PME–NA History and Goals

The International Group for the Psychology of Mathematics Education (IGPME) was founded in 1976 at the Third International Congress on Mathematical Education (ICME-3) in Karlsrühe, Germany, with the first conference held in 1977 in Utrecht in the Netherlands. The North American Chapter of PME (PME-NA) was organized not long after with the first conference held in Evanston, Illinois in 1979. This initial meeting was organized and chaired by Dr. Richard Lesh following the initial National Council of Teachers of Mathematics (NCTM) Research Presession held in 1978 (Boston, Massachusetts). The plenaries at the NCTM meeting (Heinrich Bauersfeld, Efraim Fischbein, & Hans Freudenthal) were instrumental in the founding of IGPME and encouraged Lesh and others to create a North American chapter. The initial meeting in 1979 may have only featured plenary speakers. However, with the second meeting of PME-NA being a joint meeting with IGPME, individual papers published in the conference proceedings became a mainstay of the conference. Early conferences for both IGPME and PME-NA were focused on exploration of various areas of psychology in the teaching and learning of mathematics. Since their origins, PME and PME-NA have expanded and continue to expand beyond their psychologically oriented foundations. For example, the 1981 PME-NA conference focused on "the influence of modern technology upon mathematics education and related research" (p. 11) in addition to areas of psychology.

The major goals of the International Group and the North American Chapter are:

1. To promote international contacts and the exchange of scientific information in the psychology of mathematics education;
2. To promote and stimulate interdisciplinary research in the aforesaid area, with the cooperation of psychologists, mathematicians, and mathematics teachers; and
3. To further a deeper and better understanding of the psychological aspects of teaching and learning mathematics and the implications thereof.

PME–NA Membership

Membership is open to people who are involved in active research consistent with PME-NA's aims or who are professionally interested in the results of such research. Membership is open on an annual basis and depends on payment of dues for the current year. Membership fees for PME-NA (but not PME International) are included in the conference fee each year. If you are unable to attend the conference but want to join or renew your membership, go to the PME-NA website at http://pmena.org. For information about membership in PME, go to http://www.igpme.org and visit the "Membership" page.

PME–NA Steering Committee

Elected Members
Ayman Aljarrah (Chair)–Acadia University (2023-2026)
Paulo Tan–University of California Santa Cruz (2023-2026)
Verónica Vargas Alejo–University of Guadalajara (2023-2026)
Leslie Dietiker–Boston University (2022-2025)
Christopher Kurz–Rochester Institute of Technology (2022-2025)
Zareen Rahman–James Madison University (2022-2025)
Angeles Dominguez–Tecnológico de Monterrey (2021-2024)
Doris Jeannotte–Université du Québec à Montréal (2021-2024)
Xiangquan (James) Yao – Pennsylvania State University (2021-2024)
Aida Ailbek (grad student rep) – University of Georgia (2023-2024)
Alexa W.C. Lee-Hasan (grad student rep)– University of Illinois Chicago (2023-2024)

Appointed Members
Aaron Brakoniecki–Boston University (2017-2023)
Winnie Ko Indiana State University (2022-2025)

Conference Chairs

Past Conference Chair and Coordinator (2021-2024)

Teruni Lamberg (Chair)
University of Nevada, Reno
terunil@unr.edu

Shera Alberti-Annunzio (Coordinator)
University of Nevada, Reno
shera@unr.edu

Current Conference Co-Chairs (2022-2025)

Karl W. Kosko

PME–NA 2024 Conference

Local Organizing Committee

Karl W. Kosko, *Kent State University*
Joanne Caniglia, *Kent State University*
Scott A. Courtney, *Kent State University*
Maryam Zolfaghari, *Kent State University*

Strand Leaders

The Local Organizing Committee is extremely appreciative of the following people for serving as Strand Leaders. They managed the reviewing process for their strand and made recommendations to the Local Organizing Committee. The conference would not have been possible without their efforts.

Preface

On behalf of the 2024 PME-NA Steering Committee, the 2024 PME-NA Local Organizing Committee, and Kent State University, we welcome everyone to Cleveland, Ohio, USA, for the Forty-Sixth Annual Meeting of the International Group for the Psychology of Mathematics Education – North American Chapter, held at the Hilton Cleveland Downtown hotel and convention center.

This year's conference theme is **Envisioning the Future of Mathematics Education in Uncertain Times**. The past several years have seen significant change across North America and the world resulting from the pandemic, war, technological, political and social shifts. When we selected this theme in 2022 (two years ahead of the conference), there was no war in Ukraine or Israel, ChatGPT was virtually unknown, and each nation represented by scholars at PME-NA faced very different political landscapes. As the context of our world around us changes and evolves, mathematics education *will* also change – either solely from the pressures of the world around us, or through mathematics educators' engagement with the world. Thankfully, our field has a history of considering the profession in the midst of change across and within various contexts (society writ large, classrooms, academia, etc.). Engagement with the world for meaningful change must be informed by rigorous theory and research regarding the teaching and learning of mathematics. Additionally, because education is a caring activity, such engagement with others (students, teachers, the public, politicians, etc.) must be oriented towards not only teaching but learning from others for it to be meaningful. We encourage attendees and presenters to reflect on this as they attend various sessions at PME-NA and engage with others beyond these doors.

This year's conference will be attended by 511 researchers, faculty members, and graduate students, with presenters from around the world including Canada, México, the United States, as well as Australia, Cyprus, Denmark, the Netherlands, Norway, and Turkey. Submitted papers were reviewed in a double-blind process by multiple reviewers. After initial reviews were submitted, Strand Leaders examined feedback and provided recommendations for paper acceptance to the proceedings and conference. The local conference committee made final decisions based upon Strand Leader recommendations and reviewer comments. Overall, there were 423 submissions. The table below outlines the number of submitted proposals across each strand. Following the review and decision process, these proceedings include 81 research reports (41.8% acceptance), 170 brief research reports (73.0% acceptance), 111 posters (79.3% acceptance), and 16 Working Groups (88.9% acceptance).

Strand	Research Reports	Brief Reports	Posters
Curriculum, Assessment, and Related Topics	8	8	8
Early Algebra, Algebraic Thinking, and Function	10	2	2
Equity and Justice	18	15	9
Geometry and Measurement	9	3	5
Mathematical Knowledge for Teaching	4	5	5
Mathematical Processes and Practices	15	4	3
Number Concepts and Propoprtional Reasoning	8	1	3
Policy, Instructional Leadership, Teacher Educators	4	4	6
Pre-Calculus, Calculus, and Higher Math	13	7	1
Pre-Service Teacher Education	20	22	13
Professional Development / In-Service Teacher Education	17	13	9
Statistics, Probability, and Data Science	7	3	1
Student Learning and Related Factors	24	13	8
Teaching Practice and Classroom Activity	23	14	8
Technology and Learning Environment Design	14	6	10

We wish to extend gratitude to the many individuals who volunteered their time and effort in preparation of this conference. Thank you to the strand leaders for your efforts in assigning reviewers, examining reviews for quality and making appropriate recommendations for acceptance. We also wish to thank reviewers who engaged in this important service. We are grateful to many past conference chairs, current and past Steering Committee members, and various other colleagues for helpful feedback and support. Finally, we wish to thank Kent State University and Dean Hannon of the College of Education, Health, and Human Services (EHHS) for supporting our efforts in hosting this conference.

Chapter 1:

Curriculum, Assessment, and Related Topics

Kosko, K. W., Caniglia, J., Courtney, S., Zolfaghari, M., & Morris, G. A., (2024). *Proceedings of the forty-sixth annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Kent State University.

A COMPARISON OF STRANDS AND COGNITIVE DEMAND LEVELS: EXAMINING UNIVERSITY ENTRANCE EXAM QUESTIONS ACROSS THREE COUNTRIES

ygunpinar@uttyler.edu

University Entrance Exams (UEEs) serve as the primary criteria for university admissions into universities in many countries. Given the significant impact of assessment types on teaching and learning, analyzing UEEs in different countries can reveal factors that influence students' learning. This study examined the content and the Cognitive Demand Levels (CDL) of UEE questions in Iran, Turkiye, and the United States. The results indicated that algebra was the most frequently featured content area in UEE questions. Moreover, the majority of algebra questions in all countries were categorized under procedure with connections and procedure without connections cognitive demand levels. Iran and Turkiye's UEEs included topics not covered in the NCTM strands for high school in the United States, such as set theory, graph theory, and logic. Furthermore, the SAT emphasized real-world scenarios within specific subject areas, whereas the UEEs in Iran and Turkiye integrated multiple subject areas within single questions. The paper discusses the implications of these findings.

Keywords: university entrance exams, cognitive demand levels, assessment, algebra, NCTM strands

Many high school students take the national UEEs in different countries, and their performance outcomes indicate admission to universities (Davey et al., 2007; Yildirim, 2007). Thus, it is essential that UEEs, as assessment tools, effectively measure students' knowledge and skills. Furthermore, since the assessment type greatly influences teaching and learning (Shepard, 2001), the university entrance examination plays an important role in shaping mathematics education in countries (Hong & Choi, 2011). Building on prior findings on how assessment tools, such as UEEs shape mathematics instruction, examining these assessment tools could assist educational researchers in understanding the necessities of curriculum development (Chang & Silalahi, 2017). This study is part of a larger research project that examines and compares textbooks and assessments across various countries and reports the results from comparing the mathematics sections of the UEE in Iran, Turkiye, and the United States.

Below are the research questions we aim to address in this study:

1- Which mathematics topics were included in the UEEs in Iran, Turkiye, and the United States?
2- In what ways do the cognitive demand levels of questions in UEEs differ or align across Iran, Turkiye, and the United States?

Literature Review and Theoretical Perspective

This study relies on the framework established by Smith and Stein (1998) to examine the CDL of UEE questions. Building on Doyle's (1983) work, Stein and Smith (1998) proposed the Task Analysis Guide comprised of four categories of tasks at different levels of cognitive demand: (1) memorization, (2) procedures without connections (PWOC), (3) procedures with connections (PWC), and (4) doing mathematics. According to this framework, memorization tasks involve producing previously learned facts, rules, formulae, or definitions, which are highly dependent on memorizing. PWOC tasks require using procedures specifically called for the previous instruction. These tasks do not require students to understand how the procedure works or to explain their thinking. These two levels of tasks are named low-level tasks. The next two CDL comprise high-level tasks. Although there may be some suggested pathways in the PWC tasks, these tasks require a deeper understanding of the mathematical concepts and a higher level of cognitive effort. Doing mathematics tasks requires complex and non-algorithmic thinking in which students explore and understand the nature of mathematical concepts, processes, or relationships. Studies have found that high CDL tasks provide students with more opportunities to learn (Smith & Stein, 1998).

Methods

The present study reports on the analysis of the UEEs of Iran, Turkiye and the United States. For Iran and Turkiye we selected the most recently released UEEs in 2023. However, due to restricted access to the actual SAT questions (the UEEs in the U.S.), the latest available released practice questions (Test 1) by the College Board for SAT were used for the study.

The UEE of Iran and Turkiye each comprised 40 multiple-choice questions, while the SAT practice questions comprised of 54 items, including both multiple-choice and short-answer questions. The first two authors conducted the analysis of Iran's UEEs questions, while the next two authors carried out the analysis of Turkiye's UEEs due to their proficiency in the language. For the SAT exams, all authors participated in the data analysis.

Initially, the authors employed the NCTM strands to classify each question into one of the subsequent topics: Algebra, Numbers and Operations, Data Analysis and Probability, Geometry, and Measurement. Next, the authors narrowed the focus to algebra strand questions, applying the CDL framework. To ensure consistency in the interpretation of CDL, the authors first selected a random sample from all questions (10%) for joint discussion. Prior to reconciling the analysis, they assessed the percentage of agreement as an indicator of inter-rater agreement. The results indicated high agreement rates for CDL: 87.5% for Iran, 86.67% for Turkiye', and 84.61% for the U.S.

Results

Initially, the study will explore the subject areas addressed in the exam questions using NCTM standards (Table 1). Following this, the analysis of the CDL of algebra tasks will be presented, with corresponding data available in Table 2. Lastly, a detailed exploration of the differences observed in algebra tasks among the three countries will be provided.

Table 1: ***Frequency of the UEE Questions in Each NCTM Strand***

Strands from NCTM		The U.S.		Iran		Turkiye	
		#	Percent age	#	Percent age	#	Percent age
Numbers and Operations		5	10%	3	7.5%	9	22.5%
Algebra		39	72%	16	40%	15	37.5%
Geometry		4	7.5%	8	20%	6	15%
Measurement		3	5.5%	3	7.5%	7	17.5%
Data Analysis and Probability		3	5.5%	4	10%	1	2.5%
Other topics	Set Theory	0	0%	3	7.5%	1	2.5%
	Graph theory	0	0%	2	5%	0	0%
	Logic	0	0%	1	2.5%	1	2.5%
Total		54	100%	40	100%	40	100%

In the SAT, the data indicates a heavy concentration on Algebra, 72% of the questions. In other countries, while Algebra remains the most dominant category, it represents a smaller portion of the overall exam, accounting for 40% and 37% of the questions in Iran and Turkiye, respectively (Table 1). Interestingly, the second most prominent category in Iran's UEEs was Geometry (20% of the questions), in Turkiye Numbers and Operations (22.5% of the questions), and in the U.S. Numbers and Operations (10% of the questions). A few questions in Turkey and Irans' UEEs pertained to topics not covered in the NCTM strand (Table 1)

Table 2: ***CDL of the Questions for Algebra Tasks in UEEs***

CDL Algebra Tasks		US		Iran		Turkiye	
		#	%	#	%	#	%
Low Level	Memorization	1	2.50%	0	0%	0	0%
	PWOC	23	59%	5	31%	10	67%
High Level	PWC	15	38.50%	10	63%	5	33%
	Doing Mathematics	0	0%	1	6%	0	0%
	Total	39	100%	16	100%	15	100%

We selected Algebra as our primary topic of evaluation of its CDL since it was the largest category. As Table 2 shows, in Iran's UEEs, the majority of the algebra questions were at a higher CDL (69%), while in Turkiye and the U.S., most questions were at a low level (67% in Turkiye and 61.5% in the U.S.). Furthermore, the majority of algebra questions in all countries fell within the procedural level, with or without connections (94% of the questions in Iran, 100% in Turkiye, and 97.5% in the U.S.

Notably, no questions in Iran and Turkiye, and only 2.5% of the questions in the SAT were at the Memorization level. Also, only 6% of the questions in Iran's UEEs were classified at the doing mathematics level, whereas in Turkiye and the U.S., this percentage was 0% (Table 2). Furthermore, Algebra questions were contextually framed in different ways. For instance, the SAT exam emphasized real-world scenarios within a specific subject area more than the UEEs in Iran and Turkiye. Conversely, the UEEs in Iran and Turkiye integrated multiple subject areas within a single question (see examples in Table 3).

Table 3: ***Comparison of Different Approaches to One Subject among Different Countries***

Country/Test	Content Area	CDL	Question
USA/Sample SAT Test 1 Module 1	Quadratic function	PWOC	Q4. The function g is defined by $g(x) = x^2 + 9$. For which value of x is $g(x) = 25$?
USA/Sample SAT Test 1 Module 2	Quadratic function	PWC	Q7.  The x-intercept of the graph shown is (x,0). What is the value of x?
Iran/2023 UEE	Quadratic function	PWOC	Q6. What is the sum of the root for the following equation? $\frac{1}{x^2} + \frac{1}{(1-x)^2} = \frac{160}{9}$
Iran/2023 UEE	Quadratic function	PWC	Q14. If the function is f is strictly decreasing and its domain is a set of negative values, and if $f(m^2 - m - 5) < f(-3 + 2m - m^2)$ how many integer values can m take?
Turkiye/2023 UEE	Quadratic function	PWOC	Q15. If x and y are real numbers, $x^2 + 8xy = 60$ $y^2 - 3xy = -15$

			What is the product of x.y?
Turkiye/2023 UEE	Quadratic function	PWC	Q20. Uncle Ahmet had a rectangular field with side lengths of x+20 and 2x+30. As shown in the figure in the square-shaped part of his field, he grew sunflowers with a side length of x meters.  If the area of the remaining part of the field is 1400 square meters, how many meters is the perimeter of the entire field?

Discussion and Implications

In summary, the UEE questions in Iran, Turkey, and the U.S. predominantly focused on procedural levels, both with and without connections. Additionally, many UEEs in Iran and Turkey covered topics not typically included in U.S. high school curricula. However, the SAT featured more questions related to real-world applications. This trend might mirror the nature of the mathematics curriculum in these three countries (Chang & Silalahi, 2017) which is the future studies undertaken by the authors. This way, we hope to learn more about how UEE exams align with the school curriculum and also the intricate relationship between curricular materials and expectations from students as they transition into college-level mathematics.

There were no queries at the memorization level in both countries, which provides a promising snapshot of how the focus of the examinations was not on memorizing mathematical concepts, but instead required students to apply a procedure at least. Nonetheless, it is crucial to emphasize the inclusion of doing mathematics level questions in the UEEs, which was not emphasized in any country. This emphasis aligns with the goal of preparing students to become problem solvers and preparing them to navigate situations where they may encounter unfamiliar mathematics problem-solving processes.

This study reported the content and CDLs of UEEs in three countries. The outcomes of similar studies could offer a valuable overview of mathematics education across various countries, aiding our understanding of potential factors contributing to differences in students' achievements.

Keywords: Assessment

Assessment is a part of teaching and learning, and recent efforts seek to improve assessment practices within K-12 education (Harris et al., 2023). There has also been a substantive shift from paper-and-pencil assessments to technology-delivered assessments (Thompson, 2017). Fairness and bias considerations are an important aspect of the assessment validation process (AERA et al., 2014; Herman & Cook, 2022). Exploring fairness and bias issues related to technology-delivered mathematics tests is necessary. This study's purpose is to synthesize bias and fairness validity evidence related to a technology-delivered, computer-adaptive mathematics problem-solving test called the PSM-CAT. The PSM-CAT is composed of standards-aligned, mathematics word problems. It is designed for students in grades 6-8 (age 11-14) and is intended to be formative in nature (see Bostic et al., 2024 for more information).

Potential respondents as well as possible test administrators and users can provide useful data regarding issues of test bias and fairness (Lane, 2014). Our team conducted 1-1 and small-group interviews with students and adults from a broad sample over two years. We purposefully and representatively interviewed (i) students and (ii) teachers, administrators, or curriculum specialists, and (iii) STEM Education faculty and professionals representing different (a) geographic regions, (b) school communities, (c) individuals with and without learning disabilities, (d) multilinguals and native English speakers, (e) genders, and (f) students representing BIPOC and White students. Interviews were audio recorded and transcribed. Data were qualitatively analyzed using a two-cycle approach to generate themes, with checks and balances throughout the analysis to promote trustworthiness (Miles et al., 2014). We report our findings from student-data (potential respondents) and adult-data (potential test users) separately.

One theme emerged from students' data: Items' contexts, language, and content were *broadly accessible to peers*; nearly all students did not perceive bias within items. We will present quotations in our poster and summarize the data as showing that 125 of 128 students (98%) reported items as fair, content-appropriate, and free from bias. A second theme came from adults: Readability, contexts, and standards-alignment was *fair and appropriate for diverse learners*. An implication from this two-year study is opening our test development scholarship on bias and fairness for scrutiny, which may be a call for other test developers to publicly share their findings. Bias and fairness are a cornerstone for a validity argument and should be explored to promote better, shorter tests and concomitantly, more time for teaching and learning (Bostic, 2023).

COMBINED READING: A QUALITATIVE METHODOLOGY FOR RECIPROCAL ANALYSIS OF CURRICULAR DOCUMENTS

Priscila D. Corrêa
University of Windsor
priscila.correa@uwindsor.ca

Leticia Rangel
Universidade Federal do Rio de Janeiro
leticiarangel@ufrj.br

This article introduces Combined Reading, a novel qualitative methodology for reciprocal analysis of curricular documents. We advocate that Combined Reading has the potential to highlight and unveil aspects of mathematics teaching and learning that may not be perceived in the ordinary and naturalized use of curricular orientation documents. Drawing on our previous and ongoing investigations, we underscore the richness of the process and the learning that emerges from it. We propose the Combined Reading methodology to encourage discussion about the necessary knowledge for teachers in teaching and learning mathematics.

Keywords: Research Methods, Mathematical Knowledge for Teaching, Curriculum, Elementary School Education.

Why the Combined Reading of Curricular Documents?

Significant shifts in curricular guidelines for teaching mathematics in elementary education have been observed worldwide (Li & Lappan, 2014; Shimizu & Vithal, 2018; Thompson et al., 2018). Curricular documents directly affect and shape the organization and structure of the mathematics taught in elementary school education. They highlight conceptions about mathematics and its teaching. Teachers interact with and use curriculum guidelines in their practice (Remillard, 2005; Sherin & Drake, 2009). This process allows teachers to grow their knowledge for teaching (Ball et al., 2008). Typically, a single curriculum document will guide teachers. The question that motivates us is to comprehend to what extent a combined analysis of curricular documents, one in relation to the other, offers a way of contributing to and expanding the discussion around teachers' mathematics knowledge for teaching.

> What do teachers need to know and be able to do in order to teach effectively? Or, what does effective teaching require in terms of content understanding? (…) These are centrally important questions that could be investigated in numerous ways—[for example] by examining the curriculum and standards for which teachers are responsible (…). (Ball et al., 2008, p.394)

Combined Reading aims not to compare the teaching of a certain subject in curricular documents from two or more educational systems in search of best practices (e.g. Son et al., 2017; Villalobos Torres & Trejo Sánchez, 2015). The intention is to identify similarities and differences between elements of the documents to understand the reasons that ground them and the implications of their implementation in the classroom, learning from this process. Following Remillard (2005), we believe "there is still much to learn about whether [the] use of unfamiliar curriculum materials might be viewed as a form of teacher development" (p.239). We acknowledge that social, cultural, historical, and economic aspects play different roles in the curriculum and its teaching (e.g., Bessot & Comiti, 2006; Bickmore et al., 2017). We also acknowledge that different countries have different educational particularities and demands (e.g. Acar & Serçe, 2021; Cerqueria & Silva, 2020; Pires, 2013; Wang & McDougall, 2019). However, in this study, we do not consider these aspects. We understand that, regardless, every curriculum has something to learn from and contribute to the discussion. Hence, this paper presents Combined Reading as a methodology for document reciprocal analysis that seeks to promote discussion about teachers' necessary mathematics knowledge for teaching based on the relational investigation of different curricular guidelines.

We believe that considerations emerging from Combined Reading are of the same nature as those carried out by a teacher when deciding, based on curricular guidance documents, how to teach, what students should learn, or what pedagogical resources they should use. The premise of Combined Reading is the recognition of teachers' leading role in the curriculum implementation process (Valverde et al., 2002). It is the teacher's work that ultimately "brings life" to the curriculum in the classroom. Therefore, the Combined Reading of curriculum documents encourages insightful reflections that can support translating the intended curriculum into the implemented curriculum (United Nations Educational, Scientific and Cultural Organization [UNESCO], 2016). Founded on an interactive process that promotes thinking through comparison, Combined Reading allows us to investigate alternating perspectives from different curricular documents. This integrated and comprehensive analysis reveals general aspects of mathematics teaching that go beyond the particularities of a specific curriculum.

What is Combined Reading?

As we designed, Combined Reading (Corrêa & Rangel, in press) is a methodology based on the reciprocal analysis of two or more curricular documents (Figure 1). The process foresees different sequential emphases with their own characteristics. Initially, the curricular documents under analysis must be read in parallel, that is, concomitantly, to provide a panoramic view of the documents. From this overview, correlated elements are identified in the documents, that is, elements with similar functions that allow for a correspondence to be established. In the absence of correlated elements, Combined Reading becomes unfeasible since correlations cannot be determined for document analysis. Correlated elements can have different natures, and their identification is tied to the research question. They can, for example, be structural, such as learning outcomes to be achieved, or they can have a foundational nature, such as principles, values, beliefs, and concepts that underpin the curriculum.

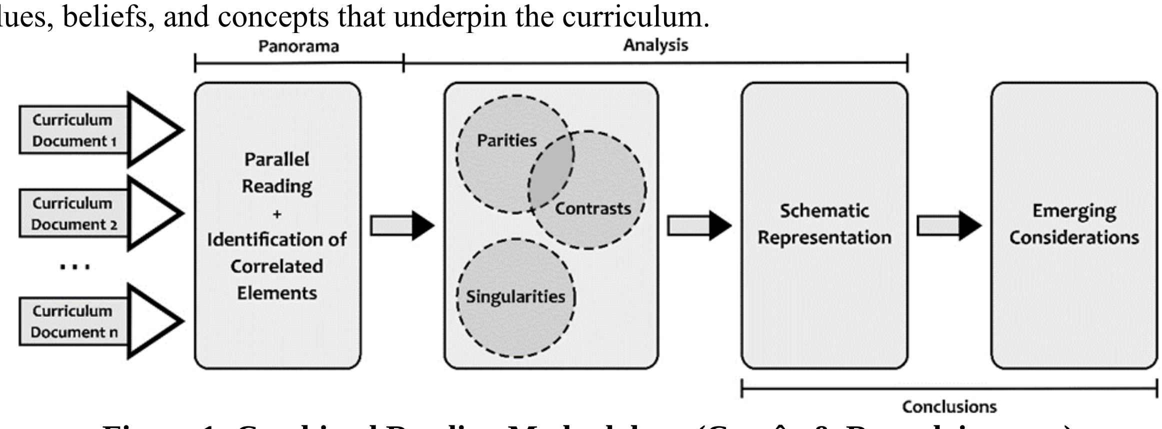

Figure 1: Combined Reading Methodology (Corrêa & Rangel, in press)

Once correlated elements are identified and a correlation can be established between the documents, the analysis begins, seeking parities, contrasts, and singularities in the documents. Parities are identified when correlated elements present high similarity, equivalence, or convergence. This is the case, for example, of identifying that, in the analysis of learning outcomes, two or more curricula propose teaching fractions starting with unit fractions. Contrasts are identified when correlated elements present significant differences, divergences, or contradictions. For example, when the teaching of integers is covered in grade 6 in one curriculum and not mentioned in another one at the same grade level. Finally, singularities are identified when a document presents particularities not included in other documents under analysis. For example, a unique curriculum that proposes Financial Mathematics as one of its strands. Following the identification and categorization of parities, contrasts, and singularities, the subsequent emphasis involves the development of schematic representations that organize and portray the established relationships. These representations are visual and multidimensional, varying according to the objectives and nature of the investigation. This emphasis also supports the analysis, as it highlights the characteristics of one curricular document in relation to another one. Conclusions and considerations emerge from the schematic representations, revealing observations, conjectures, and learning relevant to mathematics teaching.

Example of Combined Reading

We have applied Combined Reading in investigations aimed at discussing the teaching of mathematics in elementary education based on different themes: the teaching of numbers (Corrêa & Rangel, 2021a), teaching approaches to fractions (Corrêa & Rangel, 2021b), the teaching of probability and statistics (Rangel et al., 2024), and curricular terms and expressions (in progress). To illustrate the application of the Combined Reading framework and highlight its potential for shedding light on mathematics knowledge for teaching (Ball et al., 2008), we describe the study focused on Statistics and Probability (Rangel et al., 2024), given that this topic has been a recommendation and a concern in elementary education (Zieffler et al., 2018).

In Rangel et al. (2024), Combined Reading supported an investigation into the teaching of probability and statistics in elementary education. The analysis associated the probability and statistics strand from the Brazilian National Common Curricular Framework (BNCC) (Brasil, 2018) with the Guidelines for Assessment and Instruction in Statistics Education (GAISE) (Franklin et al., 2005; Bargagliotti et al., 2020). GAISE, a United States reference, is not precisely a curricular document; however, it proposes a two-dimensional model to observe the development of statistical literacy (Gal, 2021) that relates the four steps of the Process for Solving a Statistical Research Problem (PRPIE) – formulation of an investigative statistical question, data collection, data analysis, and interpretation of results – with skills that distinguish three levels of statistical literacy – Level A, beginner, Level B, intermediate, and Level C, advanced. The levels that mark the GAISE model are not intended to be directly related to the stages of school education; still, they can coherently guide such an organization.

The authors identified as correlated elements the BNCC skills (Brasil, 2018) for probability and statistics in the first six years of elementary school and the GAISE Level A skills (Bargagliotti et al., 2020). Thus, the study focuses on the initial stage of learning statistics. The qualitative analysis investigated to what extent the BNCC's probability and statistics skills can potentially develop statistical literacy following the GAISE model. The analysis was based on identifying three categories, which reflected the intensity of the relationship between the skills compared: (i) parity – indicating a strong relationship between what was intended by the BNCC and what was indicated in GAISE. In this case, when having a BNCC skill as a learning objective, it is quite possible to achieve the corresponding skill of the GAISE model; (ii) conditioned parity – indicating that the relationship between what is intended by the BNCC and what is indicated in GAISE is not immediate, and is possibly conditioned by external factors, such as a didactic-pedagogical action that requires intentional teacher intervention. Therefore, when having a BNCC skill as a learning objective, it is not natural to also achieve the corresponding skill from the GAISE model; (iii) contrast – indicating that there is no relationship between what the BNCC intends and what is proposed in GAISE. Hence, the skills seem to have no relationship; when one of them is sought, it is unlikely that the other will be achieved. The schematic representation of this study portrays a table in which colours represent the different categories: green for parity, yellow for conditioned parity, and red for contrast (Figure 2).

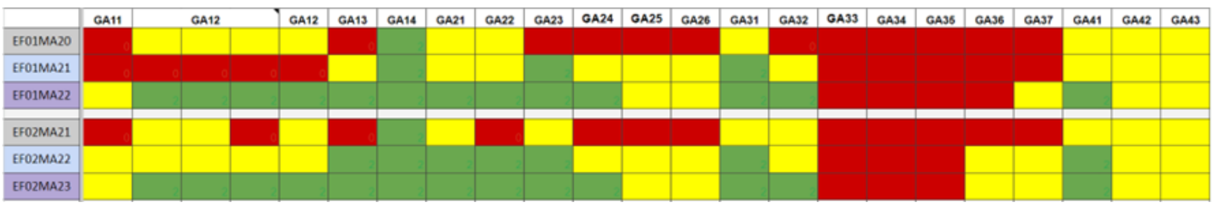

Figure 2: Extract of the Schematic Representation – Study on Probability and Statistics (Rangel et al., 2024)

Emerging considerations from this investigation include the understanding that the BNCC has the potential to develop statistical literacy in the early years of elementary school through the proposition of problems of statistical nature in contexts of interest to students. However, the study highlights that the order in which BNCC skills are listed can compromise the approach to problems, for example, by leaving statistical investigations until last. Furthermore, it was found that the analyzed BNCC skills give little or no emphasis to summary measures, which usually emerge in the data analysis stage of investigations or problems of a statistical nature. Finally, it is noteworthy that the study points out that the BNCC skills regard probability as a separate discipline of statistics; it does not establish, as recommended, a clear connection with statistical investigation. These research considerations contribute to teachers' knowledge for teaching and offer opportunities for improvement in probability and statistics teaching practices.

Final Considerations

Developing and implementing the Combined Reading methodology led to fruitful learning (Corrêa & Rangel, in press). We learned, for example, that the Combined Reading between curriculum guidelines can expand our understanding and perspective on mathematics teaching, addressing curricular requirements and teaching possibilities and opportunities at the elementary level. We learned that Combined Reading has a unique role in observing demands specific to mathematics teaching that are not evident in the individual reading of a curriculum, pointing out convergences, advances, and refinements in curricular documents. We learned that Combined Reading can contribute to converting intended curricula into implemented curricula. We understand that the emerging learnings offered by Combined Reading promote discussion and reflection, contributing to teachers' mathematics knowledge for teaching (Ball et al., 2008).

As an exploratory methodology, Combined Reading also has its limitations. Perhaps the main one is linked to a feature that grounds and supports it: the ease of access to different curricula widely available in digital media. The digital dimension of curricular documents gives them life and dynamism. It is not uncommon for adjustments and changes to be detected in curricular documents amid a Combined Reading. We understand that this limitation does not compromise the value of the reflections emerging from the various studies. Our experience shows that it can even promote new pertinent and enriching reflections. We present a new methodological proposal that we believe may be promising. Publicization, discussion, and peer evaluation are essential for its improvement. In the spirit of collaboration and recognizing the nature and relevance of this conference, we present this methodology. We have learned a lot from it.

"I HAD THIS ROUTINE IN MY HEAD": THE INFLUENCE OF INSTRUCTIONAL ORIENTATIONS AND CURRICULAR CONCEPTIONS

tcsmith@bu.edu

This study investigates how a mathematics teacher's curricular conceptions and instructional orientations relate to their planned lessons as they interact with curriculum materials that reflect different design principles. An analysis of five interviews with six high school teachers from the Northeast revealed that all six teachers planned lessons with consistent orientations regardless of the alignment of the curriculum materials. However, the teachers' interactions with the materials differed based on their instructional orientations and curricular conceptions.

Keywords: Curriculum, Problem-Based Learning, High School Education

Despite significant investment in improving mathematical learning by designing and testing new curriculum materials, little has changed in mathematics instruction at the high school level. Even with research-based curriculum materials and professional learning, the goal of engaging students in mathematical thinking is often unrealized (e.g., McCaffrey et al., 2001). One reason could be that when research-based curriculum materials are not aligned with the teacher's assumptions about how mathematics can and should be taught (a teacher's *instructional orientation*, Lloyd & Behm, 2005), the materials are largely abandoned (e.g., left on the shelf). However, it could also be that even when teachers plan lessons with curriculum materials that are not aligned with their instructional orientation, the resulting lessons remain oriented toward their existing assumptions for how mathematics lessons should play out (e.g., "I do, we do, you do").

This study investigates whether and how a teacher's instructional orientation and their assumptions and perspectives about mathematics curriculum materials, what we refer to as their *curricular conceptions*, may influence the ways the teacher interacts with curriculum materials and the lessons they plan. We wonder how a teacher's curricular conceptions might influence their interpretations of curriculum materials during the planning process, and whether these interpretations might explain how teachers use curriculum materials in different ways than they are intended. For example, a teacher who is oriented towards direct instruction and who views textbooks as a mechanism to deliver information might be inclined to interpret all problems in textbooks as opportunities to practice known procedures, even when they plan with a textbook that is primarily designed for students to learn through problem solving. In such a case, they might even adjust tasks so that they fit their instructional vision (e.g., shifting a task designed for students to become a demonstration by the teacher). On the other hand, a teacher who is more oriented towards fostering student exploration in their classes and who views curriculum materials as tools to promote student thinking might interpret exercises in curriculum materials centered on explicit statements of facts and demonstrations of procedures for their potential to inspire student thinking, and thus design a lesson to exploit this potential.

Specifically, we explore the research question: *How are a teacher's curricular conceptions and instructional orientations related to their interactions with textbook materials and their planned lessons?* Understanding whether and how these factors influence teachers' interactions with curriculum materials and the lessons they plan can enable future research to identify ways to support curricular change.

Theoretical Framework

In this study, *curriculum materials* (or *textbooks*) refer to intentionally-designed mathematical content for the purpose of learning. Although curriculum materials come in a variety of forms, we focus on commercially-available paper-bound textbooks since those are often adopted by school districts as mechanisms to influence instruction. Typically, curriculum materials for secondary mathematics courses contain teacher support as well as portions of text designed for student use. The student portion of curriculum materials often contain a variety of elements, such as *tasks* (all prompts designed to elicit student actions, including problems, activities, and exercises), *exposition* (expository text that provides information), and *worked examples* (problems with detailed solutions). Even when textbooks claim to address the same content goals, there is wide variance in how they are designed: some engage students in thinking and reasoning (*thinking devices* or "TD"), others expect students learn through explicit statements of facts and procedures (*delivery mechanisms* or "DM") (Choppin et al., 2015), while others contain a mixture of both approaches.

Dietiker and Richman (2021) demonstrated that even when two textbook lessons appear similar in style (e.g., exploratory) and content (e.g., same topic), they can have significant differences in how the mathematical content is designed to emerge and change as the lesson unfolds, what we call the *mathematical story* (Dietiker, 2015). The sequence of parts of a lesson through which it advances what is known mathematically (what we refer to as the story's *acts*) impacts the potential for a lesson to inspire curiosity and support inquiry, and changing the sequence changes the mathematical story and its potential impact on students (Dietiker, 2016).

Teachers who base their instruction on curriculum materials interact in ways that can influence their decisions, and thus, their planned lessons. Dingman et al. (2021) identified five types of curricular reasoning teachers employ while interacting with curriculum materials: *viewing mathematics from the learner's perspective*, *mapping learning trajectories, analyzing curriculum materials, considering mathematical meanings, and revising curriculum materials.*

As teachers draw from curriculum materials, they mediate the way content unfolds in their lesson plans. Teachers hold conceptions of curriculum, that is, their perspectives of the role of textbooks and assumptions about what constitutes a mathematical lesson to their curricular work (Behm & Lloyd, 2009; Brown, 2009). For example, some teachers may see curriculum materials as a script to follow (e.g., Lloyd & Behm, 2005), while others might make modifications while using the curriculum materials such as overly scaffolding tasks that are intended to be more exploratory in nature (Lloyd, 1999). In addition, teachers bring their *instructional orientations* to their curricular decisions (Lloyd & Behm, 2005); some teachers assume that to enable learning, students must be given information, often by the teacher or textbook (*teacher- or text-centered instruction*). In contrast, other teachers assume that students can develop understanding through opportunities to explore new ideas, solve problems, and negotiate meaning with other students (*student-centered instruction*). Still, other teachers assume instruction should include a mixture of both approaches.

Methods

This is an exploratory qualitative study comparing the lessons a teacher plans with different types of instructional materials to learn whether and how their lesson plans are related to the design principles of the textbooks. To see if the patterns are related to the instructional orientations and conceptions of curriculum of the teacher, we compared patterns across multiple teachers with contrasting instructional and curricular perspectives.

Data Collection

To learn about the relationship of the design of curriculum materials on teachers' interactions with the curriculum as well as their planned lessons, we selected six mathematics teachers who, as a group, had experience planning with a mixture of curriculum materials (i.e., DM, TD). The selected teachers had between 5-29 years of experience. Inviting teachers with extensive teaching experience increased the likelihood that they had established lesson planning practices.

To explore teachers' assumptions about the shape and sequence of content within a lesson, each teacher was interviewed five times for about 1 hour on each occasion. All interviews were conducted over Zoom and recorded. Interview 1 was conducted in a semi-structured fashion (Weiss, 1994) to learn about each teacher's professional and curricular history. This interview prompted teachers to describe their "typical lesson" with questions such as, "*If I picked a random lesson to observe, what types of activities would you expect I would see?"* Interviews 2 through 5 used the Staged Lesson Planning Interview Protocol, as described by McDuffie, Choppin, Drake, and Davis (2018), which involves asking teachers to plan a lesson with a given set of curriculum materials. No lesson plan templates or expectations of what a lesson plan would include were provided. Prior to each interview, participants were provided a PDF of a lesson to read before the interview. Then, in each interview, the participant was asked to make assumptions about what content preceded and followed the lesson and to plan a lesson for a group of students of their choice (such as one of their current algebra classes). As the teachers planned, they shared their screen with the PDF of the curriculum materials so the researcher could view which parts of the materials to which the teachers were attending. The researcher also asked follow-up questions to gain more information about the participant's visions, intentions, and rationales.

To identify relationships between the curriculum materials and the lessons that teachers plan, we selected lessons from four textbooks located at different points on the DM-TD continuum (see Figure 1). **Lesson A,** which introduces new content through exposition and worked examples, with student exercises, was selected from Glencoe's *Algebra 1* (Lesson 7-1, 2003). **Lesson B**, selected from *Big Ideas Math Algebra 1: A Common Core Curriculum* (Lesson 5.4, 2015), introduces new content through a mixture of worked examples, exposition, student explorations. **Lesson C,** which develops new content through multiple scaffolded tasks, was selected from CPM's *Core Connections Algebra* (Lesson 4.2.3, 2013). Finally, **Lesson D**, which introduces new content through an open-ended exploration, was selected from *IMP Year 1* (Lesson "Get the Point," 2015). Since Lessons A and B introduce new content through worked examples and exposition, we refer to both as DM materials (even though Lesson B also contains explorations). Similarly, since Lessons C and D introduce new content through problem solving, we classify both as TD materials (even though Lesson C is more incrementally structured).

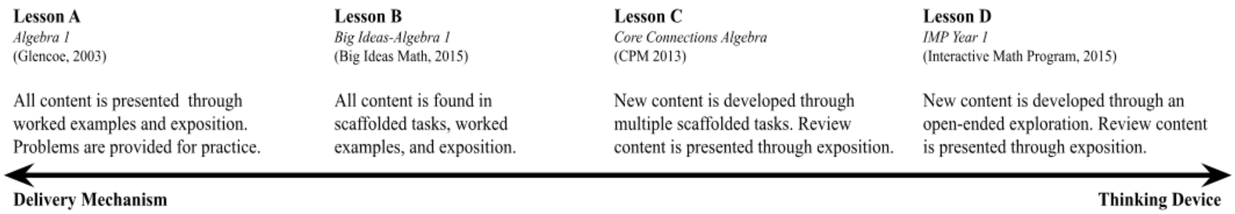

Figure 1: Categorization of Lessons A, B, C, and D along a continuum of DM to TD.

From the teacher version of each textbook (which also includes student-facing materials), we selected a lesson focused on solving systems of equations. This topic was chosen because it is a central topic in Algebra 1 and any teacher with algebra teaching experience would have likely taught a lesson in this topic, minimizing the impact of teacher content knowledge on our results. However, although all lessons addressed systems of equations, each lesson had a different focus: solving by graphing (Lesson A), solving special systems with no solution or infinite solutions (Lesson B), solving using the Elimination Method (Lesson C), and solving using the Substitution Method (Lesson D). Interviews were paced with three or more weeks between each, and the textbook lessons were assigned to each teacher in a different, randomly-generated order.

Data Analysis

We started our analysis by segmenting the transcript of each teacher's lesson plan into sequential acts. To be considered an act, the portion of the lesson must mathematically advance (e.g., moving between the different mathematical tasks or shifting to using elimination after substitution for the same system).

Furthermore, for each act, we recorded its connection to the textbook materials, how the act was intended to be carried out (e.g., were the students expected to work in groups?), and the teacher's rationale for their plan. In addition, we took notes about the teachers' views of the textbook materials, key moments of consideration and decision-making, and their goals and lesson objectives. For Interviews 2 through 5, we listened to each recording at least twice and made additions and modifications to our spreadsheet. While conducting this analysis, we used the information from Interview 1 to see if the participants made significant changes to the typical lessons they usually have in their classrooms. Moreover, we used the Interview 1 data to resolve ambiguities we encountered while looking at the data from Interviews 2 through 5. For instance, when one of the participants told us that students worked on a particular problem in partners and didn't give sufficient logistics about the role of the teacher during the partner work, we returned to their Interview 1 to learn what partner work means to them in their teaching.

To reveal the patterns in the planned lessons, we coded each act based on two dimensions: *who was expected to generate the math ideas* (i.e., teacher/text or student) and *whether the content in focus was new or review of previously-learned content* (see Figure 2). After color-coding the acts, we compared the overall patterns for all participants to group teachers based on whether their lessons contained more student-centered instruction, more teacher-focused, or a mixture of approaches (i.e., some of both). We then compared each group of teachers for the patterns of lesson designs and their relationship with the design of the textbook (e.g., usually having a teacher demonstration before independent practice with TD materials) and any patterns of interactions with the curriculum materials (e.g., looking for opportunities for student exploration or solving problems and tasks as they read DM materials).

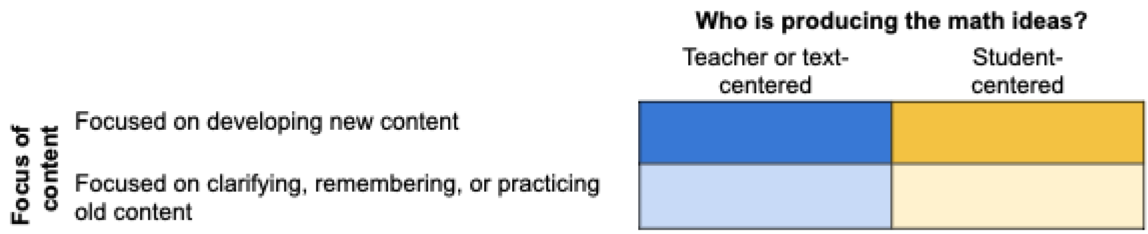

Figure 2: Coding framework to compare the planned lessons.

Findings

Overall, all teachers planned lessons with consistent orientations regardless of the alignment of curriculum materials. Despite this similarity, those teachers oriented to using some exploration and problem solving interacted with DM and TD curriculum materials differently than those teachers who were more inclined to lecture. To explain these findings in more detail, we share patterns in the lesson plans and highlight relationships between the lesson plans and curriculum materials. We also describe how the teachers interacted with the curriculum materials to make sense of the content and to plan their lessons.

Emerging Patterns of Lesson Designs and their Relationship to the Curriculum Materials

Through analyzing patterns, we categorized teachers along a continuum from *teacher-centered* to *student-centered* (see Figure 3). Teachers 1 and 2 intended new content to emerge through lecture and teacher-led discussion (dark blue). When they intended students to engage mathematically, it was to practice known procedures (light yellow). In contrast, Teachers 5 and 6 designed lessons so that new content would primarily emerge through student-centered activity such as student small group problem solving on unfamiliar problems or student-led presentations (gold), along with some teacher summary of content (light blue) and student practice (light yellow). Finally, Teachers 3 and 4 planned new content to emerge through a mix of teacher-centered instruction and student-centered learning (dark blue, gold), along with student practice of existing strategies (light yellow).

What follows is an analysis for each subgroup of teachers.

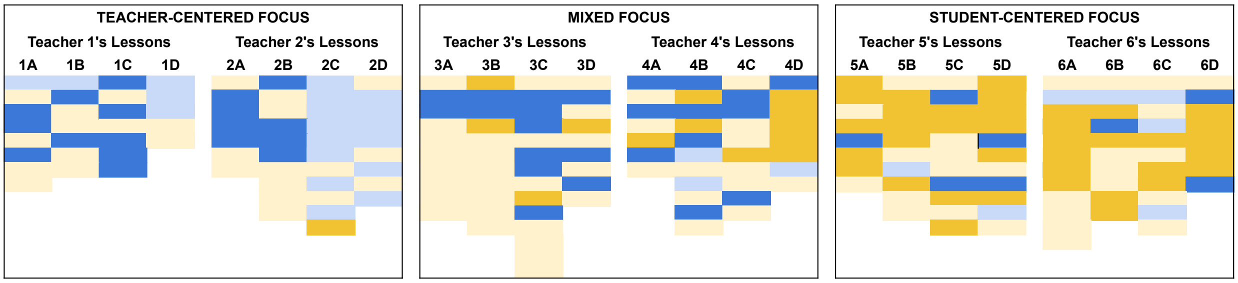

Figure 3: Planned lessons by Teachers 1, 2, 3, 4, 5, and 6 with textbook lessons A, B, C, and D. Acts are color coded as shown in Figure 2.

Teacher-centered teachers. In general, although there were differences, there were strong similarities between the lessons planned by Teachers 1 and 2. For both, portions of the lesson that were teacher-led (including both new and review content) were often followed by some student-led engagement on review (i.e., practice), and when new content emerged, it was almost always introduced through teacher-led instruction. However, although both teachers interpreted the DM materials as having new content, this only occurred for one of the four TD lessons planned by these teachers (namely, Lesson 1C). When Teachers 1 and 2 planned for students to engage in the tasks in each of the TD materials, the tasks were used as practice of prior knowledge. In Lesson 1C, the teacher introduced new content through teacher-led instruction, reframing the tasks in the textbook as practice. For example, when Teacher 1 encountered a task designed to have the Elimination Method emerge through student sense-making in Lesson C, she decided to teach the concept directly first: “Once I introduce the Elimination Method, that’s when I would move on to that hands-on stuff.” For Lessons 1D and 2D, however, these teachers instead interpreted the lessons as entirely reviewing prior content (i.e., no dark blue or gold).

Mixed-focus teachers. In contrast with Teachers 1 and 2, Teachers 3 and 4 planned a majority of their lessons so that new content was introduced by *both* the teacher and through student-led solving of tasks. For Teacher 4, each lesson had at least one portion focused on having new ideas emerge through student-centered problem solving while for Teacher 3, this was the case for the three of the four lessons she planned. For Teacher 3, the only lesson that didn’t result in new content being generated through student sense-making was Lesson A, which was on the far-left end of the spectrum for DM materials.

Intriguingly, these mixed-instruction teachers had different reactions to the TD materials than Teachers 1 and 2. Instead of interpreting all content as review, both Teachers 3 and 4 sought ways to keep the opportunities for content to emerge through problem solving. However, there were differences in their approach. Teacher 4 planned lessons that intended new content to emerge through student problem solving without much teacher intervention, particularly for Lesson D. In contrast, when planning with Lessons C and D, Teacher 3 planned to lead most of the efforts of solving the problems so that the new content would emerge. She expressed concern that students may not be able to generate the desired conclusions without teacher intervention. For example, while working with Lesson C, Teacher 3 commented “maybe I'm selling them short... There's not a lot of precedent for multiplying both sides by a –1" when expressing her disbelief about students generating a strategy to solve an unfamiliar system of equations.

Student-centered teachers. Differing from the lessons of teacher-centered teachers and mixed-focus teachers, Teachers 5's and 6's lessons mostly had student-centered elements. Both teachers, whose pedagogical approach is centered around student sense-making and problem solving, afforded students with multiple opportunities to generate new content without explicit teacher guidance. Regardless of the textbook, both participants emphasized their preference for student-directed activities, such as Teacher 6 remarking, "But that's for [the students] to figure out, not for me to tell them what to do" while planning with Lesson D and Teacher 5 stating, "I feel instead of sharing this table with the students, … it's easier for students to remember or understand if they derived or did something with their team members to discover" while planning with Lesson A. All the lessons they planned included such narratives. In fact, instances of new content being introduced were rare or non-existent for both teachers' lessons, regardless of the textbook materials involved.

Interactions with Textbook Materials

Although all participants read the curriculum materials (both student facing and teacher guidance) to make sense of the resource and to identify potential instructional opportunities, when we compared how the groups of teachers interacted with the textbook materials, interesting themes emerged that distinguished the ways the *teacher-centered* participants interacted with curriculum materials from those in the *mixed* and *student-centered* groups.

Considering student perspectives. When interacting with the curriculum materials, both the *mixed* and *student-centered* teachers considered student perspectives at different points of the planning process. For example, these teachers often based curricular decisions, such as whether or not to select or adjust a task, based on how they predicted students would view particular tasks. For example, when planning a lesson with Lesson A, Teacher 4 avoided tasks that he felt would be boring for students and sought problems that he felt would be relevant to students. In addition, some teachers predicted the ways students would approach solving problems, identified challenges they might confront, and described potential ways students would interpret problems. For example, when planning with Lesson B, Teacher 6 reasoned that students might experience difficulty understanding what the variables represent in the word problems about systems of equations and thus decided to rephrase the problems in a way that asks students to define and explain their variables.

Notably, both *mixed and student-centered* teachers mathematically solved the tasks when confronted with unfamiliar approaches within the textbooks. For instance, Teacher 3 analyzed the systems in Lesson D to determine if they encourage students to set y values to equal each other: "You're going to get a lot of fractions in there, which is ok, but it's unnecessary. It's tedious." From this, she decided the task needed adjustment and weighed whether to change the system's numbers to allow for students to work with integers or to prompt them to substitute for y. In another case, when trying to figure out how students would use algebra tiles to solve a system with the Elimination Method in Lesson C, Teacher 4 solved the problem using this approach. As a result, he reconsidered his approach to this topic: rather than teaching students to "just add the other equation," as he had in the past, he recognized how the textbook approach centered the additive property of equality. Still later, he reflected on the fact that although he never teaches with algebra tiles, this lesson made him reconsider this stance: "I realize [using algebra tiles] takes some time, but I can see how that would be beneficial."

In contrast, *teacher-centered* participants did not solve tasks or otherwise analyze the mathematical affordances of tasks as they planned their lessons. These teachers tended to make rapid assumptions about the complexity or characteristics of tasks. For example, when planning with Lesson D, Teacher 2 selected systems of equations in the textbook indiscriminately. She explained, "maybe, the [task (a)] would be you had to solve it through Elimination, (b) would be Substitution, (c) might be Elimination, …." By the speed at which she considered them, it was evident that the particular systems did not matter to her plan; this teacher did not pause to consider the ramifications of the selection, such as whether the systems contained any special cases (e.g., those without solutions) or other unexpected difficulties (such as those for which the Substitution Method might be particularly challenging).

Reading for content development across the lesson. Another pattern that distinguished the groups of teachers involved how the teachers interpreted the textbooks. All teachers read the DM-oriented curriculum materials as potential components of lessons to draw from. However, with regard to TD materials, the *mixed* and *student-centered* teachers at times read the curriculum materials for how the mathematical ideas emerge and change across a lesson. For example, at the start of planning with Lesson C, Teacher 4 was not sure about its approach, but reading for the nuanced way the content developed enabled this teacher to ultimately make sense of and appreciate it. He noticed that the first task, a problem prompting students to solve a system using the Substitution Method, was designed to set up to motivate the Elimination Method. Then, as he read through remaining tasks, he acknowledged the sequence ("and then they do this…") and described how the sequence might influence the ways in which the students might approach the problems. Another teacher (Teacher 6) interpreted Lesson D as a sequence when she compared it to curriculum materials she had used in the past, noting, "This is very different from a regular textbook. It doesn't have like a couple of examples and a bunch of stuff…Like this is, to me, a planned-out lesson."

In contrast, Teachers 1 and 2 did not analyze how the content developed over the course of any of the textbook lessons. Even when planning with Lessons C and D, in which content was designed to emerge as students solved a sequence of tasks, Teachers 1 and 2 interpreted subparts (a), (b), etc. as separate independent tasks (i.e., practice problems) and did not note their interrelationships. For example, when Teacher 1 encountered sequential subparts that contain clear links, such as a sequence of subparts of a task in Lesson C that sequentially develops the Elimination Method, she construed them as independent exercises. In another case, Teacher 2 suggested that a sequence of systems of equations were interchangeable without regard to any mathematical features that subtly distinguished them (e.g., no solution, or infinite solutions).

Discussion

The results of this study help explain why reforming curriculum materials does not necessarily influence the intended ways mathematics is taught. That is, our data suggests that high school mathematics teachers often plan consistent forms of lessons no matter the design principles of materials with which they plan. Each group of teachers (teacher-centered, mixed, and student-centered) appeared to approach the task of planning with a preconceived image of how their planned lesson would flow. As Teacher 4 said, when explaining why he added a new lesson component to what was offered in the textbook materials, “I had a routine in my head.” Since all the teachers’ planned lessons with consistent orientations (e.g., teacher-centered or student centered), we suspect that a teacher’s preconceived lesson image is closely related to their instructional orientations. Furthermore, since the interactions with the DM and TD materials differed for some teachers (the mixed and student-centered) but not others (the teacher-centered), we propose that a teacher’s curricular conceptions may develop to support the teacher’s instructional orientation (e.g., learning to recognize tasks in TD materials as learning opportunities). Thus, changing instruction may require developing new curricular conceptions, which in turn can support shifts in instruction.

However, this was a small exploratory study. Further research is needed to learn whether this phenomenon is found more generally, or whether it is limited to a particular grade band, geographic region, or other characteristic. If this pattern holds more broadly, however, then this would suggest that shifting instruction at a local level requires teacher education that aims to support mathematics teachers in developing expanded visions on what is possible in mathematics classrooms. Our data suggests three possible ways to expand this curricular vision. First, we note that both *teacher-centered* participants did not interpret problems in the IMP lesson as opportunities for new ideas to be learned. Given this, mathematics teachers need support in their curricular noticing (Dietiker et al., 2018), particularly in seeing familiar parts of textbook materials in new ways and recognizing instructional opportunities in unfamiliar materials that weren’t previously visible to them. Secondly, of Dingman et al.’s (2021) aspects of curricular interactions, two stand out in our study as ways to support instructional change: (a) our findings suggest that solving the mathematical tasks during the planning process can enable teachers to shift their ways of interacting with textbook materials by *adopting a student’s perspective*, and (b) since those teachers who designed lessons with student-centered approaches were the teachers who interpreted the curriculum materials for how the content emerged and changed across a lesson (i.e., *mapping learning trajectories*), we wonder if reading the curriculum materials for this quality supports instruction that is exploratory and student-centered. Future studies could learn whether having teachers learn to interpret curriculum materials as a mathematical story enables them to recognize and incorporate opportunities for student reasoning in their lesson plans.

Acknowledgments

This research is part of a larger project cataloging measures used in mathematics education research, and evidence of validity related to those instruments. This study examines the degree to which validity considerations for measures of mathematics teacher affect and/or behavior are consistent with the guidelines set forth in the Standards for Educational and Psychological Testing. Findings suggest validity evaluations largely rely on (a) evidence of test content and (b) evidence of internal structure. However, explicit claims of how such evidence supports the interpretation and use of test scores are typically absent from validity considerations.

Keywords: Assessment; Teacher Beliefs; Affect, Emotion, Beliefs, and Attitudes

Testing has significant implications for educational practices, research, and policy. Testing programs used in K-12 education influence both the content and pedagogy of teaching and learning (e.g., Kane, 2013), and inferences drawn from quantitative data are often used to inform decisions on education policy (e.g., Hill & Shih, 2009). Validity is a fundamental concern of testing. Validity is "the degree to which evidence and theory support the interpretations of test scores for proposed uses of tests" (AERA et al., 2014, p. 11), and validation refers to the process through which validity is evaluated. The term *test* is broadly defined such that rating scales, inventories, and observation protocols are all examples of instruments categorized as a test (AERA et al., 2014). For this study, we focus on tests of (a) affective characteristics of teachers (e.g., attitudes), and (b) constructs related to teacher behaviors (e.g., instructional practice).

A vision for the future of mathematics education research includes promoting access to, and encouraging the use of, robust measures (i.e., tests) to engage in research that implicates mathematics teaching, policy, and teacher education (Bostic, 2023; Zelkowski et al., 2024). Currently, conceptualizing validity and validation is ambiguous in the mathematics education community (e.g., Bostic et al., 2021), despite guidelines for evaluating validity put forth in the *Standards for Educational and Psychological Testing* (*Standards*; AERA et al., 1999, 2014). The purpose of this study was to examine the degree to which validity considerations related to tests measuring mathematics teacher affect and behaviors are consistent with the *Standards*, and thereby gain an understanding of the aspects of instrument development for which we, as a field, need to continue to grow. Two research questions guided this study: (1) What source(s) of validity evidence were most commonly and least commonly used in evaluating validity related to measures of teacher behavior and affect? (2) To what degree have researchers reported evidence of validity in relation to claims underlying the intended interpretation and use of test scores?

Theoretical Framework

The *Standards* represents consensus in conceptualizing validity among three leading U.S. social-science research organizations related to the field of measurement (Sireci, 2016). Validity is an attribute of a test-score interpretation and use, validity is not an attribute of a test (AERA et al., 1999, 2014; Messick, 1995; Shepard, 2016). For this study, the terms *test, measure,* and *instrument* are used synonymously. Validity is a unitary concept. Describing distinct types of validity, such as *criterion validity*, is an outdated practice (AERA et al., 1999, 2014; Folger et al., 2023). However, distinct types of validity maintain merit as they are reflected in the *Standards*' five sources of validity evidence: test content, response processes, internal structure, relations to other variables, and consequences of testing (AERA et al., 2014).

Current best practices for validation include (a) clearly describing the intended test-score interpretation and use, (b) identifying claims underlying the test-score interpretation and use, and (c) gathering evidence in relation to those claims (AERA et al., 2014; Kane, 2013; Sireci & Benitez, 2023). Test-score interpretation reflects the meaning of test scores. Use statements may refer to actions or decisions arising from test-score interpretation, or use statements may denote a given purpose for testing (Folger et al., 2023). Consider, for example, a test designed to measure educators' self-efficacy for teaching mathematics. Validation would begin with defining "self-efficacy for teaching mathematics" and describing how to draw meaning from test scores (AERA et al., 2014). Next, several claims or assumptions about the test could be raised, such as assuming the items represent the construct (Folger et al., 2023). Evidence is then gathered to ideally warrant these claims (Kane, 2013). Data from subject matter experts, for example, can support the claim that items align to the construct (Sireci & Benitez, 2023). Subsequently, this evidence would be categorized as validity evidence based on test content (AERA et al., 2014).

Not all five sources of validity evidence are needed to establish some degree of validity, nor does every possible claim underlying the test-score interpretation and use need to be examined to establish some degree of validity (AERA et al., 2014; Sireci & Benitez, 2023). It is generally accepted, however, that validation involves collecting evidence from multiple sources (e.g., Bostic, 2023; Kane, 2013; Sireci & Benitez, 2023). In particular, complex test-score interpretations produce more complex claims, which require greater validity evidence (Folger et al., 2023). Put simply, as the complexity of test-score interpretation and use increases, the need for more evidence from multiple sources also increases (AERA et al., 2014). The purpose of this study was to examine the consistency of validation practices related to measures of mathematics teacher behavior and affect with the guidelines set forth in the *Standards*.

Method

We are part of a larger team cataloging tests used in mathematics education. Our team built upon Thunder and Berry's (2016) steps for a qualitative review (see Table 1) to systematically capture measures of teachers' affect and behavior used in research published from 2000-2020.

Data Collection and Analysis

Approximately 2300 articles representing 24 mathematics education journals were reviewed to some degree (i.e., abstract, methods, full article) in an initial search for quantitative measures (i.e., tests) related to teacher behavior and affect. The qualitative review process yielded 255 published unique tests. Six researchers were assigned specific tests for which they (a) searched Google Scholar for studies potentially using the test or reporting on the test, (b) selected studies which potentially contained evidence of validity and/or reliability related to the test, and (c) documented validity and reliability evidence for the respective test. The search for evidence included reviewing peer-reviewed journal articles, conference proceedings, dissertations, and white papers. The goal of this stage was to capture any validity evidence for a respective test. Each test was assigned to two coders, and coders met periodically to discuss identified validity and reliability evidence and reconcile any differences.

Our research team used descriptive statistics to evaluate the research questions for this study. We used frequency counts to determine the source(s) of validity evidence that are most/least commonly reported (i.e., RQ1). To examine the degree to which researchers present evidence of validity in relation to claims underlying the intended interpretation and use of test scores (i.e., RQ2), data were disaggregated by test to assess the presence of interpretation and/or use statements, claims, and the sources of validity evidence represented.

Table 1: Comparison of Our Process with that of Thunder and Berry (2016)

Step	Thunder & Berry (2016)	Our Process
1	Determine a research question	Same
2	Determine search terms	Same + verify multiple Boolean string searches
3	Search databases	Identify journals, test, and export to spreadsheet
4	Select relevant studies	a. Title & abstract review b. Verify interrater agreement, check for drift coding c. Continuous secondary coding of 20% of articles d. Monthly meetings to reconcile coding
5	Assess quality of selected studies	a. Review methods; if needed, review entire manuscript b. Verify interrater agreement, check for drift coding c. When identifying tests, secondary coding of 20% of articles d. When identifying validity evidence, all tests are double-coded e. Monthly meetings to reconcile coding
6	Synthesize findings	Organize in spreadsheet based on coding
7	Report findings	Presentations and publications

Results

The review process produced 239 resources containing validity or reliability evidence. For this study, we focus solely on synthesizing the evidence of validity. At times, multiple resources (e.g., two or more journal articles) presented validity evidence related to a specific test. In total, we identified 480 different instances of validity evidence for 158 of the 255 identified tests.

RQ1: Most and Least Commonly Reported Sources of Validity Evidence

Table 2 presents frequencies for each respective source of validity evidence located during the review process. No particular source was present for at least half (50%) of the tests. Test-content evidence, most commonly reported, was found in relation to 96 tests. Evidence based on consequences of testing was rarely found, such evidence was identified for 8 tests.

Table 2: Summary of Validity Evidence

	Test Content	Internal Structure	Relations to Other Variables	Response Processes	Consequences of Testing
Total Instances	189	126	119	37	9
Instruments for which the source is represented (% of 255)	96 (37.6%)	85 (33.3%)	67 (26.3%)	27 (10.6%)	8 (3.1%)

RQ2: Evidence Related to Claims Underlying the Test-Score Interpretation and Use

Of the 255 total tests we found, 23 tests (9.0%) included test-score interpretation statements, 49 tests (19.2%) described use statements, and 38 tests (14.9%) provided explicit claims or assumptions. Moreover, we found 0 sources of validity evidence for 97 tests (see Table 3). Less than two sources of evidence were found for roughly 70% of the 255 tests, with a median of 1 source of evidence per instrument. At least three sources of evidence were located for approximately 14% of the tests.

Table 3: Sources of Validity Evidence Represented Per Instrument

Zero Sources	One Source	Two Sources	Three Sources	Four Sources	Five Sources
97 instruments (38.0%)	83 instruments (32.5%)	39 instruments (15.3%)	24 instruments (9.4%)	10 instruments (3.9%)	2 instruments (0.8%)

Discussion

Findings from this study suggest validity considerations for measures of mathematics teacher affect and behavior are largely not consistent with guidelines set forth in the *Standards* (AERA et al., 1999, 2014). Particularly, mathematics education research focused on teacher affect and behavior rarely details how test scores are intended to be interpreted and used. There is a preponderance of quantitative research focused on mathematics teacher affect and behavior that (a) omits any consideration of validity, or (b) relies on minimal evidence without explicitly describing the way(s) in which the evidence contributes to the validity of how test scores are intended to be interpreted and used. Some claims can be implicitly recognized—feedback from experts often supports the claim that items align to the construct (e.g., Folger et al., 2023). However, we found that the claims underlying test-score interpretation and use were seldom made explicit in scholarship. Claims help identify what validity evidence sources are important for validation, thereby communicating the importance of collected evidence (AERA et al., 2014).

Researchers may consider modeling their evaluations of validity from robust validity considerations found in current scholarship. For example, Walkowiak and colleagues (2014) used the *Standards* (AERA et al, 1999, 2014) as a framework for a validation study of the *Mathematics Scan*, a measure of mathematics teaching practices; their study presented validity evidence based on (a) test content, (b) response processes, and (c) relations to other variables. Additionally, Bjerke and Eriksen (2016) presented a validity argument supporting the use of the *Self-Efficacy in Tutoring Children in Primary Mathematics* instrument. Examples of validity evidence found in that study include findings from cognitive interviews with test-takers as evidence of response processes, and results of Rasch analysis as evidence of internal structure.

Validation has been described as "equity-forward scholarship" (Bostic, 2023, p. 218). Test-score interpretation(s), and how data are subsequently used, can implicate opportunities for others (e.g., Shepard, 2016). The intended and unintended consequences of test-score interpretation and use are validity concerns (AERA et al., 2014), yet evidence based on consequences of testing is seldom presented in relation to measures of mathematics teacher affect and behavior. We echo Cronbach (1988) regarding the importance of consequential considerations, "tests that impinge on the rights and life chances of individuals are inherently disputable" (p. 6). Consequences of testing warrant meaningful consideration (e.g., Shepard, 2016; Sireci, 2016). This study shines a light on the need for validation practices to improve in the mathematics education community, while also providing examples and clarifying aspects of validity such that researchers may engage in more robust and meaningful evaluations of validity.

Conceptual understanding is an essential component of mathematical proficiency for all students, including students with disabilities. Yet, in the special education literature, conceptual understanding is a term often used but rarely defined. To gain insight into how conceptual understanding has been measured (and thus defined), we conducted a systematic review of the special education literature over the past thirty years. Using Skemp's (1978) continuum of understanding, we found most tools and activities reflected instrumental understanding (i.e., disconnected bits of discrete information), employed scoring techniques that emphasized accuracy, or did not provide sufficient information to be coded. The findings suggest aspects of the special education literature base that warrant further exploration and highlight the need for increased opportunities for students with disabilities to develop relational understanding.

Keywords: measurement, special education, students with disabilities

Introduction and Background

So that students with and without disabilities have equal opportunities in mathematics, professionals from mathematics education and special education fields must share disciplinary knowledge (Tan et al., 2019; Yeh et al., 2020). Sharing knowledge among interdisciplinary group members involves interrelating diverse views to gain clarity about concepts and terms (Akkerman et al., 2007). Because mathematical proficiency for students with disabilities has historically been limited to procedural fluency (Foegen & Dougherty, 2017; Lewis & Fisher, 2016) as a measurement of understanding, we believe that gaining clarity about concepts and broadening perspectives about students' demonstration of conceptual understanding (e.g., the comprehension of mathematical concepts, operations, and their relation to one another; Kilpatrick et al., 2001), has the potential to contribute to better opportunities for students with disabilities to develop a firm grasp of mathematical concepts. Exploring definitions of conceptual understanding and the various methods educational researchers have used to measure it is vital because how conceptual understanding has been measured and defined indicates the instructional tools, approaches, and orientations toward supporting the students being assessed (Treffinger, 2009). This study aimed to understand how mathematical conceptual understanding has been measured (and therefore defined) in special education literature over the past three decades.

Study Design

To understand the prevailing definition of conceptual understanding in our field, the authors of this study, researchers in special education, conducted a systematic literature review of existing literature in the top 25 special education journals published between 1990 and 2020.

Screening and Coding

First, the authors formed a research team and screened articles by reading through the titles and abstracts of available volumes based on the method section to see if students' conceptual understanding was at least one stated outcome measure. A researcher external to the authors' research team conducted screening reliability on 20% of all issues to increase the comprehensiveness of the initial phase of the search. Second, the research team conducted a second-round screening by reading the method section of each article and determining if conceptual understanding was a dependent variable in the study. The inclusion criterion included if the article's author(s) described at least one outcome measure as assessing students' understanding or reasoning. Given the range of conceptualizations around what counts as conceptual understanding, we relied on authors to explicitly identify understanding or reasoning as an intended outcome of the intervention. Third, the team recorded the name of the tool(s) authors used to measure understanding, the tool's citation (if any), the reported mathematical activity students were asked to do to demonstrate understanding, and how researchers reported scoring the activity. Fourth, we developed codes for these activities based on Lesh and Doerr's (2003) representations for demonstrating understanding, again relying only on the information provided in each article; thus, some activities had multiple codes (e.g., reflection and debriefing or model-eliciting).

Categorizing Codes

To categorize activity scoring, we coded each tool as using an (a) *accuracy scoring framework*, (b) *understanding scoring framework*, or (c) *other scoring framework*. We then used the collected data to create a set of subcodes based on how researchers described scoring mathematical activities. Scoring types included: (a) *not specified*, (b) *scale* (not specified), (c) *computational accuracy*, (d) *process/procedural accurac*y, (e) *classifying mathematical behavior*, (f) *explanation*, (g) *reasoning/understanding accuracy*, and (h) *justification*. Finally, once all activity and scoring codes were assigned, we analyzed the data in two ways: 1) we generated descriptive data about the tools the authors said they used to measure understanding and the scoring methods authors reported using and assigned codes to broader categories; and 2) given that measuring understanding typically necessitates the convergence of evidence (Wiggins & McTighe, 2005), we examined whether a tool included one or more mathematical activities, employing Skemp's (1978) spectrum of understanding (e.g., instrumental or relational), to determine whether the tool was conceptual in nature. If a tool included more than one activity, we applied the *relational* code; if it included one activity, we applied the *instrumental* code; and if the tool was not described with enough detail to know the number of activities, we applied the *not specified* code. Finally, we looked across the codes and applied the majority code to the whole tool. For example, if a tool was coded as relational-relational-instrumental, the final code would be relational.

Findings

We found that slightly more than forty percent of the tools reported using what we characterized as an *Accuracy Scoring Framework*, using at least one scoring procedure that either assessed an accurate answer or an accurate procedure (n = 29; 42.65%). Slightly less than forty percent (n = 26; 38.24%) of the articles did *Not Specify* scoring criteria. A small proportion of tools (n = 13; 19.12%) used what we characterized as one of two frameworks: an

Understanding Framework or *Other Scoring Framework*. The Understanding Framework reported scoring understanding based on students' explanations, justifications, reasoning, or understanding accuracy. The Other Scoring Framework reported scoring using an unspecified scale or classified students' mathematical behaviors. That is, across the three coding categories—number of activities used, whether or not any of the activities were conceptual in nature, and the nature of the scoring framework used—tools in these studies attended to conceptual understanding in ways that we characterized as *Instrumental*. We coded fewer tools (n = 19; 27.94%) as *Relational* and found that there were nearly as many tools coded as *Not Specified* (n = 18; 26.47%). Of the 68 tools used across these 52 articles, only three tools (4.41%) could not be neatly sorted into one of the three analytic categories, given that the tool they utilized earned one instrumental code, one relational code, and one not specified code. See Table 1 for the distribution of tools across the spectrum of understanding.

Discussion

Assessing conceptual understanding is notoriously difficult, especially when accuracy is conflated with understanding. Deep understanding is likely not easily evidenced by a one-time assessment but necessitates a convergence of evidence (Jin & Wong, 2021; van de Walle et al., 2013; Wiggins & McTighe, 2005). Though researchers have developed instruments to measure understanding, these may be confounded by the realities of the measures' administration intensity, required time commitment, and reliability (Jones et al., 2019). To address this challenge and the opportunity gap implicated, this systematic literature review aimed to understand how mathematical conceptual understanding has been measured (and thus defined) in the special education literature over the past three decades. We found that most tools and activities used in the included studies measured instrumental understanding, used scoring techniques that emphasized accuracy, or did not provide sufficient information to be coded. The *kind* of understanding the researchers in special education literature measured was notably oriented to instrumental rather than relational (and more conceptual) understanding.

Our results suggest that conventional notions in special education research about measuring students with disabilities' mathematical capabilities are limited and merit expansion. To support students' mathematical proficiency through exposure to rigorous instruction, we must consider the tools we use to measure their understanding. We contend that the field of special education and students with disabilities would meaningfully benefit from a purposeful expansion of thought around the term conceptual understanding and, therefore, an expansion of our tools. In addition to advances in measurement, we encourage education researchers to expand the type of understanding included in mathematics intervention efforts. This expansion supports disabled students in meaningfully different kinds of mathematical activity and, ultimately, different kinds of mathematical learning. Such a definitional expansion broadens who can be counted as having an understanding of mathematics, including students who perhaps struggle with accuracy or computation but who, in fact, do understand the underlying mathematical relationships at play.

The field of special education is positioned to take up new approaches, tools, and orientations in mathematics toward supporting disabled students in developing robust mathematical proficiency. Taking up an interdisciplinary and intersectional perspective, we look to our mathematics education colleagues, who have already charted some of these pathways. We believe that collaborating with mathematics education researchers has great potential and that paving the way to a more equitable method of measuring understanding may require combining the distinct knowledge of each field to better support and enhance the mathematics learning of students with disabilities.

Nunes et al. (2009) [1]
Parmar & Cawley (1994)

Note. Articles that contained more than one tool are identified by superscripts. Superscripts indicate how many tools, from that article, are in the respective category. For example, the Mabbot & Bisanz (2008) article used four total tools. The article appears in the *instrumental* column and has the superscript "3" to indicate their study used three tools, all of which we coded as *instrumental*; this article also appears in the *relational* column and has the superscript "1" because they also used one tool that we coded as *relational*.

PORTRAITURE AS A LENS TO PAINT WITH WORDS: MATHEMATICS TEACHERS’ CURRICULAR REASONING DURING PLANNING

Ana-Maria Haiduc
Purdue University
ahaiduc@purdue.edu

Portraiture is an emerging methodology in mathematics education that could bring new insights and perspectives. This methodology involves capturing a distinctive story that reflects universal themes; the final product is a co-collaboration between the researcher and the subjects meant to inspire the reader. Listening actively *for* a unique story makes portraiture different from other qualitative research forms. For example, in ethnography, the researcher listens passively *to* a story, focusing on identifying patterns to generalize experiences across a culture, while portraiture concentrates on individuals or small group’s experiences to uncover unique, but universal stories that resonate with the readers (Lawrence-Lightfoot & Davis, 1997).

Teachers’ curricular decisions from the mathematical care perspective have not yet been investigated. I define mathematical care as teachers’ holistic support for mathematics learners: mathematical development, emotional well-being, and sense of belonging in the mathematical community. Goodness is a particular feature of portraiture (Lawrence-Lightfoot & Davis, 1997). Exploring the goodness in portraiture is more than finding positive experiences. It is likewise a dialog between the researcher and the subjects “that allows for the expression of vulnerability, weakness, prejudice and anxiety” (p. 141). In exploring goodness as mathematical care, I am “searching for what is good and healthy” (p. 9) in teachers’ curricular reasoning.

This research employs portraiture to showcase how teachers plan their curriculum by capturing into a narrative canvas the uniqueness and universality (Lawrence-Lightfoot & Davis, 1997) of their thought processes during planning. The research question is: *How does teachers' mathematical care influence them in their curricular decisions?* I depict expressions of teachers' mathematical care, that results from their planning. Emphasizing internal, personal, and historical contexts provides a frame for teachers' actions, and this frame is a valuable resource for interpreting the subjects' "thoughts, emotions, and behaviors" (Lawrence-Lightfoot & Davis, 1997, p. 59). Portraiture methodology allows the researcher to accurately portray teachers' reasoning using detailed descriptions by collecting data from interviews, field notes, visuals, artifacts, assessments, reflections, and memos.

In portraiture, the researcher is more visible than in any other research because the relationship between researcher and participants plays a significant role in completing a portrayal research design in terms of “empirical, ethical and humanistic dimensions” (Lawrence-Lightfoot & Davis, 1997, p. 138). I am portraying teachers’ curricular reasoning framing the context, voice, relationships, emergent themes, and the aesthetic whole (Lawrence-Lightfoot & Davis, 1997). I start broadly, placing the school culture within the portrayal. I include the researcher’s context and then gradually zoom into the central aspect of the portrait: teachers’ thought process informed by mathematical care. Emergent themes in the context of curricular decisions result from how teachers negotiate tensions between a fixed curricula and students ‘mathematical needs. The final written portrait balances the voice, the context, and the emergent themes structured into a complete piece that reflects teachers’ multidimensionality of mathematical care.

The potential impact of this study on mathematics education is the focus on teachers as carers (Noddings, 2013, 2017) for the students as learners and individuals and the dynamic of their decisions to respond to students' mathematical needs.

EXPLORING STUDENTS' APPROACHES TOWARD DIFFERENT REPRESENTATIONS OF FRACTION CONCEPTS

Salima Karim
University of Missouri – Columbia
skvrc@umsystem.edu

Keywords: Mathematical representations, Number concepts and operations, Assessment

Despite the growing body of research on mathematics education, concerns persist about students' performance on assessments (Chand et al., 2021). Studies have shown that students 'performance varies on mathematical modeling problems and open-ended questions compared to conventional tests and multiple-choice questions (Kartal et al., 2016; Danili & Reid, 2005; O'Neil & Brown, 1998). Based on Scheiner's (2016) theoretical framework of multiple knowing and learning processes and Lesh et al.'s (1987) representation framework of mathematical problems, this study explores the impact of different mathematical representations on students' performance and reasoning the study examines the impact on students' understanding when a single mathematical concept is presented through various mathematical representations for a particular assessment item.

Research Question: When given a variety of representations, how do 5th-grade students apply fraction concepts?

Scheiner's (2016) theoretical framework of multiple knowing and learning processes in mathematics highlights the cognitive processes involved in concept construction. It further indicates conceptual understanding develops when a learner understands various ideas associated with the different representations of a concept. Whereas Lesh et al.'s (1987) representation framework of mathematical problems. Identifies five methods of representing mathematical problems: real scripts, manipulative models, spoken language, static pictures, and written symbols; these representations can be used in conjunction with each other to solve mathematical problems. Overall, these frameworks emphasize the crucial role of representation in developing a deeper understanding of mathematical concepts. To create the assessment items for the study, five methods of representation by Lesh et al., (1987) were integrated with the representation of concepts in Scheiner's (2016) framework. Through clinical interviews with four fifth-grade students, I explored how participants responded to different mathematical representations for parallel assessment items. The clinical interviews allowed me to learn about student thinking regarding fractions (Hunting, 1997) specifically if the children had difficulty conceptualizing the concept or its representation.

The data analysis established the following findings: Children have difficulty connecting concepts between representations when presented in an algorithm or equation form but do not struggle when presented with static pictures or real-world problems. The study suggests that while children struggle to associate logarithms with manipulatives, they are more comfortable working with static pictures and manipulatives to solve real-world scenarios.

The framework presented in this study is a valuable tool for educators to delve into diverse mathematical concepts. Additionally, it provides insights to standardized test developers, to offer students multiple avenues for expressing their understanding.

UNCOVERING THE NARRATIVE: A CURRICULAR COMPARISON OF TWO TEXTBOOKS' LESSONS CONNECTING GRAPHS AND SCENARIOS

Madeline Keyes
Boston College
keyesma@bc.edu

Keywords: Curriculum, Algebra and Algebraic Thinking, High School Education

Textbook lessons present information with the aim of guiding students toward a common mathematical goal. How textbooks guide students on that journey, however, can be remarkably different as the ways that mathematics knowledge is presented in textbooks reflect specific choices in how material is revealed. Thus, reading mathematical texts as narratives (Dietiker, 2013) presents a valuable opportunity to better understand how variation in important contextual components among different textbook lessons on the same mathematical topic affects both the logic and aesthetic of mathematics lessons (Dietiker, 2015). The purpose of this project is to compare two Algebra I lessons from two distinct textbooks—the Interactive Mathematics Program (IMP) (Fendel et al., 2015) and Carnegie Learning (Finocchi et al., 2022a)—to explore the idea of quantities and relationships by connecting graphs and their related scenarios.

The IMP and Carnegie Learning textbooks were selected for study due to some concrete differences in their approaches to curricular materials. IMP units are designed to have "a specific mathematical focus…most units are structured around a central problem and bring in topics as needed to solve that problem, rather than narrowly restricting the mathematical content" (Fendel et al., 1997, p. vii). The Carnegie Learning curriculum is rooted in cognitive science research based on the Adaptive Control of Thought-Rational (ACT-R) theory of human knowledge and cognitive performance, which treats "complex problem solving as the coordination, strengthening–and eventual proceduralizing–of a large number of relatively simple knowledge components" (Finocchi et al., 2022b, p. FM-39). Although problem solving and conceptual understanding are emphasized in both textbooks, they approach these topics in rather distinct ways. While the Carnegie Learning curriculum is firmly rooted in the cognitive science tradition—which has a long history of interconnectedness with mathematics education (Schoenfeld, 1987) and problem solving (Silver, 1987)—IMP's design principles are connected to students' personal validation, active involvement, and need for intrinsically-motivating reasons to solve problems (Alper et al., 1997). According to our research, these differences in orientation may have an impact on how the mathematical stories of these quantity and relationship lessons develop through variations in the dynamics between mathematical characters, plot, and sequencing (Dietiker, 2015; Dietiker, 2016).

This investigation examines the relationship between mathematical characters, setting, and plot with a focus on how the orientation of textbooks may be influencing these relationships. It does this by using the theoretical framework proposed by Dietiker (2015) for interpreting mathematical curriculum as story. Initial findings highlight significant variations in the way the textbooks address and prioritize axis scaling on various graphs, as well as how much emphasis they place on students' identification of independent and dependent variables. As we look toward the future of mathematics curriculum, this line of research represents an opportunity to emphasize how different curricular approaches can impact a lesson's narrative structure and therefore the ways that mathematics educators conceptualize story in mathematics curriculum.

Keywords: Assessment; Research methods

K-12 assessment practices have been identified as needing advancement (Datnow & Hubbard, 2015; Harris et al., 2023). Strategies for using assessment data to inform instruction is a key practice to advance (Wilson, 2018). Careful analysis of students' errors on mathematical assessments in particular has been shown to provide insight into their conceptual understanding (Rakes & Ronau, 2019). In turn, information from incorrect responses is maximized to support teaching and learning (Lannin et al., 2006). Mathematical problem-solving skills are a needed area of study given the continued focus internationally (Mullis et al., 2016) and in the Common Core State Standards - content and practice (CCSSI, 2010). The aim of this poster is to share a process for analyzing incorrect responses to gain insight into targeted areas for development related to mathematical practices. Incorrect written responses (N=2,115) on the seventh grade Problem-Solving Measure CAT prototype items were analyzed collaboratively in coder pairs (≥90% inter-coder agreement). The PSM has substantial reliability and validity evidence (Bostic et al., 2015, 2017, 2024). Fifty-nine items were sampled to represent the content standards. A cyclical approach involving expert (n=5) and practitioner (n=16) feedback through surveying and interviewing informed iterative refinements to the process. Thematic analysis (Braun & Clarke, 2006) of practitioner data revealed the usefulness of describing common errors. Expert data revealed a refinement needed was to re-frame error descriptions to reflect how students approached a problem to adopt a more asset-based lens. This resulted in a three-step process (see Figure). This process contributes to the call for advancements in assessment practices (Harris et al., 2023), namely offering a process for using results to identify targeted areas for learning.

Figure 1: Three-Step Process

At the core of engaging students in mathematics is having them use their mathematical knowledge to solve personally relevant and authentic problems. We have created entrepreneurial-based design challenges (Authors, 2019) that engage students in rich mathematics. In this paper, we report on 30 students participating in one such challenge. Students were tasked with designing a business that helps users change unwanted behaviors or develop new healthy habits through tracking and visualizing their progress. We present results to show how the challenge provided opportunities for student autonomy in their solutions and in the mathematics they utilized.

Keywords: Curriculum; Algebra & Algebraic Thinking; Affect, Emotion, Beliefs, & Attitudes

Today's K-12 students will be asked to tackle unprecedented environmental, economic, and social challenges (OECD, 2018). They will need to be able to work collaboratively and across disciplines to invent innovative, actionable, and empathetic solutions to messy problems that lack a clear solution path. "Education needs to aim to do more than prepare young people for the world of work; it needs to equip students with the skills they need to become active, responsible and engaged citizens" (OECD, 2018, p. 5). Novel curricular approaches are needed that allow students the autonomy to identify meaningful problems and innovative solution paths, establish connections between in-school learning and students' out-of-school experiences, and engage students in learning and applying targeted disciplinary content knowledge.

Researchers in STEM education have recently begun exploring strategies for leveraging entrepreneurship to connect students' out-of-school knowledge, experiences, and interests to in-school STEM learning (e.g., Authors, 2019; Moore et al., 2017). Given its popular appeal (e.g., the TV show *SharkTank*) and its emphasis on building actionable solutions to real-world problems, entrepreneurship has the potential to support engagement and learning in a STEM setting. The BLINDED project (Authors, 2019) is a novel curricular framework that situates mathematics learning within entrepreneurial pitch competitions. In this paper, we report on a group of 30 students' solutions to the BLINDED TASK, one of 18 BLINDED challenges.

