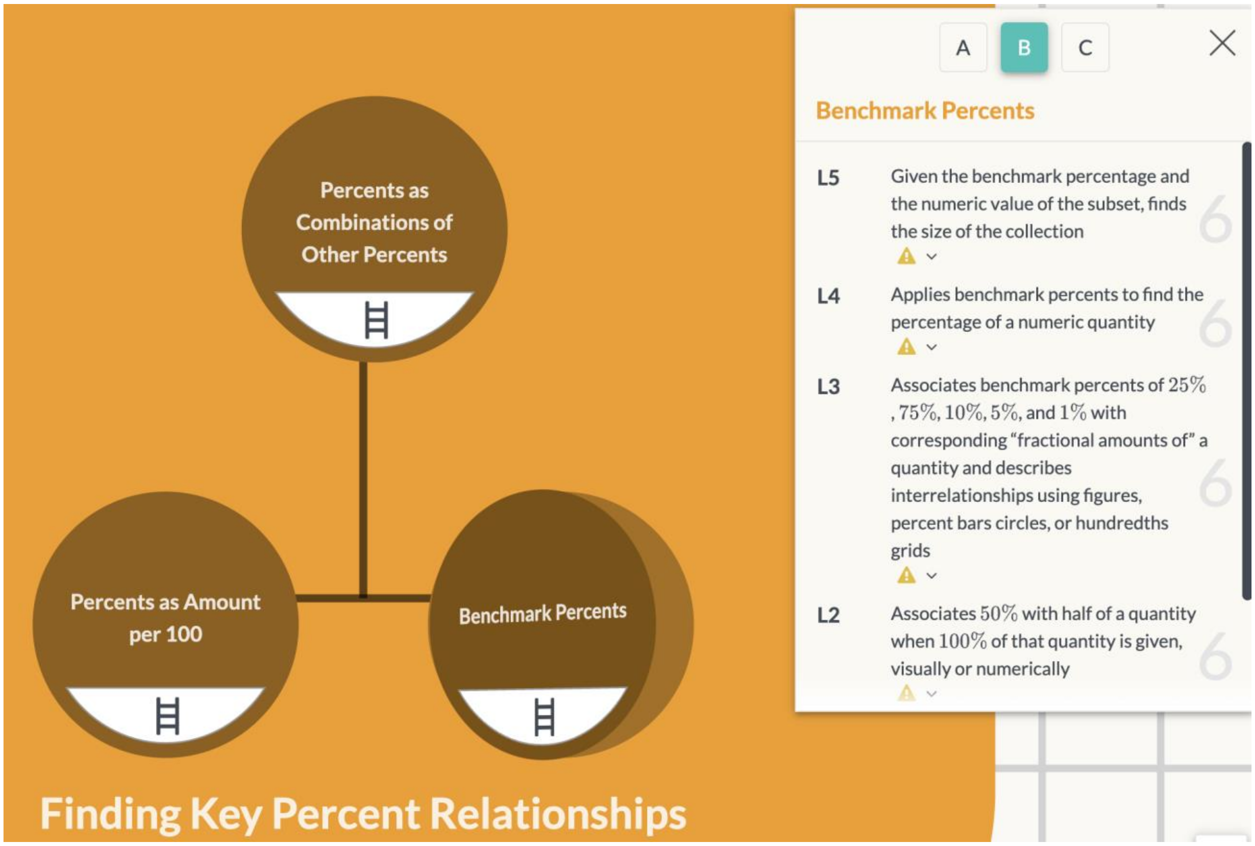

Figure 8: A Close Up of the Cluster "Finding Key Percent Relationships" in the Big Idea "Compare Quantities as Ratio, Rate or Percent and Operate with Them"

To illustrate the system, I will use a single, relatively simple LT, Benchmark Percents (Table 3). We list learning trajectories to mirror the climbing wall from bottom to top. In this LT, the first level children typically can learn to associate 100% with all of a quantity, and 0% with none. At level two, they can associate 50% with half of the quantity when 100% of that quantity is given. And so it goes up the levels, students learning to identify 25%, 75%, 10%, 5%, and 1%, and then applying those to solve problems. An important thing about this trajectory is that it is not based on the teaching of definitions. It builds from the learner's experiences in the world. And they have a lot of experience with percentages as some form of numeric measure. They see percentages on cell phones with the amount of battery left. They see them when they download apps, looking at what percentage has been downloaded. And they see them, of course, in prices and sales in other places out in the world. Therefore, our expectation is that students come to school with some familiarity with the idea, flavored with their own experiences.

Table 3: Learning Trajectory for the Construct "Benchmark Percents"

Level 5	Given the benchmark percentage and the numeric value of the subset, finds the size of the collection
Level 4	Applies benchmark percents to find the percentage of a numeric quantity
Level 3	Associates benchmark percents of 25%, 75%, 10%, 5%, and 1% with corresponding "fractional amounts of" a quantity, and describes interrelationships using figures, percent bars, circles, or hundredths grids
Level 2	Associates 50% with half of a quantity when 100% of that quantity is given, visually or numerically
Level 1	Associates all of a quantity with 100% and none of a quantity with 0% visually and numerically given the value or size of the whole

In the learning map, the learning trajectory for Benchmark Percents is situated in a group of three related LTs which also include Percents as an Amount per 100 and Combinations of Percents (Figure 8). There are also LTs for solving percent problems for the part, the whole and the percentage, and solving multi-step percent problems.

The Context

Two districts were contacted and agreed to work with us on how to meet the individual needs of students more effectively, while striving to improve their scores on state tests. Our district partners differed. One was a rural district with a nearby military base, serving a diverse, high-need, student body (27% African American, 10% Hispanic and Mixed, 53% White, with 57% FRL [free and reduced lunch]). Student mathematics performance at the school, measured on an annual state test, was bimodal. The principal was a strong advocate for the LTDA, and most of the time there was no mathematics supervisor. The other district was suburban, relatively wealthy, and much less diverse (4% AA, 8 % Hispanic and Mixed, 79% White and 10% FRL). Performance measured with the PARCC exam was one of the strongest in the state. The mathematics supervisor was a school leader and a key participant in the design of new affordances in the LTDA.