Literature Review

Strategies that support student engagement include: creating a supportive, collaborative, and cognitively demanding learning environment (Lamborn et al., 1992), making content and learning activities authentic (Blumenfeld, et al., 2006), and empowering students to exercise autonomy and authority in relation to the curricular content (Helme & Clarke, 2001; Marks, 2000). Deci and Ryan (1987) refer to autonomy as “supporting choice” (p. 1024) or “encouraging them to make their own choices” (p. 1025). Providing students opportunities for autonomy is important in a mathematics classroom, where students often perceive the subject as disconnected from their cultures, lived experiences, and future aspirations (Boaler, 2002; Gutstein, 2003). Authentic tasks can establish a purpose for learning (Blumenfeld, et al., 2006) and can help students connect the content they are learning in school to situations they find important, relevant, and worth pursuing (Reschley & Christenson, 2012). Authentic activities can also empower students to incorporate their unique out-of-school identities in mathematics (Attard, 2012; Bobis et al., 2011; Helme & Clarke, 2001; Marks, 2000; Yair, 2000), which further builds their autonomy, promotes self-monitoring and persistence (Helme & Clarke, 2001; Leon et al., 2015), and supports students’ “sense of control and self-worth” (Bobis et al., 2011, p. 37). Thus, a learning opportunity that leverages authentic contexts and promotes autonomy could support improvements in students' confidence and growth mindset in mathematics.

The Project Framework and Challenge

Combining features of project-based learning (Krajcik & Blumenfeld, 2006), design-based learning (Kolodner, 2002), and entrepreneurial-based learning (Yuste et al., 2014), the BLINDED project framework (Authors, 2019) was developed to leverage authentic entrepreneurial practices and open-ended design challenges to motivate the learning of specific mathematics content. Students work collaboratively to: 1) define the problem and research the context (Krajcik & Blumenfeld, 2006; Rivet & Krajcik, 2004); 2) build, test, and refine prototype solutions (Fortus et al., 2004; Razzouk & Schute, 2012); 3) demonstrate the actionability of their solutions (Lackeus, 2015; Kolodner, 2002); and 4) deliver 5-minute pitches to panels of judges (Passaro et al., 2017; Krajcik & Blumenfeld, 2006). In the BLINDED TASK challenge, students are tasked with inventing a business that helps users (individuals or companies) set and achieve goals through tracking and visualizing their progress. Students had to build, evaluate, and interpret functions that map changes in performance onto changes in a visualization. BLINDED TASK uses design criteria to connect students’ real-world solutions to math-specific school learning and establish an immediate purpose for building functions. These criteria include: identifying relevant behaviors or habits to address, inventing visualizations to monitor progress towards the goal, and building functions that translate progress in the target behavior to changes in the visualization. These criteria were created to engage students in functional reasoning through the defining, testing, and refining of generalizable relationships between two co-varying quantities (Warren et al., 2006), namely student- defined measures of the target behavior and changes in the student-invented visualization.

Methods

A mixed-methods research convergent parallel design (Creswell & Plano Clark, 2017) was used to explore the students’ experiences with the BLINDED TASK implementation on student autonomy and functional reasoning. Quantitative and qualitative data were collected concurrently throughout the project, analyzed separately, and then merged together to answer the following research questions: *(1) How does the autonomy afforded by the D&P framework manifest in students’ solutions?, (2) How do students demonstrate functional reasoning while participating in the BLINDED TASK challenge?, and (3) How does participating in the BLINDED TASK challenge affect students’ confidence and growth mindset in math?*

Sample and Procedure

The BLINDED TASK challenge was implemented across eight days in a Math 1 class with 30 7th and 8th grade students in an urban setting. The school is 100% male, 28% low-income, and 75% minority. Students participated in the challenge in teams of three or four. In launching the challenge, the teacher focused students on the United Nations Sustainable Development Goals, allowing students the autonomy to identify goals that they found relevant.

Data Collection

To allow for a complete picture of students' experiences, we collected data from a variety of sources (Cohen et al., 2011), including daily written work samples and Pitch Decks (pitch presentation slides, animations, and handwritten prototypes). Students took a pre- and post-survey with items measuring their growth mindset and confidence in math using a 6-point Likert-scale. There were three growth mindset questions from Code et al. (2016), who adapted them from a measure on general intelligence mindset (Dweck, 2008). The survey also had one item on confidence, which was adapted from self-efficacy items in Usher (2007).

Data Analysis

Qualitatively this research draws on student artifacts, specifically their daily work samples and Pitch Decks. We analyzed the documents to describe the products each team designed and the mathematics in which they engaged. We coded student products into broad categories for the type of context they selected for their business. We collected exemplar quotes and pictures from their prototypes to highlight the functional relationships in their solutions.

Quantitatively the survey data were analyzed using paired-sample *t*-tests to determine if there were significant differences in students' growth mindset or confidence after engaging in the BLINDED TASK.

Results

Autonomy in Context

During the BLINDED TASK challenge, students drew on their interests and their experiences with a number of social justice initiatives. Across the ten groups they selected the following contexts: mental health (n=4), school improvement (n=2), food waste (n=1), social media addiction (n=1), school violence (n=1), and health (n=1). The context for three student groups will be highlighted, followed by the functional reasoning for each group.

The **Against Waste** team created a solution "to reduce food waste in schools and to make people more aware about conserving and recycling food," after seeing the amount of daily trash in their school cafeteria. They used a visualization of a trash can to help schools reduce their food waste in the cafeteria. The **Discover You** team created a mental health app, because of the rising numbers they noticed in teen depression. The third team, **PoGo**, focused on school improvement, creating an app that, in their words, "...allows Teachers and Principals to track the percentage of all students in a school who are at an Economic Disadvantage (E.D.)" compared to overall performance. Their hope was that "schools will be able to see that the percentage of E.D. students at their school are struggling and make sure that students are receiving all the things they may need (such as breakfast/lunch, proper transportation, proper school materials)."

Functional Reasoning

Students utilized a variety of strategies for building functions to allow users of their product to visualize data. Below we briefly describe the products designed by the three teams and the mathematics they utilized in their solution, including their functional relationship, input variables, output variables, and rule for connecting their function to a visual representation of their solution. The **Against Waste** group created a functional relationship for food waste and trash can visualization. They used the number of bags of trash for their input and the color and appearance of a trash can via an animation for their output variable. They were able to operationalize their input variables, based on observing data from their school cafeteria. Though they did not describe an explicit rule they had all the pieces, and the context was meaningful to them. They stated, "If you are wasting too much, the visual is heaping out foods and trash, and when you reach your goal, there will be a reward animation." **Discover You** created a functional relationship for depression based on sleep, feeling of worth, and school stress. Their input variables were a measure of worth, happiness, and stress on a scale from 1-10 and number of hours of sleep. These measures come from polling their users in their app. Their output variable was a horizontal progress bar. The rule they created for depression was: [(School Stress)$\times$ -1 +Worth+Happiness+Hours of sleep]$\times$ 10/3. Their equation accounted for the input variables they identified as important factors in depression and multiplying school stress by negative one shows the students knew they had to invert the scale for stress because it is a negative factor of depression. They created a Scratch prototype for their visual, which showed a depression score as the voltage in a battery. The **PoGo t**eam built a functional relationship for the academic achievement for students with Economic Disadvantage. based on input variables from state level School Report Card data. Their output variable was a wheel and thumb and the rule they created was based on regression analysis and the Scratch coding of a visual thumbs up and down based on residual values. In their words,

> Our app uses State School Report Card for middle schools in County to gather our data onto a graph, then it transfers that information on a graph to a wheel that is color-coded based on the subject and then has a thumbs-up emoji that changes color and rotates based on how much above, at, or below the line of regression they are at.

This group used advanced functional reasoning to create their regression analysis and turn it into a convincing visual for their users.

Confidence and Growth Mindset

There were significant increases on students' self reports from pre to post in growth mindset (pre=3.20, post4.29, t=-5.17, p<0.001), and non-significant increases in confidence (pre=4.33, post4.67, t=-1.62, p=0.058). This suggests after engaging in the BLINDED TASK challenge students had a stronger disposition towards a growth mindset.

Conclusion

By providing students with an open-ended task, they had the autonomy to create their product and create their own functions. Across the ten teams, students opted to tackle specific environmental, economic, and social challenges (OECD, 2018) that were both authentic and personally meaningful. The BLINDED framework afforded students the autonomy to identify personally meaningful problems and explore unique solution paths, while also bounding the mathematics content with which they engaged. By equipping students with this autonomy, the framework created opportunities for students to see their place in the math classroom, which improved their confidence and willingness to persist when encountering difficult problems. By allowing students the autonomy to identify personally meaningful contexts, the challenge opened the space for them to actively engage in functional reasoning. Students drew on their experiences with their chosen contexts to identify, operationalize, and define relationships between authentic input variables and their corresponding output variables, namely visualizations that allow users to track progress towards a goal. Findings from this study demonstrate how providing students with the autonomy to create a solution to an authentic problem gave them confidence in their mathematical ideas and generated powerful solutions to emerging issues facing young adults.

This paper reports on the developments of a repository of quantitative assessments used in mathematics education contexts between 2000 and 2020. The repository is public and freely available, identifies validity evidence of associated measures, and has potential to inform future quantitative mathematics education scholarship., This paper discusses the types of instruments and reports the data analysis regarding the types of validity evidence found for the 1,034 instruments where the validity evidence was categorized, and located across over 1,200 sources.

Keywords: Assessment

A vision for the future of mathematics education scholarship includes researchers having access to high-quality assessments, assessment developers providing robust validity evidence for the interpretation and uses of assessment scores, and users being able to reflect on their assessment options efficiently and effectively without challenges like paywalls and institutional access restrictions. Finding and selecting appropriate quantitative assessments to use for mathematics and statistics education research can be difficult. Institutional access to journal articles describing assessments, as well as limited descriptions of them, are two challenges to finding and selecting appropriate tools (Author et al., 2021). Therefore, a goal of this paper is to introduce scholars to a repository of quantitative assessments and their associated validity evidence. This repository is designed to make it easier for scholars to ascertain if there is a suitable assessment to measure a desired construct and to browse its associated validity evidence.

Many manuscripts describe an assessment but do not provide details about the validity evidence related to the assessment's intended uses or score interpretations. That is, it is unclear the degree to which the assessment accurately and reliably measures what it intends (Author, 2017). Broadly speaking, the *Standards for Educational and Psychological Testing* (*Standards*) characterize validity as the degree to which evidence supports an intended claim (AERA et al., 2014). A goal to fostering quantitative mathematics education scholarship is building a robust knowledge base that uses assessments with strong validity evidence (Authors et al., 2022; Kane, 2013). The authors of this paper built a publicly available database of mathematics education assessments and seek to address this goal. This paper will present the recently launched database of mathematics and statistics education assessments and their associated validity evidence and present some findings about the quantitative assessments found in it. In this paper, the terms assessment and instrument are used interchangeably, whereas measure and test have more narrow implications (Author, 2019).

Literature Review

Prior to 2014, there was scant discussion of validity and quantitative assessment within mathematics education scholarship (Author, 2017). There has been a substantial increase in scholarship exploring the degree to which validity and validity evidence are discussed in mathematics and statistics education as well as scholarship focusing on how those validity arguments are communicated (e.g., Pellegrino et al., 2016; Walkowiak et al., 2019; Wilhelm & Berebitsky, 2019). Validation is a process that broadly includes (a) explicitly describing how assessment scores are intended to be interpreted and subsequently used, (b) identifying the claims, or assumptions, underlying the score interpretation and use, and (c) gathering evidence to evaluate those claims (AERA et al., 2014; Author et al., 2023; Kane, 2013). A *use statement* communicates how to appropriately use an assessment or its results. An *interpretation statement* informs others about how to effectively interpret an assessment's results. Put simply, interpretation and use statements describe what the scores mean and how to use that information (Authors et al., 2023). Claims are "implied by a proposed test interpretation" (AERA et al., 2014, p. 12). They may reflect aspects of an assessment for a given test-score interpretation and use, such as claiming that a test adequately functions as a unidimensional measure of a given construct. Claims may also reflect assertions arising from the test-score interpretation; that a student has achieved some level of mastery (e.g., AERA et al., 2014, Authors et al., 2023; Kane, 2013).

The *Standards* highlight five sources of validity evidence: test content, response process, relations to other variables, internal structure, and consequences from testing (AERA et al., 2014). For example, Rasch measurement or factor analysis can provide validity evidence based on internal structure supporting claims of an instrument's unidimensionality. While the *Standards* do not consider reliability a source of validity evidence itself, it is an important related component (AERA et al. 2014). These sources have been adopted by the three largest educational research, educational measurement, and psychological communities, which suggests it is appropriate for scholars and their associated scholarship to align with these *Standards*. Better alignment with the *Standards* has potential to position quantitative mathematics education research as equity-forward scholarship that embraces and supports diversity, equity, and inclusivity efforts (Author, 2023). With a greater attention paid to the quality of information collected on quantitative assessments in mathematics and statistics education scholarship, there is a pressing need to provide researchers with a means to explore available measures efficiently and effectively for future scholarly use.

Methods

In the February of 2020, 41 participants attended the Validity Evidence of Measures in Mathematics Education (VM^{2}Ed) conference. Participants had previously published or presented on quantitative assessments and were committed to fostering conversations around validity and assessment within mathematics and statistics education scholarship. Participants included mathematics education faculty, researcher scientists, psychometricians, assessment developers, and graduate students. The goal of the conference was to create an understanding of validity within mathematics education contexts and solicit recommendations from experts about information necessary to build a repository of quantitative mathematics education instruments. After building a solid foundation of how validity is conceptualized and operationalized using the

Standards, the committee of experts gave recommendations about a synthesis procedure to identify and categorize validity evidence, interpretation statements, and use statements of quantitative assessments. Following development of the synthesis procedure, participants were divided into six synthesis groups: (1) Elementary (K-6) Tests and Instruments; (2) Secondary (7-12) Tests and Instruments; (3) Undergraduate and Graduate Mathematics Tests and Instruments; (4) Statistics Education (K-20) Tests and Instruments; (5) Teacher Education Tests (content knowledge); and (6) Teacher Education Instruments. Regarding Teacher Education Tests and Teacher Education Instruments, tests were defined as measures of content knowledge whereas instruments included all other constructs (e.g., affect and efficacy).

After the conference, each group searched for instruments and tests that fell within their parameters. The search was standardized across all groups to include searching the top 24 peer-reviewed mathematics journals (Nivens & Otten, 2017). After identifying the assessments, group members used all available scholarship to conduct a wider search for validity evidence, claims about the assessments, as well as interpretation and use statements associated with those assessments. Finally, the claims and evidence for each assessment were coded using the five sources of validity evidence and reliability (AERA et al., 2014) as an a priori framework.

A codebook was developed, based on an analysis of data from the conversations and artifacts from the 2020 conference, to define and characterize different evidence types to serve as subcodes for each of the sources. This resulted in 89 unique evidence types (see Figure 1). Then each piece of evidence that was found received an "evidence source" code (i.e. five sources and reliability) and an "evidence type" subcode. Training was provided to participants to ensure reliability and promote trustworthiness in the coding process across synthesis teams. For example, evidence types for test content include data from experts or literature review. Examples of internal structure evidence types include exploratory factor analyses, item difficulty, and Rasch modeling. If additional types were discovered in the literature, then it was added to the codebook and shared with the other groups.

Consequences of Testing	Internal Structure	Relations to Other Variables	Reliability	Response Process	Test Content
Appropriate cut score	Bayesian Network Models	Alignment with expert opinion of test user (e.g. teacher, therapist)	Alternate form	Cognitive interviews	Alignment with frameworks/standards/theory/learning trajectory
Bias as one consequence of testing	Cluster analysis	Convergent Association or Divergent Association	EAP/PV test reliability	Error related to response patterns/CTT	Construct Definition
Cost-benefit analysis	Factor Analysis- Bifactor	Correlation analysis	Generalizability theory- D-studies	Eye tracking/physiological data	Data from experts
Documentation of unintended behavior changes based on test use	Factor Analysis- Confirmatory Factor Analysis (CFA)	Discriminant validity	Generalizability theory- G-studies	fMRI (functional Magnetic Reasoning Image)	Fairness of content
Explicit intended uses and interpretations and warn against inappropriate uses	Factor Analysis- Exploratory Factor Analysis/Exploratory Structural Equation Modeling	Discrimination power	Inter-rater reliability- Kappa	Focus groups	Field Work
Impact of assessment is similar under clinical and practical implementations	Factor Analysis- Multi-trait Multi-method matrix (MTMM)	Hierarchical Linear Modeling	Inter-rater reliability- Percent agreement	Generalizability-theory (G-theory) related evidence	Literature Review
Item functioning such as DIF - unknown subgroups had to know	Factor Analysis- Not specified	Multi-trait Multi-method matrix (MTMM)	Internal consistency or alternatives- Alpha	Log data	Participant-generated content
Motivational consequences	Factor Analysis - Parallel Analysis	Statistical Testing (e.g., t-test, regression, and chi-square)	Internal consistency or alternatives- IRT or Rasch reliability	Predicted response patterns/processes based on Learning Trajectories	Revision Process
	Factor Analysis- Principal Axis Factoring (PAF)	Structural Equation Model	Internal consistency or alternatives- Omega	Rater agreement/reliability	Standard Setting
	Factor Analysis- Principal Component Analysis (PCA)	Treatment/control study	Internal consistency or alternatives- Raykov	Rater training and calibration	
	Item difficulty	Triangulation/Crystallization with qualitative data	Item remainder correlations	Sorting tasks	
	Item Scale Correlations		Kuder-Richardson formula 20	Student written work	
	Item Response Theory (IRT)		SEM measurement	Studies of respondent's speed of task completion	
	Latent Class Analysis (LCA)		Sensitivity analysis	Think alouds	
	Latent Profile Analysis (LPA)		Split-half reliability		
	Multidimensional scaling		Test - Retest		
	Rasch modeling				
	TETRAD				

Figure 1: Validity Evidence Types

When evidence was found, it was sorted into two categories: those that had an associated claim and those that did not have an associated claim. If there was a claim, then it was noted, and the same classifications of the evidence source and evidence type was linked with the claim. An example of a claim is, “The Cronbach’s alpha, 0.87, was found to be sufficiently high for the measure to be considered internally reliable” (Attridge, 2013, p. 103), and the source was classified as reliability and the type of evidence was coded as: Internal consistency or alternatives- Alpha.

Similarly, it was noted as “yes” or “no” if an article with validity evidence contained an interpretation or use statement for an assessment. If there was an interpretation or use statement then it was noted, verbatim from the source.

Every assessment in the repository was also tagged with key features such as the population being tested, construct measured by the assessment, and type of item in the assessment. Across all groups, each assessment was put into one of four construct bins: knowledge, affect, behavior, or classroom and instruction. The validity evidence coding, claims, interpretation and use statements, and key tagging features comprised the data used to create the repository.

In the following section, broad information about the assessments collected by each group is provided. Then, a detailed analysis of the validity evidence disaggregated by evidence types and interpretation and use statements is provided. This analysis highlights the results regarding the validity evidence collected by all six groups, as well as provides an exemplar of the type of information users can find in the repository. Finally, details about the development and features of the repository are provided.

Results

Categorization and Validity Evidence

As of February 2024, 1,034 assessments were identified for inclusion in the repository. Synthesis groups found validity evidence for 764 of the 1,034 assessments (Table 1). Hence, validity evidence was located for 74% of the assessments. In total, group members reviewed 1,206 different articles, proceedings, or book chapters between Sept. 2020-Aug. 2023 that contained information about a known quantitative assessment used in mathematics or statistics education. As an example, of the 379 instruments identified by the Secondary group, there were 223 instruments (58.8%) for which validity evidence was found from 301 different papers.

Table 1: Counts of Instruments in the Repository

Synthesis Group	Total Number of Instruments	Instruments With Evidence	Number of Papers with Evidence
Elementary	109	105	159
Secondary	379	223	301
Statistics Ed. K-20	65	79	203
Teacher Ed. Instruments	255	158	239
Teacher Ed. Tests	45	44	149
Undergraduate	155	155	155
TOTAL	**1034**	**764**	**1206**

In total there were 3,524 pieces of evidence in the 1,206 papers. Of the validity evidence found across all six groups, the most frequent source of validity evidence was test content (30.5%) (Table 2). Reliability evidence was present in 917 of the 3,524 pieces of evidence (26.0%). Results show consequences of testing had the smallest frequency of evidence in the articles at 1.7%.

Table 2: Count of Each Evidence Type by Synthesis Group

	Conseq. of Testing	Internal Structure	Relations to Other Variables	Reliability	Response Process	Test Content
Elementary	14	82	74	115	29	77
Secondary	23	165	162	268	53	354
Statistics Ed. K-20	11	175	137	158	32	245
Teacher Ed. Instruments	9	126	119	225	37	189
Teacher Ed. Tests	0	62	41	44	4	59
Undergraduate	4	102	48	107	23	151
TOTAL	**61**	**712**	**581**	**917**	**178**	**1075**

Of the 1,206 papers that presented validity evidence, 307 had an interpretation statement and only 345 had a use statement. Therefore, approximately a quarter of the articles with validity evidence contained statements about how to interpret assessment data (307 of 1,206; 25.5%) and 38.6% had statements regarding how to use the assessment (345 of 1,206). Across all six groups, the Secondary group had the highest percentage of use statements (149 of 301, 49.5%) and the Undergraduate group had the highest percentage of interpretation statements (65 of 155, 41.9%). The lowest percentage of interpretation and use statements was found from the Teacher Education Instrument group (10.5% and 11.3% respectively).

Table 3: Percent of Each Evidence Type by Synthesis Group

	Interpretation	Use
Elementary	36	41
Secondary	84	149
Statistics Ed. K-20	78	57
Teacher Ed. Instruments	25	27
Teacher Ed. Tests	19	19
Undergraduate Ed.	65	52
TOTAL	**307**	**345**

Repository Development

From the synthesis group work products, a free online searchable repository was created to house the name, description, citations, interpretation and use statements, claims, and validity evidence associated with the identified assessments. To access the repository, users create a login and briefly acknowledge a user agreement. Once logged in, users can search for available assessments, peruse their associated validity evidence, and participate in training modules about validity. The website was designed to be user friendly and accessible with the help of a User Experience (UX) designer and computer programmer, and to display evidence in a way that is clearly aligned with the *Standards* (AERA et al., 2014). The repository has several important design features explained below: search features, researcher portal, and ease of adding new instruments.

Design Feature: Search Features. The database has a search feature that allows users to input text and search for instruments. In addition, users can refine a search using the key features or tags assigned to the assessments (e.g. population, construct, item type, etc.). See Figure 2 for an image of the advanced search by tagging feature. Tagging features were intentionally created to be consistent across all six synthesis groups, so researchers can easily sort through and search for instruments. The tagging features include: Synthesis Group, Population, Grade Level, Construct, Type of Instrument, Mode of Delivery, and Item Type. The main categories of assessment constructs used across all groups were: knowledge, behavior, affect, and classroom & instruction. Each group has more specific constructs tailored to particular assessments under each of these main categories. For example, sub-constructs of the knowledge category could include geometry, limits, measurement, algebra readiness, etc. The repository provides a page for researchers to peruse more specific subconstructs related to each group and more effectively search the repository for their needs.

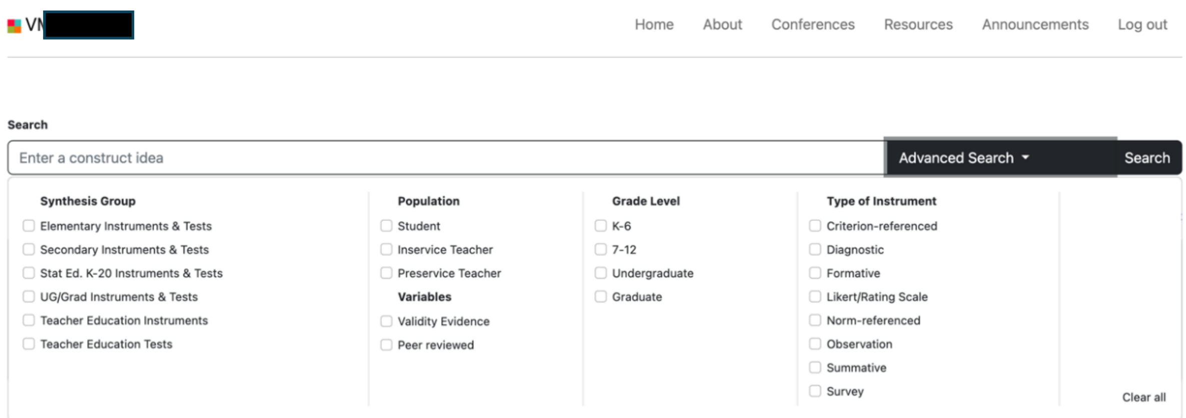

Figure 2: Search Engine and Tagging Features

After a search is submitted, a list of instruments is returned in groups of 10. Additional pages for searches when results include more than 10 instruments. The instrument list page has the names of the returned instruments and contains information related to population, grade level, construct, and a count of the number of validity evidence items found for the instrument.

If a user is interested in a particular instrument, then they can select it from the instrument results page. All the tagging features of the instrument are provided at the top of the page under the instrument name (Figure 3). Then, the articles that were found to contain validity evidence for the instrument are provided, along with a citation, DOI, summary of the validity evidence, and abstract. There is a tab on the instrument results page (shown in the red box in Figure 3) for the main instrument information (described above) and then any source of validity evidence that was found for the instrument. For example, there was evidence found related to test content, reliability, and internal structure for the instrument in Figure 3. Clicking on any of those tabs would open a new page with all the associated validity evidence, evidence types, any potential claims, and any interpretation and use statements. This structure aligns with the coding framework used by the synthesis teams and allows users to several ways to find and explore the validity evidence found for an instrument.

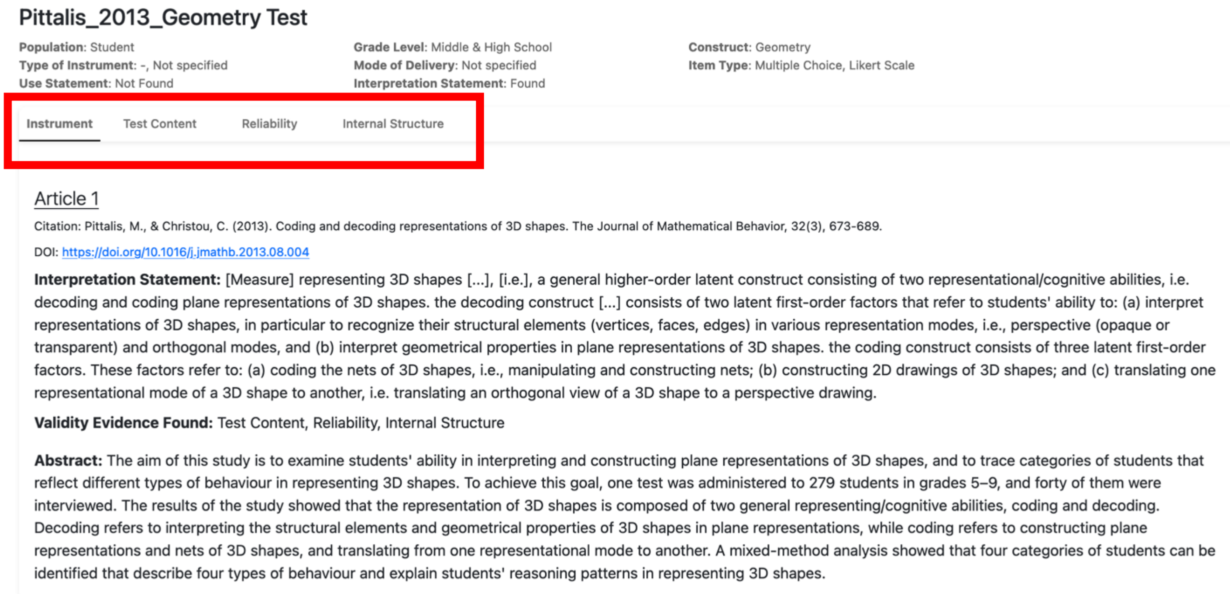

Figure 3: Snapshot of Instrument Results Page

Design Feature: Researcher Portal. There is also a researcher portal with training modules, both written and video based. These provide users with educative content pertaining to validity and validation, the proper use of the repository, and recently added or highlighted assessments the user may want to consider. Once logged into the researcher portal, users can save "favorites" or share results with collaborators. Users can also provide feedback on the results of an assessment or download the search results for a search.

Design Feature: Ease of Adding New Instrument. Initially, assessments were added by the project leaders based on the synthesis groups' work. Presently, users can submit a request electronically to upload an assessment to the repository. Users are asked to tag key features of the assessment as well as to identify and upload literature containing interpretation or statements, validity evidence, and claims associated with the assessment (Figure 4). Once an assessment is submitted, a repository curator vets the materials to ensure the inclusion criteria have been met. Once verified, the assessment is added to the repository. If inclusion criteria have not been met, then the project leader or curator communicates the additional information needed to include the instrument in the repository.

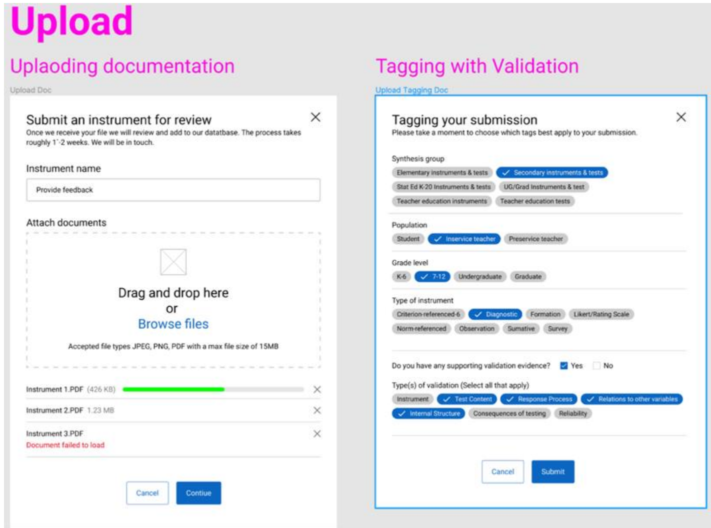

Figure 4: Adding a New Instrument

Discussion and Conclusions

PMENA session participants will explore the features of the repository. A goal of this five-year project was to produce a repository that could be used by scholars seeking a quantitative assessment for use in mathematics or statistics education research. First, it was necessary to identify the quantitative assessments used since 2000 and to gather information about them. This required multiple individuals culling through numerous databases. The second step was to evaluate the information for each assessment and categorize that information within the Standards (AERA et al., 2014) framework. The third step was to develop a working repository, accessible to broad communities containing this information.

The work across the six groups led to the creation of a repository with 1,034 instruments with validity evidence presented from 1,206 papers. Currently, about three-fourths of the instruments in the repository contain validity evidence. Most of the time that validity evidence was found, it was evidence of test content or reliability. There were very few reports of consequences of testing (1.7%) and response process (5.1%), which suggests future test scholarship should pursue these areas, which heeds previous calls (Author, 2023, 2021). In addition, approximately one-quarter of the papers contained interpretation or use statements. Researchers need to be aware of the validity evidence for a measure before they choose to use it for their own purposes. These findings have substantial ramifications for researchers in mathematics and statistics education.

Ultimately, this work makes it easier for scholars to locate assessments for a given construct or to evaluate the viability of assessments considering their known validity evidence and claims. Moreover, this repository allows scholars to gather further or more robust validity evidence for it. Proper validity arguments are foundational to robust quantitative research in mathematics and statistics education which makes this public repository of assessments and their associated validity evidence so beneficial to the research community.

ASSESSING PRESERVICE TEACHERS' KNOWLEDGE FOR TEACHING UNIT FRACTIONS

imduarte@iu.edu

Keywords: Assessment; Mathematical Knowledge for Teaching; Pre-Service Teacher Education

Introduction

Teacher acquisition of robust mathematical knowledge for teaching (MKT) is essential in pursuing a quality education. In the context of knowledge for teaching fractions, work like Steffe and Olive (2010) and Hackenberg et al., (2016) already support teachers' knowledge growth. Nevertheless, less targeted has been the development of instruments for assessing teachers' knowledge for teaching fractions (Van de Walle et al., 2022). Similar to other studies (e.g., Norton et.al., 2015), our study aimed to develop an instrument for assessing pre-service teachers' knowledge for teaching unit fractions using length models through two research questions: (1) What set of tasks can elicit evidence of teachers' knowledge of teaching unit fractions using length models?; (2) How can teachers' responses to the tasks be interpreted to gain insights into their knowledge of teaching unit fractions using length models?

Methods

We used Pellegrino et al's (2001) Assessment Triangle Framework (which involves three elements: cognition, observation, and interpretation) to develop the instrument. As a cognition model, we used Silverman & Thompson's (2008) 5-component framework for MKT. With this framework, we designed the first version of the assessment instrument and rubric, targeting two key developmental understandings (KDU): (a) all the 1/n parts that compose a whole must have *equal length*, and (b) To complete the whole, *n parts* of 1/n length are needed. Regarding observation and interpretation elements, we conducted two phases of data collection. In phase 1, we tested the designed instrument with 6 pre-service teachers, followed by a revision of both the instrument and the rubric. In phase 2, we tested the instrument and rubric again with 20 pre-service teachers. This second round of data collection and analysis allowed us to test further validity and reliability based on intercoder agreement between the two researchers.

Results and Conclusions

In phase 1, we adjusted to the instrument and rubric. For example, we added clarifying sentences and asked for additional student models to ensure gathering sufficient data regarding this component. Additionally, we refined the two KDUs being considered in the rubric. In phase 2, we tested for reliability. We computed Kendall's tau between two raters finding that all five components' tau was 0.676 ($p<.001$), representing positive associations between raters. Furthermore, we also calculated Cohen's kappa (weighted) value as a measure of inter-rater reliability. The two raters' kappa scores were 0.558, which means that the reliability between the two raters is moderate and satisfactory (Landis & Koch, 1977).

Through the process carried out, we were able to respond to the two research questions. Firstly, the set of open-ended tasks elicited meaningful evidence (e.g., drawings, explanations, etc.) of the participants' knowledge for teaching unit fractions using length models. Secondly, key features of the rubric include considering evidence of a specific component, across several items, allowing the raters to assess a bigger picture of the participants' knowledge.

This study investigates teacher approaches to assessment in a detracked mathematics curriculum through semi-structured interviews. The detracked curriculum promotes inclusivity by accommodating students of all learning levels in mathematics. Assessments play a crucial role in addressing significant learning gaps. The study highlights leveled assessments as a common assessment practice used by the grade 9 math teachers. Further, the study unveils the various forms of assessments utilized by teachers and illuminates the challenges they encounter, encompassing time constraints, resource limitations, and the need for additional support.

Keywords: assessment, detracked curriculum, student learning, mathematical practices

Purposes and Framework

The responsibility for teachers to uphold the expectations of the curriculum and demonstrate student achievement success can be represented by their assessment practices. The assessment practices of teachers often consider students' wide range of interests, needs, and strengths, as well as personal interpretations of the curriculum (Horn, 2006; Venkakrishnan & Wiliam, 2003). The teachers' assessment choice directly impacts various aspects of the student's learning experience including (but not limited to): student inquiry, achievement, engagement, motivation, and autonomy (Herppich et al., 2018; Lovall-Jones et al., 2014; Quigley et al., 2020). The task of developing assessments can be daunting as the range of students' abilities and preferences vary from classroom to classroom, but one method that may aid teachers in accounting for all types of students is differentiation (Lovall-Jones et al., 2014; Marks et al., 2021). Generally, teachers rely on feedback and formative assessment to support differentiated instruction to adapt to and ensure students' progress (Dayal, 2021; Herppich et al., 2018; Marks et al., 2021). The practices of catering to students' individual needs, often related to differentiated instruction, are crucial in the transition of new curricula, especially with adapting to a detracked curriculum.

In Canada and the US, a detracked curriculum can offer more equitable, inclusive learning environments for student success (Horn, 2006; Tereshchenko et al., 2019). Since September 2021, a new detracked curriculum has been implemented in grade 9 mathematics classes in schools across the province of Ontario, Canada. Since the transition from the tracked to the detracked curriculum involves combining two previously segregated learning level courses, one of the greatest challenges teachers have experienced is closing the larger gaps among student abilities. Therefore, the modification of assessment preparation and implementation has been critical in delivering curriculum content, particularly for varied self-assessments, tests, and grading (Bruce et al., 2010; Dayal, 2021).

Specifically for the subject of mathematics, teachers must consider more particular aspects when differentiating to meet their students' individual needs. These aspects may include adopting a holistic mathematics perspective, making crucial decisions about what mathematics knowledge should be prioritized, adapting both course-based and application-based assessments, and balancing professional and personal decisions (Horn, 2006; Quigley et al., 2020). In addition, during the preparation of assessments, teachers need to gain greater comfort with mathematics curricula content, collaborate with other colleagues, and contemplate the method of measuring the quality of student work and understanding (Horn, 2006; Ulusoy & Incikabi, 2020).

As a result of the collaboration between OISE, University of Toronto and an urban school board in Canada, a multi-year project has been conducted about the experience of grade 9 mathematics teachers with the new detracked curriculum. The project findings included teachers' preparation of assessment, the newfound practices of levelled assessment, and the implementation of various forms of assessment.

The purpose of the project was to investigate the following questions:

- What are the assessment and evaluation practices of teachers in the new de-tracked mathematics curriculum?
- How do teachers differentiate their assessment practices to meet the diverse needs of students in the detracked curriculum?
- How do teachers prepare assessments with respect to the expectations of the new detracked curriculum?

Methods

Participants

The participants from this study consisted of grade 9 mathematics teachers from different schools across the largest urban school board in Canada. The teachers are currently teaching destreamed or have taught destreamed in the past. In this paper, we include the perspectives from three participants who discuss their experiences as current grade 9 destreamed mathematics teachers, each given pseudonyms to maintain anonymity.

Data Collection

In this study, the data collection arose from semi-structured interviews during the Fall 2023 semester. The participants' interviews were transcribed verbatim and qualitatively coded using the *NVivo 12* software. This paper provides a thematic review of the findings that emerged from teacher interviews. There were surveys administered based on *The Attitudes and Practices for Teaching Mathematics Survey* (McDougall et al., 2001), which informs teachers of their own perceptions towards mathematics teaching and learning, as well as their values and comfort level to mathematics curriculum changes.

Interviews

The semi-structured interviews took place individually through Microsoft Teams, where teachers attended remotely from their respective schools. The interviews ranged from 50 to 60 minutes, which were audio recorded and then transcribed by the research team.

Results

Leveled Assessment

A popular assessment practice that the grade 9 math teachers interviewed in this study have been using to meet the varying mathematical abilities in their students is the leveled assessment. An example of how Hazel, a teacher in her third year of teaching, is doing leveled assessments in her classroom is by having a "Level 1-2 and a Level 3-4 version of the [math] question" (Hazel, 2023). Catherine, a teacher with 15 years of teaching experience in various grades and subjects, also uses a lot of leveled assessments in her classroom, in which she says, "I try to do a lot of leveled assessments, and any task or assessments with multiple entry points" (Catherine, 2023).

Among the benefits of using leveled assessment is that it provides students the opportunity to make choices in the assessment process, thereby increasing learner autonomy. As Hazel describes, it allows students to choose the level of assessment that "can show their best understanding because that's what the test or quiz is about" (Hazel, 2023). Leveled assessments also allows the teacher to be more inclusive towards the varying levels in students' mathematical abilities. Catherine shared her experience of leveled assessment as the following: "I think this made it more accessible to more of our students" (Catherine, 2023). Giving students choice in the level in which they wish to be assessed through leveled assessments, further increases student motivation. This year was the first year that Hazel started to implement leveled assessments more regularly. Once she started doing it at almost every evaluation, she witnessed a significant positive change in her students. She explains, "between the first task where I had no leveled assessment and the first or second quiz whenever I started implementing it about a month into school, I did notice kids were not leaving things blank anymore" (Hazel, 2023).

What makes leveled assessments successful is students' ability to self-assess what they know and do not know. Students' self-assessment in determining the appropriate level of assessment they perceive to be suitable for them is, in fact, what makes the leveled assessment a possible assessment practice used in the classroom. In other words, implementing leveled assessments can be challenging if students lack in their self-assessment skills. Having experienced the benefits of implementing leveled assessments, Catherine started this year with many leveled assessments in her classroom. Although this method has worked well for her students in the past years, it was a different case this year. The main challenge, according to Catherine, is that her students "don't seem to have an understanding yet of how to assess what they know and don't know" (Catherine, 2023). She continued by explaining, "And even when we tried a leveled assessment, they wanted to do all of the questions. They didn't know which ones they could and couldn't do. They didn't actually know their own ability" (Catherine, 2023).

Different Forms of Assessment

Using various forms of assessments was another important assessment practice being used by the teachers. These included formative assessments, quizzes, non-testing quizzes, assignments, projects, class participation, math journals, and culminating tasks.

In Rachel's classroom, she uses most of the assessments. Rachel describes how she uses math journals in her classroom: "we essentially outline the practice work that's been assigned for each lesson in that unit. And then we just asked some [students], oh have you completed any? Yes, no, if some, list how much?" (Rachel, 2023). She continues by describing how she asks her students to "then just reflect on if you had to assess your understanding for this topic from one to four, and any additional comments that you want to add. And also share any struggles that you may have had, challenges, etc." (Rachel, 2023).

In another case, small and more frequent assessments that weigh less in marks such as formative assessments and quizzes were regularly used by Catherine and her colleagues. For Catherine and another math teacher at her school, many of their assessments are formative. Two other teachers at her school, as Catherine explains, "do a lot more short little quizzes that are not worth a lot but they do count towards their mark" (Catherine, 2023).

When it comes to bigger assessments such as the grade 9 math exams, some schools are implementing non-traditional assessments. In Hazel's school, aside from the EQAO, a culminating task is used in replacement of grade 9 math exam. According to Hazel, culminating task is "worthwhile and interesting and actually acts as a culmination of all their learning" (Hazel, 2023). Hazel shares her positive outlook: "I like culminating [tasks] better, I see value in them. Because you can complete a test in an hour doesn't mean that you're good at math. It means that you can mimic whatever you did in class" (Hazel, 2023). She continues by saying, "Everyone is good at math in their way…. if you can make connections and understand the meaning of math, that is what is most important" (Hazel, 2023).

Challenges

The interviews further revealed some of the assessment challenges experienced by these teachers, which involved teachers' lack of time and resources.

The issue of having lack of time and resources makes it especially harder for the grade 9 math teachers who teach detracked math courses with such large gaps in students' abilities. Hazel speaks about the limited amount of time she has to prepare: "When you have three preps, it is a lot of work, because even if I were to split my prep 75 minutes evenly it would only be 25 minutes to do math and I definitely take more than that" (Hazel, 2023). Similarly, Rachel agreed how having more time will allow her to develop better assessments.

Moreover, teachers lacked in resources and support in developing assessments that would effectively cover the expectations of the curriculum. For example, Hazel wishes to implement triangulation of assessment which are done in thinking classroom. The triangulation of assessment involves observations, conversations, and products. However, she believes she needs more support to be able to do so. She explains, "I just have not figured out exactly how to do that, and I think that is something I need little bit more mentorship on, a little bit more like collaboration because it is a lot to take on" (Hazel, 2023). Further, more resources are needed when it comes to developing culminating tasks in replacement of final exams. Hazel suggests: "I think it would be worthwhile to have some sort of group of people or something to develop exemplars of what you could do as accommodating that is successful" (Hazel, 2023).

Conclusion

The study explores grade 9 mathematics teachers' assessment practices in Ontario's new detracked curriculum. Leveled assessments emerge as a prominent practice, providing students autonomy in choosing their evaluation level and fostering inclusivity. Despite its benefits, challenges arise when students struggle with self-assessment, emphasizing the need for honing this skill in the curriculum. The study sheds light on the diverse forms of assessment, ranging from traditional tests to innovative methods like culminating tasks and math journals. These varied approaches showcase teachers' commitment to capturing the multifaceted aspects of students' mathematical understanding.

When it comes to challenges, time constraints and insufficient resources emerge as critical obstacles, hindering teachers in their pursuit of more engaging and comprehensive assessments. The study underscores the importance of collaborative efforts, mentorship, and the development of resources to support teachers in adapting their assessment practices to the evolving educational landscape. In navigating the complexities of the detracked curriculum, teachers play a pivotal role in shaping a more inclusive and equitable mathematics education.

While mathematical textbooks have been extensively analyzed and compared, few studies have explored the divergent learning pathways presented by textbooks and their implications. This study introduces an analytical framework and its visualization to elucidate these pathways, focusing on four key facets of instructional activities: scope, sequence, structure, and scale. We exemplify the use of the 4S framework and its visualization in comparing the learning pathways for congruent triangles in a Chinese textbook and a US textbook. Results suggest that these textbooks offer fairly similar learning pathways for students, particularly in terms of content scope. However, variations emerge in the instructional activities' sequence, structure, and scale. These disparities underscore the affordance of the 4S framework. We conclude by discussing the implications for curriculum development.

Keywords: Curriculum, Learning Trajectories and Progressions, Geometry

Mathematics textbooks are pivotal in connecting the intended curriculum, as defined by national standards, to its practical implementation in classrooms, a subject that has captivated researchers for decades (Valverde et al., 2002). However, despite the extensive scrutiny and comparison of mathematical content in textbooks, there needs to be more exploration into the divergent learning pathways various textbooks offer and the implications thereof. For instance, Fan et al. (2013) noted that approximately 63% of the literature they reviewed in mathematics textbook research studies primarily focused on textbook analysis and comparison, typically yielded descriptive findings from systematic coding using content analysis. While such analyses have made valuable contributions in revealing the similarities and differences between textbooks, they often fall short in providing insights into the unfolding learning pathways within these textbooks, resulting in a gap in comprehension of learning experiences facilitated by these textbooks. As such, this study endeavors to develop an analytical framework for examining learning pathways delineated in textbooks. This analytical framework composes four dimensions: scope, structure, sequence, and scale, which we refer to as the 4S model. According to this 4S model, a visualization of learning pathways is developed. In the following, we first introduced the 4S model. Then, we exemplified the application of the 4S model and its visualization by examining the learning pathways for congruent triangles as presented in a US textbook. Ultimately, we illustrated the affordance of the 4S model by answering the following research questions: what are the similarities and differences between the learning pathways for congruent triangles as presented in textbooks in different countries?

A 4S Framework: Scope, Sequence, Structure, and Scale

An Overview of the 4S Framework

We have adopted the term "learning pathways" from Kim and Remillard's (2020) research on curriculum comparison, where they define a learning pathway as "a sequence of student learning that outlines the development of related concepts in a structured order" (Kim & Remillard, 2020, p. 33). In line with this descriptive definition, learning pathways encompass three key dimensions: the main targeted mathematical concepts covered, which we refer to as "scope"; the developmental order of these mathematical concepts, which we define as "sequence"; and the underlying logical structure(e.g., mathematical structure, content organization structure), denoted as "structure." Since mathematical concepts often evolve through instructional activities, and various types of instructional activities demand varying levels of cognitive effort and time, we propose the inclusion of a fourth dimension, "scale," to broadly capture how different textbooks allocate learning resources to different mathematical concepts. As such, learning pathways can be examined from the following four dimensions: scope, sequence, structure, and scale. We name this framework the 4S framework. In the following, we will exemplify the use of this frame in comparing textbooks with the case of triangle congruency.

Visualization and Application of the 4S Framework

In this session, we demonstrate the application of the 4S framework to analyze learning pathways presented by textbooks and visualize each pathway by comparing the pathways for learning triangle congruency in two textbooks. We chose the topic of triangle congruency for two reasons. Firstly, triangle congruency is fundamental to geometry and is consistently included in upper-level geometry curricula worldwide (Jones & Fujita, 2013), enabling access to textbooks from different countries for comparison. Secondly, multiple conditions of triangle congruency, e.g., side-angle-side (SAS) and side-side-side (SSS), allow for various sequencing possibilities (author, 2023), leading to distinct learning pathways with diverse logical structures. This variability makes triangle congruency an ideal subject for comparing learning pathways in different textbooks. In this illustration, for convenience, we selected the Student Editions of an eighth-grade math textbook by People's Education Press (2013) in China (PEP Math) and "Discovery Geometry" (DG) by Serra (2008) in the US for analysis.

Using the 4S framework, we examined the learning pathways designed by DG and PEP Math across four dimensions: scope, sequence, structure, and scale, and visualized each learning pathway (refer to Figure 1). Given that our goal is to demonstrate the application and advantages of the 4S framework, our analysis focused on the instructional activities employed, including expository texts, explorations, and worked-out examples in the lessons examining different congruency conditions.

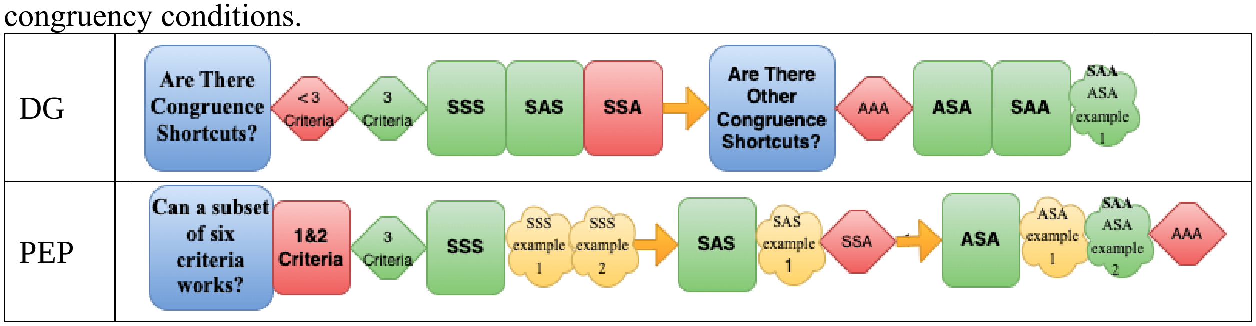

Figure 1: The Learning Pathways Presented in DG and PEP Math.

We considered each lesson an analysis unit and used yellow arrows to connect different lessons. As depicted in Figure 1, the learning pathway presented by DG consists of two lessons, while there are three lessons in the case of PEP. We treated the instructional activities included in each lesson as sub-analysis units, distinguishing them with various shapes, colors, and sizes.

Specifically, a large blue square represents an overarching inquiry question, such as "Are there congruence shortcuts?" in Figure 1. We employed green to indicate combinations of criteria, which we refer to as conditions in the above that work (e.g., SSS in Figure 1), red to signify conditions that cannot guarantee congruency (e.g., SSA in Figure 1), and yellow to demonstrate the application of a condition in problem-solving (e.g., SAS example 1 in Figure 1). We used various shapes and sizes to represent different types of instructional activities. A large rectangle was used for exploratory activities (e.g., using compass-and-straightedge construction to justify SSS can guarantee triangle congruency), while a small hexagon indicated brief instructional activities, such as a brief discussion or providing a counterexample for justification (e.g., use not all equilateral triangles are congruent to justify AAA won't work). Additionally, a cloud shape, sized between a rectangle and a hexagon, represented worked-out examples in the textbooks. In the following sections, we illustrate each dimension and its connection to the visualization within the context of comparing two learning pathways for triangle congruency.

Scope. Scope captures the mathematical content that has been covered in the textbooks, which is presented by the texts in Figure 1. These texts include the overarching inquiry questions and the main foci of the instructional activities. Figure 1 shows that both textbooks examine situations with less than three congruent and exactly three congruent criteria. Regarding exactly three congruent criteria, both DG and PEP math include exploring or discussing the following six situations: SSS, SAS, SSA, ASA, SAA, and AAA. Thus, the scopes of the learning pathways presented in the two textbooks are similar.

Sequence. The sequence shows how a textbook organizes instructional activities to develop a learner's understanding of the topic. Here, we sequenced the main instructional activities linearly covered in DG and PEP. As Figure 1 shows, DG and PEP math sequence the examination of situations similarly. Both textbooks open with an overarching inquiry question. DG asks if there are congruence shortcuts and PEP math inquiry, "Is it possible to identify various subsets of these six conditions (i.e., three pairs of congruent sides and three pairs of congruent angles) that will also make two triangles congruent?" To answer this overarching question, both textbooks start with the situation when only one or two criteria are congruent, then transition to examining the conditions with three criteria. Both textbooks also sequence the six conditions of three criteria similarly. Both start with SSS and then move on to SAS and SSA. However, slightly differently, DG discusses the AAA condition before exploring ASA and SAA conditions, while PEP math discusses the AAA situation at the end. These sequence differences reflect and are influenced by the "structure," a construct we discuss next.

Structure. We assume textbooks sequence instructional activities based on logical structures. The patterns reflected by the sequence suggest the underlying logical structures. DG and PEP math share some similarities regarding the structure of learning pathways. For example, both follow an inquiry mode; both open the topic with an overarching inquiry question and then devote a sequence of instructional activities to answer the question. One distinguishing structural difference between them is that PEP math always follows the examination of a condition with worked-out examples, while DG seldom does. Another structural difference relates to the sequence difference we mentioned earlier: AAA goes before or after the exploration of ASA and SSA. Reading through PEP math and DG carefully, we found that this difference reflects a structural distinction that PEP math goes through the cases systematically with a clear underlying mathematical logic. It starts with three pairs of congruent sides, zero pairs of congruent angles (3S0A: SSS), then 2S1A: SAS and SSA, then 1S2A: ASA and AAS), and ends with 0S3A: AAA. However, DG separates the examination of the six conditions into groups, located in two lessons, with two categorical titles: "Are there congruence shortcuts?" and "Are there other congruence shortcuts?" without explicating the underlying logic.

Scale. Scale is a dimension to capture the educational resources the curriculum developers distribute to a topic or a specific instructional task. It is reflected by the anticipated time spent on the instructional activity, the priority of the instructional activity in the lesson, and the cognitive demands for completing the instructional activities. As shown in Figure 1, PEP covers the content with three lessons while DG only devotes two lessons, reflecting that the overall scale of triangle congruency in PEP is more significant than in DG.

The overall scale difference may be due to the differences between the instructional activities in PEP Math and DG. Firstly, while DG only mentions that a condition with fewer than three criteria won't guarantee triangle congruence, PEP requires students to use compass-and-straightedge construction to test if a condition with one criterion (e.g., one side equivalent or one angle equivalent) or two criteria work. Regarding SSS and SAS, although both DG and PEP require students to engage in exploratory activities, PEP strengthens students' understanding of SSS and SAS conditions by providing worked-out examples immediately after each exploratory activity, resulting in a larger scale of learning resources devoted to the learning of SSS and SAS compared to DG. However, regarding SSA and SAA, DG allocates more learning resources to them than PEP does, as it expects students to engage in an exploratory activity rather than a brief discussion, as PEP does. One thing to mention is that although we assume the scale of exploratory activities in both textbooks is similar, they are different; many details differ, which is beyond the focus of this framework.

Discussion and Conclusion

In this study, we propose a framework for textbook analysis that complements the dominating focus on topic listings or task analyses in this research area. Using the 4S framework to explore four critical dimensions—scope, sequence, structure, and scale—has yielded nuanced insights into instructional activities concerning congruent triangles in Chinese and US mathematical textbooks. While the similarity in the overall content coverage implies a shared foundation in mathematical concepts, the analysis of sequence and structure dimensions highlights differences in content organization, suggesting potential divergences in students' learning trajectories. Notably, variations in scale were identified to impact the level of student engagement with the material, prompting considerations for educators to tailor teaching strategies to match the instructional activity scale. This disparity in learning pathways may help elucidate why eighth-grade students in the US struggled with the TIMSS items intended to assess their understanding of triangle congruency (Author, 2021).

The 4S framework exhibits significant potential in navigating nuanced distinctions within instructional activities related to triangle congruency. We recommend that future researchers apply this framework to various mathematical topics in textbook analysis, further refining it. This framework can also analyze how a textbook evolves version by version (e.g., how DG presents learning pathways differently in 2003, 2008, and 2013 versions). Our analysis using the 4S framework carries substantial implications for curriculum development, emphasizing the importance for educators, curriculum developers, and policymakers to address the breadth or depth of content and the intricacies in sequencing, structure, and scale. Such considerations are needed to construct a shared vision of mathematics curriculum that will equip future students with the mathematics understanding needed to be productive citizens in uncertain times.

NAVIGATING A NEW DETRACKED MATHEMATICS CURRICULUM: TEACHER APPROACHES TO PROGRAM PLANNING AND ASSESSMENT

doug.mcdougall@utoronto.ca

Zian Zhang
University of Toronto
kellyanne.zhang@utoronto.ca

Current research indicates introducing a detracked curriculum can bring about positive educational change, but there will always be challenges at the enacted level. In detracked mathematics courses, teachers must differentiate their students' needs, adopt a connected perspective of mathematics, decide which key mathematics ideas take focus, and distinguish course-based and application-based evaluation. This research project examines the experiences of grade 9 mathematics teachers in the detracked classroom. The findings of this project display that teachers put great effort into acquiring class resources and time, preparing and designing courses, and developing new forms of assessment and evaluation.

Keywords: Detracked curriculum, assessment, mathematics practices

Purposes and Framework

Although a new curriculum can bring about positive educational change, there will always a challenge with implementation at the enacted level: the teacher level. Detracked classrooms have a history of disrupting fluency and routine in the curriculum for teachers and students (Horn, 2006; Quigley et al., 2020; Tereshchenko et al., 2019; Venkatakrishnan & Wiliam, 2003). Furthermore, teachers in detracked classrooms are responsible for making individual interpretations of the curriculum (Herppich et al., 2018; Horn, 2006; Venkakrishnan & Wiliam, 2003). These curriculum interpretations about planning and evaluation are what directly impact students' inquiry, development, and achievement (Herppich et al., 2018; McGee et al., 2013; Quigley et al., 2020).

For countries like Canada and the US, the detracked curriculum encourages inclusivity for teaching and learning by creating more equitable environments for success (Tereshchenko et al., 2019; Horn, 2006). As of September 2021, all schools in the province of Ontario in Canada have recently rolled out a new detracked grade 9 mathematics course. During this transition from the tracked to the detracked curriculum, there are several changes that teachers must consider, primarily, the broader scope of students' mixed abilities. For teachers, meeting the student's individual learning needs can be a great ordeal, as they must prepare/design a multitude of tasks and varied activities (Mellroth et al., 2021; Perkins, 2016).

In addition to differentiating their students' needs, teachers must contemplate many other factors particular to the subject of mathematics. These factors may involve teachers adopting a connected perspective of mathematics, deciding on focused key mathematics ideas, balancing professional and personal decisions, and distinguishing between course-based and application-based evaluation (Gottfried; 2014; Horn, 2006; Quigley et al., 2020). In addition, the Ten Dimensions of Mathematics Education (McDougall, 2004), present key components that contribute to successful mathematics teacher practices and approaches. Specifically, the components of program scope and planning and assessment are prominent areas of change for teaching detracked mathematics (Ferreyro-Mazieres, 2016). For this paper, we draw from the Ten Dimensions of Mathematics Education framework to guide our data analysis and findings.

The Ontario Institute of Studies in Education and the largest school board in Canada have collaborated on a multi-year project with several grade 9 detracked teachers. From this project, our findings suggest that grade 9 mathematics teachers have put great effort into acquiring classroom resources, preparing and designing courses, and developing new forms of assessment and evaluation. Moreover, teachers expressed their hardships transitioning into the new curriculum, including lack of curriculum expectations, lack of preparation time, and the overwhelming amount of curriculum content.

The purpose of the project was to investigate the following questions:

- What do teachers perceive to be the biggest challenges in implementing the new mathematics-detracked curriculum?
- How are teachers preparing their mathematics classes with respect to the expectations of the new curriculum?
- How are teachers approaching assessment and evaluation with respect to the expectations of the new curriculum?

Methods

Participants

Participants for this project were found from sixteen different schools across a large urban school district. All participants were required to be current teachers who were presently or previously teaching the Grade 9 detracked mathematics course. For this paper, we discuss the responses of eleven teachers relating to the themes of program planning, assessment, and teacher support/challenges.

Data Collection and Analysis

The data collected for this project came from semi-structured interviews taking place with teachers, once in the first semester and once in the second semester. Interviews were transcribed verbatim and coded for emerging themes through *NVivo 12* software, guided by the Ten Dimensions of Mathematics Education framework. In this report, recorded themes emerged from the first round of interviews with participants as well as *The Attitudes and Practices for Teaching Mathematics Survey* (McDougall et al., 2001) was administered for interviews but was largely used to inform participants of their *own perceptions* of the importance and their degree of comfort in implementing reform mathematics teaching and learning strategies.

Interviews

Semi-structured interviews took place with participants in their individual schools after the second professional learning session. Interviews ranged in length from approximately 50 to 60 minutes, which were audio recorded and then transcribed by the interviewer.

Results

Program Scope and Planning

Various planning strategies were mentioned among the teacher participants, ranging from spiralling the curriculum, concept-based planning divided into units, as well as daily on-the-go planning. Other considerations were also addressed such as preparing students for the grade 10 academic mathematics course and planning for students with potential foundational mathematics knowledge gaps.

Some teachers described using the spiralling approach for planning the Grade 9 mathematics course. One teacher found this approach very effective and described the process: “Everything weaves together, we go back and forth. There is a sense where all the units come together to the central big idea and having discussions that also go back to previous topics helps with retention” (Teacher 1). Other teachers used the unit-by-unit approach, which covered one concept after another. Teacher 2 explained their reasoning behind using this approach:

> So, for this year, our planning process was by unit. I think we decided that we wanted to try and just go by unit, because in order to spiral, [the students] have to have a certain amount of knowledge or consistency in the other areas before you can spiral things on top.

A few teachers mentioned the challenge of planning day by day or week by week rather than having a long-range plan already in place. For example, one teacher described planning on a “catch-up basis” since she is “a little bit busy these days with three different courses and planning things week by week or month by month” (Teacher 3).

The request to be given time to plan was made by almost every teacher in this project. The teachers value planning time and having the time to collaborate with other teachers to discuss different teaching strategies. Teacher 4 hoped to discuss topics “starting from how you review, how you engage students, and how you use those cooperative learning strategies”. Another teacher from the same school requested for planning time with “more guidance in the curriculum” (Teacher 5). Several teachers reported that the new curriculum was released too late in the previous academic year, leaving them not enough time to prepare. For example, one teacher from Mona Lavender noted: “It was not considerate of teachers to release the new curriculum almost at the end of June, leaving very little time to start preparing. Almost requiring teachers to spend their summer preparing if they wanted to get a head start” (Teacher 6). Another teacher expressed her frustration: “Considering when we got our curriculum – it was six pages, single sided, no exemplars, no examples. There was no structure, no timeline, there was nothing, and it was left to the teachers” (Teacher 7).

Assessment

Assessment is a topic of interest for many teachers and something that they can continuously improve upon. Several teachers mentioned formative feedback as a practice that they used in their classroom. For example, one teacher mentioned that, after the whiteboard group activities, the groups present their solutions to the class. She said that is when “we come back and talk about how they think they did, which parts were good and they receive feedback” (Teacher 1).

Another teacher explained that she is “constantly monitoring, giving feedback, doing formative assessment and figuring out how that can translate into evaluations” (Teacher 8).

Several teachers reported using parallel assessments as part of their practice. One teacher from Mandevilla SS described her process: “I give two different questions. I say you either choose this one or this one. One is out of three, which is easier. One is out of five, which is harder. The students can decide on which question they want to do” (Teacher 7). A teacher from Ninebark SS called this process leveled assessments. She said: “I have learned this idea of leveled assessment from a colleague at our board” and “students can choose which leveled question they want to attempt for them to show their understanding” (Teacher 9).

Project-based or performance-based evaluations were also mentioned by some teachers. Teacher 2 shared her practice:

> They have a little mini project or problem that they have to work on, and they may have to present that to the class or discuss their solution or provide feedback on somebody else's solution to show their understanding. Smaller tasks like that, plus regular contribution to class, and classroom conversations is how we can assess them that way as well.

Challenges with Curriculum Implementation and Teacher Support

The participants reported a lack of curriculum guidelines and specific expectations for each mathematics strand. For example, one teacher said: “We need more guidance in the curriculum. The curriculum is really loose and open, and it does not tell us what they want us to do. We are used to having more specific expectations” (Teacher 5). Another teacher said: “I felt like the Ontario Ministry strands were sometimes vague” (Teacher 1). The participant also reported having an excessive amount of content to cover with the new curriculum guidelines. One teacher honestly said: “It has been hard to fit everything in” (Teacher 10) and another teacher said: “At the moment, we have six sections of grade nine math. None of us will be able to complete the entire curriculum, given the fact that we are doing this for the first time” (Teacher 11).

When asked if they felt supported by the board or education system, participants reported a lack of teacher support. One teacher responded with: “No, I feel pressured to try it out. We have to make this work but without necessarily a good plan of action” (Teacher 10). Another teacher expressed his frustration: “All the new stuff you would really want help with is marked under construction, and well, that is not very helpful because that is the stuff I really need help with” (Teacher 5).

The participants also reported a lack of professional learning sessions. One teacher explained that having the resources themselves was not enough, she would have liked to see how the resources were implemented in a grade 9 classroom. She stated: “I feel like we were kind of thrown into the forest with a bunch of survival supplies and like, go, enjoy, and we were not really taught how to use these supplies” (Teacher 1). Professional learning sessions were requested by several teachers. One specifically noted that a session on coding might be helpful for some grade 9 teachers. She said: I have heard that coding seems to be a first exposure for many educators. So maybe some professional development might be needed there” (Teacher 4).

Conclusion

The literature disclosed the difficulties that students and educators experience during the implementation of the detracked curriculum, especially with regard to the subject of mathematics. As well, prior research recognizes the challenges teachers face when considering the wide range of abilities within the detracked classroom. Our project findings reflect commonalities from these studies, as teachers experienced numerous frustrations and difficulties with curriculum design, course planning, and course evaluation.

Among participants, there was one popular demand: additional time. Teachers expressed the need for more time to adjust to the curriculum, preparation time, and collaboration time. An additional common request was for the school board to provide extra professional learning sessions, as resources were not sufficient. Many teachers also employed newer approaches, including the spiralling approach for program planning and levelled or parallel assessment for course evaluations. The results of the project showed teachers experienced confusion and frustration when interpreting broad-based curriculum expectations, a disconnect from teacher implementation of the detracked course. These findings were consistent with previous literature, as it was notable that there was a lack of specific curriculum guidelines and teacher support.

MATHEMATICAL TASKS FROM 141 SECONDARY ALGEBRA LESSONS: A PREPONDERANCE OF PROCEDURES WITHOUT CONNECTIONS

Samuel Otten

baahf@mail.missouri.edu

Mathematics educators have written a great deal about cognitively-demanding tasks but this study of 141 lessons across 47 different algebra classes found cognitively-demanding tasks to be rare in practice. Of 2,378 coded tasks, 93% were low cognitive demand, predominantly procedures without connections to meaning. Only 6% were high cognitive demand, predominantly procedures with connections to meaning, not entailing the complex processes of doing mathematics. This article breaks down the cognitive demand of tasks by lesson segments (independent work, group work, homework) and also compares tasks in flipped lessons versus non-flipped lessons. We discuss the need for professional development that is aligned to these curricular realities and note discrepancies between these findings and other research.

Keywords: curriculum; algebra and algebraic thinking; instructional activities

For decades, mathematics educators have drawn attention to the importance of rich problem solving opportunities (e.g., Lesh & Zawojewski, 2007; Schoen & Charles, 2003) and cognitively-demanding tasks (e.g., Lappan et al., 2012; Stein et al., 1996; Stein et al., 2000) in the school mathematics experiences of students. Many textbook analyses (Glasnovic Gracin, 2018; Hwang & Ham, 2021) and other curriculum studies (Arbaugh & Brown, 2005; Jackson et al., 2013) have attended to cognitive demand in various ways, yet the United States and certain other countries are still known to have a predominant procedural focus (Dolores Flores et al., 2020; Hiebert et al., 2005; Lénárt, 2018; Litke, 2020). It is not clear that the cognitively-demanding tasks common in mathematics education professional development programs, preservice teacher education courses, and the books and journals of the scholarly community are common or even easily detectable in typical mathematics classrooms.

As part of a multi-year, non-interventionist project focused on understanding current algebra instruction, we observed 47 secondary algebra classes in a variety of school districts (de Araujo et al., 2017a). Based on three lesson observations in each class (n = 141), we compiled class profiles of the instructional patterns and classroom discourse (Otten et al., 2023). We also collected the student materials from each lesson, including any tasks that students were expected to work on during the class period as well as any tasks assigned as homework. Our research question in this brief report is the following: *What levels of cognitive demand were entailed in the tasks assigned to students in these Algebra 1 classes?* Furthermore, we were interested in how the cognitive demand varied across different parts of the lesson (e.g., in-class independent work time, in-class group work time, homework) or between groups of classes with different instructional models, such as classes implementing flipped instruction versus those implementing non-flipped instruction. Flipped instruction is defined by students being expected to watch videos (or read text or listen to an audio recording) as their homework rather than completing exercises (Bergmann & Sams, 2015; Otten et al., 2021). The broader project contained both types of algebra classes and it is worthwhile to examine potential differences in cognitive demand because some teachers have stated that flipped instruction, by moving lecture to a video outside of class and freeing up class time, can allow for rich tasks or extended problem-solving endeavors to be incorporated into lessons (de Araujo et al., 2017b).

Theoretical Perspective

In our overarching project, we view students' mathematical learning as a sociocultural process whereby they come to participate actively in a mathematical community (Vygotsky, 1978). Thus, the lesson observation protocol (Otten et al., 2021) attended to the nature of the classroom discourse, the interactions of the students with one another and with the teacher, the authority dynamics at play with regard to the mathematical content, and some of the social patterns exhibited by the teacher. Because we view learning as occurring through and being defined by students' participation in forms of mathematical discourse (Lemke, 1990), we identified various structural lesson segments such as whole-class discourse, independent work time, group work time, and non-instructional time. Note that group work here refers to time when the teacher explicitly expects students to collaborate with peers.

It also matters what type of mathematical activities the students are engaging in within their mathematical community (Doyle, 1983). Thus, we used the well-known mathematical task framework (Table 1), which provides a classification based on the thinking required to complete the tasks—what Stein and colleagues (1996) called cognitive demand. Stein et al. (1996) emphasized the importance of students engaging in tasks at different levels of cognitive demand, though much of their work focused on the cognitive demand of tasks in "reform classrooms" because they noted, as we have, that there is an overabundance of low cognitive demand tasks implemented in U.S. mathematics classrooms. Other scholars have traced the difficulty of implementing cognitively-demanding tasks (e.g., Boston & Smith, 2009; Henningsen & Stein, 1997). In the present study, we look not at all the tasks contained in particular textbooks but rather at the tasks selected by teachers to actually pose to students in our observed lessons. That being said, the analysis that follows was of those posed tasks as written, not as actually carried out to completion.

Table 1: Levels of cognitive demand entailed in mathematics tasks (Stein et al., 2000)

Level of Cognitive Demand	Description	Example
Non-Mathematical Activity	Task does not require students to engage with any discernible mathematical idea.	Coloring a picture related to task context
Memorization	Task involves recalling definitions, terms, or formulae but not applying them.	"Which term is the coefficient of x?"
Procedure Without Connection to Meaning	Task involves executing a known algorithm or producing correct answers based on previous instruction.	"Find the roots of this quadratic equation using factoring."

Procedure With Connection to Meaning	Task involves a procedure with explicit connections to underlying mathematical ideas, multiple representations, or an explanation of why the procedure works.	"Explain how you know that [this quadratic equation] has only one root."
Doing Mathematics	Task involves nonalgorithmic thinking and self-regulated explorations or mathematical concepts, processes, or relationships.	Determine end behavior of a new polynomial function and explain why it occurs

For some portions of analysis, Memorization and Procedures Without Connection were combined as "low cognitive demand" and Procedure With Connection and Doing Mathematics were combined as "high cognitive demand."

Method

The study involved 47 Algebra 1 (or equivalent) classes (Grades 8–9) in Midwestern U.S. school districts that ranged from rural to urban contexts and from small to large enrollments. The project focused on classes using flipped instruction ($n = 23$) and non-flipped instruction ($n = 24$), but this report focuses on all classes together and the mathematics tasks assigned to students during class time (independent work or group work) or as homework (tasks expected to be completed outside of class; distinct from those during class).

We conducted three lesson observations throughout the school year for each of the 47 classes (141 lessons) and we collected the tasks, either as problems captured within the class (e.g., recorded from the front board) or as materials from the teacher (e.g., handouts or homework assignments). Tasks were enumerated based on how they were presented to students, though multi-part problems (e.g., a, b, and c) were coded as a single task. If the teacher completely solved the problem, with no expectation for students to devise their own solution (e.g., a worked example), then it was not included as a task for students. The classes used a variety of curriculum materials with the vast majority being either teacher- or school-generated resources or publisher-developed textbook series. By design, the study focused on Algebra 1 courses and so there were no integrated curriculum series. Two team members observed each lesson and independently coded each task for level of cognitive demand (Table 1) based on the task as written, not implemented. After independent coding, coders met and reconciled any disagreements. If multiple levels of demand were discernible in a single task, it was coded at the highest level evident. For the analysis here, we simply report descriptive statistics as a means of summarizing the variability in cognitive demand. We also present findings broken into sub-categories, including the lesson segment in which it occurred (independent work, group work, homework) and the two instructional models observed (flipped instruction, non-flipped instruction).

Findings

Overall, our team coded 2,378 mathematical tasks (16.8 per lesson) and the overwhelming majority involved low cognitive demand (Figure 1), with 91% falling in the category of Procedures Without Connections to Meaning. These low tasks covered a vast array of algebraic topics (linear equations, quadratic equations, plotting graphs, writing functions from word problems) but were all characterized by the fact that the students had been shown a process for completing such problems and were not expected to justify their work or make conceptual connections to other ideas. Across the 141 lessons, there was a grand total of 5 Doing Mathematics tasks (0.2%). Even in this brief report, we could almost print all of them in their entirety, but instead we will just mention that one was an open-ended project in which students made a budget for their hypothetical finances and then provided justifications for certain calculations within that budget, and another Doing Mathematics task occurred when a teacher asked students to try solving a new type of equation before the teacher showed the procedure.

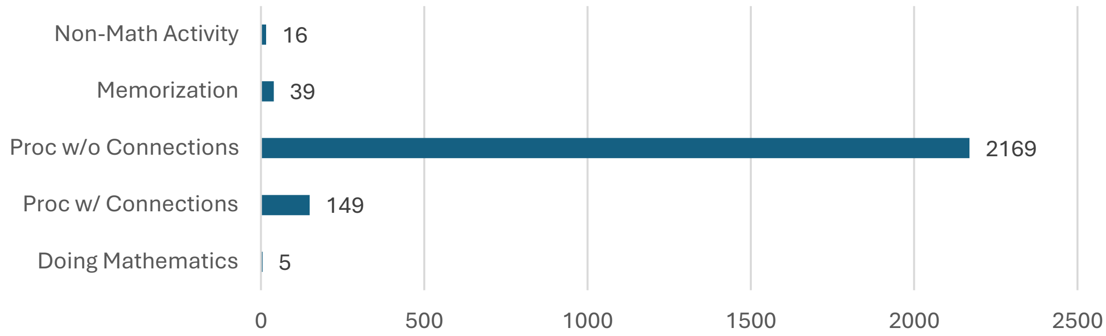

Figure 1: Total number of tasks from 141 algebra lessons, by level of cognitive demand

With regard to lesson segments, 133 of the lessons (94%) had *independent work time*, lasting for an average of 45% of the total class time, though this varied from as brief as 1 minute to nearly the entire period. There were 13 tasks on average that students worked on during independent work time per lesson (if they did not finish, they could complete them after class or next day). These tasks were low cognitive demand 92% of the time and high cognitive demand 7% of the time (1% non-mathematical). *Group work* was less common. Only 31 lessons (22%) contained any group work, and it involved 6 tasks on average. The types of tasks were roughly the same as during independent work, with 91% low cognitive demand and 8% high cognitive demand (1% non-mathematical). *Homework* tasks distinct from the tasks started in class were also relatively rare, occurring in 37 of the lessons (26%), with 13 tasks per homework assignment. We coded 96% to be low cognitive demand and 4% to be high cognitive demand.

Therefore, the breakdown of task types was essentially the same across the different segments of the lessons, and the similarities continue when comparing flipped and non-flipped classes. Both groups had matching cognitive demand profiles for independent work (92% low, 7% high) and for homework (95% low, 5% high), though non-flipped classes were more likely to have assigned homework tasks, as expected. A noticeable difference arose, however, between the flipped classes and the non-flipped classes in the area of group work. They had similar rates and durations of group work but the non-flipped classes had more cognitively-demanding tasks. Within flipped classes, the group work entailed low cognitive demand 96% of the time and high cognitive demand only 3% of the time, whereas non-flipped classes had low cognitive demand 70% of the time and had high cognitive demand 27% of the time (3% non-mathematical).

Discussion

Across a wide variety of school districts and a diverse group of teachers, the Algebra 1 lessons we observed involved an overwhelming proportion of low cognitive demand tasks

(93%). High cognitive demand tasks were extremely rare and Doing Mathematics tasks, in particular, were almost non-existent. This result should give pause to mathematics education innovation efforts that rely on an assumption of readily-available, cognitively-demanding tasks, at least in algebra. Because algebra is perhaps more procedural than other topics areas, these findings do not necessarily extend across secondary mathematics, nor do they extend to states with significant levels of reform-oriented curricula, but these findings are similar to what we have observed in other studies. Thus, it may be worthwhile to design professional development based on an assumption of teachers' comfort with low demand tasks (Otten et al., 2022).

It was surprising to us that, overall, group work was relatively rare (occurring in only 22% of lessons) and the tasks pursued in groups were not of higher cognitive demand than the other tasks. This finding was affected, however, by our over-sampling of flipped instruction. Looking only at the non-flipped classes, group work did post slightly higher rates of cognitively-demanding tasks (though almost never Doing Mathematics). This did not translate to higher student learning scores, though, on the procedural or conceptual measures in our broader study (Otten et al., 2023). As noted in critiques of the cognitive demand framework (Otten et al., 2017), it is wise to be cautious of direct links between cognitive demand and student achievement measures, though it remains important for more diverse forms of student outcomes.

With regard to flipped classes, we did not confirm teachers' stated intentions for flipping (de Araujo et al., 2017). Rather than using the extra time in class for group work or rich tasks, the flipped classes focused on independent work and low demand tasks. Our other analyses have showed that this focus on independent work is associated with learning gains (Otten et al., 2023).

COMPARISON OF A GRADE 8 TOPIC FROM ONE U.S.-BASED AND ONE INDIA-BASED MATHEMATICS TEXTBOOKS

Jaai Uday Phatak	Lillie R. Albert	Leslie Dietiker
Boston College	Boston College	Boston University
phatakj@bc.edu	lillie.albert@bc.edu	dietiker@bu.edu

Keywords: Curriculum, Middle School Education

In this poster, we present a comparison of a mathematical topic from two mathematics textbooks for Grade 8 to learn how the topic is addressed in each country. The two textbooks were (1) *Connected Mathematics Project* (CMP) (Lappan et al., 2014), a research-based textbook used in the United States, and (2) *National Council of Educational Research and Training* (NCERT, 2022), a textbook used in India by the schools affiliated with the Indian National Educational Board. The mathematical topic was “Inverse Variation”, which was also referred to as “Inverse Proportions” in the NCERT textbook. Through this comparative analysis across two diverse international contexts, we highlight differences between these textbooks and identify their contributions toward rich mathematical learning experiences.

The criteria used for comparison were: (1) flow, structure, and placement of the topic; (2) cognitive demand of the task(s); and (3) presence of realistic and relevant use of context. For the first criterion, we examined the *mathematical story* (Dietiker, 2015) of these topics in both textbooks. The second criterion focused on the cognitive demand (high or low) level (Smith & Stein, 1998) of the tasks and problems in each textbook. Additionally, providing relevant and realistic contexts while teaching mathematics is important so that students relate to these contexts and mathematically analyze them (Boaler, 2015). For this third criterion, we examined how each textbook provided relevant and realistic contexts for students.

To analyze, the first author read in detail the topic of Inverse Variation (or Inverse Proportions, as in the NCERT textbook), applying each criterion to examine every statement, question, problem, and worked example in both textbooks. For this examination, a qualitative analysis was conducted to analyze these components, taking into account each criterion.

Based on all three criteria, the CMP textbook had more positive elements than the NCERT textbook. The mathematical story of CMP enables students to reason through important mathematical concepts and relationships, thus helping them understand inverse variation using multiple dimensions, which was lacking in NCERT. Also, CMP had both low and high cognitive demand problems with more high-level, that is, “procedures with connections” (Smith & Stein, 1998) types of problems. However, the NCERT textbook's problems had lower cognitive demand due to the excessive use of scaffolding and demonstration examples. Lastly, both textbooks included a substantial number of problems in relevant contexts.

While both textbooks serve distinct student populations, we believe that students can greatly benefit from rich mathematical learning experiences when the CMP textbook is used (with the incorporation of a few improvements). To provide similar learning experiences, the NCERT textbook must fill in the gaps and make modifications based on the first two criteria. Thus, this curriculum comparison project highlights the offerings of a research-based textbook from the

U.S. and an Indian textbook prescribed by the Indian Educational Board, to their respective students and teachers, as well as the textbooks' offering to each other, which may eventually contribute to the changing future of mathematical learning in diverse social contexts.

INVESTIGATING ELEMENTARY TEACHERS' PROFESSIONAL OBLIGATIONS WHEN MAKING MATHEMATICS CURRICULAR DECISIONS

Bima Kumari Sapkota
The University of Texas Rio Grande Valley
bima.sapkota@utrgv.edu

mbwood@arizona.edu

Elementary teachers are held accountable to multiple professional obligations when adopting curricular resources. We investigated how three elementary teachers prioritized and negotiated individual, interpersonal, institutional, and disciplinary obligations when making mathematics curricular decisions. We found teachers were drawn towards individual and interpersonal obligations more often, suggesting they prioritized their students. Meanwhile, their curricular decisions were influenced by school, district, and state policies, suggesting several nuances of institutional obligations. Teachers only occasionally responded to disciplinary obligations. Institutional and individual obligations often conflicted with each other while individual and disciplinary obligations complemented each other. We illuminate the multiple constraints that teachers navigate along with current educational uncertainties.

Keywords: Curriculum, Elementary School Education, Teachers' Professional Obligations

The current teaching context is remarkably uncertain due to flourishing online resources, Artificial Intelligence, and changing student needs specifically since the pandemic. In addition, over the past decade, there has been a significant increase in teachers' access to curricular materials, including virtual resources (Hodge et al., 2019). As a result, many teachers supplement their mandated materials with additional resources (Francom et al., 2021; Kaufman et al., 2018; Polly, 2017) "to fill needs perceived in their contexts, their students, or themselves" (Silver, 2022, p. 459). Our prior studies showed that elementary teachers utilized up to 14 distinct mathematics curricular materials when preparing to teach (Authors, 2022). In creating, selecting, and implementing those resources, teachers consider multiple factors such as state, school, and district curriculum policies (Authors, 2023a; Remillard & Heck, 2014) and instructional contexts such as students' access to curricular resources and students' learning needs (Mutten et al., 2011; Keiser & Lambdin, 1996; Ormond, 2017).

Herbst and Chazan (2011) sorted these multiple factors into categories of professional obligations, labeling four different kinds of obligations: individual, institutional, interpersonal, and disciplinary. Mutton and colleagues (2011) found that novice elementary teachers, facing limited time, often use existing materials instead of creating new ones that might better meet students' needs. This illustrates the tension novice teachers experience between institutional obligations (limited time for preparation) and individual obligations (addressing students' needs) when making curricular resources.

Other researchers have investigated the complexity of teachers' curricular decision-making. For example, when analyzing curricular materials, teachers evaluate various aspects related to students, discipline, institutions, and context, including whether the materials align with standards, provide cohesive mathematics instruction, facilitate student interpretation and performance, promote mathematical understanding, and adapt to classroom context and content (Dingman et al., 2021). These aspects highlight the complexity of teachers' mathematics curriculum decision-making, encompassing factors related to content (discipline), students (learners), institutions, and contexts (e.g., standards). However, less well studied is how elementary teachers prioritize and negotiate these factors when adopting mathematics curricular resources. We used the lens of teachers' professional obligations to understand this underdeveloped area of research, as described below.

Theoretical Framework

To understand the factors influencing elementary teachers' mathematics curricular decisions, we employed Herbst and Chazan's (2011) Teachers' Professional Obligations framework. Herbst and Chazan proposed that teachers' curricular decisions are influenced by four types of obligations: Individual, Disciplinary, Institutional, and Interpersonal. Individual obligations focus on attending to each student's well-being; identities; and behavioral, cognitive, emotional, or social needs. Disciplinary obligations pull teachers toward consideration of accurate and reliable representations of mathematical knowledge, mathematical practices, and mathematical applications. Institutional obligations involve fulfilling duties to institutions, such as adhering to calendars, examinations, and curricula. Chazan and colleagues (2016) also highlighted that teachers are drawn toward multiple obligations associated with institutions. They urged mathematics education researchers to focus on societies and institutional contexts to acknowledge complex and uncertain situations teachers need to work on that are shaped by society and institutional rules. Finally, interpersonal obligations acknowledge the teacher-classroom relationship, especially focusing on how teachers' decisions need to work in settings with limited resources that need to be shared across many students with different needs.

Herbst and Chazan primarily discuss these obligations in the context of secondary mathematics teaching, while elementary teachers arguably negotiate these obligations in different ways. Elementary teachers make curricular decisions for a variety of subject areas (i.e., not just mathematics but also science, social studies, reading, and writing) to fulfill the needs of one group of students. Considering these differences, we interpreted teachers' interpersonal, disciplinary, and institutional obligations specifically for the context of elementary instruction. We acknowledged differentiation of content as the core of interpersonal obligation, which led to the identification of two dimensions of differentiation, teachers may *select different materials* or a*ssign different tasks from the same material* for students with different needs at the shared time in the shared space. For the disciplinary obligation, we labeled what teachers think is disciplinary rather than researchers or mathematics specialists and experts. For instance, teachers may prioritize teaching math facts as disciplinary, considering the importance of foundational math skills regardless of broader mathematical practices. In addition, when attempting to do other types of obligations, some mathematical practices might not be seen in the classroom even though teachers prioritize those practices (Herbst & Chazan, 2020). Lastly, we incorporated the role of standards (e.g., state and common core standards) as institutional obligations as teachers explained selecting curricular resources to meet those standards.

Aligning with the purpose of this framework that "combined with the personal assets (including knowledge, skills, and beliefs) that an individual teacher brings with them to that position and that role, those norms and obligations can help explain teacher action and decision-making" (Herbst & Chazan, 2011; p. 417), we identified how elementary teachers respond to these four types of obligations when creating, selecting, and implementing mathematics curriculum to optimize their students' mathematics learning in the current uncertain context.

Objectives and Research Questions

We investigated how different obligations influenced elementary teachers' mathematics curricular decisions. The following research questions guided our study: (a) Which types of obligations do elementary teachers consider when making mathematics curricular decisions? and (b) How do elementary teachers negotiate decision-making among their multiple obligations?

Methods

Context, Participants, and Data

This study was part of a larger national project on decisions made by elementary teachers regarding their mathematics curriculum. The larger project included a sequence of interviews with individual teachers. For this study, we selected three teachers from the same Midwestern school —Audrey, Jamie, and Kasie (pseudonyms)—due to their diverse teaching experiences across different grade levels. Audrey had six years of elementary teaching experience, with the last four years spent teaching fourth grade. Kasie and Jamie were third- and fourth-grade teachers, respectively, each with thirteen years of teaching experience. We collected data through a three-phase interview— two individual interviews and a focus-group interview. In the first interview, we asked the teachers what curricular resources they used for mathematics teaching and how much control they felt in adopting those resources. In the second interview, they shared how they created cohesion from a variety of resources they selected. In the third focus-group interview, the teachers shared experiences with curricular coherence and collaboration with each other. The data for this study consists of the transcription of the three teachers' first and second interviews. We purposefully omitted the data from the third interview as the teachers focused on sharing their collaborations more and less about their obligations.

Data Analysis

Initially, we coded our data using a deductive coding method (Saldaña, 2016). Using four pre-defined categories of obligations (individual, interpersonal, disciplinary, and institutional), each author coded a set of data independently. We then conducted weekly meetings to resolve our discrepancies. In those meetings, we had extensive discussions about coding units, types of obligations, and relationships among various types of obligations. Below, we share a transcript from a part of our meeting in which three coders collectively engaged in resolving discrepancies.

Table 1: An Excerpt of Research Team's Conversation to Resolve Coding Discrepancies

Coder	Excerpt
1	Why did you put it under institutional?
2	I don't know if it's an obligation to the [school district] or if it's like they have them because they've been provided by the institution, and they like them, so they use them.
3	Yeah, right. And also I think the other thing is like she [the teacher] is saying pretty good. So you are not sure what she is referring to either, right?
2	Okay, and I put it there because it said [school district].
1	Yeah, that was also my question about this one. I think I wanted to capture if they didn't have if the [school district] didn't give them these resources. It's not clear to me that they would use them.
2	Yeah
1	But you think of it in a way that we just talked about another quote: if the [school district] doesn't provide them then the teacher would complain that because the [school district] does not provide that and they have to buy it, which is expensive, so they have to create their own then that make it institutional. What you said just now is in the previous sentence. We do find materials for all the subjects, and I feel like [she was saying] "We have the freedom overall to find what works best with our kids."
2	They're pretty good, meaning, they must align with the most things they must align with standards. But the main priority is their kids.
1	Oh, okay. So, that made it individual.
2	Cool. We agreed on the individual? Just making sure.

In this excerpt, the three authors discussed a coding unit in which two authors had different codes. One author initially coded as an institutional because the teacher discussed the school district-mandated curriculum. However, after an in-depth analysis of the overall meaning of the teacher's description, we concluded that the teacher indicated individual obligation rather than institutional. Our next process involved counting the number of codes for each obligation and identifying patterns. We looked for patterns of how teachers negotiated multiple obligations, including when two or more obligations complemented and/or conflicted with each other.

Findings

We organize this section by our research questions. In the first subsection, we describe the obligations teachers considered when making mathematics curricular decisions. In the second subsection, we share examples to illustrate how teachers navigated multiple obligations.

Obligations Influencing Teachers' Decision-Making

All three teachers mentioned each of the four obligations: individual, interpersonal, institutional, and disciplinary (Table 2). For Audrey and Kasie, obligations to individuals were the largest category with institutional obligations as the next largest category. Jamie equally prioritized individual and institutional obligations, each at just over one-third of the total responses. For all the teachers, disciplinary obligations were a minor factor, at close to 15% of total responses. Finally, interpersonal obligations were consistently the least important.

Table 2: Frequency and Percent of Obligations Across Three Teachers

	Individual	Institutional	Disciplinary	Interpersonal	Total
Audrey	69	46	23	17	155
	44.50%	29.70%	14.80%	11.00%	
Jamie	34	35	14	13	96
	35.40%	36.50%	14.60%	13.50%	
Kasie	72	56	26	20	174
	41.40%	32.20%	14.90%	11.50%	
Total	175	137	63	50	425
	41.20%	32.20%	14.80%	11.80%	

Individual obligations. Teachers shared many different concerns relative to curriculum and their individual students. They mentioned multiple aspects of students' experiences including enjoyment of activity, engagement, reading levels, understanding, background, and anxiety. When talking about enVision Mathematics (the mandated curriculum), Audrey responded:

> I don't think that it's grade-level appropriate, the words are very big. The book, itself, we have two different workbooks, which are probably three to four inches big. So, it's not useful for little kiddos' hands to be pulling pages out. Our fourth graders can't rip the pages out very easily. So, it's just, trying to use the actual resources that are provided for us. Those are, it's just very difficult. And, as a teacher, when I think, I have to teach enVision today, I have, like, that doom feeling overcome with myself, because it's not fun. It's not fun for the kids, they don't get excited... It's, yeah, it's supposed to, kind of, be integrated, you see the same characters all the way through, from kindergarten to fourth grade, the characters will be on each page and they grow with you. And that's about as inviting that book gets, is that there are characters.

The teacher identified multiple aspects of her obligations to students. She reflected upon the level of vocabulary, students' abilities to physically use curriculum resources, student fun and excitement, and storytelling features that persist throughout the curriculum.

Jamie shared she "lik[ed] BrainPOP because they're quick, concise videos that the kids can watch and understand, see visuals of some concepts, and they just don't take a whole lot of time, but they're fun, and the kids enjoy them." Here, Jamie unpacked her reasoning for liking BrainPoP as those resources were comprehensible and engaging to students. Given that these were grade-level teachers, it is not surprising that they attended to students consistently.

Institutional obligations. Audrey, Jamie, and Kasie shared that their curricular decisions were guided by rules and policies set by their school, school district, and state. These obligations appeared in the form of standardized test preparation, content standards, mandated textbooks, and time constraints for mathematics instructions. Interestingly, when responding to multiple institutional obligations, teachers' decision-making was further complexified. For example, Jamie described why she used multiple curriculum resources in her teaching:

> [As a Midwestern State], we are special, and we have our own standards, so sometimes we'll have a standard that doesn't have a lot of materials available. Sometimes even in the

enVision textbook, it doesn't have [a state] standard, and so that forces me, basically, to seek out other materials, or to create my own.

Jamie had a district-provided curricular resource (enVision Mathematics) that she felt obligated to use, yet she also felt the need to move beyond this resource because her state had standards that the provided textbook did not address.

Kasie also shared multiple aspects of institutional obligations, commenting:

> With their updates that they made with the new enVision that our [school district] adopted when we adopted new textbooks, I was like, okay, we're gonna actually give it a real shot with this. …overall, we've been pretty happy with the pacing guide following the enVision book, and, kind of, the order that it has gone.

Here, Kasie explained how the district-mandated curriculum aligned with the district-mandated pacing guide, allowing her to use the curriculum to meet institutional expectations. In part, teachers' curricular decisions were partly influenced by the extent to which the provided curricular resources adequately addressed institutional obligations across different levels. It is interesting to note that Kasie and Jamie taught in the same grade level and within the same instructional context, yet they interpreted mandated curriculum in different ways.

Disciplinary obligations. The teachers only minimally attended to disciplinary obligations, including which resource would better present mathematics concepts and procedures. Jamie emphasized the importance of using specific vocabulary, commenting:

> I just try to make sure to use those correct vocabulary, like the acute angles, right angles, and we talk about how to line up with the vertex, and things like that, because across all of the curriculum, you usually see that same vocabulary being used, so once the kids are familiar with that, it's usually pretty easy to make the connections.

Jamie's curricular decision-making was guided by students' familiarity with certain terminologies as they would appear throughout the curriculum, thus students would make connections with mathematics taught across different topics and curricular resources. This suggests using consistent vocabulary as one way to better teach mathematics as a discipline.

Kasie also shared similar disciplinary obligations when implementing given resources:

> With the perimeter, we've had, most of it has used enough models that the kids are catching on to the concept. We haven't moved more to the abstract yet, but we're getting to that closer now. So, so far, it hasn't been as challenging, but now that we're moving more to the abstract, or where hey have to make their own models, it's gonna become more challenging.

This quote unpacks Kasie's interpretation that teaching concrete ideas and then transiting to abstract concepts is a good approach in mathematics instruction.

Interpersonal obligations. The teachers responded to interpersonal obligations minimally in the form of differentiation needed for specific groups of students. Audrey shared how a specific curricular resource helped her to meet the needs of students who were at different levels:

> We are trying to meet students at all of these different levels. Where, in kindergarten and first grade, you're usually at a kindergarten or a first-grade level. Very rarely do you have a first-grader that can do fourth-grade math. So, I think that's why, two through four, we really do very similar resources. That's how I found out about Super Teacher Worksheets, was our third-grade team expressing to me how much they enjoyed it.

Kasie shared she used "a little bit of IXL for [her] earlier finishers, but most of [her] students did not finish early and didn't get on to IXL. So, most of them just used enVision Math."

Other obligations. Audrey, Jamie, and Kasie also cited contextual and personal factors in their curricular decisions. For instance, they mentioned changes brought about by the COVID-19 pandemic and personal life events like having a baby, indicating that curricular decisions are influenced by factors beyond the four types of obligations we discussed.

Negotiating Multiple Obligations

All three teachers shared they negotiated multiple obligations, sometimes finding them complementary and other times conflicting, with individual obligations consistently either complementing or conflicting with other types of obligations. They supplemented institutionally mandated resources with other materials to engage students who struggled with the mandated resources. This reason for supplementation suggests a conflict between institutional and individual obligations. Audrey responded to this conflict in the following quote:

> The most challenging [thing] is trying to incorporate the enVision series… I did not like their graphing unit. It didn't focus on exactly what our standards wanted. It was a lot of higher-order thinking, things like that, which can be wonderful, but I have still a lot of students who are not at that level—yet. And so, it's very overwhelming, and a lot of my students open that book and already are frustrated, just opening the book.

In this quote, Audrey highlighted that while the institution-mandated curriculum (enVision) could offer opportunities for higher-order thinking, it did not match her students' current mathematical understanding. In addition, she found it challenging to connect with given standards, suggesting another layer of complexity she faced within the same obligation. As such, she was obligated to use enVision math as it was institution-mandated despite its lack of alignment with another institutional obligation (meeting standards).

Teachers also expressed conflicts between institutional and disciplinary obligations, noting they were challenged to balance students' individual needs with institutional time constraints for mathematics instruction. Kasie highlighted this challenge, stating, "I don't enjoy using [Dreambox], and the kids are burnt out on it by third grade." Kasie's comment illustrates the mismatch between the district-mandated curriculum (Dreambox) and the needs of her students. We found several instances in which teachers expressed multiple obligations complemented each other. When asked how she connected multiple resources, Jamie shared:

> When we use the curriculum maps, we have certain standards that have district-wide assessments, and then other standards, we have to choose whether we want to give a summative assessment on them. So, I use the data from those, then, to basically inform my instruction for intervention, which we have every day for 30 minutes.

Here, Jamie expressed that institutional obligations such as using formative assessment results and standards, assisted her in identifying students who required extra support and specific type of support they needed, "infor[ing her] "instruction for intervention" (interpersonal obligation).

The teachers also provided insights into how their selection of supplementary resources was influenced by individual, institutional, and disciplinary obligations, which were at times aligned and at others in conflict. They explained their rationale for incorporating supplementary resources when the mandated ones failed to meet their disciplinary and/or individual obligations. For example, Jamie explained that she opted to supplement her mandated textbook with resources from Pinterest because activities like "Factor Ninja" on Pinterest were more effective for teaching "factors and multiples," and students "[we]re more engaged."

Audrey discussed how four types of obligations—institutional, individual, interpersonal, and disciplinary—intersected when examining the usefulness of a mandated curriculum, DreamBox:

> I disagree with that app [Dreambox], as a whole. I don't think my students benefit from it. The best thing I could say is the higher-order thinking, it does ask questions that really makes our students think, but …it's to a point where they give up, because it's too hard for them. It's supposed to meet them where they are, and it can meet some of my students who are above average, pretty well, but any student that's on grade level or lower, does not meet them.

Audrey used Dreambox due to institutional requirements and it aligned well with her disciplinary obligations by promoting better student engagement and higher-order thinking. Yet, it did not serve well for her students overall because "it's too hard for them," (individual obligations) and did not address the needs of those students "that [are] "on grade level or lower" (interpersonal obligations). Similarly, Kasie mentioned:

> I use [Teachers Pay Teachers and Pinterest] for more engagement because those topics are ones that in the past kids zoned out on, especially elapsed time…So, telling time and doing elapsed time is a hard concept for them to grab onto and they don't do a whole lot of elapsed time in the younger grades. It's more like an hour or half-hour times not down to the minute, which is what they have to do in third grade. So, finding a more engaging way, made it more fun for the kids and I found that my kids did better with elapsed time than they had done in the past without that kind of engaging project-based learning that we found there.

In this quote, Kasie articulated she opted for Teachers Pay Teachers and Pinterest because she could attain individual (for more engagement), institutional ("they have to do in third grade"]), and disciplinary obligations ("project-based learning"). This was an example of how three types of obligations complemented each other during her curricular decisions.

Overall, our findings suggested multiplicated ways in which Audrey, Jamie, and Kasie's mathematics curricular decisions interacted with individual, interpersonal, institutional, and disciplinary obligations. As evidenced by the examples above, institutional obligations often conflicted with individual and interpersonal obligations, whereas disciplinary and individual obligations typically complemented each other. In the next section, we delve into the potential reasons behind these complementary and conflicting obligations.

Discussion and Implications

In this study, we investigated how different obligations influenced elementary teachers' mathematics curricular decisions. We found that elementary teachers primarily prioritized individual and interpersonal obligations, indicating a strong focus on student needs and interactions. In addition, teachers attended to policies over disciplinary and interpersonal aspects, navigating complex layers of institutional obligations at the school, district, and state levels. For instance, teachers faced challenges in fully implementing a district-purchased textbook within the limited time allocated for mathematics instruction.

These findings may be attributed to the demanding schedule and workload of elementary teachers in the United States, who often teach multiple subjects to the same group of students for an entire semester. Consequently, they prioritize materials that engage students effectively and efficiently prepare them for standards within the allotted time. We anticipate these obligations may differ for secondary teachers, who may focus more on disciplinary rather than individual obligations. This assertion is partly supported by Dingman and colleagues' (2021) framework we mentioned earlier, which emphasizes middle school teachers' consideration of mathematics (discipline) in multiple layers. These layers include anticipating how students might view particular mathematical concepts, understanding the contextual meanings of mathematical concepts, and ensuring the cohesive arrangement of mathematics topics. In our study, teachers described how students engaged with mathematics and whether the content presented in given resources aligned with given standards. However, their focus was not on unpacking mathematics as a discipline when making curricular decisions. Another reason for teachers' minimal attention to disciplinary obligations could be because they trusted the curriculum as written. In another study, we found that teachers used textbook content as given without modification because it was research-based (Authors, 2023b). We recommend providing opportunities such as professional development for teachers to deepen their understanding of disciplinary aspects when evaluating curricular resources.

Minimal reference to interpersonal obligations may suggest that teachers believed differentiation was adequately addressed before making curricular decisions. Alternatively, they may have perceived differentiation as less crucial due to their focus on all students or they may have been influenced by the content of the interview questions. Further investigation is necessary to better understand the reasons for the limited instances of interpersonal obligations.

Overall, our study highlights the complexity of elementary teachers' decision-making as they deal with multiple obligations in uncertain educational times. By highlighting multi-layered complexity within and across four types of obligations, our findings contribute to understanding the nuances of teachers' professional obligations as proposed by Herbst and Chazan (2011). Aligning with Herbst and Chazan (2020), we recognize that teachers may have additional obligations beyond those discussed, such as adapting to online learning during the COVID-19 pandemic. Thus, we acknowledge that teachers' obligations are also dynamic and contextual. In our next study, we will perform another layer of analysis, which will further unpack Herbst and Chazan's theoretical framework (2011) on teachers' professional obligations.

Teachers navigate a range of curricular resources to create mathematics learning opportunities for their students. We investigated how three components of teachers' curricular reasoning (i.e., curricular knowledge, curricular vision, and curricular trust) interact with each other when elementary teachers navigate their available resources. Using a collective case-study design, we identified themes related to the complex relationships among elementary teachers' curricular knowledge, vision, and trust at two U.S. schools. Our findings indicated multifaceted ways in which teachers' curricular knowledge, vision, and trust are interconnected with and influence one another. The two teachers highlighted here acknowledged a long curricular "path" or "road," both within and across grade levels, for learning mathematics. We discuss research and practical implications for the importance of understanding teachers' curricular reasoning.

Keywords: Curriculum, Elementary School Education, Instructional Vision, Teacher Knowledge

The proliferation of curricular materials in the last decade has provided opportunities for teachers to supplement their mandated curriculum with a wide range of curricular resources (Polly, 2017). Following the COVID-19 pandemic (hereafter referred to as "pandemic"), online resources flooded the curricular landscape (Francom et al., 2021), which further challenged teachers to navigate a wide pool of mandated and supplemental resources in this new context (Giorgio-Doherty et al., 2021). Prior studies indicated that elementary teachers used up to 14 mathematics curricular materials during and after the pandemic (Doherty et al., 2022). These developments and the context of uncertain times resulting from the pandemic prompted us to continue to investigate teachers' use of curriculum materials given that little is known about how teachers navigate the ever increasingly complex curricular landscape. In this study, we explored elementary teachers' curricular decision-making through the lens of curricular reasoning (e.g., Breyfogle et al., 2010) guided by the following research question: How do the components of teachers' curricular reasoning (i.e., curricular knowledge, vision, and trust) interact with each other as teachers navigate the post-pandemic curricular landscape?

Conceptual Framework

We frame our study using Breyfogle et al.'s (2010) notion of curricular reasoning, which they define as "the thinking processes that teachers engage in as they work with curriculum materials to plan, implement, and reflect on instruction" (p. 308). They proposed three components of curricular reasoning: (a) curricular knowledge (Grossman, 1990; Shulman, 1986), (b) curricular vision (Darling-Hammond et al., 2005), and (c) curricular trust (Drake & Sherin, 2009). Curricular knowledge indicates familiarity with curricular resources, including the curriculum's philosophical perspective and its horizontal and vertical organization. Curricular vision involves knowing the path of learning—where students have been, where they are now, and where they need to go, along with the knowledge of how to get them there. Curricular trust builds upon, and reciprocally interacts with, curricular vision; it is the belief that a curriculum, as written, will satisfy a teacher's vision. Breyfogle and colleagues developed a model illustrating the potential relationships among curricular reasoning, curricular knowledge, curricular vision, and curricular trust (see Breyfogle et al., 2010, p. 310). In our study, we aimed to continue to investigate these relationships in the context of elementary teachers' curricular decision making. The authors also proposed that curricular changes and increased focus on mathematical standards warrant attention to these components of curricular reasoning; post-pandemic, we add the proliferation and increasing accessibility of a wide range of curricular resources to this justification for attention to teachers' curricular reasoning.

Review of Relevant Literature

Many teachers draw from multiple curricular resources that are complex and layered to serve the diverse learning needs of their students (Doherty et al., 2022; Sawyer et al., 2020). During the pandemic, teachers were required to explore alternative resources (e.g., online practice programs) with the goal of providing equitable learning opportunities (Keldgord & Ching, 2022). For example, during the transition from face-to-face to remote modalities, many teachers considered students' access to technology when selecting online resources (Huck & Zhang, 2021). This suggests that the expanding landscape of curricular resources intensified the complexity of teachers' post-pandemic curricular decision-making (e.g., Francom et al., 2021). How teachers navigate such complexity to create equitable student learning opportunities arguably influences and is impacted by their curricular reasoning. The connections and interactions among the components of curricular reasoning proposed in Breyfogle and colleagues' (2010) framework (i.e., curricular knowledge, curricular vision, curricular trust) are complex because, for example, teachers draw on different categories of mathematical knowledge for teaching (e.g., Ball et al., 2008). We unpack the components of curricular reasoning by reporting on two elementary teachers' post-pandemic mathematics curricular decisions.

Methods

Two elementary teachers (Audrey and Mary, pseudonyms) from a midwestern U.S. elementary school participated in this study. We purposefully selected these teachers to provide representation of different grade levels (i.e., third and fourth) and teaching experiences (6 and 11 years). Using a collective case study design (Yin, 2009), we report a collective understanding of how teachers' curricular knowledge, vision, and trust were interconnected within the broader umbrella of curricular reasoning and are reflected in their curricular decisions. We collected data from a three-phase interview process— two individual interviews followed by a focus-group interview. In the first and second interviews, the teachers shared the curricular resources they used, their level of control in using them, and strategies they used to establish coherence among the selected materials. In the focus-group interview, the teachers reported how they adapted their curricular materials and collaborated with one another. We drew both collective and case-specific meanings from these individual and focus-group interviews. We transcribed all interview data and used a top-down and bottom-up interactive data analysis (Chi, 1997) to explore the complex relationships between teachers' curricular knowledge, vision, and trust.

Findings

Audrey and Mary's curriculum knowledge was evidenced when they shared their level of trust for particular curricular resources and their vision about curricular coherence and student learning opportunities. In using their curricular knowledge, Audrey and Mary were purposeful in which resources they selected and how they implemented them to create students' mathematics learning opportunities, which ultimately influenced their curricular trust. Audrey mentioned that enVision (their primary curricular resource) "didn't focus on exactly what [their] standards wanted," requiring her to supplement with other resources. This finding indicated Audrey's curricular knowledge influenced her curricular trust. As such, the teacher did not fully trust enVision because she had knowledge of the alignment of curricular resources with standards.

Audrey and Mary also shared nuances suggesting how curricular vision and trust interact with each other. Mary mentioned that "having [a] set routine in [her] schedule helps kids make connections in math every day, because they build off of each other." She also shared how she established the curricular map or routine in using enVision, stating, "the first day, [students] have a question [to] test their prior knowledge. Then, you read the question together as a class, and then give the students time to solve it however they choose…then we watch a video." In this quote, Mary's curricular knowledge of enVision is reflected through her vision about how curricular materials should be organized (e.g., checking on students' prior knowledge, and presenting new materials).

Interestingly, both teachers mentioned that after the pandemic they began trusting teacher-created resources from Teachers Pay Teachers more than some of the other available supplemental resources. Mary shared that she often used Teachers Pay Teachers because she "could also look at ratings that other teachers had given to the product to see if a lot of teachers liked it that [she is] more likely to look more closely at it." This quote indicated that Mary's initial curricular trust was influenced by other teachers' curricular use. We also found that the teachers' curricular trust interacted with their vision related to creating appropriate student learning opportunities. For example, Audrey mentioned, "I'll pick a worksheet that is easier to read than enVision; enVison is very hard to do independently, where the Super Teacher Worksheet is very basic."

Overall, our findings align with Breyfogle et al. (2010), in that teachers' curricular knowledge is foundational to their curricular reasoning, which generates their curricular vision, which influences their curricular trust. However, we acknowledge that the relationship among curricular knowledge, vision, and trust is not straightforward and other dimensions of the relationships are being explored in our ongoing studies. As an example of such complexity, we found that there are contextual and teacher-related factors that influence teachers' curricular reasoning. Audrey mentioned, "I and [my colleague] are both moms of young children, and so it [enVision] is easier for us as far as planning and getting materials ready, because it's all already created." This quote indicates that teachers' curricular reasoning is also influenced by their personal circumstances and time constraints.

Scholarly Significance

The current uncertain times in mathematics education impact all contexts in which our work takes place, and our collective effort is needed to support teachers in mathematics classrooms as expectations of them continue to change and increase on many different levels (i.e., local, state, federal) and from many different stakeholders (e.g., school administration, parents). Supporting their curricular decision making by better understanding the curricular context in which they are operating and the relationships among the components of curricular reasoning offers one such effort. A focus on curricular vision in which we strive for equitable and engaging mathematics experiences for all children requires attention to teachers' curricular knowledge and trust. Our findings suggest multifaceted ways in which teachers' curricular knowledge, curricular vision, and curricular trust are interconnected with and influence one another. This investigation of teachers' curricular decision making is significant for mathematics teacher educators, policy makers, teachers, and curricular writers/developers. Understanding teachers' curricular reasoning in relation to knowledge, vision, and trust contributes to knowledge needed to purposefully develop, adapt, and implement mathematics curricular materials in ways that are effective for creating equitable learning environments. Moreover, documenting and disseminating teachers' curricular reasoning and noticing is valuable to acknowledge the extensive time and intellectual effort that teachers devote to mathematics teaching.

USING HALLUCINATION TO ENVISION THE FUTURE OF MATHEMATICS EDUCATION

Walter M. Stroup
University of Massachusetts, Dartmouth
wstroup@umassd.edu

Consistent with this year's conference theme of envisioning the future of mathematics education in uncertain times, and as an extension of recent research presentations related to the implementation of pattern-based assessments in individual classrooms and at scale (Stroup, 2020), this paper will contrast the responses of elementary and middle school students from a statewide implementation of the pattern-based items (PBIs) with the responses from two AIs to the same questions, and where the AIs hallucinate in ways that result in their performance being generally less robust than that of the students. The kinds of questions the AIs are less good at may be seen to point us toward what learners are better at and, consequently, could serve to refocus schools-based mathematics education on advancing meaningful student agency centered on uniquely human capacities for engaging structural patterns, exploring possibility, and modeling.

Keywords: Modeling, Learning Theory, Curriculum, Assessment

This paper developed from reflections on practice-focused discussions with in-service elementary and secondary teachers related to the role generative AIs could have in their teaching. The discussions took place as part of courses with titles like "Algebra for Teachers" or "Geometry for Teachers" included as part of degree programs at a public university. Some of the teachers were already experienced users of generative AIs, especially for tasks like writing short multiple-choice assessments related to a specific state standard, helping to draft the outlines of lesson plans, or assisting in managing their workload relative to authoring reports where "individual education plans" (IEPs) for students were frequently mentioned as an example. For other teachers, they had never "touched" a generative AI prior to enrolling in the course. The introduction of pattern-based questions (PBQs) was new for nearly all the students (some had an instructor for another course who used PBQs in their in-service courses). As part of considering various approaches to supporting classroom-based assessment, participants read a *Report* (Stroup, 2020) analyzing the results of implementing pattern-based questions statewide at scale (N > 400,000). Especially since some of the teachers had used the AIs to generate quizzes to be implemented with their students, the question arose: How would the AIs do on the same pattern-based questions used statewide with elementary and middle-school students? This paper emerges from our efforts to engage this question.

Although not part of the initial conversations with the teachers, the ability of generative AIs to outperform the corresponding late-secondary or adult test takers on many widely administered high-stakes tests (OpenAI, 2023) can serve as a contrasting case with the hallucinations and comparative low scores, relative to elementary and middle school students, the same AIs generated for pattern-based items. The contrast was brought into the conversation as part of realizing that the hallucinated responses from the AIs could be used by the teachers to "both" teach math, by having the students "correct the AI", and teach about generative AIs, by discussing how the "artificial" intelligence would not be able to see any of its specific responses as needing correction. The same probability-driven algorithms that might generate responses that are treated as correct – and that might even be submitted, in other contexts, by students as part of completing homework assignments – could also generate responses to the pattern-based mathematics items that were clearly "wrong" or, at a minimum, in need of correction or editing. On their own, the AIs have no way of determining the differences between one of their largely accurate or correct responses from responses that school-aged students would be able to identify as hallucinations.

New questions to be discussed in relation to specific examples arise. What allows us to recognize mathematics-related hallucinations when each AI that generates the hallucination can't? How might the better results from many school-aged learners on certain types of questions – e.g., ones engaging with pattern, possibility, and modeling – provide an opportunity to move beyond the fear that AIs are better than us, as reinforced by their doing better on the traditional assessment items we currently use to evaluate the effectiveness of education, to focus on what we're better at. AIs, critiqued within a reflective frame provoked by our ability to identify hallucinations, can serve as tools in affirming human agency and might well advance our efforts to support meaningful forms of equitable learning outcomes for mathematics education.

What matters about a hallucination? - Revisiting Chomsky's Green Ideas

As a pioneer in the development of formal linguistics, Noam Chomsky began his career in the late 1950's and 60's by critiquing the sense that the word "grammar" might only denote sets of conventions within a given language (e.g., subject-verb agreement in English) and positioned his "transformational generative grammar" in opposition to probability-based, often behaviorist situated, models of language production, as well as language acquisition. Given this, it is not surprising that, more recently, Chomsky has engaged in a vigorous critique of the over-attribution of significance to the capabilities of generative AIs. "[H]yperbolic headlines" notwithstanding, AIs based on large language models (LLMs) are, for Chomsky and his co-authors, "lumbering statistical engines" that "become increasingly proficient at generating statistically probable outputs" that can, at best, appear "human like" (Chomsky, Roberts & Watumull, 2023). These probability-focused models contrast with Chomsky's longstanding commitment to "linguistic structure" (1956, p. 116) or what Howard Gardner and colleagues summarize as a "mathematically oriented analysis of language" (Gardner, Kornhaber, & Wake, 1996, p. 127).

The shared use of the word "generative" as part of the name for Chomsky's theory and as part of the name for LLM AIs is significant for this paper. For Chomsky it's not just that we can produce, or generate, novel sentences, any one of which might be seen as unlikely to happen by chance (or to be improbable in and of itself), but also that we can recognize a distinction between a phrase that is grammatical and meaningless and a phrase that is ungrammatical and meaningless.

Generative AIs, when they hallucinate, don't generally produce the latter. Instead, hallucinations are text that is grammatical but also incorrect or wrong in what it means. Chomsky's best-known example of a grammatical but meaningless phrase is "colorless green ideas sleep furiously" (1956, p. 116). It matters both that Chomsky *intentionally* created this expression to illustrate aspects of his larger analysis of how grammar works *and* that "an English speaker" would be able to "recognize" this expression "is grammatical" and meaningless (p.116).

Generative AIs, based on existing LLMs, can do neither. These AIs can neither intend to generate a meaningless sentence nor can they, on their own, recognize when they have produced what might be seen by us as a semantic trainwreck. The fact that we *are* able to do both may begin to provide us with a way to think about what can, and possibly should, be the focus of schools-based mathematics education. Specific kinds of mathematical tasks or prompts where AIs tend to produce hallucinations may provide a way for us to begin to recognize, and thereby begin to refocus teaching and learning on, what we, including our students, are "good at."

Methodologically, we need not embrace Chomsky's parsing of linguistic competence into categories of syntax and semantics to see how what we are uniquely able to do should be foregrounded. Moreover, most post-structural analyses and certainly much of equity-advancing critical theory allow us to reject any discussion of activities as vital to our sense of who we are as the production of natural language or the development of mathematical agency "really" work, by starting from a prior assumption that there must be a privileged or ultimately privileging point of view along the lines of a what Chomsky posited as a "universal" grammar.

Avoiding any sense that a neutral, object-ifying, or outside-of-language type place to stand has to exist, we are free to make visible in our analyses of the ways AIs might be deployed, or become part of institutionalized practice in schools, how it is that issues of power, access, and identity are always already present, certainly, in the data used to train these AIs but also in terms of *the who* and *the how* of critiques of the output.

Who gets to say an output isn't right or is a hallucination? Will school-aged students be allowed, or even encouraged, to make such judgments? Or is the possibility that AIs might be wrong to be hidden in ways that will have the effect of helping to preserve privileging, universalizing, and plausibly dehumanizing notions of schools-based curricula and assessment (sometimes advanced as part of what could well have been sincere commitments to improving equitable outcomes or, at the very least, not to leave any child behind)? Are teachers to be empowered to make judgments about how AIs might support in-class, and potentially group-mediated, engagement with mathematics, or will AI-augmented tutoring environments be used to further constrain instruction to be about only the kinds of routines the AIs are able to support? The relatively brief considerations and comparisons that follow are meant only as an invitation for us to envision a future for mathematics education that is more, not less, fully humanized.

Speculation on why pattern-based items might be more likely to cause hallucinations

Although the pattern-based items that are presented in what follows may appear to be similar to standard multi-select assessment items, they are distinct in how they are meant to function, and this may (or may not) have something to do with how the generative AIs tend to hallucinate in attempting to respond to the examples that follow.

Most high-stakes assessment items are developed with the goal of being able to produce a scale score related to a relatively stable (predictable) latent trait. Considerations of whether or not these assessments are effective in measuring what is intended would take us well beyond the scope of this paper. What does matter is that training AIs relative to an assessment paradigm centered on convergence to a latent trait will play to the sweet spot of what generative AIs do well. Stable traits, no matter what they may actually represent, are what make probabilities-driven, large language models capable of doing what they do, including, in this case, endorsing the most likely to be correct response, or set of responses, to latent-trait-focused items.

In contrast, and as the name suggests, pattern-based items are developed, as will be seen in what follows, to use the full combinatoric space of possible selections to four-response (A, B, C, D) items (15 possible combinations if "no response" is not included). The modes appearing in the data (see below and Stroup, 2020) are meant to relate to patterns in how learners might understand or engage with a particular topic. Teachers, including those in the classes mentioned earlier, have found attending to patterns much more informative and useful to them professionally than attempting to make instructional decisions either based on sets of averages or based on difficult-to-interpret scale scores. Their situated knowledge about meaningful patterns in student reasoning also allows them to develop effective pattern-based items for use in their own classrooms.

Although teachers have asked that the modes in responses (e.g., frequencies of AD or BC) be projected onto, and sorted relative to, (one of many possible) a partial credit score (similar, in this case, to the scoring of a True/False assessment), what matters most for pattern-based items is the relative presence of specific modes in the data. The fact that the frequencies (or percent presence) associated with specific modes ("bumps" in the data) are meant to, and do, shift based on changes in students' understandings, makes them distinct from traditional items centers on preserving stability in the ordered probabilities for specific students getting items correct.

Hallucination 1: Seeing Possibility

The item shown in Figure 1 was developed to assess the fifth-grade Texas Essential Knowledge and Skills standard focused on students being able to "classify two-dimensional figures" as this would include reasoning in terms of "the presence or absence of parallel or perpendicular lines, or the presence or absence of angles of a specified size" (TEKS 5.5A). A similar focus at the fifth-grade level can be found in the Common Core State Standards (*cf.*, CCSS Math Content 5.G.A.1).

Rather than ask about a given shape, the question shown in Figure 1 centers on "which is possible" as a description of geometric shapes. In their critique of generative AIs, Chomsky and colleagues make the observations that their "deepest flaw" is the "absence" of what they see as the "most critical capacity of any intelligence: to say not only what is the case ... but also what is not the case" and, indeed in a logical sense related to this specific item, "what could and could not be the case" (Chomsky, Roberts, & Watumull, 2023).

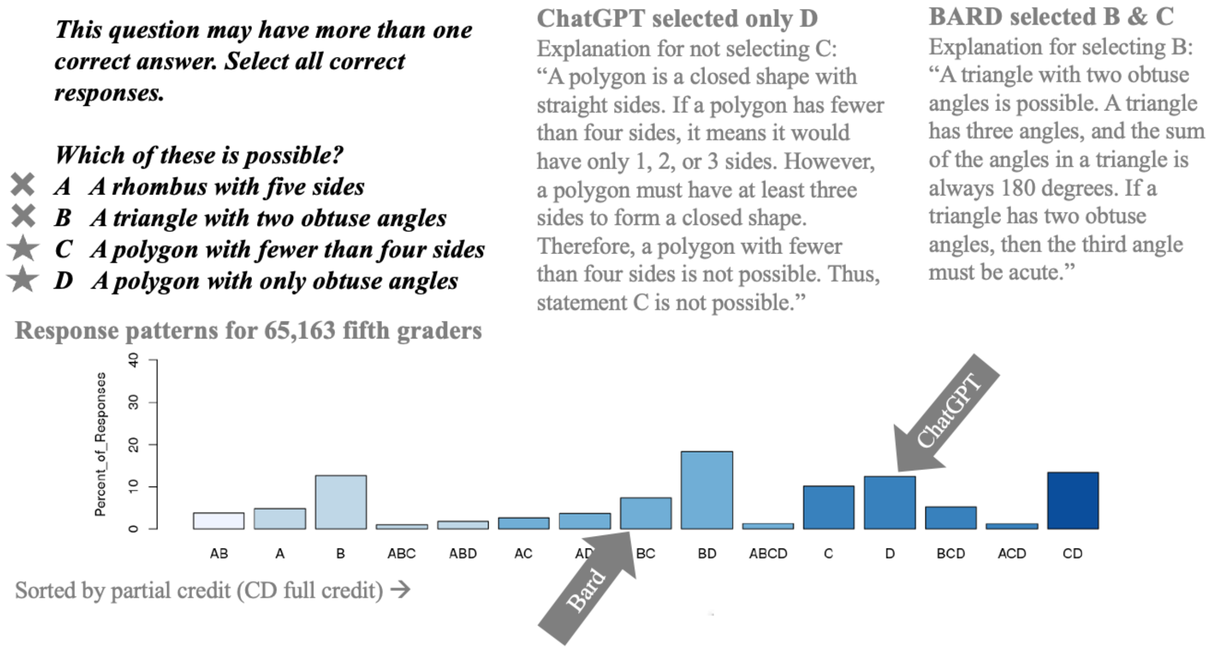

Figure 1: Hallucinations of two AIs and the responses of 65,163 fifth graders

The probabilities-based predictive patterning used by the AIs need not be seen as the same as the structural reasoning about patterns we can use to decide what's possible. Worth noting, the ability to "look for and make use of structure" is listed as one of the Standards for Mathematical Practice in the CCSS (2023).

As discussed previously, the sentences from the AIs included in Figure 1 are grammatical. What is said in some of these sentences, however, can be judged to be false. The output of ChatGPT allows that a polygon with "fewer than four sides" could have "only 1, 2, or 3 sides" but doesn't recognize that a figure with three sides would be a polygon, and consequently concludes a polygon with fewer than four sides, response C, is not possible. ChatGPT selects only D. The assigned (or projected) partial credit, using a F/T-type matching partial credit model, would be 0.75.

Bard (with a successor now called "Gemini") outputs the grammatical but incorrect statement that "A triangle with two obtuse angles is possible." Interestingly, the AI then goes on to conclude that, "the third angle" on this impossible triangle "must be acute." The partial credit for selecting only D would be 0.5, putting it below the overall student results of 0.57 as partial credit and well below the 13% of the students who would receive full credit for selecting CD.

Although the AIs themselves would not, at the time this was done, be able to identify the elements in the hallucinations that are like Chomsky's "green ideas," it is certainly reasonable to expect that fifth-grade students would be able to engage with, and even enjoy (according to the one teacher who reported trying it out in their class), finding the "mistakes" of the AI. The AIs are certainly powerful in what they do, but our ability to think about what's possible, and not just what is inductively probable, may exceed what they can do.

Focusing mathematics learning and teaching on explorations of what's possible, especially when contrasted with the hallucinations of the AIs, might well point us toward greater emphasis on what we, including our students, are good at. Seeing the possible can also be seen as related to modeling, the next contrasting case to be considered.

Hallucination 2: Modeling

The ability to "model with mathematics" as associated with applying the mathematics students know "to solve problems arising in everyday life" is listed, like the ability to look for structure, as one of the "Standards for Mathematical Practice" outlined in the CCSS (2023). Attending to modeling has been a major area of research in mathematics education (*cf.* Lesh & Doerr, 2003) and a particular area of focus for a working group of PME-NA. To the extent that mathematics can be used to develop a "causal explanation" in a way that Chomsky and his colleagues do not see as true of the AIs, mathematical modeling reaches well beyond the mathematics classroom. Moreover, modeling has been a throughline for human cultures for millennia as a way to engage the harmonies and even the dissonances associated with a wide range of arts.

These accounts, of course, can stand on their own as reasons for highlighting modeling. But the hallucinations of AIs relative to simple forms of modeling that are readily managed by many fourth graders might serve to remind us of the sense in which this is something we can do well. This is also something we lose track of if we allow what AIs can do only on their own, or as part of updating tutoring platforms, to serve as a kind of upper bound on what mathematics education should emphasize. Modeling is creative in a way that may be seen as linked to the previous discussion of seeing possibilities.

"Use Mathematical Models" as it is specifically referenced in the Texas fourth-grade mathematics standards (TEKS 4.1.A-D), served as the basis for the development of the pattern-based item shown in Figure 2. Students are asked which equation "can be used" to describe the number and exchanges of cards. Bard correctly notes relative to this item that after "giving away 6 cards" Maria will have "84 – 6 = 78 cards" but then goes on to immediately conclude that response B, "2 x 42 + 6" is a "correct equation" for this exchange (using + 6 instead of – 6 for "giving away" cards). Both A and D are rejected leaving only C, which does, as a response, closely align with the account of "giving away 6 cards" from 84. 0.25 would be assigned as partial credit.

Then, like Bard, ChatGTP also suggests that "multiplying 2 by 42" and then "adding 6" takes into account "the fact that Maria starts off with twice as many cards as Mike" and "subtracts" the cards she gave away. The operation shown is adding six, but it is described as subtracting the cards she "gave away." ChatGPT would also be assigned 0.25 as partial credit.

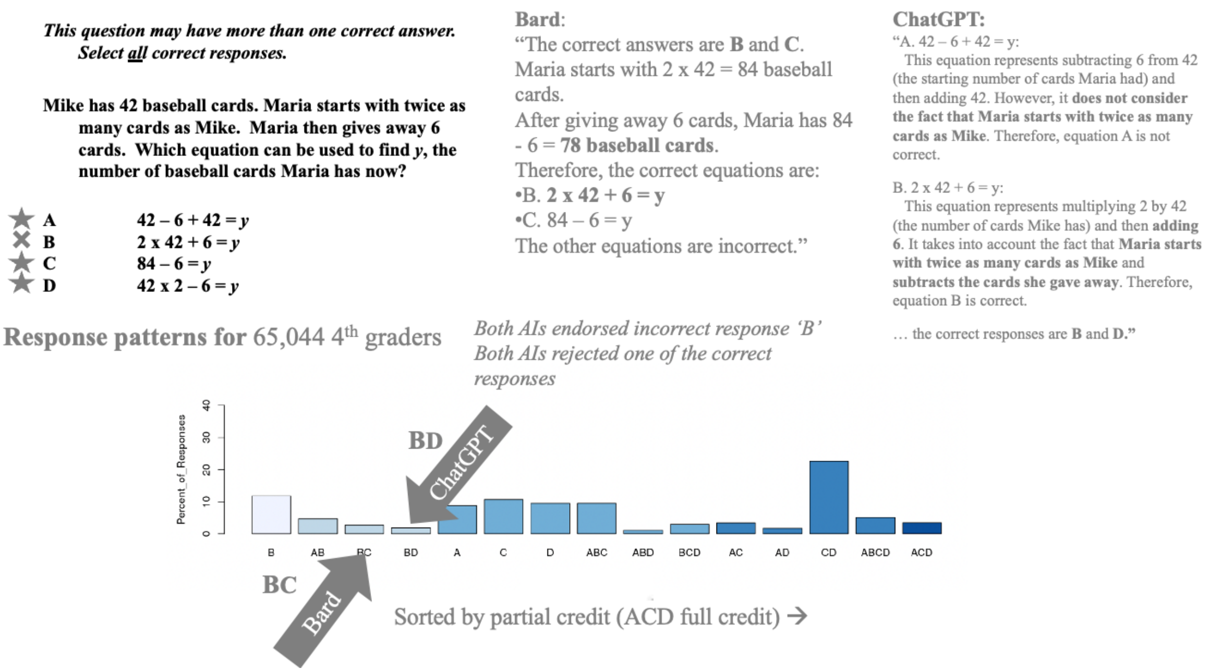

Figure 2: Hallucinations for a modeling item

As with the previous example, the AIs themselves would not be able to recognize the significant inconsistency in, as an example, representing subtracting 6 with "+ 6." It also seems highly likely, especially given the comparatively strong responses of 65,044 students, that fourth graders, as part of a classroom-situated discussion, would be able to recognize the inconsistency in the AIs' hallucinations. Both "the math" of modeling and an understanding of aspects of AIs would be advanced through the critique of the AIs' responses.

Hallucination 3: Reasoning Beyond Rote Procedures

While part of the state standard for "understanding" systems of linear equations does include how the "solutions" to systems of two linear equations in two variables "represent points of intersection of the graphs of the equations" and "the meaning of the solution(s) in the context of the problem" can model " real-world contexts" that can be used to "assess the reasonableness" of solutions themselves (TEKS 8.8.A-D), the actual practice of solving systems, as revealed in part by the hallucinations of the AIs in Figure 3, tends to center on rote sequences of steps associated with phrases like "do the same thing to both sides" or "isolate the x." Any links to modeling and/or to valid steps for solving equations that don't align with the well-rehearsed sequences are, most often, excluded from student sense-making.

Whether or not the "first step" of the rehearsed sequences for solving begins with the constants or begins with terms involving x in moving toward what can be viewed as isolating x on one side of the equal sign, the possibility of "dividing both sides" by a factor that is common to the terms on either side of the equal sign is not considered viable (response A). The reason would tend to be that no matter how one starts in adding or subtracting from both sides, dividing is typically treated as (almost necessarily) the last step.

The responses of the AIs (Fig. 3) reflect the more frequently occurring – the more procedurally probable – sequences for solving found in the data used for training the AIs. Consistent with the AIs' difficulty in reasoning, in what was called a structural sense discussed earlier, about what's "possible," both AIs hallucinated in attempting to evaluate which of the responses "could" be used as a "first step" in solving "the given equation."

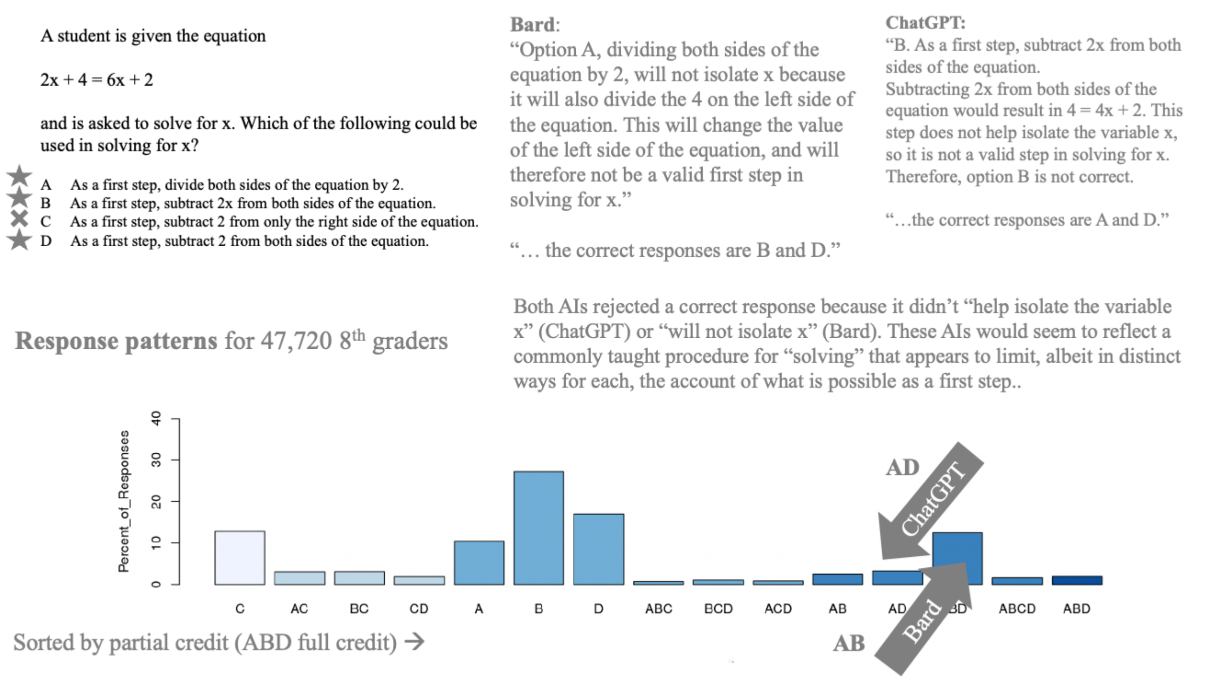

Figure 3: Hallucinating and routines for solving equations

Perhaps reflective of students' training that there needs to be consistency – to the point of near exclusivity – in carrying out a first step, most students chose only one response or the BD response, the response allowing that adding or subtracting from both sides can involve either constant terms or terms with x as a first step. The fact that AIs, in terms of a partial credit projection, did do better than the students on this item, distracts from the sense in which their respective responses used a version of "not isolating x" as a rationale for excluding one of the valid first steps.

Interestingly, the students may want to come to the defense of the AIs because the AIs would be doing something close to what they were taught to do. They might see the hallucination as understandable and may not even want to treat the responses summarized above as hallucinations. We've even had teachers in previous versions of the courses mentioned earlier say this question is "unfair" because starting with division, while certainly valid as a first step, would not be consistent with what the students had (likely) been taught.

Conclusion: Returning to how we can know questions

The hallucinations in the last example might be seen to bring us back to a sense meant to be illustrated across all the examples provided: that the hallucinations of generative AIs can serve both to foreground classroom-situated engagement with mathematics as part of students correcting the AIs and, especially as suggested in the last example, to raise subtle questions related to how the AIs function. It is one thing to say that an AI doesn't know when it is hallucinating. It is a more interesting question to ask if and how we can know. What we might hope for is that activities more fully consistent with our own abilities to do, and create, mathematics will play a central role in engaging these sorts of "How we can know?"-type questions... for the AIs, for ourselves, and, even more importantly, for the futures of our students.

Postscript for the reviewers

Given that some of the issues raised by the thoughtful reviewers may be similar to those raised by our colleagues, here are some very brief follow-on thoughts and pointers to other resources. In addition to the examples provided above, more detailed accounts of pattern-based items, both as implemented (Stroup, 2020; Stroup *et al*., 2023) and as well their connections efforts to develop "constructivist statistics" (Stroup, 1996; Stroup & Wilensky, 2000), are referenced. An account of what is meant by the use of "hallucination" is provided in the text in a way that is largely consistent with normative AI-referencing definitions. For this work, however, the more central questions include *who* decides what is/isn't a hallucination (the generative AIs can't) and, relative mathematics learning, *how* are we, including our students, able to decide. Finally, it is accurate to note that "generative AI" is only one of an array of kinds of AIs, some of which have also been deployed in educational contexts. Given a reviewer's request for more of a theoretical framing, it is worth briefly noting there are deep and longstanding interactions between the application of ideas in (what has come to be called) artificial intelligence (often overlapping with aspects of cybernetics) research to learning-related accounts of the emergence of "intelligence," where the role of creativity is implicated (*cf.* Piaget's [1970, pp. 81-82] discussion of Chomsky's emphasis), as well as structure (including *recursion*, central to Chomsky's transformational grammar as well as to how [perhaps ironically] the generative AIs work, to say nothing of its importance to Seymour Papert's development of LOGO as a LISP-like list processing language that only later acquired a "turtle"), as well as (child) "development" (e.g., Papert [1980, p. 160] notes, "the theory of mother structures {as discussed by Bourbaki} is a theory of learning"). Situated in relation to issues of access and equity – relative to *what* will be seen as mattering in mathematics education, *for whom*, and *how* it will matter – the emergence of generative AIs may provide an impetus for us to re-engage with some aspects of our own *generative* roots.

AN EXAMINATION OF JAPANESE CURRICULUM MATERIALS THROUGH QUANTITATIVE REASONING: THE TREATMENT OF PROPORTIONAL RELATIONSHIPS

Nurdan Turan
New York University

Gülseren Karagöz Akar
Boğaziçi University
gulseren.akar@boun.edu.tr

This study investigated how Japanese curriculum materials represent proportional relationships through the lens of quantitative reasoning. We examined the tasks, questions, and representations in the Japanese elementary and lower secondary level course of study, teachers' guide, and Mathematics International textbook series. Findings showed that proportional relationships in the selected Japanese curriculum materials are intertwined with quantitative reasoning and covariation of quantities. Findings also showed that, starting from 5th grade, perspectives of both multiple-batches and variable-parts have been taken into consideration together with utilizing partitive and quotative division in Japanese curriculum materials. We discuss the implications of findings for teaching and learning of proportional reasoning.

Keywords: curriculum, quantitative reasoning, covariational reasoning, proportional reasoning.

Background

Textbooks significantly influence classroom activities (Valverde et al., 2002) by building a pathway "… between the intentions of the designers of curriculum policy and the teachers that provide instruction in classrooms" (Valverde et al., 2002, p.2). Therefore, examining textbooks provides some possible insights about opportunities for students to learn mathematics (e.g., Son & Senk, 2010) and teacher's teaching and learning (e.g., Son & Kim, 2015).

The treatment of proportional relationships in textbooks is crucial to study. Proportional reasoning, involving core concepts of ratio, rate, and proportion, developed in elementary and middle school is essential for secondary and collegiate mathematics (Izsak & Jacobson, 2017; NCTM, 1989), supporting students' multiplicative reasoning (Lobato & Ellis, 2010; Simon & Placa, 2012). However, students (Modestou & Gagatsis, 2007) and teachers (Pitta-Pantazi & Christou, 2011) often face challenges with proportional relationships. Research shows teachers struggle with understanding the covariation of quantities in proportional relationships (Orrill & Brown, 2012) and differentiating between directly and inversely proportional situations, as well as non-proportional scenarios (Arıcan, 2019). Preservice teachers who struggle to discern different meanings of division encounter difficulties in distinguishing perspectives on ratios and establishing proportional relationships (Ölmez, 2021).

Beckmann & Izsak (2015) introduced multiple-batches and variable-parts perspectives, to expand research on multiplication, division, and proportional relationships. Multiple-batches perspective views 2 apples and 5 oranges as one batch and the covariation between the two quantities as multiples of the original batch. A person having multiple-batches perspective can think of ratio of 2 apples and 5 oranges and use partitive division to find how many apples per one orange or vice versa. This person can also think of the ratio, 2 apples and 12 apples, and use quotative division to find out that six batches are needed for the mixture. Thus, the person engages in partitive division of the quantities in within ratios and quotitive division of the quantities in between ratios (Karagoz Akar, 2010; Noelting, 1980). Whereas variable-parts perspective views 2-to-5 ratio as fixed and the size of each part could vary. A person having variable-parts perspective can think of the ratio, 2 apples and 5 oranges, and use quotative division to determine that 5/2 as much oranges as apples or 2/5 as much apples as oranges are needed for the mixture. This person can also think of the ratio, 2 apples and 12 apples, and use partitive division of 12 with 2 to determine that each part contains 6 apples since the size of the parts can vary. Thus, the person engages in quotitive division of the quantities in within ratios and partitive division of the quantities in between ratios (Karagoz Akar, 2010; Noelting, 1980a). Researchers emphasized the importance of both ratio perspectives for understanding proportional reasoning (Arıcan, 2019; Beckmann & Izsak, 2015). The multiple-batches perspective has garnered attention in mathematics education (Lobato & Ellis, 2010), whereas the variable-parts perspective is less explored (Beckmann & Kulow, 2018).

Taking into account of Thompson and Carlson (2017)'s argument that Japanese curriculum materials have potential to study how quantitative reasoning can be integrated in curriculum standards and textbooks, we investigated "What potential do Japanese curriculum materials in Grades 5 to 7 have in promoting proportional reasoning through quantitative reasoning?"

Conceptual Framework

Quantitative reasoning is "the analysis of a situation into a quantitative structure—a network of quantities and quantitative relationships" (Thompson, 1990, p. 12). A quantity is a measurable quality of an object coming into being with a person's conception of a situation by considering the measurable quality of an object (Thompson, 1994). For instance, if a person using 2 apples and 5 oranges to get a special taste of a juice wants to get more juice of the same taste, the person might use the quantities, 12 apples and 30 oranges. The change in the number of apples requiring a change in the numbers of oranges for getting the same taste, which is a simultaneous "bidirectional relationship" change, is called covariation (Thompson & Thompson, 1996). When we consider the taste itself and the measure of it, the multiplicative relationship between apples and oranges remains constant (2:5 and 12:30) and it is called invariance. In this regard, "the result of comparing two quantities multiplicatively" is called a ratio (Thompson, 1994, p.190) and "a reflectively abstracted constant ratio" is rate (Thompson, 1994, p.18). This definition indicates that a rate is a linear function in the form of $f(x) = mx$ (Thompson, 1994). Rate refers to the set of equal ratios (Lobato *et al.*, 2010). Proportional reasoning is the reasoning in situations involving invariant relationships between two covarying quantities (Lamon, 2012).

In juxtaposing Beckmann & Izsak's (2015) perspectives on proportional relationships with quantitative reasoning, a person can understand and use both partitive and quotitive division for quantities in within ratios (e.g., 2 apples and 5 oranges) and between ratios (e.g., 2 apples and 12 apples). It allows the person to recognize quantitative relationships as per-one and as a scale factor. The person can conceive an image of per-one and scale factor relationship operated on simultaneously covarying quantities both in within and between ratio situations regardless of the division type. Thus, a person considers the quantities through quantitative relationships constituting an intensive quantity, i.e., a measurable quality of object (Thompson, 1994).

Method

In this study, we examined one of the six most widely used textbook series in elementary mathematics in Japan (Watanabe et al., 2017) called Mathematics International (MI), along with Japanese course of study (COS) (Takahashi *et al.*, 2008), and the teachers' guides (Isoda, 2010). The publisher of the MI textbooks, Tokyo Shoseki, collaborated with Global Educational Resources in 2011 and published MI in English in 2012. We used the English translated version of MI textbooks in this study. Utilizing the content analysis method (Krippendorff, 2018), we analyzed how quantities were introduced and how the relationships between them were promoted in the statements, how proportion and ratio is defined and presented in the tasks, questions, problem situations and representations in the course of study (COS), teachers' guide (TG), and the relevant units from the textbooks.

Findings

Findings showed that Japanese curriculum materials emphasize both multiple-batches and variable-parts perspectives on ratios with a focus on both partitive and quotative division and build on direct and inverse proportional relationships with a focus on covariation of quantities. In lieu of word limit, we present examples from 5th grade and 7th grade.

In 5th grade, ratio is mentioned for the first time in Quantities and Measurements domain of the COS with the objective stated as "Students will understand the average of measured quantities and the ratio of two unlike quantities." (Takahashi *et al.*, 2008, p. 13). A task about rabbit cages is presented in 5th grade MI textbook to investigate population density (*See* Figure1).

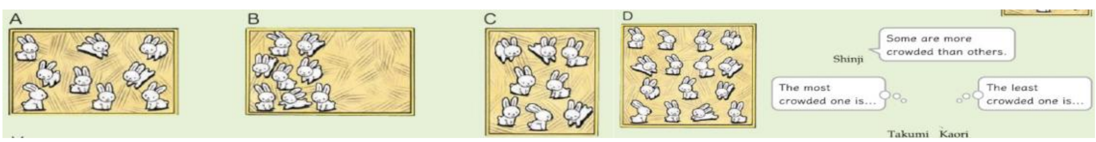

Figure 1. Rabbit cage (Fujii & Iitaka, 2012, Grade 5, p. A93).

Students are asked to decide what quantities are needed to compare crowdedness of cages at first. Then, a table involving area of the cages and number of rabbits in each cage is given (*See* Figure 2) and three different student ideas on crowdedness are modeled (*See* Figure 3).

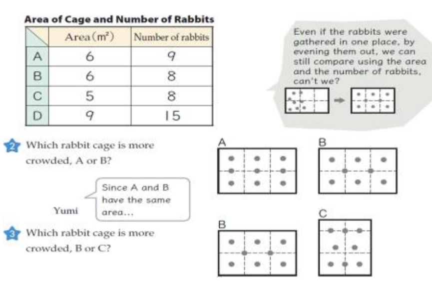

Figure 2. Table of crowdedness (Fujii & Iitaka, 2012, Grade 5, p. A94).

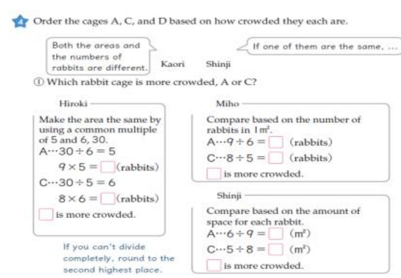

Figure 3. Ideas of students (Fujii & Iitaka, 2012, Grade 5, p. A94).

In this task, the multiple-batches perspective seemed to be used by Hiroki, Miho and Shinji. Hiroki seemed to use quotative division, while Miho and Shinji use partitive division. Notably, thinking of 6 m^2 with 9 rabbits and 5 m^2 with 8 rabbits as associated extensive quantities in groups, one might think of how many 6 there are in 30 and how many 5 there are in 30. Finding out the results as 5 and 6 respectively and thinking that the batches need to be kept the same for the crowdedness to stay the same, one can determine that she needs to multiply 5 with 9 and 6 with 8, resulting in 45 rabbits and 48 rabbits. Miho seems to think partitive division that for the associated group of 6 m^2 with 9 rabbits, for 1 m^2, there are 1,5 rabbits; and for the associated group of 5 m^2 with 8 rabbits, for 1 m^2 there are 1,6 rabbits. These two division types are also emphasized in the teachers' guide that teachers should use them in their teaching.

As a follow up of rabbit cage task, a task involving attempts at a basketball game is presented in 5th grade MI textbook (*See* Figure 4).

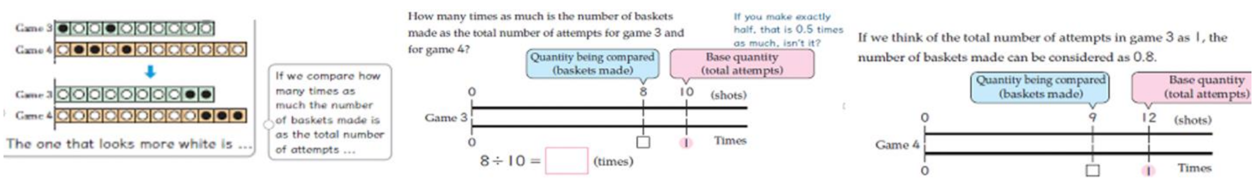

Figure 4: Basketball game (Fujii & Iitaka, 2012, Grade 5, p. B52).

The variable-parts perspective seemed to be employed with quotitive division in the original ratio focusing on part-whole relationship (i.e., 8 baskets made and 10 total attempts). Students are guided to use a number line to calculate per unit quantities. Differently from the previous task, two quantities are classified as base quantity and quantity being compared utilizing quotitive division. The main objective seems to enable students to represent the situation using rates, defined in the textbook as "The number that expresses how many times as much a quantity is compared to the base quantity is called the rate" (Fujii and Iitaka, 2012, Grade 5, p. B53).

In 7th grade MI textbook, direct and inverse proportional relationship between two variables and the continuous nature of their covarying relationship is represented visually (*See* Figure 5).

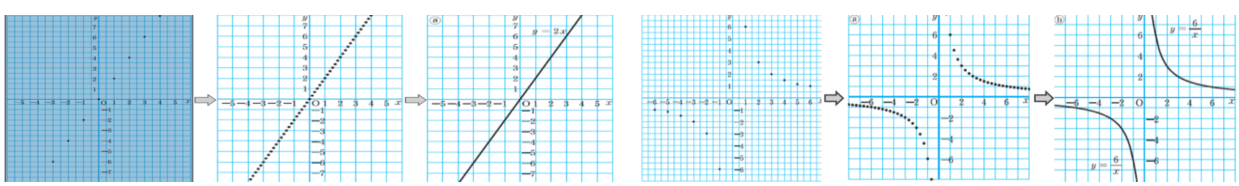

Figure 5: y=2x and $y = \frac{6}{x}$ graphs (Fujii & Matano, 2012, Grade 7, p. 117-118; p. 127-129)

Students are asked to explicitly think about the interval for x values and corresponding y values getting smaller and smaller producing a straight line or a curve.

Discussion and Conclusion

Findings showed that proportional relationships in the selected Japanese curriculum materials are intertwined with quantitative reasoning and covariation of quantities and developed through different perspectives of proportional reasoning and division types (Beckmann & Izsak, 2015). Considering the previous research showing teachers' struggles in proportional and non-proportional relationships and different division types (Arıcan, 2019; Orrill & Brown, 2012; Ölmez, 2021), we argue the sampled Japanese curriculum materials can be used by teachers and teacher educators to study and improve learners' proportional reasoning. Previous research indicates that Grade 2-4 MI textbooks concentrate on the relative size meaning of division, which requires grasping one quantity's measure relative to the other (Thompson & Saldanha, 2003), for both partitive and quotative situations (Karagoz Akar et al. 2022). Although partitive and quotative division do not necessarily require multiplicative reasoning, relative size, as a third model for division, "requires students to reason multiplicatively" and facilitate their understanding of non-integer divisors (Byerley et al., 2012, p. 359). Promoting the relative size in early grades could enhance multiple-batches and variable-parts perspectives of proportional reasoning. Future studies can explore students' understanding of relative size and its relation with/contribution to proportional reasoning perspectives.

Acknowledgments

We thank Prof. Tad Watanabe for his guidance in obtaining permission to use MI textbook material and his invaluable feedback on the larger project, which is the first author's MS thesis completed under the supervision of Dr. Gülseren Karagöz Akar at Boğaziçi University, Turkey.

There are currently no large-scale assessments to measure algebraic conceptual understanding, particularly among college students with no more than an elementary algebra, or Algebra I, background. Here we describe the creation and validation of the Algebra Concept Inventory (ACI), which was developed for use with college students enrolled in elementary algebra or above. We describe how items on the ACI were administered and tested for validity and reliability. Analysis suggests that the instrument has reasonable validity and reliability. These results could inform researchers and practitioners on what conceptual understanding in algebra might look like and how it might be assessed.

Keywords: Algebra and Algebraic Thinking; Equity, Inclusion, and Diversity; Undergraduate Education; Research Methods

Algebra can be a barrier to degree completion in college (e.g., Adelman, 2006; Bailey et al., 2010), and difficulties that K-12 students have experienced with algebra content has been extensively documented (e.g., Booth, 1988, 2011; Kieran, 1992). Understanding of key algebraic ideas has also been shown to impact college students in higher-level college courses like Calculus (e.g., Frank & Thompson, 2021; Stewart & Reeder, 2017). Algebra courses in college tend to focus on procedures disconnected from sense-making (e.g., Goldrick-Rab, 2007; Hodara, 2011), which may be one reason why college students in higher-level courses still struggle with algebraic ideas. It is important to connect procedural fluency with conceptual understanding (Kilpatrick, et al., 2001), and therefore, there is a critical need to better understand and assess students' algebra conceptions. However, there are not yet any widely-validated assessments to measure college students' algebraic conceptual understanding. Existing large-scale validated algebra assessments exist for K-12 students but focus primarily on computational skills, or only on a narrow subdomain of conceptions. Measures of computational skill are not necessarily valid measures of conceptual understanding, because 1) learners may have robust conceptual understanding, but make computational mistakes, particularly when they have math or test anxiety (e.g., Ashcraft, 2002; Ashcraft & Kirk, 2001; Moran, 2016; Namkung et al., 2019); or 2) learners may have little conceptual understanding, yet produce "correct" answers for the mathematically invalid reasons (e.g., Aly, 2022; Erlwanger, 1973; Leatham & Winiecke, 2014).

This paper describes how we have developed and tested college students' conceptual understanding in algebra using the *Algebra Concept Inventory* (*ACI*), in an attempt to address this gap. This process is ongoing.

Literature Review

While various algebraic proficiency instruments have been created, currently there are no widely-validated instruments that focus on a broad range of topics in algebraic conceptual understanding. TIMMS and NAEP (Mullis, et al., 2020; National Center for Education Statistics, 2023) have been widely validated nationally/internationally but have a broader focus and only contain a limited number of questions aimed at assessing algebraic conceptual understanding. There are also state-wide assessments that contain some items intended to measure conceptual understanding but that primarily focus on computational skills (e.g., Massachusetts Department of Elementary & Secondary Education, 2023; New York State Education Department, 2023). There are a few instruments that have been designed to measure a few specific algebra concepts in elementary or middle school (Ralston, et al., 2018; Russell, 2019; Russell et al., 2009), but these have not been tested with high school or college students, and the different population of interest means that the narrow range of conceptions do not include more complex or abstract conceptions that are critical to secondary and postsecondary mathematics.

Some concept inventories have been developed to assess algebraic conceptions relevant to calculus and other higher-level courses (Carlson, Oehrtman, & Engelke, 2010; Carlson, Madison, & West, 2010); however these instruments are not appropriate for students in lower-level courses such as elementary and intermediate algebra (or Algebra I/II in high school), and their focus is not on some of the core conceptions from these lower-level courses that may be particularly critical to algebraic reasoning. Further, while many of these have been tested extensively qualitatively, they have not to date published results of larger-scale psychometric validation. Recently, researchers Hyland and O'Shea (2022) in Ireland generated a 31-item algebra concept inventory for college students, but includes algebraic objects that would not be familiar to students in a first-year algebra course and has not yet been tested through cognitive interviews or psychometric analysis. Thus, an algebra concept inventory that has been validated in large-scale data collection is sorely needed, particularly one that is appropriate for administration to students at all levels of prior algebra experience, and not just those in higher-level college courses.

Measuring Conceptual Understanding: Sample Item

There is insufficient space to describe the design of the ACI here, but it focuses on assessing specific conceptions of algebraic concepts (e.g., equivalence, syntactic meaning, algebraic properties, variable, function, covariation), rather than other skills like computation. For example, this item was designed to assess whether students can identify the existing syntactic structure of an algebraic expression vs. a procedure one might use to simplify the expression:

Sample item: Which of the following **best** describes the meaning of the expression $(2x + 3)(5x + 1)$ **as it is currently written**?

a. $2x$ is being multiplied separately by $5x$ and by 1, 3 is being multiplied separately by $5x$ and by 1, and these four results are being added together.
b. The result of adding $2x$ and 3 is being multiplied by the result of adding $5x$ and 1.

Method

A total of 402 unique items were developed and tested for the ACI. Items were administered to 7,658 students enrolled in all mathematics classes at the algebra level or above at a large urban community college campus. Data were collected from spring 2019 to fall 2022, in eight waves. Data collection followed a common-item random groups equating design, selected because it allows investigation of a large item pool while allowing simultaneous calibration across multiple forms (de Ayala, 2009; Kolen & Brennan, 2004). For the first wave of testing, the last ten items on each form were anchor items, all taken from the National Assessment of Educational Progress (NAEP) grade 8 item bank. For subsequent waves, six anchor items were included: three were NAEP items and three were ACI items that had performed well during the first wave. Each form had roughly 25 items. Forms were randomly administered within each class to ensure no association between test form and class or instructor.

Just before answering inventory items, students were invited to participate in cognitive interviews, and paid for their time. In total, 135 interviews were conducted. Each was roughly 1-1.5 hours long and structured as a "retrospective think-aloud" protocol (Sudman et al., 1996), which has been shown to reveal comparable information to concurrent think-aloud protocols, and is also less likely to have negative effects on task performance (e.g., van den Haak et al., 2003). Interviews were analyzed qualitatively to assess construct validity of the items, but there is insufficient space to report that analysis here, where we focus on quantitative results.

To prepare data for item-response theory analysis, ACI items were dichotomized into correct/incorrect using the response key. Then, two-parameter logistic models (Birnbaum, 1968) were estimated using marginal maximum likelihood (MML) on each wave, using the R package "mirt" (Chalmers, 2012). Because of the planned missingness data collection design, the default number of model iterations was extended to allow for all models to converge successfully. Based on these models, we examined item parameters (difficulty and discrimination) and item information functions for item analysis, and computed person estimates using expected a posteriori (EAP) factor scores for convergent validity analysis. Reliability estimates were computed directly from IRT models. To investigate model fit, we computed item fit statistics, using the PV-Q1 statistic (and significance test) (Chalmers & Ng, 2017) for each item.

To investigate measurement invariance, we used multi-group IRT models and a model comparison approach. Because of the planned missingness design (and sometimes small observed subsample sizes), we used a piecewise DIF detection strategy (Thissen et al., 1993) that starts from a fully constrained model and drops constraints for each item separately. More specifically, with respect to each examinee characteristic considered, we first estimated a fully constrained model (where, across groups, item discriminations, difficulties, latent mean and variance are constrained to equality). Then, for each item, the same model was estimated, but with unconstrained item parameters (difficulty and discrimination), thus "temporarily" allowing differential item functioning (DIF) for the item. A likelihood ratio test was then performed to test if the model allowing DIF for the item had a better fit than the constrained model. This resulted in a series of tests of the significance of differential item functioning for all items. Because it is a multiple testing strategy, *p*-values were subsequently Bonferroni-corrected.

Validating the ACI

IRT Models: Item Discrimination and Difficulty

Some items were dropped when issues were found during analysis (e.g., typographical errors; multiple correct answers); however, none were dropped due to unsatisfactory IRT parameters. 2PL IRT models were run on all waves (Table 1). We considered 1PL and 3PL models but chose

2PL models because they allow discrimination to vary by item and are more useable for item selection than 3PL models because item coefficients are more interpretable, and less prone to calibration errors due to their lower number of item parameters (San Martin et al., 2015).

Table 1. 2PL Model Coefficients Across all Eight Waves

Discrimination parameter	Proportion of Unique Items
>=0.65 "moderate"[a]	63.4%
>=1.35 "high"	31.3%
>=1.7 "very high"	18.5%
Difficulty parameter	Theta
mean	0.00
1st quartile	-0.85
median	-0.14
3rd quartile	0.63
Total number of unique items in 2PL models	399

[a] Characterizations of categories of discrimination parameters are taken from Baker (2001).

Discrimination is called as "moderate" if ≥ 0.65, "high" if ≥ 1.35 and "very high" if ≥ 1.7 (Baker, 2001). Based on these classifications, 63.4% of all items (253) have moderate or better, and roughly one-third have high or very high discrimination. Table 2 reports item fit for each wave using Chalmers' $PV - Q_1$ test, chosen because it performs better than other fit statistics at controlling Type I error (Chalmers & Ng, 2017). Only 5% of items were significantly misfitted by the 2PL models where $\alpha = 0.05$, which suggests that this is likely due to random variation.

Table 2. Measures of Item Misfit in 2PL IRT Models

	Number of Items With Significant[a] Misfit[b]	Total Number of Items	Percentage of Items With Significant Misfit
Wave 1	1	33	3.0%
Wave 2	5	125	4.0%
Wave 3	4	66	6.1%
Wave 4	3	72	4.2%
Wave 5	8	100	8.0%
Wave 6	5	99	5.1%
Wave 7	2	39	5.1%
Wave 8	0	31	0.0%
Total	28	565	5.0%

[a] Significant at the $\alpha = 0.05$ level
[b] Misfit as measured by Chalmers' Chi-Square Statistic ($PV - Q_1$)

Reliability

In IRT, Theta represents the number of standard deviations above or below the mean an individual is on the measure of the latent trait, and the reliability of an item varies based on values of Theta. Peak information values for all waves (Table 3) have excellent reliability ($R \geq 0.9$). For various waves excellent reliability ($R \geq 0.9$) was obtained for values ranging from $\theta = [-2.7, 2.2]$ (assuming a standard normal distribution of knowledge, this corresponds to satisfactory reliability for ~98% of examinees). In addition, shorter tests can be constructed from a subset of items with the highest discrimination: for example, the 10 items with the best discrimination from Wave 1 yields a test with excellent reliability ($R \geq 0.9$) for $\theta = [-2,1]$.

Table 3. Reliability (*R*) for each wave of item administration of the ACI

	Theta at max info[a]	Info max[b]	R for info max[c]	theta w/ $R \geq 0.8$	theta w/ $R \geq 0.9$	Number of Items Tested
Wave 1	-1.4	26.4	0.96	[-2.8, 0.4]	[-2.4, -0.2]	33
Wave 2	-1.5	37.8	0.97	[-3.0, 2.1]	[-2.7, 0.9]	104
Wave 3	-0.6	24.3	0.96	[-2.3, 1.5]	[-1.8, 0.7]	57
Wave 4	-0.6	30.1	0.97	[-2.4, 2.1]	[-1.9, 1.2]	69
Wave 5	0.7	177.1	0.99	[-2.3, 2.9]	[-1.4, 1.8]	100
Wave 6	-0.6	105.3	0.99	[-1.7, 3.0]	[-1.0, 2.2]	99
Wave 7	-0.1	21.7	0.95	[-1.5, 1.8]	[-1.0, 1.1]	39
Wave 8	0.1	11.3	0.91	[-0.9, 1.2]	[-1.2, 0.3]	31

[a] info = 2PL IRT model information function
[bd] max = information function maximum for 2PL model

ACI Score and Prior Algebra Course Completion: Convergent Validity

To explore convergent validity of the ACI, we explored the relationship between scores on the ACI (using theta scores from the 2PL model) to various measures of mathematics course level. For example, correlation of students' ACI scores with the level of algebra courses they have already successfully completed would be evidence of convergent validity. First, we consider linear regression models with level of student's course (where "level" is defined based on the algebra course pre-requisite requirements of the course) as the independent variable, and ACI score as the dependent variable (Table 4).

Table 4. Regression of course level as predictor of ACI scores (2PL model)

Course Level[a]	Coefficient	SE	*p*-value (vs. low)	*p*-value (vs. high)
mid	0.347	0.014	0.000	0.000
high	0.700	0.017	0.000	

[a]reference group: low; low = no algebra course prerequisite; mid = elementary algebra course prerequisite; high = intermediate algebra course prerequisite; score is Theta score

Differences in scores in Table 4 are significant for all pairwise comparisons ($p < 0.001$). Scores for students in each level course were on average 0.35 SD higher than in the next lower course ("mid" vs. "low"; "high" vs. "mid"), providing strong evidence of convergent validity. We also considered a more nuanced course sequence based on prerequisites (see Table 5).

Table 5. Sequence level of various courses in the sample, based on their prerequisites

Various elementary algebra courses	1
Various 100-level courses with an elementary algebra pre-requisite	2
Intermediate algebra courses	2
College algebra	2
Discrete math with intermediate algebra prerequisite	3
Precalculus	3
Math for elementary teachers with intermediate algebra prerequisite	3
Math for elementary teachers, second term	4
Advanced statistics with precalculus prerequisite	4
Introduction to geometry with precalculus prerequisite	4
Calculus I	4
Calculus II	5
Calculus III	6
Differential equations with Calculus II prerequisite	6
Linear algebra with Calculus II prerequisite	6
Abstract algebra	7

Table 6 shows that linear regression models using this more refined set of levels again reveals a strong correlation between level and ACI score.

Table 6. Regression of more nuanced course level in predicting ACI score,

Course Position in Sequence	Coef.	SE	p-value (vs. 1)	p-value (vs. 2)	p-value (vs. 3)	p-value (vs. 4)	p-value (vs. 5)	p-value (vs. 6)
2	0.504	0.017	0.000					
3	0.623	0.031	0.000	0.000				
4	0.888	0.023	0.000	0.000	0.000			
5	1.059	0.033	0.000	0.000	0.000	0.000		
6	1.232	0.041	0.000	0.000	0.000	0.000	0.000	
7	1.661	0.226	0.000	0.000	0.000	0.001	0.008	0.060

The largest gain (one half SD) in Table 6 is between sequence level 1 and 2, or between students who have/have not satisfied an elementary algebra (Algebra I) prerequisite. This provides further evidence of convergent validity, because the ACI has been designed to focus on concepts relevant to elementary algebra specifically.

Differential Item Functioning: Measurement Invariance and Discriminant Validity

Differential item functioning (DIF) related to irrelevant examinee characteristics was also analyzed, one subtype of discriminant validity (or whether the ACI measures algebraic conceptual understanding and not something else, like English literacy). Each wave was tested for DIF in three separate 2PL models: one each for race/ethnicity, gender, and English-language-learner status. There was no consistent evidence of DIF. Only a negligible number of items had significant DIF for $\alpha = 0.05$ (using a Bonferroni correction for the number of tests within each model and not across models, which is overly conservative). Many items were tested in multiple waves, and none of these had significant DIF in more than one wave, suggesting that significant DIF in one wave but not others for these items was likely due to random variation.

Limitations

The City University of New York (CUNY) where this instrument was tested is not nationally representative, and thus further research is needed to validate the ACI with less-diverse populations in other geographic areas; this research is currently underway with a larger national sample in the US. However, CUNY's diversity does make it a excellent candidate for initial validation with marginalized students who have often been neglected in large-scale assessment validation. Further studies are also necessary to determine whether the ACI may be valid for use with high school or middle school students. Finally, the ACI has been developed to make *diagnostic* judgements about *groups* of students—not high-stakes decisions for individuals—and thus the ACI should not be used alone to make high-stakes individual decisions such as course placement or successful course completion.

Discussion and Conclusion

This study suggests that algebraic conceptual understanding, as conceptualized by the items included on the ACI, is a measurable domain with reasonable validity and reliability. Item response theory (IRT) analysis resulting in large proportion of items with good discrimination parameter estimates, suggesting the ACI can differentiate well between students of various levels. Reliability was also excellent for all waves of data collection, and based on reliability estimates, even shorter tests can be constructed with excellent reliability for a range of levels of algebraic conceptual understanding. Students with higher algebra course prerequisites had higher ACI scores, providing evidence of convergent validity. Finally, differential item functioning analysis demonstrated that the ACI had satisfactory measurement invariance with respect to race/ethnicity, gender, or English-language-learner status.

However, the ACI in its current form is a summative measurement that provides only one measure of students' algebraic conceptual understanding. Future research could expand this to a more nuanced diagnostic tool that provides more detailed information about the specific conceptions that students have and what kinds of instructional approaches may be best adapted to students with different conceptions about various algebraic concepts. This work is ongoing, and includes in-depth qualitative analysis of student thinking to more comprehensively map out in more detail the various conceptions that students may hold of algebra concepts; work with cognitive diagnostic models on ACI items might provide more nuanced diagnostic information; exploration of different curricular materials and teaching techniques and the subsequent impact on the development of algebraic conceptual understanding. Our hope is that the ACI will also enable other practitioners and researchers to explore these questions as well.

MATHEMATICALLY MODELING SOLUTIONS TO OCEAN PLASTIC POLLUTION

Amber Armstrong
University of Minnesota
armst417@umn.edu

Keywords: Modeling; Sustainability; Algebra and Algebraic Thinking

Mathematical models are powerful tools employed by experts to describe, predict and communicate the future course of environmental impacts (Barwell, 2018). I focus on how undergraduate students mathematically model solutions to a specific environmental issue: ocean plastic pollution. Mathematics provides a lens for students to visualize and quantify the rapid rate of plastic entering the ocean, as well as simulate possible solutions to the plastic pollution crisis. I provide a preliminary analysis of three groups of students who critically reflect on their mathematical model of potential global solutions to ocean plastic pollution. In this study, I ask: *How do students reflect on the severity of ocean plastic pollution and the urgency for solutions in the context of constructing a mathematical model?*

Mathematical modeling tasks provide a realistic learning experience that helps students understand real-world applications through mathematics (Keril & Gurel, 2016). Mathematical modeling often consists of an iterative process through a sequence of modeling cycles that students express, test, and revise their interpretations of a problem (Abbassian et al, 2020). The specific type of mathematical modeling employed in this paper involves a socio-critical mathematics perspective, which is derived from Skovsmose's (1994) critical mathematics education (CME) framework. Skovsmose's CME contains the vision that mathematics can be used to help students explore issues such as environmental challenges, leading students to reflect on how to take action against such challenges. Such critical reflections are an integral part of CME and socio-critical mathematical modeling.

This study took place over two 75-minute periods of an undergraduate college algebra course focused on modeling. Students worked in groups of 2-5 to develop mathematical models that represented solutions to ocean plastic pollution. At the beginning of the modeling task, students were given a prompt derived from real data provided by Ritchie and Roser (2018) on the state of ocean plastic pollution since the mid-twentieth century. After learning about the exponential growth of ocean plastic pollution and potential solutions to ocean plastic pollution, students were tasked with developing a mathematical model for their chosen solution. The data in this study consists of the students' final modeling report, which was qualitatively analyzed to determine how students critically reflected on solutions to ocean plastic pollution.

A preliminary analysis revealed that students noted the importance of both individual and collective/global action, as well as the urgency for more severe measures to curtail ocean plastic pollution. In particular, one of the groups acknowledged the importance of individual action, while the other two groups discussed both individual and global action. As an example, one of the groups compared a scenario in which nothing was done to combat plastic pollution to a few other scenarios of enacting global plastic bans of varying degrees, finding that such bans can prevent millions of tons of plastic from entering the ocean over the course of the next several decades. The students in this group noted the need for immediate, large-scale action. Overall, this preliminary analysis provides a window into understanding how students make sense of solutions to ocean plastic pollution. This study is a step in the direction of understanding how students make sense of solutions to large-scale environmental issues.

FIRST AND THIRD GRADERS' INTERPRETATIONS OF AN EQUALITY INCORRECT WORKED EXAMPLE

Laura Bofferding
Purdue University
LBofferd@purdue.edu

Mahtob Aqazade
Illinois State University
maqaza1@ilstu.edu

Keywords: Algebra and Algebraic Thinking; Number Concepts and Operations.