Over 2,500 original, conceptually-oriented items (16% 1-letter answer such as T/F; 27% multiple-choice; 27% numeric response; 18% multiple-select items; 12% parameterized, algebraic manipulation items), each associated with a single level on a LT, were authored by the research and development team. An assessment of a construct (LT) or a cluster (multiple LTs) comprising 8-12 items, requiring about 20-30 minutes, can be assigned and administered to a class. Once students complete their assessment, the MM system generates individual and class-level data reports. Psychometrically equivalent tests are provided to support repeated assessments in a proficiency-based achievement framework. Students also have access to practice items at any LT level.

High quality, intuitive data reports for students, teachers, and administrators are critical to the diagnostic assessment model. Upon completion of an assessment, each student can access their own data report. Figure 9 shows a student report for the cluster “Finding Key Percent Relationships” (this includes the construct for “benchmark percents” on which the student scored 89%). At the right, the student’s detailed performance on each selected construct is provided using a color-coded ladder that indicates which levels were assessed and the student’s performance on each level (shown: results for construct “Percents as Combination of Other Percents”). The student can also scroll down to access each item on the test, their results, and tools for revising and resubmitting or, alternately, revealing answers for each item (not shown). The green sectors of the circles in Figure 9 indicate that the student has already submitted a correctly revised response.

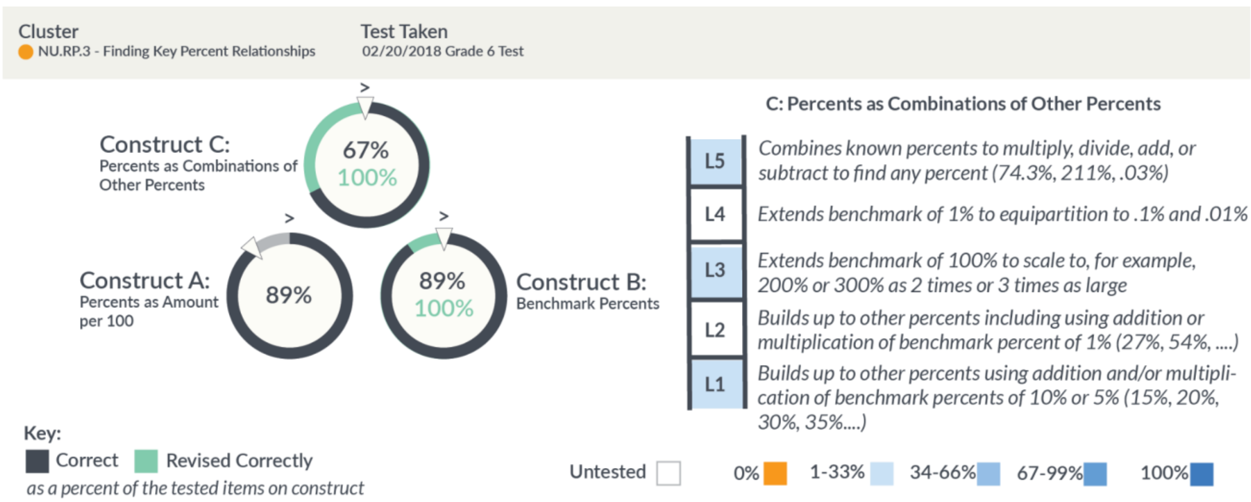

Figure 9: The top half of a student data report on a cluster assessment for “Finding Key Percent Relationships”

As students complete the assessments, teachers have access to all the students’ results in the form of a *heat map* (Figure 10), with a color-coded scale (orange to blue) indicating the percentage correct or designating an untested level (grey) on the particular assessment. Each column (“stack”) represents a student’s score profile for the construct. Students’ score profiles for each construct (LT) are ordered from least to most proficient for that assessment administration.

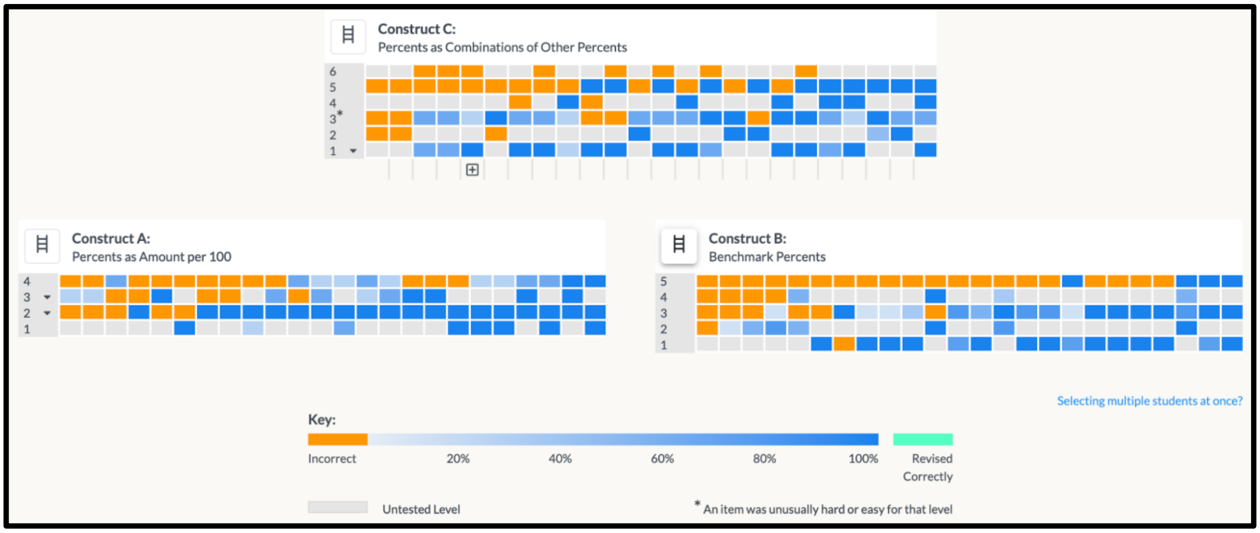

Figure 10: Heat map for assessment for cluster "Finding Key Percent Relationships"

During professional learning sessions, we use Figure 11 to teach teachers how to interpret heat maps (only teachers have access to student names on heat maps; during in-class discussions, they use heat maps without identifiers).