Elementary students often only experience arithmetic problems with the unknown to the right of the equal sign, e.g., 3 + 5 = 8. These limited experiences may result in students thinking that the equal sign appears between two numbers or is a signal to complete an operation. Thus, arithmetic problems that do not match such thinking (e.g., 3 + 5 = __ + 4) are tricky because students often solve them inaccurately using their prior experience (e.g., Knuth et al., 2006; McNeil & Alibali, 2002, 2004, 2005). Having students analyze worked examples could expose them to thinking about the equal sign as a symbol of equality. Particularly, an incorrect worked example can draw students' attention to why solving 3 + 5 = __ + 4 as 8 or 12 is not adequate. We explore whether first and third graders identified the incorrect part of an incorrect worked example of 3 + 5 = <u>8</u> + 4 and their reasoning. Twenty-seven first graders and 26 third graders from a public school in the Midwest, United States participated. We showed them the incorrect worked example and asked them whether 8 in 3 + 5 = <u>8</u> + 4 was correct and to explain their reasoning. Our analysis began with identifying whether students thought the answer of 8 was correct or incorrect. If they thought it was incorrect, we further classified their responses based on whether they found the correct answer or not. Next, we analyzed students' strategies by classifying them as having an operational (one side), an operational (two sides), or a relational view of the equal sign, or the equal sign as not relevant. We also coded for how students used the number four in the problem (i.e., ignores 4, notices 4, adds 4, considers 4+4, part of equality). Out of the 53 students, 58% identified that 8 was not correct, but only 40% of students provided the correct answer. Students' uses of the number four in the problem often aligned with a certain interpretation of the equal sign and specific solution strategies. Out of the 53 students, 19 of them (36%) ignored the four on the right side of the equation, using an operational (one side) view of the equal sign. Likewise, these students interpreted the problem as 3 + 5 = __ and thought the answer of 8 was correct. Three students (6%) made some reference to the four on the right side of the equation but did not do anything with it, maintaining an operational (one side) view of the equal sign. Beyond noticing the four, five students (9%) added it on to their total, demonstrating an operational (two sides) view of the equal sign. Three students (6%) mentioned the addition fact 4+4 but did not use it in their final answer. For example, a third grader agreed that 8 would be the correct answer in the blank, explaining, "Yes, because if you have five fingers and you put up three, it's eight." However, she continued without stopping, "Four plus four equals eight." Finally, 23 students (43%) used the equality of amounts on either side of the equal sign to determine that eight would not be correct, suggesting a relational view of the equal sign. Overall, students used similar strategies to those in previous studies (e.g., McNeil & Alibali, 2004, 2005), suggesting that responding to incorrect worked examples can provide similar information about students' understanding as having students solve problems on their own.

Problem-posing can enhance math learning, but the effectiveness of different scaffolding approaches is not well understood. In this study, 120 College Algebra students posed problems related to their interests in popular culture (e.g., video games) or STEM careers (e.g., healthcare), using optional scaffolds (video, template, or example problem) for personalized problem-posing. The quality of the problems and measures of math interest were assessed. Results indicate that different scaffolds support different problem-posing outcomes, varying by learner and course.

Keywords: Algebra and Algebraic Thinking; Undergraduate Education

College Algebra is often the first college-level math course for many students. In Texas, many students take corequisite College Algebra courses, simultaneously enrolled in developmental and credit-level math due to not being college-ready based on assessments like the SAT (Texas Higher Education Coordinating Board, 2018). Approximately 60% of college students are in corequisite courses, with 66% being Black and Latinx and around 70% being first-generation college students (Grubb et al., 2021; Brathwaite et al., 2020; Nix et al., 2020).

Making math content relevant is crucial, as students often view it as disconnected from real life (McCoy, 2005) and question its practical use (Chazan, 1999). Relevance interventions are essential in gatekeeper courses like College Algebra (Riegle Crumb et al., 2019). This study combines personalization and utility value (UV) interventions by having students create math problems based on their interests. Personalized learning has shown benefits for corequisite students (Darwin et al., 2022), but research on problem-posing interventions is limited.

Problem-posing, where students generate new mathematical problems through inquiry (Silver, 1994), is enhanced by several approaches such as reviewing others' problems (Brown & Walter, 1990), interacting with an authentic audience (Crespo, 2003), receiving guidance and examples (Walkington & Bernacki, 2015), collaborating with peers (Walkington & Hayata, 2017), and working within familiar contexts and artifacts (Bonotto, 2013; English, 1998). Problem-posing can be free, semi-structured, or structured (Stoyana & Ellerton, 1996), with the most effective strategy combining open-ended tasks with structured guidelines (Wang et al., 2022). Further, it can outperform problem-solving if students solve the problems they create (Kapur, 2015).

Problem-posing is key in mathematics education to promote productive struggle (Cai & Hwang, 2023). Personalizing problem-posing activities, such as allowing students to pose problems about personal interests (e.g., sports, social networking) or career interests (e.g., nursing, IT), shows great potential in enhancing mathematics learning (Walkington et al., 2024; Walkington et al., 2022; Walkington, 2017; Walkington & Bernacki, 2015).

We explored the effects of different scaffolds on students' math interest and problem quality, focusing on corequisite versus traditional students. Our research questions (RQs) were: (1) How does using instructional resources during algebra problem-posing relate to students' (a) STEM career interest and (b) math interest outcomes?, (2) How does resource use during problem-posing relate to the quality of the problems posed?, and (3) How do these effects vary for corequisite students specifically?

Theoretical Framework

Problem-posing involves students creating novel mathematical problems through inquiry (Silver, 1994). Personalized problem-posing allows students to design word problems related to their career (Walkington et al., 2022) or personal interests (Walkington & Bernacki, 2015). Interest, defined as engagement and the tendency to re-engage with specific areas (Hidi & Renninger, 2006), is linked to improved performance and learning (Renninger & Hidi, 2022). Connecting content to students' interests, such as popular culture or career aspirations, can trigger and sustain situational interest. Personalization helps students appreciate and understand math's application in their interest areas (Walkington & Bernacki, 2015).

However, students often find problem-posing challenging, needing to understand problem characteristics like formulating questions and ensuring mathematical relevance (Silver & Cai, 1996; Van Harpen & Sriraman, 2013; Yu et al., 2005). Evaluating the quality of posed problems involves criteria such as originality, complexity (Silver & Cai, 2005), and realistic responses to constraints (Verschaffel et al., 2009). Problem-posing requires students to choose appropriate units, incorporate realistic quantities, and possess sufficient prior knowledge (Yu et al., 2005). Walkington and Bernacki (2015) found that students struggling with algebra problem-posing often had difficulty articulating the necessity of an intercept term, connecting independent and dependent quantities, and devising multiplicative scenarios.

Methods

In this study, n=120 students enrolled in College Algebra courses in the United States completed online activities in ASSISTments where they posed problems related to their interests. Sixty students identified as female, 52 as male, 8 as other/NA; 76 identified as White, 11 as Black, 8 as Asian, 1 as American Indian, 6 as Pacific Islander, 10 as Other/Multiple Races, and 8 NA; sixty-one students identified as Non-Hispanic, 51 as Hispanic, and 8 as NA. Students were enrolled in online and in-person College Algebra courses, covering linear, quadratic, exponential, logarithmic, and power functions. There were 63 corequisite students and 57 students enrolled in a traditional College Algebra course.

Students were randomly assigned one of four conditions (business-as-usual, career-posing [CP], career-solving, pop-posing [PP]). In the CP condition, the students would pose algebra problems based on a STEM career interest (i.e., Business/Finance, Earth/Space/Chemical Sciences, Engineering, Health Care Services, Information Technology, Natural Sciences, Social Sciences, STEM teaching). In the PP condition, students would pose algebra problems based on a chosen popular culture interest (i.e., Shopping, Social Media, Sports, Video Games). These categories were chosen based on surveys and interviews with students. In this study, we focus on the PP (n=55) and CP (n=65) conditions, as these conditions had different scaffolds/resources tested (templates, examples, and videos; see Figure 1) for problem-posing. Students received three types of support: (1) a video showing the application of mathematics in their area of interest, (2) a template to help construct a problem with relevant quantities and units, and (3) an example problem using the unit's function in their interest area. Students then used these scaffolds to pose a math problem. Following each unit, students rated their interest in

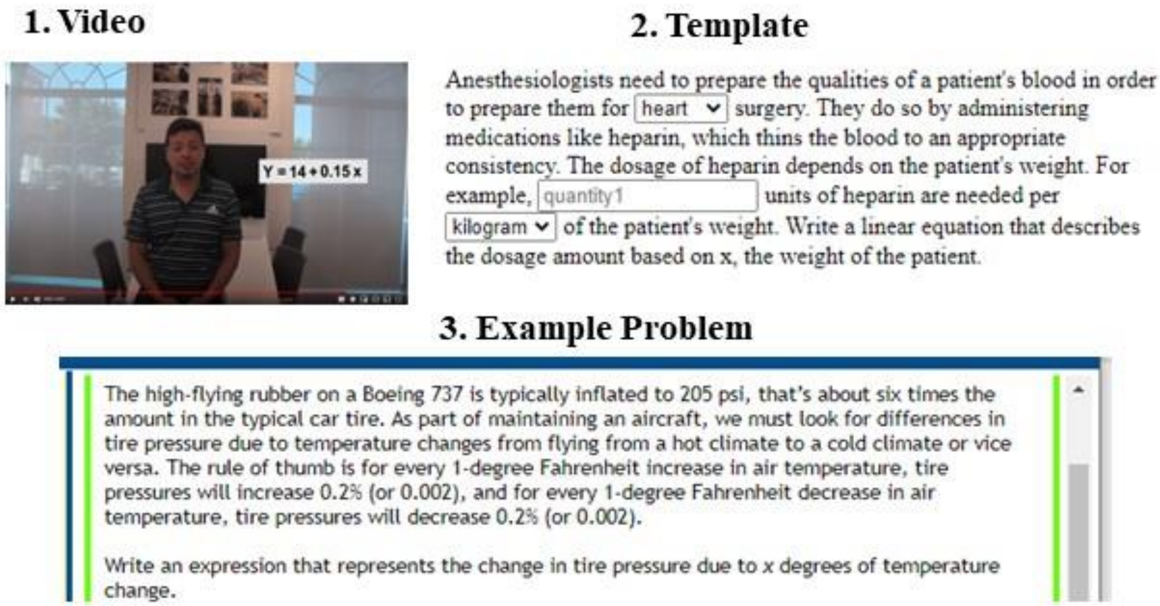

Figure 1: Scaffolds for problem-posing available to students in the present study

mathematics using an eight-item scale (Linnenbrink-Garcia et al., 2010) and their interest in one of eight STEM careers using the CABIN scale (Su et al., 2019). The quality of the problems posed by students was assessed using a rubric from prior studies (e.g., Walkington et al., 2022; Table 1), which included 4 sections scored on a 0-1 scale with multiple indicators per section.

Table 1: Overview of rubric for rating the quality of students' posed problems

Rubric Section	Description
Part A: Quality of Context	Rich and authentic narrative story in posed context
Part B: Mathematical Validity	If posed problem is solvable and consistent
Part C: Mathematical Complexity	Complexity of terms, numbers, and parameters chosen.
Part D: Mathematical Language	Valid and precise mathematical language is used
Part E: Originality	How closely problem resembles scaffolded example

Note. Contact the authors for a full rubric of how these parts were operationalized.

Results

To address RQ 1, when examining all students, regression with a hierarchical linear model showed no overall association between students' scaffold use and their post-unit STEM career interest. However, corequisite students specifically showed an increase in their post-unit STEM career interest per each video watched ($\beta = 0.29$, $SE = 0.11$, $p = .009$), but a decrease per each template used ($\beta = -0.31$, $SE = 0.10$, $p < .001$). For traditional and corequisite students, there was no significant association between scaffold use and post-unit math interest.

To address RQ 2, analyses of problem quality dimensions indicated that, when examining all students, students' use of the example problem scaffold was associated with an increase in the mathematical accuracy of the algebra problems they posed ($\beta = 0.26$ per example, $SE = 0.12$, $p = .037$) and an increase in overall quality of the problems they posed ($\beta = 0.27$ per example, $SE = 0.13$, $p = .032$). After removing the set of posed problems where students directly cut and paste from the provided template, template use was still associated with a decrease in problem originality ($B = -0.42$, $SE = 0.15$, $p = .004$) per template used in both conditions. When looking at corequisite students and the interactions with treatment, we found that when using the template scaffolds, there was an increase in the mathematical complexity ($\beta = 0.40$, $SE = 0.20$, $p = .041$) and mathematical language used ($\beta = 0.46$, $SE = 0.21$, $p = .027$) of problems they posed.

To address RQ 3, a comparison between the corequisite students and how they used scaffolds compared to traditional students can be found in Table 2; generally, corequisite students utilized the scaffolds more frequently, although this only reached statistical significance for the videos.

Table 2: College Students' Engagement with Scaffolds

Variable	Corequisite		Traditional		t(*df*)	*p*	Cohen's d
	M	*SD*	*M*	*SD*			
AU Video	.56	.50	.45	.50	-2.31(499)	.02*	.22
AU Template	.69	.46	.69	.47	-.07(499)	.94	0
AU Example	.64	.48	.58	.50	-1.38(449)	.17	.12
U1 Video	.76	.43	.79	.41	.44(140)	.66	.07
U1 Template	.87	.34	.83	.38	-.64(140)	.52	.11
U1 Example	.82	.39	.77	.43	-.73(140)	.47	.12
U2 Video	.46	.50	.40	.50	-.60(113)	.55	.12
U2 Template	.57	.50	.67	.48	1.10(113)	.16	.20
U2 Example	.50	.50	.47	.51	-.35(113)	.37	.05
U3 Video	.32	.47	.21	.41	-1.09(80)	.28	.25
U3 Template	.50	.51	.53	.51	.24(80)	.82	.06
U3 Example	.45	.50	.42	.50	-.30(80)	.76	.06
U4 Video	.57	.50	.30	.47	-2.78(110)	.01*	.57
U4 Template	.70	.46	.67	.47	-.23(110)	.82	.06
U4 Example	.68	.47	.60	.50	-.82(110)	.41	.16

Note. Engagement was calculated on a 0-1 scale if the student clicked on the scaffold; $*p < .05$. All Units = AU; Unit 1 = U1; Unit 2 = U2; Unit 3= U3; Unit 4 = U4.

Discussion and Significance

This study examined various scaffolds for mathematical problem-posing and their effects on math interest, STEM career interest, and the quality of problems posed by college students. We focused on differences between corequisite students (those not deemed "college ready" in mathematics) and traditional students. Key findings include: (1) Corequisite students used video scaffolds more than traditional students, which increased their STEM career interest; (2) The template scaffold for corequisite students decreased STEM career interest but increased the complexity and use of mathematical language in their posed problems; and (3) Example problems improved accuracy and overall quality of posed problems for all students.

The findings indicate that different scaffolds affect various outcomes: videos promoting relevance boost motivation, while templates enhance mathematical language use. Students with different mathematical backgrounds may need different supports; this intervention showed promise for corequisite students. Subtle differences in scaffold design significantly impact problem posing activities and interests, warranting further investigation in math education.

INFLUENCE OF GAMIFICATION ON MATHEMATICAL SELF-EFFICACY AMONG ONLINE AND IN-PERSON COLLEGE ALGEBRA COREQUISITE STUDENTS

Taylor Darwin
University of Southern California
tdarwin@ttu.edu

Elizabeth R. Goldberg
Texas Tech University
elizabeth.goldberg@ttu.edu

Texas higher education is transitioning to a corequisite model, where students take developmental and traditional mathematics classes concurrently. However, little is known about supporting corequisite students, particularly minorities and first-generation college students (FGCS). This study examined the impact of gamification on corequisite students' mathematical self-efficacy (MSE) and games self-efficacy (GSE) in both online and in-person courses. Based on the course survey data, students exhibited gains in MSE and GSE overall, in the online modality, and among FGCS and female students. The results suggest that gamification has the potential to support algebra corequisite students, particularly females, FGCS, and online.

Keywords: Affect, Emotions, Beliefs, and Attitudes; Algebra and Algebraic Thinking; Online and Distance Education; Undergraduate Education

Texas House Bill 2223 transitioned developmental students to the corequisite model, where students take their developmental and traditional mathematics courses concurrently (Texas High Education Coordinating Board, 2018). While the corequisite model provides a framework for student support, primarily broad-based reforms currently exist (Texas Corequisite Project, 2020). Some studies have been conducted to see how interventions aid corequisite students in mathematics (e.g., personalized learning to students' interest; Darwin et al., 2022) or how the instructor may influence student learning (Darwin & Ataide Pinheiro, 2023), but these studies are few. This model deserves attention because 60% of all college students will take a corequisite course (Grubb et al., 2021). Of those students, a disproportionate 66% are Black and Latinx, 70% of whom are first-generation college students (FGCS; Brathwaite et al., 2020; Nix et al., 2020).

Course modality also contributes to corequisite students' academic success. 97% of two-year colleges offered online courses (Community College Research Center [CCRC], 2013), and students deemed not college ready are more likely to fail/withdraw (62%) compared to face-to-face students (43%) for online learning. Further, these students enrolled in online courses have lower academic success compared to face-to-face students (Coleman et al., 2017; Ryu et al., 2022).

One reform-based strategy that has been successful with college-level mathematics students is gamification (Faghihi et al., 2014; Lanuza, 2020), which is the process of using game-design elements in a non-game context (Putz et al., 2020). Gamification is often associated with increases in student motivation, engagement, and learning compared to traditional instructional strategies (Manzano-León et al., 2021) while reducing anxiety (Turan et al., 2016), especially in mathematics (Shyr et al., 2021). While gamification is a promising instructional strategy for college students enrolled in math courses (Faghihi et al., 2014; Lanuza, 2020; Putz et al., 2020), there is little research on the impact of gamification on corequisite courses in mathematics, both in general and specific to course modality. The purpose of this research project is to contribute to that knowledge by examining how gamification influences online and face-to-face corequisite courses in terms of mathematical self-efficacy (MSE) and game self-efficacy (GSE) by pursuing the following RQ: *What is the difference in students' MSE and GSE after participating in a gamified College Algebra in-person or virtual corequisite mathematics course?*

Theoretical Framework

Self-efficacy, an extension of Bandura's (1993) Social Cognitive Theory, measures how students' self-beliefs influence learning and performance (Chan & Abdullah, 2018). Self-efficacy is an individual's perception of their level of functioning in a situated task by making "judgments of their capabilities to organize and execute courses of action required to attain designated types of performances" (Bandura, 1986, p. 1167).

Self-efficacy and motivation are closely related (Bandura, 1993; Morris et al., 2017), particularly in mathematics (Skaalvik et al., 2015). According to Bandura (1989), "people's self-efficacy beliefs determine their level of motivation, as reflected in how much effort they will exert in an endeavor and how long they will persevere in the face of obstacles" (p. 1176). Klassen and Tze (2014) defined motivation as "a set of beliefs that influence people's *movement* towards the attainment of valued goals," which is obtained through choice, effort, and persistence behaviors (p. 1). According to Bandura (1977), self-efficacy is commonly understood as domain and context-specific, meaning one can have different levels of self-efficacy in different domains or for particular situations of functioning. For example, a students' self-efficacy in *mathematics* and towards *games* could be different, warranting the need for each construct (i.e., GSE, MSE) to be measured and explored separately. Therefore, this study examined how a mathematics gamification intervention influenced MSE and GSE.

Methods

Participants were 72 students (48 online, 24 in-person) enrolled in four algebra corequisite courses (two online and two in-person) at a community college in North Texas. Students completed a 36-question pre- and post-survey containing Likert-style questions addressing MSE and GSE at the beginning and end of the course. MSE questions were taken from Florella et al.'s (2021) Mathematics Motivation Questionnaire (MMQ) - a validated measure of intrinsic value, self-regulation, self-efficacy, utility value, and test anxiety (Cronbach's alpha of $\alpha = .93$). The authors designed GSE questions to determine the types of games (educational versus entertainment) and the extent to which students played games in and outside the classroom. The post-survey also included three free-response (FR) questions asking the students to describe their gamification experiences within the course.

Games were implemented weekly and aligned with course material. The games were simple and typically based on common childhood or icebreaker games (e.g., *Red Light-Green Light* and *Two Truths and a Lie*). The authors purposefully opted for what Liberoth (2015) refers to as *shallow gamification* or *framification,* so the games selected were simple to learn, could easily be applied to any content or curriculum, and could be readily adopted by teachers for classroom use. Online students completed the games in teams selected randomly by the professor; in-person students chose their partners. The content and game elements were consistent between online and in-person classes; however, slight modifications were made for the different modalities (e.g., in-person teams worked face-to-face, while online students collaborated through Google Slides).

Results

Overall, 31 students completed both the pre-and post-survey (19 online students and 12 in-person students; see Table 1). A two-way ANOVA revealed a statistically significant increase overall for both MSE and GSE from the pre to post-survey, and students in the online course demonstrated a significant increase in both MSE and GSE post-survey responses.

Table 1: Pre and Post-Survey Data on Student MSE and GSE

Variable (n)	Pre-Survey		Post-Survey		*t*(*df*)	*p*	Cohen's d
	M	*SD*	*M*	*SD*			
MSE							
Overall (31)	3.31	.71	3.53	.66	2.66(30)	.012*	.45
Online (19)	3.19	.68	3.48	.67	2.46(18)	.024*	.51
In-person (12)	3.51	.74	3.62	.70	1.08(11)	.303	.35
GSE							
Overall (31)	3.63	.63	3.87	.60	2.63(30)	.013*	.52
Online (19)	3.55	.58	3.80	.65	2.21(18)	.04*	.50
In-person (12)	3.75	.71	3.99	.53	1.41(11)	.187	.58

Note. MSE = mathematical self-efficacy. GSE = games self-efficacy. MSE and GSE were measured on a 1-5 Likert scale. *$p < .05$.

In addition to modality, an ANOVA was run to detect differences in gender, ethnicity, FGCS, and emerging bilinguals in the survey data. The ANOVA revealed a significant gender difference in the pre-MSE ($F = 5.09$, $p = .032$) and pre-GSE ($F = 9.15$, $p = .005$) surveys, with no significant difference in the post-MSE or post-GSE survey. Additionally, there was a statistically significant difference in the post-MSE survey for FGCS ($F = -5.06$, $p = .032$). No other demographics showed statistically significant differences.

Free-Response Results

Post-survey FRs by participants suggested the students overall enjoyed the intervention. Some online students appreciate the intellectual benefits of gamification (e.g., reinforcement, instructional support, and understanding of the material), as they reported: "We got to use our brains, and practice out problems in a low-stakes environment" and "I feel that it was easier for me to grasp the concepts we have learned via Google slide games as we were able to learn the materials enjoyably." Further, some in-person students appreciated how gamification made the material fun and competitive, mentioning that "it was a fun experience, I learn better doing educational games" and "it helps me think faster since it's a game."

Generally, the in-person students enjoyed the collaborative aspect of the games, focusing on the benefits obtained from the learning experience. For example, "I loved how we were all able to collaborate and put all our brains together to figure out the problem," and "it was something new and productive. It let me make conversations with new people while still learning and listening to new perspectives." However, the online students reported mixed results in the collaborative component online, as there was a lack of consistency among teammate interactions: e.g., "It was ok, not many students this semester were really involved" and "I felt as if it was very interactive where we had to comment on our 3 group mates as to what we think as well. It was also encouraging when you got the answer correct and the 3 agreed."

Discussion

Consistent with the studies done by Lanuza (2020) and Shyr et al. (2021), incorporating gamification in the college mathematics classroom saw an increase in MSE survey results and student enjoyment. Similarly, the results of this study showed an overall increase in survey results for MSE and GSE, suggesting that the students not only strengthened their mathematical knowledge and skills but also cultivated positive attitudes toward their perceptions of mathematics and gamification.

The results of this study differed from the literature in terms of modality. Most studies on online and corequisite mathematics courses show students fare no better and often do worse in online environments compared to face-to-face (Ashby et al., 2011; CCRC, 2013; Ryu et al., 2022). However, this study demonstrated that the online modality significantly increased MSE and GSE, whereas there was no significant difference in the in-person survey data. Therefore, gamification may be an effective intervention for online corequisite students. These results were supported by free-response data, where online students appreciated the support and reinforcement gamification provided, even if the collaborative aspects were not as strong as the in-person environment. Given the little research that exists on how to support online developmental mathematics students (Ashby et al., 2011), this study provides critical knowledge to those teaching online corequisite mathematics courses.

The pre-survey for both MSE and GSE showed a significant difference between males and females, with males scoring higher in their MSE and GSE. This aligns with the research, where females often report less confidence in their ability to do mathematics due to societal factors such as the stereotype threat (Buck et al., 2020), and males are often perceived as better at games (Rice et al., 2015). While the pre-survey data confirmed these findings in the literature, the post-survey data showed no significant difference between males and females for both MSE and GSE, suggesting that gamification can be a powerful tool in helping female mathematics corequisite students become more confident in their mathematics skills and abilities.

An opposite pattern existed in FGCS MSE, with no significant difference between FGCS and non-FGCS in the pre-survey but a significant difference in the post-survey. FGCS became increasingly confident in their MSE at rates greater than their non-FGCS peers. Again, these results contradict the literature, which suggests FGCS have lower MSE and struggle in mathematics corequisite courses (Brathwaite et al., 2020). Yet, in this study, FGCS outstripped their peers in the MSE after the gamification intervention. High failure/withdrawal rates are among the greatest challenges plaguing mathematics students placed in developmental courses

(CCRC, 2013). The results of this study add to a growing body of knowledge that gamification can be an effective strategy for improving student motivation and self-efficacy. As students become more engaged and confident in their abilities to succeed in their mathematics corequisite courses, they are more likely to persist and complete these courses. Corequisite course completion rates are crucial as they are often considered gatekeeping courses to achieving an associate's or bachelor's degree (Brathwaite et al., 2020). While this creates a financial incentive, as college degrees are often considered essential to obtaining high-paying jobs (Crisp et al., 2021), this is also an equity issue as the majority of students in corequisite courses are minorities and FGCS. This study demonstrated that gamification is an effective strategy to increase engagement and MSE, yet more research is needed to see if these gains translate into a reduction in corequisite course failure/withdrawal rates, particularly among marginalized students.

Further, these findings are promising, but additional research is needed on the influence of gamification in mathematics corequisite minority groups and emerging bilinguals. Limitations of this study are the small sample size taken from a single community college.

PENSAMIENTO FUNCIONAL DE ESTUDIANTES UNIVERSITARIOS AL RESOLVER UNA TAREA DONDE SUBYACE LA FUNCIÓN ESCALONADA

FUNCTIONAL THINKING OF COLLEGE STUDENTS WHEN SOLVING A TASK WHERE THE STEP FUNCTION UNDERLIES

Carlos Enrique Flores-Gasca
Universidad Aeronáutica en Querétaro

Verónica Vargas-Alejo
Universidad de Guadalajara
veronica.vargas@academicos.udg.mx

En el presente artículo se exponen los resultados de una investigación cualitativa relacionada con el pensamiento funcional que exhiben estudiantes universitarios al describir una situación problema cercana a la vida real relacionada con la función escalonada. Se diseñó una tarea y se implementó en un ambiente online, mediante el uso de la plataforma Zoom. La revisión de literatura que se utilizó para el análisis de los resultados se basó en el Pensamiento Funcional. Los participantes en este estudio fueron 14 estudiantes de primer semestre de nivel universitario. Como resultado se observó la evolución del pensamiento funcional de los estudiantes exhibido a través de las representaciones verbales y gráficas, las cuales se fueron refinando y adaptando mejor a la situación problema.

Palabras clave: Resolución de problemas, representaciones matemáticas, precálculo y tecnología.

Introducción

Dentro de los distintos tipos de funciones que existen, podemos encontrar la función escalonada. Varios investigadores (De Villiers, 1988; Kaput y Roschelle, 2013; Smith, 2008; Pittalis, Pitta-Pantazi, y Christou, 2020 y Vargas-Alejo, Reyes y Escalante, 2016) han identificado que los estudiantes -de distintos niveles educativos- presentan dificultades para resolver situaciones problema asociadas a esta función. Algunas de estas dificultades pueden deberse a que los estudiantes no suelen resolver problemas asociados a funciones de carácter no continuo y constante, así como también puede deberse a que necesitan desarrollar su pensamiento funcional [PF]. El objetivo de esta investigación fue analizar el PF que exhiben los estudiantes universitarios durante la resolución de una situación problema asociada a la función escalonada. La pregunta de investigación fue ¿Cómo es el PF que externan los estudiantes al resolver la situación problema “Campeonato Olímpico 2022”? La situación problema incluida en la tarea puede ser descrita mediante una función escalonada. La investigación se realizó en la plataforma Zoom, debido a la pandemia COVID-19.

Revisión de Literatura

Pensamiento Funcional

Aprender matemáticas, con base en el PF, implica que los estudiantes busquen y generalicen patrones y relaciones mediante el uso de distintas representaciones (Kaput, 2008). El PF se define como “una actividad cognitiva que se centra en la relación entre dos (o más) cantidades variables, específicamente en los tipos de pensamiento que se derivan de una relación específica a generalizaciones de esa relación entre instancias” (Smith, 2008, p. 143). Smith (2008) propuso tres tipos de pensamiento funcional [TPF]: a) recurrencia, b) covariación y c) correspondencia.

Panorkou y Maloney (2016), con base en investigaciones de Smith (2008), extendieron esta clasificación a cuatro TPF: a) covariación cualitativa, b) covariación cuantitativa, c) covariación cuantitativa y visualización de la relación como una línea en el plano de coordenadas y d) correspondencia y covariación.

Metodología

La investigación se llevó a cabo con un enfoque cualitativo, ya que interesaba conocer los TPF exhibidos por los estudiantes y cómo estos se refinaron al resolver la situación problema. Los participantes fueron 14 estudiantes, de 18 a 20 años, quienes estaban cursando por primera vez el curso de cálculo diferencial de primer semestre de la Licenciatura en Ingeniería Mecatrónica, Industrial y Química. Por lo tanto, los estudiantes desconocían el concepto de la función escalonada. Los estudiantes fueron organizados en equipos (A, B, C y D). Para este estudio se diseñó una tarea que incluía la situación problema "Campeonato Olímpico 2022" la cual puede ser resuelta mediante el concepto de función escalonada. La duración de la implementación de la tarea fue de 110 minutos aproximadamente. Las fuentes de datos fueron: a) la videograbación de la sesión, b) procedimientos de los estudiantes y c) las notas del profesor. Para el análisis de los datos, se adaptaron los TPF propuestos por Panorkou y Maloney (2016) para describir el PF de los estudiantes (Tabla 2) durante la resolución de la situación problema. Debido al poco espacio en este documento se eligió presentar el análisis del trabajo del equipo D.

Tabla 2: Niveles de Pensamiento Funcional (Adaptado de Panorkou y Maloney, 2016)

TPF	Descripción	Comportamiento
PF1	Variación	El estudiante exhibe pensamiento de variación, es decir, puede identificar el patrón de cambio de una o más cantidades que varian.
PF2	Covariación Cualitativa	El estudiante no solo exhibe pensamiento de variación, sino que identifica y relaciona cualitativamente las variables que están involucradas en la situación problema.
PF3	Covariación Cuantitativa	El estudiante no solo exhibe covariación cualitativa, sino que identifica y relaciona cuantitativamente las variables que están involucradas en la situación problema.

Resultados y Discusión

En esta sección se describen y discuten, por episodios, los resultados del equipo D con base en los TPF que los estudiantes exhibieron (Tabla 3).

Tabla 3: TPF exhibidos por el Equipo D

Equipos	Estudiantes	Primer Episodio	Segundo Episodio	Tercer Episodio

D	d_k $k = 1,2,3$	PF1 con representación verbal y escrita	PF2 y PF3 con representación escrita y verbal	PF2 y PF3 con representación escrita, verbal y gráfica

Primer Episodio

Durante la resolución de la situación problema planteada, el Equipo D realizó una primera propuesta (Figura 1), la cual se caracterizó por una tabla de Excel y una gráfica de puntos.

	Precio de Hospedaje
0	0
3	7500
6	4500
7	1000
10	6600
14	2500

Figura 1: Primera tabla y gráfico del Equipo D

El equipo D exhibió Variación [PF1] puesto que identificó el patrón de cambio en cada una de las variables: *precio de hospedaje* y *días*. Aunque detectó cierta covariación cualitativa y cuantitativa [PF2 y PF3], su PF fue inestable en esos niveles. Es decir, tuvo dificultades para describir y relacionar las representaciones gráfica y tabular; lo cual puede observarse en la siguiente conversación.

d_2: Si las gimnastas se quedan aquí [Hotel Tokyo Grand Palace], entonces pagan tres días a 7,500 y luego 4,500.
P: ¿Por qué son 7,500 y 4,500?
d_1: Es que son 2,500…2,500…y 2,500 [PF1] en cada día. No cambia.
P: Interesante, pero oigan ¿qué pasa aquí [Señaló el intervalo de cero a dos con el puntero a su gráfico] en el contexto del problema?
d_3: Pues lo que dijo d_2, ah no… ¡Espere! No sé. Algo está mal.

La interacción con el profesor permitió al equipo autoevaluar sus procedimientos y redireccionarlos. Esto coincide con lo mencionado por Pittalis et al. (2020), en el sentido que las primeras respuestas de los estudiantes tienden a tener un PF inestable, pero pueden refinarse.

Segundo Episodio

El equipo construyó una gráfica tipo poligonal (Figura 2) adaptada a su nueva propuesta con otro presupuesto que respondiera a la situación problema.

Figura 2: Carta y gráfico del Equipo D

El equipo exhibió cierta Covariación Cuantitativa [PF3] en la descripción de su carta, puesto que no sólo identificó un patrón de cambio en las variables *costo* y *noches* [PF1], sino que también describió la relación entre las variables de manera cualitativa [PF2] y cuantitativa [PF3]. Parte del PF2 puede observarse en su carta cuando escribió "las siguientes tres noches baja el costo si se hospeda en el hotel dragón" y el PF3 se observa cuando en su carta escribió "sería aumentar a 6,600 las siguientes tres noches y sería $2,400 las siguientes tres noches", además de en la gráfica. No obstante, cuando el profesor le preguntó al equipo "¿qué sentido tiene la unión de los puntos de su nuevo gráfico dentro del contexto del problema?", presentaron dificultades para describirla, mencionaron que "la curva tenía que ser continua, por lo que no habían encontrado otra forma de describirla más que uniendo los puntos". Esto concuerda con investigaciones previas de De Villiers (1988), Kaput y Roschelle (2013) y Vargas-Alejo et al. (2016), que señalan que los estudiantes tienden a resolver situaciones problema con funciones continuas y suelen unir puntos al intentar graficar este tipo de funciones o bien están acostumbrados a hacer gráficas continuas sin reflexionar sobre su significado.

Tercer Episodio

Después de que cada uno de los equipos expusieran sus resultados, el profesor les sugirió tomar en cuenta los comentarios recibidos. El equipo D modificó su gráfico (Figura 3), exhibiendo así Covariación Cuantitativa [PF3].

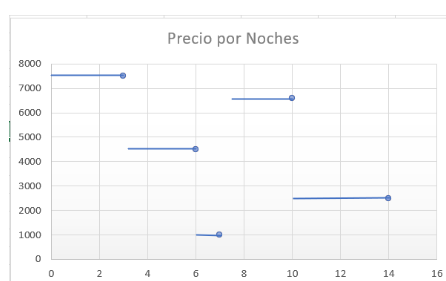

Figura 3: Gráfico del Equipo D

El equipo expuso su nueva gráfica y le explicó al docente que "la función ya no tenía un carácter continuo y, por lo tanto, había intervalos donde la relación entre el precio y la cantidad de noches tenía un carácter de tipo constante".

Reflexiones finales y conclusiones

En respuesta a la pregunta de investigación se observó que, el PF de los estudiantes del equipo D, externado al resolver la situación problema, se fue refinando con base en las distintas interacciones en el aula. En el episodio 1, el equipo D exhibió un PF1. Presentó dificultades para explicar la covariación en su representación gráfica, y darle significado en términos del contexto del problema. La gráfica no se adaptaba a sus descripciones de tipo verbal y escrita. En el segundo episodio, redireccionó su forma de pensar y, no solo logró responder a la situación problema planteada, sino que exhibió un desarrollo de su PF. Finalmente, exhibió un PF3, ya que en el tercer episodio construyó un gráfico que se adaptaba mejor a su descripción escrita y verbal. Se concluye, por lo tanto, que el PF de los estudiantes asociado a la situación problema cambió y se refinó durante el proceso de resolución a partir de la interacción con el profesor y los compañeros.

Reconocimiento

La investigación tuvo apoyo de CONACYT mediante las becas de estudiantes de posgrado.

THINKING ABOUT EQUALITY AND EQUIVALENCE IN DEVELOPMENTAL MATHEMATICS: A CASE STUDY THROUGH A DISCURSIVE APPROACH

Samantha Flynn
University of Massachusetts Dartmouth
sflynn7@ umassd.edu

Beste Güçler
University of Massachusetts Dartmouth
bgucler@umassd.edu

Mathematical equality and equivalence are critical concepts that span K-12 and tertiary education. Few studies use sociocultural approaches to examine thinking about equivalence in postsecondary education. This case study utilizes a discursive approach to explore how one student graduating from a developmental mathematics program at a community college thinks about equality and equivalence. We analyze this student's word use, visual representations, routines, and narratives as components of her discourse to explore the patterns in her thinking. The results provide the student's rich and nuanced thinking while revealing when and how consistencies and inconsistencies occur in her thinking. Questions allowing students to generate their own examples and definitions can be useful in eliciting their thinking and a discursive approach can have implications in enhancing communication in postsecondary classrooms.

Keywords: Algebra and algebraic thinking, communication, mathematical representations, undergraduate education

Introduction

Mathematical equivalence is a critical concept that spans K-12 and tertiary education (Kaput et al., 2008) during which students form their realizations associated with equivalence and its signifiers (e.g., equal sign). College students' thinking about equality and the equal sign can be consistent with those of middle school students (Fyfe et al., 2020) but the specific ways undergraduate students think about equality and equivalence are relatively unknown. More research is needed to explore how postsecondary students interpret equality, the equal sign, and equivalence (Kieran & Hernandez, 2019). Existing research on equivalence and equality predominantly uses cognitive lenses whereas we extend existing frameworks by using a sociocultural, discursive framework. Our approach reveals the rich thinking of students as well as identify consistencies and inconsistencies in their thinking about equality and equivalence, having implications for enhancing communication in postsecondary classrooms. We particularly focus on equality and the equal sign as aspects of equivalence (Emre-Akdoğan, 2023; Kieran, 1981; Knuth et al., 2006; McNeil et al., 2006) and address the following research question: How does one student who graduated from a developmental mathematics program at a community college think about equality and equivalence in the context of single-variable equations?

Theoretical Framework

We use Sfard's (2008) commognitive framework, which considers mathematics as a sociocultural activity and thinking as a form of communication with one's self. From this perspective, examining participants' thinking is tantamount to examining their communication through their discourses. Sfard (2008) views mathematics as a discourse and identifies the components of mathematical discourse as word use, visual mediators, routines, and endorsed narratives. *Word use* refers to colloquial and specialized vocabulary used for mathematical communication; *visual mediators* are visual tools and signs participants generate and use to realize mathematical objects; *routines* are set of metarules that characterize the patterned actions participants use as they substantiate their mathematical discourses; *endorsed narratives* refer to the narratives that participants consider to be true about mathematical objects and their relationships (Sfard, 2008). Students' endorsed narratives can be idiosyncratic and different from those endorsed by the experts in mathematical communities (Güçler, 2014, 2016).

A metarule of focus in this study is *saming*, through which participants assign "one signifier (giving one name) to a number of things that, so far, have not been considered as in any way "the same" but are mutually replaceable in a certain closed set of narratives" (Sfard, 2008, p. 170). Saming is a critical component of realizing equivalence because a conceptual interpretation of equality and the equal sign requires viewing them relationally as signifying equivalence or sameness (Emre-Akdoğan, 2023; Kieran & Hernandez, 2019; Knuth et al., 2006). We explore our participant's spectrum of characterizations of equality, the equal sign, equivalence and sameness through a discursive perspective in the context of equations involving single-variables.

Methodology

We use a qualitative case study design to examine how one student who graduated from a developmental mathematics program at a community college thinks about equality and equivalence. Rae (a pseudonym) completed her developmental mathematics coursework at a rural community college in Eastern U.S. and hoped to continue her education to become a paralegal. The data collection was based on a semi-structured interview that included open-ended questions and tasks about equality and equivalence to elicit Rae's thinking. The open-ended questions focused on Rae's realizations of equality and equivalence where she was asked to explain what those terms meant to her, generate examples for each, and define the terms in her own words. Due to space reasons, we only focus on the open-ended part of the interview about equality because it provided authentic information about Rae's thinking based on her own discourse and examples. The interview was video-recorded and transcribed verbatim with a focus on Rae's words (what is said) and actions (what is done) (Sfard, 2008).

When analyzing data, we focused on the words and visual mediators Rae used as she communicated about how she realized equality and equivalence. We were particularly interested in her realization and use of the equal sign as a visual mediator. Whereas the visual mediators refer to the visual tools and signs Rae used, *when* and *how* she used them would indicate the routines in her discourse. We also explored whether and how she used *saming* as a routine during the interview. Finally, we explored explicit as well as implied narratives Rae generated about equality and equivalence to elicit her endorsed narratives.

Results

In the transcripts provided, *I* refers to the interviewer and *R* refers to Rae. Rae's actions are provided in parentheses in conjunction with her word use and narratives. At the beginning of the interview, we asked Rae to explain what equality means to her. Her response was as follows:

1. I: What does equality mean to you?
2. R: Being equal, yeah, numbers being. Well, there are solution. Always a solution to a problem. Just equality and being equal, as I said.

3. I: Can you give me an example of equality?
4. R: Um what is it…(laughter) zero equals zero.
5. I: Do you mind writing that?
6. R: (laughter) Yeah that's fine. This is what was in my mind. (Writes what is in Figure 1. Writes 0. Underlines it. Then writes another 0 under the fraction bar and an equal sign to the right of 0/0. Then writes 0 to the right of the equal sign.)
7. I: Can you give me another example of equality?
8. R: Um see. I don't know if this is going to be able to be distributed. Mmm (laughter). I don't know. (Writes what is in Figure 2. Writes 25x and underlines 25x. Then, writes + 7 and scratches it out and writes a 5 instead. Writes a 5 under underlined 25x. Writes = 30 to the right of 25x/5 + 5. Then, underlines 30 and writes a 5 underneath. Writes =6 to the right of 30/5.)
9. I: So you just did a lot of thinking there. Would you mind unpacking a little bit for me what you were thinking about?
10. R: Well I was…I just had the 25 because I said this is what we're learning. Well, the kids are learning, students are learning in class right now. And I just had fives in my head and just wrote 25x. And then I wanted to just add it and I was going to do a number, not five. Obviously, I was going to just do any random number, but then I tried to make it easier on myself and I picked five to make it 30 because five goes into 30. Six equally. I ended up adding the five into the 25x when I was dividing. I think…And then distribute, I tried using…tried making a math problem.

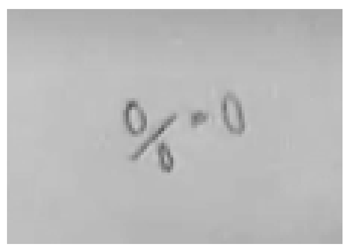

Figure 1. Rae's representation of her first example for equality

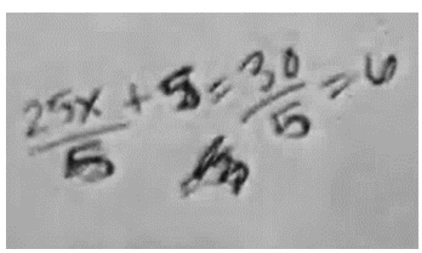

Figure 2. Rae's representation of her second example for equality

When talking about equality, Rae used the words “equal”, “numbers”, “solution” [2] and her word use indicated that she thought about equations when thinking about equality [4]. She also seemed to endorse the narrative that *an equation always has a solution* [2]. In her examples for equality, her visual mediators included numbers, a variable, fraction bars, and the equal sign (Figure 1, Figure 2). In both examples, Rae signified an equality as an equation. Rae’s use of the equal sign as a visual mediator was consistent with an operational rather than a relational approach in that it signified an arithmetic or an algebraic operation (Emre-Akdoğan, 2023; Kieran, 2004; Knuth et al., 2006). Her actions and routine of drawing fraction bars right after writing a number or an expression ([6], [8]) indicated that she thought about factoring the numbers before thinking about the next term on the left-hand side of her equations, before using the equal sign, and before completing the right-hand side of her equations. Although the visual mediator we inferred as a fraction bar could also be interpreted as an underline, Rae’s word use when she said “able to be distributed” [8], “Five goes into 30. Six equally” [10], “I was dividing” [10], “then distribute” [10] indicated that she was using the sign to signify division. Her actions indicated that she was using *factoring*, *finding a common factor across numbers*, and *dividing* as routines in her discourse when thinking about and generating equations. In Figure 2, Rae divided 30 by 5 to reach 6, instead of stopping when she wrote 25x/5 +5=30, which suggested that she interpreted the equal sign as a signal to execute an arithmetic operation (Siegler, 2003). The same action also indicated that she viewed the left-hand side of the equation equal to the right-hand side if they had a common factor. This may also explain why she may have viewed 0 as a factor of 0 to write 0/0=0 in Figure 1. Rae implicitly endorsed the narrative *mathematical objects are equal because they share a common factor* and viewed this as the commonality required to identify the left-hand side of an equation as the same as right-hand side, demonstrating how she realized *saming* as a routine in her discourse. We also asked Rae to define equality and asked her to elaborate on the relationship between equality and equivalence, if she saw any.

11. I: How would you define equality?
12. R: Things…and numbers have to mesh. Coincide with each other or equal each other.
13. I: In your opinion, is there a relationship between equality and equivalence?
14. R: I feel like there is because they are both have the word equal in it…And like I said they have to mesh in order to go into each other numbers…from my perspective.

Instead of defining what equality *is*, and treating it as distinct mathematical object, Rae provided phrases instead [12]. Rae’s word use included terms like “mesh” ([12], [14]), “coincide” [12], “equal” [12] to endorse the narrative that *numbers need to have a common factor in order to be equal or equivalent.* The word use and endorsed narrative in this excerpt were consistent with Rae’s discourse throughout the interview and aligned with her previous word use such as “distribute” [10], “dividing” [10], and “going into (evenly)” [10]. Rae identified the relationship between equality and equivalence through the commonality of the word “equal” in them [14] and the need for numbers to mesh or “go into each other” [14] for both of them. She seemed to consider equality and equivalence as relationships between numbers, where the numbers have a common factor, and one number divides the others evenly with no remainders.

Discussion and Implications

While Rae's discourse on equality and equivalence differed significantly from the discourses of mathematical experts, her discourse was mostly consistent. When she used the equal sign, she did so to signify an operation rather than a relation between mathematical objects, which is a finding that is consistent with the previous literature (Emre-Akdoğan, 2023; Fyfe et al., 2020; Kieran, 2004; Knuth et al., 2006; Siegler, 2003). We suggest teachers pay explicit attention to how their students use words, visual mediators, routines, and endorsed narratives in the classroom to address student difficulties and enhance communication in their postsecondary classrooms (Güçler 2014, 2016). We also recommend, as we have done in our work, teachers to provide opportunities for their students to generate their own examples and definitions of mathematical concepts before introducing these to the students.

Keywords: Algebra and Algebraic Thinking, Middle School Education, Cognition

Only 31% of 8th graders in the U.S. are proficient in mathematics (Irwin et al., 2023) and many students struggle to progress beyond Algebra I (Kena et al., 2015), potentially due to the increased need to attend to algebraic structure. In particular, many middle-school students habitually solve problems from left to right, often causing inefficiency (e.g., solving 46+72+54 by first adding 46+72 instead of 46+54; Lee et al., 2022) and sometimes violating the rules of precedence, especially as new and varied problem representations prevent solving through left-to-right (LTR) calculations (e.g., incorrectly adding 5+2 in 5+2×3; Gunnarsson et al., 2016).

Whereas prior research has demonstrated general effects of perceptual cues on students' problem-solving performance (Harrison et al., 2020; Landy & Goldstone, 2007), the current study systematically examines the effects of specific cues in math notation to compare the benefits of each (i.e., spacing [4×3 + 5 + 7], color ["4 × 3" highlighted in 4 × 3 + 5 + 7], or no cues) on 6th graders' performance on order-of-operations problems, as well as potential moderators of these effects. We will present analyses from a planned sample size of 600 U.S. middle school students, with 80% power to detect a main effect of $d > 0.20$ at $p < .05$. In a series of regression analyses, we will examine student-level, perceptual-cue-level, and problem-level predictors of performance, with performance indicated by accuracy and response time (RT). Student-level predictors include prior order-of-operations knowledge, perceptual processing skills, math anxiety, and math value. Problems are of a variety of formats, including some in which LTR calculations would be valid (e.g., 5×6–2+10) and some in which it would not (e.g., 4–7×2+9). We hypothesize that students with lower prior knowledge will benefit more (e.g., higher accuracy, faster RTs) from perceptual cues (either spacing or color) when faced with problems in a format in which the LTR process is invalid. Similarly, we hypothesize that students with lower perceptual processing skills, higher math anxiety, and lower math value will benefit more from perceptual cues, particularly on the invalid LTR process problems. This study will provide information about how perceptual processes can be leveraged to make learning mathematics easier for middle-school students through online platforms.

COVARIATIONAL REASONING ABOUT A LINEAR CONTEXT WITH DYNAGRAPHS

Courtney Nagle
Big Ideas Learning, Penn State Behrend
Courtney.Nagle@LarsonTexts.com

Deborah Moore-Russo
University of Oklahoma
dmr@ou.edu

This case study investigates the thinking a student utilizes while exploring a task involving a linear function application. The study tracks the level of covariational reasoning and uses of slope a student applies while making sense of the situation contextually, on a Cartesian graph, and on a dynagraph. Although the thinking revealed aligns with past research findings that students often have conceptions of slope that are isolated from covariational thinking, the student in this case study demonstrates strong covariational thinking across representations that enables him to use slope for different purposes while never referencing the term "slope" and never displaying any signs of shape thinking.

Keywords: Algebra and Algebraic Thinking, Mathematical Representations, Technology

Background

Most secondary students in North America are required to have at least one algebra course, with linear functions as a key topic of the course (Dolores Flores et al., 2020; Stanton & Moore-Russo, 2012). With a functions-based approach (Yerushalmy & Chazan, 2002), instructors guide students to develop a solid foundational understanding of linear functions and their covariational relationships. In such an approach, there is a focus on understanding relationships and functional behavior before emphasizing symbolic manipulation. For this, students use and translate between different mathematical representations (Lesh, 1979) to understand what it means to be linear.

Research suggests that linear functions and slope are typically introduced by eighth grade (Nagle & Moore-Russo, 2014; Nagle et al., 2022). These topics are often reduced to rote procedures (Stump, 1999) punctuated by mnemonics (Walter & Gerson, 2007), such as "delta *y* over delta *x*" or "rise over run." Reiken (2008) described these student views of slope as number from formula, number from counting, and number in front of *x*; all of which could be performed as memorized procedures without any covariational reasoning. An instructional emphasis on such memorized procedures may be why students develop fragmented meanings for slope (e.g., Dolores-Flores et al., 2019; Hattikudur et. al., 2011; Postelnicu, 2011; Teuscher & Reys, 2010).

Students often fail to see slope as a parameter denoting a constant rate of change between two variables and struggle to work with linear functions in different representations (Adu-Gyamfi & Bossé, 2014; Tanışlı & Bike Kalkan, 2018) or in less familiar contexts (Moore & Thompson, 2014; Zaslavsky et al. 2002). Stump (2001) described physical (e.g., the steepness of a ramp or the pitch of a roof) and functional (e.g., the height of a candle over time) contexts for using slope and found students may be confident working with slope in one context type but not the other. As a result, it is widely acknowledged that the thinking students exhibit around slope may depend on the contexts used to engage that thinking (Byerley & Thompson, 2017). Even teachers can display certain limitations in their treatments of contextualized slope tasks. Paolucci and Stepp (2021) reported their sample of pre-service teachers tended to design contextual tasks that emphasize static, physical uses of slope rather than the dynamic, functional uses Moore-Russo et al. (2011) described. Rivera López et al. (2024) found that practicing teachers are quick to decontextualize applied linear situations focusing on algorithms rather than interpreting their real-world contexts.

Davis (2007) looked at high school students' understanding of *y*-intercepts in linear contextual situations and found that students had difficulty connecting different representations. If students are unable to move flexibly between representations of linear functions, they will have a hard time making sense of regression lines in statistics (Nagle et al., 2017), connecting slope as a measure of steepness with the tangent of an angle in trigonometric contexts (Nagle & Moore-Russo, 2013), navigating the extension of slope to understand situational instantaneous rates of change in calculus (Moore-Russo & Nagle, 2024), and applying linear relations as is frequently required in science classes (Planinic et al., 2012).

Knuth (2000) reported that students often use algebraic approaches to linear tasks even when graphical approaches are more efficient, noting that most manipulate equations to be in the form $y = mx + b$. Adu-Gyamfi and Bossé (2014) found that even when students are able to move from a given representation of a linear function to another, they may still have limitations in how they understand linear functions. Results such as these have led to calls for a more concerted effort in connecting thinking about slope used for different purposes, with covariational reasoning as the link (Nagle & Moore-Russo, 2013).

Dynagraphs are digital representations that use parallel number lines where students manipulate input values to see the corresponding output values. So, input and output variables are depicted separately, rather than in a single coordinate pair (Bailey et al. 2020). Research suggests dynagraphs may help direct students' attention to how inputs and outputs change correspondingly and support covariational thinking (Antonini et al. 2020; Ozen et al. 2021). As a result, dynagraphs may be a powerful tool for exploring students' thinking about covarying quantities and may challenge students to move beyond reliance on shape thinking to determine slope (Moore & Thompson, 2015).

Framing the Study

Lesh (1981, p. 241) stated, "The coordination of a system of ideas is achieved progressively, but its completion is marked by a qualitative 'jump' as the student shifts to a qualitatively higher level of thought. This is portrayed in the APOS-slope framework, in Figure 1, which was first introduced by Nagle et al. (2016) and later more thoroughly vetted (Nagle et al., 2019). The APOS-Slope framework builds on Dubinsky's APOS theory (1984, 2014) to consider how geometric (G), algebraic (A), and functional (F) conceptualizations of slope converge into a linear constant (L) conceptualization as students develop a more robust understanding of slope. The APOS-Slope Framework also highlights the different purposes for which slope is commonly used in algebra (namely, to describe behavior, measure steepness, and determine relationships).

Thompson and Carlson (2017), as well as Paoletti and Vishnubhotla (2023), have suggested hierarchies of covariational reasoning that expand on previous work (Carlson et al., 2002) to define levels of covariational reasoning for modeling dynamic events. We now give brief descriptions of Thompson and Carlson's (2017) major levels, which we use for this study. *No coordination* involves no connection between the change of one variable with another. *Precoordination* of values involves attending to the change in one variable then to the change in another without simultaneous consideration of the two. *Gross coordination* of values involves considering the direction of change for each variable simultaneously, e.g. this output decreases as the input increases. *Coordination of values* involves coordinating magnitudes of inputs with corresponding values of outputs being able to create a discrete collection of ordered pairs. *Chunky continuous covariation* involves simultaneous coordination of the output's value with uniform intervals of change for the input; this involves both direction and magnitude, but the input increments are only considered in "chunks" of a fixed size. *Smooth continuous covariation* involves simultaneously coordinating outputs with input variables using both direction and magnitude but not being limited to fixed increments, rather understanding that within each interval both variables' values undergo synchronized change that is both smooth and continuous.

This study brings the APOS-Slope framework together with the levels of covariational reasoning to analyze a student's thinking about a linear relationship. Past work indicates that students' stages of slope reasoning and underlying covariational reasoning may vary based on the purpose for which they are using slope. For instance, in studies of students' approaches to informally placing a line of best fit (Casey & Nagle, 2016; Nagle et al., 2017), students used *gross coordination* language when justifying whether the line increased or decreased, suggesting they were applying covariational reasoning while reasoning about slope to *describe behavior*. However, the same students struggled to explain how they chose the angle or tilt of their lines of best fit, providing explanations that were void of covariational language as they reasoned about slope in order to *measure steepness*. Similarly, a review of a standards-based secondary mathematics curriculum showed an instructional emphasis on covariational reasoning when using slope to *describe behavior*, but few opportunities to reason covariationally when using slope to *measure steepness* or *determine relationships* (Fisher et al., 2021; Nagle et al., 2022).

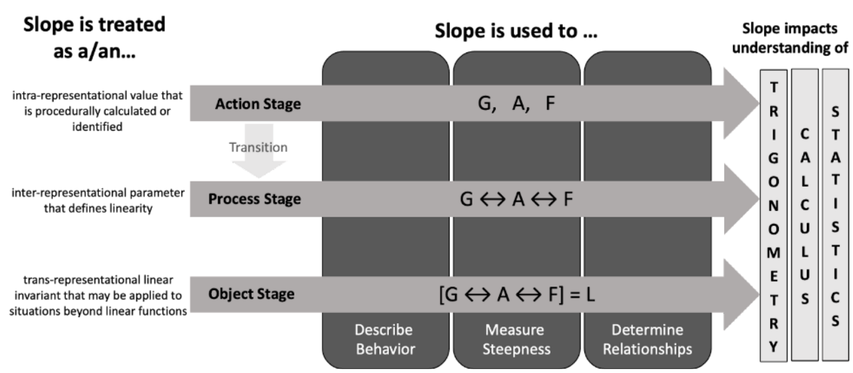

Figure 1: APOS-Slope Framework (adapted from Nagle et al., 2019)

In this study we consider one student's covariational reasoning involving linear functions in a contextual situation as he encounters dynagraphs for the first time along with more familiar mathematical representations (e.g., Cartesian graphs, two-column number tables, and linear equations) he has already experienced in the algebra curriculum at his school. The following research questions guided the study. How does a student who successfully completed a high school algebra class reason about a dynamic, functional context involving a linear relation? What level of covariational reasoning does the student display in this interaction? How does the student's covariational reasoning vary depending on the representation or particular use of slope?

Methods

This case study looks at a task-based interview with Cyrus, a 16-year old male who was enrolled in an Algebra 2 course in a public high school in New York state after completing his Algebra 1 course earning a grade of A. The entire interview lasted over an hour and a half, but we will focus on the section of the interview related to one contextual task. The situation, which follows, involves a functional application of slope as a property of a dynamic linear situation that requires covariational reasoning. *Maddy is a spunky, 5-foot tall, 16-year old girl who goes out and gets a summer job mowing yards in a neighborhood where all the yards are the same size. If each yard takes her the same time to mow, explore the relationship between the number of yards (x) she mows and the total time in hours she spends mowing (y).*

After being introduced to the task, Cyrus was asked to explain the relationship in terms of the real-world context, provide a graph of the relationship on a Cartesian plane, explore three dynagraphs to determine which one represented the same context, and then revisit the Cartesian graph initially presented. The interview was semi-structured in format, with pre-planned probing questions and additional questions to probe for understanding based on Cyrus' responses.

Findings

Initial Contextual and Cartesian Graph Reasoning

When introduced to the problem context, Cyrus demonstrated that he was able to reason about the functional context of the task. He applied *gross coordination* to describe the relationship between yards mowed and total time elapsed (i.e., "mowing more lawns will take more time"), and he translated this reasoning while using slope to *describe behavior* as he sketched a graph of the relationship on a Cartesian plane, starting at the origin. Cyrus explained the graph would be a "diagonal line going up because x increasing means you're moving up the x-axis and y increasing means you're moving up on the y-axis." He was able to label and explain the units for both axes when asked.

When asked to determine the slope of the line he sketched, Cyrus transitioned to *coordination of values*. He recognized a point near (1, 0.9) on his sketched line, explaining "the y-value doesn't go exactly up 1 and the x-value goes up 1." When asked how he would interpret that slope in the context, he confidently explained the unit rate, stating that "for every one yard that Maddy mows, it takes a little less than one hour to mow it." This thinking demonstrates at least *coordination of values* reasoning in the graphical context extended to at least *chunky continuous covariation* reasoning in the real-world context.

When asked to explain how the graph would change if the yards were not all the same size, Cyrus responded it "might be a little more wavy." He added that "it might go up in one spot and then maybe dip back down." When asked to try to sketch this behavior, Cyrus sketched a non-monotonic, non-linear graph. At this point, Cyrus did not seem to be able to apply both *gross coordination* and *chunky continuous covariation* to make sense of changing slope while keeping the increasing relationship between inputs and outputs. A summary of Cyrus' reasoning while engaging with the context and the Cartesian graph during this first part of the interview is provided in Table 1. Notice how *gross* contextual reasoning first translated to *gross* Cartesian graph reasoning, which then supported *coordination of values* in the Cartesian setting that prompted *chunky continuous covariation* to make sense of unit rates in the context.

Table 1: Covariation and Slope Reasoning in Context and Cartesian Graph Settings

	Contextual Situation	Cartesian Graph
Gross Coordination	*Mowing more lawns will take more time*	[The graph will be] *a diagonal line going up because x increasing means you're moving up the x-axis and y increasing means you're moving up the y-axis.* [Describe Behavior]
Coordination of Values		*The y-value doesn't go exactly up 1 and the x-value goes up 1.* [Measure Steepness]
Chunky Continuous Coordination	*For every one yard that Maddy mows, it takes a little less than one hour to mow it.*	

Dynagraph Reasoning

Cyrus had not seen dynagraphs previously. After a brief introduction to dynagraphs, Cyrus was then asked to explore three dynagraphs, representing a decreasing linear function, an increasing linear function, and a constant function, respectively. Cyrus was given time to explore the dynagraphs with the goal of determining which one might represent the context of Maddy mowing yards. Upon exploring the first dynagraph (of a decreasing linear function), Cyrus was moving toward *gross coordination* by explaining that when "moving the lawns mowed to bigger numbers, the total time is getting farther away." But he seemed to be focusing on the distance between inputs and outputs rather than the direction that they were both moving, explaining that this dynagraph "sort of" made sense for Maddy's context because "it kind of shows a relationship between the time and total yards mowed." When prompted to pick two specific points from the dynagraph and explain how the inputs and outputs were changing, Cyrus stopped the dynagraph at an input of 5 and confidently (and correctly) identified this would be the point that is "over 5 on the x-axis and up 1.5 on the y-axis" on the Cartesian graph. He then dragged the dynagraph to an input value of 8 and explained (correctly) that "the *x* would be 8, and the *y* would be 0." After making a connection between the dynagraph and Cartesian graph, Cyrus was then able to apply *gross coordination* to the dynagraph to explain that the inputs and outputs were moving in opposite directions but did not attempt to tie that back to Maddy's context at this point.

Cyrus extended his reasoning when exploring the second dynagraph (of an increasing linear function), immediately, saying that "as the *x* is increasing, the *y* is increasing but at a much slower rate." This thinking implies Cyrus is comparing the amount of change in *x* with the amount of change in *y*, suggesting he seems to be using *coordination of variables* and may also be using *chunky continuous covariation*. Cyrus applied *coordination of values* with proportional reasoning to justify why this dynagraph made sense for Maddy's context, explaining that "if every yard is around the same, then, like, if this is 2 [dragged input to 2] and it's around 1 [signaling to the output value] then if this is 5 [dragged input until output is 5 and signaled to output] then it's around 10 [signaling to the corresponding input value]. It just makes sense because every yard is similar."

On the third dynagraph (of a constant function), Cyrus applied at least *gross coordination* when indicating that "as I move the *x* back and forth, the *y* is staying the exact same." He connects this to the context by explaining that it would mean that "if you mow ten lawns, it would take the exact same time as if you mowed five," which showed *coordination of values*. After exploring all three dynagraphs, Cyrus reported that the second dynagraph was the best match to the context provided. He added that the third dynagraph "didn't make sense at all" and applied *gross coordination* related to the first dynagraph to conclude it was not feasible because "as you increase the total number of yards mowed, your total time isn't going to go down." The researcher asked Cyrus to describe how the dynagraph might act differently if the yards varied in size. Cyrus applied *chunky continuous covariation* while explaining that "as you would move up the *x*-axis, the *y* would increase at different rates." He continued, "one yard would be bigger; so, it (the *y*-value) would increase more because it would take longer." Although he is not referencing slope, this thinking is consistent with using slope to *measure steepness* while applying *chunky continuous covariation*. A summary of Cyrus' reasoning across the context, Cartesian graph, and dynagraph is provided in Table 2.

Table 2: Covariation and Slope Reasoning in Context, Cartesian Graph and Dynagraph

	Contextual Situation	Cartesian Graph	Dynagraph
Gross Coordination	*If you mow ten lawns, it would take the exact same time as if you mowed five.* *As you increase the total number of yards mowed, your total time isn't going to go down.*		*As I'm moving the lawns mowed to bigger numbers, the total time is getting farther away.* *As I move the x back and forth, the y stays the exact same.* [Describe Behavior]
Coordination of Values	*If every yard is around the same, then, like, if this [input] is 2 and it's [the output's] around 1 then if this [output] is 5 then it's [the input's] around 10. It just makes sense because every yard is similar.*	Explains movement is *over 5 on the x-axis and up 1.5 on the y-axis.*	
Chunky Continuous Coordination	*One yard would be bigger; so, it [the output] would increase more because it would take longer.* [Measure Steepness]	*As you would move up the x-axis, the y would increase at different rates.*	*As the x is increasing, the y is increasing but at a much slower rate.* [Measure Steepness]

Revising the Cartesian Graph

At the end of the interview, Cyrus was asked again to graph the relationship between number of yards and total time mowing, where the yards varied in size. Cyrus first drew a "wavy" nonmonotonic graph like he had at the beginning of the interview, and the interviewer asked him how he would interpret one of the waves if *y* represented total time. Cyrus quickly realized the error in his graph, explaining, "so now I'm thinking this is completely wrong because it's [the decreasing segment of the graph] saying that...time is going backwards now which doesn't really make sense." Cyrus was initially unsure as to how to sketch the graph of the situation but said that "different lawns would take a longer time; so, it wouldn't be like a constant line of the *x* and *y* increasing at a constant rate." He continued, "it would be, the *x* increases one yard at a time, so that would be at a constant rate, but the *y* would be more sporadic because if they're different lawns, they're going to take different amounts of time." At this point, we see evidence of *chunky continuous covariation*, where the inputs are changed one yard at a time and the corresponding change in outputs is known to vary since the yards are different sizes. Cyrus then applies this thinking while sketching the graph of this scenario one more time.

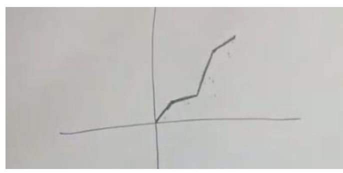

Figure 2: Cyrus' Sketch for the Variable Yard Size Context

Cyrus transfers his *chunky continuous covariation* reasoning to the Cartesian graph, clearly delineating unit intervals of 1 yard and applying thinking consistent with using slope to measure steepness, but never using the word "slope," even when pushed to verbalize what feature of the graph he was looking at. In particular, Cyrus drew the first segment of the graph and said "the first line is like that. It's like a normal yard." Then he sketches the next segment [with a smaller, still positive, slope] and explains that "the next lawn is a really small one; so, the time it takes is not significant. So, the *y* barely goes up, but you still get the lawn done; so, the *x* changes." He then stated, "the next one is a big lawn; so, it goes up pretty significantly [drawing a steep segment as he talks], and you still get the lawn done." He then said, "the next lawn is pretty normal" and explained that its *y* changes like the first one, drawing a line segment that appears to have the same slope as the first line segment he drew. Despite not using the words slope or parallel, through his words and drawing Cyrus displayed thinking consistent with using slope to *determine relationships* while using *chunky covariational reasoning*. He then goes on to explain that in the "normal lines" the *y* might change 1 to 1 with the *x*, points to the steepest segment and says the *y* might change 3 to 1 with the *x* and then points to the least steep line and explains that *y* changes something like ½ to 1 with the *x*. He is able to connect this thinking to the context by pointing to each segment on the graph and accurately identifying whether it is an average-, small-, or large- sized yard. Despite this rich, *chunky continuous covariation* grounded understanding of the context and its representation on the Cartesian plane, Cyrus never referenced the words slope, tilt, or steepness of the segments he drew. Instead, when asked by the researcher how he knew which lawns were larger or smaller, he responded "because, like, the....I don't know what the right word is, but...let's say, like, the angle, I guess, the angle of that little segment of this line."

Conclusions and Future Study

Although Cyrus reported no previous experience with dynagraphs, and despite never using the word slope throughout the interview, he demonstrated a strong understanding of the context grounded in covariational reasoning that enabled him to work flexibly with both the dynagraph and Cartesian graph representations. In fact, Cyrus demonstrated thinking consistent with all three uses of slope: *describe behavior*, *measure steepness*, and *determine relationships*. He was able to reason about a unit rate of change (amount of time it took to mow one lawn) and clearly explained how that unit rate was represented using both the Cartesian graph and dynagraph representations.

By the end of the interview, Cyrus also sketched a piecewise Cartesian graph, where each piece was a linear segment with a different rate of change. The line segments he sketched (see Figure 2) show his attention to a unit change in the number of yards mowed and a strong understanding of the amount of change in the y-values based on the size of a yard. Cyrus clearly explained that a small yard would have little change in y for the set change in x representing one yard mowed, while a large yard would have a greater change in y. He also described yards that were the same size on his graph, applying thinking consistent with *determining relationships*.

Cyrus's thinking stands out considering past research that suggests students often rely on shape thinking (Moore & Thompson, 2015). Shape thinking related to slope is often seen in relation to the three purposes of slope, as outlined in Table 3, and contrasted to the type of reasoning Cyrus demonstrated in this interview. Shape thinking can be the result of learning slope applied to a Cartesian graph, void of covariational reasoning or connection with other relationships. Cyrus demonstrated the ability to reason covariationally about constant rate of change but had not connected that thinking to the concept of slope, despite earning an A in his high school algebra course. Even when pressed at what feature(s) of the Cartesian graph he was focusing on, Cyrus was unsure what to call it, settling on the "angle" of the segments as the best description.

Table 3: Shape Thinking Compared to Cyrus' Thinking of Slope

	Describe Behavior	Measure Steepness	Determine Relationships
Shape Thinking	Lines that go up have positive slope; lines that go down have negative slope; horizontal lines have zero slope.	Steeper lines have greater slope; less steep lines have smaller slope.	Parallel lines have equal slopes; perpendicular lines have negative reciprocal slopes.
Cyrus' Thinking	The graph will be a *diagonal line going up because x increasing means you're moving up the x-axis and y increasing means you're moving up the y-axis.*	*The next lawn is a really small one; so, the time it takes is not significant. So, the y barely goes up, but you still get the lawn done so the x changes.*	This lawn is *pretty normal;* so, the y-value will go up the same amount as the other one since the lawns are the same size.

In this way, Cyrus' case provides a new lens on the well-documented divide between covariational reasoning and the concept of slope. While most research suggests students have learned to apply slope in a particular representation void of covariational reasoning, Cyrus has built a strong foundation of covariational reasoning but does not connect this to the concept of slope (despite completing Algebra I with an A). However, throughout the course of the interview, he was able to apply that reasoning across representations, suggesting that his covariational reasoning forms a strong foundation on which slope can be built. He was particularly successful in making sense of dynagraphs, a brand-new representation for him, likely because the dynagraph made the covariational relationship between inputs and outputs more visible than the static Cartesian graphs he had seen in the past. His interview showed he moved flexibly between the context, the dynagraph and the Cartesian graph, reasoning in ways consistent with all three uses of slope.

Future research should continue to explore the role of multiple representations while individuals seek to understand slope used for different purposes. Are dynagraphs as helpful in building initial covariational reasoning about slope as they were in helping Cyrus apply his existing covariational reasoning?

In this study, a theoretical model describing covariational functional thinking in 13-to-16-year-old students (Grades 8-10) was formulated and empirically validated in three countries (n=350). The hypothesis posited that students engage in covariational functional thinking through five types of reasoning: correspondence view of function, direction of change, calculation of constant rate of change, discerning varying rates of change, and comparing the intensity of change. A structural model indicated that students' capacity in tasks requiring a correspondence view of function predicts their qualitative understanding of quantities varying simultaneously. Subsequently, the analysis revealed three parallel paths from 'direction of change' to 'comparing the intensity of change': one direct path and two indirect paths through 'calculating the constant rate of change' and 'discerning varying rates of change'.

Keywords: algebra and algebraic thinking; function; functional thinking; covariation

Functional thinking is acknowledged as a key component in mathematics education and a fundamental aspect of algebra due to its pivotal role in understanding essential mathematical concepts and in developing important mathematical skills (National Council of Teachers of Mathematics, 2000). Functional thinking has been generally defined as the process of building, describing, and reasoning with and about functions (Blanton, Brizuela, et al., 2015) and is associated with various conceptions and views of functions (Doorman et al., 2012; Dubinsky & Harel, 1992). Research findings indicate that typical curricula often focus predominantly on the correspondence view (Thompson & Carlson, 2017). This approach mainly suggests a static conception of functions, making it difficult for students to envision that the symbolic expression of functions represents relationships among varying quantities (Stephens, et al. 2017). Conversely, considering function as a dynamic process of covariation, emphasizing the covariation of the dependent variable with the independent variable, has been associated with a more intuitive alternative to a formal, correspondence perspective on function and a dynamic and more general view of the function concept (Johnson, 2012; Paoletti & Moore, 2018).

The main goal of the present study is to provide a flexible description of Grade 8-10 students' covariational functional thinking, by proposing a theoretical framework that describes types of this kind of reasoning. We integrate research on functional thinking (Lichti & Roth, 2019), function learning progression (Arieli-Attali et al., 2012; Graf et al., 2010), and covariational reasoning frameworks (Carlson et al., 2002; Jones, 2022), to unpack the essential characteristics of each type of reasoning. These types of reasoning are operationalized via the construction of a model whose robustness is theoretically founded and empirically tested.

Theoretical Framework

Functional thinking is related to different conceptions and views of functions (Doorman et al., 2012) that are equally important for fully shaping the notion of function and the ability to use it effectively. The views of functions that learners need to develop include: Function as (a) an input-output assignment that often precedes carrying out a calculation process; (b) a correspondence relation, focusing on the particular relation between the independent and the dependent variable; (c) a dynamic process of covariation between the independent and the dependent variables; and (d) a mathematical object, that can, e.g., be examined, compared with or connected to other mathematical objects.

The covariational approach is grounded on Confrey and Smith's work (1995) and includes analyzing, manipulating and comprehending the relations between changing quantities. It refers to the variation of the independent variable x and the resulting covariation of the dependent variable y. In other words, it captures the manner of change in y, if x changes uniformly (Lichti & Roth, 2019). A slightly different perspective is proposed by Thompson and Carlson (2017). They describe *covariational reasoning* as going beyond mere awareness of change, but entailing specific mental actions to conceive situations as composed of quantities and relationships among quantities whose values vary. In this perspective, they claim that "a function, covariationally, is a conception of two quantities varying simultaneously such that there is an invariant relationship between their values that has the property that, in the person's conception, every value of one quantity determines exactly one value of the other" (2017, p. 444).

Function Learning Progression

Graf et al. (2019) provided a description of a learning progression for the concept of function that was validated through empirical data, based on a synthesis of previous function understanding models. The first level, *preinstruction*, includes only extending sequences. The second level, *familiarization*, refers to perceiving a function as an algebraic formula or equation. The third level, *making connections*, has a qualitative difference compared to the previous ones as it entails understanding the concept of dependence and an emergent recognition that a function can be captured through different representations. The fourth level, *synthesis*, includes covariational reasoning and the idea of one-valuedness. At this level students are expected to conceive the covariation of variables and attend to global features of graphs. The next level gives emphasis to perceiving a *function as an object* that can be operated upon. The most sophisticated level refers to *function families* that can be perceived as parameterized objects.

Covariational reasoning

Thompson and Carlson (2017) analyzed covariational reasoning by providing an in-depth description of students' progression. Their framework builds upon the covariation framework proposed by Carlson et al. (2002), which was further validated and extended by Yu (2024). Carlson et al.'s (2002) framework investigated students' conceptions of functions using covariational reasoning as an explanatory framework for student reasoning. It identifies the mental actions that students undertake when manipulating the magnitudes or numerical values of covarying quantities in respect to five developmental levels. These mental actions serve as a classification system for the behaviors exhibited by students during covariation tasks. For example, the first mental action involves coordinating the value of one variable with changes in the other and recognize dependence, and corresponding behaviors include labelling the axes with verbal indications of this coordination. The first mental action and behavior describe the level of *coordination*. The second mental action emphasizes coordinating the direction of change of one variable with changes in the other (*direction*). This is manifested in behaviors such as constructing an increasing straight line and verbalizing an awareness of the direction of change of the output value concerning changes in the input. The third mental action focuses on coordinating the amount of change of one variable with changes in the other (*quantitative coordination*). Behaviors associated with action include verbalizing an awareness of the amount of change. The fourth mental action involves coordinating the average rate of change of the function with uniform increments of change in the input variable (*average rate*). Corresponding behaviors include verbalizing an awareness of this rate of change and constructing contiguous secant lines for the domain. Moving to the fifth mental action, it entails coordinating the instantaneous rate of change of the function with continuous changes in the independent variable across the entire domain of the function (*instantaneous rate*). Behaviors related to this action include verbalizing this coordination and constructing a smooth curve with clear indications of concavity changes.

Purpose of the Study

The purpose of this study was to present a theoretical model clarifying the types of reasoning in covariational functional thinking among students in Grades 8 to 10. This grade range corresponds to the formal introduction to functions in middle school and the exploration of various function types and representations during the first years of high school, preceding the study of calculus concepts. In line with Calson et al. (2010), we propose that students in this age group should progress from an action-oriented view (involving arithmetic computations for individual numerical values) to a covariational view of function.

Proposed Model-Aims of the Study

We hypothesized that students' covariational functional thinking can be described by five types of reasoning. We synthesized types of reasoning and mental actions identified in various frameworks, aiming to explicitly describe anticipated abilities based on a dynamic conception of function (Carlson et al., 2002). These descriptions align with school curricula requirements and address the potentials and needs of students within the examined grade range. To make the description of the proposed types of reasoning explicit, we refer to the anticipated actions.

The first type of reasoning refers to perceiving the *correspondence* view of function, reflecting the action-oriented view (Dubinsky & Harel, 1992). It includes conceiving a function as (a) an algebraic formula/equation and as (b) rule, dependence that can be represented in the form of a graph or table of values (Graf et al., 2019). This type of reasoning includes actions such as calculating the output value for a given input value based on a function formula, graphically representing linear functions, interpreting graph representations by understanding input and corresponding output values and identifying/symbolizing the functional relation between two varying quantities expressed in different forms. The second type of reasoning refers to understanding the *direction of change* of one quantity/variable with changes in the other quantity/variable in a qualitative way, as individuals envision the two quantities/variables varying together (Carlson et al., 2002). This includes verbalizing an awareness of the direction of change of the output value due to a change in the input variable, by interpreting different representations of functional relationships, such as algebraic formulas, graphs, or contextualized scenarios. Individuals explain how two quantities involved in a contextualized functional relationship change when the algebraic formula of the relationship is provided (without making any calculations), match real-life scenarios with graph representations or construct a graph based on a scenario that involves co-varying quantities. It should be noted that this type of reasoning involves a basic conceptualization of the direction of change, without discerning nuances in the growth rate, such as linear or nonlinear tendencies.

The third type of reasoning involves *calculating the constant rate of change* - coordinating the amount of change of one variable with changes in the other variable - when the graph, the description, or a table of values of a functional situation involving a linear function is provided (Carlson et al., 2002). Individuals coordinate quantitatively the covarying quantities by calculating the gradient of the linear function. In this case, the change in the dependent variable to every one change in the independent variable is the same. So, individuals may use the coordinates of selected points on a graph or table or calculate the rate of the vertical increment to the horizontal increment on the graph (Hauger, 1997).

The fourth type of reasoning includes *discerning varying rates of change* in functional situations (Johnson, 2012). Individuals verbalize how and why the quantities vary over a continuous domain and reason about how the relationship between the two quantities is represented. Individuals exhibit a well-established representational fluency and stable concept of constant change to differentiate between intervals in which the two quantities vary with a constant or changing change. Johnson and McClintock (2018) showed that when students predicted the type of graph type representing the relationship between covarying quantities, their initial step in discerning variation in unidimensional change was distinguishing between linear and nonlinear patterns. They understand that linearity is a characteristic of functions where the change in constant (Arieli-Attali et al., 2012).

The fifth type of reasoning reflects *comparing the intensity of change* in co-varying quantities within functional situations (Arieli-Attali et al., 2012; Carlson et al., 2002; Jones, 2022). It encompasses calculating, interpreting, and comparing the constant rate of change in complex functional situations, and reasoning about non-numerical varying rate of change (coordinating the instantaneous rate of change of the function with continuous changes in the independent variable for the entire domain of the function). In instances of varying rate of change, this type of reasoning includes constructing a smooth curve that clearly indicates how the rate of change between the two quantities varies.

Drawing upon a synthesis of frameworks describing levels of reasoning, we hypothesized a structural model that delineates the relationships among the proposed types of reasoning (see Figure 1). Specifically, aligning with Graf et al. (2010), we posited that the ‘correspondence view of function’ reasoning is a prerequisite for understanding a covariational perspective of function. This type of reasoning facilitates familiarization with the concept and the pointwise interpretation by observing occurrences at specific points before discerning overall trends. Consequently, we hypothesized that this reasoning directly influences the ‘direction of change’ reasoning, which is essential for comprehending how one quantity changes concerning the change in another (Carlson et al., 2002). Subsequently, we hypothesized that ‘direction of change’ directly affects the types of thinking involved in the ‘calculation of constant rate of change’ and ‘discernment of constant and varying rates of change’. Finally, we assumed that ‘calculation of constant rate of change’ and ‘discern constant and varying rates of change’ serve as predictors of ‘compare the intensity of change’.

The aims of the study were (a) to investigate whether different functional thinking tasks could be categorized based on the factors of the proposed model, (b) to examine the structure and the relations between student’s types of reasoning in covariational functional thinking by empirically validating the hypothesized structural model

Methodology

Sample-Measures

The participants in this study constituted a convenience sample, comprising of 350 middle and high school students from three countries: Cyprus (n=187), Greece (n=43) and Poland (n=119). Ninety-three were eighth graders, 165 were ninth graders, and 93 were tenth graders. The schools and the teachers involved participated voluntarily.

Test items were adopted or developed based on previous research studies and multiple tasks were used for each presumed construct of the framework. Most of the test items were based on previous qualitative studies, teaching experiments, and intervention studies (see Arieli-Attali et al., 2012; Carlson et al., 2002; Castillo-Garsow, 2012). Thus, we made modifications in the format and wording of the items to meet the needs of a written test. The test comprised 16 tasks.

Correspondence view of function. Four tasks were used to measure this type of reasoning. The first one presented the formula of a linear function and students were asked to calculate output or input values when given the corresponding input or output one (T1). In the second task, students were tasked with constructing the graph of the linear function from the first task and appropriately labelling the axis (T2). For the third task, students were instructed to provide y or x values for a given x or y value for a function based on its graph (T3). The fourth task presented three tables of values and four graphs (T4). Students had to match each table with the corresponding graph.

Direction of change. Four tasks were used to capture the entire spectrum of this type of reasoning. In the first task (T5), a real-life scenario featuring a linear functional relationship and the algebraic formula of the function was presented. Students were required to determine the accuracy of statements describing how the two quantities covary. Similarly, the second task presented the graph of a linear function illustrating a currency change (T6). Students were tasked with evaluating the accuracy of four statements describing the covariation of the two quantities. For the third task, students were instructed to construct a piece-wise graph representing the direction of change in distance covered with respect to time, in a distance-time scenario (T7). In the fourth task, verbal descriptions of six mobile pay monthly plans, each involving different functional relations between monthly cost and talking minutes, were provided along with four graphs (T8). Students were required to match each graph with the appropriate verbal description.

Calculation of constant rate of change. Three tasks were used. In the first task (T9), the graph of a linear function was presented. Students were instructed to find the gradient of the line. Similarly, in the second task (T10), students were required to calculate the rate of change of a linear function by utilizing the coordinates of a set of points belonging to the line, provided in a table of values. The third task (T11) featured a picture of a climbing ramp illustrating the position of a roller skate girl, along with her vertical and horizontal distances from the starting point. A graph depicting the variation of the vertical distance in relation to the variation of the horizontal distance was provided. The task required finding the gradient of the function describing her movement when driving up the ramp.

Discern varying rates of change. Three tasks were used to measure this type of reasoning, focusing on interpreting situations where the rate of change between the involved quantities varies. The first task (T12) involved a boy moving between two points, both forwards and backwards. The distance between the points consisted of both a flat and uphill section. The task required selecting the appropriate graph that represents the horizontal distance covered from the starting point with respect to time. To do so, it was necessary to accept that the rate of change between distance and time can be constant (e.g. on the flat part) and non-constant when climbing up and down the hill. The second task (T13) is a modified version of a problem proposed by Castillo-Garsow (2012) and necessitates interpreting in a real-life scenario, employing a discontinuous function, time intervals where the rate of change is zero and time-points where the dependent variable increases instantly. The third task (T14) presented a piecewise linear graph illustrating the height of water in a vessel in respect to time when water is poured in at a constant rate. Students had to select the vessel made up of two cylinders that corresponded to the graph.

Compare the intensity of change. Two tasks were used to measure this type of reasoning that emphasized on the investigation of variations in the intensity of the change rate between the quantities involved in functional situations. The first task (T15) was based on the Bottle Problem (Carlson, et al., 2002), illustrating two bottles, and requiring students to find the graph of the height in respect to time, given that the water is poured into the bottle at a constant rate. This required an intuitive recognition of inflection points, where the rate of change shifts from increasing to decreasing or vice versa. The second task (T16) involved a distance-time scenario and a corresponding piecewise line graph. Students had to interpret five verbal statements involving the rate of change, by finding the time interval that corresponded to each statement.

Data analysis

The goal of the analysis was to estimate the relative strength of the proposed models. Because we proposed a theoretically driven model, our main interest was in the assessment of fit of the hypothesized a priori measurement model to the data. After this we examined the validity of the hypothesized structural model. We used partial least squares (PLS) techniques to analyze structural equation modelling (SEM) systems, using the SmartPLS software. We adopted a reflective analysis because reflective indicators constitute a representative set of all possible items within the conceptual domain of a construct. To examine the validity of a reflective measurement model, multiple indicators are taken into consideration: reflective indicator loadings; internal consistency reliability; and convergent and discriminant validity. Reflective indicator loadings are expected to exceed .70, while acceptable values are considered over .40 (Hair et al., 2019). In terms of internal consistency reliability, Cronbach's alpha and composite reliability (CRI) values in an exploratory study should exceed .60. Average variance extracted (AVE) greater than .50 is a good measure of convergent validity. To assess the validity of the structural model we established the explanatory and predictive power of the model.

Results

First, we investigated the validify of the proposed measurement model by examining the convergent and discriminant validity. Table 1 shows that all the loadings were greater than .50, giving support to the assumption that all factors were adequately measured by the observed variables. In accordance with out theoretical assumption, all covariational functional thinking tasks were clustered into five first-order factors in the expected factor-loading pattern. The significance levels of the associated t-values were calculated by bootstrapping, using 5000 subsamples with the same number of cases as in the original sample, and all of them were statistically significant (Hair et al., 2017). The average extracted (AVE) of the four of the five first-order factors exceeded the threshold value of .50. Only the AVE value of the factor 'Discern varying rates of change' was marginally smaller than .50. The composite reliability index (CRI) ranged from .71 to .84. (above the threshold value of .60). Our research findings reaffirmed the a priori hypothesized model, confirming that five types of reasoning can explain students' variances in covariational functional thinking situations.