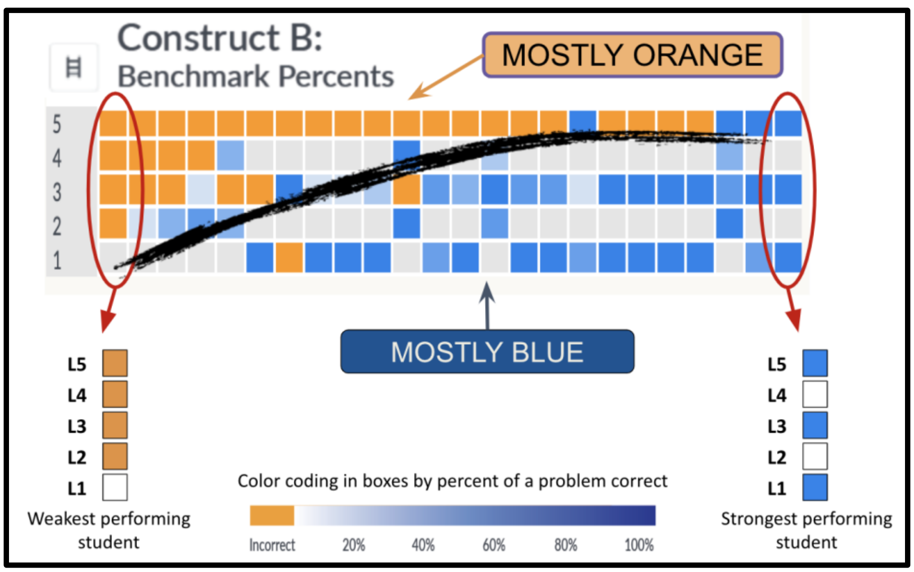

Figure 11: Heat map detail from Figure 10: construct "Benchmark Percents" (explanatory marks and labels added)

Because the items aligned to the LT-levels increase in difficulty, it typically generates a heatmap with more orange towards the upper left (high levels and weaker student performances) and blue towards the lower right (lower levels and strong student performances). Teachers learn to imagine the superimposed curve shown, as an indicator of performance above and below proficiency-level performance. Teachers learn to identify any set of students needing additional instructional help (probably the first two or three students); and any levels that the majority of the class may need to review (levels 4 and 5). To further support classroom discourse, a teacher can display the actual items used in the assessment, reveal the correct answer, display the percentage of students exhibiting misconceptions associated with that item, and examine an item analysis of the students' responses within the heatmap.

Validation of MM

MM is designed as a formative assessment system, to support student- and classroom-level reasoning and discussion. As a system producing scores, it needs to be validated, albeit to a different set of criteria than high stakes tests. The validation of an assessment is "an integrated evaluative judgment of the extent to which empirical evidence and theoretical rationales support appropriate actions in line with the purpose of the test" (Messick, 1990) in this case, feedback on students' progress on LTs that can inform the focus of subsequent instruction. As low-stakes assessments, attention to technical measures of reliability may be de-emphasized. However, fairness, as the absence of bias, must still be examined.

In this low-stakes setting, validation of an LTDA system can be informed by Pellegrino et al.'s, (2016) approach to instructionally valid "classroom assessments". Our validation methodology is described along three dimensions: the validation *argument* (Kane, 2013), the techniques or models selected, and the process of review. Validation arguments help to ensure that the way assessments are designed and are intended to be used are made explicit so that their effectiveness can be knowledgeably and fairly evaluated. We have generated numerous papers about the validation argument (Confrey, Toutkoushian, & Shah, 2019), the validation of particular LTs, and a summary review of the performance of MM based on two rounds of validation for 45 of the LTs.

The validation argument consists of five claims and evidence:

- Construct subscores for a cluster will be highly correlated, reflecting the mutual dependencies implied by the cluster's structure.
- Overall, the empirical difficulty of items will vary positively with level (positive correlation).
- Empirical item difficulties will vary within an LT level in ways closely associated with the meaning of the level; construct-irrelevant variance can be minimized.
- On class (or multi-class)-level reports (such as heat maps or compound bar displays), ordering the levels (and the items by difficulty within the levels) will reveal relative strength of students' performances across items and levels and across the class or classes.
- Based on the data on the students' performance by level, teachers target instruction appropriately.

These five claims tie together the theory of action for MM, moving from the structure of the map into clusters, the relationship between item difficulties and levels, the prediction about the shape of the results and the resulting instructional actions. Further reflection has convinced us that the validation argument needs an additional step that recognizes the importance of the classroom assessment review process.

Following the lead of others, (Lehrer et al., 2014; Wilson, 2005, Graf & van Rijn, 2015), our first step in the validation process was to employ Item Response Theory (IRT) as a psychometric test of the strength of the relationship between the difficulty of the items and the levels of the LTs. Using an iterative regression technique, we identified "potentially non-conforming items" and analyzed the items further. A summary of results from the first two rounds of validation, using 45 of the LT constructs with sufficient data (Confrey et al., 2020) reported a mean correlation of 0.71 between levels and difficulty; 68% of those constructs had strong correlations and 24% had a moderate correlation. Only four constructs had poor correlations that justified major revisions.

Our procedure for deciding what to do with the potentially non-conforming items differed from standard processes. Instead of simply discarding items that did not conform to the expected model, we developed an interdisciplinary review and documentation process conducted by learning scientists, practitioners, and psychometricians. Examining the extent and nature of the data (sample size, school, grade level, and class), we considered seven actions, ranging from discarding the item; revising items; revising, adding, or removing LT levels; collecting more data; re-examining the literature; or completely revising the LT. Building on work by Lehrer (2013) we likened our validation process to a trading zone (Confrey, 2019; Confrey et al., 2021).

Section Three: Five Fundamental Dynamics of the MM LTDA System

I have introduced and described a diagnostic assessment system, based on learning trajectories, whose primary purpose is formative. It is intended to provide learner-centered feedback to students and teachers during instruction, to locate learners' current progress and needs, and to articulate possible paths toward more sophisticated understanding of target concepts. The fine-grained LTs were based on available data from the learning sciences, and the assessments were validated and equated. The just-in-time feedback from the assessments at the teacher-level strengthens reflection and drives instruction and, at the student-level, provides awareness about specific areas that need more work.

The project, situated as "design-based implementation research" (DBIR, LeMahieu, P. et al., 2017; Penuel & Fishman, 2012) resulted in a number of studies, including studies of classroom assessments, validation studies, a lesson study, and a set of think-aloud interviews. We regularly collected data from classroom observations, PLCs, professional development sessions, administrative memos, and software design documents. DBIR involves a complex interplay over time among the theoretical premises of LTs, the software design decisions, measurement choices, student performance data, teacher professional development, curriculum, and classroom implementation.

These rich data sources provided opportunities to consider how underlying design commitments played out in the fray of implementation. Below, I identify five of these design commitments that are critical to successful implementation. I call them "system dynamics" to emphasize that 1) dynamics allow the "study of the effects of forces on the motion of objects in the system” (Wiktionary, https://en.wiktionary.org/wiki/dynamics) and 2) those forces may strengthen *or* weaken the outcomes. Thus, a dynamic here is metaphorically how forces are related to outcomes, and whose intensity and direction varies during implementation. In this context, a dynamic does not function as an independent component of the system but rather as a force that influences components of the system, making them function more or less effectively. Attention to the dynamics has a qualitative effect on the system’s operation. As the importance of these dynamics became increasingly apparent, we added affordances to the LTDA to foster and monitor them in positive ways.

Dynamic 1: Timely, fine-grained LT-situated feedback to teachers supports targeted instruction to increase learning and promote more equitable outcomes.

The central goal of formative assessment is to enact practices that improve instruction and learning over time by providing relevant, timely, and *actionable* feedback to the participants such that *every* student has the opportunity to become proficient in mathematics. To study this dynamic in the MM system, we examine compound bar graphs that describe school or district-wide assessment performance on the LTs.[12] Data from the two partner districts, by grade and class type for the LT “Benchmark Percents” are shown in Figure 12. Bar graph displays mirror the earlier heat map color coding: each bar displays, by LT level, the percentage of students who answered equivalent items aligned to this level incorrectly (orange) and correctly (blue). Note that the rural school only administered this assessment to sixth graders, because they did not group students into classes by performance level. The suburban school had “regular” and “advanced level” classes and administered the assessment in both sixth and seventh grades.

[12] We did not report data by race, gender, ethnicity or SES because we did not negotiate to do so with our partners as we sought to build the system. In our lower SES rural school, we did report evidence of correlations between the increased use of MM and data gains on the state test. We found that assignment by teachers of more of these tests of any topic (just four sections of 25 students) was correlated with the gains of.88 on a five-point scale end of-course test. Conversely, opportunity by individual students to take five more Math-Mapper tests (any topic) per year was associated with gain of.4 on the end-of-course high-stakes test.

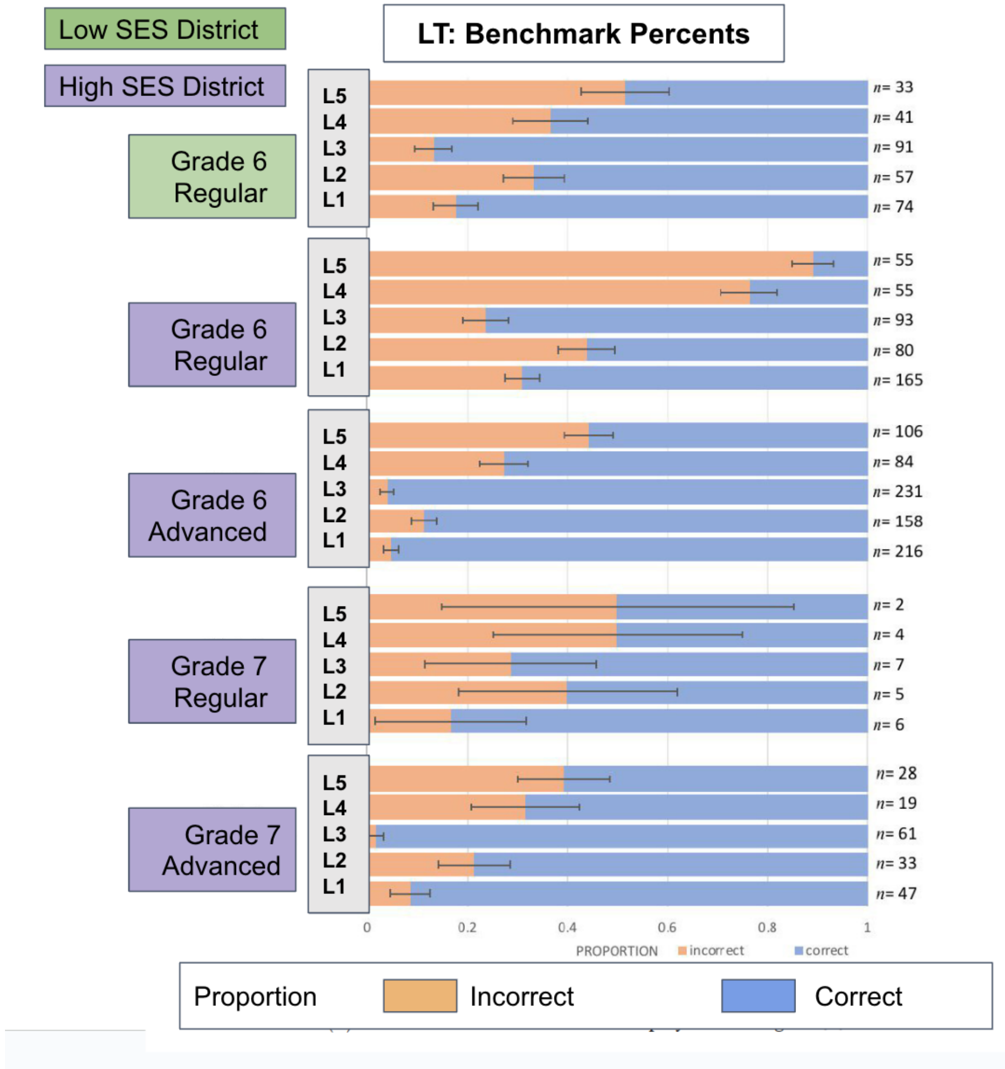

Figure 12: Compound Bar Graphs for the construct Benchmark Percents across the levels, by district, grade, and grouping

These results provide evidence that the LT behaves as expected: for the most part, the higher levels of the LT are more difficult[13].