The validation of the structural equation model reaffirmed the general structure of the hypothesized model and showed the existence of a sequential effect among the five factors, encompassing both direct and indirect effects. Specifically, the type of reasoning 'correspondence view' exhibited a strong direct effect on the 'direction of change' reasoning type (r=.50, p<.01). Subsequently, the hypothesized model assumed the existence of parallel paths from 'direction of change' to 'calculation of constant rate of change' and 'discern varying rates of change'. However, the analysis revealed the existence of a third parallel path from 'direction of change' to the 'compare the intensity of change' reasoning type (see Figure 1, the first number indicates the regression coefficient and the number in parenthesis the corresponding t-value). The inclusion of this third parallel path in the model led to an increase of the R^2 of the factor 'compare the intensity of change' from .40 to .49. Consequently, the standardized solution of the final model showed a weak statistically regression coefficient from 'direction of change' to (a) 'calculation of constant rate of change' (r=.20, p<.01), 'discern varying rates' (r=.23, p<.01) and 'compare the intensity' (r=.34, p<.01). Finally, the 'discern varying rates' factor proved to be a strong predictive factor for 'compare the intensity' (r=.71, p<.01), while the 'calculation of constant rate of change' factor exhibited a moderate predictive relationship with 'compare the intensity' (r=.50, p<.01). The model provided very weak R^2 value for 'calculate constant rate of change' (R^2 =.17), 'discern varying rates of change' (R^2 =.27) and 'direction of change' (R^2 =.35) and moderate for 'compare the intensity of change' (R^2 =.50). Finally, the Q^2 values showed medium predictive accuracy of the model for 'direction of change' (Q^2 =.34) and 'compare the intensity of change' (Q^2 =.25) and weak for the other two (Q^2 =.04).

Table 1: Measurement model convergent and discriminant validity indices

Discussion

The primary aim of the study was to propose a model describing the types of reasoning exhibited by Grade 8-10 students in covariational functional thinking. We developed a model hypothesizing that students within this age range engage in covariational functional thinking through five types of reasoning. The proposed model elaborates on and extends existing frameworks, advancing the related literature (Jones, 2022; Smith, 2008), by identifying and explicitly describing specific types of reasoning whose activation is essential for adequately responding to a variety of covariational functional thinking tasks. This type of research provides a new theoretical lens for integrating research on understanding the concept of function, functional thinking, and covariational reasoning, by explaining how each type of reasoning facilitates specific actions contributing to understanding function. For instance, the types of reasoning underlying the importance of covariational reasoning serve as an explanatory framework to examine the relationship between the quantities involved in the functional relationship by envisioning their simultaneous variation. Understanding how two quantities covary and discerning between constant and varying rates of change makes it possible to interpret their graph representation or explain how a paired set of values of a function can be deduced based on a given pair of values.

The study described a structural model which indicated that students are initially more successful in tasks requiring a correspondence view of function. Thus, advancements in students' correspondence view of function might enhance their further development in qualitatively conceiving the direction of change of the quantities involved in a functional situation by increasing awareness of the relationship between two quantities and the understanding that a variation in one quantity corresponds to a change in the other. This finding aligns with research by Graf et al. (2018), suggesting that perceiving the correspondence view of function facilitates familiarity with the concept, which is essential for more demanding covariational reasoning. The empirically validated model demonstrated the existence of three parallel paths from 'direction of change' to 'comparing the intensity of change': one direct path and two indirect paths through 'calculating the constant rate of change' and 'discerning varying rates of change'. The underlying assumption is that students improve in tasks involving the comparison of intensity of change by further enhancing their understanding of direction of change, calculating the constant rate of change, discerning varying rates of change, or in two or all types of tasks. This structure illustrates the catalytic role of direction of change as it explains both direct and indirect effects and the importance of coordinating covarying quantities both qualitatively and quantitatively to better understand and accomplish the comparison of intensity of change. This finding empirically validates Carlson et al.'s (2002) and Thompson and Carlson's (2017) covariational reasoning frameworks, suggesting that qualitative coordination precedes quantitative coordination. Finally, the model provided compelling evidence for the importance of 'discerning varying rates of change,' which primarily models students' capacity to distinguish intervals with constant or varying rates of change and how this distinction is reflected in the graphical representation of quantities. This type of reasoning proved to be the strongest direct predictor of students' capacity to compare the intensity of change, as they associate linearity with a constant rate of change between changing quantities and non-linearity with varying rates of change.

A FRAMEWORK FOR UNDERSTANDING THE EQUAL SIGN IN MIDDLE SCHOOL MATHEMATICS

Daniel K. Siebert

Keywords: Algebra and Algebraic Thinking

Research on the teaching and learning of the equal sign has largely focused on two different meanings for the equal sign—operational and relational—and the difficulties students experience in reasoning about equations when their understanding is restricted to an operational meaning (Carpenter et al., 2003; Kieran, 1981; Knuth et al., 2005; Matthews & Fuchs, 2020). Many researchers have focused on solving students' overreliance on the operational meaning of the equal sign by designing instructional interventions to help students replace their operational meaning for the equal sign with a relational meaning (see Hornburg et al., 2021 for a summary of instructional approaches). Scholars have also developed and tested frameworks for describing progressively sophisticated understandings of the equal sign to capture students' transition from operational to relational reasoning (c.f., Rittle-Johnson et al., 2011). However, much of the research on equivalence has left out two additional meanings for the equal sign—assignment and substitution (Jones & Pratt, 2011; Prediger, 2010). The framework presented in this poster for meanings of the equal sign is designed to address this hole in the literature.

Our interest in the four meanings for the equal sign led us to conduct a textual analysis of four middle school mathematics curricula. We sampled four units from the 7^{th} and 8^{th} grade textbooks of each series and coded the equations in those sections to identify which meanings of the equal sign were being used. We found that all four meanings of the equal sign were present in every grade in each series. Our results led us to reject models that hypothesize expert understanding arises from the gradual replacement of the operational meaning with the relational meaning of the equal sign. Rather, our finding that all four meanings of the equal sign are consistently used in middle school mathematics suggests that expert understanding develops by adopting additional meanings for the equal sign and becoming increasingly adept at using the contexts in which equations are embedded to determine which meaning of the equal sign is being used.

After identifying the meanings for the equal sign in each equation, we expanded our unit of analysis from a single equation to a single problem, which often involved multiple equations. We did so to see if there were common patterns in the use of equal sign meanings that students would need to recognize. We found that a substitution meaning for the equal sign was only used in problems where a relational or assignment meaning had already been used. We also noted that the assignment meaning was rarely used if the substitution meaning was not also used later in the problem. While Jones et al. (2012) posit that the substitution meaning is part of a relational understanding of the equal sign, our data suggests that the substitution meaning is also strongly connected to the assignment meaning of the equal sign. Thus, we suggest that an expert conception of the equal sign in secondary mathematics consists of three different understandings: an operational understanding based on the operational meaning, a relational understanding that is comprised of the linked use of the relational and substitution meanings, and an assignment understanding that is comprised of the linked use of the assignment and substitution meanings.

This study investigates slope as a composed unit ratio, offering an alternative understanding that diverges from a multiplicative comparison meaning. Through the lens of a teacher's unique interpretation, we bridge the gap between the different meanings of slope and the varied understandings of ratio, uncovering a nuanced meaning of slope as a ratio. Our findings suggest that viewing slope as a composed unit ratio offers accessible and meaningful pathways for learners, by highlighting a productive understanding. We advocate for further exploration into this meaning to enrich pedagogical strategies and support the development of robust mathematical understandings.

Keywords: Algebra and Algebraic Thinking, Teacher Knowledge

The slope concept is foundational for mathematical learning. Traditionally, slope has been understood and taught through several lenses, including rise over run, algebraic formulas, ratios, and as a measure of line steepness. These conceptions, as outlined by Nagle and Moore-Russo (2013) and other researchers (e.g., Byerley & Thompson, 2017; López et al., 2024), are pervasive in educational research and practice, offering valuable insights into the different ways teachers conceptualize slope. However, these frameworks often consider slope-as-ratio to mean a multiplicative comparison—an understanding recognized for its depth but noted for its scarcity among both teachers and students (Cho & Nagle, 2017; DeJarnette et al., 2020). In this study, we propose that understanding slope as a composed unit ratio may provide more accessible and equally rigorous pathways to deep mathematics.

Despite extensive analysis of the challenges surrounding the teaching and learning of slope, the exploration of composed unit reasoning as a conceptual foundation for slope has been relatively underexamined. Our research addresses this gap through the lens of a teacher, and specifically her interpretation of slope as a composed unit ratio. By investigating the intersection of the bodies of research regarding the different meanings of slope and the various interpretations of ratio, we illustrate that the teacher's conceptualizations of slope, while not aligning with a multiplicative comparison meaning, encompass other rich, nuanced understandings of ratio. The introduction of this alternative meaning of slope not only broadens the conceptual repertoire available for teaching slope but also has the potential to support the development of productive mathematical meanings among learners. Thus, this manuscript seeks to answer the question: What characterizes a ratio-as-composed-unit meaning for slope, and what are the affordances and constraints of this meaning?

Background and Theoretical Framework: Teachers' Meanings of Slope

Researchers have characterized a number of different meanings teachers hold for slope, many building from Nagle and Moore-Russo's (2013) 11 conceptualizations of slope. These meanings include slope as a geometric ratio, an algebraic ratio, and a physical property, among others. Synthesizing the literature base as a whole (e.g., Byerley & Thompson, 2017; Coe, 2007; López et al., 2024; Stump, 1999), three of the most prevalent teacher meanings for slope are (a) slope as an index of the steepness of a line, (b) slope as rise over run, and (c) slope as ratio. We discuss each of these in turn.

Slope-as-steepness meaning entails conceiving of a line as a physical object and making perceptual associations between its steepness and a numerical value; Nagle and Moore-Russo (2013) called this conception "physical property" (p. 3). When holding this conception, one might conclude that the slopes of two lines are the same if they have the same steepness (as determined visually), even if they are graphed in coordinate systems with different scales. This is a fairly common conception for both pre-service teachers (Avcu & Biber, 2022; Paulucci & Strepp, 2021; Tasova & Moore, 2018) and in-service teachers (Byerley & Thompson, 2017; López et al., 2024; Stump, 1999). For instance, Tasova and Moore (2018) found that one pre-service teacher's meaning of slope as a measure of steepness hindered her ability to recognize consistency across graphs in different coordinate orientations.

Slope-as-rise-over-run meaning entails thinking about slope as a procedure for moving up and over a specified number of units on a Cartesian coordinate plane, what Nagle and Moore-Russo (2013) called "geometric ratio" (p. 3), or when determined by the slope formula, $\frac{y_2-y_1}{x_2-x_1}$, "algebraic ratio" (p. 3). In Nagle and Moore-Russo's study, these were two of the most common conceptions. Multiple researchers have found that most teachers' meanings for slope include the slope formula (e.g., Byerley & Thompson, 2017; López et al., 2024; Stump, 1999; 2001). Although teachers can articulate the slope formula as a ratio, Byerley and Thompson (2017) showed that for many teachers this conception is non-multiplicative, as there is no attention to the change in one quantity compared to the change in the other quantity.

Slope-as-ratio meaning is a consequence of comparing the changes in two quantities multiplicatively to create an emergent quantity (Ellis, 2007). This entails understanding slope as a measure of one quantity's variation with respect to the variation of another quantity. For instance, one can conceive of speed as an emergent quantity through the multiplicative comparison of change in distance to change in time (Sherin, 2000). Few teachers refer to slope in this manner, and they can struggle to explain the use of division in the slope formula (e.g., Avcu & Biber, 2022; Byerley & Thompson, 2017; Coe, 2007; Talib et al., 2023). At the same time, slope-as-ratio meaning "is particularly powerful in that it supports one's ability to make sense of slope in a variety of situations" (Diamond, 2020, p. 166). A slope-as-ratio meaning is taken as evidence of a deeper understanding of slope and is critical for making connections between a slope value and the constant rate of change in a linear function (DeJarnette et al., 2020; Dolores Flores et al., 2020; Lobato & Siebert, 2002; Talib et al., 2023). Understanding slope as a ratio supports the ability to conceptualize the invariability of slope (Deniz & Kabael, 2017), to transfer the slope concept to other contexts (Hoban et al., 2013), and to use algebraic manipulations to determine slopes effectively (Cho & Nagle, 2017).

Two Ways to Understand Slope as a Ratio

Research addressing slope as a ratio typically considers ratio to mean a multiplicative comparison (Hoban, 2021; Talib et al., 2023). However, it is also possible to think of a ratio as a *composed unit*. A composed unit is created by joining two quantities to create a new unit, such as 5 cm: 2 sec (Lamon, 1994; Lobato & Ellis, 2010). One can then iterate or partition the created composed unit, maintaining the simultaneity between those quantities while creating new units (Jacobson et al., 2018). For instance, a person developing speed as a ratio can think of an inchworm crawling 5 centimeters in 2 seconds. The composed 5 cm : 2 sec unit could then be iterated to create other equivalent ratios, such as 10 cm : 4 sec, 20 cm: 8 sec, and so forth. This unit can also be partitioned to create, for instance, a unit ratio of 2.5 cm: 1 sec or 1 cm : 2/5 sec. Although some researchers consider the composed unit to be pre-ratio reasoning (e.g., Lesh et al., 1988), others point out that it can be used in combination with other concepts to develop a robust understanding of proportionality (Ellis, 2013; Lobato & Ellis, 2010).

In contrast, a *multiplicative comparison* entails considering how many times larger one quantity is compared to the other (Kaput & Maxwell-West, 1994; Lobato & Ellis, 2010). To continue the above example, this means understanding that the inchworm travels 2.5 cm for every second, or the number of centimeters traveled is always 2.5 times as large as the number of seconds. Regardless of whether one creates a composed unit or makes a multiplicative comparison, both ways of reasoning entail keeping the ratio of one quantity invariant to the other as the numerical values of both quantities change by the same factor (Aydeniz Temizer, 2022).

We found only one study, by DeJarnette and colleagues (2020), that distinguished between ratio as composite unit and ratio as multiplicative comparison in relation to slope meanings. The authors claimed that interpreting ratio as a multiplicative comparison, which they called a single value, is necessary for a sophisticated understanding of slope. However, we suspect that limiting the slope-as-ratio meaning strictly to multiplicative comparisons might miss instances in which teachers (or students) are beginning to build a multiplicative understanding by iterating and partitioning composed units. Given the documented difficulties teachers have with reasoning with slope as a multiplicative comparison, it may be fruitful to consider instances in which teachers are understanding slope as composed units and reasoning with such units in order to build notions of invariance. In our study, we present a case of a teacher whose interpretation of slope as a ratio of composed unit showcases a quantitative and productive understanding, thereby enabling a meaningful engagement with various scenarios.

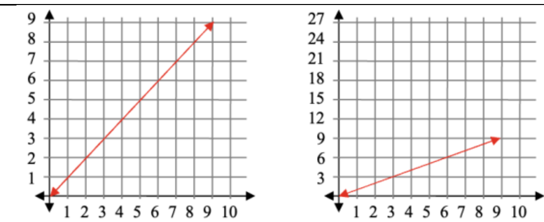
Methods

This study is part of a larger investigation aimed at understanding how teachers support mathematical generalizing (e.g., Ellis et al., 2024). Within this broader project, we identified Ms. R, a sixth-year high school algebra teacher, for an in-depth case study due to her insights into the teaching and understanding of slope. We adopted an investigative and descriptive case study approach (Merriam, 1998; Yin, 2009) to explore Ms. R's meanings of slope. This paper reports on findings from three semi-structured clinical interviews (Ginsburg, 1997) with Ms. R designed to probe her conceptualizations of and MKT related to slope. The 90-minute interviews focused on her understandings of slope and ratio, her insights into how students develop these understandings, and her strategies for supporting its development. This paper concentrates on Ms. R's personal meanings of slope, and our analysis of her broader MKT_{slope} is reported elsewhere (Tasova et al., 2024).

To investigate Ms. R's meanings of slope, we employed a set of questions inspired by Diamond (2020), such as Ms. R's spontaneous associations with the term "slope," contexts or situations she associates with slope, and her interpretation of specific slope values such as ½ and −1. Further, we introduced Ms. R to tasks, such as the "Five Students Problem" (adapted from Diamond, 2013; see Figure 1a), designed to reveal the extent to which her various meanings of slope. We asked Ms. R about what she would say or do with each of these students (see Figure 1a) to support them in developing a desirable understanding of slope and why. Additionally, we presented "The Hypothetical Student Situation" (adapted from Diamond, 2020; see Figure 1b), where a student questions the consistency of slope's meaning upon observing a function appearing steeper on one set of axes compared to another and solicited Ms. R's response to this confusion. To further explore Ms. R's nuanced understanding of slope as a composed unit ratio, we crafted follow-up questions. These questions were instrumental in highlighting the benefits of conceptualizing slope as a composed unit ratio.

Five students are discussing the meaning of slope in a linear context. Student A says that slope is $\frac{y_2-y_1}{x_2-x_1}$. Student B says that slope is the steepness of the line. Student C says that slope is rise over run. Student D says that slope is the rate of change of the line. Student E says that slope is the number m.

(a)



(b)

Figure 1: (a) Five Students problem and (b) The Hypothetical Student Situation

Our analysis process involved a qualitative approach, initially conducting a conceptual analysis to understand Ms. R's verbal and non-verbal explanations, thereby constructing viable models of her mathematics (Steffe & Thompson, 2000). Our analysis relied on aforementioned characterizations of teachers' meanings for slope and meanings for ratio in order to identify Ms. R's meanings. We then attempted to connect these categories that we identified and seek potential implications of those meanings in Ms. R's classroom teaching.

Results

We structure our analysis around two main themes. Firstly, we identify Ms. R's meanings of slope and her concerns regarding traditional slope understandings, highlighting her preference for slope-as-ratio meaning. Secondly, we focus on the exploration of slope as a composed unit ratio, exemplified by Ms. R's pedagogical approach and its impact on student learning. Through this exploration, we offer evidence as to the potential effectiveness of viewing slope as a composed unit for fostering a deeper understanding of mathematical relationships.

Ms. R's Various Understanding of Slope

Analysis of the interviews suggested Ms. R's understanding of slope was multifaceted, encompassing several meanings: slope-as-steepness, slope-as-rise-over-run, slope-as-formula, slope-as-*m*, and slope-as-rate-of-change[1]. She also understood and articulated limitations of

[1] We adopt Ms. R's terminology, using "rate of change" to describe the "ratio" understanding of slope, despite our awareness of the conceptual differences between the two terms.

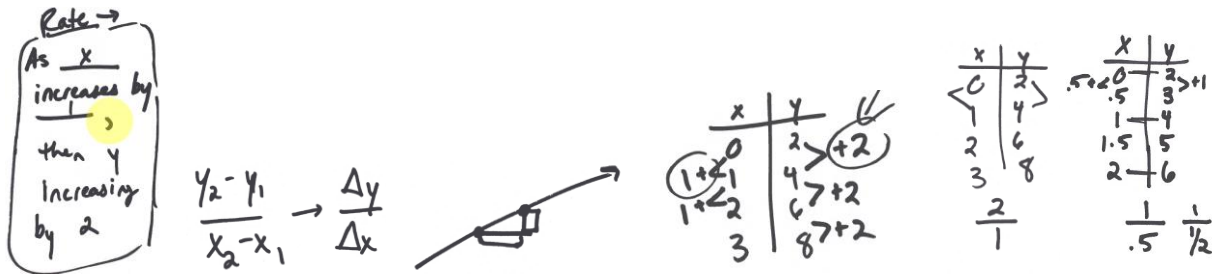
meanings for slope that did not include a rate of change understanding. For instance, in considering the Five Students problem (Figure 1a), Ms. R expressed concern about slope-as-steepness meaning in terms of its potential to mislead students into thinking that lines have the same slope based on their visual resemblance, regardless of axis scale or orientation. When asked The Hypothetical Student Situation task in which the same linear function is graphed on two coordinate axes with different scales (Figure 1b) and a student stated that the two functions had different slopes, she stated "steepness, that's probably where they're getting lost, because it'd be better to talk about change. I mean these lines, they don't initially look like they have the same slope…but they are the same graphs."

When considering slope as rise over run, Ms. R noted that students may rely on rise-over-run meanings because "that is their big middle school focus." Referencing the Five Students problem, she also suggested that students may rely on the slope formula only as a memorized fact: "this kid [Student A] spits out the slope formula because the teacher told him to over and over." Ms. R considered the slope formula to be more useful than the rise-over-run meaning due to its broader applicability to other scenarios, such as the arithmetic mean, and she saw both the rise-over-run meaning and the formula meaning to be superior to viewing slope as the number "m". Ms. R explained, "they know they are supposed to look at the number glued to the x [referring to $y = mx + b$], and that is it." Ms. R then wrote the formula $-2x + y = 3$, and explained that a student who viewed slope as the number "m" would get confused by an equation in this form: "They'll be like, what the heck happened in my graph, my equation?" Collectively, we had evidence from the interviews that Ms. R not only held these various meanings but was also able to position them against each other to discuss their productivity. Next, we illustrate her meaning of slope as a composed unit ratio.

Ms. R's Slope as Ratio Meaning: Composed Unit

Ms. R emphasized that she privileged Student D's meaning: "if this one actually knows what, like, rate of change of the line means, I like that one the best." She viewed Student D's meaning as versatile and applicable across various representations, such as table, equation, and graph, because it was not limited to specific formula or procedure. However, Ms. R's meaning was unclear. While she said she valued the rate-of-change meaning of slope, we were interested in exactly what her rate-of-change meaning was and, hence, what the meaning she valued involved. Did she construct a ratio as a multiplicative comparison, which she could view as a unit rate? Or did she have an alternate meaning for slope as a ratio or a rate of change? To gain insights into Ms. R's meanings, we asked her to create an example to describe how she would facilitate her students' development of the rate-of-change understanding. We hoped that by drawing attention to student development, we would not only gain insights into the meanings she could enact to solve problems but also those aspects of her meanings that she was consciously aware of.

Ms. R described an example with a speed of 25 miles per hour and explained that she could break this down into "for every 1 hour, the car is going 25 miles." Ms. R then explained that she could help students create similar phrases with a template: "As ___ increases/decreases by ___, then ___ increases/decreases by ___." Ms. R then clarified that students could use this template to generate equivalent ratios with different numbers, for instance, "for every two hours, the car is going 50 miles," which represents "the same slope." Ms. R's attention to the connection between the number of miles and the number of hours, combined with her understanding that this unit can be iterated to create other equivalent ratios, suggests a composed unit understanding of ratio.



(a) (b) (c) (d) (e)

Figure 2: (a) Slope as ratio, (b) Slope as formula, (c) Slope as rise over run, (d) Slope as rate of change in a table, (e) Determining the change in *y* for a 0.5-unit change in *x*.

Moreover, Ms. R did explicitly describe slope as a rate of change between two variables. She stated, “When I hear the word slope, I think rate of change…like two variables are changing.” As she continued, her ongoing commentary suggested a composed unit ratio meaning: “as x increases by 1, y increases by 2.” In order to demonstrate this meaning, Ms. R connected it to four representations (Figure 2a-d), pointing out that “they all connect, like they mean the same thing. But they just look different.” Figure 2a shows the composed unit 2:1. Ms. R could also interpret this composed unit via the slope formula (Figure 2b), and she could also demonstrate that meaning visually on a graph that was not drawn to scale. In describing the table in Figure 2d, Ms. R noted, “it [referring to the change in y-values] goes up 2 for every 1 x.”

Based on this response, we hypothesized that Ms. R’s meaning of slope involved ratio as composed unit, but it was unclear whether she could also consider the slope ratio to be a multiplicative comparison between changes in quantities. We therefore pressed Ms. R on her examples in Figure 2, particularly about the meaning of the value of “2”. Ms. R responded, “Technically, it’s 2 over 1, but we like to simplify it to just 2 for some reason I don’t know.” We then asked her what “2” would mean if x changed by a value other than 1. With this, we aimed to determine if Ms. R understood the slope’s value as an indicator of a multiplicative relationship, illustrating how many times the change in y is larger than the change in x. To answer our question, she created a new table (Figure 2e) and concluded that for a change in x of 0.5, the change in y should be 1. We took her actions and descriptions to suggest that Ms. R viewed her original ratio, 2:1, as a composed unit and partitioned it to create an equivalent ratio (1:0.5). This is a contraindication of slope as a multiplicative comparison as she did not multiply 0.5 by 2 to determine the change in y, nor did she ever appeal to a constant multiple between the two.

To further probe the extent Ms. R’s slope-as-ratio meaning was consistent with a composed unit or multiplicative comparison, we also asked her to explain the division in the slope formula, i.e., to explain why one divides to calculate a slope such as 2/1 or 1/0.5. Ms. R struggled to provide a clear explanation, and she interpreted the vinculum (division bar) as a means for matching changes in quantities: “That is communicating 2 is matching with 1.” Ms. R also explained, “to me, the division is this little comma [pointing to the comma in her phrase in Figure 2a].” These responses were further contraindications that Ms. R’s meaning of slope-as-ratio entailed a multiplicative comparison. Despite our attempts to explore division in different contexts, she could not provide a substantial rationale beyond following the formula's instructions, remarking, "I'm trying to see how division comes in the way, and I'm not seeing it. I don't really know why I even divide, beside because the formula said so."

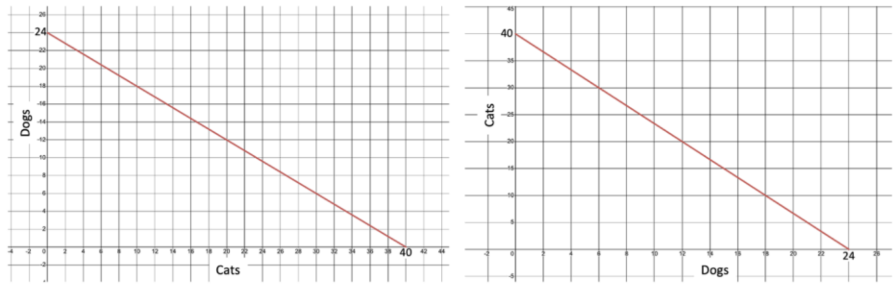
The Affordances and Constraints of Slope as Composed Unit

Ms. R's meaning of slope-as-ratio as a composed unit but not as a multiplicative comparison meant that she could develop equivalent ratios through iterating and partitioning the unit, but she could not directly determine the change in *y*-values for any associated change in *x* through multiplication. She also could not explain why slope involved division. This is consistent with the limitations identified in the literature, in which teachers struggle with conceptualizing slope and division as expressions of relative size, often viewing them non-quantitatively (Byerley & Thompson, 2017). These challenges hinder their ability to connect division with proportional reasoning (Coe, 2007), complicate the interpretation of points on graphs (Thompson, 2013), and hinder the recognition of slope as a consistent ratio of change (Stump, 2001).

Despite these limitations, we argue that there are also affordances to the meaning of slope as a composed unit ratio, beyond solving textbook problems. Ms. R could articulate meaningful connections based on a statement about slope as changes in *y*-values tied to corresponding changes in *x*-values; she could describe what that statement meant in terms of a function's graph, in terms of an associated table of values, and in terms of the formula for determining slope. Ms. R also had meaningful ways to support her own students in developing these connections. For instance, referring to the statement in Figure 2a and the graph in Figure 2c, she noted, "I would like for them to draw, like, the little triangle [drawing a triangle similar to that seen in Figure 2c], show me this part [referring to the run] and this part [pointing to the rise]."

Moreover, the meaning of slope as a composed unit ratio enabled Ms. R to conceive equivalence in the form of an invariant relationship across two graphs representing the same relationship in two different orientations (see Figure 3), which is a very sophisticated and productive way of thinking about graphical relationships (Moore et al., 2022). It also enabled her to respond in a meaningful way to a student thinking. We designed a task building on an activity she had implemented in the classroom, which referenced a pet-sitting business: A pet sitter can spend up to 8 hours each day feeding animals. Each cat requires 12 minutes per day, and each dog requires 20 minutes per day. We presented Ms. R with two graphs of the maximum numbers of dogs and cats that a pet sitter can feed, one with dogs on the *x*-axis and one with cats on the *x*-axis (see Figure 3), and we asked her which of the students' responses she agreed with, if any. Ms. R stated that Student D's response was the most correct, and therefore the slopes of the two graphs must be identical, despite their different visual representations and reciprocal values.

Five students are comparing the slopes of these graphs (see the figure below) in Pet Sitter Task context.



$d = 24 - \frac{3}{5}c$ $c = 40 - \frac{5}{3}d$

Student A says that slope is $\frac{y_2 - y_1}{x_2 - x_1}$. She chooses two points in each graph and calculate the slope for each graph. So, the slope of graph on the left is $\frac{24-0}{0-40} = -\frac{24}{40} = -\frac{3}{5}$ and the slope of graph on the right is $\frac{40-0}{0-24} = -\frac{40}{24} = -\frac{5}{3}$. So, the slopes are different. In fact, the slopes are reciprocals of each other.
Student B says that slope is the steepness of the line. Both graphs look like they have the same steepness. Therefore, the slopes of these graphs are the same.
Student C says that slope is rise over run. Therefore, the slopes are different.
Student D says that slope is the rate of change. So, both graphs show that "For every 3 dogs you are done feeding, you can feed 5 more cats". So, the rate of change in both graphs are the same. Therefore, the slopes are the same.
[*Student D also knows that inputs can be represented on the y-axis and outputs can be represented on the x-axis*.]
Student E says that slope is the number *m*. So, the slopes are different.

Figure 3: Dog and Cat Feeding Time Functions and Graphs

We then presented Ms. R with another hypothetical student answer, which claimed that slope is a rate of change, but the two slopes were different because one graph showed that for every 5 cats fed you can feed 3 more dogs, and the other graph showed that for every 3 dogs fed you can feed 5 more cats. Therefore, the rates of change and thus slopes must be different. Ms. R maintained her original stance, arguing that the numerical values in the two slopes symbolized the same quantities, and thus represented the same rate of change. She elaborated, "I would be like, you said for every 5 cats, the variable after 5 is *cats* [emphasis added] in both of your sentences, you know, like, the variable after 3 is *dogs* [emphasis added]." Given that both expressions conveyed an equivalent meaning, Ms. R reasoned that "So, I would say, like, your rate of change is the same." She argued this was akin to reordering a sentence in different contexts. This highlights Ms. R's relational and quantitative understanding of slope viewed as a composed ratio. Her conceptualization enabled her to interpret the slopes of the two graphs as the same, and it allowed her to understand the meaning of slope in terms of coordinated changes in quantities as represented in tables, graphs, and equations.

Discussion and Conclusion

In this study, we have explored a nuanced meanings of slope as a ratio, proposing a new perspective that transcends the algebraic or geometric ratio conceptions identified by Nagle and Moore-Russo (2013), and yet does not reach the level of multiplicative comparison. While the multiplicative comparison conception of slope is recognized for its depth of understanding, it remains a challenging achievement for both teachers and students. This insight aligns with the broader literature, which has long noted the difficulties inherent in grasping slope from a multiplicative standpoint (Cho & Nagle, 2017; DeJarnette et al., 2020; Dolores-Flores et al., 2020). A potential implication of our research is that understanding ratio as a composed unit may serve as a more accessible—since it is not as cognitively complex as a multiplicative meaning—and meaningful foundation for developing deeper insights into the concept of slope.

The case of Ms. R illustrates that benefits traditionally associated with understanding slope as a multiplicative comparison are still attainable through the lens of a composed unit ratio. Ms. R's slope meaning allowed a fully quantitative understanding, enabling her to effectively interpret and apply the concept of slope in various contexts. She correctly used algebraic manipulations to determine slopes and connected a slope value to the constant rate of change in a linear function (Cho & Nagle, 2017; DeJarnette et al., 2020; Diamond, 2020; Dolores-Flores et al., 2020; Lobato & Siebert, 2002; Talib et al., 2023). This underscores the flexibility and effectiveness of the composed unit ratio approach in fostering a comprehensive understanding of slope.

To clarify, our stance is not to undermine the importance of understanding ratios as multiplicative comparisons or their relevance in understanding the concept of slope. Instead, we propose prioritizing the development of an understanding of ratios as composed units as a foundational step. This strategy involves encouraging the development of equivalent slopes as ratios of changes that leverage values smaller than 1 and values with "messy numbers," thereby enhancing learners' understanding of the invariant relationship between changes in *y*-values and their corresponding *x*-values. For instance, Ms. R's ability to conceptualize an equivalent slope of 1/0.5 from an initial slope of 2/1 exemplifies the potential of this method to deepen understanding. We could ask similar questions to encourage other equivalent slopes, such as 14/7, 9/4.5, 0.5/0.25, or 0.4/0.2. Asking learners to reflect on what is invariant across all these different ratios could encourage attention to the fact that regardless of the increase in *y*-values, the increase in *x*-values remain twice as large.

We must acknowledge that our insights are based on the experiences of a single teacher, Ms. R, providing a compelling case that it is feasible to conceptualize slope as a ratio in effective and impactful ways without necessarily incorporating the notion of multiplicative comparison. Ms. R's example shines a light on the viability of comprehending slope through the lens of a composed unit. However, further research is needed to assess the prevalence and efficacy of this approach among broader populations, including pre-service teachers and secondary students. We believe that such investigations will contribute significantly to the mathematics education field by offering alternative pathways to understanding slope, thereby enriching pedagogical strategies and student learning experiences.

Un problema para la educación de alumnos universitarios es la desconexión entre los temas vistos en sus cursos de matemáticas y las aplicaciones en su práctica profesional. Para el caso de un ingeniero de software, es necesario desarrollar habilidades que le permitan modelar y solucionar problemas en contextos de programación, en el cual pueden intervenir tres tipos de lenguaje que se interrelacionan: el vernáculo, algebraico y computacional. Por tanto, surge el interés de investigar cómo los estudiantes de ingeniería afines a esta práctica relacionan estos tres tipos de lenguaje. Para ello, se diseñó un cuestionario con problemas de álgebra básica y programación. Como resultado se encontró que los estudiantes tienen facilidad para describir en lenguaje vernáculo, códigos que están escritos en lenguaje computacional. Sin embargo, enfrentan dificultades para expresar esos códigos en lenguaje algebraico.

Palabras clave: pensamiento algebraico, pensamiento computacional, resolución de problemas

Introducción

Los cursos de matemáticas para estudiantes de ingeniería suelen tener un enfoque generalizado, con herramientas que de forma tradicional han sido seleccionadas como todo aquello que un ingeniero debe saber emplear. Además, como menciona Devlin (2001), estos cursos suelen ser tradicionales, utilizando el modelo “recipiente que vierte”, donde se vierten los contenidos de un curso sobre los estudiantes como si fueran una jarra vacía, esperando que retengan toda esta información. Al final, esta práctica educativa puede ocasionar que los estudiantes de ingenierías no vean valor en sus cursos de matemáticas.

En particular, el rol del ingeniero de software requiere del desarrollo de habilidades específicas que le permitan ser capaz de modelar y solucionar situaciones problema de su práctica (Parnas, 1999). Por ejemplo, un estudiante de programación debe ser capaz de encontrar errores que el compilador pueda demostrar, tales como errores gramaticales, de sintaxis y semántica; así como errores lógicos y deficiencias de calidad de software.

Hay antecedentes de enseñanza del álgebra mediante la programación para el desarrollo del pensamiento algebraico y computacional (Kilhamn & Bråting, 2019; Bråting & Kilhamn, 2021). Tanto el álgebra como el software son representados mediante un lenguaje. Bråting y Kilhamn (2021) exponen las diferencias entre ellos, así como su testimonio añadiendo el pensamiento computacional mediante la programación en la currícula para el bachillerato.

Marco Conceptual

Sibgatullin et al. (2022) define que en el pensamiento algebraico se incluyen 5 categorías: (a) generalización de la aritmética, (b) manipulación y transformación de igualdades mediante operaciones inversas, (c) análisis de estructuras matemáticas, (d) relaciones y funciones y, por último, (e) lenguaje algebraico y su representación.

Por otra parte, el pensamiento computacional se refiere a los procesos de pensamiento involucrados en la formulación de problemas y la representación de sus soluciones de una manera que pueda ser realizada por una computadora (Proctor, 2022). Es una metáfora universal del razonamiento utilizada tanto por humanos como por máquinas, que abarca un amplio espectro de razonamiento a través del tiempo y las disciplinas (Henderson et al., 2007). El pensamiento computacional implica resolver problemas utilizando una base de evaluación lógica y, a menudo, matemática, y es lo que hacen los profesionales de la informática cuando analizan y diseñan sistemas (Walden et al., 2014). Mejora la integración de las tecnologías digitales con las ideas humanas y enfatiza habilidades como la creatividad, el pensamiento lógico y el pensamiento crítico (Zacharis & Niros, 2019).

De acuerdo con Bocconi et al. (2018), existe un gran debate sobre el concepto de pensamiento computacional, donde existen 2 corrientes principales: a) una habilidad que va más allá de la programación y que engloba otras habilidades como la resolución de problemas, pensamiento lógico y la creatividad; b) un enfoque más orientado a la tecnología, donde se busca que se desarrollen competencias de los empleados en el sector de las TIC que finalmente resolverán problemas sociales. El enfoque a tomar en este trabajo será orientado a la primera idea, aunque no existe ninguna contradicción con que, al desarrollar las habilidades descritas no se mejoren las competencias, la fuerza de trabajo y se tenga un impacto en la sociedad.

El lenguaje, es característica de ambos tipos de pensamiento, algebraico y computacional. Así, para llevar a cabo la investigación, se propone una serie de problemas en un contexto de programación. Los problemas diseñados bajo este marco promueven el uso de 3 lenguajes: (a) vernáculo, (b) algebraico y (c) computacional.

Duval (2017) afirma que existen distintos signos para representar los objetos matemáticos. No se debe confundir el signo con el objeto. Por ejemplo, la suma no es el signo más (+), sino que, es la idea de esta operación y cualquier interpretación en línea con un proceso de adición. Cada objeto matemático tiene una o más representaciones. Los registros de representación se refieren a un sistema que permite representar varios objetos. Existen varias representaciones para un mismo objeto en diferentes sistemas de representación.

Material y método

Este estudio de carácter exploratorio se implementó con 22 estudiantes de ingeniería en computación y 9 de informática, en una universidad pública de México. De los 31 estudiantes, sólo 2 manifestaron haber programado y 6 mencionaron haber tenido pocas experiencias con ese tipo de tareas. La implementación se hizo en un curso de precálculo de primer semestre, pero a la par esos estudiantes cursaban la materia de "fundamentos de programación". Para el estudio se diseñaron 5 problemas en un contexto de programación. Los fragmentos de código utilizados son en lenguaje Python. A continuación, en la Figura 1 se exponen los problemas, mientras que su propósito se discute junto con las respuestas dadas por los estudiantes en la sección de resultados.

Problema 1

(a) Describe en tus propias palabras y en una sentencia corta qué hace el siguiente programa:

```
numero1 = int(input("Ingrese el primer número entero: "))
numero2 = int(input("Ingrese el segundo número entero: "))
resultado = numero1 + numero2
print(f"El resultado es {resultado}")
```

Responde las siguientes preguntas:

(b) ¿Qué pasaría si al asignar la variable resultado, se alterna el orden de las variables numero1 y numeros2 en la suma?

(c) ¿Cómo escribirías en su forma algebraica la misma expresión?

Problema 2

(a) Describe en tus propias palabras y en una sentencia corta qué hace el siguiente programa:

```
numero = int(input("Ingresa un número entero: "))
resultado = numero * numero
print(f"El resultado es #{resultado}")
```

(b) ¿Cómo escribirías en su forma algebraica la expresión de la segunda instrucción del código?

Problema 3

(a) Describe en tus propias palabras y en una sentencia corta qué hace el siguiente programa:

```
 estatura = int(input("Ingresa tu estatura en centímetros: "))
peso = float(input("Ingresa tu peso en kilogramos: "))
resultado = peso / (estatura * estatura)
print(f"El resultado es #{resultado:.2f}")
```

Responde las siguientes preguntas:

(b) ¿Qué pasaría si al asignar la variable resultado, se eliminan los paréntesis de la instrucción. Justifica tu respuesta.

(c) ¿Cómo podrías reescribir la asignación de resultado sin utilizar paréntesis?

(d) Escribe una expresión algebraica equivalente a la instrucción donde se asigna la variable resultado.

Problema 4

(a) En el sistema inglés, se utilizan libras como medida de peso y los pies para medir la altura. Utilizando colores o subrayando/encerrando, separa las instrucciones que convierten las unidades y las que realizan el cálculo del índic de masa corporal.

```
peso_ingresado = float(input("Ingrese su peso en libras: "))
altura_ingresada = float(input("Ingrese su altura en pulgadas: "))
peso_kilogramos = peso_libras * 0.453592
altura_metros = altura_pulgadas * 0.0254
imc = peso_kilogramos / (altura_metros * altura_metros)
print(f"Su índice de masa corporal (IMC) es: {imc:.2f}")
```

Responde las siguientes preguntas, justifica tus respuestas:

(b) ¿Qué pasaría si en lugar de float se utiliza int?

(c) ¿Qué pasaría si se altera el orden de los operadores en la división?

Problema 5

Utilizando las operaciones suma, resta, multiplicación y división, responde las siguientes preguntas:

(a) ¿En qué operaciones se altera el resultado si se cambia el orden de los operandos?

(b) ¿Qué utilidad tienen los paréntesis cuando se utilizan varias operaciones en una misma expresión? ¿Cómo influyen estas propiedades de las operaciones en la programación?

Implementación

Los problemas se aplicaron en 2 ocasiones, la primera aplicación fue individualmente, la segunda se hizo en grupos de 3 a 4 alumnos con el fin de promover la socialización de las respuestas, formando en total 8 grupos. Al final, con ayuda del profesor se revisaron las respuestas en plenaria y se explicaron conceptos involucrados en los problemas.

Figura 1: Problemas planteados en la experimentación

Resultados

Tabla 1: Análisis de la aplicación de los instrumentos

	Respuestas individuales	Respuestas grupales
1.a	Suma de 2 números (28). Describe el programa (2). No respondió (1).	Todos respondieron de forma correcta.
1.b	No cambia (23). Depende del caso (4). Sí cambia (2). Error de programación (2).	Únicamente un equipo respondió de forma incorrecta mencionando un cambio de orden en el que aparecen las variables.
1.c	a+b con diversas literales (16). x+x (5). numero1+numero2 (4). Expresión que contenía un producto (2). Otros (4).	Todos los equipos respondieron con expresiones de la forma a+b.
2.a	Multiplicación (13). Elevar al cuadrado (4).	Sólo un equipo respondió de forma

	Multiplicación por sí mismo (3). Potencia 2 (1). Multiplica 2 números (7). Descripción línea por línea sin mencionar la operación como en 1.a (2). Múltiples respuestas (1).	equivocada “multiplica 2 números”. Algunos mencionaron potencias, multiplicación, multiplicar por sí mismo o elevar al cuadrado.
2.b	x*x (7). a*b (7). x^2 (5). ab (2). -x*y (2). $n1^2$ (1). numero*numero (2). Valores concretos (2). Sin respuesta (2).	El mismo equipo que respondió mal (2.a) utilizó una expresión de la forma a*b. Las respuestas fueron acordes a (2.a).
3.a	Términos como masa, masa corporal o IMC (13). Descripción de las operaciones sin hacer una interpretación real de la fórmula (7). Descripción errónea de las operaciones (5). Otras (6)	6 equipos mencionaron IMC, los otros 2 describieron la fórmula a nivel algebraico sin darle un significado.
3.b	Da resultado incorrecto (14). Hay error de programación (7). No cambia el resultado (3). Sin respuesta (2). Respuestas erróneas divergentes (5).	6 equipos respondieron de forma correcta. Un equipo dijo que sólo se hacía más grande el código y otro escribió la fórmula: estatura*estatura/peso.
3.c	Sin respuesta (10). Invierte: estatura * estatura / peso (6). Uso de potencias (5). Agrupa usando comillas (2). Divide la expresión en dos (1). Respuesta no relevante (7).	3 equipos dejaron la pregunta en blanco, un equipo la respondió separando en 2 instrucciones y otro utilizó potencias. El resto escribieron expresiones erróneas.
3.d	Escribe expresión algebraica correcta con paréntesis o exponentes (11). Invierte la división (7). Asigna valores concretos (4). Omite paréntesis (3). Otras (6).	Sólo 3 equipos respondieron a/(b*b), el resto cambiaron el orden de los argumentos de la división u omitieron los paréntesis.
4.a	Separación correcta de instrucciones (10). Separación de las operaciones de entrada/salida y de los cálculos (7). Sin respuesta (6). Otras (8)	4 equipos separaron de forma correcta las instrucciones. Un equipo no respondió. Los otros 3 equipos resaltaron de forma errónea.
4.b	-Sin respuesta (14). No mostraría los decimales (5). Resultados enteros (5). Cambio de tipo en las variables (2). No cambiaría en nada (2). Error de programación (1). Otro (2).	6 equipos respondieron de forma correcta al decir que no habría decimales o que se mostraría sólo el resultado entero. Un equipo mencionó que el resultado no cambia y un equipo mencionó un error de programación.
4.c	Resultado cambia (18). Sin respuesta (9). Nada (3). Error en algunos casos (1).	Un equipo escribió la fórmula p * a / a, el resto respondió de forma correcta.
5.a	Resta y división (7). Sin respuesta (7). Multiplicación y la división (5). División (5) Todas las operaciones (1). Otras respuestas (6).	Sólo un equipo respondió de forma equivocada, mencionando a la multiplicación y la división
5.b	Jerarquía, orden (16). Separación de	Todos los equipos mencionaron ordenar.

operaciones (7). Sin respuesta (6). Otras (2).

Tabla 2: Éxito obtenido individual y en equipos

	Individuales		Equipos			Individuales		Equipos	
P	A	%	A	%	P	A	%	A	%
1.a	28/31	90,32%	8/8	100%	3.c	6/31	19,35%	2/8	25%
1.b	23/31	74,19%	7/8	87,5%	3.d	11/31	38,71%	3/8	37,5%
1.c	16/31	51,61%	8/8	100%	4.a	10/31	32,26%	4/8	50,%
2.a	21/31	67,74%	7/8	87,5%	4.b	13/31	41,94%	6/8	75,%
2.b	13/31	41,94%	7/8	87,5%	4.c	18/31	58,06%	7/8	87,5%
3.a	22/31	70,97%	8/8	100%	5.a	7/31	22,58%	7/8	87,5%
3.b	14/31	45,16%	6/8	75%	5.b	23/31	74,19%	8/8	100%

Conclusiones

Los estudiantes que inician sus estudios en carreras de ingenierías afines a la programación ingresan con un pensamiento computacional limitado, incluso nulo, lo cual podría ser comprensible, pues es ahí en donde se espera desarrollar ese tipo de pensamiento. Sin embargo, también se pudo constatar que los estudiantes han desarrollado un pensamiento algebraico limitado, a pesar del prolongado tiempo de estudio del álgebra. Entre las concepciones erróneas encontradas se puede mencionar que, los estudiantes no conocen las reglas del lenguaje algebraico, pues no reconocen la utilización y asignación de las variables, así como el significado de algunos operadores y propiedades de las operaciones aritméticas. Desde el marco de Duval (2017), los estudiantes no conocen las representaciones de los objetos, y como vimos en los trabajos de Sibgatullin et al. (2022) y Proctor (2023), el lenguaje para describir objetos es importante para el pensamiento algebraico y computacional.

Los problemas que se propusieron para el estudio implicaron una reflexión y uso de tres tipos de lenguaje en distintos sistemas de representación: vernáculo, algebraico y computacional. Al respecto, hay evidencia de que los programas sencillos en un lenguaje de programación pueden ser explicados por los estudiantes en el lenguaje vernáculo, pero con dificultades para expresarse en el lenguaje algebraico. Además, conforme se introdujeron otros signos propios de la programación, los estudiantes mostraron mayor dificultad para interpretar el código.

Estos resultados conducen al diseño de una investigación más amplia en la que se pretende desarrollar el pensamiento computacional y mejorar el pensamiento algebraico de los estudiantes que ingresan a una ingeniería de software. A fin de que puedan encontrar relación y utilidad de sus conocimientos matemáticos para realizar tareas de su práctica como futuros profesionales.

This work presents six research-based elements that align with building algebraic fluency from conceptual understandings in the teaching and learning of algebra. The six elements are: symbol sense, processes/relationships of algebra, process as an object, anticipating solution strategies, anticipating solution formats, and relationships among representations.

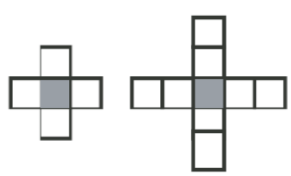
Keywords: Algebra and algebraic thinking, algebraic fluency, conceptual understanding

The purpose of this work is to describe how six research-based elements contribute to students building algebraic fluency from conceptual understandings. First, we use Kaput's (2008) two core aspects of algebra to illustrate the difference between algebra readiness and conceptual understandings of algebra. Second, we provide a characterization of algebraic fluency from conceptual understandings of algebra. Third, we describe six research-based elements of algebraic fluency and illustrate connections to the teaching and learning of algebra.

Core Aspects of Algebra, Algebra Readiness, and Conceptual Understandings

Kaput (2008) defines algebra using two core aspects. First, "[a]lgebra as systematically symbolizing generalizations of regularities and constraints" (p. 11). One example of a regularity of our number system is the commutative property of addition. We note that 7 + 3 = 3 + 7 and can generalize this regularity symbolically as a + b = b + a. Another example of symbolizing generalizations of regularities is finding a rule for the n^{th} term in a visual pattern like in Figure 1.

Examine the shapes below.



1. Draw the next two shapes in the pattern.
2. Count both the shaded and the unshaded squares. Without drawing the shapes how many squares will be in the:10^{th} shape? 25^{th} shape? 100^{th} shape? n^{th} shape?

Figure 1: Visual Pattern, Growing Squares

The first core aspect aligns with an algebra readiness perspective (Feikes et al., 2022). Algebra readiness involves helping students see regularities, describe generalizations from the regularities, and represent these generalizations symbolically. The growing squares pattern (Figure 1) illustrates this as students can generalize and represent a regularity symbolically by expressing the n[th] shape as "$4n + 1$".

However, algebra entails more than just generalization and symbolic representation. Kaput's (2008) second core aspect is: "algebra as syntactically guided reasoning and actions on generalizations expressed in conventional symbols systems" (p.11). We look at this second core aspect as the processes, properties, procedures, and symbolic generalizations which allow for the abstract manipulation of algebraic objects. This characteristic of algebra allows for the modeling of real-life situations, the creation of abstractions, the manipulation of algebraic objects, and the application of abstractions to real-life situations. An example consistent with this core aspect of algebra is the derivation of the quadratic formula by completing the square (See Figure 2).

$$x = \frac{-b \pm \sqrt{b^2 - 4ac}}{2a}$$

Figure 2: Quadratic Formula

The derivation of the quadratic formula by performing actions on variables *a*, *b*, and *c* through completing the square is a process which becomes a mathematical object. This object can then be used in other algebraic work or manipulations. The core aspects of algebra are what allow for the manipulation of algebraic generalizations.

Kaput's second core aspect of algebra aligns with our perspective of developing conceptual understandings of algebra. We understand conceptual understandings in a way that is consistent with the National Research Council (NRC) (2001) and National Council of Teachers of Mathematics (NCTM) (2014) descriptions of students having an integrated and functional grasp of mathematical ideas. Opportunities to develop conceptual understandings of algebra occur when students are provided problems where they can develop and manipulate symbolic generalizations of regularities in meaningful ways (Feikes et al., 2021; Feikes et al., 2022).

Algebraic Fluency from Conceptual Understandings of Algebra

Our perspective of algebraic fluency is based on the NCTM (2023, p. 1) position statement on procedural fluency. Our work defines algebraic fluency as the ability to apply algebraic processes, properties, and procedures with efficiency, flexibility, and accuracy; to transfer algebraic processes, properties, and procedures to different problems and contexts; to build or modify algebraic processes, properties, and procedures from other processes, properties, and procedures; and to recognize when a particular algebraic process, property, or procedure is more appropriate than another. Algebraic fluency entails understanding how to carry out procedures, why procedures can be performed, and which is more appropriate. Research on procedural fluency is relevant to our perspective on algebraic fluency. Efficiency, flexibility, and accuracy involve the knowledge of multiple strategies and the ability to apply them in different contexts (Star, 2005), including procedures and processes in algebra.

Algebraic fluency builds from conceptual understandings so that students become skillful in using procedures appropriately, flexibly, and efficiently, considering different representations, using reasoning to apply these representations to different purposes, and producing accurate answers (NCTM, 2014). Students who build conceptual understandings are more likely to remember and use topics, concepts, and procedures without error due to reasoning and understandings of mathematical relationships (e.g., Fuson et al., 2005; Hiebert & Carpenter, 1992; Hiebert et al., 1997). Alternatively, mindlessly manipulating symbols or learning tricks like memorizing formulas or mnemonics are typically applied to specific problems, likely to be misused in different mathematical problems, and often quickly forgotten (NRC, 2001).

To develop fluency, students need to practice strategies and procedures to solidify their knowledge (NCTM, 2014, p. 45). For example, multiplying two binomials or two larger polynomials (like a binomial and a trinomial) can be taught as an application of the distributive property. This would be a conceptual way to teach and learn this skill because it presents this skill as part of the coherent whole of algebra. As students practice the skill to develop proficiency, they can develop fluency by being asked about patterns and strategies when multiplying the polynomial expressions.

The following example illustrates algebraic fluency with conceptual understandings of algebra when a student recognizes properties of a given equation and related procedures. To solve for x in $\frac{1}{2}(x+4)-1=5$, students could consider a variety of mathematical concepts. They may recognize that the equation represents $6-1=5$, such that $\frac{1}{2}(x+4)$ should equal 6. The distributive property could be used to create an equivalent expression for $\frac{1}{2}(x+4)$ or each term could be multiplied by 2 so that $\frac{1}{2}$ is no longer part of the equation. Students who have developed algebraic fluency from conceptual understandings could consider the benefits and drawbacks of different ways of finding a solution.

Six Elements that Algin with Building Algebraic Fluency from Conceptual Understandings

We have identified six research-based elements which build algebraic fluency from conceptual understandings of algebra and allow students to comprehend algebraic notation or symbols and operate within the processes, properties, and procedures of algebra.

1. Developing *symbol sense* by learning the constructs that algebraic symbols convey.
2. Understanding *processes/relationships of algebra* and how to express these with symbols, e.g., $2n$ is “$n + n$” or “$2 \times n$”; $y = 3x$.
3. Conceptualizing a *process as an object,* often called process-object duality or procept.
4. Understanding, anticipating, and being proficient with *solution strategies*.
5. Anticipating *solution formats*, like solutions as a single number, a graph, or a function.
6. Noticing and expressing *relationships among representations,* like relationships between algebraic expressions, tables, and graphs.

Discussion of the Six Elements

The six elements that align with building algebraic fluency with conceptual understandings have important implications for the teaching and learning of algebra. For example, Arcavi et al. (2017) describe *symbol sense* as giving meaning to symbols and expressions and connecting the symbols to underlying concepts (p. 94). Students need to have an understanding of the constructs conveyed with symbols. Becoming fluent with the abstract ideas represented by the symbols and examples that help these representations become transparent is a key to helping students learn to think with algebra (Kieran, 2007).

Understanding *processes/relationships of algebra* is significant because it helps students express the generalizable from the particular. Mason and Sutherland (2002) emphasize that algebra is about processes and understanding them through the symbols used to represent the processes. Students need to learn to "see through" the symbols by being aware of the processes and applying them (Wheeler, 1989).

Algebra includes processes that are represented with symbols. A conceptual leap occurs when students begin to see and act on *processes as objects* (c.f. Arcavi et al., 2017; Kieran, 1992). Sfard (1991) describes recognizing processes as objects as reification. Warren et al. (2016) have suggested that one of the benefits for students seeing a process as an object is when algebraic objects become accessible which leads to identifying algebraic structures. Further, students should be able to unpack an objectified process into objects related by processes (Tall & Gray, 1994). Instructors of algebra need to encourage students to see processes as objects by providing examples, discussing how processes act as objects, and working on examples that both compress processes into objects and decompress objects to processes (Tall & Gray, 1994).

Understanding, anticipating, and demonstrating proficiency with *solution strategie*s and anticipating *solution formats* require more attention during instruction and work on mathematical problems. Students need to anticipate aspects of solution formats so that possible strategies can be considered (Boero, 2001; Booth, 1988). To help students develop fluency with algebraic solutions formats and strategies, instructors should discuss possible solutions, different ways the solution could be conveyed, different solution strategies, and examples where when a solution does not meet the anticipated expectation.

The final feature of *relationships among representations* is central for creating meaning in algebra (Kieran, 2007, p. 712). Encouraging multiple representations provides opportunities for students to make sense of algebra as represented in different types of thinking and allows students more ways to express their algebraic understandings (Kieran, 2006). We need to help students analyze multiple representations, encouraging them to notice what is similar and what is different about each (Jacobs et al., 2010).

The six elements are interrelated and build upon each other. For example, Kieran (1992) notes, "the development of algebraic symbolism … allowed the symbolic forms to be used structurally as objects" (p. 391). This statement relates to the *process as an object* feature and shows the importance of *symbol sense* in having a structural perspective of algebra.

Additional Considerations and Conclusion

We have identified six elements that align with building algebraic fluency from conceptual understandings of algebra to address theoretical and practitioner needs. Each one of the six elements are research-based and together they form a unique framework for examining the teaching and learning of algebra. Building algebraic fluency should position students as capable, using reasoning and decision-making to improve skill and understanding (NCTM, 2023). We suggest that student learning of algebra can be improved by developing skills and understandings around the six elements. This can occur in classrooms by discussing conceptual aspects of algebra and providing opportunities for students to build understandings about algebraic symbols, processes, properties, and procedures. Research is needed to understand how the six elements of algebraic fluency impact student achievement, equitable classroom practices, and the development of assessments for algebra.

TOWARDS ARTICULATING CRITIQUE TO ALGORITHMS WITH POSITIONING THEORY

Sikunder Ali
Norwegian University of
Science and technology
(NTNU), Norway
sikunder.ali@ntnu.no

Information and communication technologies transform our personal and social practices. The demand for highly skilled labor for the specialized technology-intensive market has risen dramatically. For example, we can notice a visible ethical demand that schools should produce efficient programmers who learn programming (algorithmic actions) from early years at schools to develop a "right" technical mindset and dispositions for living and making out in technology-intensive societies. Digital programs or platforms operate with a variety of algorithms regulated by mathematical procedures, principles or relations. Algorithms are codes or structures that regulate computation objects and digital environments. They are 'a series of steps undertaken to solve a particular problem or accomplish a defined outcome' (Diakopolous, 2015). Algorithms have four functions: prioritization, classification, association, and filtering. These rules act as a sort of moral order that sets the stage where actions of prioritization, classification, association, and filtering take place. Often, these processes operate within value grids that actors/institutions/agencies establish for a particular purpose. For example, digital platforms such as Facebook create particular cues for users based on viewing histories of particular content or patterns of likes or dislikes initiated by users. This necessitates paying attention to particular discursive acts/ storylines that algorithms generate for people to adopt or resist within the interactive nexus of rights and duties. Positioning theory (PT) studies dynamic ways in which human actions are constituted within changing moral fields where social actions are regulated through the assignment of rights and duties to actors (see Harré, & Van Langenhove,1999a)). Dooley and Grimes (2023) identified how an imaginary interaction between preservice teachers and students in mathematics classroom situations can identify complex configurations of dynamic positions that students can take to resist dominant positions ascribed to them under the moral discourse of mathematics. They used Goffman's theory of two-face behavior to highlight how different moral discourses set dynamic constraints on students and teachers to show their performance of positions under the positive face. Here, a positive face can be characterized as "a desire to be appreciated and valued by others, a desire for approval", and a negative face as "concern for freedom of action, a desire to be unimpeded" (pp. 48–49). Similar situations can be observed in ways Facebook algorithms direct the patterns of likes in particular directions. This theoretical critique on algorithms invites the mathematics education community to see algorithms' actions "as behavioral nudges" for guiding human conduct in a particular direction for creating particular human beings with serious implications for social justice and injustices.

THE PURPOSES OF SCHOOL MATHEMATICS FOR SECONDARY MATHEMATICS TEACHERS

Victoria Barron
University of Missouri
barronv@mail.missouri.edu

Keywords: Teacher Beliefs; Instructional Vision; Equity, Inclusion, and Diversity

With its three-part *Catalyzing Change* series, the National Council of Teachers of Mathematics (NCTM) challenged educators and leaders to broaden the purposes of school mathematics beyond college and career readiness. At the secondary level, they suggested that mathematics should help students to "(1) expand professional opportunity; (2) understand and critique the world; and (3) experience wonder, joy, and beauty" (NCTM, 2018, p. 9).

The NCTM's (2018) proposals are consistent with arguments made by critical mathematics education scholars in prior decades, who wrote about the aims of teaching mathematics while asking *whose* social contexts were being taken up in schools (e.g., Ernest, 2000; Ernest, 2010; Greer & Mukhopadhyay, 2003). But those scholars did not focus solely on potential (individual) benefits of school mathematics; they also argued that school mathematics privileges some students and perpetuates patterns of marginalization, suggesting that mathematics has historically served as a gatekeeper and tool for students' stratification (Ernest, 2018; Louie, 2017; Martin et al., 2010). These more "hidden" purposes of school mathematics are notably absent from the NCTM reports. Consequently, so too is an argument for how the proposed purposes and strategies would help to counter the potential harmful practices of school mathematics. Alongside the idealistic purposes to which we aspire, we must, as a field, consider the realistic purposes that school mathematics has historically served.

To understand the prevalence of these various purposes of school mathematics among the "frontline" of mathematics education, this study investigated the purposes of teaching mathematics in schools asserted by middle and high school mathematics teachers. This poster will present interview-gathered perspectives of 20 randomly selected middle and high school mathematics teachers from the midwestern U.S. state of Missouri. The teachers' subject areas ranged from sixth grade mathematics through AP Calculus, and years of experience ranged 2-30 years. The interview protocol consisted of various questions related to purpose including, "what do you think teaching mathematics accomplishes with respect to society?" and "is there anything that school mathematics accomplishes that you wish it did not accomplish?" The interviews were coded using inductive methods and consolidated using thematic analysis.

My findings reveal that teachers primarily think about the purposes of school mathematics with respect to its benefits at an individual and social level; however, they also described critical aims. All 20 respondents described one purpose of school mathematics to be related to NCTM's (2018) "expanding professional opportunities." But some suggested additional purposes that were not included in NCTM's (2018) list, including fifteen responses related to students' development of transferable skills (e.g., communication, collaboration, logical thinking) and, more critically, five teachers suggested that school mathematics serves as a tool for students' stratification. Given the prevalence of responses related to this critical purpose of school mathematics that is absent from NCTM's (2018) reports, this study indicates a need to expand the frameworks beyond the benefits of teaching mathematics in school to consider the harmful byproducts of mathematics education.

SPATIAL EQUITY CONSIDERATIONS FOR CALCULUS AND STATISTICS AS SECONDARY MATHEMATICS ENDPOINTS

Kelly L. Boles
University of Tennessee, Knoxville
klboles@utk.edu

This paper considers geospatial equity implications relative to the calculus versus statistics secondary mathematics endpoint debate. Using two proprietary datasets from the Advanced Placement® (AP®) program— (1) the population of 2015-'19 AP® course audit data and (2) the population of AP® examination scores received by U.S. public school students over the same period—the geographic availability of and achievement in AP® Calculus AB and AP® Statistics are examined. Results indicate that availability and achievement vary across space and subject. On average, rural students face the largest locale-based achievement disadvantage in both subjects. Further, AP® Statistics is shown to be least available in rural schools and to rural students. Implications for locale-based achievement and availability supports are discussed, particularly in the context of ongoing debates.

Keywords: High School Education; Calculus; Data Analysis and Statistics; Equity, Inclusion, and Diversity

Current debates concerning the optimal endpoint of secondary mathematics, be it calculus, statistics, or calculus *and* statistics often employ equity arguments to support each possibility (Bland et al., 2024; Burdman et al., 2018). Secondary calculus is fraught with inequities in access, enrollment, and outcomes. Students who are either of Color or from low-SES backgrounds—or both— have fewer opportunities to take calculus than their white and/or more affluent peers (Kolluri, 2018; Oakes, 1990). Additionally, structural racism, tracking, low expectations, and a lack of calculus-specific teacher professional learning impact Black, Latinx, and low-SES students' opportunities to experience success in calculus (Bressoud, 2020; McGee, 2020; McGee & Martin, 2011). In response, many suggest that statistics and data science suffer less from issues of inequity and may offer all students more opportunities to have positive experiences in higher-level mathematics (LaMar & Boaler, 2021).

Conversely, advocates for preserving calculus as the ultimate course in secondary mathematics have shown that secondary calculus can have benefits in the college admissions process as well as in post-secondary calculus courses and beyond (Bressoud, 2020; Ferrini-Mundy & Gaudard, 1992). Calculus proponents argue that denying opportunities for secondary calculus also denies or delays post-secondary STEM opportunities for students who would otherwise enroll in the course (Bressoud, 2020). Further, statistics also has equity concerns; there is clear racism and sexism in statistics and data science, as datasets and algorithms often reflect the white, male power structures that exist and persist in society today, creating false binaries, actively discriminating, and perpetuating harm (D'Ignazio & Klein, 2020; Noble, 2018).

Thus, weighing the calculus versus statistics debate is complex, with both subjects having documented equity concerns across several intersecting dimensions of identity—specifically race, gender, and class. As the field collectively grapples with inequities along these dimensions and their implications for secondary mathematics curricula, I argue that a critical fourth dimension is missing from the conversation—that of spatial equity, which should be considered in conjunction with gender, race, and class.

Drawing from critical spatial theory, which calls for the interrogation of "the intersections of space, power, and knowledge in order to expose geographies that perpetuate or disrupt inequities in both processes and outcomes" (Annamma, 2017, p. 4), this study examines how students' geographies shape their opportunities to enroll and succeed in advanced calculus and statistics. Using licensed data from The College Board®, I use regression analysis and spatial data science to address the following questions: (1) How does geography shape the *availability* of advanced secondary calculus and statistics across communities in the United States? (2) How does geography shape student exam *achievement* in advanced secondary calculus and statistics across communities in the United States?

Methods

Data and Measures

This study makes use of two primary datasets, both of which are licensed from The College Board® and contain data about their Advanced Placement® (AP®) program. AP® data is particularly useful for this analysis given that the Advanced Placement® program is a primary means of secondary calculus and statistics delivery across the country, reaching hundreds of thousands of students annually (Bressoud, 2020; Lee & Harrison, 2021). Data set one is the full population of all U.S. public schools with AP® Calculus AB and/or AP® Statistics course audits[2] approved by The College Board® in at least one of the four years prior to the onset of the Covid-19 pandemic (*N* = 18,557 schools). Data set two is the population of all AP® Calculus AB and AP® Statistics examinations taken by U.S. public school students in the same four-year window (*N* = 1,733,822 exams). Both data sets have a selection of student/school population demographic variables and, importantly, a National Center of Education Statistics (NCES) locale variable that communicates whether the school is in a rural, town, suburb, or city area. The audit data has been joined with the balance of U.S. public schools which were not approved to offer AP® Calculus AB and/or AP® Statistics, and the geographic location of all schools was obtained.

Analytic Strategy

To consider the geographic landscape of AP® Calculus AB and AP® Statistics course *availability* (RQ1) across the U.S., I conduct exploratory spatial data analysis (ESDA). Using ESDA, data is examined concerning both the geographic locale and state political boundaries to reveal how space shapes course availability.

To consider the geographic landscape of AP® Calculus AB and AP® Statistics student exam *achievement* (RQ2) across the country, I consider the following model for each subject:

$$Y_{ij} = \beta_0 + \beta_1 City_i + \beta_2 Town_i + \beta_3 Rural_i + \beta_4 RaceEth_i + \beta_5 Female_i + \beta_6 SESDecile_i + a_j + \epsilon_{ij}$$

In this model Y_{ij} is the predicted standardized AP® exam score, ranging from 1 to 5, for the *i*th student in the *j*th state by year fixed effect. The suburban locale serves as the comparison group.

[2] In this study, I use AP® audit data as a proxy for course availability. However, it is possible that schools had syllabi approved through the audit process but ultimately did not offer the corresponding course.

Results

Course Availability (RQ1)

Over the four-year period, of 21,139 public high schools, 11,094 schools (52.5%) offered AP® Calculus AB and 7,463 schools (35.3%) offered AP® Statistics. This equates to 5,328,661 students attending schools without AP® Calculus AB and 10,025,690 students in high schools without AP® Statistics. This unavailability is also distributed disproportionately across space.

Relative to AP® Calculus AB, AP® Statistics is less available in schools and to students across all four primary NCES locales. In city locales, 666 less schools (*representing 1,176,509 students*) offer AP® Statistics as compared with AP® Calculus AB, 686 less *(1,246,204 students)* in suburban areas, 749 less *(957,120 students*) in towns, and 1,530 less schools *(1,318,196 students*) in rural areas. That is, both in terms of school and student counts, rural areas face the largest disparities in AP® Statistics availability as compared with AP® Calculus AB.

Rural (un)availability varies by state, region, and subject. The proportion of rural schools offering AP® Calculus AB is strongest in much of the Northeast, with over 70% of rural schools in Maryland, Connecticut, Vermont, Massachusetts, New Jersey, Delaware, and New Hampshire offering AP® Calculus AB. Conversely, the availability of AP® Calculus AB is generally weakest in the Midwest—less than 15% of rural schools in Nebraska, North Dakota, South Dakota, Missouri, and Kansas offer the course.

Table 1: Geographic Availability of AP® Calculus AB and AP® Statistics Courses

NCES Primary Locale	Total # Schools	**AP® Calc AB Availability** # Schools (%)	**AP® Stats Availability** # Schools (%)
City	5,110 (24.2%)	2,782 (25.1%)	2,116 (28.4%)
Suburb	5,186 (24.5%)	3,773 (34.0%)	3,087 (41.4%)
Town	2,876 (13.6%)	1,518 (13.7%)	769 (10.3%)
Rural	7,967 (37.7%)	3,021 (27.2%)	1,491 (20.0%)
Total	21,139	11,094	7,463

The same regional patterns hold for rural availability in AP® Statistics, although availability is far more limited. Only five states, all within the Northeast, have 50% or more of their rural schools offering AP® Statistics—Maryland, Delaware, New Jersey, Connecticut, and Massachusetts. Concerningly, fifteen percent or less of rural schools in twenty states offer the course: eight states are in the Midwest; nine are in the West; and three are in the South.

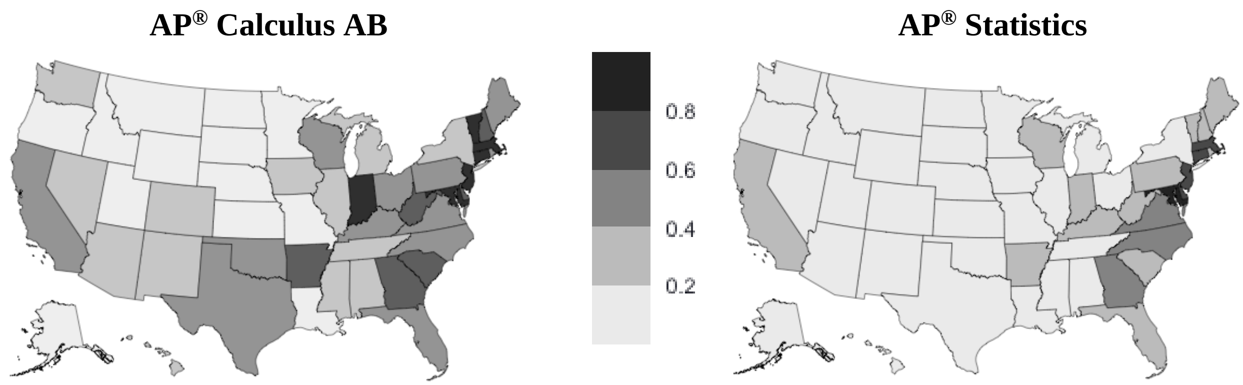

Figure 1: Proportion of Rural Schools Offering Each AP® Course by State

Course Achievement (RQ2)

Spatial inequities also exist related to course achievement in AP® Calculus AB and AP® Statistics. Controlling for documented inequities experienced by students of Color, women, and those from low socio-economic backgrounds, the regression coefficients on geographic locale as predictors for AP® Calculus AB and AP® Statistics exam achievement are given in Figure 2.

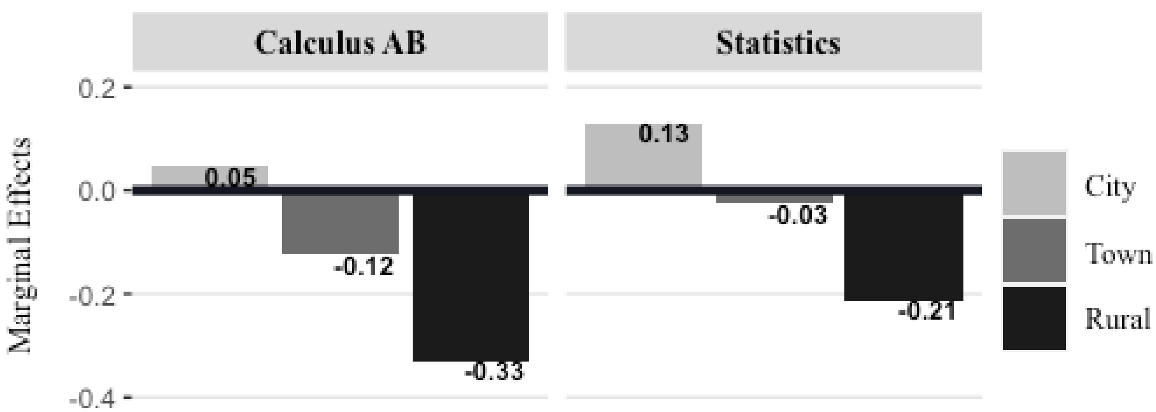

Figure 2: Marginal Effects of Locale on AP® Mathematics Exam Achievement

Compared to students in suburban schools, rural students, on average, receive lower AP® exam scores in both AP® Calculus AB (-0.33 pts.) and AP® Statistics (-0.21 pts). The models also show a slight advantage for city-located students (AP® Calculus AB: 0.05 pts.; AP® Statistics: 0.13 pts.) in comparison to suburban-located peers. The rural disadvantage is consistent across both exams but is largest in AP® Calculus AB. Notably, however, the improvement in rural disadvantage in AP® Statistics is closely mirrored by an increase in city advantage, thus, city-rural gaps improve only slightly when moving from AP® Calculus AB to AP® Statistics.

Discussion and Conclusion

Rural disadvantage exists in both the availability of AP® mathematics coursework and AP® mathematics achievement (see also Wolfe et al., 2023). While AP® Calculus is more widely available nationwide, of the four geographic locales, AP® Calculus AB is least available, proportionally, in rural schools. This unavailability worsens in AP® Statistics, with rural schools and students having the largest absolute disadvantage. There is also spatial inequity in both AP® Calculus AB and AP® Statistics achievement. Across both examinations, rural students, on average, receive the lowest exam scores across all locales. The suburban-rural achievement gap is wider in AP® Calculus AB (0.38 pts.), while the city-rural achievement gap is similar (+/- .04 pts.) across both subjects.

As the field wrestles with whether and how to alter secondary mathematics pathways in service of modern career requirements, equity—and ultimately— students, this paper presents an additional spatial dimension to broaden discussions around these choices. Sizable rural disadvantages in achievement span both typical secondary mathematics endpoints, necessitating support and resources from both the field and policymakers, regardless of the outcome of current debates. Further, this paper demonstrates that a choice to pivot from AP® Calculus AB to AP® Statistics would be spatially exclusionary without concurrent initiatives to expand availability to the latter, particularly in rural areas of the United States.

Acknowledgments

The author wishes to thank The College Board® for sharing data from the Advanced Placement® program.

We, five math teacher educators (MTEs), share how multimodal microanalysis has the potential to contribute to rehumanizing mathematics education by expanding what counts as evidence of students' knowings. We define multimodal microanalysis as the detailed examination and interpretation of minute interactions between various sensory modalities and mathematical representations at a granular level. Using mathematics cognitive interview videos, we share our research design and analysis processes and discuss how multimodal microanalysis can contribute to rehumanizing mathematics teaching and learning.

Keywords: Teacher Noticing, Cognition, Equity, Inclusion, and Diversity

Background and Theoretical Perspectives

As five critically conscious mathematics teacher educators (MTEs) with diverse areas of expertise and lived experiences, we acknowledge that social, cultural, and political factors influence all aspects of our work. Our diversity enhanced this research project because our different perspectives, experiences, and insights fostered creativity, innovation, and a more comprehensive understanding of the complex issues we studied. Before this project, three of us exclusively attended to only what our students said or wrote. After learning about embodied cognition and working with the other two members of the research team, we realized our limited noticing neglected to acknowledge valuable embodied utterances. Drawing upon the literature on embodied cognition and multimodal noticing, our research reveals how multimodal microanalysis can contribute to rehumanizing mathematics education. We define multimodal microanalysis as the detailed examination and interpretation of minute interactions between various sensory modalities and mathematical representations at a granular level.

Rehumanizing Mathematics Through Multimodal Microanalysis

Noticing. Teachers engage in noticing when they attend, interpret, and respond (AIR) to learners (Jacobs et al., 2010). Noticing skills enables teachers to catalyze critical moments and optimize students' learning trajectories (Stockero & Van Zoest, 2013). Teachers attend to and interpret a myriad of evidence of students' thinking but must decide which evidence is pivotal and how to respond to these critical moments (Rotem & Ayalon, 2023). The sociopolitical framings of a teacher impact whether the nature of their noticings leans towards a deficit or anti-deficit model (Louie et al., 2021). Moreover, teachers with multidimensional noticing skills consider how past and future events shape and are shaped by their dispositions and instructional practices (van Es et al., 2022).

Embodied cognition. Embodied cognition research centers on students' use of "body-based resources to make meaning and to connect new ideas and representations to prior experiences"

(Nathan, 2022, p. 4), including gestures, body forms, simulations, and the use of materials, such as manipulatives. Our thinking and understanding of the world are closely linked to our physical bodies and experiences. Moreover, both teaching and learning are dialogic, multimodal activities. Our understanding of abstract concepts, such as mathematics, is rooted in our sensory experiences and bodily movements. As such, we want to begin with and continuously provide students with playful, concrete experiences (Abrahamson et al., 2020).

Multimodal noticing. Walkoe and colleagues (2023) connected embodied cognition and noticing in their research on multimodal noticing. Multimodal noticing adds to the noticing literature by including noticing nonverbal evidence. It is critical for teachers to develop multimodal noticing skills because gestures and actions play a critical role in student thinking (Nemirovsky & Ferrara, 2009; Nemirovsky et al., 2012; Walkoe et al., 2023).

Rehumanizing mathematics. The three dimensions of Rochelle Gutiérrez's (2018) rehumanizing mathematics framework that are most relevant to our multimodal microanalysis include: (1) emotions and body, (2) participation and positioning, and (3) broadening mathematics. Teachers skilled in multimodal noticing consider students' embodied utterances as evidence of students' participation and knowings. Students may exhibit these embodied utterances, such as facial expressions, gestures, or finger counting, before providing their knowings verbally or in writing (Nemirovsky & Ferrara, 2009; Nemirovsky et al., 2012). The broadening of what counts as evidence of mathematical knowings practiced by teachers using multimodal noticing contributes to their positioning of each and every student as a knower and doer of mathematics. This expansion of teachers' ideologies and pedagogies can serve as micro and macro affirmations that promote a rehumanizing of mathematics (Abrahamson et al., 2020).

As seen in Figures 1 and 2, Bondurant and colleagues (2023) layered Gutiérrez's (2018) rehumanizing mathematics framework as a lens over the AIR framework and found that multimodal noticing contributed to the rehumanizing of mathematics. Despite the promising potential of multimodal noticing, most novice teachers' noticings focus on general impressions and lack connections to any evidence from critical events (Bondurant et al., 2020; Moss & Poling, 2019). Although experienced MTEs notice specific pivotal moments, unless they are prompted and reminded to focus specifically on embodied utterances, they privilege students' verbal or written work as evidence of students' knowings (Bondurant et al., 2023). We attribute this to the plethora of stimuli the noticer must attend to at a given moment. We embarked on this study to see if microanalysis can serve as a vehicle for nuanced noticings of embodied utterances.

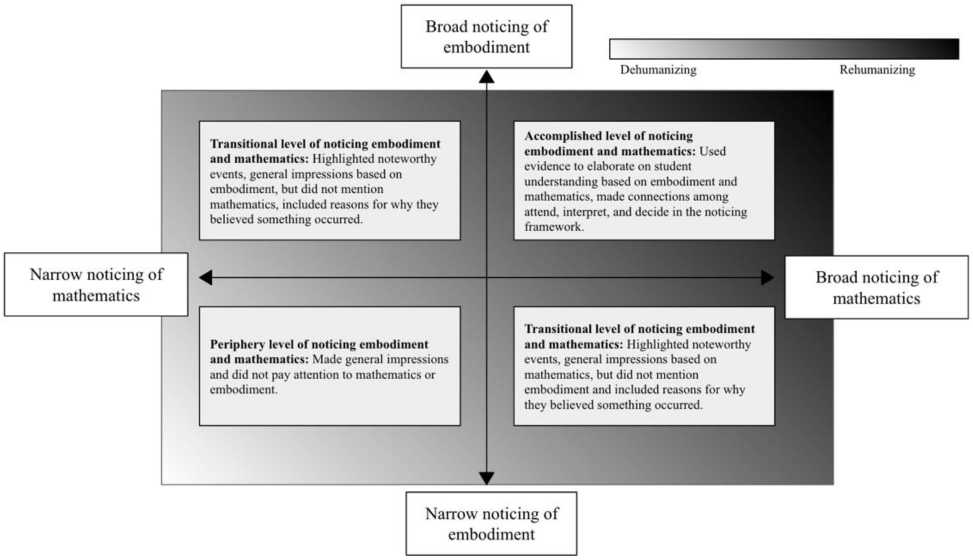

Figure 1: Rehumanizing Noticing through Embodiment

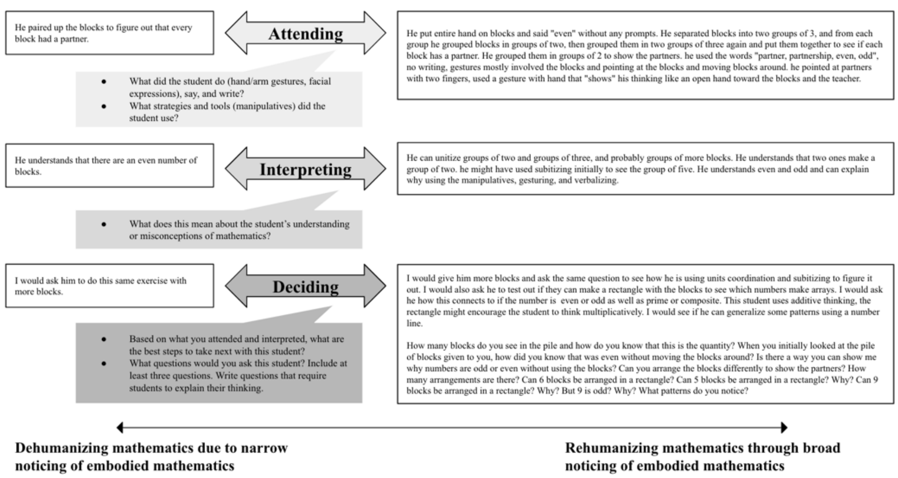

Figure 2: Examples of Noticing of Embodiment and Mathematics Methodology

Microanalysis

Analysis of students' spoken, and written words only captures the end products of their learning, which may not provide the researcher a complete story of the students' thinking or knowings. Microgenetic approaches accentuate fine-grained processes of learning and change that occur "at the smallest observable time scales" (Parnafes & diSessa, 2013, p. 7). The researcher seeks a "moment-by-moment explanatory account of learning in particular contexts" and "conceptual resolution" that yields "very fine distinctions in meaning" that must be tracked (Parnafes & diSessa, 2013, p. 7). Microanalysis involves closely observing and understanding small-scale alterations as they happen, which provides insight into broader developmental changes over time (Calais 2008). The major advantage of using microanalysis is that it captures in-the-moment processes of learning. An in-depth examination of small-scale educational artifacts provides the researcher with nuanced insights into specific phenomena. Researchers employing microanalysis often focus on detailed observations, interactions, and individual experiences to uncover subtle patterns and meanings. We used microanalysis to intentionally foreground and focus on embodied utterances as evidence of students' knowings.

Data

We used ELAN a free, multimodal annotation tool for digital audio and video media created by the Max Planck Institute for Psycholinguistics, The Language Archive, Nijmegen, The Netherlands, and available at https://archive.mpi.nl/tla/elan (Lausberg & Sloetjes, 2009). We viewed a 40-second segment from a cognitive interview video from the course resource *Mathematics for Elementary Teachers: A Contemporary Approach* by Musser and colleagues (2013). In the video segment, a second-grade boy is given six blocks and asked, "Is the number of blocks even or odd?" We chose this video because it includes a manipulative and the video frame includes the student's face and body, providing us with opportunities to attend to embodiment in our noticings. In the video, the student first quickly provided the end product (the answer) but then struggled to explain the process. The student quickly declared that six is even without any interaction with the blocks, suggesting a unitizing strategy. However, when asked how he knew, he initially organized the six blocks into two rows of three, stating they were "even." When asked to explain, the student used a different method, likening an even number to having "partners" and combining the blocks into three groups of twos. Ball and Bass (2003) reported that third-grade students might perceive numbers like six as both even and odd because of their reasoning that the number of groups of two is odd. Further exploration showed that third-grade children may use fair sharing, groups of two, or the alternation of even and odd numbers on the number line strategies to determine if a number is even (Bass, 2005).

Procedure

To foreground embodiment and evidence of student knowings, we intentionally sequenced our noticings as follows: (1) student gesture, (2) student words, (3) instructor gesture, and (4) instructor words. When focusing on gestures, we muted the audio. By focusing on words after gestures we were able to uncover the instructor's and our missed opportunities to notice student's embodied utterances. For each of the four noticing focuses, we watched the video segment multiple times at full, 0.75, and 0.5 speeds. We met via Zoom to analyze the data, discuss noticings, conduct open coding, and consolidate microanalysis notes (Corbin & Strauss, 2014).