More importantly, they show that a substantial proportion of students do **not** reach proficiency at the upper levels. Across all the LTs, these proportions of non-proficient students often exceed

[13] Note: Level 3 associates 25%, 75%, 10%, 5%, and 1% with corresponding "fractional amounts", and the items proved easier than expected. Re-examining those items during validation revealed that the presentations of the percentages using pitchers and circles could simply be ordered visually to identify the associated percents without understanding the values. The items were retired.

50%, results which run counter to a proficiency-oriented perspective on learning. During our field studies, teachers had a number of explanations for their students' weak performances at the upper levels, ranging from arguing that the levels were not aligned with standards (they are), that some students do not need to reach the top levels (low expectations), or that students had insufficient time to reach those levels. Based on discussions during professional development, we noted that these upper levels were often less well understood as targets, or that teachers asserted that top levels were more properly assigned to higher grades. We believe this result merits closer attention: teachers may lack adequate time to reach these levels, they may focus more than necessary on lower levels, or may themselves not fully understand the target proficiencies of the LT. Many times, however, we also observed a highly successful teacher explain in PLCs how she/he addressed these levels as a culmination of the LT-related instruction. We see this as an important reminder that schools have their own reservoir of talent that they can draw on to strengthen capacity using their own data from a LTDA.

Across our classroom observations, teachers' review practices varied in the extent to which they drew out student thinking (vs. telling them how to solve the problem), and how they situated the items within the LT. Later, in PLCs, they examined results and shared their interpretations and instructional practices. Re-testing with equated tests could shed some light on student progress and the effectiveness of review and modified instruction. Most teachers we observed did review the data with their classes, but unfortunately, few conducted retesting due to their pacing guide time pressures. We were, however, able to examine the results of repeated testing for a small sample of students on the cluster "Finding Key Percent Relationships" (Figure 13). The distribution of the scores suggests there is a strong potential role for using retesting after a review of the initial diagnostic assessment to support a stronger proficiency-based outcome.

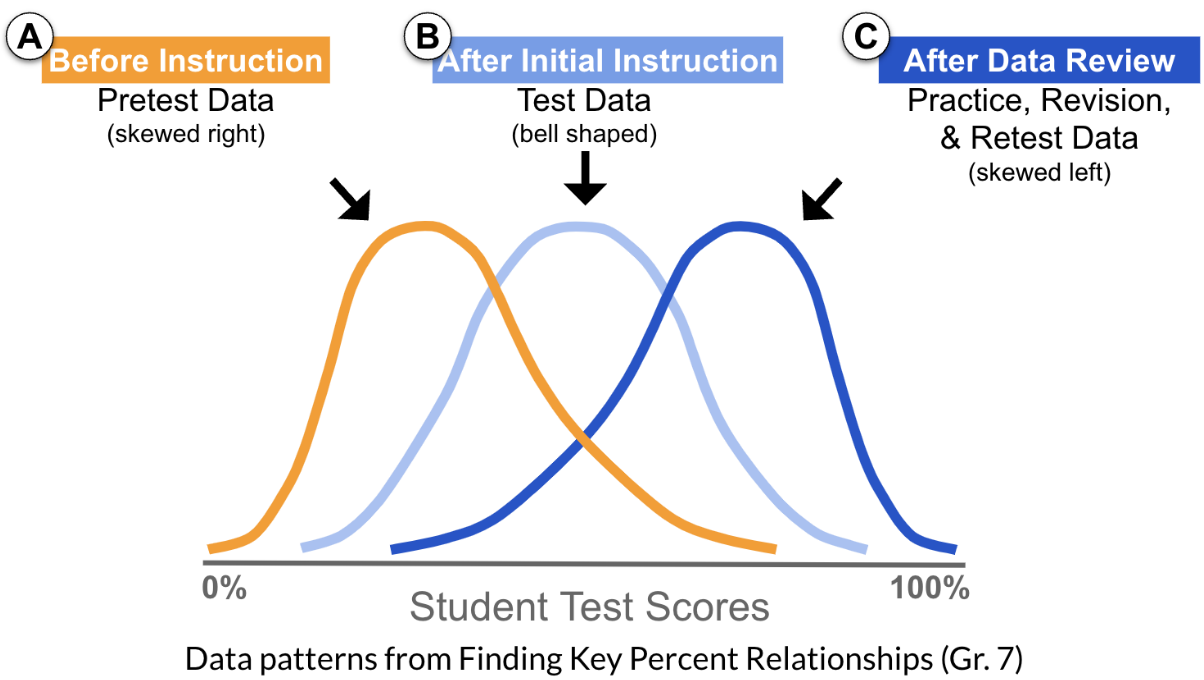

Figure 13: The distribution of student scores across three administrations of equivalent MM assessments

Dynamic 2: Personalized, fine-grained LT-situated data delivered immediately to students, in a context of assessment for learning, fosters growth mindset and student agency.

Learning trajectories place students at the center of instruction. A ground-breaking feature of Math-Mapper is the direct and immediate return of data to students, along with access to the learning trajectories. We argue that this can strengthen student agency, because the students are considered partners in learning, and can evaluate their own strengths and weaknesses based on their own data. The MM system has other affordances to both support teachers in fostering a growth mindset and provide students the opportunities to build their own mathematical strengths. For instance, MM provides students with the option to revise and resubmit answers to any item (with consistent feedback); we repeatedly witnessed students–who at the onset were sure they could not solve a problem–who, through careful reading and persistence, solved the problem.

The student experience of taking MM assessments differed from typical assessments in many ways. Teachers reported that the items were more conceptual. We designed the items, especially at the upper levels, so that students would experience some productive failure/challenge (Kapur, 2009, 2014). Students who were accustomed simply to solving clones of textbook problems found many MM items challenging; on average, overall percent correct scores ranged in the 60-80 percent range. Teachers needed to shift students' expectations of their scores: to understand that the lower range in scores left room for growth (and would not translate directly to the customary grading scale).

In these examples, one can see that teacher expertise is critical to support students in re-orienting themselves to assessment *for* learning in contrast to assessment *of* learning. In our field work, we observed sharp differences in how teachers conducted data reviews. Some treated the items as "hard", and simply explained the solution. In contrast, other teachers asked students to read the problems out loud, queried them about their initial thoughts, and invited sharing and comparison of strategies. The teachers with this second approach often reflected back on the problem with students considering *why* it had been hard and how difficult ways to approach it were warranted. Not surprisingly, when students discussed these challenges as they learned more successful paths to proficiency on the concepts, their growth in learning outcomes accelerated. Students of teachers in the second group learned to approach the assessments with more confidence and determination. These teachers' moves promoted a growth mindset in students and set high expectations.

Supporting students to become change agents for their own learning can (and should) involve groups and not just individual students. We saw evidence of students adopting the language of the LT for themselves to scaffold their own learning. A teacher grouped students with similar response profiles together and asked them to use the practice resource collaboratively on LT levels on which they were weak *before* revising and resubmitting assessment items. Students increasingly used the language of the trajectory levels to explain their reasoning while they taught each other or collaboratively solved the problems.

A recent collaboration with the Young People's Project (directed by Maisha Moses, Bob Moses's daughter and collaborator) involved working with high school students on their way to becoming math literacy (peer) workers. Together we reviewed the LTs on ratio as a means to discuss content **and** pedagogy. After working through the levels, the group somewhat reluctantly took a MM assessment, resulting in a heat map with spotty performances–some stronger, some weaker. However, rather than respond individually to their incorrect results, the group used its own collaborative process to join together and work to “turn the heat map blue”. By doing so, they reappropriated what had too often been an oppressive experience (assessment) into a shared opportunity to assert agency.

Dynamic 3: Data demonstrating variability in learners’ initial success across LTs can challenge beliefs about learning: both student’s self-limiting beliefs and teachers’ stereotyping of students’ learning potentials.

If students feel that they have low chances to succeed in school, they can develop behaviors and perceptions that reinforce failure. Unfortunately, once students are behind the expected pacing of the curriculum, it's increasingly hard to change their negative self-perceptions. Similarly, students who are advanced in their pacing may come to expect that all topics should be easily learned, and feel compelled to hide missed connections and confusion.

To counter such static evaluations, we emphasized the use of flexible grouping using the heat maps for differentiation by LT. Teachers can quickly identify groups of students who need assistance with similar issues. These groups may need instruction to strengthen prerequisite or supplemental topics, to reteach the whole topic (LT), or to focus on specific LT levels. New groupings are formed regularly by need.

MM also allows teachers to explore the consistency of students’ performances across different constructs. In a cluster heat map, for example, selecting a student’s score profile (a stack) in one construct automatically displays that student’s profile in the other constructs of the cluster. It reveals that a score of high (or low) proficiency on one construct does not always correspond to a score of high (or low) proficiency on the others; that is, students frequently do not perform consistently across constructs in a cluster. From this insight, teachers learn that students differ in what they find easier or harder to learn and why one-size-fits-all instruction is unlikely to meet learners’ needs well.

The MM heat maps also allow teachers to select multiple student profiles simultaneously. Using this feature, teachers can investigate patterns of reasoning within groups of learners within a cluster. For example, the profiles of four high-performing students have been selected in “Construct B: Benchmark Percents” (Figure 14). But their performances on the other two constructs varied (Table 4). Multiple conjectures are possible here. Perhaps student O did not understand the new construct about the additive nature of combinations of percent, while students U and E might need more explanations for using certain representations of percents (*e.g.*, using percent bars and extending beyond 100%). That gap in understanding seems to have hampered student E (but not student U) in learning Combinations of Percents. Teachers developed more nuanced understandings of difference and more curiosity about the reasons behind it.

These features of MM can challenge teachers’ and class beliefs about students’ abilities as well as tacit assumptions that mathematical reasoning ability is immutable. By using the MM tools for flexible grouping, teachers can avoid the pejorative and lasting effects of a student always being assigned to the same level or group. In addition, the content-specific conjectures offer rich insights to guide data review discussions and instructional follow-ups. This form of investigation of performance across constructs establishes the value of detailed data on student strengths and needs, using digital affordances to convey this information quickly and accurately. It provides a concrete instance of seeing personalized learning data as a means for all students to experience challenges and success.

Figure 14: Heat map of Assessment Results from Finding Key Percent Relationships. (Color coding added for interpretability)

Table 4: A Summary of Students O, U, E, and D's Proficiency across Constructs

	Student O	Student U	Student E	Student D
Construct B: Benchmark Percents	High	High	High	High
Construct A: Percent as amount per one hundred	High	Moderate	Low	High
Construct C: Combinations of percents	Low	High	Moderate	High

Dynamic 4: Gradual sustained teacher professional learning about the LTs and data use increases the effectiveness of LTDA implementation

Any complex diagnostic technology, from medicine to car repair, requires preparation and ongoing updating for proper implementation. It seems intuitively obvious, then, that making effective use of a LTDA system requires adoption of a continuous improvement approach to building teachers' expertise in implementing the LTDA while gaining their trust and buy-in. A gradual process was needed to learn to use the data effectively in both cycles of the agile curriculum feedback model.