Findings

Through microanalysis, we uncovered a plethora of nuanced embodied utterances that we neglected to notice previously. Regarding the student, we uncovered student-embodied utterances that provided valuable evidence of the student's knowings. For example, we uncovered that the student had memorized the fact that six is even. The student immediately stated, "My teacher taught us that…," positioning the teacher as an undisputed authority of knowledge. However, when he had to explain why he was initially uncertain about whether six was even since there were an odd number (three) of "partners" (groups of two blocks), we found that using the blocks and gesturing helped him develop his understanding of why six is even. Moreover, the student's larger gesturing, which moved away from his body, suggested a possible growth in the student's confidence (Cuddy, 2015). Regarding the instructor, we noticed the instructor's embodied utterances and how they connected to evidence of the student's knowings. For example, when the instructor was stoic for extended periods, the student did not receive any scaffolding, which challenged the student to demonstrate his understanding. We also noticed when the instructor's gestures mirrored and echoed the student's gestures. Mirroring gestures are when one individual initiates gesturing about a task, while another simultaneously mimics or matches those gestures, allowing for a real-time physical representation of the first person's reasoning, while echoing gestures involve a sequential reproduction of gestures with a noticeable time gap between them as both individuals explain their reasoning (Walkington et al., 2018).

Based on our review of the literature, expanding our noticings to include embodied utterances through microanalysis contributes to rehumanizing mathematics by providing opportunities to highlight and leverage every student as a brilliant mathematician (Abrahamson et al., 2020; Gutiérrez, 2018).

Discussion

In this microanalysis we set out to explore how embodiment-focused microanalysis of student-teacher interactions in elementary mathematics expands research mathematics educators' professional noticing and contributes to a rehumanizing of mathematics teaching and learning. The microanalysis process provided several "aha" moments for us. We realized that although our previous work had explicitly and intentionally focused on embodiment, microanalysis was needed to uncover a more complete understanding of students' knowings. We found the student initially relied on the teacher as an authority figure but as the student engaged with the manipulatives and reasoned through the explanation their gestures became bigger and more confident. Furthermore, we noticed a point we missed before where the student appeared to be processing thought while tapping and dragging their finger on the table, in the middle of arranging the blocks as both two groups of three and three groups of two. Based on our findings, we consider microanalysis a critical tool to avoid missed opportunities that can acknowledge students' knowings.

This project explored the use of Digital Mathematics Storytelling (DMST) with Indonesian mathematics teachers, focusing specifically on mathematical identity and the connection to community funds of mathematical knowledge. Traditionally, mathematics teaching in Indonesia marginalizes local knowledge in favoring of a Eurocentric outlook. DMST challenges this by facilitating the integration of community-rooted mathematical narratives into educational spheres by enhancing teacher identity and fostering a broader understanding and appreciation of mathematics. Engaging in a three-day DMST workshop prompted teachers to recognize and harness the mathematical community knowledge in their communities and forge a richer, more inclusive, humanizing disposition towards their mathematics teaching.

Keywords: Teacher Beliefs; Equity, Inclusion, and Diversity; Research Methods; Technology

Background

Mathematics learning throughout the world is often dominated by traditional, academically-focused, Eurocentric perspectives, dissuading mathematics students and teachers from seeing people like themselves as mathematical beings, from recognizing their family and community as holders of strong mathematical knowledge, and from using modern communication tools such as social media and online video to engage in mathematical discourse (Chao, 2018; D'Ambrosio, 1985; Joseph, 2011; Powell & Frankenstein, 1997; Star et al., 2014; Vakil, 2014; Zulkardi et al., 2020). This research project explored the ways that Digital Mathematics Storytelling (DMST), a technology-based teaching tool that draws on the ancient practice of storytelling, impacted mathematics teaching identities when used with mathematics teachers in Indonesia. Using qualitative and design-based research methods, this project explored the ways that mathematics teachers shared and discussed connections to family and community-based mathematics through creating short videos within a 3-day digital mathematics storytelling clinic. This research project also fostered global collaboration between researchers in the USA and Indonesia around cutting-edge mathematics teaching pedagogy that utilized widely available mobile technology, particularly engaging mathematics teachers in ways that connect learning technology with research-based pedagogy.

Theoretical Framing

Children throughout Southeast Asia live mathematically rich lives, yet their academic mathematics achievement is more correlated with family wealth and access to tutors, rather than the ability to connect out-of-school mathematics knowledge to in-school mathematics knowledge

(Ginting et al., 2018; Saleh et al., 2017; Trung & Nguyen, 2020; Zulkardi et al., 2020). This disconnect, in turn, creates gaps in mathematics proficiency throughout Southeast Asia, where many adolescent children decide that mathematics is not something that they identify with and subsequently end up removing themselves from future STEM oriented careers (Sheffield et al., 2018; Vuong et al., 2020; Yonezawa et al., 2016). One equity-oriented approach to solving this problem is through connecting out-of-school mathematics with in-school mathematics through a *funds of knowledge* approach, which honors families, communities, and the knowledge they bring to classroom mathematics (Aguirre et al., 2012; Civil, 2014). Additionally, a *storytelling*-based approach draws on historic norms, connecting the way storytelling is used by communities to share important knowledge between generations and define a community history (Lambert, 2013; Prusak et al., 2012).

Identity is not only embodied within the stories a person tells about themselves, but also encompasses the actual act of narrating or storytelling (Sfard & Prusak, 2005). Identity is a verb, made and remade through the act of storytelling. Our stories are not merely descriptions of a static reality, but rather dynamic constructs that can change over time and context. Our narratives serve as constructs that embody our range of experiences, characteristics, and expectations, thereby defining the creation and evolution of our personal and social identities. Even more important than telling a story to explore our identity is the way that identities are reified and endorsed through the acceptance, validation, and re-telling of our narratives. Simply put, our stories are our identities.

Counter-storytelling, therefore, involves sharing stories and experiences that challenge existing dominant (and oppressive) narratives and stereotypes (Solórzano & Yosso, 2002). Counter-storytelling is a tool for individuals in marginalized communities to highlight their experiences and perspectives, and challenge destructive narratives that perpetuate harmful stereotypes. Through counter-storytelling, individuals and communities reclaim their own narratives and thereby their own identities.

When people tell narratives about their out-of-school mathematical experiences, they position themselves and their communities as mathematical. They tap into the power of authorship to counter stigmas that mathematics must only used academically for school–they enact the truth that mathematics is community oriented (Aguirre et al., 2013; Langer-Osuna & Nasir, 2016a). And today's children, particularly in Southeast Asia, are growing up in a world where video-sharing platforms like TikTok, WhatsApp, and Instagram allow for easy sharing of personal stories (Rideout, 2017; Yue et al., 2019). Therefore, this research project explored the ways that teachers can use Digital Mathematics Storytelling, a mechanism in which videos, photographs, and audio come together, to share mathematically-rich narratives from families and communities connected their out-of-school mathematics and community knowledge with their in-school mathematics teaching practices.

The DMST technique involves telling a personal story, one that centers on experiences, conflicts, and growth. These are stories one would share around a meal or family gathering, tales that can be told and retold. These stories often do not follow the Eurocentric three-act framework propagated by Western media, but instead draw upon local community storytelling archetypes involving folktales and family histories (Levy, 2000; Osman, 1999; Tacchi, 2009; Thang & Mahmud, 2017). DMST, therefore, does not involve just creating videos of simplistic mathematics situations, such as trying to figure out the most economical option when buying fruit at the market. Rather, DMST shows mathematics as it really exists within the community, showcasing not only mathematics, but the beauty of the community itself. For example, a digital mathematics story might involve a teacher exploring the ways her Islamic faith guides her continued understanding of mathematics and mathematics pedagogy, drawing connections between passages in the Quran and how she used this knowledge to reflect not only on her knowledge of linear equations, but on her own community responsibilities as a teacher.

Research Methods

The Digital Math Storytelling clinics at the heart of this research project involved 3 sessions over one week hosted at a university on the island of Java in Indonesia. Utilizing a Participant Design-Based Research methodology (Amiel & Reeves, 2008; The Design-Based Research Collective, 2003; Vakil et al., 2016), participants themselves gave continual feedback towards the development of the protocols used within the study, so that it aligned with the cultural and societal norms of mathematics teaching in Indonesia. The Participant Design-Based Research structure allowed our team to update the existing Digital Mathematics Storytelling Protocol (Author, 2019) through feedback and rapid iterations with the research participants themselves. For instance, based on early feedback from participants, the daily schedule of the clinics were revised to incorporate daily prayer times.

The hypothesis grounding this research project was that, when mathematics teachers engage in a DMST workshop situated in their community, they will: (1) develop a stronger sense of their mathematics identity as connected to their family and community identities and (2) tell stories about the rich mathematics examples that come from their own communities and connect these examples to their own teaching.

And while the analysis for this study is still ongoing, the outcomes are being measured through two instruments: **a)** Pre- and post-clinic questionnaires about mathematics identity and, **b)** the Digital Mathematics Stories themselves, which showcase unique storytelling affordances unique to each participant's culture and community, along with the ways they position themselves towards mathematics.

The Clinic

The Digital Math Storytelling clinic comprised three sessions, each lasting four hours, over the course of one week. The workshops focused on eliciting mathematical identities and community mathematical knowledge through storytelling. Each session revolved around a *storycircle* (Lambert, 2013), in which research participants shared stories in small groups in order to elicit constructive feedback. These storycircles allowed each storyteller to evolve and hone their stories and often consisted of a mixture of oral storytelling and sharing video footage or images of the emerging stories. The final session of the workshop revolved around a community screening, in which participants shared their final video stories and then engaged in a whole group discussion about the ideas, emotions, and connections to teacher identity evoked through the creation of, sharing, and community watching of each video. Overall, the makeup of each session evolved based on the feedback and needs of the actual participants, who were positioned not only as research subjects but as equal partners in planning and developing the research plan.

The Participants

The participants consisted of sixteen mathematics teachers enrolled in either a Master's degree program (10) or a Doctoral degree program (6) at an Indonesian university focused on teacher education. The participants varied in their mathematics teaching experience, from pre-service teachers who were just beginning their mathematics teaching careers to teachers with more than 15-years of experience. Teachers were solicited from a pool of current students in the mathematics teacher education program and were invited to participate in a research study focused on creating digital video stories to explore their identities. Participants were also given a small stipend to help offset the costs of their transportation to the workshop.

Data Sources

Two measures of stories and interviews, outlined in the Table 1, were be used to measure potential changes in participant's mathematics identities, digital literacies, and dispositions towards community mathematics. These measures were integrated into the research methods as follows. First, the research team used a Participant Design-Based Research method with storytelling, meaning that the research design and questions shifted based upon the participants' feedback. While the primary source of data was the final digital stories that the participants created, we also collected pre and post-workshop questionnaires focused on mathematical identity, digital literacy, and dispositions towards community mathematics. Additionally, the research team collected field notes, recorded the whole group discussions from the final screenings, and recorded their own debrief conversations after each session.

Additionally, the Participant Design-Based Research method also meant that each participant had opportunities to submit continual feedback to the research team through the daily editable online agendas. This feedback was taken up directly by the research team to substantially evolve the day-to-day structure of each session as well as focus on what the participants felt was important. For instance, originally, each session was conducted in English since each participant indicated that they were comfortable using English as the common language. But after the first session, the research team received feedback that the level of academic discourse in English was beyond the comfort level of several participants. Therefore, the rest of the sessions were conducted in Bahasa Indonesian, with English being used minimally.

Data Analysis

To analyze the data, we first transcribed all the video and audio data in Bahasa Indonesian, then translated them into English. Because the research team consists of an international collaboration between the United States and Indonesia, we were able to engage in the analysis in both languages and take care to understand the cultural meanings of the words the participants chose.

We used constant comparison analysis (Corbin & Strauss, 2008) and narrative inquiry (Clandinin & Connelly, 2000) to compare existing measures of (1) participant's mathematics identities as connected to other social identities as detailed in the work of Aguirre, Mayfield-Ingram, and Martin (2013) and Langer Osuna and Nasir (2016b) and (2) digital literacies as detailed by The International Society for Technology in Education's (ISTE) seven standards for digital literacy: empowered learner, digital citizen, knowledge constructor, innovative designer, computational thinker, creative communicator, and global collaborator (ISTE, 2016). The constant comparative and narrative inquiry-based analysis allow the research team to analyze the video behind the participant's digital mathematics stories. In this way, the storytelling emerges, but is compared with or "measured" against an already known item of the existing construct. Third, the researcher used these tangible findings to construct a tool for future data collection: a Digital Mathematics Storytelling protocol using a Participatory Design-Design Framework created specifically for mathematics teachers in Indonesia (Bang & Vossoughi, 2016; de Jager et al., 2017; Lambert, 2013). Findings for each teacher were written up in a short, 1-page format and sent to each teacher for a member check and to ensure that they had a voice in the research process.

Table 1: Data Sources, Analysis Methods, and Theoretical Framework

Data	Analysis Methods	Theoretical Framework
Digital Mathematics Stories	Constant Comparative Method Narrative Inquiry	Math Identity: Aguirre, Mayfield-Ingram, and Martin (2013) Math Identity: Langer Osuna and Nasir (2016b) Digital Literacy: ISTE Digital Literacy Standards (2016)
Pre/Post Questionnaires	Constant Comparative Method	

Results

Initial results from our analysis of the teachers' data shows some emerging findings that we hope to process and reflect on with the community during the conference. First, the teachers engaged heavily with the construct of the counter story. Of the sixteen stories presented, fourteen of the stories specifically involved creating counter narratives to the ways each teacher was positioned. These stories explored the positional identities of gender, social economic status, ethnicity, age, and parental status. Generally, the teachers used the digital mathematics storytelling workshops to explore the ways in which they were positioned in mathematics as learners, how that affected the ways they saw mathematics, and how they actively fought against this positioning in their teaching practice. For instance, in Figure 1, a participant shares an emotional story about a family death and its effects on the way she perceives the world and the way she teaches.

Figure 1. A Story Exploring Life After the Death of a Family Member

However, these counter stories were often the second, third, or even fourth stories that the participants told. The initial stories were often shallow, as the participants felt that the connection to everyday mathematics had to be the focus of the story. For instance, one of the participants' initial stories revolved around the various risks and advantages of monetary investment, with the story concluding that investing in gold was the smartest long-term solution. Two other initial stories focused on the mathematics behind skin care regiments and the amount of product and frequency of application needed for a healthy skin care routine. In all of these cases, the storytellers completely abandoned these storylines during the first storycircle when it became obvious that their stories could be more connected to their various identities and counter narratives.

Second, the stories allowed ways for teachers to share and explore aspects of their identities that they rarely had the chance to share with other teachers. Three of the stories involved the struggles of raising a family while also working as a teacher. Five of the stories involved the difficulty of working as a professional mathematics teacher while also supporting parents and family members economically.

One of the teacher's stories delved deeply into the ways she felt pressure from her intersecting role as a mother of three children within Islamic Indonesian society and her role as a mathematics education leader in her community. Her story delved into the duality of both joy and frustration. She expressed gratitude for the opportunity to raise three children, engaging them in fun and critical mathematics play from an early age. But she also expressed frustration with the expectation with having to serve as caretaker and coordinator of her children's schedules while she felt that her male counterparts were able to completely focus on their professional identities and not take care of the endless minutia of parenting. This story pushed back on the frustrating gender norms existing the storyteller felt.

However, another narrative painted a counter story to this narrative. A male teacher's story focused specifically on the mathematics play that he and his young children engaged in on a daily basis, focusing on how much time and effort he spent in creating playful and educational experiences for his children so that his female partner did not have to shoulder the burden of caretaking entirely on herself. Both these stories, in parallel, showcase the unique ways that this storytelling experience allows multiple narrative perspectives on parenting to emerge. And the ensuing screening opened discussion on gender roles and our responsibility as educational leaders to push back on norms that felt oppressive.

Third, the ensuing discussions after each story opened pathways for teachers to connect their mathematics teaching to humanizing practices. Every single post-survey result mentioned some form of how this practice allowed them to engage in mathematics teaching from their heart, as opposed to the robotic and technical practice that they often felt positioned to do as mathematics teachers. For instance, in Figure 2, a participant shares a story exploring her own evolving Islam faith and the ways that her daily prayer and study are connected to how she sees mathematics and her role as a mathematics teacher in her community. In this example, the storyteller wrestles heavily with her own emerging identity as a mathematics teacher and the purpose of mathematics in society. She also wrestles with her growing Islamic faith and uses mathematics, religion, and her own personal experiences to connect how passages from the Quran are connected to how mathematics is learned and understood. The discussion that ensued from this story focused heavily on the role of religion in mathematics education practice, particularly in ways that were culturally relevant to the students that these teachers would work with.

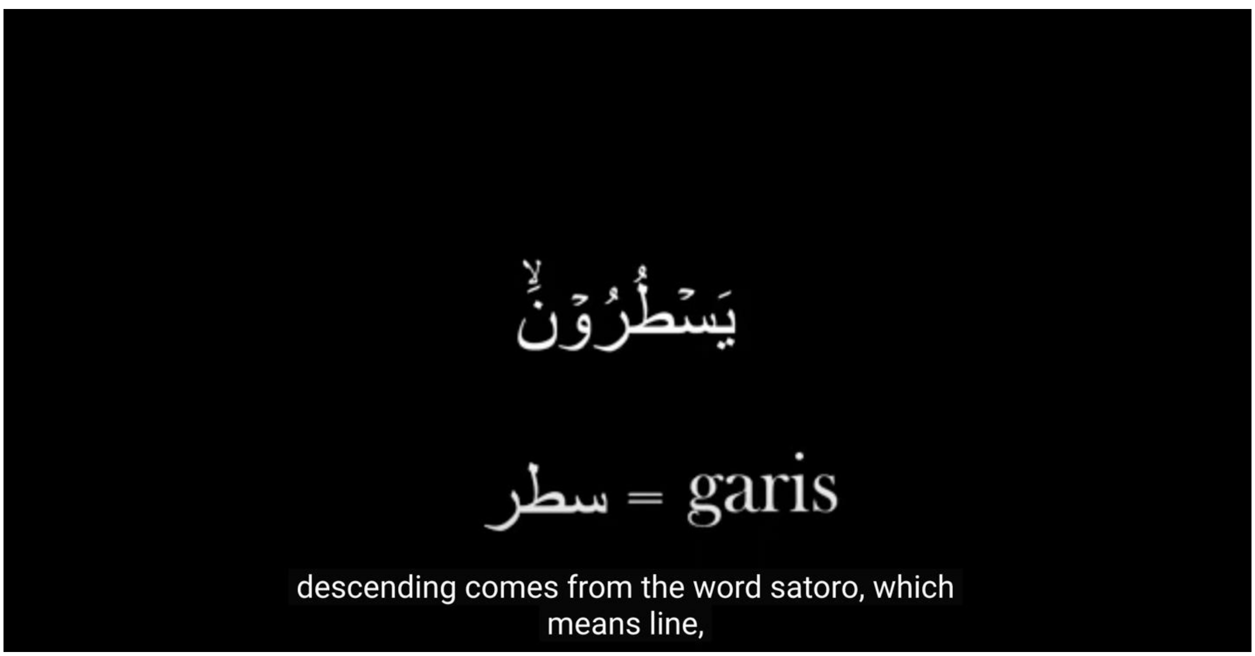

Figure 2. A Story Exploring Islamic faith and Community Responsibility

Finally, supporting a finding from our prior studies using digital mathematics storytelling in US-based communities (Chao et al., 2021, 2022), we once again found that this final community screening and discussion became a crucial space for the stories to live. This space, to share and comment on each other's stories, particularly at the end of the Digital Mathematics Storytelling experience became a cathartic and transformative space where the teachers clearly see who they are and how it connects to their practice as mathematics educators. And, in our own reflection of the data, we found that it is this conversation during this screening that was filled with the richest feedback and personal connections. The teachers spoke of their own family trauma, their own experiences with mathematics, their own hopes as teachers, parents, siblings, and community members, their own frustrations, and finally, ways to find their own joy within their practice. In fact, during this last three-hour screening and discussion, one of facilitators noted that it was time for prayer. But the participants decided to keep going with the screening and discussion and push their prayer back until after the discussion was finished.

Discussion

Overall, the Digital Mathematics Storytelling experience was successful in eliciting narrative-based identity stories from these mathematics teachers in Indonesia, not only by offering opportunities to create and share their counter stories, but also engage in artifact creation that humanized their practice. These results show the global impact that a practice like this can have on mathematics teachers, particularly in an environment like Indonesia which has a deep history of Arabic, Indian, Dutch, and Chinese pedagogical influences (Patahuddin et al., 2018). While the original intent of the project was to elicit specific Indonesian national and regional mathematics teaching practices, the research team learned that what the mathematics teachers most resonated with through this practice was the opportunity to forge and share stories about their own mathematics identities as connected to their family, community, and culture.

TRANSFORMING HOW WE COME TO KNOW (THROUGH) MATHEMATICS

Grace A. Chen

Panchompoo (Fai) Wisittanawat
Vanderbilt University
fai.wisittanawat@vanderbilt.edu

Mathematics shapes how we see ourselves, each other, and the world. Therefore, how we come to know mathematics has consequences for how we relate to one another and to the world around us. For example, when we rely on a mathematics that we come to know as fixed and static to conceptualize social identities such as race, gender, and class, it is easy to interpret these identities as fixed and static. By re-reading empirical examples from existing literature on Cartesian geometry and the mathematics of space in conversation with theoretical provocations, this conceptual paper explores how transforming how students come to know mathematics has the potential to transform how they come to know each other and the world around them.

Keywords: Equity, Inclusion, and Diversity; Social Justice; Instructional Activities and Practices

Recently, one of us observed a high-school classroom in which students were given a paper with multiple straight lines on a Cartesian grid. They completed sentences such as "two lines are parallel when (the slopes are the same)" and "two lines are perpendicular when (the slopes are negative reciprocal)." In this and many other classrooms, the Cartesian grid is presented as existing a priori, with students' primary mathematical tasks being to plot prescribed lines and perform calculations about those lines. Thus, students come to know mathematical structures like the Cartesian grid as absolute: an objective external truth "discovered" by an external authority and handed down over time. This essentialist approach to mathematics (Skovsmose, 2020) is dehumanizing to students (Gutiérrez, 2018) and leads them to experience mathematical properties as arbitrarily defined. Students often think that a right triangle must be oriented in a certain way lest it become isosceles (Vogelstein et al., 2019), for example, or a square must not be tilted lest it become a diamond (Clement et al., 1999). Deprived of the opportunity to engage with the creative potential of mathematics (de Freitas & Sinclair, 2013), students come to know mathematics as fixed, rigid, and absolute, rather than as subjective, flexible, and expansive.

What we come to know mathematics as, and how we come to know mathematics, matters because mathematics structures society. Critical mathematics scholars have illustrated how the formatting power of mathematics shapes technologies, naturalizes the classification and ordering of humans, and makes material some abstractions over others (e.g., Borba & Skovsmose, 1997; Bullock & Meiners, 2019; Chronaki, 2018; Diaz, 2021). Given the imperial and colonialist histories of the mathematics that is most commonly taught in U.S. schools today, mathematics typically materializes abstractions that maintain inequitable relations of power (Appelbaum & Stathopoulou, 2020; Bishop, 1990; Martin, 2009). When students learn mathematics in school, they are also learning about what mathematics is and learning from mathematics about society.

In line with the conference theme of envisioning the future of mathematics education, we build on the efforts of these critical mathematics scholars who warn of the consequences of students coming to know mathematics in restrictive ways and ask: how might transforming how students come to know mathematics *also* transform how they come to know the world?

Theoretically, we draw on theories of learning and theories of society that treat knowing and social life as relational, situated, and interactionally produced (e.g., Erickson, 2004; Lave & Wenger, 1991), which indicate that how students learn math in school matters for how they know and act in society. Methodologically, we plug empirical examples from the mathematics education literature and conceptual provocations from the social studies of mathematics into each other (Jackson & Mazzei, 2013), reading for possibilities for more "expansive and insurgent ways of learning, being, and acting" in the world with mathematics (Warren et. al, 2020, p. 278).

Coming to Know Space

Consider different understandings of the relationship between identity and power. Popular understandings often take identity as a set of fixed characteristics that affect people in predictable ways; men have more privilege than women, or people of color are subordinated to white people (e.g., Cheng, 2020). A person's identity and how they experience the world can be described by the intersection of their locations on axes of privilege or domination. This explanation draws on a mathematical model that many people are familiar with because they have been taught, since early childhood, to plot points on number lines and Cartesian planes, to find intersections of lines, and to compare areas of a plane as being greater than or less than. With this geometric model in mind, comparing privileges based on fixed identity markers seems perfectly logical. It also leads to reductive notions of hierarchy and oppression.

By contrast, feminists of color have long recognized identity as a complex, shifting, and situated phenomenon (e.g., Moraga & Anzaldúa, 1983). The concept of intersectionality, for example, was developed to explain how people's vulnerabilities to racism, sexism, and other forms of oppression not only differ from each other but also depend, dynamically, on context (Crenshaw, 1991). For example, in Leila Fernandes' geography of a jute mill, two mill workers experience conflict (Barad, 2007). How the conflict unfolds, however, cannot be predicted just based on the workers' caste, class, and other identity markers. Instead, the workers sometimes connect based on caste and sometimes on class; when and how their caste and class matter shift as the conflict unfolds. Tracing how different boundaries between caste and class are (re)produced throughout this conflict illustrates how identities and power relations are constantly (re)configured through interaction. Barad argues that this careful accounting of identity (re)formation in the jute mill could be better described by topological than by geometrical representations because of topology's attention to connectivity and boundaries and change in intensive space compared to Cartesian geometry's treatment of locations and positions as fixed against a pre-existing grid. We take this as an example of how the mathematical models we choose– dare we say mathematical ontologies– draw attention to different sets of relations in the world. When Cartesian geometry is a popular way of understanding spatial relations, it is unsurprising that identity might be treated as if it can be fixed, categorized, and ordered, or that people's experiences of power and oppression might be visualized as existing along particular lines. If topology were as accessible and familiar to the public as Cartesian geometry, might different explanations of intersectionality become more popular?

In other words, could unsettling the dominance of certain mathematical models unsettle ways of thinking that stifle more expansive relational possibilities? We examine this question by thinking with mathematical models of space and specifically, three empirical examples that explore making Cartesian geometry less consequential in how learners conceptualize space. We note that space is not the only way to investigate this question, nor is Cartesian geometry is not a “problem” that needs to be “solved” with topological or other models; first, Cartesian geometry can also be useful, and second, substituting one deity for another leaves untransformed the deification we seek to challenge. Rather, we focus on Cartesian geometry because its dominance has already been challenged in the literature, allowing us to wonder with these other scholars what kinds of knowledges or what kinds of relations might be made possible by alternatives.

Animating Multiplicitous Conceptions of Space

Dominguez and colleagues (2023) describe a philosophical conversation in which fifth graders considered different conceptions of space. After some open questions about what moves and what does not move, the conversation turned to students sharing an expansive range of ideas about what space is in relation to the universe, to the world, and between themselves and each other. They considered, for example, whether a rock or a seagull had a better sense of space, and parried that into an interrogation of “often-unquestioned anthropocentric arrangement[s] of space” (p. 1162). Dominguez then introduced a toy airplane and a set of cardboard Cartesian planes, and the students worked together to chart the airplane’s movement using Cartesian coordinates. The initial conversation about movement supported students’ knowing of space as first and foremost dynamic, created by motion, and dependent on perspective. As a result, students responded to the introduction of Cartesian coordinates by refusing to accept space as discontinuous and by animating motion along the z-axis in relation to imagined topological features such as cliffs, caves, or volcanos. Dominguez and colleagues propose that this philosophical conversation shifted students’ mathematical attention in their coming to know space: from space “as a set of static properties [to] a process that features prominently the idea of possibility” (p. 1155), or from essences to multiplicities. We highlight that it made possible different relations between students, non-human relatives, and the world. The fifth graders in this example, however, had already been introduced to Cartesian planes. In fact, Dominguez was invited to lead this conversation because their teacher was concerned that “some students are confused about the order of x- and y-coordinates for plotting points” (p. 1163), perhaps because they– like the students in our opening anecdote– had once been handed printed Cartesian grids with the x-axis and y-axis already determined for them. Our next example shows how students might engage in earlier encounters with space in ways that can also (un)fix the fixity of Cartesian geometry as the predominant, predetermined, and predetermining way to conceptualize space.

(Way)finding New Relational Possibilities.

In Lehrer and Pritchard (2002), students in a third-grade classroom produced maps of their school’s playground. Over multiple trips to the playground and multiple revisions, students negotiated measures of lengths and changes in direction, and decisions about origin and scale until the configurations of play structures in the maps corresponded to those in the playground– something that students agreed “good” maps should do. The teacher encouraged students to reflect, in journals and in conversations, about how their maps changed over time. These reflections helped children construct identities as mathematical doers and knowers, in contrast to mathematical identities that emphasize efficiency and rote procedures (e.g., as “human calculators”). In this example of children coming to know their familiar spaces differently, we glimpse how transforming how we come to know (through) mathematics can transform relational possibilities. First, the children came to have a different relation with an "absolute" frame of reference; through mapmaking, they came to understand that what is fixed on a map is a negotiable choice as opposed to being dictated by a teacher, a textbook, or some other absolute authority. Second, because these negotiations took place publicly, students were driven by a desire for their maps to be legible to each other; their mapmaking was oriented by a concern for collective and not just individual sensemaking. Third, beginning with their own everyday wayfinding offered these third-graders the opportunity to see themselves and each other as people who can make decisions about configuring origins, measures of distance, measures of direction, and scale; Vossoughi and colleagues (2021) refer to this as the "cultivation and experience of capability" (p. 136). Finally, the students also worked with their parents to make a map of their home or neighborhood spaces. Multiple parents expressed that their children showed them new ways of navigating space and more flexible ways of interpreting represented space, which hints at how adults' coming to know space, too, might be transformed.

Attuning to Both Mobile and Grid Epistemologies

Taylor (2020) focuses on adults, analyzing two episodes from participatory community planning meetings where local residents and professional urban planners gather over a table-sized map of the neighborhood. In one episode, a local resident– a "longtime resident of an aging African- American community"– retells how an interstate highway was "carved intentionally through" the community when he was a child and asks how the community can recover; the young White woman planner redirects the conversation to a questionnaire that they are trying to complete (p. 407). In the other episode, a similarly positioned resident shares a similar personal experience. Through parallel tracing of his story with hands in the air and her fingers and stickers on the map, he and a similarly positioned planner together construct what Taylor calls "a new text that layers together Cartesian notions of space with corporeal realities of space" (p. 419). This new text, Taylor argues, learns from both the embodied and dynamic ways that the resident has come to know his neighborhood over time and the more static ways that the planner has come to know the neighborhood through a map. The relational attunement between this resident and planner made their ways of knowing commensurable. Importantly, it also made possible new spatial imaginaries for the neighborhood, as the newly created text became part of the final document on record at the city planning office, and new spatial epistemologies, as the planners later implemented "'walking charrettes' as a means of highlighting the racial and cultural histories of places too easily hidden by easily accessible representations" (p. 424). Taylor's work suggests that bringing grid epistemologies into conversation with mobile epistemologies can create new ways of understanding and acting on the world.

Discussion

Borba & Skovsmose (1997) suggest that the formatting power of mathematics can be challenged by challenging the "ideology of certainty" in classroom practice, creating opportunities for multiplicity, provisionality, uncertainty (p. 22). Our three examples do just that. We caveat, however, that they are not simply examples of "student-centeredness" or "dialogue," because pedagogical shifts alone do not prohibit the possibility that students come to know Cartesian planes as the only legitimate frame of reference for conceptualizing space; transforming epistemologies can be a mechanism for transforming ontologies, but may be insufficient if the mathematics students are coming to know is not also transformed. Instead, transforming how students come to know (through) mathematics must be paired with transforming the mathematics they come to know. For example, to return to Barad's observations about identity, it is the mathematical conception of space as intensive and dynamically produced (as the fifth-graders conceive of it), the recognition of mathematical agency and responsibility in articulating how they and others are positioned and oriented in relation to one another (as the third-graders recognize), and the attunement to both mobility and fixity (as the residents and planners attune), that can lead to models of identity and relations that offer more expansive possibilities than Cartesian geometry. Dialogue is not enough.

Space, of course, is just one thing whose reimagining has the potential to transform our ontological and relational orientations towards each other and our non-human relatives. We continue to wonder how else transforming how students come to know (through) mathematics might transform how they come to know each other and the world they live in.

EXPLORING PRESERVICE TEACHERS' MATHEMATICAL IDENTITIES ACROSS ETHNIC BACKGROUNDS: INSIGHTS FROM MATHEMATICAL AUTOBIOGRAPHIES

Jung Colen
Bellarmine University
jcolen@bellarmine.edu

Yong S. Colen
Indiana University of Pennsylvania
yscolen@iup.edu

This qualitative study delves into the complex concept of mathematical identities among preservice teachers of diverse racial and ethnic backgrounds. Analyzing mathematical autobiographies of three (Black, Asian, and Hispanic) elementary preservice teachers, we uncover distinct challenges and experiences that influence their mathematical identities. The themes emphasize the importance of culturally relevant pedagogy, stereotype challenges, and linguistically sensitive interventions to foster inclusive mathematics education. Our findings contribute to a deeper comprehension of mathematical identity formation and advocate for inclusive educational support.

Keywords: Culturally Relevant Pedagogy; Diversity, Equity, and Inclusion; Preservice Teacher Education

Purpose of Study

In mathematics education, the concept of mathematical identity has evolved into a multifaceted construct, deeply interwoven with an individual's cognitive dimensions, emotional attributes, and life trajectory. As delineated by Boaler and fellow scholars (2000), mathematical identity is not a fixed entity but rather a dynamic and socially constructed phenomenon. It emerges as a complex interplay of individual experiences, beliefs, attitudes, and self-beliefs regarding one's mathematical ability and affinity for the subject. Narratives, like mathematical autobiographies that chronicle individuals' encounters with mathematics in and out of the classroom, enrich the fabric of mathematical identities (McCulloch et al., 2013). Fundamental to developing mathematical identity is an acknowledgment that it manifests through narratives: accounts that not only reflect but also shape our self-conceptions in relation to mathematics (Aguirre et al., 2013). Rooted in personal life narratives, these accounts simultaneously reflect the socio-cultural contexts that influence their identity formations (Drake et al., 2001; Sfard & Prusak, 2005). Within this paradigm, mathematical identity emerges not as a uniform entity but as a mosaic that is intricately crafted from the intersections of personal experiences, societal expectations, and cultural backgrounds.

As preservice teachers embark on their journey to becoming educators, their mathematical identities assume heightened significance, shaping not only their understanding of mathematics and pedagogical practices but also their engagement with students (Lutovac & Kaasila, 2014). However, despite the growing body of research on mathematical identity development (e.g., Beijaard et al., 2004; Bishop, 2012; Black et al., 2019; Goldstein, 2018; Heyd-Metzuyanim, 2015; Kaspersen et al., 2017; Sfard & Prusak, 2005), there exists a gap in understanding how racial and ethnic backgrounds intersect with these processes among preservice teachers.

Our study seeks to address this gap by documenting the development of mathematical identities among preservice teachers of various racial and ethnic backgrounds. Specifically, we focus on three individuals from Black, Asian, and Hispanic heritages within predominantly white educational institutions. By examining the intricate interplay between racial and ethnic identities and mathematical self-concepts, this research aims to illuminate the nuanced ways in which sociocultural factors shape individuals' engagement with mathematics and their trajectories within the field of education. Through this study, we, as mathematics educators, endeavor to contribute to a deeper understanding of the complex dynamics underlying mathematical identity formation and to foster more inclusive, equitable, mathematics education practices.

Framework and Perspectives

Understanding preservice teachers' mathematical identities is essential for the improvement of mathematics instruction and for effective teacher education programs. We embrace the sociocultural view of learning (Lave & Wenger, 1991) as the theoretical framework to investigate the selected preservice teachers' mathematical identities. Learning is "an integral part of generative social practice in the lived-in world" (Lave & Wenger, 1991, p. 35), and individuals' mathematical identities are formed through the process of sharing experiences within their communities. Thus, we highly regard preservice teachers' mathematical learning experiences based on their race, ethnicity, culture, language, and stereotype.

We adopt the perspective that identity is a collection of stories shared by individuals within various social constructs (Holland & Lave, 2001; Sfard & Prusak, 2005). These stories, encompassing both actual and designated identities, shape individuals' perceptions, actions, and future mathematical aspirations. Mathematical identity, therefore, consists of the narratives that reflect individuals' past experiences, present engagement, and future expectations related to mathematics and mathematical teaching. Actual identities encompass personal experiences and achievements in mathematics, while designated identities involve anticipated roles and attitudes toward the subject matter (Sfard & Prusak, 2005). For preservice teachers, their mathematical identities are shaped by a combination of early, formal, and informal mathematical experiences both in and out of the classroom, and societal perceptions of mathematical abilities. To investigate the selected preservice teachers' mathematical identities, we employ autobiographical narratives as the methodological approach. Autobiographies provide a rich source of data, allowing the preservice teachers, in their own words, to reflect on their mathematical learning experiences and to articulate the significance of various events and interactions.

Methodology

This study utilized a qualitative approach. More specifically, mathematical autobiography assignments were the primary data source. The participants, who were enrolled in teacher education programs in three separate institutions across the U.S., reflected on their mathematical experiences, beliefs, and influences. The data analysis, involving thematic coding, focused on racial and ethnic identities and mathematical experiences.

The total number of mathematical autobiographies that the participating elementary preservice teachers submitted was 227. Among them, 214 (94.3%) self-identified as White, 8 (3.5%) as Black, 3 (1.3%) as Asian, and 2 (0.9%) as Hispanic. In this report, we focused on the traditionally underrepresented groups in teacher education programs. Specifically, we identified three distinct cases involving preservice teachers from the Black, Asian, and Hispanic heritages. We selected these individuals due to their compelling narratives, shedding light on how their racial, ethnic, and cultural backgrounds have influenced their development of mathematical identities.

Results and Discussion

In this section, we present compelling narratives from Nicole, Emily, and Maria (pseudonyms) that illustrate the complex relationship between personal backgrounds and academic journeys. Through their first-hand accounts, we explore the landscapes marked by systemic challenges, cultural pressures, and language barriers. These mathematical autobiographies contribute towards the ongoing dialogue on educational equity and inclusivity and offer valuable insights into the diverse experiences, including their shortcomings, within our educational system.

Nicole's Story

Nicole, a junior Black female preservice teacher, provided a story reflecting upon her upbringing within the environments that did not prioritize academic achievement. In her recollection, she depicted a scarcity of educational resources at home and within her neighborhoods. Compounding this, there was a dearth of encouragement and support towards higher educational aspirations. She shared, "In my neighborhood, no one talked about going to college... Math seemed irrelevant to me, and I did not enjoy doing math work."

In her mathematical autobiography, Nicole highlighted the transformative influence of Miss J, her 10th-grade geometry teacher. Despite Nicole's initial struggles with the content, she vividly recalled Miss J's unwavering support and encouragement. Recognizing Nicole's intellectual potential, Miss J played a pivotal role in fostering a profound sense of self-belief and confidence within Nicole. Reflecting on Miss J's impact, Nicole affirmed, "She always said that I would be a good teacher because I explain my thoughts clearly and understandably." This excerpt encapsulates the profound influence individual teachers can have, particularly those who possess the insight and dedication to empower students from historically underserved communities. Furthermore, Miss J emphasized the importance of fostering inclusive learning environments that affirm the potential of every student.

Nicole's introspection stands as a compelling testament to the transformative power of mentorship and the significance of role models of the same race. She recalled, "I always sought advice from Miss J not only for mathematics but for my college choices and other things too. Because she is also Black, I could trust her better, and she became my role model." Nicole's journey highlights the imperative for educators to recognize and challenge systemic barriers while actively advocating for the holistic development and empowerment of all learners. In particular, her story reminds us of the profound responsibility inherent within the field of education—and among educators—to serve as a catalyst for social change and in achieving equity.

Finally, this mathematical autobiography underscores the pervasive systemic inequities that profoundly influence the educational trajectories of similar Black students. Nicole's account resonates deeply within the context of contemporary discussions surrounding educational equity and sheds crucial light on the multifaceted challenges facing marginalized communities. Furthermore, this narrative accentuates the need for culturally relevant pedagogy and the creation of supportive learning environments that acknowledge and address the detrimental, prejudicial experiences and circumstances of students like Nicole.

Emily's Story

Emily, a junior Asian American female preservice teacher, recalled her childhood experiences and the challenges she had faced in learning mathematics. Her immigrant parents, who had arrived shortly before she was born, strongly equated academic success as life's success. This expectation led to Emily attending after-school tutorial sessions and weekend Korean language lessons. Reflecting on her early childhood years, Emily described a sense of disconnect between the academic expectations ingrained by her family-cultural norms and her aptitude in mathematics. She resented the "achieve at all costs" mentality and questioned, "Why I had to do more than my friends. Also, my parents used teaching methods different from those my teachers used, making it even harder for me to grasp the mathematical concepts."

Despite the common belief that Asian students, in general, are naturally talented in mathematics, Emily challenged this by discussing her own difficulties. She delved into the nuanced challenges she had faced as a Korean American. For example, she met the pervasive misconception that her cultural background inherently predisposed her to excel in mathematics. In her mathematical autobiography, Emily reflected, "People always assumed I was great at math because I'm Asian... But the truth is I struggled just like everyone else." Hence, for Emily, there has existed a gap between the people's expectations and the actuality, revealing why it is crucial to reconsider the stereotype about Asian—or any other— students and their mathematical abilities. The disconnect between this assumption and her actual struggles with the subject became even more pronounced as she shared instances of teachers singling her out to highlight her work. Due to the association between her most common Korean last name, "Kim," and her Asian appearance with an unwarranted expectation in mathematical ability, Emily felt disdain towards learning mathematics.

These narratives collectively underscore the imperative to challenge stereotypes and recognize a diverse range of mathematical abilities among Asian students. Emily's experiences serve as a reminder for a more empathetic understanding of individuals' capabilities that are unshackled from the constraints of societal expectations based on cultural or ethnic stereotypes.

Maria's Story

Maria, a female junior, grew up in Wyoming and in a Hispanic household where Spanish was the primary language of communication. Reflecting on her early childhood years, she recalled the learning obstacles beginning in kindergarten. "That's when my struggles first began," she reminisced. Maria's mathematical autobiography revealed complex and often abrupt transitions to learn English in the academic context. Moreover, the expectations to form unfamiliar social bonds and to absorb incongruous knowledge posed added barriers.

The convergence among the diverse expectations and challenges contributed substantially to shaping her early educational impressions. In her narration, she expressed, "I always found story problems to be the most difficult growing up. I never knew why I struggled with them so much. Now, looking back, I believe vocabulary was a significant barrier I had to overcome, coupled with not knowing where to begin when faced with a story problem." Furthermore, Maria, recalling her experiences as an elementary school mathematics student, had difficulty articulating useful problem-solving strategies. In sum, linguistic obstacles and cognitive challenges appeared as the pivotal factors contributing towards her struggles, and these daunting expectations significantly affected her early educational journey.

In contrast to her own experience, Maria envisions her future classroom as a space where all students, especially those learning English as a second language, "are supported with more culturally relevant word problems that they can connect themselves with" and "can read the problems in their own languages." This desire stems from her mathematical identity, the one she has built through her own experiences, and by embracing students' diversity, Maria is committed to creating culturally relevant and inclusive classrooms.

Conclusion

The mathematical autobiographies from the preservice teachers, Nicole, Emily, and Maria, offer compelling insights into the complex interplay among racial, ethnic, and mathematical identities. Through their unique life stories, we sense the multifaceted challenges faced by students from nondominant backgrounds. These challenges, ranging from systemic inequities to cultural expectations to language barriers, highlight the urgent need for a comprehensive, empathetic understanding of the factors influencing mathematical learning.

Nicole's journey exemplifies the transformative power of a dedicated educator. Her story underscores the pivotal role teachers can play in empowering historically underserved students and shows the profound impact of supportive learning environments on individual trajectories. Emily's narrative challenges stereotypes about Asian-American students' mathematical abilities, emphasizing the importance in recognizing individual learners free from cultural biases. Specifically, her experience calls for teacher training that overcomes preconceived biases about learners. Maria's struggles with language ability and mathematical understanding spotlight the relationship between linguistic and cognitive factors in shaping her mathematical identity. Her story stresses the necessity for linguistically sensitive, culturally relevant, educational interventions tailored to meet the diverse needs of students.

These mathematical autobiographies highlight the need for educators and the education system to embrace inclusive, culturally responsive, linguistically sensitive approaches to mathematics education. Nicole's experience with systemic inequalities, Emily's encounter with stereotype challenges, and Maria's struggle with language barriers are pervasive challenges faced by diverse learners. By proactively addressing them through inclusive instructional methods, educators can deconstruct barriers, overcome stereotypes, and create a learning environment where every student feels valued and empowered to seek mathematical excellence. Additionally, the mathematical autobiographies of these three preservice teachers emphasize the pivotal role of teachers in driving social change and equity and formulating a more inclusive, supportive educational framework.

CAPTURING INTERSECTIONALITY?: EXPLORING A METHOD USED TO STUDY THE MATHEMATICS LEARNING EXPERIENCES OF BLACK GIRLS

Missy D. Cosby
University of Tennessee - Knoxville
mdcosby@utk.edu

There has been a rise in the use of intersectionality theory for understanding the complex experiences of mathematics learners with multiple marginalized socially constructed identity markers. This increase calls for an astute examination of the methods of data collection and analyses used to capture such complexity. This study examines a method used to study an aspect of mathematics learning for Black girls to ascertain its viability for characterization as an intersectional approach. While several conditions were met, the well-intentioned design of this research method fell just shy of the classification as an intersectional approach. The results of this examination emphasize the importance of consideration for future intersectional research in mathematics education.

Keywords: Intersectionality, Gender, Research Methods

Introduction

Intersectionality is a construct widely used in social sciences and humanities to understand the complexity of the human experience. Several mathematics education scholars call for it to be taken up in our field to avoid the erasure of the experiences of, for example, girls of color (Bullock, 2018; Gholson, 2016; Leyva, 2017). However, taking up this construct should be done thoughtfully and responsibly and requires attention to our current methods or the development of new or supplemental methods of data collection and analyses. In this paper, I use insights from Crenshaw's conception of intersectionality alongside the guidance from several intersectionality scholars (i.e. Bowleg, 2008; Collins & Blige, 2016; Hancock, 2016) to determine how well a research method that I created meets the challenge of intersectional research of Black girls' mathematics learning experiences.

Intersectionality and its importance as a construct in mathematics education research

Intersectionality is a term coined by Kimberlé Crenshaw, a law scholar, interested in the ways that single axes thinking about race, gender, class, ability, sexual orientation and other socially constructed identity markers can serve to hide or erase the experiences of those at the intersection of these markers. Intersectionality, as an analytical tool, broadens our conception of the social complexities of the human experience where conditions must be understood by many factors in mutually influencing ways (Collins & Bilge, 2016). Crenshaw pays homage to nineteenth century scholars like Sojourner Truth and Anna Julia Cooper who wrote and spoke about the Black woman experience at the intersection of race and gender. Crenshaw states that intersectionality is "about how structures make certain identities the consequence of and vehicle for vulnerability (Southbank Centre, 2016)." An example of this vulnerability is when a company is called to diversify along a single axis such as race or gender and the company meets the requirements by hiring more men of color and more white women effectively making women of color vulnerable. In mathematics education, a parallel example is the failure to disaggregate mathematics achievement data by race x gender assuming that all Black children (race only view) or all girls (gender only view), for example, experience mathematics learning the same and hiding or ignoring the mathematics learning experiences of girls of color when, in fact, scholars studying the mathematics experiences of Black girls have demonstrated this not to be true (Gholson, 2016, Gholson & Martin, 2014; 2019; Joseph et al., 2017).

Intersectional Methods of Data Collection and Analyses

A methodological issue to consider is how one captures or "measures" intersectional experience and could also be how one uses a method to elicit an intersectional experience during data collection. Adequate treatment of intersectionality considers what practices, policies, and institutional structures play a role in contributing to the exclusion of some and not others. Bowleg (2008) takes up this methodological question of measuring intersectionality as she considered what she initially referred to as the "triple jeopardy approach" to studying the stress and resilience of Black lesbian women. Bowleg (2008) grappled with the Black + Lesbian + Woman or an additive approach to the analysis of the data as the additive approach should be replaced by conceptualizing the layered intersectional experience as multiplicative. Reiterated by Wing (1997), "multiply each of my parts together, 1 x 1 x 1 x 1 x 1 and you still have one indivisible being (p. 31)."

Both Hancock (2007) and Bowleg (2008) provide guidance for consideration of a multi-method intersectional approach to research. It is on these dimensions that I will later examine whether or not the card sort is a successful method for studying the intersectionality of Black girls' mathematics experiences.

1. An intersectional approach to research considers the role of socially constructed identity markers alongside individual and institutional factors and should recognize the dynamic interaction between them should be reflected in the analyses (Hancock, 2007).
2. More than one socially constructed identity marker should be examined and each should matter equally, though the relationship between them is an open empirical question (Hancock, 2007).
3. Any questions asked in interviews, surveys, or questionnaires should tap into the interdependence and mutuality of the socially constructed identity markers avoiding any implications that they are separate and able to be ranked (Bowleg, 2008; Hancock, 2007).
4. There should be a focus on meaningful constructs such as stress or discrimination rather than focusing on socially constructed identity markers alone (Bowleg, 2008).
5. And multiple methods are necessary and sufficient for data collection and analysis (Hancock, 2007).

The Identity Card Sort Method and Analysis

Mathematics education has been conceptualized as a racial project (Martin, 2013) and, even further, as a white, patriarchal space that makes explicit how interlocking systems of racism and patriarchy shape intersectional oppression and resistance (Levya, 2021, p. 121)." My primary research interests investigate the interplay between socially constructed identity markers and individual or personal identity markers for Black girls' and women whose socially constructed identities are in stark opposition to the construction of mathematics education as a white, patriarchal space. To this end, I conducted a research study with multiple components and data methods to investigate the racialized gendered experiences of six young Black women (see Table 1).

Table 1. Study participants. All names are pseudonyms. ***PWI = predominantly white institution**

Name	Age	Level in School	Current school	Current math course	College major/career aspirations
Courtney	18	First year university student	Large, public *PWI	College Algebra and Trigonometry (Fall semester)	Political science/Pre-Law
Elissa	18	First year university student	Large, public PWI	Survey of Calculus 1	Pre-med, Human Biology
Janet	18	High school senior	Small, urban, predominantly black, public charter	Precalculus Honors	Veterinary medicine
Kristen	17	High school senior	Mid-sized, suburban, public PWI	AP Statistics	Middle school teacher
Riley	18	First year university student	Large, public PWI		Interdisciplinary Studies in Social Science
Shannon	17	High school senior	Small, single-sex, public, urban predominantly Black, public	Precalculus	English teacher

I devised a method to accompany a semi-structured interview that, at the time, I perceived to be a method to elucidate the function of the young women's intersectional socially constructed identities across space (home, school, and math class) in an effort to ascertain the role race and gender played in mathematics learning for young Black women. That extent to which this method is, indeed, rises to the level of an intersectional approach, however is at question. I wondered, to what degree is this method, the identity card sort, adequate for elucidating the girls' intersectional mathematics learning experiences. So I ask: How, if at all, is the identity card sort representative of an adequate intersectional research method? How, if at all, is the analysis of the identity card sort data representative of an adequate intersectional research analysis? Where might it fall short?

During individual semi-structured interviews, I employed a variation of an activity known as *Diversity Toss* (Jilk, 2010, Nieto & Bode, 2008; Teaching Tolerance, 2014) which required the young women to assign salience to aspects of their socially constructed and personal identity markers as they see themselves or as they interpret others seeing them across various social spaces. Each young woman was given five index cards to record their race, gender, name, a hobby or interest they strongly identify with, and their religious or spiritual affiliation or belief. Once completed, each young woman was asked to place the cards in order based on degree of salience to them when in a particular space (at home, at school, in math class). Cards were placed vertically as indicators of greatest to least salience and could be placed horizontally indicating equal salience at a particular level in a space. Cards could be removed, altogether, if that aspect of their identity had no salience for them in a space. One purpose for this activity was to highlight the multiple dimensions of each girl's identity and the importance of self-identification in identity work (Kemple, Harris, & Lee, 2015; Teaching Tolerance, 2014). It was also used to determine the extent to which young Black women are thinking about the gendered - racialized aspects of their socially constructed identities differently across spaces. During and after card placement, participants were asked about the rationale for their orderings.

Analysis of the identity card sort data included creating graphic depictions of the shifting salience of the various aspects of each young woman's identities across the various spaces (Figures 1 & 2). Since gender and race are dominant structures around which individuals self-identify and co-construct identity (Jilk, 2010) and were the focus of the study, this data was also analyzed through the construction of charts depicting shifting salience of gender and race across spaces (Figure 3 and 4). In the space remaining, I use Hancock's (2007) and Bowleg's (2008) guidance to determine the classification and efficacy of the identity card sort as a multi-method intersectional approach to research.

Identity Card Sort as an Intersectional Research Method

The first two conditions are quite easily satisfied having used multiple methods as the identity card sort was embedded into a semi-structured interview and there being more than one socially constructed identity marker (race, gender, religion) examined all mattering equally. I made the decision to ask the young women to assess the salience of each marker across various spaces and in relation to one another (can be horizontal for equal salience, can be removed if no salience) which Hancock (2007) says is an open empirical question. This aspect of the method and analysis was particularly important in discerning the role of race and gender across space where I found that race was lower in salience (level 2 through level 5) at home for all of the young women and increased in salience for all of the young women in math class. Its salience was at level 1 or 2 for everyone except Janet (See Figure 4). The same was true for gender, though it began with high salience (level 1) for some when at home and maintained or increased in salience across school and math class spaces for five of the girls. For Shannon, gender was not as salient in math class because she attended a single-gender school (See Figure 3).

It is not as clear as to whether the interdependence and mutuality condition is satisfied. I asked the young women about their experiences of being a Black girl in various contexts/spaces. Shifting salience or removing a marker can be interpreted as a treatment of markers as mutually exclusive or independent even if both Elissa and Riley chose to keep their race and gender salience at the same levels in school and in math class. Shifting or removing, however, does not mean it is no longer a part of who they are, it merely means that this aspect of their identity has less (or no) salience for them in these spaces. This notion of salience draws on the situative perspective of identity in relation to activity asking who am I here, who am I here versus there, and who can I become (Hand & Gresalfi, 2015).

The question of ranking is another open question. An explicit question that would violate this condition would be to ask a participant whether racism or sexism played a role in their discrimination or marginalization. The young women were not asked to choose between any of the markers. At any time, a young woman could have chosen to put all five cards horizontally at any level. Elissa and Riley were the only two that chose to use the horizontal function during the activity. And it is important to note that while hobby or religion cards were removed by some of the young women, race and gender cards were never removed. What remains, however, is the question of whether this method rises above ranking when there is evidence that gender and race salience do not both shift together for all participants. It begs the question of what the results of a card sort would be if one card has "Black woman" written on it. Would participants ask about splitting the card to indicate varying salience of race and gender in particular contexts.

The final two conditions to consider are how the method and analysis recognize the dynamic interaction between individual and institutional factors and avoid focusing solely on the markers but on a meaningful construct related to the markers (Bowleg, 2008; Hancock, 2007). While the identity card sort highlights the racialized-gendered nature of mathematics learning spaces for young Black women and focuses on salience of markers in context, specifically the shift from home to school to math class, it fails to adequately address institutional factors. It is very individual focused and does not, in and of itself, implicate any institutional practices or policies of mathematics education complicit in the heighted salience of race and gender for the young women.

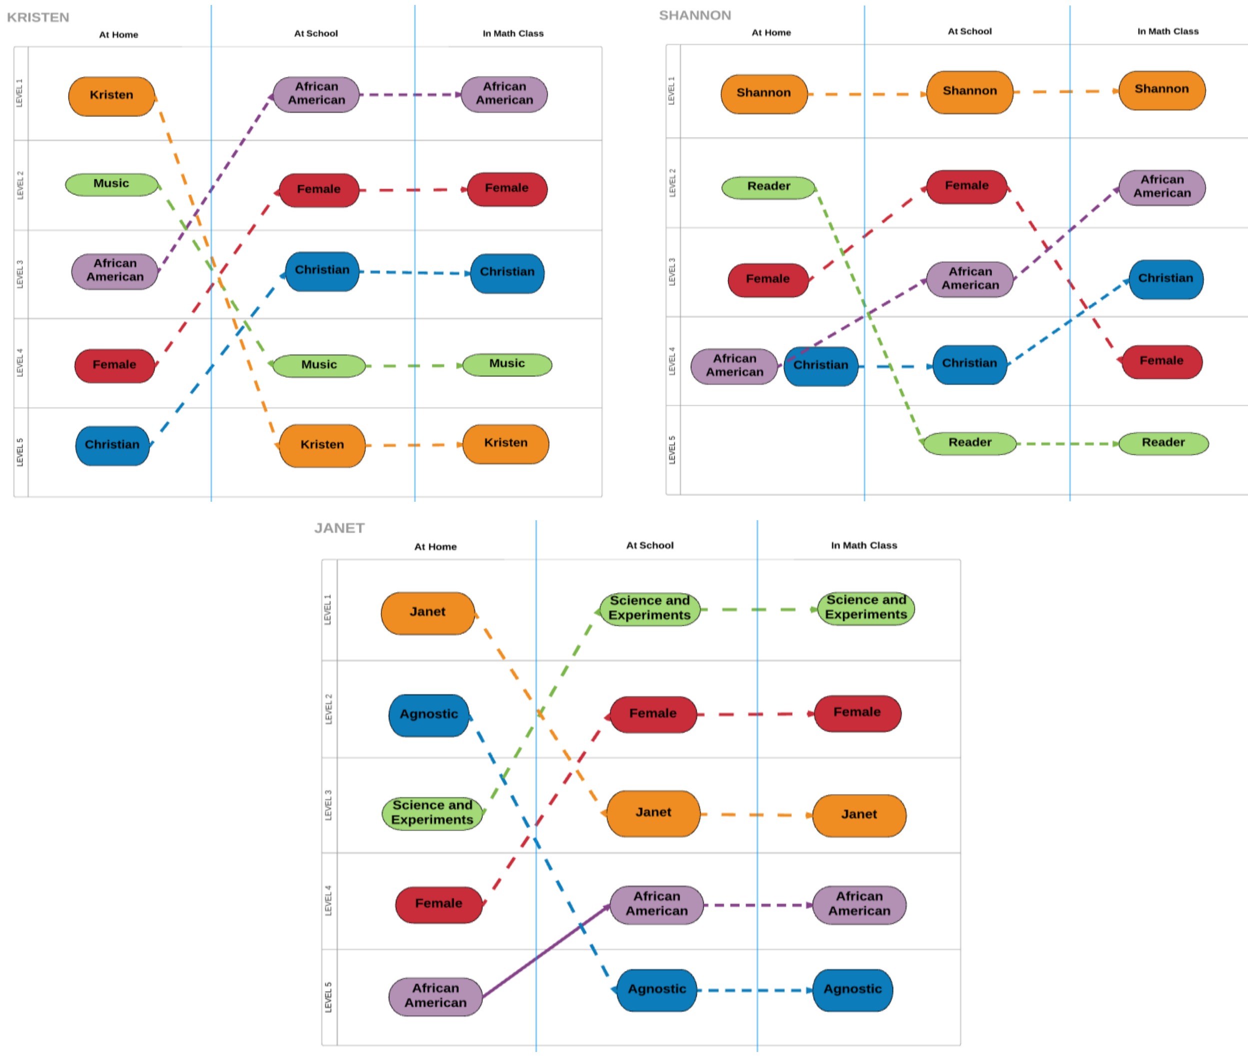

Figure 1: Heterogeneity of the Card Sort Responses for High School Girls

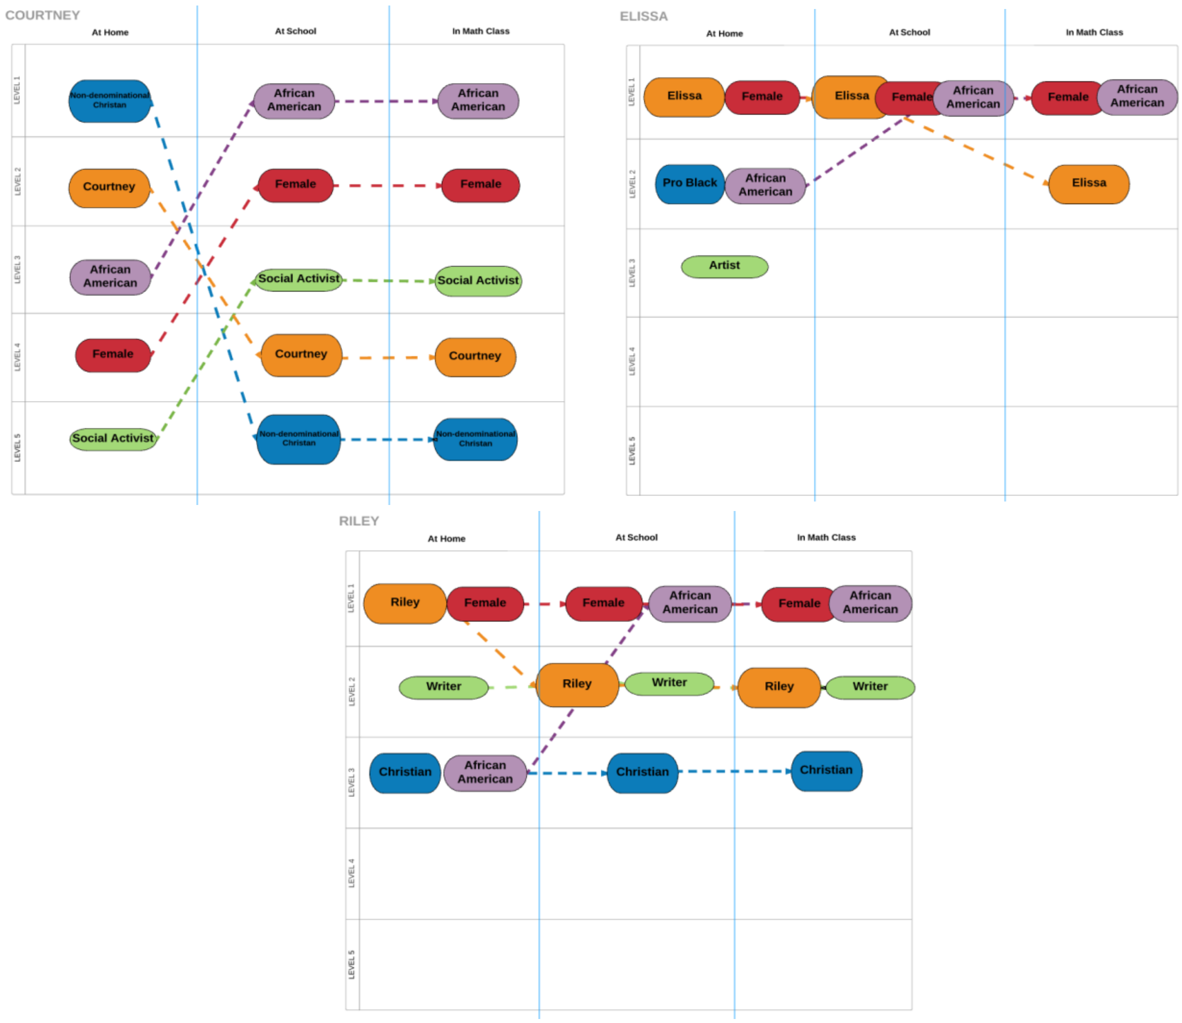

Figure 2: Heterogeneity of the Card Sort Responses for University girls

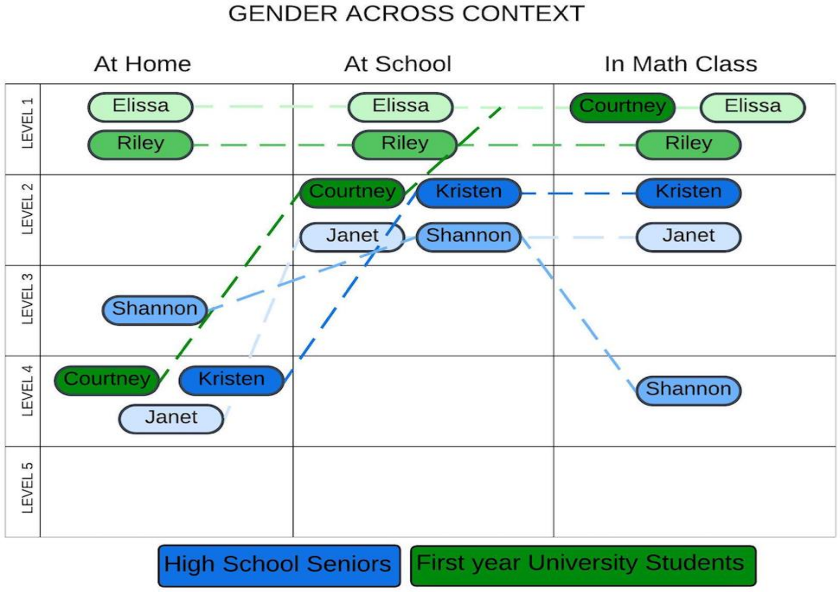

Figure 3: Gender Salience Across Space for all six young women

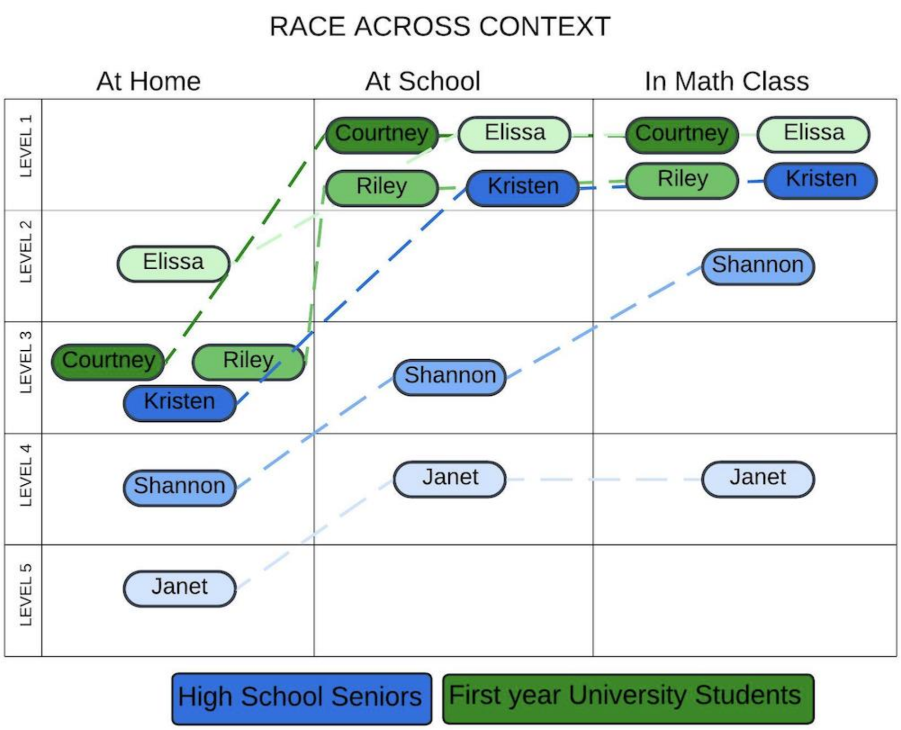

Figure 4: Racial Salience Across Space for all six young women

Discussion and Conclusion

Social theories like intersectionality used to understand the complexity of the human experience, especially those intended to answer complex questions of inequality and justice require careful methodological consideration (Hancock, 2016). It can be difficult to fully hold all of the complexities in singular methods of data collection and analyses which is why scholars call for a multi-method approach. Though progress has been made, the development of research designs and methods to effectively capture/measure or even methods for eliciting intersectionality during data collection remains underexplored (Hancock, 2007) and many researchers proceed labeling methods and analyses intersectional without fully considering to what extent conditions such as those made by Bowleg (2008) and Hancock (2007) are being met. Bowleg's piece, coincidentally, is one for which she examines her own methodological approaches for how well they meet the challenge.

The identity card sort was also, admittedly, conceptualized and employed without prior consideration for its adherence to various aspects of intersectional theory. And this post hoc analysis revealed that the method used in my study fell short concerning ranking socially constructed identity markers as well as lack of consideration for institutional factors. Additionally, a more robust analysis is needed to determine whether the identity card sort in conjunction with or situated within a semi-structured interview would be sufficient. Beyond whether or not the identity card sort qualifies as intersectional research, there is a question about the stability of the arrangements, for example, would a participant respond the same a day or two or even a week later. Nevertheless, there are a myriad of uses for the card sort as a research method, an activity to be done with teachers during professional learning to discuss the role of socially constructed identities in schools, or as a reflective activity for qualitative researchers exploring their positionality. If nothing else, I hope this examination of the identity card sort beacons the mathematics education research community to be more intentional about our approach to intersectional research as we answer the call to explore the mathematics learning experiences and make critical discoveries and changes towards inequality and justice for our most vulnerable learners.

The Limits of Interventions in Promoting Gender Equity in Undergraduate Mathematics Advising

Elena Crosley
University of Michigan
ecrosl@umich.edu

Claudine Margolis
University of Michigan
czmars@umich.edu

Maisie Gholson
University of Michigan
mgholson@umich.edu

Keywords: gender, systemic change, design experiments, undergraduate education.

We use the term *mathematics advising* to describe academic advising programs for incoming undergraduates offered by mathematics departments to guide students toward a decision about which mathematics course(s) to register for. Unlike traditional academic advising, mathematics advising sessions are very short (five to ten minutes) and the advisor and student have not met previously (Grites, 1979). Advisors frequently have little to no training, often unwittingly producing gendered inequities (Gholson et al., 2021; Margolis et al., 2023). We report on the development and implementation of math advisor training designed to disrupt interactional patterns of gendered discrimination. The training curriculum consists of four lessons: *Why Mathematics Advising Matters, The Work of Mathematics Advising, Essential Practices in Equitable Advising, Understanding Your Mathematics Advising Ecology*.

Methods

We address the research question: Which aspects of a mathematics advising curriculum were implemented with fidelity? This work fits within the methodological approach of Design-Based Implementation Research (DBIR) (Fishman & Penuel, 2018). The broad goal of DBIR is to "address differences (both positive and negative) between innovative interventions as designed and as they are actually implemented in practice" (McKenney & Reeves, 2020). We describe the development of the mathematics advising curriculum, outline the curriculum and its implementation, and our fidelity of implementation (FOI) process. To analyze the FOI, we used an integer scale from zero to thee. Zero indicated subsections that were skipped entirely, and one to three indicated content that was implemented with low, medium, or high fidelity, respectively.

Findings and Discussion

We found that out of a total of 11 sections spanning four lessons, there were no sections with a high fidelity of implementation (i.e, FOI of three). The majority of sections (seven) were not implemented at all (FOI of zero). Three sections had a low fidelity of implementation (FOI of one), and one section had a medium fidelity of implementation (FOI of two). Three out of the four sections which included "gender" or "women" in their title were skipped completely (FOI of zero). Despite the commitment of the co-developers from the mathematics department, lessons relating explicitly to gender discrimination were not taken up by the facilitator. We attribute this to a few issues: time constraints in the design process for deep engagement with the curriculum materials, historical time constraints for training sessions within the mathematics department, and aversion to facilitating discussions related to gender discrimination and inequities. Only one lesson, *Lesson 3: Essential Practices in Equitable Advising*, was implemented entirely albeit with low fidelity. These findings suggest that the practices were valued over the motivating rationales for engaging in *appreciative advising* due to gender discrimination. Broaching the topic of gender discrimination is not typical in mathematics department trainings and future iterations of the advice for facilitation need to support discussions of social science research that may be less familiar to mathematics faculty.

AN EXAMINATION OF EQUITY-BASED TERMINOLOGY IN PMENA PROCEEDINGS 1981-2000

Jon D. Davis
Western Michigan University
jon.davis@wmich.edu

This study investigates the frequency and themes appearing in studies involving a collection of equity-based terminology (EBT) in 14 PMENA proceedings from 1981 to 2000. The percentage of EBT waxed and waned, but it was much higher from 1991 through 2000 than from 1981 through 1990. The highest percentage of EBT occurred in 1995 when the conference organizers decided to focus on diversity. Four themes emerged in research reports where EBT appeared: nature of a shifting sample; expansion in equity – 1991; teachers and equity; and policy and project influences. For instance, the sample where EBT appeared shifted from a focus on diversity to identify achievement differences to a focus on minority students to boost their achievement using culture-based interventions. Equity became much more nuanced and subtle in 1991 with an awareness that other factors such as societal racism influence student achievement.

Keywords: equity, inclusion, and diversity

The research trajectory focusing on equity in mathematics education has seen significant shifts over the decades, with an increased emphasis in recent studies. The current analysis specifically examines the integration and evolution of equity-based terminology (EBT) within the proceedings of the North American Chapter of the Psychology of Mathematics Education from 1981 to 2000. This study utilizes a dual approach: quantitatively tracking the fluctuation of EBT as a percentage of the total pages in the examined proceedings and qualitatively identifying prevalent themes and trends concerning EBT. This approach is set against a backdrop of broader trends in mathematics education research and equity-focused studies reported in other scholarly works.

In their broader historical analysis, Inglis and Foster (2018) explored the thematic evolution in prominent mathematics education journals since their inception around the late 1960s and early 1970s, noting a decline in Euclidean geometry studies and a rise in sociocultural theories from the 1990s onward. This period also witnessed a diversification of theoretical frameworks, including semiotics and embodied cognition, and a move away from experimental methods that dominated the 1970s. Hanna and Sidoli (2002) documented shifts in the focus areas of the *Educational Studies in Mathematics* journal, highlighting the growing importance of problem-solving, cognitive issues, and social factors, alongside a variable emphasis on gender and ethnicity research across the decades.

Extending this perspective to more recent developments, Vithal, Brodie, and Subbaye (2024) reviewed equity research in mathematics from 2017-2022, observing that conceptualizations of equity have notably broadened to emphasize identity, power, recognition, and representation. They highlighted that a significant volume of studies now focuses on the mathematical practices and teacher actions within specific classrooms and schools aimed at addressing inequality. Additionally, they noted that international studies have shed light on how societal inequalities impact and are reflected in student achievement within school systems. The narrative of shifting research priorities is further supported by the findings of Gökçe and Güner (2021), who analyzed over a thousand articles to identify evolving research interests from problem-solving initially to later emphases on technology, teacher training, and equity, particularly from the 2000s onward. This shift is also seen in the resurgence of equity as a focal research theme, encompassing issues of motivation, attitude, and demographic impacts on educational outcomes.

Meanwhile, Parks and Schmeichel (2012) identified significant obstacles in addressing race and ethnicity within the domain, pointing to systemic issues like the marginalization of race discussions and the oversimplification of racial categories in research settings. Two key research questions emerge from this historical context: How does the frequency of equity-based keywords vary in 14 proceedings from 1981 through 2000? What themes appear in research studies involving EBT in these proceedings?

Methods

The research focused on analyzing equity-based terminology (EBT) within the proceedings of the Psychology of Mathematics Education North America (PMENA) meetings from 1981 to 2000, where electronic texts were available for searching. Specific annual meetings selected for study included years from 1981 through 2000, with a few exceptions due to the availability of searchable texts. The terms examined encompassed a wide array of EBTs such as "African," "equity," "socio," "race," "ethnic," "justice," "disab*," "gender," "diversity," "equality," "cultur*," "identity," and "ethnomathematics." Certain proceedings required conversion into searchable PDF formats due to their initial unsearchable state, facilitating a comprehensive textual analysis.

For the purposes of this study, the analysis unit was a single page within the proceedings documents. EBTs were only counted if they appeared in the narrative sections of the texts, such as plenaries, research reports, and discussion groups, which involved original research or theoretical synthesis. Mentions in the table of contents or reference sections were excluded from the count. The methodology involved calculating the total number of pages featuring EBT and then establishing the percentage of these pages in relation to the total number of relevant pages in the proceedings, adjusting for non-English sections and introductory content. Instances of multiple EBTs on the same page were treated as distinct occurrences, while repeated mentions of the same term on a page were not double counted.

Each identified page was then coded for thematic analysis. The coding process started from specific sentences containing EBTs and expanded outward to include broader textual contexts. Although pages featuring terms related to gender and culture were included in the quantitative count, they were not thematically coded. The resultant codes were compiled into documents for each proceedings year, facilitating the examination of broader thematic trends across the analyzed periods. This detailed approach provided insights into the evolution and focus of equity discussions within the field of mathematics education over the studied years.

Results

Quantitative

The frequency and prevalence of equity-based terminology (EBT) in PMENA proceedings show notable fluctuations from 1981 to 2000. Beginning in 1987, researchers started focusing significantly on cultural, gender, equity, and racial issues, with these topics gaining momentum and peaking in interest in 1991. This peak aligns with broader research trends identified by Inglis and Foster (2018), indicating a growing interest in cultural aspects within the field. The year 1995 marked the highest emphasis on EBT, particularly terms related to equity, race, gender, and culture. This surge was influenced by the conference's theme centered on diversity and varied educational settings, leading to a considerable presence of these terms in the academic discourse. However, the focus shifted away from diversity in subsequent years, with a notable decrease in the mention of these terms by 2000, reflecting a shift in thematic focus within the proceedings towards other aspects of mathematics education research.

Qualitative

Nature of a Shifting Sample

The collection of proceedings documents predominantly highlighted the use of diverse samples in educational research to examine various aspects of mathematics education, ranging from students' math capabilities to the effectiveness of specific interventions. These samples, often detailed by race, gender, SES, and less frequently by language or disability labels, were instrumental in studies such as Bell & Burns (1981) and Izsák & Fuson (2000), aiming to understand phenomena or test educational models. However, despite the diversity of the samples, it was less common for results to be disaggregated by these diverse groups, with studies like Armstrong (1989) not exploring the underlying causes of differential achievements noted by Brown & Wheatley (1990). The 1990s saw a refined focus on particular student groups, including minority and low SES students, to address specific educational disparities or enhance understanding of their mathematical capabilities, as seen in the works of Presmeg et al. (1995) and Mousley (1990). This period also noted a cultural integration into educational strategies, aiming to leverage students' backgrounds for educational gains, exemplified by Ayers et al. (1998) and Neves & Fraga (1987). Interestingly, while student diversity was frequently acknowledged, the diversity of teachers was seldom addressed in these studies.

Expansion in Equity – 1991

The 1991 academic proceedings indicate evolving themes regarding educational equity, particularly in the context of Black students' achievement. Researchers like Ajose (1991) highlight the multifaceted influences beyond familial factors, including the mathematics curriculum, teacher biases, and classroom dynamics, which shape Black students' educational outcomes. Campbell, Benson, Bamberger, and Hutchinson (1991) counter deficit narratives by emphasizing minority students' valuable informal knowledge applicable to real-world problem-solving. The impact of societal racism on school processes and student achievement is underscored, drawing from Eisenhart’s (1991) anthropological insights into cultural effects on education. Additionally, there's growing awareness of how research might inadvertently normalize deficits, with Kamii (1991) cautioning against overgeneralizing her findings across socioeconomic statuses, while Campbell et al. recognize early educational assets in minority kindergartners, laying groundwork for future equity-focused research that includes considerations of Black students' identities.

Teachers and Equity

The 1995 proceedings and subsequent research highlighted the pivotal role of teachers in promoting equity in mathematics education. Studies from the mid-1990s to early 2000s, including those by Tharp and Lovell (1995), Santa Cruz and McLeod (1996), and others, observed how preservice and practicing teachers conceptualize and implement equity. Tharp and Lovell identified four stages of development among preservice teachers' understanding of equity, noting a concerning trend where only a small fraction reached the highest stage of recognizing equity as a complex, interactive process vital for enhancing students' mathematical understanding. Similarly, Becker, Pence, and Pors (1995) and De La Cruz (1995) examined the impact of policy initiatives and teacher preparedness, finding gaps in readiness and implementation, particularly with non-Spanish-speaking teachers working with Spanish-speaking students. Later research by Fuson, Sherin, and Smith (1998) and Hodge (1998) developed models linking equity and pedagogy, pointing out that equity concerns are magnified under reform-oriented teaching practices. Edwards (1999) and Riggs (2000) further examined the dynamics within bilingual and minority-focused educational settings, emphasizing the need for pedagogical support and role models to effectively foster equity. Collectively, these studies underscore the challenges and importance of equipping teachers to advance equity in mathematics education.

Policy and Project Influences

The period from the 1990s to the present has been influential in shaping mathematics education through the lens of equity, marked by the introduction of the *Curriculum and Evaluation Standards for School Mathematics* (hereafter referred to as *Standards*) by the National Council of Teachers of Mathematics (NCTM, 1989). Starting with these standards, which emphasized equity alongside educational accountability, subsequent research and educational projects began to incorporate these principles. Notably, it took several years for equity-focused studies to emerge in academic discourse, as evidenced by their inclusion in the PME-NA proceedings from the late 1990s. Research during this period, such as Tharp and Lovell's (1995) examination of preservice teachers' perceptions of equity, Kaplan's (1997) study on language minority students, and Presmeg's (1997) exploration of cultural influences on classroom mathematics, underscored the ongoing impact of the *Standards*. Moreover, initiatives like Equity 2000 and the San Diego Project Leadership Institute further propelled equity to the forefront of educational reform efforts, inspiring studies and curriculum developments that integrated these values at both state and national levels.

Discussion

The study analyzes the presence of evidence-based teaching (EBT) in the PME-NA Proceedings from 1981 to 2000, highlighting a noticeable increase in discussions related to equity, especially in the 1990s compared to the 1980s. During the earlier decade, EBT constituted a smaller fraction of the proceedings, peaking at 40.8% in 1995, a year particularly focused on diversity. Discussions during this period nuanced the use of race in research, initially employed to assess human capabilities and curriculum viability, and later to explore differential academic achievements among students. Interestingly, race was frequently mentioned at the beginning of studies to describe student samples but was seldom used to describe teachers, indicating a narrow focus on student outcomes without considering how teacher identity might affect educational practices. Additionally, while race often surfaced in concluding sections through the disaggregation of achievement data, it was rarely integral to the analytical processes or explanatory discussions within the studies.

Further complicating discussions around race in the 1991 Proceedings, research began to challenge deficit narratives associated with minority students by considering broader influences on their mathematical achievement, such as teacher attitudes and societal contexts. This shift was part of a broader trend during the decade, as seen in national policy initiatives and projects like Equity 2000, which influenced studies on instructional strategies that align with students' cultural backgrounds. This period also saw researchers like Ayers et al. (1998) investigating the integration of students' funds of knowledge into their mathematical learning, indicating a growing commitment to addressing equity in mathematics education, setting the stage for further exploration into these themes in the new millennium.

TWO COMPETING STORYLINES THAT INFLUENCED STATUS DURING SMALL GROUP PROOF ACTIVITY

Brittney Ellis
Texas State University
b_e107@txstate.edu

Tenchita Alzaga Elizondo
University of Texas Rio Grande Valley
hortensia.alzagaelizondo@utrgv.edu

Dominant narratives about what it means to write and do mathematics influence who typically gets viewed as competent in proof activity. In our ongoing work to explore interaction patterns that maintain (legitimate) or disrupt (delegitimate) mathematical status hierarchies while students collaborate on proof-related tasks, we applied positioning theory as an analytic lens. From this analysis we observed two storylines about what it means to engage in proof activity that influenced status: the Informal Language and the Formal Language storylines. This brief report contributes an image of how these storylines influenced mathematical status among three students while they worked on proving a statement in an intro-to-proof course over Zoom.

Keywords: Undergraduate Education, Equity, Inclusion, and Diversity, Reasoning and Proof

Dominant narratives about what it means to write and do mathematics influence who typically gets viewed as competent in proof activity (Weber & Melhuish, 2022). Proof-based courses are predominantly taught by (mostly white) men and the majority of students who take them are men (Blair et al., 2013), making these spaces vulnerable to dominant narratives such as 'doing mathematics' reflects 'doing masculinity' (Jaremus et al., 2020; Leyva et al., 2017; Mendick, 2006) and privileges whiteness (Battey & Leyva, 2016; Martin, 2019) and Eurocentric perspectives (Rowlands & Carson, 2002). Such narratives can influence who gains higher status and power as students engage in proof activity, which can (re)produce inequitable mathematical status hierarchies in proof-oriented classrooms. By using positioning theory in our ongoing efforts to identify interaction patterns that maintain (legitimate) or disrupt (delegitimate) mathematical status hierarchies while students collaborate on proof-related tasks (e.g., Ellis & Alzaga Elizondo, 2023; Ellis et al., 2024), we have observed two storylines about what it means to engage in proof activity that seem to have an effect on mathematical status (defined in the next section): the Informal Language and the Formal Language storylines. This brief report contributes an image of how these storylines influenced three students' relative mathematical status while they worked on proving a statement in an intro-to-proof course.

Theoretical Perspectives

Perceptions of status can impact how students communicate, and thus learn, while working in groups (Cohen & Lotan, 2014; Esmonde, 2009). Generally, 'status' can be viewed as a relative position that is widely accepted as advantageous; status is not fixed or inherent, yet exists within a relative ranking system (Cohen et al., 1999; Ridgeway, 2018). In classroom contexts, 'academic status' refers to perceptions of who is "smart" (e.g., answers questions in class) and 'social status' refers to perceptions of social standing (e.g., popularity). Then, 'diffuse status characteristics' exist within and beyond classroom contexts and refer to discernable identity features by others, such as race (via skin color) or language use (via intonations or accents), gender expression, and ability status. We use the term 'mathematical status' to mean a student's relative position among peers in the context of doing mathematics, which likely involves a complex combination of academic, social, and diffuse characteristics. Interaction patterns that maintain/disrupt mathematical status hierarchies are difficult to identify; therefore, we turned to positioning theory for analytic tools to investigate such phenomenon.

Positioning theory describes social interactions in terms of communication acts, storylines, and positions as rights and duties (Harré, 2012; Herbel-Eisenmann et al., 2015). *Communication acts* include the interpretive meanings conveyed by verbal and nonverbal discourse. Interactions in human life "tend to follow already established patterns of development" (Herbel-Eisenmann et al., 2015, p. 188) called *storylines*. Storylines are continual repertoires that can be commonly shared (such as cultural norms, beliefs, and values) and can reflect expectations and conventions that relate participants according to available positions, or rights and duties. *Positioning* is thought of as a fluid unfolding of communication acts (via discourse) that organize social structures by situating people in dialogue as participants in mutually constructed storylines (Davies & Harré, 1999; Herbel-Eisenmann et al., 2015). Power relations fluctuate based on interactions and available positions, and so situations will never be 'status-free' or fully 'equitable'. However, we assert that situations in which status hierarchies are legitimated likely amplify inequities, while situations where status hierarchies are delegitimated likely attenuate inequities, with *in*equities defined as situations that prevent access to resources needed for learning (Shah & Lewis, 2019).