Initially, we documented that during the "short-cycle" feedback process (Figure 6) teachers tended to treat solving each item itself as the direct target of discussion. Gradually, and often with coaching, they learned to shift their focus to 1) treat each item as *representative* of a level, and 2) treat LT levels as *situated within* the trajectory, thereby focusing on movement up the levels as a goal of instruction. Overall, we interpreted this process as the teachers gradually recognizing and coming to trust the LTs as valid frameworks for learning and instruction. During the "long-cycle" feedback process, teachers needed opportunities and coaching to become effective at reading and interpreting data patterns, linking them to potential causes or larger trends, and designing responsive instructional adjustments. Initially, they would jump to propose interventions without careful data examinations. This led us to develop a data-driven PLC framework to guide teachers in the process of 1) closely examining and understanding the student data, led by one teacher, 2) generating conjectures and explanations about connections and possible causes, and 3) planning how to adjust, supplement or change curricular materials or instructional approaches (Figure 15). As an illustration of the value of data use, at our rural school, a sixth-grade teacher shared data showing weak performance for L4: "Builds Up to Percents Larger than 100" within the LT "Percents as Combinations of Other Percents." When other teachers confirmed similarly weak performance in their classes, the teachers as a group realized the topic had simply been overlooked, with the main source of the problem having been the scope and sequence and pacing guides. Some of these problems can be relatively easy to address, with data to guide its identification.

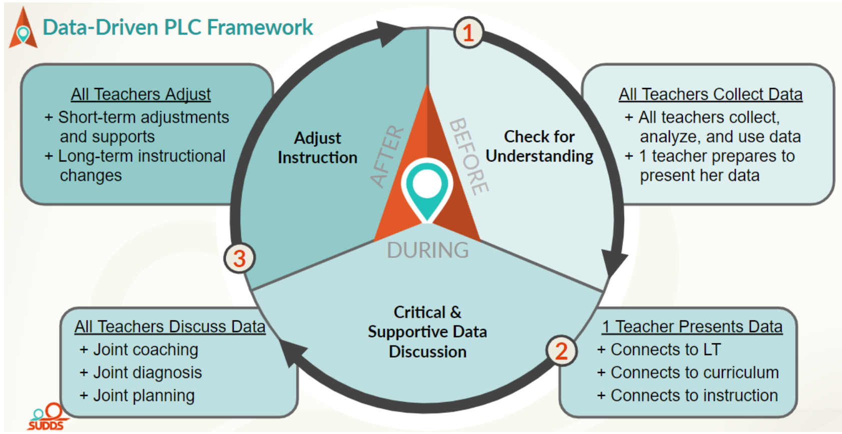

Figure 15: Data-Driven PLC Framework for analyzing and interpreting formative diagnostic assessment data, and making data-grounded short- and long-term instructional adjustments

It is imperative to note that the school or district leaders' commitment, and content- and instructionally focused leadership, are essential for the eventual success of any such adoption. Our schools were more successful from the outset of implementation, when they had the consistent and substantive leadership of the lead district administrator and a mathematics education curriculum specialist, instructional coach, or district supervisor. Success also required school or district commitment to prioritizing the LTDA's use (avoiding competing formative assessment initiatives) and establishing expectations for: 1) content-focused conduct of PLCs, and 2) documented evidence of gradual and sustained improvements in student learning. Supervisors were needed who oversaw the conduct of the PLCs and communicated the district's long-term vision and commitment. To be effective, supervisors should conduct observations of the use of the tool and promote teacher leadership at individual schools. They must co-develop a logistical plan to fully implement MM including choosing focal units to start with after coordinating instruction and common assessments with the pacing guides and the scope and sequence across teachers, and scheduling heatmap review classes and PLCs. The lack of substantive support from those professionals could undercut an implementation.

To enact the high-leverage practices supported by a formative diagnostic assessment system, schools should plan a multi-year ramp to full implementation, even if initial benefits accrue more quickly. Clusters and domains place varying demands on teachers; for most teachers, descriptive statistics and probability and inference are less familiar and more challenging than fractions and decimals. It may take several years to rotate the content focus among the 11 big ideas and 32 clusters: schools should make use of their teachers' varied expertise in different domains. Implementing a LTDA is a systemic enterprise. that dramatically deepens content-based discussions and sharing among teachers. Studies of teachers using MM (Confrey, Shah, Persson, Ciliano, 2019) showed that the most successful teachers exhibited the following patterns:

- emphasis on “assessment for learning,”
- conceptual understanding of, and growing trust in, the LTs, as instructional foundations
- increasingly consistent focus on student reasoning,
- participation in and fostering of peer (teacher) interactions around valid and reliable data,
- growth in the ability to query data in a principled way, and
- commitment to achieve gradual, steady professional growth as a community member.

Dynamic 5: Trading Zone-style collaboration among learning scientists, psychometricians, teachers, *and* students promotes iterative improvement of the design, implementation, and effectiveness of the LTDA.

In general, LTDAs should and can be designed and implemented as dynamic systems to accomplish these dynamic principles (summarized in Table 5). By its nature, an LTDA encompasses all the stakeholders, researchers, and software professionals, as well as the technology product itself. Today’s technology development can be fast and flexible. The map and the LT’s function as a boundary object, that is an object that is meaningful to a variety of communities in different ways, but which also has a common meaning that fosters communication. In this context, changes to LTs and assessment items are expected, including adding, modifying, or removing some, grounded in the validation process. New formats for items can be added. Video exemplars of student reasoning can be shared. As reported, our validation process already alters the interaction patterns among learning scientists, psychometricians, and practitioners to resemble more of a trading zone (in which, the exchange is based on debate and evidence about the relative value, to participants, of various objects at a point in time). A community of stakeholders (now including researchers) with multiple concerns and sets of expertise collaborate, respectful of their different perspectives, with the common goal of promoting growth in all students’ learning.

Changes in MM arose from research, technological advances, and the perspective of practitioners. For instance, integers were originally grouped in the same cluster as fractions and decimals, under the header of “rational numbers”. Teachers pointed out that most curricula do not teach these topics in the same unit, some putting integers in closer proximity to actions on the coordinate plane, so we moved integers to its own cluster. Change can also be initiated based on new research or changes to standards. For example, the constructs encompassing probability were significantly reworked as the topic of early inferential statistical reasoning emerged from research.