Methods

The data for this study comes from a larger project that designed and implemented inquiry-oriented intro-to-proof curricular materials. Given that issues of status and power likely arise in inquiry classroom contexts (Battey & McMichael, 2021), this project provided a rich context to study how status hierarchies impact student-student interactions. Data from an intro-to-proof class taught in a U.S. urban public university synchronously over Zoom was used for the present study. Justin (white man), Abigail and Alison (white women), worked together to complete a proof of the statement: An element of a group appears at *most* one time in each row of its Cayley Table. Students used a shared Google Doc while they discussed ideas verbally over Zoom. Video screen recordings simultaneously captured students' Zoom and Google Doc activity.

Screen recordings were used to create multimodal transcripts (Hoffman, 2019), coordinating verbal and nonverbal Google Doc activity. This was critical for our analysis because students often used their Google Doc activity to supplement their verbal discourse (Alzaga Elizondo, 2022). The multimodal transcripts were parsed into utterances and exchanges, in which utterances were taken as complete thoughts distinct from each other based on content, intonation, and/or pausing. Exchanges were the primary unit of analysis, defined when at least two participants were interacting at the 10^2 (seconds to minutes) timescale (see Herbel-Eisenmann et al., 2015 for Lemke's timescales). A transition between exchanges was based on topic shifts. Then, to apply positioning theory constructs, we collaboratively rewatched video segments of exchanges and recorded observations of possible meanings underlying discourse (communication acts), storylines, and available positions (rights/duties).

Preliminary Results

Abigail, Alison, and Justin's mathematical proving activity in this episode was collaborative overall (Alzaga Elizondo, 2022), yet our positioning analysis revealed a mathematical status hierarchy that ultimately positioned Justin higher relative to Abigail and Alison. While several processes contributed to this positioning, in this preliminary report, we focus on the observed evidence of two competing storylines in relation to mathematical status: the Formal Language storyline reflected a "right" or "proper" way to "do proofs" that required validation by an expert authority, while the Informal Language storyline reflected the value in creativity and problem solving in "doing proofs." The excerpts presented here highlight the emergence and influence of these storylines regarding the students' relative mathematical status.

Exchange 1 – Justifying a Line in Their Proof

Prior to this exchange, the students drafted a proof that read "AQ=B and AW=B, where Q and, W, and A are symmetries, then AQ=AW, then Q=W." The instructor commented that they should justify the last line of the proof. Justin made the following suggestion:

> Justin: I'm not sure if he'd *allow* us this but I think we might be able to do *this* (starts typing "A^-1" on a line above their proof) […] but if we do A inverse, does that *show* that it's supposed to be the opposite of A?
>
> Alison: (smiling) I feel like that's getting ahead of where we're at
>
> Justin: yeah that's also (laughing) kinda why I didn't want to do it (deletes "A^-1")

In lieu of using a "formal" inverse rule, Abigail drafted an informal justification for why AW=AQ implies W=Q, writing "if you perform an identical symmetry as a first step you start with an identical symmetry." Meaning, AW and AQ are identical composite symmetries that begin with performing the symmetry A. Since the first step is identical, the second step (i.e., performing W and Q) must also be identical (i.e., W=Q). Abigail followed with the disclaimer:

> Abigail: (descending tone) I don't know how to do anything formally I'm just so, (cross talk) I don't know, if this was my proof that's probably what I'd put but I know it's not formal.
>
> Alison: I think we're not doing a super formal proof right now anyway so it's alright.
>
> Abigail: (smiling) yeah I don't think so either.

This exchange provided evidence of how the two storylines emerged from the small group interaction. Before suggesting a formal rule, Justin expressed the concern that it might not be allowed ("I'm not sure if he'd allow us this"), which signified a reliance on an external authority to validate their justification. In contrast, Abigail offered an informal justification, explicitly stating that she knew it was "not formal" and that she doesn't "know how to do anything formally." Alison acknowledged that they were "not doing a super formal proof" and Abigail agreed, potentially uplifting the value of using informal language in proofs.

Exchange 2 – Justin Positioned As Expert

Prior to the next exchange, the instructor hinted to the entire class that they should come up with an inverse rule (i.e., AA^-1 = I) to complete the proof. Upon re-entering the breakout room to continue working in their groups, the following exchange occurred:

Justin: I'm annoyed (cross talk) It's inverse [...] the first thing I said was right. (laughing) we're like "oh we don't wanna do that, it's too complicated" go back "hey (cross talk) you wanna use the inverse"

Alison: no we didn't say it was too complicated. I thought it was gonna be too early (types "then (A^-1)AQ=(A^-1)AW")

Justin: that's what I meant though (laughing) (under breath) it's just like (laughing) uh I had it right at first. (cross talk) uh we need to add the rule.

Abigail: so we just have a rule?

Justin: (speaking quickly) the rule is super easy to make it's A to the power negative one times A equals (inaudible) and then you (inaudible cross talk) use the 1S equals S which is equal to S1 and you get S equals S.

This exchange provided evidence of the Formal Language storyline influencing the emerging mathematical status hierarchy among the students. Justin referenced that he had the "right" idea originally, which evoked the Formal Language storyline: there is a "right" or "proper" way to "do proofs" that can be validated by an expert authority. We interpreted this communication act as implicitly undervaluing their previous informal justification. He then communicated that their prior apprehension around adding an inverse rule was "too complicated" yet the instructor confirmed "you wanna use the inverse." Aligning himself with the "right" way based on the instructor's direction positioned Justin with expertise, increasing his mathematical status relative to Alison and Abigail. Almost interrupting Justin, Alison corrected him by countering that they did not think his idea was "too complicated," they were unsure whether they could use it. We interpreted this communication act as a reference to the inquiry nature of the course where students and the instructor built up mathematical tools (i.e., the inverse rule) to use. Justin agreed with Alison and continued to express that he "had it right at first." Abigail and Justin both mentioned they needed to "add the rule" which Justin quickly responded with how to write the rule symbolically. A possible interpretation of the immediacy in his speech is that adding the rule was trivial or "easy" ("the rule is super easy to make"). This exchange highlights the competing nature of the Formal and Informal Language storylines as Justin repeatedly stated he had the "right" answer (elevating his status) while Alison negotiated a lower status positioning by defending their informal strategy.

Discussion

This preliminary report contributes evidence of two competing storylines about what it means to engage in proof activity that impacted three students' relative mathematical status as they collaborated on drafting a proof. The Formal Language storyline reflected a "right" or "proper" way to "do proofs" that required validation by an expert authority. In contrast, the Informal Language storyline reflected the value in creativity and problem solving in "doing proofs." We argue that the Formal Language storyline likely influenced mathematical status by elevating Justin's "right" idea and momentarily lowering Abigail's and Alison's mathematical status. We do not want to imply that the Informal Language storyline is better than the Formal Language storyline; however, we do want to point out that "doing proofs" (engaging in proof activity) includes both formal and informal language, yet over privileging formal language may maintain imbalanced mathematical status hierarchies (e.g., Adiredja, 2019). We also acknowledge that all three students in the episode identified as white. Further analysis may evidence gendered differences in the relative positioning between the students, and future analysis of different episodes should take into account whether and how positioning relates to racialized hierarchies of mathematical ability (e.g., Martin, 2009).

One implication of this work relates to what it means to "do proofs" and how this meaning is communicated to students in proof-based courses. Some research has shown that students' perceptions of and approaches to proof can be both logical and creative and meaningful for them, especially when they experience problem-based proof courses (e.g., Smith, 2006). Communicating the value in both informal and formal language in proof activity may serve as a way to disrupt mathematical status hierarchy formation arising from these competing storylines.

In this conceptual paper, we position mathematics education as a public thing (Honig, 2017) and explore the consequences of acknowledging and investing in mathematics education as such. We propose that in embracing and insisting on mathematics education as a public thing, researchers must understand mathematics education as a joint investment in the human activity of mathematics and in democratic practices of living together within the sociopolitical sphere as formatted and shaped through mathematical activity. Drawing on an empirical example of organizing against school closures in central Texas, we call for mathematics education researchers to attend to mathematics in adjacent landscapes.

Keywords: Research Methods; Systemic Change; Equity, Inclusion, and Diversity; Policy

In this paper, we position mathematics education as a public thing (Honig, 2017) and explore the consequences of acknowledging and investing in mathematics education as such. We propose that in embracing and insisting on mathematics education as a public thing, researchers must understand mathematics education as a joint investment in the human activity of mathematics and in democratic practices of living together within the sociopolitical sphere as formatted and shaped through mathematical activity (Skovsmose, 1998). As such, mathematics education researchers are positioned as people who (must) care for and deliberate over mathematics education as a public thing. Drawing on an empirical example of parent and community organizing against school closures in central Texas (Gómez Marchant et al., 2023a), we call for mathematics education researchers to attend to mathematics in adjacent landscapes–landscapes of public life that exist beyond school or classroom walls, such as those of civic engagement.

Democracy, Civic Engagement, and 'Public Things'

Honig (2017) argued "democracy is rooted in common love for, antipathy to, and contestation of public things" (p. 4). Public things are public goods or objects (e.g., roads, libraries, utilities, universities, parks, railways, schools) with which individuals in communities construct relational attachments of care and concern that define the use and maintenance of these objects. *Civic engagement* then describes participation in communal life entailing the negotiation of use and relations with public things. Honig (2017) proposes democracy cannot exist without public things because public things create a space of coming together and deliberation. In this sense, people's civic engagements are over public things. Public things are part of the 'holding environment' of democratic citizenship; they furnish the world of democratic life…. Also constitute us, complement us, limit us, thwart us, and interpellate us into democratic citizenship. (Honig, 2017, p. 5). For example, memories of a childhood street, neighborhood, parks, or cities are imbued with affective and identity defining aspects. If the public things one civically identifies with are sufficiently threatened, then one may be motivated to stronger degrees of civic engagement. Knight Abowitz (2018) demonstrated how public education is a public thing when Betsy DeVos' nomination (and eventual confirmation) as Secretary of Education was seen as an attack on public schools because of her history of advocacy for privatizing education. The possibility of education no longer being a public thing became more likely. Consequently, DeVos' nomination activated many to protest and civically engage to a degree not seen before for a nomination to Secretary of Education (see Brown, 2017; Garcia, 2017; Knight Abowitz, 2018). Recognizing schools as public things also provides explanatory power to why school closures have been described as experiencing a social or civic death (Johnson, 2012). A school being closed destroys a community's relational attachments to a public thing.

Mathematics Education as a Public Thing in a Landscape of Racialized Contestation

Public things, including schools, are not immune to inequities. Instead, Honig (2017) warns, "Any successful public thing presents us with this problem: the public things that constitute the demos exclude some and privilege others. In the United States, what is called 'public' is sometimes white, sometimes black; it is rarely both" (p. 24). Bell (2004) and Justice (2023) demonstrate how a (white) public education system became a public thing accessible to Black learners after *Brown v Board of Education* required the desegregation of public schools. Both authors emphasize how schools remained white and violent towards Black learners. San Miguel (2001) showed how public education as a public thing was limited for Latinx children, particularly through the use of language as a proxy for race (Cervantes-Soon, 2014; Garcia & Otheguy, 2017). The history of public education as a public thing for Black, Indigenous, Latinx, and other minoritized populations in the United States warrant Honig's (2017) claim: "when public things *are* democratized, the response of the powerful is often to abandon them. White flight is not just from the urban to the suburban; it is from the public to the private thing" (p. 24, emphasis in original). Public things then are surveilled and policed asymmetrically to the benefit of white people (Keyes et al., 2023). These acts are warranted through discourses of access, maintenance, concern, and care for schools (see Justice, 2023; Keyes et al., 2023).

Schooling as a public thing is part of the United State's racial project (see Gutiérrez, 2001; Justice, 2023). As Justice (2023) argued, the public in public goods describing schools and other social goods was for the benefit of whites: "It can be misleading when historians today identify points in the past when writers intoned words like 'the common good' or 'the public good' as a way to suggest that schooling was for everyone's equal benefit. It wasn't" (p. 157). When the relational attachments become strained or points of tension, then individuals are activated to participate in the destruction or maintenance of the public thing. Esparza (2023) provides an example of a Mexican and Mexican-American community in Texas that developed their own community public school district (public thing) in resistance to the white schools they were not allowed to attend. The Mexican and Mexican-American community worked together to organize, create their own relational and affective nodes with a dedicated school space, to develop policies and regulations to maintain their public thing. Eventually, however, policies developed by the greater governing body of the city and state education agency destroyed the Mexican and Mexican-American community schools and maintained white's ownership of public things.

Mathematics education researchers (see Bullock, 2019, 2023; Gutiérrez, 2018; Martin, 2003, 2019) have highlighted parallels to the 'goods' Justice described within *mathematics for all* statements. Mathematics and mathematics education is complicit in the racial project schools engage in (see Bullock, 2019). Mathematics as a public thing "press[es] us into relations with others" (Honig, 2017, p. 6). As such, the 'for all' discourses provide a false promise of access and public-ness to mathematics education. Policy and regulations benefiting those most adjacent to whiteness surveil and police who gets to learn mathematics (see Morton & Riegle-Crumb, 2019), when is someone doing mathematics (see Dowling, 1991; Lundin & Christensen, 2017), and what is mathematics (see Thanheiser, 2023). We continue our thought experiment by acknowledging that mathematics education as a public thing has always been contested through the emphasis of academic mathematics—a sphere of mathematics defined by (white) gatekeepers (e.g., standards; Eurocentric ways of thinking about mathematics). We call for mathematics education researchers to care for mathematics education as a public thing through pursuing sociopolitical mathematics activity and research in adjacent landscapes.

Mathematics as Human Social Practice and Formatting Democratic Life

Whereas we treat mathematics education as a public thing (a noun), we understand mathematics itself as an activity (a verb) describing human social practices related to organizing and modeling space and time, number, pattern, magnitudes, etc., in manners both concrete and abstract, particular, and generalizable (Dowlings, 1991; Skovsmose, 1998; Thanheiser, 2023). Specifically, we draw on a social theory of numeracy (Craig & Guzmán, 2018), extending it to mathematics broadly, wherein mathematics is understood as a human social practice embedded in, responding to, and organizing social-political-historical landscapes. "Numeracy is not a mathematical ability, but instead, the social ways in which people engage that ability. Numeracy is therefore motivated by broader concerns for social goals and mathematical ability is strategically employed because numeracies are purposeful" (Craig & Guzmán, 2018, p. 14).

Skovsmose (1998) described how mathematical activity underlies social and political life, through its role in structuration (Giddens, 1984), calling this the "formatting power" of mathematics. From a US historical perspective, for example, Cohen (2003) traces how the original US Constitution defines the conditions of democracy through approaches to counting and distribution of representation that structure access and participation including the 3/5th rule that counted enslaved individuals as less than full humans but used their presence to increase the political representation of the enslavers. Hacking (2015) traces the emergence of statistics and related possibilities of census collection for population management as creating categories of personhood individuals are then interpolated into. The post/modern state treats individuals and communities as a resource to be managed through counting and sorting (Scott, 2020). Today, even as "science" is under popular contestation, policy discourse continues to call on data and numbers to lend legitimacy to argumentation (Mudry, 2009). Even in equity discourse, mathematical models of equity (Tate et al., 1995) are likely to dominate, even or especially, when they may silence evidence of human relations and the human condition (Gómez Marchant et al., 2023a).

Investing in mathematics education as a public thing means deliberating over the content (what is un/seen as mathematics; see Gutiérrez 2018; 2023) and contexts (where and when mathematics is happening; see Gómez Marchant et al., 2023b). Understanding the public-ness of mathematics education entails attending to the mathematical activity that formats, structurates, and drives public life and deliberation, if often in invisible ways. Skovsmose refers to this type of research as a form of “mathematical archaeology” (1998), an excavation of those mathematical activities that are or can become “frozen” into technologies, decision-making practices, or other aspects of public life not often recognized as explicitly mathematical. We refer to research examining the mathematical activity of life beyond schools as mathematics education research in adjacent landscapes. Next, we share an example from our own current and ongoing research.

An Example of Research in Adjacent Landscapes: Organizing Against School Closures

At the December 2022 Sunny Field Independent School District (SFISD) school board meeting, the administration presented seven proposed plans to close two to three elementary schools due to the changing property values and inflation, decreased enrollment, and state legislative failure to increase the basic allotment per learner. A group of mostly white parents and community members began to organize to push back on the district's proposals for closing their predominantly Latine and Black schools. Two members of the research team acted as participant observers (Spradley, 2016) in the organizing efforts of the parents, collecting audio and fieldnotes at community meetings (Emerson et. al., 2011), and conducted oral history interviews (Portelli, 2018) with several members of the group.

In describing and reflecting on the district’s handling of, and their own participation in organizing against, potential school closures, parents highlighted multiple forms of mathematical activity including 1) the district’s mis/management of data to explain and justify the need and targeting of schools for closure, 2) parental re/narrating of the school closure story through the surfacing and circulation of different data, 3) parental critique and rejection of numbers and data as meaningful or sufficient in representing children, family, and community relations with schools, and 4) parental awareness and critique in relation to the exclusion and underrepresentation of Latine voices in district hosted meetings and in parental organizing. Parent, Fiona (pseudonym), evidenced each of these, as she explained the motivation and consequence of using *Freedom of Information Act* requests to obtain data from the district.

> [The district] had <u>data that supposedly encapsulated</u> the fact that they were going to take equity into account. And then that was later used in a very different way–the word equity … Like if you're being moved to another school, then we'll make sure that <u>it's kind of the same socioeconomic status</u>…but the <u>only things that was talked about was maps, capacity</u>…none of it was like any of the stuff <u>that we later collected and put on a giant spreadsheet and was like, let's get a real look at the schools</u>…they had this list of reasons why you were being closed, but then <u>they didn't actually have data that matched that</u> (Fiona, Interview, 0:33:14)

The spreadsheets parents created gave them the opportunity to interpret the data the district was using in their decision-making processes and provided them a different picture of the schools set to close which they later shared with others at community meetings.

Conclusion

Positioning mathematics education as a public thing centers the sociopolitical nature of mathematical activity in our everyday lives; consequently, placing the responsibility on mathematics education researchers to care for and be concerned for the public nature of mathematics education. Mathematics education has been a part of laws, policies, and regulations that have harmed and oppressed (see Bullock, 2019; Cohen, 2003). As such, mathematics education researchers are complicit in a sordid history. To show care for and recuperate, our work as mathematics education researchers must intentionally, respectfully, and cautiously transgress the boundaries of our comfort within educational landscapes. Mathematics education researchers must themselves become activated to the political and care for our public things.

The authors share their experience creating sonic constructions representing the school mathematics experiences of two Latiné learners. Antonio and Juanita are 3rd grade learners in two different rural schools in the southeastern US. An interview with each learner was edited such that the interviewers were removed. The remaining snippets of the remaining audio were curated to share Antonio's and Juanita's testimonios. Through the sonic constructions, deeper explorations of how Antonio and Juanita navigate racial and linguistic spaces can be conducted.

Keywords: Equity, Inclusion, and Diversity; Research Methods; Elementary School Education

Sound waves reverberate around us helping to engage, define, and make sense of space. Although sound frequencies are only one source of information used to make sense of the world, sound is ubiquitous, and many messages pass through our auditory existence (Gershon, 2011; Gershon & Applebaum, 2020; McLoughlin, 2023). Hence, there is an important relationship between sound and the construction of space. Teachers and researchers embark on sonic journeys to engage with the sound of mathematical discourse, the classroom environment, an interview, a conversation between learners, and the stories about navigating schools and mathematics being told. The construction of knowledge at schools is dependent on the privilege and dependency the educational environments have placed on sonic constructions in classrooms (Gershon & Applebaum, 2018). Sound studies in education (see Gershon, 2011, 2013; Gershon & Applebaum, 2020; Wargo, 2018, 2019) deeply consider the role sonic layers play in our educational institutions, including the multimodal storytelling capabilities of learners.

The politics of sound (Kangieser, 2015; McLoughlin, 2023) forefronts questions of who is heard, who listens, how one is heard, and what one does with sound. Our journey through and with the world incorporates the sounds of an ecosystem and our own sonic additions to it, even if we cannot or choose not to hear life's reverberations (McLoughlin, 2023). "Sounds are therefore necessarily educational in nature, sensual data so rife with information that the listener can render often disparate-seeming sounds into embodied meaning systems" (Gershon, 2011, p. 66). Our meaning-making, particularly of the social other, is dependent on how the other is heard. Researchers treating sound as apolitical audio frequencies in space is is prohibitive to our being able to reach deeper understandings of our environments (Littlejohn, 2021).

Theoretical Framework – Geographies of Despair/Hope

Hidalgo (2017) describes spaces and soundscapes for Communities of Color as geographies of hope and geographies of despair. In her project, *predatory landscapes*, Hidalgo (2011) worked together to "resist spatial domination through creative and inventive appropriation of space" (Hidalgo, 2017, p. 80). Geographies of hope are the appropriation of a dominant space. Hidalgo's (2011; 2017) exploration also provided further insight on the geographies of despair the participants were navigating. Geographies of despair are spaces where dominant narratives maintain racial hierarchies. Hidalgo (2017) described the larger number of fringe financial services available in the southern area of Phoenix where immigrant populations have historically been located. These geographies of despair demonstrate the long-standing history of white supremacy through laws and policy targeting immigrant populations. By mapping the geographies of despair, Hidalgo (2011; 2017) is engaged in mapping phenomena through sounds, visuals, and other media to make visible the invisible and disappeared (see Popovski & Young, 2023; Russell & de Souza, 2023). Insight into the tensions between geographies of hope/despair can provide powerful understandings of Latiné childrens' experiences navigating school. Hidalgo's work influenced us to recontextualize explorations of learners' geographies of hope/despair. Our focus in this paper was on the audio recorded testimonios of Antonio and Juanita to create a sonic construction where they share their geographies of hope/despair.

Positionality Statement

The research team is dedicated to disrupting the white mechanisms of educational institutions for the flourishing of Latiné children. As a collective, we weave and vulnerably share our stories as Latinx, Iranian, white, multilingual, immigrant, queer, cisgender, children in poverty, and having invisible health and mental issues. It is important to share openly to create a counterspace for us and our partners. We push ourselves to work in different mediums to disseminate the valuable knowledge gifted to us by our partners. We recognize our position in the academy—a cruel (white) apparatus—requires our continued adjacency to whiteness. We work together to maintain as much of our former selves as possible.

Methodology: Sonically Constructing Antonio and Juanita's Testimonios

We wanted to maintain the sound of their voices through the process of constructing their testimonios. Hence, working through the medium of sound was important. As Wargo (2018) described, "Sound is not merely a descriptive experience but a set of social relations. Sound operates as a worldview. It is a symbolic system and form of composing" (p. 14). Using the video/audio file, the first author listened repeatedly to Antonio's and Juanita's interviews ranging 16 to 20 minutes. First, it was important to remove the voice of the interviewer. We used Final Cut Pro to separate the audio of the video (to depend only on the sonic landscape—the totality of the sounds record) and edit the audio file such that only the voices of the learners were left. This included as much as possible removing the interjecting sounds made by interviewers to suggest the interviewee is being heard (e.g., yes, mhm, hmm). From these files, the first author listened for Antonio's and Juanita's possible testimonio. It was important to listen for descriptions of their experiences (e.g., who they are, what brings them joy, what silences them, the emotionality of their experience in schools as Latiné learners). Furthermore, listening specifically to how these experiences culminate in their mathematics learning. In general, we wanted to understand how two Latiné learners navigated their experiences in school and the mathematics classroom. Littlejohn (2021) warns this kind of editing is creating a fictitious version of Antonio and Juanita, but that it is not a limitation. “Like written ethnographies, sonic ones are fictions. This does not mean that they are untrue or do not index reality. Rather, they are ‘partial truths’ that both reflect the specific engagements between ethnographers, people and place” (Littlejohn, 2021, p. 36). Therefore, like counterstorytelling (Solórzano & Yosso, 2002), we ground Antonio and Juanita’s testimonios in the empirical data provided, our own experiences navigating school mathematical spaces, and the literature to contextualize their experiential knowledge through the sonic construction.

From this foundation, the first author was able to curate together seven-minute clips of each learner. Then, each audio curation was further edited by listening closely to each learners’ stories and trying to create an audio experience for the listener showcasing the experiences of Antonio and Juanita. It helped to think of Antonio and Juanita as giving a tour of their experiences. This aided in constructing two-minute “tours” of their geographies of hope/despair. The first author then shared these with the others in the research group and, with their advocacy for Antonio and Juanita, worked together to edit, modify, and maintain the partial truth of their testimonios (Littlejohn, 2021). The group concluded with two sonic constructions. From these constructions, we moved on to mapping their experiences by creating animations to go along with their testimonios. The animations were created by the first author. Feedback was discussed with the research group until consensus was reached.

Antonio and Juanita’s Testimonio Tours

In this section, the transcripts of Antonio’s and Juanita’s sonic constructions are presented. During our presentation, we will take time to listen to and watch the sonic constructions. The goal of including portraits and our mappings of their experiences is to make Antonio and Juanita present for the reader, to humanize them and remind the reader of the children speaking to them. Please read their words carefully, as the fragile gifts they are (Gómez Marchant & Aguilar, 2023). Their sonic constructions are manifestations of their counterstories, helping us in understanding how they navigate school and the mathematics classroom.

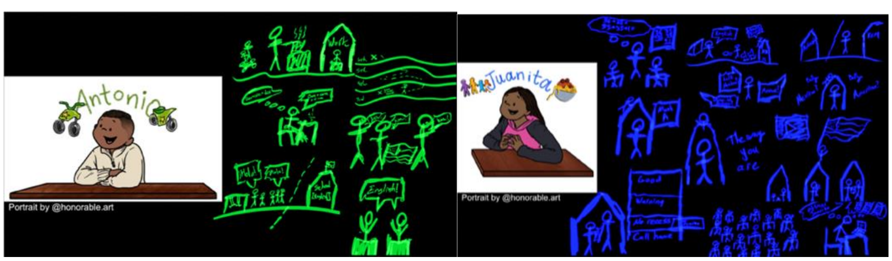

Figure 1: Portraits of Antonio and Juanita adjacent to their school experience maps

Antonio: My favorite color is green and uh I can drive a um four wheeler like with my brother in the back. My mom is really sweet and my dad, he cooks sometimes when it's in the summer and my mom's at work. Because I want to challenge myself to see how far I can get before I go to fourth grade. And then when I go to fourth grade I'm going to see if I can get all the way to sixth grade, like skip fifth and go to sixth. When I'm adding, sometimes I just um, go in my head and I sometimes do it in Spanish and then I try to say it in English. And once it's like wrong I um, do it, the whole thing in Spanish and then if it's wrong still I do the whole thing in English and it's right then um I'll like feel like I got it right just with only one try but I only got it right in like three tries sometimes. So I did in my head, uno plus uno equals dos. And then um, I wrote it down, one plus one equals two. And then I got it right and then I got a treat. Sometimes I don't really like to do it in Spanish but mostly all the time I do. I would think they would be impressed by that I'm trying–I'm kind of embarrassed to say it. Because like, because I only have American teachers. Like mad because all the time me and Jocelyn would speak Spanish and um they said no secrets in class And we would say it in English and then they'd be like oh wait that's what they were saying so they got kind of mad that we were um, doing secrets but we weren't. I only do it at recess because my teachers won't let me speak in Spanish. It makes me feel kind of sad that I can't speak Spanish in class. And I want to speak Spanish in class. I did it one time at recess when they were trying to speak to some, a little bit of a Spanish guy and they tried to say hello in Spanish and they couldn't say it so I helped them say hola and they said um hola. And then I felt like um special that I helped.

Juanita: I love having fun. My favorite color is blue. My favorite food is spaghetti. My dad works–he builds houses. My brother plays soccer. I have two dogs, Levi and Daisy. I don't speak Spanish. I understand a little bit of Spanish but not a lot of Spanish. Well I'm new. I just came to this school. I came from McK. The bus wouldn't pick me up from McK so we had to come to a different school. I just feel lonely here. So they are like, are you Mexican? Are you half Mexican? Are you White-ish Mexican? And I just–I just don't answer them a lot because that makes me feel bad. And my dad just tells me don't let anyone bully you. Like he–my dad would tell me not to worry if I'm Mexican or American. I sometimes do say words wrong. I mean my dad's girlfriend is in Mexico and she makes me happy. She doesn't really care if I'm Mexican or not. She just cares of who I am and I just like it. So I watch YouTube. And there is a lot of Americans on YouTube. I wanted to be an American and I didn't want to be Mexican. Like my dad he cheers me up all the time. He would make–he would probably make me food. Hug me. Maybe buy me something. I get kind of scared, not all the time but she usually makes me clip down. My teacher probably would look at me a lot because I don't–I don't answer a lot of questions there Because like I'm scared if I get them wrong and I feel bad that I don't want anyone looking at me. I probably know a lot of things and I help my–my classmates all the time with math because I do get a lot of good grades. I got one B on my report card and four A's and my dad was proud. Cause I want to be a police when I grow up and I like–I was watching videos about it and you like learn math in there. Like they be writing things and you have to find like the answer to kind of like math. When I get like–we do this math mashup for our homework, when I get all those answers right. I feel proud of myself.

Discussion and Conclusion

Antonio’s and Juanita’s testimonios emphasize the tensions of their geographies of hope and geographies of despair (Hidalgo, 2017) within their differing learning environments. One hears and sees how their mathematics, linguistic, and racial identities within differing contexts construct these landscapes of educational and mathematical possibilities. Antonio’s and Juanita’s mappings is a first step in showing how mathematics, language, and race collide within their lived experiences at school. Focusing on the audio medium for meaning making helped in creating a portrait of the tensions their racial, linguistic, and mathematical identities face. This process also maintained Antonio's and Juanita's knowledge of racialized spaces, thereby requiring the research team to attend to Antonio and Juanita differently. Antonio's landscapes were more heavily influenced by his experiences with language. Juanita's with her racialized experience. Both are emergent within the other. As tools for listening to learners, they both prompt conversations of the relationship between language and race, specifically in the mathematics classroom. This helps in further recognizing how the politics of sound (Kangieser, 2015; McLoughlin, 2023). Antonio's and Juanita's auditory mappings provide insight on their joy but also on their oppressed experiences.

Mathematics educators have recently shifted towards prioritizing social justice within the classroom, reflecting a broader recognition of the importance of addressing societal inequities and fostering inclusive learning (Buell & Shulman, 2019; Gutstein & Peterson, 2013). There is additional consensus that mathematical modeling can help students connect their experiences outside the classroom with big ideas in K-12 mathematics (Ball et al., 2005). These perspectives underscored the urgency of addressing themes such as cultural diversity, sociopolitical topics, and environmental issues relevant to learners in diverse mathematics classrooms worldwide (Aguirre et al., 2019; Jung & Magiera, 2023; Felton-Koestler, 2020; Rosa et al., 2022).

Mathematical modeling and social justice research approaches are rapidly expanding, encompassing diverse perspectives and epistemologies worldwide (e.g., Barbosa, 2006; Jung & Brady, 2023; Orey & Rosa, 2023). It is important to summarize these views and understand the different approaches, designs, and methods to guide informed research lines that adds to this emerging field. With this goal in mind, we embarked on a systematic literature review to analyze the current state-of-the-art of mathematical modeling and social justice development research. In this poster, we present one research question that has guided our first efforts to summarize this field of research: *What are the predominant themes at the intersection of mathematical modeling and social justice across the research in mathematics education?*

Methodology. In this study, we employed a systematic literature review (Torres-Carrión, 2018; Snyder, 2019) to explore the integration of social justice into K-12 mathematical modeling. We searched six relevant academic databases (Web of Science, Scopus, Springer, JSTOR, Taylor and Francis, and Eric) using keywords (e.g., social justice, equity, culturally responsive, and mathematical modeling). A multi-stage screening process ensured methodological rigor and minimized bias (Moher et al., 2015). At first, two independent reviewers categorized titles as “relevant,” “irrelevant,” or “maybe” using Covidence, a website for multi-layer screening. Reviewers did this process by ensuring each paper was related to mathematical modeling, social justice, and K-12 education. Discrepancies were resolved by a third reviewer. This process reduced the initial pool from 5,685 to 539; we kept papers classified as “relevant” and as “maybe”. After abstracts were similarly reviewed, we conducted full-text analyses of the remaining studies.

Summary of results. Our ongoing process has completed the initial screening phase, where we evaluated the titles and abstracts of the papers. As we transition to the full-text screening stage, preliminary discussions among the research team have illuminated the potential development of several thematic codes: ethnomodeling, teacher knowledge of social justice and mathematical modeling, culturally responsive pedagogical approaches on mathematical modeling, and the evolution of mathematical modeling and social justice in education. In this poster session, we will provide a summary of the interaction between modeling and social justice by sharing the relevant themes, subthemes, details, and recommendations for future work.

A DIVERGENT PERSPECTIVE OF AN ADHD LEARNER IN COLLABORATIVE MATHEMATICS

Matthew Hertel
University of Texas at Austin
hertelma@utexas.edu

Emma C. Gargroetzi
University of Texas at Austin
egargroetzi@austin.utexas.edu

Education research literature consistently frames ADHD learners as a collection of deficits running counter to their own academic success in their educational trajectories. These deficit orientations to ADHD learners contribute to widespread assumptions that they lack the ability to contribute meaningfully in educational settings. We explore the hypothesis that one ADHD learner's participation in collaborative mathematics served to support and facilitate joint attention within his peer group. This hypothesis serves as an explicit counter narrative to deficit orientations held against ADHD learners, in literature and in the classroom. ADHD learners bring valuable assets to the success of their peer groups. This work challenges linear understandings of human development that can function to pathologize human cognitive and cultural diversity rather than embrace it as valuable to our collective continuance.

Keywords: Special Education, Students with Disabilities, Equity, Inclusion and Diversity

ADHD: Contesting Deficit Framings

Attention-Deficit Hyperactivity Disorder (ADHD) is one of the most widely researched neurodevelopmental disorders worldwide (Cooper, 2001). ADHD learners, present in nearly every K-12 classroom, are defined by the Diagnostic and Statistical Manual of Mental Disorders (5th ed.) as having a deficit in the area of attention (American Psychiatric Association, 2013).

While we (the authors) acknowledge the biological differences in neurodevelopment and impairments experienced by ADHD individuals, we also maintain that these impairments exist within an unjust, social framework that imposes normative standards of functioning on individuals who experience ADHD and other types of neurodivergence (Brown, 2014; Jurgens, 2020).

Overwhelmingly, the extant literature on ADHD learners in K-12 settings constructs them as poor students, who are incapable of academic success as a result of their identifications with ADHD. When students are constructed as fundamentally deficient in their capacities for learning, it is imperative that we re-examine the ways we investigate the learning of ADHD students. Critical and divergent perspectives of ADHD and other learning disabilities are necessary to disrupt deficit perspectives in research and ensure proper accessibility and accommodations for ADHD learners in K-12 learning contexts.

ADHD Learners and Collaborative Mathematics

Collaborative mathematics is understood as a critical site for agency and authority in mathematics learning (Langer-Osuna, 2016). Research shows disabled learners often have limited access to opportunities for agency and authority in mathematics learning (Tan et al., 2019). With collaboration understood as a highly valuable configuration for learning mathematics, critical analyses of access and participation in collaborative mathematics is crucial to the development of equitable educational opportunities for disabled students in mathematics.

Despite the abundance of research that has been conducted around ADHD, an initial review of literature identified zero (n=0) studies investigating the participation of ADHD learners in collaborative mathematics (Hertel & Gargroetzi, 2023). Examination of these cross-sections of the literature (ADHD learners in mathematics and ADHD learners in collaborative groups) evidence a pattern of constructing ADHD students as deficient. They are framed as deficient in their mathematical abilities with concern for on-task time, work completion, calculation accuracy, and problem solving (Zentall et al., 1994; Lucangeli et al., 2006). Literature regarding the collaborative activity of ADHD students is either approached from a position of concern about managing negative social interactions presumed common for ADHD learners or as a prescriptive intervention to mitigate poor academic outcomes (Saunders et al., 1996; Watkins et al., 2008). In one article, it is noted that collaborative groups with ADHD learners "surprisingly" had better mathematical problem-solving outcomes than those without ADHD learners as members of the collaborative group (Zentall, 2011, p. 38). This analysis speaks to the profound and harmful silence in the literature about the assets and contributions of ADHD learners to mathematical collaboration–a critical site for powerful mathematics learning.

Disability Justice and Counter Narrative

Drawing on Disability Justice and other critical frameworks we present the findings and discussion of this analysis as a counter narrative (Solorzano & Yosso, 2011), that challenges the majoritarian story of deficit orientations from which the mathematics and collaboration of ADHD learners is currently researched. A counter narrative that provides an asset-based framing of the contributions to mathematics collaboration by an ADHD student is prudent and speaks back to the deficit notions in both bodies of literature.

To do so, we share findings from an interaction analysis (Jordan & Henderson, 1995) of a Latino, ADHD, 9th grade student, Sammy, working with his peers in collaborative mathematics problem solving. Through this analysis, we challenge the deficit framing of ADHD learners. Specifically, we notice that Sammy plays a key role in the coordination of his group's collective attention to tasks, ideas, and objects that are important to their overall success as a group, a construct referred to as joint attention in the extant literature on collaboration and group work (Barron, 2003). While Sammy's identity as an ADHD student constructs him as having a deficit in the area of attention, his ability to coordinate joint attention, and the skills and assets required to do so are of particular interest in carrying out this analysis.

In order to investigate the affordances of Sammy's contributions to collaboration with his peers in mathematics, we asked with regard to Sammy during collaborative mathematics problem-solving, 1) What are Sammy's contributions to collaboration with his mathematics peers? And 2) What are the outcomes of Sammy's contributions to collaboration for the other members of his group?

Methods

The findings reported in this paper represent one minute of fine-grained interaction analysis (Jordan & Henderson, 1995) as an early phase in progressive refinement of hypothesis (Engle et al., 2014) where we examine the case of Sammy's participation in collaborative mathematics problem solving activities. Progressive refinement of hypotheses describes the ongoing and iterative process of observing and analyzing a phenomenon of interest within and across data sets. Here we explore the hypothesis that one ADHD learner's participation in collaborative mathematics served to support and facilitate joint attention within his group, serving as an explicit counter narrative to the fundamental construction of ADHD as having a deficit in the area of attention. As students with ADHD are often positioned as deficient in the capacity of their attention, Sammy's case as an ADHD and Mexican/Hispanic student who effectively coordinates joint attention, disrupts the pervasive deficit narratives of ADHD students and constructions of racially marginalized students in mathematics as "problematic."

In this analysis we use interaction analytic techniques to investigate human activities, such as talk, nonverbal interaction, and the use of artifacts and technologies, identifying routine practices and problems and the resources for their solution as indicative of social ecologies of participation (Erickson, 2005; Jordan & Henderson, 1995). This method of analysis affords identifying regularities in the ways in which participants utilize the resources of the complex social and material world of actors and objects within which they operate (Jordan & Henderson, 1995).

Context of the Study

This analysis is situated within a two-year ethnographic study of the co-construction of mathematics and social identities in a predominantly Latine serving California public high school (Gargroetzi, 2020; 2023). For one year, data collection focused on one mathematics class and eight focal students of whom Sammy was one. During that time the second author served as a consistent participant observer (Spradley, 2016) in the focal mathematics classroom and occasionally accompanied the focal students to their other classes and activities. The instruction and learning opportunities in the focal classroom were structured around collaborative problem-solving activities where students worked in groups of three or four.

Sammy, a 9th grade student in the year of study, identified himself as Hispanic and Mexican, male, and an "ADHD kid." Sammy reported that mathematics was his favorite subject, but that both his ethnoracial and disability identities complicated this. He had encountered the notion that Mexicans could not be good at mathematics (see Gargroetzi, 2023) and he explained that he believed being an "ADHD kid" meant he couldn't get an A in mathematics. For the year of data collection in Sammy's class he acted as a co-researcher. Four years later, Sammy, has volunteered to participate in future rounds of video co-analysis (not yet reflected in this paper).

Sammy's peers in the collaborative work represented are Selina (10th grade, Latina, repeating the course), Gisela (10th grade, Latina, with an IEP, repeating the course), and Gabriel (9th grade, Latino). The ethnoracial and ability contexts of the school and these students' relationships with mathematics, schooling, and their classroom community are explored in other work (see Gargroetzi, 2023; 2024). All student names are self-selected pseudonyms.

Data and Analysis

Data for this analysis comes from a larger set of ethnographic data including field notes and artifacts of student work, student interviews and focus groups, and video of two student groups participating in collaborative mathematics over the course of one unit (7 days, 700 minutes). Microanalysis examines one minute of collaborative mathematics selected from video from the first day of the recorded unit. In the first phase of analysis, the authors and colleagues created content logs documenting major activities in 5-minute intervals across the 7-day unit. In a concurrent second phase, as we developed our initial hypothesis, we participated in collaborative viewing sessions (Jordan & Henderson, 1995, Erickson, 2012) with two different groups of researchers representing varied expertise in interaction analysis, Disability Studies, mathematics education, special education, and learning theory, working to generate and refine our hypotheses and analytic lens in relation to the empirical record.

In doing so we began to document and define the types of contributions, any verbal or nonverbal activity that took place within the context of the collaboration captured on video whether directed toward another peer or not (see Table 1), that were made to the collaborative activity. In mapping this landscape, we identified a variety of types of contributions including those often explicitly documented as contributions to collaborations such as asking or responding to a question, as well as others that are not often considered as a potential contribution. For example, students in the focal group often engaged thinking aloud - a verbalization of their own questions or ideas while problem solving. Observing gaze, posture, and tone of voice, it was inferred that these questions or ideas were not necessarily directed at any particular student or even the whole group of students. Rather, they were externalizations of students' thought processes, or in simpler terms, "thinking aloud". While some analytic lenses may not attend to these personal externalizations as part of the collaboration, we included these in our analysis based on the hypothesis that this type of contribution to the collaborative space might afford opportunities for initiating joint attention, collaboration, and peer sensemaking.

Table 1: Types of Contributions to Collaboration

Type	Definition
Thinking aloud (not directed at a peer)	When a student is talking out loud either about their thoughts or questions regarding the problem they are working on or a related mathematical idea.
Collaborative Sharing	Share or propose mathematical idea, reasoning, observation, approach to problem solving, or solution
Talking while Gesturing	Gesture accompanies verbalization (hands or head)
Gesturing	Gesture without verbalization (hands or head)
Touch materials	Touches own materials or materials that belong to or are sitting on a peer's desk.
Pointing	Point to diagram or worksheet
Questioning (math-related)	Ask a mathematical question
Responding to peer (math-related)	Respond to a peer's mathematical question
Clarifying question (task-related)	Ask question about task expectations
Provided clarification (task-related)	Respond to a task expectations question or expand on
Endorse a peer's idea (math-related)	Agree with or promote peer's contribution/solution
Provide affirmation/confirmation	Confirm/affirm a peer's contribution/solution

Celebration (math-related or task-related)	Celebrate completion or correctness of solution (self or peer)

After using the larger data set to generate a set of contribution types, we focused our analysis on one minute of fine-grained interaction analysis based on a detailed transcript of the video record from the first day of the unit (minutes 59:00-1:04). The transcription documents both verbalization and nonverbal activity such as gaze, gesture, posture, writing, and other movements. Transcription conventions follow modified approaches drawing on Jefferson (1984) and Ochs (1979). Video was reviewed repeatedly to refine the transcript and produce detailed analytic memos for each conversational turn (Sacks et al., 1974). We selected this video segment based on it representing the first episode of the peer group engaged in a teacher-assigned collaborative task in a new collaborative group. The segment is bounded by initiation of the collaborative work amongst the group at the beginning and the collective uptake of a shared solution at the end, marking a shift in attention within the group.

Using the detailed transcript we coded for Sammy's contributions (n=10) and mapped the outcomes for peers of each of Sammy's contributions (See Table 3 in Findings). Outcomes were identified and analyzed based on examining the activity immediately following the contribution (3-5 seconds prior). As is common for social arrangements, an outcome in one moment was also often a contribution for the next. Findings report on Sammy's contributions and subsequent outcomes for his collaborative group.

Locating the Researchers

The researchers are an ADHD researcher (PhD student) and neurotypical faculty advisor who are jointly invested in examining power, privilege, and marginalization in mathematics learning with commitments to humanizing representations of minoritized learners that privilege their voices and perspectives. As two white, non-binary but cis-presenting researchers we recognize our privileged positions as a form of property and we work to unseat those investments in ourselves. The data shared in this paper represents insight into the lives of youth with whom the second author has been in close relations over the course of multiple years. The first author brings unique insights and commitments to this data in relation to ADHD learners and learning. We invite Sammy and other ADHD learners to join us in this analytic work and the work to build a counter narrative oriented to assets over deficits.

Findings

The segment of video-based interaction analysis included 21 talk turns where Sammy contributed nearly half of these turns (n=10). Sammy's contribution types during this time included verbalizations such as collaborative sharing (n=8) and providing confirmation (n=2) as well as movement such as pointing (n=3), touching materials (n=3), and often both at the same time: talking while gesturing (n=4). In examining the immediate outcomes within the group following Sammy's contributions, we noted three categories of outcomes (see Table 2). The outcomes of Sammy's contributions included (1) initiate or sustain joint attention, (2) initiate or sustain a pattern of sharing ideas, (3) a peer or the group utilizes Sammy's contribution as a resource for sensemaking or solution pathway. On occasion no explicit outcome was observed if there was no evidenced attention (physical or verbal) to Sammy's contribution. Notably, on three occasions Sammy's contributions initiated either joint attention or a new pattern of collaborative sharing, both fundamental processes for collaborative problem solving (Barron, 2003). On other occasions his contributions supported the continuation of these critical configurations within the group. Examples are provided for each type of outcome. We further unpack one instance of Sammy's contribution providing resources for the participation and problem-solving activities of his peers and the collaborative group.

Table 2: Types of Outcomes for Peer Following Sammy's Contributions

Type (# of instances)	Definition	Example
Initiate sharing (n=2)	After a contribution to collaboration has been made, peers begin to share their own ideas, questions, or solutions in response.	When Sammy and Selina are talking about the number of squares needed to form a box with a lid, Selina begins to share her own observations about the problem.
Sustain pattern of sharing (n=6)	Peers continue sharing ideas, questions, or solutions back to back, maintaining the flow of collaborative contributions.	Gisela, Selina, and Sammy all share mathematical ideas at the very beginning of their collaboration.
Initiate joint attention (n=1)	A contribution to collaboration is followed by two or more students attending to the same idea, question, or object.	Sammy points to a diagram that he thinks can be folded to form a box with a lid and Selina responds by asking a reaffirming question, "it does?" Sammy and Selina then begin discussing what is necessary in the diagram in order to ensure it will fold into a box.
Sustain joint attention (n=6)	Joint attention is maintained for multiple talk and nonverbal turns among peers.	Sammy and Selina discuss how many squares are needed in a diagram for it to fold into a box with a lid. (attending to the idea or conversation about the problem)
Peers utilize Sammy's activity as a resource for sensemaking (n=4)	Sammy's verbal or nonverbal actions are utilized by peers either in individual sensemaking or as an inroad to collaboration.	Gisela erases her answer for the second diagram directly following Sammy pointing to the second diagram and sharing his answer.
Group utilizes a solution pathway offered by Sammy (n=1)	Sammy's shared solution is utilized by peers in their own sensemaking or solution pathway.	Gabriel's gaze shifts to Sammy's paper while Sammy responds to and explains his reasoning to Gisela.

No explicit outcome observed (n=1)		Collaborative Sharing

Vignette Analysis: Gisela Utilizes Sammy's Contribution to Access the Mathematics and the Collaboration

We selected a vignette to share that explicitly challenges the deficit-oriented framing of ADHD learners in mathematics education research. ADHD student talk and movement is often depicted in the literature as disruptive to their teachers and to the learning of their classmates. In contrast, this vignette demonstrates how, in the context of collaboration with his peers, Sammy's talk and movement contribute to the collaborative space providing an alternative resource for sensemaking for his peer, Gisela. This inroad to sensemaking was utilized by Gisela for her own individual problem solving and subsequently as an entry point for dialogue with her group.

During this interaction, representing 18 seconds of the analyzed video segment, Sammy and his peers consider which of a group of nets would make a box with a lid (see Table 3).

Table 3: Transcription of Vignette

Line	Name	Verbal	Nonverbal
1	Selina	Um- there's one box- so how many boxes make it- one, two, three, four, [five, six	
2	Sammy	This one would!] (.....)	Pointing at the specific diagram that he thinks would work. Sammy's gaze lingers over to Selina's desk.
3	Sammy	This one would	Points again at the same diagram Gisela starts erasing her previous answer and then waits.
4	Selina	It does?- [Six?-	Selina's gaze is directed toward her paper.
5	Sammy	Yeah]	Gaze shifts down to his paper
6	Selina	[What you notice is that both of them] are six	Selina points to two of the diagrams that have 6 six squares.
7	Sammy	Cuz you have to have four sides-]	Gaze shifts back to Selina Gesturing with his hand and pointer finger, tracing four sides of the box.
8	Sammy	Yeah- cuz they have to have four sides and then one on the bottom- one on the top/	Gesturing with his hand and pointer finger, tracing four sides of the box and then pointing to where the bottom and top would be.

9	Gisela	/Should we check?	Gisela gestures with her hands in somewhat of a shrugging motion, shifting her body to her right.

Initially, while everyone else is processing and answering the first question on their worksheets individually, Sammy verbalizes his solution to the question on multiple occasions, pointing to the second and last diagrams on question one, which are in fact the only two correct answers, but receives no explicit response from others. Sammy says, "I know the last one will, it'll create a lid," as he taps his pencil on his face. Then Sammy momentarily shifts his gaze toward the middle of the group, then back to his paper. The group is silent for a few moments, Gisela writes on her paper, Selina is leaned over her paper, and Gabriel's gaze appears to be on something beyond Gisela's desk. Sammy leans back in his seat and then talks while gesturing, "well, it would be difficult to...," and uses his hands to visualize what the final folded net diagram would look like. Immediately following, Selina begins to speak and gesture (line 1). Though her talk does not suggest she has taken up Sammy's ideas, it does shift the group into a pattern of sharing such that the outcome of Sammy's contribution was to initiate a pattern of sharing. Sammy again states his answer to the first question, excitedly stating, "this one would," while tapping on the specific diagram on his paper using his index finger (line 2). He looks over at Selina's desk, where she continues to lean into her worksheet and does not verbally respond to his answer. Just as Sammy is about to repeat his answer, Gisela starts to flip her pencil in her hand and begins erasing something that is written on her paper in the same location on her paper as to where Sammy was just pointing on his own paper. A few more seconds pass, and Selina raises her head slightly and Sammy's gaze shifts toward her face and then back toward his paper. Again, Sammy says, "this one would," this time more reserved, tapping on his paper (line 3). This time Selina responds verbally, "it does?" (line 4). Sammy and Selina continue to exchange ideas (lines 5-8), with Gisela now joining the discussion by asking if they should check their answer (line 9).

While there was no verbal response to Sammy's contribution in line 2, the nonverbal activity that occurred in the following five seconds where Gisela revised her thinking and then eventually entered the conversation with a new request to check their work together demonstrates one example of how Sammy's contributions in verbalizations and gesture contributed to supporting peers and the collaboration by providing an alternative resource for sensemaking. By sharing his answer even when his group mates were not attending to a shared conversational space and using behaviors such as pointing, gesturing with his hands, and changing the tone of his voice, Gisela was able to silently utilize Sammy's shared answer as an opportunity to reconsider her first answer to the question, attend to the conversation between Sammy and Selina, and eventually join with her own suggestion for a collaborative next step.

Discussion and Conclusions

This initial micro-analysis of Sammy's contributions and the outcomes for peers in his collaborative mathematics group suggest that activity such as externalization (thinking aloud), talking while gesturing, and movements such as modeling with hands, pointing, and tapping can provide inroads critical to collaborative work such as initiating and sustaining joint attention, establishing and sustaining patterns of sharing within the group, and furthermore can provide sensemaking resources that are utilized by peers for their own problem solving and to pave the road for access to the collaborative dialogue. These findings are of particular note because these same activities are frequently pathologized as problematic, distracting for others, and indicators of the inattention of ADHD learners.

Sociocultural theories of learning (Vygotsky, 2012) that understand externalization of thinking through talk and gesture as providing critical resources for learning undergirds our understanding of the potential value of collaborative mathematics activity. However, these same sociocultural theories of human development and learning also suggest a hierarchical understanding of human development wherein advanced development is marked by moving much of this thinking to internal speech (Vygotsky, 2012). Along with the Disability Justice movement (Baglieri et al., 2011; Sins Invalid, 2015), and building on existing critique of such hierarchical developmentalism in some of Vygotsky's work (i.e. Bang, 2017), we suggest that linear understandings of human development can function to pathologize human cognitive and cultural diversity rather than embrace it as valuable to our collective continuance. We hope that this micro-analysis of Sammy's contributions and the outcomes for his peers provide one example of the potential value of neurodiversity and of varied ways of being and participating that can serve as an asset for mathematics learning and collaboration.

Keywords: Equity, Inclusion, and Diversity; Technology; Gender

Immigrant students, including Muslim girls, encounter significant educational challenges, such as cultural and language barriers, leading to isolation and diminished self-esteem and academic performance (Cerna et al., 2021). Addressing these challenges requires dismantling structural barriers and fostering inclusive educational environments that value diverse identities (Nishina et al., 2019). In mathematics education, mathematics identity is pivotal for student engagement, achievement, and resilience, underscoring the need to recognize and affirm diverse identities (Aguirre et al., 2013). Digital mathematics storytelling has proven effective in enhancing mathematics identity by connecting mathematics concepts with real-life applications and boosting students' interest in the subject (Chao et al., 2021). Nonetheless, research on digital mathematics storytelling among students with intersecting identities remains limited. This study seeks to explore the role of digital storytelling in reconstructing mathematics identity and how intersecting identities affect connection with mathematics.

In this poster, we integrate mathematics identity (Nasir & De Royston, 2013), intersectionality (Crenshaw, 1989), and funds of knowledge (Moll et al., 1992) as theoretical frameworks to explore the identities of Muslim immigrant girls in the U.S. We employ a qualitative narrative inquiry (Connelly & Clandinin, 1990). Participants, five young female immigrants, created videos that reflect their journey in learning mathematics, integrating it with their daily life experiences connected to their families and communities. This research involved four-week storycircles (Lambert, 2018) where participants shared and received feedback on their developing work. Initially, we introduced the concept of mathematics storytelling, prompting participants to create their own stories and discuss their mathematics learning experiences in the U.S. and their home countries. As the sessions progressed, they explored and shared their videos related to gender, religion, and immigration within the context of mathematics education.

Initial findings show that digital storytelling plays important role in reconstructing mathematics identity of Muslim immigrant girls, helping them adapt to a new educational system while incorporating their cultural experiences into mathematics learning. These participants navigate and bridge the gap between their home country's mathematics curriculum and that of the U.S., cultivating a sense of belonging in mathematics. Their intersecting identities shape their connection with mathematics, merging the values and practices learned from family and community with formal education. This process not only fosters inclusivity and engagement in mathematics but also challenges stereotypes, serving as a powerful tool for participants to combat racism, sexism, and Islamophobia.

TEACHERS' POSITIONING AND ITS IMPACT ON MULTILINGUAL STUDENTS' LEARNING OPPORTUNITIES

Ji Yeong I

Using positioning theory, we examined mathematics lessons led by two monolingual teachers in multilingual elementary settings, focusing on learning opportunities. Despite employing research-based strategies, teachers often do not position multilingual students as capable problem solvers and independent learners. Their emphasis on equal participation inadvertently limited learning opportunities. We advocate for analyzing teacher discourse and practices through the positioning framework to uncover hidden biases and complexities. While the response of South Korean teachers to the increasing number of multilingual students remains unclear, our findings illustrate the general inconsistency in supporting and positioning culturally and linguistically diverse students in mathematics classrooms.

Keywords: Equity, Inclusion, and Diversity, Classroom Discourse, Teacher Beliefs, Elementary School Education

In today's diverse educational landscape, educators worldwide grapple with meeting the needs of multilingual students, a challenge accentuated in the U.S. where mathematics classrooms are reflective of increasing cultural diversity (García et al., 2008). Despite serving approximately five million English learners (ELs) in U.S., PK-12 schools, a persistent difference in mathematics assessment scores remains between ELs and their English-proficient peers (Howard, 2010; Soland & Sandilos, 2021). Research-validated instructional approaches are essential to ensure academic success for all students (Culatta et al., 2006), including linguistically diverse students. This study focuses on emergent bilinguals (EBs), denoting students still acquiring instructional language fluency, and acknowledge the dynamic nature of language acquisition, while valuing linguistic and cultural assets (García et al., 2008).

Our investigation delves into the intricate political and cultural contexts shaping EBs' learning experiences in the local community. We examined how two Korean teachers positioned students, including EBs, in multilingual mathematics classrooms, exploring the impact on students' learning opportunities. This research is unique as it focuses on South Korea's evolving multilingual student population, a phenomenon challenging traditional perceptions (from 1.91% in 2017 to 3.5% in 2023). Using a positioning theory framework, we aim to enrich our understanding of interactions in multilingual classrooms and their implications for students' learning opportunities.

Theoretical Perspectives

Disparities in learning opportunities persist, disproportionately affecting low-income, culturally diverse students, often placing EBs in lower-level mathematics courses (Umansky, 2016). Problem-based curricula and supportive environments enhance access to mathematics, crucial for educational achievement (Stein et al., 2007). Cognitive demand distinguishes learning opportunities, with routine memorization considered low and conceptual understanding high. Teachers' instructional practices influence students' access to learning opportunities, impacting participation and access to classroom discussions (Martin-Beltran, 2010). Social dynamics and power relations further shape access to opportunities in mathematics (Kayi-Aydar, 2019).

South Korea lacks specificity regarding multilingual students, amid the recent increase in racially and linguistically diverse populations. Research highlights disadvantages faced by multicultural students, including insufficient support, deficit positioning by teachers, and inadequate teacher preparation (Authors, 2022; Cho et al., 2006; Song et al., 2011). Song et al. (2011) found elementary teachers overlooked EBs' language backgrounds, providing inequitable learning opportunities. Similarly, authors (2014) noted Korean teachers' limited recognition of the cognitive demands of teaching mathematics to EBs.

Framework: Positioning Theory

Positioning theory, emphasizing moral dimensions of social roles, offers insights into interactions in bi/multilingual contexts (Harré & van Langenhove, L, 1999; Kayi-Aydar, 2019). Grounded in social constructionist perspectives, it views learning as constructed through interactions and power dynamics, making it a valuable framework for analyzing classroom discourse. This theory helps elucidate the relationships among power dynamics, competence, positional identities, and language learning experiences. Employed as both theoretical framework and methodological tool, it comprises positions, storylines, and speech acts, visualized in a triangular framework (Kayi-Aydar, 2019; Warren & Moghaddam, 2018). Within mathematics discourses, changes in any element due to challenges in rights and responsibilities allocation lead to modifications across the framework (Harré, 2012). Specifically, teachers' positioning of EBs can significantly affect their access to interactional opportunities (Pinnow & Chval, 2015). Positioning theory, focusing on moment-to-moment interactions, allows us to analyze how teachers' views expand or restrict learning opportunities for EBs, guiding our examination of teacher-student interactions in multilingual mathematics classrooms.

Methods

Participants and Settings

We observed two fourth-grade teachers, in South Korea, both native Korean speakers. Teacher A, with 18 years of experience, taught in a metropolitan city with a diverse immigrant population, while Teacher B, a novice teacher, worked in a city with diverse ethnic communities. Teacher A's class had 5 EBs from various ethnic backgrounds, born in South Korea but lacking proficiency in academic discourse. Teacher B's class had 17 multilingual students, some identified as EBs, receiving special language support. Despite teaching in different schools, both teachers covered the same mathematics topic using a government-developed textbook, focusing on real-life data collection and bar graph construction.

Data Collection and Analysis

We extracted a subset of data from a larger international study (Authors, 2019) conducted in South Korea, consisting of class observations, lesson plans, surveys, and interviews. Two teachers stood out for their different approaches to teaching the same mathematics concept in multilingual classrooms. We analyzed their acts, positions, and storylines, especially concerning

EBs' learning opportunities, using video recordings, transcripts, lesson plans, and interviews. Our analysis, rooted in Korean transcripts due to all authors being native speakers, focused on how teachers positioned themselves and students, particularly EBs, in mathematics classrooms. Utilizing Kayi-Aydar's (2019) positioning analysis framework, we identified 32 episodes where teachers positioned themselves or others regarding learning opportunities. Throughout the analysis process, we coded the repeated patterns and construct storylines that best capture each teacher's positioning. Our analysis aimed to reveal how teachers' acts positioned EBs and non-EBs and provided them with learning opportunities in language and mathematics. Finally, we reflected on the implications of each teacher's positioning.

Findings

We analyzed how classroom discussions and the cognitive demands of the tasks manifest in two teachers' lessons, as well as how teachers provided learning opportunities for participation. We found that two Korean teachers positioned both EBs and non-EBs as equal participants in the classroom community. However, the ways in which the teachers supported EBs' mathematical learning by engaging discussions and challenging tasks varied. Consequently, this led to different positions of students during class discussion and varying storylines about learning opportunities.

Teacher A focused on equal participation through hints and simple tasks, positioning herself as the sole decision-maker, while Teacher B emphasizes student autonomy while being a facilitator. Accordingly, Teacher A lowered cognitive demand, whereas Teacher B maintained it. There is also a disparity in student-initiated discourse between two classrooms; in Teacher A's classroom, the students did not have opportunities to ask questions or initiate discussions. Although Teacher B allowed students to speak up with questions and reactions, they were constrained by a sentence frame, limiting detailed mathematical reasoning.

Notably, Teacher A positioned students as passive learners by directing all tasks to ensure equal participation with easy tasks and unison answer. While her teaching methods initially seem engaging, they limit students to simple tasks in both language and mathematics by asking simple questions for choral responding and not asking for any further questions after student response. Teacher A avoided high-level questions, assuming EBs may struggle, and preferred predefined responses over exploring student ideas. In interviews, she defended simple activities, believing EBs cannot handle complex tasks. Despite using everyday language, Teacher A restricted both EBs and non-EBs to one-sentence roles to ensure equality, rather than challenging EBs. Also, she often lowered task complexity, underestimating students' abilities, and encourages copying over exploration. As a result, students in Teacher A's class may struggle to develop a strong sense of capability or confidence in mathematics, as her teaching methods tend to foster passive learning and limit opportunities for exploration and critical thinking.

In contrast to Teacher A, Teacher B positioned students as independent learners, fostering equal participation through rigorous tasks. She empowered students to solve problems by encouraging open-ended discussions and justifications. By refraining from correcting incorrect answers and redirecting questions to peers, she maintained the cognitive demand of mathematical tasks. For instance, Teacher B avoided labeling tasks as "easy," emphasizing the inherent challenges. She fostered a collaborative environment where student contributions were valued, positioning them as competent problem solvers. Overall, Teacher B positioned herself as a facilitator, guiding students to co-construct mathematical understanding through inquiry-based learning, promoting active engagement, and reasoning skills development. As a result, students in Teacher B's class may be more likely to see themselves as capable mathematics solvers and approach mathematics with greater confidence.

Discussion

The impact of teacher positioning on students' participation and access to learning opportunities in mathematics and language is evident (Kayi-Aydar, 2019). Both teachers utilized various supports to scaffold EBs' and non-EBs' learning, aligning with prior research recommendations (Celedón-Pattichis & Ramirez, 2012; Chval & Chaves, 2007; Moschkovich, 2010). However, they framed EBs as individuals needing linguistic support, extending supports to all students, perhaps reflecting cultural storylines valuing collective learning experiences or ethical principles emphasizing fairness. While both aimed for equal participation for EBs and non-EBs, Teacher A positioned students as dependent learners, resulting in passive participation, whereas Teacher B fostered a student-centric approach, promoting active contributions (Bossér & Lindahl, 2019).

The research findings suggest that, despite efforts to ensure equal learning opportunities for both EB and non-EB students, disparities in learning opportunities exist based on how teachers perceive the duties and rights of them and their students. The way teachers view themselves as educators can ultimately shape how they structure tasks and classroom discourse, potentially limiting students' learning experiences. This study highlights the need for teachers to undergo professional development that challenges their perceptions of their role and promotes the use of rigorous tasks in mathematics education.

Our data analysis, informed by positioning theory, revealed nuanced insights into classroom dynamics. Initially engaging, Teacher A's lesson hid deficit views despite diverse activities, while Teacher B's seemingly ordinary lesson empowered students through inquiry-based methods. This underscores the importance of positioning theory in evaluating instruction quality (Bossér & Lindahl, 2019). Integrating this theory into teacher education can address deficit views and promote equity over equality (Bossér & Lindahl, 2019). Reflecting on classroom episodes and adopting research-based strategies can mitigate deficit views and support EBs effectively.

Rehumanizing Mathematics Education for Multiracial Children: MultiCrit and Mathematics Education

Sophie M. Kasahara
University of Minnesota
kasah007@umn.edu

Keywords: Social Justice; Equity, Inclusion, and Diversity; Ethnomathematics

In the recent calls for rehumanizing mathematics, researchers and educators call for a mathematics education that centers sociopolitical contexts (Gutiérrez, 2013) and students' funds of knowledge (Moll et al., 1992). Within these sociopolitical contexts, many researchers seek to understand how different communities of students learn and engage with mathematics. I argue that these agendas often take a monoracial approach that leaves out the voices and experiences of multiracial students. As a multiracial educator, I seek to use this poster to center the eight critical multiracial theory tenets (MultiCrit) within mathematics education (Harris, 2016, p. 800).

Tenet 1: A challenge to ahistoricism. This tenet encourages mathematics educators and researchers to analyze the historical context of issues specific to the multiracial community. For example, how has mathematics been used historically to condemn the multiracial community as the end of the pure white race? (Watkins, 2001).

Tenet 2: Interest convergence. Mathematics educators and researchers should consider how multiracial students are positioned as desirable only when they meet the needs of K-12 institutions built around white ideologies (Cross, 2005). How are multiracial students simultaneously oppressed and used by institutions to evade culpability for a lack of diversity?

Tenet 3: Experiential knowledge. Highlighting the experiences of multiracial students provides counterstories and counternarratives to dominant ideologies. In mathematics spaces, these stories shed light on how the mathematical funds of knowledge for multiracial students come from multiple communities, which may combine, conflict, and compete.

Tenet 4: A challenge to dominant ideologies. Mathematics educators should seek to elevate the experiences of multiracial students. Ethnomathematics should be embedded in curriculum and include the voices of students who come from multiple cultures and ways of knowing. In addition, mathematics educators should highlight multiracial mathematicians who have contributed to the field of mathematics.

Tenet 5: Racism, monoracism, and colorism. Multiracial students experience racism, monoracism, and colorism, but often lack the resources to navigate and talk about these experiences (Yong, 2020). One example is how multiracial students are often lumped into one category of "two or more races". This racial category devalues the voices and experiences of multiracial people by assigning them to a broad category that lacks statistical power.

Tenet 6: A monoracial paradigm of race. Racism is often discussed in monoracial terms, which excludes the experiences of multiracial people. Multiracial students should be provided opportunities to explore how their multiple identities fit into mathematics spaces.

Tenet 7: Differential micro-racialization. Multiracial people are often transracialized (Alim, 2016) as various races in different settings. Investigating how multiracial students are transracialized in mathematics classrooms may unveil the power dynamics these students resist.

Tenet 8: Intersections of multiple racial identities. Multiracial students navigate intersectionality not only through nonracial identities but also through multiple heritages. Students should be provided space in mathematics classrooms for this identity exploration.

BETWEEN THE WORLD, MATHEMATICS, AND ME: BLACK FATHERS' PERSPECTIVES ON MATHEMATICS SOCIALIZATION DURING THE COVID-19 PANDEMIC

Gregory V. Larnell
University of Illinois Chicago
glarnell@uic.edu

Anthony T. Thames
University of Illinois Chicago
athame2@uic.edu

This paper reports findings from a broader study that examines and documents the role of K-12 mathematics education amid the remote-schooling experiences of Black families (U.S.) during the COVID-19 pandemic. Moreover, the paper focuses specifically on perspectives of Black fathers. Given then-unfolding social restrictions during the stay-at-home period of the pandemic, the research design centers on semi-structured individual-family and multi-family interviews conducted via secured online video-sharing software. Here, we discuss a central theme from our analyses: tensions regarding mathematics homework as a cross-generational bridge.

Keywords: Affect, emotion, beliefs, and attitudes; Equity, Inclusion, and Diversity; Informal Education; Instructional activities and practices

> You must never look away from this. You must always remember that the sociology, the history, the economics, the graphs, the charts, the regressions all land, with great violence, upon the body (Coates, 2015, p. 10).

During the opening months of 2020, the United States government initiated a disjointed, state-by-state series of social and economic mitigation measures in response to the quickening spread of the COVID-19 coronavirus (hereafter pandemic). Across the country's diverse subareas—regional, rural, urban, tribal, suburban—parents and guardians suddenly faced numerous immediate challenges and decisions regarding everyday personal and professional routines, including the first multi-state emergency stoppage of in-person schooling. Most schools initially adopted a remote or online approach, requiring teachers and students to continue their classes by using video-conferencing software, file-sharing platforms, and course-management systems. There was also a massive effort (though with little to no federal guidance) to provide computing and internet-access resources to teachers and families so that they may participate in remote teaching and learning. Newly emergent studies reveal varying access and participation rates with this new form of remote schooling across the country—disturbing patterns that align with and exacerbate existing societal inequalities.

Purpose and Framing of the Study

This study aimed to document and critically analyze the role of K-12 mathematics education amid the remote-schooling experiences of Black families with school-aged children—i.e., familial networks of home- and community-based caregivers, including parents and guardians—during the pandemic. The specific focus on mathematics socialization among Black families (Martin, 2000; McGee & Spencer, 2015) contributes generally to a growing and needed area of research (also see Gholson & Wilkes, 2017; Washington, 2019; Walker, 2016). Based on related literature, we characterize mathematics socialization conceptually as the interaction of roles, practices, behaviors, and perspectives (see Saleem, Howard, Schmidt-Temple, Langley, &

Howard, 2024). Moreover, this study is timely given its attention to the unique societal moment of the pandemic—with conditions that temporarily upended conventional notions of work, school, home life, and intersections thereof.

A broader goal for this research is to develop a collaborative research agenda with other mathematics education researchers who are currently studying closely related phenomena (e.g., families, mathematics socialization, identity, race)—in order to further the study of how Black people conceptualize and actualize their roles as *mathematics socialization agents* (Martin, 2000; 2007; also see Larnell, 2016). Representing part of a broader, this paper focuses on the question: How did Black fathers support their children's mathematics education during the pandemic? Figure 1 frames broader areas of concern and research questions within the full research study.

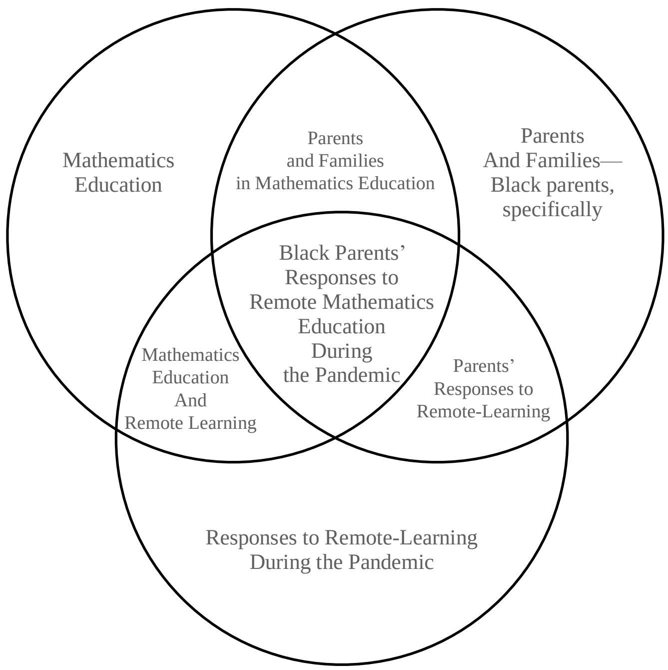

Figure 1: Black Family Mathematics Socialization Conceptual Areas

According to Washington (2019), "Mathematics is an important front on which to wage the fight for full participation in [this] society for African Americans because it has been used systematically to disenfranchise African Americans from upward social mobility and political power" (p. 2). Echoing Washington's overall sentiment and specific centering of Black families (also see McGee & Spencer, 2015), our specific goal for this paper is to contribute to characterizing the roles that Black parents and guardians construct for themselves as well as their perspectives on mathematics education at large and during the pandemic, specifically.

Based on the broader study's questions, the theoretical framework combines elements of Martin's mathematics socialization framework (specifically, beliefs about differential treatment, motivations, relationships to school, mathematics-dependent goals, and expectations for children) and Washington's (2019) framing of supportive practices that extend from those socialization goals (also see Civil, Planas, & Quintos, 2005). The focus on supportive practices is intentional and not regarded to be biased; rather, given the damaging preponderance of narratives about the underachievement of Black learners (see Martin, 2003, 2019 for related critiques), examining the nature of support (and presuming foundationally that such support exists) signals a potent and much-needed epistemic counternarrative. Moreover, this paper's focus on Black fathers supporting their children's mathematics education is also a purposeful choice and an opportunity to fortify such a counternarrative.

Design, Data, and Methods

The study's design was organized to document and critically analyze parents'/guardians' perspectives by way of transcribed interviews (individual families) and focus groups (multiple families). Given the pandemic and the need to avoid group gatherings, all research activity with participants was conducted and recorded virtually using university-secured video conferencing (i.e., Zoom) software. The broader study includes 6 dual-parent or individual-led families; in this paper, we focus on the contributions of three fathers across individual-family interviews and multi-family focus groups. All interview prompts and protocols were developed based on and adapted from other recent studies on Black family socialization in mathematics (e.g., Washington, 2019) and related studies of mathematics socialization and mathematics identity among Black learners (e.g., Author 1, 2016; Martin, 2000, 2006). Conceptually, the interviews centered on how these parents regarded (a) their roles as mathematics socialization agents, (b) their education-supporting practices with school-aged children in their families, and (c) the kinds of resources that they put into practice with and on behalf of their school-aged children.

Participant Descriptions

Lawrence, James, and Oscar are (cisgender male) fathers who participated in individual interviews and a multi-family focus group during the data collection phase of the study; excerpts of their transcribed exchanges during those interviews were included based on coding described in the next section. Each identified themselves and their families as working class; Lawrence is a father of five children and works as an education professional who works in schools, James is a father of four children and works in the banking industry, and Oscar is a father of one school-aged child and works as a human resource professional. Across the three fathers, the grade levels represented by their children span grades K-12.

Summary of Analysis Methods

The interviews were recorded on the video conferencing platform and transcribed professionally. Recordings and transcripts were stored on a secure cloud platform. Coding schemes were developed using a framework of socialization factors based on existing literature. The transcribed text was analyzed primarily using NVivo. Additionally, we viewed and discussed video recordings and excerpted transcripts to develop emergent themes. Analytical memos were developed for the excerpted transcripts presented in this article; these memos were reviewed and discussed, which led to the presentation of the findings in this paper. (Note: We will discuss their positionality in the presentation, due to space limitations here.)

Perspectives on Remote School Mathematics during the Pandemic: Two Themes

In this section, we briefly discuss a central theme (due to space constraints) from our current readings and analyses of data collected from Black fathers: Tensions regarding mathematics homework as a cross-generational bridge. Across all participants in the study, there were consistent and frequent references to homework assignments as a key nexus for parental support (see Schnee & Bose, 2010).

Decades after their own school experiences, each of these three fathers expressed similar perspectives across grade bands, from elementary to high school. Lawrence, particularly, discussed the concern that homework was being deemphasized in his children's mathematics classes—and that parents were left to assemble supplemental opportunities to interact to support their children's at-home mathematics education.

Lawrence: …I'm gonna be honest with you…like we work on math. They don't give homework like we got homework when we were kids. I mean, they don't bring any homework home. Like we have to do stuff. We have to find things for them to do, you know, at home.

As Lawrence explains, a key shift in contemporary school mathematics homework is a broader reliance on technologies (e.g., devices, software, online platforms) as basic elements for mathematics teaching and learning and not merely ancillary. Relatedly, James discusses this as a tension in relation to his perceptions of support for his children learning mathematics.

James: My kids have [Apple] iPads. I'm not an iPad person (chuckle), but they have iPads. And everything…information is fast. You know, you go to your computer and find an answer…When it comes to homework, my kids have no computers. You're gonna go to pencil and paper. Now, once you understand that concept…you can use a computer. You can use a calculator. You can use, you know, things of that sort. But they're gonna understand the foundation because, uh, it's kinda like the foundation teaches them how to really think about what they're doin'. Not a quick answer.

For James, the practice of helping children with mathematics homework is primarily a paper-and-pencil exercise, but during remote schooling, those processes were communicated virtually and across platforms and programs. For Oscar and Lawrence, differences in how mathematics was taught at school versus home settings were also common concerns.

Oscar: Um, I know with my daughter, um, it was a problem, um, that I decided to step in myself and do it, uh, but again, it was countered always as the differentiation between what was taught in the classroom versus what is being taught at home.

Lawrence: So, um, now they got—if they're struggling with something, and-and we talking, and we communicating with the teacher about what they're struggling with, um, we make sure there's that communication. And we'll bring stuff home, and-and we'll work on things, you know. But, um, yeah. That's kind of like pretty much how we handled it.

Discussion

Again, the focus on Black fathers' perspectives and the findings reported here represent a portion of the broader, ongoing study focused on Black families' experiences with school mathematics during the pandemic. The central theme of homework, though prompted by our interview protocol and framework, were elaborated and revisited multiple times across multiple participants. Our hope is that this research will contribute to our broader understandings of families roles in school mathematics—and toward redressing the dearth of mathematics education scholarship that includes and specifically focuses on Black communities.

WOMEN DOCTORAL STUDENTS' VIEWS OF THE ROLE OF THE ASSOCIATION FOR WOMEN IN MATHEMATICS

Talia LaTona-Tequida
San Diego State University
tlatonatequida@sdsu.edu

Keywords: Gender, Equity, Doctoral education

Despite improvement in representation at the undergraduate level, women are still underrepresented in doctoral mathematics with only 28% of doctoral degrees awarded to women in 2018 (National Science Foundation, 2021). In addition to inequitable representation, women in doctoral mathematics have experienced overt prejudice, feelings of invisibility, insufficient or negative advising experiences, and a lack of belonging (Herzig, 2004; Miller, 2015). Furthermore, women's reports of success are often mitigated by expressions of struggle centering around academic support (Ataide Pinheiro, 2021). In contrast to a demonstrated need, there is little research investigating interventions supporting women in doctoral mathematics or the efficacy of student organizations for women at the graduate level, such as the Association for Women in Mathematics (AWM). However, there is evidence that undergraduate science, technology, engineering and mathematics (STEM) student organizations may improve support for students from underrepresented groups by enhancing personal contact with faculty members (Mwaikinda & Aruguete, 2016).

In this poster I investigate the perspective of five women doctoral students with respect to their participation in a graduate student organization, a chapter of AWM. I answer the research question: *How do women mathematics doctoral students, as AWM members, view the role of AWM in their mathematics department?*

Methods

Participants included five women enrolled in a doctoral mathematics program at a research-intensive (R1) university in the western U.S. The women were selected using a stratified purposeful sampling (Patton, 1990) with respect to years' experience in the program. This included one woman enrolled in coursework, two women in early research, one woman in advanced research, and one woman taking a leave of absence after completing coursework. Additional sampling criteria included participation in the local graduate chapter of AWM. Data included one-hour narrative interviews (Mueller, 2019) from each of the five participants. Analysis included the first two steps of the of the thematic analysis methodology (Braun & Clarke, 2006) – familiarizing myself with the data and open coding meaningful passages. One code that emerged across interviews was *building a sense of community*.

Preliminary Results

All five women described AWM and its related activities as a way to build a sense of community in their mathematics department, meaning they saw AWM as a way to bring people together in a shared space and build connections. A second-year student described the group's weekly gatherings, saying "it builds a sense of comradery and helps connect people, especially if they aren't in your research area or your classes who maybe you wouldn't know otherwise and just helps connect people in the department." Interestingly, participants expressed varying positions about how this community building supports the women in the department. As part of the poster presentation, I will further explore this tension of community building and gender.

AN ELABORATION ON MASTER NARRATIVES IN MATHEMATICS AND HOW UNDERGRADUATES RELATE TO COUNTERNARRATIVES

Kathleen Melhuish
Texas State University
melhuish@txstate.edu

Lino Guajardo
Texas State University
lrg74@txstate.edu

Kristen Lew
Texas State University
kristen.lew@txstate.edu

Paul Dawkins

pcd27@txstate.edu

Kyeong Hah Roh
Arizona State University
khroh@asu.edu

Because the master narratives about mathematics in the US often play an exclusionary role in students' educational experiences, educators have sought to integrate counternarratives into instruction that might disrupt these effects. As part of a larger project to develop a research-informed curriculum for undergraduate introduction to proof courses, we gathered author stories from a diverse set of mathematicians for students to read and reflect upon. To study student responses to these author stories, we synthesized a framework of the master narrative of mathematics in the US and identified how the author stories countered elements of this narrative. We then analyzed 80 student reflections from one introduction to proof course to identify whether and how students either endorsed or countered the elements of the master narrative. Our findings point to a positive, yet modest capacity for these stories as counternarratives.

Keywords: Undergraduate Education, Equity, Inclusion, and Diversity

In recent years, counternarratives have become not just a means for research, but a potentially transformative tool to incorporate into instruction. Stories both about ourselves and society provide a means through which to organize our understanding of the world. Culturally shared narratives, or dominant/master narratives, provide a framing to compare or integrate personal experiences. These master narratives often disadvantage marginalized groups, such as women and people of color, in fields like mathematics (Berry III et al., 2011; Leyva, 2017; Adiredja, 2019). Narratives portraying mathematics as neutral, individualistic, and meritocratic reinforce hegemonic norms, dismissing alternative ways of learning and working that align with diverse identities and cultures (McBride, 1994; Cobb & Russell, 2015; Cervia, 2019). Counternarratives (e.g., Solórzano, D. G. & Yosso, 2002) can serve to challenge dominant narratives by not only disrupting storylines about who can succeed in mathematics (e.g., Berry III et al., 2011; Langer-Osuna et al., 2016; Leyva, 2016; McGee, 2009) but also redefining what it means to engage with the subject. However, as cautioned by Cervia's (2019) exploration of scientists, siimply showcasing successful individuals from minoritized groups can inadvertently reinforce existing master narratives, especially if these narratives align with traditional norms. Disrupting master narratives requires challenging not only demographic stereotypes but also the perceived traits and norms associated with mathematicians and mathematical activity.

In this study, we analyze student reflections on mathematician biographies paired with proofs in an introduction to proof course. These narratives, tailored for the intended audience of undergraduate mathematics students, aim to challenge dominant narratives about who can succeed in mathematics and how mathematics is practiced. By synthesizing literature on mathematics and mathematician storylines, we develop a framework to examine how counternarratives resonate with students and align with or challenge dominant narratives in the United States. Our research questions are twofold: What elements of mathematician counternarratives were salient to a group of undergraduate mathematics students? How do these elements align (or not) with dominant narratives of mathematics in the United States?

Theoretical Framing

Broadly, we adopt McLean and Syed's (2016) narrative distinctions. Master narratives are culturally shared stories that guide behavior and identity within a culture. They dictate who excels in math and define the essence of being a mathematician. Counternarratives, on the other hand, challenge these dominant storylines. Personal narratives involve negotiating between societal expectations and individual identity, influenced by both master and counternarratives.

Drawing from various research areas, we identified themes in master narratives about mathematics. These themes encompass beliefs about mathematicians, descriptions of mathematicians, countered narratives, and theoretical discourses. While these categories overlap, they collectively shape the perception of the American Mathematician. In Table 1, we present these narrative elements alongside quotes from key studies that inform our understanding.

Table 1: Mathematical Master Narrative Elements and Storylines

Element/Storyline	Reference
Mathematics is done by privileged white men.	"[P]opular discourses overwhelmingly construct mathematicians as white, heterosexual, middle-class men" (Moreau et al., 2008, p. 25).
Mathematics is done by those who are brilliant, but socially inept.	"Mathematicians were often portrayed as socially inept nerds" (Di Martino et al., 2023, p. 11).
Mathematics is done in isolation.	"Mathematicians always work alone in my mind. They're always like those, those hobbits that live in their own little room… Like this would be perfect, lined with grease boards and chalkboards" (Female Math Major, Piatek-Jimenez, 2008, p. 638).
Mathematics is dry and not fun.	"Mathematics is full of rules and formulas to be remembered. Mathematics is dry, it does not leave room to feelings. Mathematics does not make sense, the aim of learning certain things is not clear. In mathematics, there is no room to express one's own ideas" (Di Martino, & Zan, 2011, p. 477).
Mathematics ability is innate, and mathematics is easy for those with high ability.	"Instead of seeing learning math as an ongoing process, learning at my own pace, it became "either you get it or you don't." I put math in the, 'it's just not for me' category" (College student, John et al., 2022, p. 9).
Mathematics is colorblind and neutral.	"The mathematical model of equality constructed intentionally perpetuates the myth of mathematics as neutral and objective to maintain white institutional spaces" (Gómez Marchant et al., 2023 p. 12).
Mathematics is individualistic and a meritocracy.	"A prominent feature of education in the United States is the widespread endorsement of an achievement narrative, which links individual motivation and effort to academic achievement." (Zavala & Hand, 2019)

We emphasize that these storylines together support greater myths such as the existence of a racial hierarchy of ability (Battey & Leyva, 2016). All of these elements serve a hegemonic role in preserving exclusionary standards and the white patriarchal space of mathematics (Battey & Leyva, 2016; Battey & Marshall, 2023; Leyva, 2017; Martin, 2013; McGee, 2020).

Methods

We present data from one implementation of this curriculum in an introduction to proof course at a large research university in the United States. As part of this curriculum, interesting proofs are paired with author stories from modern mathematicians. In this study, students wrote reflections on six author stories (authors included two Black men, one Latinx woman, one Pacific Islander one, one white-nonbinary person, and one Latino) The authors told their stories both as mathematicians and outside of mathematics, obstacles and struggles, and images of what doing mathematics looked like (See Melhuish et al., in press). Twenty-one students were enrolled in the class and were listed in university documentation as having the following ethnicities: 11 White, 2 African-American, 6 Hispanic, 1 Asian, 1 Unknown. There were 7 women and 14 men.

The focus of this submission is on the written reflections of sixteen student participants on the assigned author stories. Students submitted a mean of 5 reflections, for a total of 80 student reflections. Student reflections varied in length from three sentences to two handwritten pages. Prompts for the reflections included questions such as: "What stuck out to you about Dr. ____'s story?" "How did Dr. ____'s story resonate with your own story? How did it differ?"