A communal process should include critical discussions concerning how to strengthen LTDA design, implementation, and/or practices to equitably support mathematical learning by subgroup, based on race, ethnicity, gender or SES, special education needs, and ESL. The use of the LTDA should be regularly examined for its effects on instructional quality overall and the delivery of quality instruction at all performance levels. Schools should report on the data in easily understandable formats, to support the reduction in learning gaps and improvement in overall performance without shifting its use to a high-stakes entity.

Table 5: Five dynamic principles underlying MM LT-based Diagnostic Assessment System

Dynamic 1: Timely, fine-grained LT-situated feedback to teachers supports targeted instruction to increase learning and promote more equitable outcomes.
Dynamic 2: Personalized, fine-grained LT-situated data delivered immediately to students, in a context of assessment *for* learning, fosters growth mindset and student agency.
Dynamic 3: Data demonstrating variability in learners' initial success across LTs can challenge beliefs about learning: both student's self-limiting beliefs and teachers' stereotyping of students' learning potentials.
Dynamic 4: Gradual sustained teacher professional learning about the LTs and data use increases the effectiveness of LTDA implementation.
Dynamic 5: Trading Zone-style collaboration among learning scientists, psychometricians, teachers, *and* students promotes iterative improvement of the design, implementation, and effectiveness of the LTDA.

Concluding Remarks

By describing Math Mapper's features and identifying dynamics associated with its implementation, I have sought to illustrate a concrete vision of the potential value of diagnostic approaches in a low-stakes feedback data-rich assessment-for-learning environment. MM is both flexible and valid for its purpose as a formative assessment tool. Its validity is enhanced by its proximity and relevance to instruction, and its goal is to stimulate student progress towards more sophisticated reasoning about specific mathematical concepts. Learning trajectories put the learning sciences to work by conveying the richness and diversity of student thinking. In MM, we have synthesized the research on LTs on a full range of the big ideas in middle grades math and accomplished an unprecedented degree of scale in linking those findings to diagnostic assessments. MM's flexibility resides in the way in which it is compatible with a variety of choices of instructional materials whose scopes and sequences vary.

MM provides timely and useful feedback to its users in three notable ways. First, both students *and* teachers immediately and directly receive the data from assessments. Secondly, the data reports are situated within a learning map of the topics, and the underlying learning trajectories provide an overview of the knowledge under study. Thirdly, the data displays include an array of affordances that encourage interactive data review processes. Students are able to revise and resubmit incorrect initial responses. They can practice collaboratively on levels needing more work and then can take equivalent retests supporting the ultimate goal of proficiency at each level. Teachers work with their classes using heat maps to strategically focus instruction at the appropriate levels and to identify students needing additional support to reach proficiency. Affordances of the heat maps allow teachers to project problems that merit further discussion, and to provide access to relevant answers and/or item analysis of the array and percentages of learner responses. Teachers share data with colleagues in search of patterns and alternative approaches or curricular materials.

Through Math-Mapper, we have contributed to the field our methodology for building and refining assessments. Building assessment items specific to the LT levels led us to develop a large base of original items, which were conceptually oriented and nuanced in their cognitive distinctions. Widely accepted psychometric techniques were used to check assumptions about how LTs should behave and identify potentially non-conforming items. Typical practice relies on psychometricians to decide how to modify or remove troubled items; however, our practice was to include learning scientists, psychometricians, and practitioners, all on equal footing. These teams examined the data and decided how to modify items, LT levels, or entire LTs, as we generated explanations based on data characteristics (size of sample, population sampled). With each round of validation studies, we saw the association between LT level and item difficulty improve. Math-Mapper's design made careful use of measurement, and its results supported teachers in making innovative instructional adjustments to meet and record student progress and needs. However, measurement was but one component of this formative diagnostic assessment system. So, I would suggest we have rescued the baby (measurement) and placed it in a new low-stakes context of assessment for learning.

Working at scale within a DBIR project with multiple data sources allowed the identification of five "dynamics." The term "dynamics" was chosen to identify forces that would act on, and interact with, the components of implementation to affect outcomes. Their influence could enhance or diminish the quality of implementation; hence the dynamics are not just additional components. We saw how progress was fostered by a clear understanding of, and focus on, the structure of the LT and on student participation, as evidenced by the methods of review. We observed how fostering a growth mindset and recognizing students as partners and collaborators to each other in learning strengthened student agency. We watched how stereotypes about who can and cannot learn math were diminished as the focus moved to sharing different ideas, challenges, and strategies. And we observed teachers engaging in more specific content-based exchanges about strategies and resources.

The last, perhaps most essential, dynamic was the final one, recognizing the need for transparency and the value of inclusivity[14] in the design and use of formative diagnostic assessment systems in a *low-stakes* context. In settings with strong and energetic leadership, with leaders tuned into their teaching staff, feedback on the tool's use and features accompanied and enhanced the entire endeavor. Absent leadership with actual knowledge of curricular pacing and level of coordination among staff, communication became muddled, and resistance could build. When information flowed in both directions, however, teacher suggestions for changes to MM resulted in notable enhancements. The beauty and power of a low-stakes LTDA is that it can also be improved on a shorter and more flexible timeline because ownership is shared among users and experimentation with techniques can be encouraged.

Bob Moses implored us that it cannot be good enough to return to "normal", because normal has failed to serve such a large proportion of our youth, and has actively disadvantaged specific

[14] Parents are also stakeholders for implementation of an LTDA. They were not included in the current version of MM due to funding and time constraints.

groups. We are suggesting that the next round of LTDA innovation must also be learner-centered with ways to document progress within feedback systems and examine fairness in achieving the system's formative goals. Collaborative contributions by a diverse group of experts and stakeholders must be a central feature. Designed well to produce relevant, timely, and easily used data and implemented in partnership, we can simultaneously make progress on achievement to high levels of mathematical proficiency *and* equity.