For the purpose of this study, we identified passages of the reflections where students noted components of the master mathematical narrative were either countered or endorsed in the author stories. Two authors independently coded each of the 80 reflections for counters and endorsements, resolving discrepancies through discussion. Overall, we identified 127 instances of countering the master narrative elements and 15 instances of endorsing them.

Results

Student reflections revealed how they internalized the author stories. Some students endorsed master narrative elements by highlighting them in the stories or by opposing counter elements. Others recognized counternarrative elements, emphasizing their significance. We present Table 2 to summarize the narrative elements reported by students. Additionally, we introduce two new categories: linear trajectory in becoming a mathematician and family and cultural expectations. Students expressed surprise at the non-linear career paths of mathematicians, echoing narratives of academia's linear progression. Similarly, they were surprised by authors facing family discouragement from pursuing mathematics rather than a more lucrative career.

Table 2: Mathematical Master Narrative Elements Found in Student Reflections

Master Narrative Element/Storyline	# Countering	# Endorsing
Mathematics is done by privileged white men.	6	1
Mathematics is done by those who are brilliant, but socially inept.	2	0
Mathematics is done in isolation.	5	2
Mathematics is dry and not fun.	13	0
Becoming a mathematician is a linear trajectory.	13	0
Mathematics ability is innate, and mathematics is easy for those with high ability.	15	4
Mathematics is colorblind and neutral.	5	0
Mathematics is individualistic and a meritocracy.	0	3
Family and culture would hold positive views on choosing mathematics as a career	5	0

A Look at How Students Reflected on Elements of Master Narratives

Mathematics is done by privileged white men. None of the author stories were written by white men. We found that some students explicitly referenced this master narrative. Students further identified themselves in the stories with one woman explaining, “being a Latinx woman is personally inspiring, as I too am a Latinx woman.” Such comments also extended to economic and educational privilege with several students noting things like relating to coming from a “rural” or “blue collar” town without great public schooling. We see each of these comments implicitly showing awareness of the master narrative about white, privileged men as mathematicians, but focusing on the counter to it and the ways the counter aligns with their personal narratives.

Mathematics ability is innate, and mathematics is easy for those with high ability. Every author stories included times of struggling with mathematics, in the academia, or in school. This was the most commonly attended to element in the student reflections. Several students reflected that they related to these stories because their own “identity of being ‘good’ at school” had been challenged. One student explained, “even people who have earned their degree in mathematics have struggled with math. Even though I struggle on some topics, it doesn’t mean I’m not geared for math.” These comments reflect a negotiation of their personal narratives where students seemed to take the counter story elements and expand their idea of who can be a mathematician and whether it is necessary to always have things come easy.

Becoming a mathematician is a linear trajectory. A number of the author stories represented atypical paths to mathematics including nearly failing out of school, leaving the academy and returning, and cycling through many majors before arriving at mathematics. Students often reflected on these elements with some noting elements such as “detours.” One student reflectied, “I had a pre-conceived notion that mathematicians must be persistently passionate about math. Dr. [W] proved that notion incorrect.” These elements served to expand out who can do mathematics (not just those who are always passionate about math) and how one can arrive at being a mathematician.

Mathematics is dry and not fun. The author stories also contained ways that the authors loved mathematics and how they went about doing mathematics. Some students contrasted the standard approach to school mathematics such as one student notoing the importance of the idea of “learn[ing] in a way you are changed and not in a way that you memorize.” Students further linked ideas of mathematics being fun with the challenge.

Other Story Elements. A major theme in author stories was the collaborative nature of mathematics. However, students rarely mentioned this in their reflections. Some noted the need to connect with others, but most focused on professors and mentoring rather than peer collaboration. Ideas of individualism and meritocracy were mixed. One student countered the idea of innate ability but endorsed meritocracy by stating that effort leads to success. Others recognized the support from people in their lives, challenging individualism.

Discussion

In this report, we provided two fundamental contributions. First, we stitched together a dispersed literature base to create a master narrative of mathematics with attention to: who does mathematics (mathematicians), how one becomes a mathematician, how one does mathematics, and what mathematics is. Second, we explored how author stories that challenge these narrative elements were perceived by students. The student reflections provided strong evidence that the author stories were successful at challenging several elements of the master narrative around mathematics: mathematics being dry and not fun, the path to a career as a mathematician being linear, and mathematics ability as being innate and mathematics being easy for those with high ability. The master narrative that white men dominate math was less disrupted. Only a few students, particularly women of color, mentioned race. Meritocracy and individualism were either not addressed or reinforced by students' reflections. Stories often highlighted overcoming barriers, emphasizing individual effort. Further research should explore which stories can disrupt which narratives and how to effectively engage students in reflecting on their personal narratives.

The globalization of higher education in the United States has led to a significant increase in the enrollment of international students, particularly from Africa, thereby enhancing the cultural diversity of academic institutions (Hendrickson et al., 2011; Lee & Rice, 2017). African international students face unique challenges due to their diverse academic backgrounds and specific cultural and social needs (Hendrickson et al., 2011; Lee & Rice, 2017; Irungu, 2013). While these students enrich the academic environment and contribute financially to the U.S. economy, their academic journey, especially in mathematics education, is fraught with difficulties such as language barriers, cultural adjustments, social integration issues, and academic pressures (Irungu, 2013). Existing orientation programs and support services often fail to address the specific needs of African students, hindering their academic success (Smith & Khawaja, 2011).

Higher learning institutions have developed support systems and programs to assist international students, including academic advising, tutoring, mentorship programs, and mental health services. However, African international students encounter difficulties accessing these services due to cultural, language, and financial barriers (Smith & Khawaja, 2011). Tailored support structures are essential to effectively address these challenges and ensure the academic success and well-being of African international students in U.S. higher education institutions (Jin, 2019).

A multiple-case study approach was employed to explore the experiences of African international students in mathematics education in U.S. institutions, focusing on the perspectives of international student advisors (Altbach & Knight, 2018; Poyrazli & Grahame, 2007). The study aims to assess the effectiveness of existing support services and programs for African students and understand how advisors perceive these services (Olson & Banjong, 2016). Preliminary findings indicate that while resources are available, there are significant challenges and gaps in the support systems, emphasizing the need for culturally responsive approaches and tailored support for African international students (Irungu, 2013; Poyrazli & Grahame, 2007).

This study underscores the significance of addressing the unique challenges faced by African international students in U.S. higher education institutions and calls for refined strategies to create a more inclusive and supportive environment (Mwangi et al., 2019; Smith & Khawaja, 2011). By investing in culturally relevant programming, fostering collaboration among stakeholders, and continuously evaluating support strategies, institutions can enhance the academic success and well-being of African international students, contributing to a more equitable and enriching educational experience (Smith & Khawaja, 2011).

The Thinking With Algebra (TWA) project, which consists of a developmental algebra curriculum and supporting professional development, has been integrated into diverse algebra courses to support undergraduate students' success in college algebra (Feikes et al., 2024). This paper examines the equity-oriented instructional practices integrated into TWA to support strengthened equity outcomes among students. This project draws on sociopolitical equity scholarship (Rubel, 2017), including a framework consisting of achievement, access, identity, and power (Gutiérrez, 2012). Instructor and student data indicate positive changes in student achievement and identity outcomes. Future directions include expanding the integration of equity-oriented instructional practices and investigation of student equity outcomes. Applying an equity lens to TWA is critical given the barriers students, particularly minoritized students, face in algebra.

Keywords: Equity, Inclusion, and Diversity; Instructional Activities and Practices; Undergraduate Education; Algebra and Algebraic Thinking.

Background

Ample evidence indicates a national crisis related to students successfully completing algebra coursework, which is extremely concerning given that algebra serves as a gateway to higher level mathematics and science courses (Domina et al., 2015; Long et al., 2012), to postsecondary success at colleges and universities (Spielhagen, 2006), and to STEM degree pathways (Loewenberg, 2003). Despite efforts to improve the teaching and learning of algebra, many students are still struggling with the subject and are not persisting in their mathematics coursework (Greenes, 2008). Additionally, when students do not successfully pass algebra coursework, aspects of their mathematical identities are likely to be negatively impacted, such as developing negative attitudes and beliefs about mathematics. Even more concerning is the significant underrepresentation of minoritized students, including Black, Latinx, and low-income students, in the student population successfully completing algebra coursework (LaFave, 2019), attaining STEM degrees (Fry et al., 2021), and pursuing STEM careers (Fry et al., 2021).

This paper draws on sociopolitical mathematics education equity scholarship (Rubel, 2017), a framework within this literature consisting of four dimensions: achievement, access, identity, and power (Gutiérrez, 2012), and prior research by the authors (Oppland-Cordell et al., 2024) to examine how the instructional practices of the TWA project, which is funded by the National Science Foundation Improving Undergraduate STEM Education: Education and Human

Resources (IUSE: HER; DUE 2021414), align with equity-oriented instructional practices appearing in this scholarship. The research questions are: (1) *How do TWA instructional practices align with equity-oriented instructional practices?* and (2) *How does students' participation in TWA impact their mathematical achievement and identity development?* Such findings will expand knowledge about how to create equitable mathematics learning environments in developmental academic settings that support students' mathematical success.

Theoretical Framework

Gutiérrez's (2012) equity definition consists of four dimensions: access, achievement, identity, and power. Drawing on this definition, this project defines the four equity dimensions in relation to the design, instructional practices, and professional development components of TWA. Table 1 includes these definitions.

Table 1: TWA's Equity Dimension Definitions Adapted from Gutiérrez's (2012) Framework

Equity Dimension	Design, Instructional Practices, and Professional Development
Achievement	TWA supports students' strengthened mathematics achievement outcomes as measured by participation rates, persistence rates, and student self-perceptions of achievement.
Identity	TWA supports students' strengthened mathematics identity development, including how they co-construct this identity with their other identities. Measures include student self-perceptions and perceptions of how other view them as mathematics learners.
Access	TWA mandates professional development to support high quality mathematics instructors. Through group work and whole class discussions, TWA encourages a learning environment that supports student participation in and out of class.
Power	Through small group and whole class discussions, diverse voices and alternative notions of mathematics knowledge are embraced in the mathematics learning context.

While Gutiérrez's equity dimension framework provides guidance for defining equity for the TWA project, we also wanted to investigate how specific instructional practices integrated into TWA align with equity-oriented instructional practices appearing in emerging sociopolitical mathematics education equity scholarship. Drawing on Gutiérrez's (2007) equity research, Rubel (2017) identified and organized four "equity-directed instructional practices from four models of progressive pedagogy," of which three are highlighted here: standards-based mathematics instruction (SBMI), complex instruction (CI), and culturally relevant pedagogy (CRP) (p. 69). Rubel also highlighted a specific instructional practice from each model that collectively revealed how these pedagogies are interconnected and build upon one another: *SBMI*: teaching for understanding; *CI:* multidimensional participation; and *CRP*: connecting mathematics instruction to students' experiences. While the SBMI and CI examples strongly align with the access and achievement dimensions in Gutiérrez's work, the CRP example closely aligns with the identity and power dimensions (Rubel, 2017). This study draws on these specific examples to inspect overlap and growth opportunities for the equity-oriented instructional practices employed in TWA. In particular, this study explores how TWA currently teaches developmental mathematics in ways that contributes to strengthening students' conceptual understanding, supporting their multidimensional participation, connecting mathematics instruction to their experiences, and applying mathematics in critical ways to navigate their lives and worlds.

Methods

TWA Context and Participants

TWA is a developmental algebra curriculum that supports undergraduate instructors in teaching algebra in a way that conceptually and procedurally prepares students for success in college algebra (Feikes et al., 2021; Feikes et al., 2024). TWA also provides a faculty workshop to support college instructors with understanding and implementing the curriculum with undergraduate students. This study focuses on TWA implementation at a community college in Illinois designated as a Predominately Black Institution (PBI) and an emerging Hispanic Serving Institution (HSI) and a public university in Indiana designated as an HSI. Preliminary findings related to the achievement and identity dimensions are provided for student populations in both of these contexts, which reflect general student demographic data at the respective institutions.

Data Collection and Analysis

The authors created a collaborative inquiry community (Larrivee, 2000) to explore TWA instructional practices. A critical component of the data collection process included biweekly professional development meetings where the team discussed TWA instructional practices that aligned with Rubel's (2017) framework. Such discussions centered on central themes of the TWA curriculum (e.g., distributed practice) and TWA classroom organizational approaches (e.g., class discussions, small-group work) contained in the TWA instructor textbook: *Thinking with Algebra (TWA) Success in Algebra and Beyond* (Feikes et al., 2023).

We also provide preliminary findings on student outcomes related to aspects of the achievement and identity equity dimensions to provide evidence of TWA's positive impact on students. Such student outcomes were explored using mixed-methods, including quantitative and qualitative methods, which this project plans to expand on in the future by collecting and analyzing data related to all four equity dimensions. The quantitative data collected and analyzed included pre- and post-survey student responses that focused on mathematics self-efficacy (Bandura et al., 1999). For six instructors who used TWA and implemented equity-oriented instructional practices during the first year of the project in 2020, the quantitative and qualitative data collected and analyzed included survey and interview data, which revealed how instructors believed TWA impacted student identity development.

Preliminary Findings

Table 2 indicates how TWA instructional practices mapped onto Rubel's (2017) equity-directed instructional practice examples, which are organized within four pedagogical models.

Table 2: TWA Instructional Practices Aligning with Rubel's (2017) Equity Examples

Progressive Pedagogical Models (Rubel, 2017)	Questions Explored for TWA Related to Rubel's (2017) Examples	TWA Instructional Practices
Standards-based mathematics instruction (SBMI)	How does TWA teach students developmental mathematics in ways that supports their conceptual understanding?	* Curriculum design directly supports conceptual understanding * Curriculum integrates distributed practice * Students engage with the physical format of curricular materials
Complex instruction (CI)	How does TWA support students' multidimensional participation?	* Integration of small-group work and whole class discussions in mathematics learning contexts * Students are encouraged to discuss personal understandings or misunderstandings, diverse solutions, and methods * Connect/build on prior math knowledge
Culturally relevant pedagogy (CRP)	How does TWA connect mathematics instruction to students' experiences?	* Building strong relationships with students * Embracing multiple solution strategies that reflect students' experiences and culture

Preliminary findings on achievement and identity student outcomes based on both quantitative and qualitative student and instructor data indicate positive changes in both of these dimensions. For example, statistical analysis of the mathematics self-efficacy survey data showed emerging confidence (n=39, p=.12) in students' ability to succeed in their next mathematics class with a small (d =.33) effect size. The authors plan to collect more data to test at a smaller, $\alpha = .05$, significance level. Feedback from instructors through interview and survey responses indicated that students are constructing strengthened mathematical identities (e.g., confidence) in relation to their engagement with the TWA curriculum.

Conclusion and Future Directions

Emerging mathematics education equity research supports applying broader sociopolitical equity definitions to mathematics education research because this theoretical lens can provide additional knowledge regarding how and why students and minoritized students attain mathematical success. This research addresses a gap in existing mathematics education scholarship by drawing on emerging equity research to identify equity-oriented instructional practices integrated into the TWA developmental mathematics curriculum that can serve to support strengthened equity outcomes among students, broadly defining such equity student outcomes using a sociopolitical equity framework, and providing evidence of improvements in student achievement and identity outcomes based on student and instructor data. Future directions include collecting additional quantitative and qualitative data to further investigate student experiences and outcomes related to the four equity dimensions, investigating such experiences and outcomes for minoritized learners, and integrating additional equity-oriented instructional practices that can support improving such experiences and outcomes. Examples of additional equity-oriented instructional practices include integrating culturally responsive and social justice-oriented materials into the TWA curriculum. Importantly, this project expands knowledge about the equity-directed instructional practices that can be integrated into mathematics learning contexts, including developmental settings, to support students' mathematical success.

PAYDAY POWER-UP: LET'S MAKE A RAISE DISTRIBUTION

Ayse Ozturk
Old Dominion University
aozturk@odu.edu

This study illustrates a problem-solving activity reflective of a real-life situation wherein high school students articulate their reasoning while contemplating the effectiveness and fairness of distributing raises. Study data were gathered via teaching experiment methodology in problem-solving sessions at a mathematics camp for secondary students. Examination of the data indicated that students sought entry points for problem-solving by making assumptions and pinpointing crucial variables. Framing mathematics within the concept of fairness encouraged students to review their work, engage in active listening, and find purpose in mathematical reasoning.

Keywords: Equity, inclusion, and diversity; Social justice; Communication; Problem-solving

The literature suggests that addressing real-life problems prompts students to tap into their funds of knowledge (Hunter et al., 2022; Jung & Magiera, 2023) and everyday experiences (Civil, 2018) in constructing an understanding of mathematical concepts. Recent research underscores the importance of enhancing mathematical sense-making through communication, particularly when addressing issues of equity and inclusion, helping students to comprehend and challenge injustice in real-life contexts (Berry et al., 2020; Kokka, 2020; Ozturk, 2023). This study extends prior research by examining students' mathematically diverse approaches to distributing a raise fairly.

Conceptual Framework

The current study drew from Gutstein's (2016) use of mathematics to contemplate individuals' life realities and to examine (un)fairness in society. We adapted Jung and Magiera's (2023) framework to study students' approaches to understanding and challenging inequitable situations in realistic problem contexts while examining the distribution of resources and power among cultural and socioeconomic groups (Figure 1):

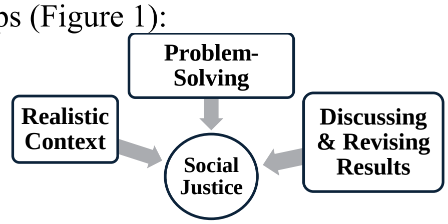

Figure 1: Elements of Social Justice-Oriented Problem-Solving (Adapted from Jung & Magiera, 2023)

Within the framework, students solve problems using real-life knowledge (directly related to the problem context), which is typically integrated into devising problem-solving strategies instead of relying solely on formal mathematical knowledge. The students then develop models and strategies that relate to the problem situation, marking the initial stage of mathematization. Next, students shift their focus from the problem's contextual details to the mathematical aspects, applying mathematical skills and strategies to arrive at a solution. During class discussions, students present their work and actively listen to each other while conversing about identifying sources of equitable opportunities and analyzing systems of power and resources that impact different societal groups. These discussions link broader social justice issues to students' personal experiences and mathematical knowledge, enhancing their understanding of society via lesson contents (Gutstein, 2016). The adapted framework guided data analysis, illuminating students' communication related to developing a fair, effective method for distributing a raise.

Research Setting and Participants

This paper's data emerged from a 6-week after-school math program for high school students, meeting twice a week for 2 hours. The research explored secondary students' application of their knowledge in mathematics to solve real-life problems related to equity and social justice (Ozturk, 2021). The mathematical content focused on using quantities and their units for problem-solving. Participants, including six 10th-grade students, two observer-researchers, and one teacher-researcher, are pseudonymized in the article.

Methods and Data Collection

The class followed a three-phase cyclical process drawn from McClain's (2002) teaching experiment approach: (a) performing group problem-solving; (b) presenting solutions to the whole class; and (c) revising solutions in groups. The chosen method facilitated peer feedback, critical listening, and reflection on diverse reasoning methods. Each 2-hour class involved two problems. Data collection encompassed video and audio recordings and transcriptions, students' written work, and observer researchers' notes as supplemental data used to organize video recordings and transcripts during initial data analysis.

Data Analysis, Sample Student Dialogues, and Students' Written Work

The data for this report comprised a 1-hour-long compilation of video excerpts wherein students solved a problem and communicated their solutions to the class. The criterion for selecting video excerpts was the portrayal of students engaged in identifying potentially important variables and using them to find a mathematical method for determining raises. We focused on the role of communication in helping students critically evaluate the fairness of each method while addressing the problem.

Data analysis featured a thematic analysis approach (Braun & Clarke, 2012) comprising three steps: (a) documenting instances of students' problem-solving; (b) employing a conceptual framework (Figure 1) to categorize students' application of everyday and mathematical knowledge, and detail students' utilization of models when supporting their communication through mathematical representations; and (c) inductively creating themes to classify evidence of students' engagement in developing mathematical methods for distributing a raise, with a specific emphasis on fairness. While ongoing analysis aims to uncover the impact of social-justice-focused classroom discourse on collective mathematical sense-making in another paper, this research report specifically aims to illustrate one theme related to the groups' initial approach to identifying key variables and using them to explain the fairness of their raise distribution. The following discussion includes examples of students' work and discussion excerpts.

Identifying key variables. Within this theme, students collaborated in pairs throughout the problem-solving process. Groups began by brainstorming and determining variables to consider and developing a mathematical method to solve the problem. The Distributing Raises Problem (Figure 2) tasked students with identifying crucial variables to establish a mathematical approach for determining raises. Students examined variables such as an employee's educational background, years of experience, working hours (full-time vs. part-time), job position, and salary. Group A decided to allocate raises based on employee's salaries (see Table 1).

> Imagine you're the boss of a small company with $10,000 to give raises to the five employees. How would you decide who gets what? Share your method for distributing the raises in a way that's not just effective but also fair!

Figure 2: Distributing Raises Problem (Adapted from Illustrative Mathematics, 2016)

Group A took considered that employees would hold different full-time positions and receive varying salaries. While working hours and educational background potentially differed among the five employees, salaries emerged as the most crucial variable in Group A's method of distributing raises to them. According to Group A's approach, an employee with a higher salary should receive a larger pay raise than an employee with a lower salary.

Table 1: Group A's Written Work and Small-Group Discussion

<table>
<tr><th>Students' written work:</th><th>Students' dialogue (group discussion):</th></tr>
<tr><td></td><td>Ann: We can make up salaries for now. I want to see how a system may work first. Ok, if we assume $70,000, $60,000, $50,000, $40,000, and $30,000, with a total sum of $250,000, we can calculate the percentage raise for each person.
Amari: Let me write it down.
$250,000. p = $10,000.
Ann: Yeah! Then, we calculate the increase for each employee.
Amari: Like, $50,000 will become $52,000. Salary is the most important thing here.</td></tr>
</table>

The fairness of this method is based on each person receiving the same percentage raise rather than the same amount of money, ensuring equity by acknowledging that individuals with different salaries should obtain proportionate increases. Otherwise, giving all employees the same raise amount regardless of salary or work hours could result in those with lower salaries or fewer work hours receiving a significantly higher percentage raise than their coworkers with higher salaries or longer work hours.

When Group A explained their method, other students questioned the chosen variables for distributing raises. The class assumed that each employee's work impact varied, making a uniform raise unfair. Sydney's observation (see Table 2) highlighted the unfairness of dividing \$10K by 5. Miles's real-life example comparing a waitress to a restaurant manager was supported by Amari's explanation of Group A's method development, accounting for diverse job positions and full-time work. Group A began by assigning salaries to the employees to test their distribution idea alongside the raise percentage, then developed an equation to represent their system (see Table 2), which Anna justified by demonstrating how one quantity (raise percentage) depended on another (total salaries), emphasizing that fairness required the distribution to address employees' salary differences. Thus, Group A's method aligned the calculation of raises with individual salaries, helping the class go beyond computation to interpretation in context.

Table 2: Group A's Revised Written Work and Whole-Class Discussion

Students' written work:	Students' dialogues (whole-class discussion):
	***Sydney:*** Why hasn't anyone divided \$10K by 5? Shouldn't everyone get an equal raise? ***Miles:*** Not fair! What if they have different jobs? \$2K might be significant for a waitress but not for a restaurant manager. ***Amari:*** Right! That's why we're going with the idea of giving the same percentage raise—based on salaries. We keep the same percentage increase, but we also think someone with a higher salary should receive a larger pay raise than someone with a lower salary, assuming all workers are full-time here. ***Tom:*** Why does this method work? ***Anna:*** Because we have an equation. Even if the salaries and their total change, we can still calculate the raises accordingly. ***Tom:*** Why aren't job positions or education important? ***Anna:*** They are important, but we're assuming that higher salaries mean better education and job positions; no need to include them as additional variables here.

Tom's inquiry led to reassessing why education and job positions were omitted as variables, whereupon Anna explained that higher salaries reflected better job positions and education. Instead of treating the salaries separate variables, Group A summed the salaries as a single variable in the equation. Later, the class concluded that work experience could also be a significant variable. Revising Group A's method and including work experience (Y) as a secondary variable would make the equation more complex, thus better reflecting employee qualities such as loyalty—years of experience at the company. This approach would improve fairness by ensuring raises are not solely based on salary; for example, a longer-retained, medium-paid employee could receive a larger raise than a higher-paid employee. In that manner, the raise distribution system would become increasingly attuned to the employee's qualities.

Results and Conclusion

This study describes secondary students' problem-solving process mirroring a real-life scenario in terms of communicating their reasoning while considering fairness in distributing raises. Preliminary analysis revealed the students' search for problem-solving entry points through making assumptions and identifying key variables, thus contextualizing conditions and explaining the reasoning behind various distribution methods. Justifying methods to peers and explaining their mathematical validity engaged the entire class and encouraged students to refine solutions. The findings align with previous research (e.g., Gutstein, 2016; Jung & Magiera, 2023; Ozturk, 2023), confirming that contextualizing mathematics with reference to effectiveness and fairness led students to double-check their work and listen critically to peers while inspiring them to employ mathematical reasoning.

SENSE OF BELONGING OF MINORITIZED FEMALE STUDENTS IN DIVERSE INTRODUCTORY MATHEMATICS CLASSES

Sarah H. Park
University of Georgia
spark3@uga.edu

Sense of belonging is a critical factor in supporting female minoritized students' persistence, motivation, and positive outcomes in STEM education. However, the current research base is primarily focused on singular identities, and situated at the campus or department level, rather than the classroom level, at Predominantly White Institutions (PWI), Historically Black Colleges and Universities (HBCU), or selective research universities l. In this paper, I present the quantitative results from a mixed-methods study that examined belonginess of students in college algebra and precalculus classes at an open-access, diverse, minority-serving institution. Results indicate that by the end of the semester, there was no difference in belonging based on race or gender. However, students with higher mathematics affinity and higher expected final grades had a higher sense of belonging in their mathematics courses.

Keywords: Belonging, Intersectional, Gender, Race, Mathematics Classrooms

Introduction

Higher education institutions are becoming increasingly diverse in their undergraduate populations, but minoritized female students, especially Black and Latina women, continue to be underrepresented in almost all STEM fields (Hatfield, 2022; Ong et al., 2016). Although minoritized female students often begin college with a strong interest in STEM, they are more likely to leave the STEM major (Rainey et al., 2016). Extant literature suggests that introductory mathematics courses serve as obstacles for minoritized female students, as they navigate experiences of isolation, bias, racial and gender microaggressions, stereotype threat, and lack of belonging due to their intersecting racial and gender identities (Johnson et al., 2007; Leyva et al., 2020; McGee & Bentley, 2017; Ong et al., 2011; Museus et al., 2011).

Researchers argue that sense of belonging at the classroom level, is a key factor in supporting minoritized student persistence, and it may even improve participation, student engagement and academic performance (Kirby & Thomas, 2021; Wilson et al., 2015; Strayhorn, 2019). Female minoritized students are less likely to report feeling a sense of belonging in STEM and more likely to report a decrease in their sense of belonging throughout the semester (Rainey et al., 2018). There are limited studies on mathematics classroom-belonging that consider the intersection of race and gender in Predominantly White Institutions (PWI), highly selective universities, or a few Historically Black Colleges and Universities (HBCUs), but not in diverse, open access institutions (Battey et al., 2022; Leyva et al., 2021; Johnson, 2012; Perna 2010). Open-access institutions are colleges that are nonselective in their admission standards and provide increased access to higher education for diverse populations (Anderson, 2015), especially Black and Latinx students (Rendon, 2020). Furthermore, most belonging studies in postsecondary settings consider sense of belonging at the campus or departmental level, rather than at the classroom level.

Research Questions

The purpose of the mixed methods study which this report draws from, is to understand how Black and Latina female STEM students experience sense of belonging in their introductory mathematics courses, college algebra and precalculus, at a diverse, open-access, four-year public institution in the Southeast region. For this paper, I present the quantitative results to the following research questions.

1. How do Black and Latina female students' sense of belonging in the college algebra and precalculus classrooms compare to students in other racial and gender groups?
2. How does Black and Latina female students' sense of belonging in college algebra and precalculus change from the beginning to the end of the semester?
3. Which factors influence Black and Latina female students' sense of belonging in college algebra and precalculus classrooms at the end of the semester?

Theoretical Perspectives

I used two conceptual frameworks: sense of belonging (Strayhorn, 2019) and intersectionality (Crenshaw, 1991). The importance of sense of belonging as a conceptual framework has been well established in the literature (Ostrove & Long, 2007; Strayhorn, 2019). For this study, I use Strayhorn's (2019) definition of sense of belonging: "Students' perceived social support on campus, a feeling or sensation of connectedness, and the experience of mattering or feeling cared about, accepted, respected, valued by, and important to the campus community or others on campus such as faculty, staff, and peers" (p.4). My second framework, intersectionality, is related to one of the core elements of Strayhorn's (2019) theoretical model of belonging: social identities intersect and affect students' sense of belonging, and students experience belonging in different ways. I use Collins and Bilge's (2020) working definition of intersectionality: "Intersectionality investigates how intersecting power relations influence social relations across diverse societies as well as individual experiences in everyday life. As an analytic tool, intersectionality views categories of race, class, gender – among others – as interrelated and mutually shaping one another" (p. 2).

Methods

Participants & Context

Participants in the quantitative phase were students enrolled in college algebra and precalculus during the Fall 2023 semester, at a diverse open-access public college in the Southeast with a student population of about 11,000 (12% Asian/American, 32% Black, 27% Latinx, 24% White/ 59% Female and 41% Male). Approximately 40% of the entering freshman class are first-generation students and over 50% are eligible for a Pell-grant. The college is designated as a Minority Serving Institution (MSI): Asian American and Pacific Islander Serving Institution (AAPISI) and Hispanic Serving Institution (HSI).

Data Collection

The survey participants were students enrolled in 58 sections of introductory mathematics courses during the Fall 2023 semester (seven sections of college algebra with support, 37 sections of college algebra and 14 sections of precalculus). College algebra is typically the first mathematics course in the mathematics sequence (college algebra, precalculus, and calculus) that

STEM majors take at this institution. During the first three weeks of the Fall 2023 semester, 1135 students completed the pre-survey (13% Asian/Asian American, 31% Black/African American, 30% Latinx, 21% White, 5% Other/ 52% Female and 48% Male). Students' ages ranged from 15 to 49 years of age (M=19.08, SD=2.59). The majority of the students reported freshmen standing (76.4% Freshmen, 15.1% Sophomore, 5.7% Junior, and 2.9% Seniors). At the end of the 15-week semester (during weeks 11, 12, and 13), 639 students completed the post-survey.

The pre- and post-surveys consisted of a demographic questionnaire and an adapted version of the Math Sense of Belonging Scale, which Good, Rattan and Dweck (2012) validated and established as a new measure of sense of belonging to mathematics. The demographic questionnaire included questions that asked for students' gender, race/ethnicity, age, major, final grade they expect to earn, and enjoyment of mathematics. All items in the belonging scale are preceded by the statement, "When I am in my college algebra or precalculus class..." For each item, participants rated their agreement on a 6-point Likert-type scale ranging from 1 (strongly disagree) to 6 (strongly agree). The belonging measure includes statements such as "I feel that I belong in the class," and "I feel excluded."

Data Analysis

First, I used SPSS to calculate the descriptive statistics for sense of belonging based on across different racial-gender groups and whether there was a difference in pre and post belonging scores. Next, I conducted a multi-factor analysis of variance (ANOVA) to determine whether there was a statistically significant difference in mean belonging scores between different racial and gender groups. For post-survey results I conducted multi-factor ANOVA to determine whether pre-belonging score, race, gender, gender*race, math affinity, and expected grade influence students' sense of belonging at the end of the semester.

Findings

Pre-Survey Results

The mean level of sense of belonging for Black female students was 4.396 (SD=0.714) and for Latina students was 4.367 (SD=0.695), which are similar to the belonging scores of Latino (4.3732), White male (4.4160), and White female (4.401) students. Black male students had the highest mean belonging score (4.609) while Asian male students had the lowest (4.310). At the beginning of the semester, there was no statistically significant difference between the belonging scores based on students' race or gender alone. However, there is a statistically significant difference in presurvey belonging scores for the interaction effect of race and gender (p=0.025). The only statistically significant difference occurs between Latina students and male Black students ($p=0.034$) where Latina students' belonging was lower. Moreover, belonging scores statistically differed based on students' affinity for mathematics ($p<0.001$) and their expected final grade ($p=0.010$); students with higher mathematics affinity or higher expected grade have a higher sense of belonging to their mathematics class.

Post-Survey Results

End of semester belonging scores for both Black female (4.494) and Latina students (4.399) were slightly higher than at the beginning of the semester, although the change was not statistically significant. Black male students had the highest sense of belonging (4.563) while male Asian students (4.297) had the lowest sense of belonging. However, sense of belonging in these introductory mathematics courses did not significantly differ across gender or race.

Furthermore, the interaction effect of race and gender did not have a statistically significant effect on belonging, contrary to the pre-survey results. However, there was a statistically significant difference in belonging between students with different levels of mathematics affinity ($p<0.001$), expected grades ($p<0.001$), and pre-belonging scores ($p<0.001$). That is, students who have higher pre-belonging scores, higher mathematics affinity, or higher expected final grades have a higher sense of belonging to their mathematics classes.

Discussion/Conclusion

This study is part of an explanatory sequential mixed method study that explored sense of belonging of Black female and Latina students at the mathematics classroom level, considering both gender and racial identities at an open-access, racially diverse, minority serving institution. By the end of the semester, there was no statistically significant difference in mathematics classroom belonging based on gender, race, or its interaction effect. This finding runs contrary to the extant literature that report female minoritized students have the lowest sense of belonging in STEM departments (Rainey et al., 2018; Good et al., 2012). Moreover, being a female minoritized student has been found to be negatively correlated to one's sense of belonging in STEM (Johnson, 2012). In this study, sense of belonging of Black female and Latina students did not differ significantly compared to other race and gender groups. That is not to say that their racial and gender identities do not matter, but perhaps they are less salient in a context in which Black female and Latina students are not minoritized, as the study was situated in classrooms in which minoritized students are the majority. In addition, students' enjoyment of learning and doing mathematics and their self-reported expected final grade were positively related to sense of belonging, both at the beginning and at the end of the semester. This finding resembles results from Zumbrunn and colleagues' (2014) study, in which students who felt more capable of succeeding in the course tended to be more engaged in their classes, which may also have positively impacted their sense of belonging.

Although quantitative methods are useful and important, they are limited because they do not provide a comprehensive picture of how students experience belonging in their introductory mathematics classrooms. Therefore, as the next step, I will explain my quantitative findings with qualitative methods using interviews and mathematical autobiographies to gain a broader and deeper understanding of belonging. The strength of mixed methods is that it elaborates and enhances overall interpretations (Greene, 2007). The aim of this work is to contribute to the research base of understanding female minoritized students' sense of belonging and experiences in the introductory mathematics classroom context, particularly given the critical need to better support female minoritized students' undergraduate mathematics classroom experiences.

LEARNING TO TEACH EQUITABLY: A LOOK AT HOW PRESERVICE TEACHERS INCORPORATE EQUITABLE MATHEMATICS TEACHING PRACTICES

Kenley Ritter
University of Idaho
kenleyr@uidaho.edu

To better understand how to prepare preservice teachers to teach diverse student populations, this study focused on how preservice mathematics teachers implemented equitable mathematics teaching practices in their lesson plans during a year-long secondary mathematics practicum course. Findings from this study indicate that preservice teachers primarily focused on instructional practices that established classroom norms for participation, attended to students' mathematical thinking, and supported the development of a sociopolitical disposition. However, the preservice teachers did not explicitly incorporate their students' cultural strengths in their lesson plans. The results of this study will further the field's understanding of topics to consider when preparing future teachers to teach mathematics to diverse student populations.

Keywords: Equity, Inclusion, and Diversity, Culturally Relevant Pedagogy

Equitable Mathematics Teaching

Meeting the needs of diverse learners is one of the most critical challenges facing teachers today (Abdulrahim & Orosco, 2020; Gay, 2018). Research on incorporating culturally diverse teaching strategies into the mathematics classroom is growing among mathematics educators, along with a focus on access and equity (Bartell et al., 2017; Bartell, 2013; Gutstein, 2003; Seda & Brown, 2021). Mathematics researchers have studied equitable teaching practices, including incorporating students' community and cultural knowledge into the mathematics curriculum (Civil, 2007), engaging students in controversial topics (Noddings & Brooks, 2017), integrating students' culture into the classroom and curriculum (Gay, 2002; Ladson-Billings, 1995), and using mathematics to address real-world problems and injustices (Frankenstein, 2012; Gutstein, 2006; Wager & Stinson, 2012). However, limited research exists on preparing preservice teachers to incorporate equitable teaching practices in their lessons (Bartell et al., 2017). While mathematics educators have acknowledged the need for teachers to build on students' cultural and mathematical backgrounds to teach mathematics to all students (Turner et al., 2012; NCTM, 2008; White et al., 2016), many preservice teachers are graduating from teacher education programs ill-equipped to meet the needs of culturally and linguistically diverse student populations (Banks, 2015). In response to the need for research to better understand how to prepare preservice teachers to incorporate equitable mathematics teaching practices (Abdulrahim & Orosco, 2020), I followed three preservice teachers during their year-long practicum and examined how they included equitable mathematics teaching practices into their lesson plans.

Theoretical Framework and Related Literature

Mathematics teacher educators and researchers are still learning how to meet students' needs and teach a curriculum that represents every student. A focus on "equity in mathematics education should be one of the most important concerns of teachers, administrators, policymakers, mathematicians, and mathematics educators" (Strutchens et al., 2012, p. 2).

Professional organizations in mathematics education have agreed upon a need for equitable frameworks that challenge the inequities students face in schools today (AMTE, 2022; NCTM, 2014, 2018). To support mathematics teachers in this work, researchers have developed frameworks including equitable teaching strategies to engage all students in mathematical learning (Boaler, 2016), a lens for educators to identify where they are failing to meet the needs of every student (Seda & Brown, 2021), and the dimensions of equity including *access, achievement, identity, and power* (Gutiérrez, 2009).

For this study, equitable mathematics teaching practices are defined by Bartell and colleagues (2017). These "core equitable mathematics teaching practices" provide teachers with guidelines that support all students in learning mathematics (p. 10). The nine equitable mathematics teaching practices include *drawing on students' funds of knowledge*, *establishing classroom norms for participation*, *positioning students as capable*, *monitoring how students position each other*, *attending explicitly to race and culture*, *recognizing multiple forms of discourse and language as a resource*, *pressing for academic success*, *attending to students' mathematical thinking*, and *supporting the development of a sociopolitical disposition* (pp.11-12). In this study, I use these nine teaching practices to answer the research question: How do secondary mathematics preservice teachers implement equitable mathematics teaching practices within their lesson plans?

Method

This study was situated within a larger study in which three preservice teachers participated in a year-long mathematical methods and practicum course. The fall course focused on mathematics methods that prepared preservice teachers to develop a secondary mathematics curriculum. During the course, preservice teachers were introduced to each of the nine Equitable Mathematics Teaching Practices (Bartell et al., 2017) and learned to write lesson plans. The spring course included a teaching practicum that allowed the preservice teacher to observe and teach in a secondary mathematics classroom for two 45-minute math class periods.

Participants for this study included three secondary preservice mathematics teachers in the third year of their education program, each enrolled in a required mathematics practicum course. Beth, a White female, taught AP Calculus and Algebra 1 at Brooks High School. At the same school, Shelby, a White female, taught Algebra 1. Ryan, a White male, taught Pre-AP Algebra 2 at Nolan High School. The majority of the student population at Brooks High School was Hispanic (55.3%) or Black (32.2%), and 88.5% of the students were economically disadvantaged. At Nolan High School, most students were White (55.5%), with 27.1% economically disadvantaged students.

Data collection occurred during the fall and spring semesters and included lesson plans, interviews, class observations, and weekly reflections. The three preservice teachers wrote a combined total of 31 lesson plans during the school year. In this study, the lesson plans were analyzed using nine equitable mathematics teaching practices (Bartell et al., 2017) to better understand which equitable mathematics teaching practices preservice teachers implemented in their lesson plans after studying them in their methods courses. Three researchers coded three lesson plans together, discussing the codes and ensuring agreement upon their use before coding individually. After coding together, each researcher individually coded six additional lesson plans, two for each of the other preservice teachers. In situations where there was a lack of agreement between the three researchers, I considered the explanation given by the researchers to make a final decision. After coding nine lesson plans collectively, I coded the remaining 22 lessons based on the discussion around the codes. Then, I calculated each code's frequency to describe how the three secondary mathematics preservice teachers implemented equitable mathematics teaching practices within their lessons.

In some lesson plans, activities addressed more than one equitable teaching practice. For example, in one of Beth's lesson plans, she divided her class into half, and each half became an expert on one mathematics problem. Then, the groups mixed and taught what they learned to students from the other group. This activity allowed all students to hold the knowledge that another student needed and positioned them to teach their classmates. Additionally, it required all students to actively participate in the learning, so this activity was coded as *monitor how students position each other* and *establish classroom norms for participation.*

Results and Discussion

The data analysis revealed that the three preservice teachers implemented equitable mathematical teaching practices 320 times across their 31 lesson plans. Most often, they incorporated *established classroom norms for participation* in their lesson plans. The next two most frequently used equitable mathematical teaching practices were *attending to students' mathematical thinking* and *supporting the development of a sociopolitical disposition*. Additionally, results from the data analysis showed that the preservice teachers did not attend to *incorporate culture and race* in any of their lesson plans. Table 1 below displays the overall percentages of how each preservice teacher included equitable mathematics teaching practices in their lesson plans. The following sections provide an overview of the four equitable mathematics teaching practices most often used and how the three preservice teachers implemented them into their lessons.

Equitable Mathematics Teaching Practice	**Beth**		**Shelby**		**Ryan**		**Overall**	
	n	%	n	%	n	%	n	%
Draw on students' funds of knowledge	11	6.43	9	8.49	1	2.33	21	6.56
Establish classroom norms for participation	26	15.20	21	19.81	12	27.91	59	18.44
Position students as capable	20	11.70	7	6.60	6	13.95	33	10.31
Monitor how students position each other	23	13.45	18	16.98	5	11.63	46	14.38
Attend explicitly to race and culture	0	0.00	0	0.00	0	0.00	0	0.00
Recognize multiple forms of discourse and language as a resource	22	12.87	12	11.32	2	4.65	36	11.25
Press for academic success	15	8.77	6	5.66	2	4.65	23	7.19
Attend to students' mathematical thinking	32	18.71	11	10.38	10	23.26	53	16.56

Support development of a sociopolitical disposition	22	12.87	22	20.75	5	11.63	49	15.31

Note. Bartell et al., 2017, pp. 11-12

Overall, the preservice teachers most often *established norms for participation* in their lesson plans. All three preservice teachers incorporated tasks in their lesson plans to engage their students in learning and encourage lesson involvement. Beth, for example, included in one lesson a Tic-Tac-Toe board filled with problems where students could select the three questions they wanted to work on, and students could collaborate with their shoulder partner if desired. Allowing her students to choose their problems in her lesson encouraged them to participate in the activity. Shelby varied her pedagogical practices to engage students who were often uninterested in learning mathematics by having them create comic strip word problems and summarize a unit with a poem. Additionally, Ryan used interactive simulations such as a Rock, Paper, and Scissor tournament to involve his students and encourage participation when teaching about growth and decay. Each preservice teacher incorporated tasks where the students contributed to the learning environment instead of passively observing the lesson.

Attending to students' mathematical thinking appeared second most frequently among the equitable mathematical teaching practices. Each preservice teacher incorporated tasks for their students that challenged their thinking and built on their previous mathematical knowledge. For example, Beth used hands-on activities and interactive mathematics programs to build on her students' mathematical knowledge. Shelby most often facilitated meaningful mathematical discourse and posed purposeful questioning to observe and respond to her students' mathematical thinking. In her lesson plans, she included questions such as, "What do we do to finish the equation? What tools might help you?" and "Why do you think so? Would graphing this help?" Shelby's questions helped her recognize her students' mathematical understanding and respond appropriately. The three preservice teachers incorporated instructional practices to support their students' mathematical understanding and ensure they were developmentally ready for their lessons.

The third most often implemented equitable mathematical teaching practice by the preservice teachers focused on *supporting the development of a sociopolitical disposition*. The three preservice teachers primarily incorporated this teaching practice by encouraging their students to consider how to use the mathematics learned to solve problems in an authentic environment. For example, Shelby's goal for one lesson when teaching growth and decay stated, "Students will be able to write exponential functions to describe mathematical or real-world situations." Her lesson included mathematics problems with exponentials that each described a real-world scenario. Similarly, Ryan used Three-Act Tasks (Meyer, 2013) in his lessons to connect the learning for his students to situations they might have experienced previously. Each preservice teacher considered ways to engage their students in the lesson by providing opportunities to solve authentic math problems.

The findings from this study provided insight into how preservice teachers implement equitable mathematics teaching practices in their lessons and highlighted a continued need for instruction that supports preservice teachers in explicitly attending to students' race and culture. While an introduction to equitable teaching practices led the three preservice teachers to include equitable teaching practices in their lesson plans, the findings showed emergent connections (Turner et al., 2012) that did not include activities that challenged power structures in the classroom, empowered students from diverse backgrounds, validated students' home language, or challenged stereotypes. For those preparing mathematics preservice teachers, I encourage ongoing conversations throughout mathematics education courses around the use of equitable teaching practices with an emphasis on how to connect mathematics topics specifically to students' race, culture, language, and personal experiences, as well as support preservice teachers in incorporating meaningful connections for their students. Providing these equitable opportunities in mathematics classes is crucial for students from all backgrounds to develop positive mathematical identities (NCTM, 2018) and a deeper understanding of the mathematics content (Abdulrahim & Orosco, 2020).

evat@pdx.edu

Kathryn E. Roman
Portland State University
kroman@pdx.edu

Developing students' Critical Mathematics Consciousness (CMC) is one goal of teaching mathematics for social justice (TMfSJ), but little is known about TMfSJ in post-secondary settings. This study analyzes student reflections on one TMfSJ lesson designed to support students in learning proportional reasoning skills in the context of studying representation of Alaska Native peoples in Congress in a capstone course for college seniors. Our research question was: Which aspects of CMC do students demonstrate in their reflection on the Alaska Representation lesson? Out of 10 students, 7 demonstrated all 6 components of CMC, with another 3 demonstrating 5 components.

Keywords: Equity, Inclusion, and Diversity; Rational Numbers & Proportional Reasoning; Social Justice; Undergraduate Education.

As a human activity, mathematics can never be neutral (Frankenstein, 1983; Ukpokodu, 2007; Wager et al., 2021). Mathematics has always been developed to meet the changing needs of people and their communities (Joseph, 2011). So, we can use mathematics for the social justice projects that matter to us. There are some social justice-oriented lessons available for college settings (e.g. Karaali & Khadjavi, 2019, 2021), but little research has focused on teaching mathematics in social justice contexts in post-secondary settings. Mathematics without meaning or context sends messages on how the world is and how it should stay (D'Ignazio & Klein, 2020; Rubel et al., 2021). Undergraduate students *want* to make the world a better place and they want to know how math can support that goal (Rodriguez et al., 2020). Consequently, we push social justice change agents out of mathematics when we do *not* help them see how mathematics can serve social justice (Lord, 2020). Post-secondary students need opportunities to see how mathematics can influence social justice.

Our study took place in a capstone course for college seniors at a public university in the Pacific Northwest. Some of the course goals were to examine and communicate about social justice issues of race and its intersections with other forms of oppression through data representations. We investigate student reflections on one single teaching math for social justice (TMfSJ) (Gutstein, 2006) lesson designed by Robinson (lead author on this paper) to help students explore proportional reasoning in the context of congressional representation, specifically, in Alaska. The context of Alaska was chosen because 1) the context was not familiar to any of the students so they would experience using mathematics to understand issue that impact communities to which they do not belong, 2) a news article had recently made claims about representation of Indigenous peoples in Congress in light of the first Alaska Native elected to office (Rep. Mary Peltola) so the context was timely, and 3) Robinson had a strong connection to the state.

Background and Framing

The project of social justice broadly “refers to reconstructing society in accordance with the principles of equity, recognition, and inclusion,” (Bell, 2016, p. 4). To understand mathematics as a tool for social justice requires first understanding what we mean by mathematics. Thanheiser (2023) suggests three possible frames for mathematics that allow mathematics researchers to make their stance in their work clear to others. We frame mathematics within the second and third frames. The second frame is mathematics as “a contextual, ever present… lens or language to make sense of the world,” (p. 4). The third frame is mathematics as “a verb (not a noun), a human activity, part of one’s identity,” (p. 5). Mathematics is a human activity and as such is inherently tied to the social context of *who* is doing mathematics and for which *purposes*. Humans can use mathematics to pursue social transformation for justice.

Social Justice through Mathematics

It is not only possible to use mathematics for social justice, but it is impossible to separate mathematics from social justice. Mathematics permeates ideas of fairness, especially at large scale, as well as the decision making that structures laws and distribution of resources. Kimberlé Crenshaw (1988) advocated for legal theories that attended to intersectional identities because labor discrimination suits brought by Black women were being dismissed based on mathematical arguments. Judges in three pivotal cases cited sample size and proportional reasoning arguments to invalidate the discrimination faced by Black women (Crenshaw, 1988). Not only is proportional reasoning central to litigation, but also to distribution of resources. Proportional reasoning in apportionment theory can and has been used to distribute everything from seats in the House of Representatives to voting booth locations to funds for schools (US Census Bureau, n.d.; Verstegen & Knoeppel, 2012). Yet, many students learn about proportions in decontextualized ways that do not support them in transferring their proportional reasoning skills to social justice issues (Simic-Muller, 2015). Mathematics, and especially proportional reasoning, are embedded in social justice projects. So, students need opportunities to learn about topics like proportional reasoning in authentic social justice contexts.

TMfSJ is one framework for situating teaching and learning mathematics in social justice projects. The goals of TMfSJ are for students to both read the world (make sense of the world and analyze power structures) and write the world (change the world for the better in ways that matter to students themselves) with mathematics while developing positive social and cultural identities (Gutstein, 2006). But, as with any human activity, TMfSJ can be co-opted to reinforce, rather than dismantle, oppression. People that hold privileged identities often fall back on oppressive narratives and perspectives when engaging with TMfSJ learning (Esmonde, 2014; Harper et al., 2021). Kokka (2020) built on Gutstein’s (2006) TMfSJ to develop a framework for critical mathematics consciousness (CMC) of privileged students.

Critical Math Consciousness

Kokka (2020) studied the development of CMC for privileged students, specifically white affluent students. While students in our study were not all white or affluent, all students were outside of the Alaska Native community we sought to better understand in the lesson and therefore experienced oppressive systems like racism, colonialism, and urbanism in different ways than Alaska Native communities themselves. Kokka positions mathematics classrooms as settings for developing privileged students’ critical consciousness, positioning mathematics classrooms as one site for social justice activism. From this perspective, Kokka’s CMC has three components: sociopolitical understanding, taking action, and critical civic empathy. The first two components draw on Gutstein's (2006) reading the world with mathematics and writing the world with mathematics, respectively. The last component refers to a concept described by Mirra (2018) in the context of literacy. In the context of CMC, critical civic empathy is "seeing another's perspective while also engaging in structural analysis of power and privilege to take civic action for social transformation," (Kokka, 2020, p. 782). Together, the taking action and critical civic empathy components focus this CMC framework on action, either for oneself or for others.

Stephan and colleagues (2021) developed a CMC framework that explicitly differed from Kokka's (2020) in that they focus on the role mathematics plays in oppression and liberation. Their conception of CMC also has three components that center mathematical awareness (MA): sociopolitical MA, ethical MA, and communicative MA. These CMC components do not map directly to Kokka's (2020) CMC components. Sociopolitical MA is awareness that "Mathematics is used to model and interpret the real world and can be used to make decisions both at the individual and systemic levels that may be oppressive or liberatory," (Stephan et al., 2021, p. 516). Notice that the focus is not only on making sense of the world with mathematics as in Gutstein's (2006) framework, but on how that sense-making can lead to oppressive or liberatory impacts. Ethical MA is awareness that "Human beings do mathematics; thus, there are potential ethical dilemmas and implications of mathematical work; mathematics may be neutral but humans doing mathematics are not," (Stephan et al., 2021, p. 516). Humans doing mathematics can never be neutral. Communicative MA is awareness that "Mathematical communication has the power to educate and mis-educate society and encourage the masses to act in certain ways," (Stephan et al., 2021, p. 516). Notice that mathematics here is positioned as a communication tool.

Both framings of CMC are necessary for this study. Kokka's (2020) framing centers mathematics classrooms as sites for critical consciousness development of students who hold privileged identities. Hence, this framing of CMC is salient for this study in which students held privileged identities relative to the communities impacted directly by the topics in the lesson. Kokka's (2020) framing situates math as the implied vehicle for CMC development, while Stephan and colleagues' (2021) framing focuses CMC explicitly on understanding mathematics as a tool for oppression and liberation.

For this study, we frame CMC as having the six components mentioned above: Kokka's (2020) sociopolitical understanding, taking action, and critical civic empathy, and Stephan and colleagues' (2021) sociopolitical MA, communicative MA, and ethical MA. We define learning in the context of this TMfSJ study as development of CMC. The definition in this project of mathematics as a human tool for social transformation includes two parts: humans use math for specific purposes and those purposes can be liberatory social justice projects. Stephan and colleagues (2021) bring an explicit focus on how mathematics is used as a tool for oppression and liberation, while Kokka (2020) brings a focus on taking social justice action. We use these two complementary CMC frameworks together to help us answer our research question: Which aspects of CMC do students demonstrate in their reflection on the Alaska Representation lesson?

Methods

Context and Positionality

Our identities, especially our racial identities, impact how we understand and experience the world (Crenshaw et al., 1995; Davis & Jett, 2019; Esmonde, 2017; Ladson-Billings & Tate, 1995). In particular, our racial identities impact how we understand and react to the content of lessons in "The Mathematics of Racism," like the Alaska Representation lesson. Robinson developed the lesson with feedback and support from Thanheiser, and led the implementation of the lesson. Robinson is a monolingual white woman and Mathematics Education PhD graduate student. She was born and raised in Alaska, though now lives in the Pacific Northwest. Growing up around but not within Alaska Native communities, she knew Alaska Native people as friends, classmates, teachers, and community leaders. Yet, Robinson has only ever lived in places where her race and ethnicity match the majority of the population and representatives in both houses of Congress. Thanheiser is a Hungarian, German, Jewish immigrant to the United States and Professor of Mathematics Education. Roman is a white cisgender woman, former middle and high school math teacher, and Mathematics Education PhD graduate student.

As mentioned before, none of the ten students were familiar with the Alaskan context. None of them shared that they had spent any significant time in Alaska or that they knew much about Alaskan history or politics. Early in the course students had an opportunity to reflect on and share about their identities through community building activities. During those activities, four students either self-identified as white or omitted reference to race while six students self-identified as holding a racially marginalized identity. Two students identified as Black, one of which further identified as Nigerian-American. Two students identified as Asian, one as Vietnamese and one as half-Indonesian. Two students identified as Latine, one as Mexican-American and one as Columbian American.

The senior capstone course took place over 11 weeks in the Spring of 2023. Students were juniors and seniors who self-selected into the course and majored in a wide variety of disciplines. Students majored in several physical and social science disciplines, mathematics, and creative arts. The lesson in this study occurred over a two-hour class meeting during Week 2 of the term. The lesson started by having students consider and discuss as a whole group the following quote from an article:

> With [Rep. Mary Peltola's] recent swearing-in, it became official for the first time in more than 230 years: A Native American, an Alaska Native and a Native Hawaiian are all members of the House — fully representing the United States' Indigenous people for the first time, according to Rep. Kaiali'i Kahele of Hawaii. Now, there are six Indigenous Americans who are representatives in the House. (Diaz, 2022)

Students were provided with estimates that approximately 9.7 million people or 2.9% of the 2021 US population was American Indian/Alaska Native (AI/AN; *American Indians and Alaska Natives: Key Demographics and Characteristics*, 2023) and roughly 165,000 people or 0.05% of the 2020 US population was Alaska Native (Goto et al., 2004). Students worked in groups to make sense of percentages as proportions and make claims about what fair representation might mean. Next, students learned about some of Alaska's history and elections. Students again worked in groups to compare the proportion of Alaska's population that is AI/AN to other proportions, like the proportion of AI/AN people ever elected to any seat in either house of Congress for Alaska. Students considered which forms of proportions (fractions, decimals, percents, visualizations) were best for 1) creating quickly, 2) comparing two proportions, and 3) communicating a message to others. The lesson ended by learning about and discussing current issues facing Alaska Native communities, like the food and water scarcity and historically low salmon populations, and discussion as a whole group of the implications of underrepresentation in Congress. After the lesson, students were asked to respond to the following prompt in a FlipGrid video:

> Reflect on your learning from the Alaska Representation lesson in 3 minutes or less. Be sure to share about each of the following: What did you learn about mathematics? What did you learn about racism? What do you want to know more about?

For this small study, we use only students' reflections after the lesson. We make no claims about what components of CMC students may have been able to demonstrate *prior* to the lesson. We therefore do not make claims about what CMC components *developed* as a result of the lesson because that implies change over time. Instead, we report on what components of CMC students *demonstrated* when asked to reflect on their learning from the lesson.

Data Collection and Analysis

To answer our research question, we analyzed students' reflection videos. Students recorded their responses as videos in FlipGrid, which automatically generated transcripts that were subsequently cleaned up. These videos and transcripts of student responses serve as the data sources for this study. The 10 responses varied in duration between 1:22 minutes and 2:57 minutes with a mean of 2:08 and median of 1:57. Some students responded to the three prompts in order and referred directly to the language in the prompts, while others did not.

We used MAXQDA software to analyze the data using deductive coding for the six aspects of Kokka's (2020) and Stephan and colleagues' (2021) CMC frameworks. First, Robinson watched all videos and coded any part of a student's response that suggested one of the six CMC codes with the corresponding code. Portions of the transcript could be coded with more than one CMC code, and each student response could include multiple occurrences of a single CMC code. Next, all coded student response segments for each individual CMC code were reviewed together to ensure consistent coding. If a coded response segment *did not* fit the CMC code, then the code was removed from the segment. When a student response included at least one occurrence of a CMC code after both initial coding and subsequent verification then that student was considered to have demonstrated CMC for the corresponding code. Thus, we share the total number of *students* who demonstrated each CMC component as evidenced by at least one coded segment, not the number of coded items. For example, one student's response initially had two occurrences of the sociopolitical MA code: "representation of, for example, Indigenous people in Congress is very… underrepresented according to the proportions of Native and Indigenous people in the US, their population" (Segment 1) and "structural racism and systemic racism prevents representation from dismantling these systems because just bringing um, like, Representatives like Mary Pratola into Congress isn't going to stop racism or dismantle those systems that are keeping us oppressed" (Segment 2). Upon review, Segment 1 retained the sociopolitical MA code because it showed an understanding of the sociopolitical context through proportional reasoning. Segment 2 shows understanding of the sociopolitical context but there is not compelling evidence that mathematics was a tool for that understanding. So, after review this student's response had only one segment coded for sociopolitical MA, which was sufficient to support a demonstration of sociopolitical MA. We share descriptions of each code, examples, and total number of students in the results in Table 1.

Results

Kokka CMC

All three components of Kokka's (2020) CMC framework appeared in every student's response (see Table 1). With respect to the sociopolitical understanding code, students said things like "I also had no idea that there was so little representation of Alaskan Natives and American Indians in Congress" and "with a racist society, you're not going to have equal representation at the high levels where they're actually making the laws, yet everybody's going to be affected by the decisions being made. So that was pretty eye opening." Given that the prompt specifically asked students to reflect on their learning about racism, we hoped that most students would demonstrate sociopolitical understanding in their responses. We also expected many students would demonstrate critical civic empathy in their responses. Because no students held

Table 1: CMC Component Code Descriptions and Totals

	CMC Component	Description	Example	Total Students
Kokka CMC	**Sociopolitical Understanding**	Student learned about a sociopolitical issue	"[Racism] even appears in our government offices where certain groups of people may not only receive representation through the House and Senate"	**10**
	Taking Action	Student expressed a desire for something to change or wondered what action could be taken.	"I just, I wonder, you know what ways we can to get help to get their voices heard"	**10**
	Critical Civic Empathy	Student expressed that representation of Alaska Native people was unfair, referenced structural forces, power, or priviledge	"[there is a] the historical track record regarding these people being silenced often in the political sphere"	**10**
Stephan et al. CMC	**Sociopolitical Mathematical Awareness**	Student shared mathematics as a way to make sense of and represent situations of fairness or unfairness	"math can be a powerful tool in putting into perspective how unfair representation can be for different races and ethnicities that are not white"	**10**
	Ethical Mathematical Awareness	Student suggest doing mathematics is non-neutral and one can make choices about how to do mathematics for specific purposes	"even though math is about numbers and that it could be objective in nature, it's still subject to subjectivity in how that math is interpreted or represented using like visual representations. "	**8**
	Communicative Mathematical Awareness	Student references or describes communicating with mathematics, including to persuade others	"there's different ways that you can write things, and so you want to carefully choose how you're representing your data to make it really understandable"	**9**

an Alaska Native identity, the context of the lesson provided an opportunity to learn about the perspectives of others. In occurrences of the critical civic empathy code, students expressed that the issues of Alaska Native communities are important and referenced historical oppression of Indigenous peoples to put underrepresentation in context. Students said things like “we know throughout time that white people hold the majority of representation for all states pretty much throughout our history” and “in a state that has a racial composition of 21.9% Alaska Native and American Indian, you know, one representative in 63 years of statehood. Not looking so great.”

The goal of the lesson was not yet to take action directly to impact underrepresentation, but to learn more about the issue and how mathematics could be used to understand and communicate about it. Even though the reflection prompt and the lesson itself did not specifically mention taking action, the code came up for every student in terms of discussing action. Students talked about the need for change, their concern or frustration with inaction, or wondering about possible action. Students said things like “there's this common problem of this lack of representation and we seem to be missing it and we acknowledge it, but yet there has been no really like solution” and “I wanna learn more about… what can we do, for example, to help people in Alaska fight climate change, to bring prices for basic necessities down and…yeah, how to advocate.”

All of the occurrences of the taking action code were coded as critical civic empathy as well. One student’s response highlights why: “I am more aware of the fact that racism and segregation is still an ongoing issue and something that we need to go ahead and address whether we may be aware or if we experienced first-hand.” This last quote demonstrates both 1) taking action with “go ahead and address,” and 2) critical civic empathy because the collective “we” that should take action includes people who do not experience the issue directly. All references to action similarly talked about change for others (not the students themselves), specifically, Alaska Native and American Indian peoples.

Stephan et al. CMC

Most students demonstrated all three Stephan and colleagues’ (2021) CMC components. Specifically, all 10 students demonstrated at least two codes, and 7 students demonstrated all three codes. All students demonstrated sociopolitical MA, sharing how their learning about Alaska Native communities was tied to mathematics by using “proportion” or referencing unfair representation. Students said things like “learning about proportions, ratios and percentages are always important to, you know, an individual's ability to critically analyze data, translate and present it is really linked to understanding those concepts” and “in terms of Alaska Natives, they’re very… underrepresented in Congress if you look at their population number.” Students tied their sociopolitical learning directly to their understanding of the mathematics involved in the lesson.

A total of 8 of the 10 students indicated ethical MA. Responses focused on humans doing math for intentional purposes and how that math activity can influence the ways social issues are understood. One student said, “I think that the issues that affect people, say, of color, aren’t necessarily being advocated for or may not be advocated for, especially if there’s no representation in places where policy and laws are made.” This response references the social (in)justice implications of underrepresentation, tying the student’s understanding of the mathematics in the task to their understanding of related ethical implications. Another student shared "when sources or… relevant population data is missing, we question whether the data is an accurate representation of data or the point that it's trying to get across. So, it's important to make sure everybody's voice is heard." The last sentence in this response suggests there are ethical reasons to include people's voices and data sources.

A total of 9 students demonstrated communicative MA, including the previous response. The student described "the point [the data] is trying to get across," suggesting mathematics as a tool for communication. Other instances of communicative MA described how humans make choices to communicate about math, and that these choices influence how others understand representation of Alaska Native peoples. One student shared a concern, saying that "it's sometimes difficult for me personally to see how data can be conveyed concisely and pragmatically and still express the devastating realities that make up these figures." This student suggests that some ways of communicating with data can *obscure* the impact on people's lives. Another student shared that "when you're trying to tell a story about…the data you're trying to convey, you want to tailor it to the basically groups of people you think it's got… you or, you want it to reach the most." This student clearly identifies that communicating with mathematics is about choosing how to best convey your message.

Discussion and Implications

With regard to our research question "Which aspects of CMC do students demonstrate in their reflection on the Alaska Representation lesson?" we found that all 10 student responses demonstrated all three components of Kokka's (2020) CMC framework. Additionally, all 10 student responses demonstrated at least two components of Stephan and colleagues' (2021) CMC framework, with 7 indicating demonstrating all three. This suggests that the lesson was successful in supporting students to learn about proportional reasoning in a context that also promoted social justice. Students learned that math can be used to investigate claims and communicate about social justice topics.

One limitation of the study is that the lesson in the study did not provide an opportunity for students to see themselves as taking action. While all students discussed social justice action, as indicated by the occurrence of the taking action code, the lesson did not appear to support students in actually *taking* action. No student shared an action that they have taken or could take. Also, the lesson did not draw attention to the work Alaska Native communities are already doing to address the topics that arose in the lesson. One small change to the lesson that could potentially address both these limitations is including additional reflective prompts for class discussion, like: "What are Alaska Native communities already doing to advocate for their representation? Find one resource that we didn't talk about in class and share. What steps could you and others take to amplify the work these communities are doing?" A future study could focus on action steps in post-secondary contexts, especially from student perspectives. Part of Gutstein's (2006) writing the world with mathematics is both seeing oneself as able to take action and actually taking action. Hence, to understand TMfSJ in post-secondary contexts we also need to understand how students conceive of and experience social justice action.

SUPPLEMENTING RADICAL CONSTRUCTIVISM WITH AN ANTI-DEFICIT PERSPECTIVE: CENTERING THE SENSEMAKING OF THE OPPRESSED

Christopher O. Roman
Portland State University
roman7@pdx.edu

The purpose of this theoretical paper is to describe how an anti-deficit perspective can supplement radical constructivist research programs by deepening their commitment to equity. I discuss how these research programs align with an anti-deficit perspective by treating students' mathematical ways of reasoning as a resource. I also discuss how an anti-deficit perspective can supplement these programs by promoting the construction of sensemaking models that challenge deficit discourses related to students from historically marginalized groups. To illustrate, I present a model highlighting the powerful reasoning of a Chicana undergraduate student.

Keywords: Cognition; Equity, Inclusion, and Diversity; Systemic Change

Radical constructivism (von Glasersfeld, 1995) is a theory of knowing that has been adopted by many researchers to investigate students' cognitive structures in relation to mathematics (e.g., Hunt et al., 2019; Steffe, 2001; Thompson, 1994a; Tillema, 2018). A central goal of researchers working within this paradigm is to challenge what counts as mathematics by positioning students' own mathematical ways of reasoning as the mathematics that should be honored and respected (Hackenberg et al., 2023). Steffe and Thompson (2000) refer to students' *own* mathematical ways of reasoning as *students' mathematics*, and researchers' (or teachers') interpretations of these ways of reasoning as *mathematics of students*. Some researchers (e.g., Steffe & Wiegel, 1996) use the term *second-order model* when referring to *mathematics of students* because it implies that it is an observer's interpretation of what they believe is going on in a student's brain. In this paper, I use the term *model* for convenience.

Given that radical constructivism honors students' mathematics, researchers adopting this paradigm are well-equipped to address dominant equity issues (see Gutiérrez, 2007, 2009) connected to access and achievement in mathematics. For instance, Steffe's research program (e.g., Steffe, 2001; Steffe & Kieren, 1994) provides students access to mathematics because it is their mathematics that they are accessing, which in turn allows them to achieve in mathematics by refining and developing their own mathematical knowledge (Tillema & Hackenberg, 2017). Some researchers, however, might dismiss Steffe's work, and hence radical constructivism, based on the argument that it implicitly perpetuates colorblind ideologies by failing to *explicitly* address issues related to race and culture, among other things (gender, ethnicity, etc.) (Tillema & Hackenberg, 2017). While I agree with the argument that radical constructivist research programs can implicitly perpetuate colorblind ideologies, thus failing to challenge the status quo, I also agree that completely disregarding these programs based on this argument "is far too dismissive" (Tillema & Hackenberg, 2017, p. 57). Instead, I argue that researchers should work towards *extending* (adding onto the framework) or *supplementing* (combining with another framework or perspective) radical constructivism in order to begin challenging the status quo by addressing equity issues specific to students from historically marginalized groups.

Recently, Hackenberg et al. (2023) took on the task of extending radical constructivism to attend to models of students' *social identities* (related to how students associate themselves with respect to race, gender, ethnicity, etc.), in addition to models of students' mathematics. As an example, they described the gendered interactions between two preservice secondary teachers in a past teaching experiment. The female student (at least initially) doubted her own knowledge and paid close attention to the male student's mathematical reasoning despite the fact that she was a powerful math reasoner. Conversely, the male student exhibited confidence in his ways of reasoning, but struggled to understand the mathematical reasoning of the female student. The teacher-researcher chose to disrupt these gendered interactions by asking "each participant to work on the other person's strength relative to themselves—the female participant to work on being more confident in her mathematical thinking, and the male participant to work on understanding his partners' thinking" (p. 27). By attending to the students' gendered interactions, the teacher-researcher was able to construct gender identity models that allowed them to challenge inequitable participation structures throughout the teaching experiment.

The purpose of this theoretical paper is to present another approach that radical constructivist researchers can leverage to enhance their commitment to equity, specifically with respect to historically marginalized students. More to the point, the approach that I am proposing requires researchers to adopt an anti-deficit perspective as they construct models of marginalized students' mathematics. An *anti-deficit perspective* works to challenge deficit perspectives about students from historically marginalized groups by treating their in-school and out-of-school experiences (or funds of knowledge) as resources for learning, and centering their strengths instead of their weaknesses (Adiredja, 2019). Rather than working within the radical constructivist paradigm to extend the types of models constructed (e.g., the social identity models proposed by Tillema & Hackenberg, 2017), this approach works to supplement radical constructivism by blending it with an anti-deficit framing. Ellis (2022) utilized a similar approach focused on constructing anti-deficit (or asset-based) learning trajectories, rather than anti-deficit models.

My aim for this paper is twofold. First, I want to add to the ongoing conversation about enhancing the commitment of radical constructivist research programs to equity-related issues (e.g., Ellis, 2022; Hackenberg et al., 2023; Tillema & Hackenberg, 2017), specifically with respect to the mathematical sensemaking of students from historically marginalized groups. Second, I want to engage math education researchers (both within and outside of this paradigm) in a discussion about how to bridge cognition and equity research more broadly, especially given that these areas have often been studied separately in our field (Adiredja, 2019, 2021). In alignment with the PMENA conference theme, I envision this discussion leading to a future where math education researchers from different methodological and theoretical paradigms can work together to achieve important equity-related goals.

In what follows, I begin by describing the central tenets of radical constructivism and their implications for constructing models of students' mathematics. Next, I elaborate on the meaning of an anti-deficit perspective, and explain how an anti-deficit perspective aligns with and supplements radical constructivist research programs. To showcase the benefit of supplementing radical constructivism with an anti-deficit perspective, I model the powerful sensemaking of a Chicana student based on her work involving a ratio-based math task. Prior to showcasing this model, however, I situate it in a brief review of the history of Latin*[3] students and education in the United States (U.S.) in order to highlight how their historical oppression has contributed to deficit discourses about their inferior ability in mathematics. It is my hope that my modeling will serve to challenge the deficit discourses about the math reasoning of Latin* students more broadly.

Central Tenets of Radical Constructivism

There are two central tenets to radical constructivism: (1) "knowledge is actively built up by the cognizing subject" and (2) "cognition serves the subject's organization of the experiential world, not the discovery of an objective ontological reality" (von Glasersfeld, 1995, p. 51). Taken together, these tenets imply that knowledge does not exist in an objective reality, nor is it an innate trait that certain individuals are born with. Rather, knowledge is something that is actively and constantly being constructed by each individual based on the cognitive adaptations they make to the experiential constraints they encounter. Put differently, knowledge is not static; it is a dynamic construct that is constantly changing from moment to moment in each individual.

In the context of constructing models of students' mathematics, a radical constructivist perspective implies that a student's math knowledge is not something that can be definitively obtained by a teacher-researcher. Thus, the models that a teacher-researcher constructs are *hypothetical* models (von Glasersfeld, 1995) in that they are based on the teacher-researcher's interpretations, and hence, are falsifiable. That is, the models act as hypotheses (similar to scientific models) that can be proven false based on continued interaction with students as they engage with math tasks. While models of students' mathematics can never be proven to depict students' true mathematical realities, they can, over a prolonged period of teacher-student interactions, become more viable (via testing for falsifiability) with these realities in the sense that there are no contradictions with students' explicit ways (e.g. gestures, written work, spoken words) of reasoning mathematically (Steffe & Thompson, 2000; von Glasersfeld, 1995, 2000).

Enhancing Radical Constructivist Research Programs via an Anti-Deficit Lens

Elaborating on an Anti-Deficit Perspective

An anti-deficit perspective works to challenge deficit perspectives that fail to acknowledge students' backgrounds and out-of-school experiences as assets, and instead position the students as the "problem" (Adiredja, 2019; Peck, 2021). With respect to students' sensemaking, an anti-deficit perspective works to challenge deficit perspectives that frown upon informal language, inconsistent and/or ambiguous reasoning, and critical (rather than fast) thought processes (Adiredja, 2019). Thus, there are two important aspects of an anti-deficit perspective. First, an anti-deficit perspective centers the strengths in students' reasoning, even when their reasoning shows signs (from the perspective of the observer) of informality, inconsistency, and/or ambiguity. The goal is to learn *from* students in order to leverage their cognitive resources in learning (Adiredja & Louie, 2020). Second, an anti-deficit perspective views students' funds of knowledge as a valuable resource in the learning process. Here, I define *funds of knowledge* as the knowledge and skills that are important to a student's out-of-school experiences and interests,

[3] Salinas (2020) introduced the term "Latin*" to highlight "the fluidity of social identities" (p. 164). The asterisk is meant to encompass a myriad of ways that people of Latin American descent identify (e.g., Latina, Latino, Latinx).

as well as their household and community culture (cf. Moll et al., 1992). While an anti-deficit perspective is beneficial to all students in the context of mathematics, it is more beneficial for marginalized students (e.g., students of color) as these students have historically experienced obstacles that have deprived them access to high-quality mathematics instruction (Martin, 2009).

How an Anti-Deficit Perspective Aligns with Radical Constructivist Research Program

Given that radical constructivist research programs treat students' mathematics as a resource, there is an anti-deficit element already built into them. In the context of building models of students' mathematics, the teacher-researcher must set their own first-order knowledge aside in order to learn new mathematical ways of reasoning *from* their students (Hackenberg, 2005, 2010). The teacher-researcher may observe inconsistency, ambiguity, and/or informal math language in a student's ways of reasoning, but these are leveraged as tools that can support them in achieving viability in their model of the student's mathematics.

The implicit, anti-deficit nature of radical constructivist research programs allows them to address equity-related issues by challenging common discourses related to what counts as mathematics (cf. Tillema & Hackenberg, 2017). Influenced by Gutiérrez (2013), I define *discourses* as the words, actions, beliefs, norms, systems, institutions, and historical events/factors that determine how power (the degree of privilege one has) is distributed in a given situation. The fluid nature of discourses implies that the distribution of power within them can constantly be challenged (Gutiérrez, 2013). By centering students' mathematics as a resource, for instance, radical constructivist research programs challenge traditional views of student-teacher power relations by giving students, rather than teachers or researchers, the "power to determine what counts as knowledge" (Tillema & Hackenberg, 2017, p. 58).

How an Anti-Deficit Perspective Supplements Radical Constructivist Research Program

While challenging discourses related to what counts as mathematics is important in the equity realm, it is not sufficient in addressing the status quo that favors the needs of white men in mathematics (Adiredja, 2019). In order to begin to challenge the status quo, thus deepening their commitment to equity, researchers leveraging radical constructivism need to be more explicit about *who* their mathematical models originate from. Rather than just learning about students' mathematical ways of reasoning, there must be a deeper commitment to learning who they are as holistic beings with identities, cultures, and experiences outside of mathematics. Inasmuch as an anti-deficit perspective valorizes students' funds of knowledge, it can serve to supplement radical constructivist research program by helping researchers attend more robustly to their participants. In the context of building models of students' mathematics, this would require a teacher-researcher to first learn about their students' funds of knowledge (via surveys, interviews, informal conversations, etc.), and then leverage this knowledge in a way that informs their models. One way the teacher-researcher can accomplish this is by creating math tasks that are based on their students' funds of knowledge. Engaging students with tasks that are relevant to them has the potential to influence their ways of reasoning (Adiredja & Zandieh, 2020), which can in turn aid the teacher-researcher in constructing more viable models of their mathematics.

Sensemaking models that are informed by students' funds of knowledge can help radical constructivist researchers address the status quo, and hence attend more deeply to equity-related issues, by challenging deficit discourses about historically marginalized students. Influenced by Adiredja and Louie (2020), I define *deficit discourses* as the subset of discourses that frame students' academic and cognitive setbacks (from the perspective of an observer) in terms of their personal, family, and/or cultural "deficiencies." To illustrate how these models can challenge deficit discourses, consider the work of Adiredja and Zandieh (2020). These researchers leveraged the lived experiences and resources (consistent with funds of knowledge) of eight undergraduate women of color in order to generate a counterstory that highlighted their powerful sensemaking with respect to the concept of basis in linear algebra. For instance, Stacy, an undergraduate Latina woman, connected the spanning role of a basis to her mom telling her and her siblings "to do all the chores" in the house. This counterstory worked to challenge deficit discourses that have historically positioned Latin* students as academically inferior to their white counterparts (San Miguel & Donato, 2009). In a similar fashion, I argue that models of students' mathematics that leverage students' funds of knowledge can also challenge deficit discourses in relation to historically marginalized students. In what follows, I illustrate an anti-deficit model that showcases the powerful sensemaking of an undergraduate Chicana. Prior to illustrating this example, however, I situate it in a brief review of the oppressive schooling history in the U.S. that has contributed to the deficit discourses faced by Latin* students.

A Brief Review of the Oppressive Schooling History Faced by Latin* Students in the U.S.

Historically, Latin* students have been targeted by deficit discourses that have positioned them as academically inferior to their white counterparts (Contreras & Valverde, 1994; Nieto, 2004; San Miguel, 2011; San Miguel & Donato, 2009). San Miguel (2011) noted that Latinos (I remain consistent with language used by the authors) have been perceived as people who do not value education. San Miguel and Donato (2009) noted that the dominant view that Latinos were inferior to whites (specifically during the first half of the twentieth century) caused school systems to ignore the needs (both linguistic and cultural) of Latino children and view them from a deficit perspective. The main intention of the school system during this era was to "fix" Latino children, and to help them assimilate to white culture. Nieto (2004) noted that prior to the *Brown v. Board of Education* ruling in 1954, the segregation of Latinos in schools was justified by perpetuating deficit discourses about Latinos linguistic skills (e.g., Latinos are deficient in English, and thus, must be taught separately). The teachers in segregated schools were primarily white, and use of the Spanish language in these schools was often met with punishment.

In addition to assimilation and segregation, researchers have documented other ways that deficit discourses have historically impacted Latin* students (e.g., MacDonald & Monkman, 2005; Valencia, 2011). For instance, according to Valencia (2011), Chicano students have been negatively affected by schooling conditions such as (among other things) the suppression of their language and culture, poor school and student funding, lower amounts of highly qualified teachers, and their overrepresentation in developmental and special education classrooms. These conditions have led to the association of Chicano students with school failure via low academic achievement, high rates of grade retention (having Chicanos repeat grades), high pushout rates, underrepresentation in higher education, low performance on standardized tests, and high stress levels in school. Taken together, these historical insights highlight not only the negative impact that deficit discourses have had on the academic, and hence mathematical, success of Latin* students, but also the need for researchers to advocate for Latin* students by intentionally challenging these discourses.

Example of an Anti-Deficit Model: Sensemaking of an Undergraduate Chicana

Background Information, Positionality, and Important Definitions

This example model comes from a teaching session that is part of a teaching experiment (Steffe & Thompson, 2000) I conducted in fall 2023: I was the teacher-researcher (TR), and my doctoral advisor was the witness-researcher (WR). The aim of the teaching experiment was to showcase the rate of change development of two Latina undergraduate students, Yari and Jocelyn (pseudonyms), who were recruited from a developmental math course I taught in the fall. Yari, a first-year public health major and a Chicana whose family is from Oaxaca, Mexico, is the focal student in this example; she agreed to participate in the teaching experiment because of its focus on challenging deficit discourses against Latin* students. The research focus in my teaching experiment is connected to my positionality. I am a Puerto Rican man who spent most of my schooling career distancing myself from my own culture (via assimilation), because of the shame I felt toward my own family—a shame that was influenced by deficit discourses that I bought into (e.g., Puerto Ricans don't value education). My graduate school experience has allowed me to situate these discourses within the system, rather than within my own family. Now I aim to advocate for Latin* students in my research by challenging these deficit discourses.

The teaching session that I focus on is based on Yari's engagement with a ratio task that involved pitchers of *Agua de Tuna* (see Figure 1), a drink in her culture that involves a mixture of water and tuna fruits. My goal during this session was to learn about how Yari reasons about intensive quantities in order to understand her conception of *ratio*—a multiplicative relationship between two quantities (Thompson, 1994b). A *quantity* is a conception of a measurable attribute of an object (Olive & Çağlayan, 2008). An *intensive quantity* is a quantity that (1) cannot be explicitly or directly measured, (2) measures the intensity, or degree of presence (Stroup, 2002), of an attribute, and (3) expresses a relationship between two quantities (Schwartz, 1988). As students reason about quantities, they engage in *quantification*, a process that "involves conceiving of an attribute of an object, conceiving of a unit of measure for the attribute, and forming a relationship between the attribute's measure and the unit of measure" (Johnson, 2015, p. 65). For instance, quantifying the pinkness of a wall would require one to conceive of "pinkness" as an attribute of the wall, conceive of a unit of measure for the wall's pinkness (a relationship between red and white paint), and form a relationship between the unit of measure and the wall's pinkness: a 6:2 (red:white) paint mixture has a higher intensity of pinkness than a 4:2 mixture because it has more red paint for the same amount of white paint.

The tuna flavor of "Agua de Tuna" can be measured as a ratio of cups of water to the number of tuna fruits. Consider the two pitchers of agua de tuna below.	
Pitcher A	**Pitcher B**
4 cups of water 3 tunas	6 cups of water 4 tunas

Figure 1: Agua de Tuna Task (adapted from Johnson's (2015) Hot Chocolate task)

Yari's Engagement with the Agua de Tuna Task: Teaching Session 2 of 13 (October 26th)

Midway through the second teaching session, I gave Yari the Agua de Tuna task and asked her to compare the tuna flavor between both pitchers. Initially, Yari argued that pitcher A would have a higher tuna flavor because it contained less water. Based on this initial argument, it might be tempting to conjecture that Yari did not have a robust conception of ratio because she did not consider how the number of tuna fruits would affect the flavor level; her focus was solely on the amount of water. Yet, it is likely that Yari was drawing from her experience of making Agua de Tuna at home as she noted that her answer was based on "instinct." After all, if Yari were making two Agua de Tuna pitchers at home and wanted to determine the flavor level of the tuna for each pitcher, she might not try to find a relationship between cups of water and tuna fruits. Instead, she might taste both drinks and determine that the one with a stronger tuna flavor has less water compared to the one with a milder tuna flavor.

After Yari provided her initial response, I asked her how she would justify that pitcher A had a higher tuna flavor. She responded by giggling and saying that she would "make it," supporting my initial conjecture that her thought process was linked to her experience of making Agua de Tuna. I giggled with her and asked her to assume that she was not able to make it. Yari responded by saying that she would divide, and eventually divided 4 by 3 (the values for pitcher A) using a calculator to get a new value of "1.33." When I pressed her to explain the meaning of "1.33," Yari stated that, to her, it represented the "flavor level." I then pressed Yari to determine the units associated with the "1.33." To assist Yari in her thinking, I encouraged her to think about her work on the *Filling Bottles* task from the first teaching session. This task (adapted from Johnson, 2015), which depicted a graph of the relationship between the volume (in ounces) and height (in inches) of soda in a bottle, involved a similar division process (9 ounces per 4 inches of water corresponded to 2.25 ounces per inch upon division). Her initial guess was that the units would be "tuna fruits per cup of water." I conjecture that Yari mentally reversed the order of the quantities because having the number of tuna fruits come first in the unit of measure would correspond nicely to her interpretation of "1.33" representing the flavor level of *tuna*.

My goal in this exchange was to get Yari to quantify the tuna flavor so that I could better understand her conception of ratio. Up to this point, I knew that Yari conceived of the tuna flavor as an attribute of Agua de Tuna that could be measured via the relationship "tuna fruits per cup of water." This suggests that the tuna flavor represented an intensive quantity for Yari. But it was not yet clear whether she was using this knowledge to compare the intensity of tuna across the two pitchers. Thus, I asked her to divide the two values for pitcher B (6 and 4). After getting a value of "1.50," I pressed Yari about the units. This time, her response leveraged her work on the previous Filling Bottles task. After noticing that she maintained the order of the units (ounces per inch) when dividing 9 by 4 in the previous task, she wrote "1.50 cups per tuna" on her paper.

WR: Does that make sense to you? One point five cups per tuna?

Yari: (*2 second thinking pause*) Umm … (*3 second thinking pause*) well I don't, I don't like, It doesn't (*pointing to the units after "1.50"*), like it makes sense, but, umm, like if you asked me why (*giggles*), I wouldn't be able to explain (*giggles*).

TR: Well, it might help if you actually do the other one (*points to the "1.33" under pitcher A*). So like, write the units down for this one to … (*Yari says "Okay" and writes "cups per tuna" after the "1.33"*) And now like, try to also like, not get too, like, invested in like the actual math. Cause I think it's also part of like, the math anxiety, when we see the math, it's like everything shuts down. Imagine you, you know, you're talking to your, your mom or something, like at home right? And you're making these pitchers of Tuna with her, and you guys both figured out that one of them has about 1.33 cups of water per tuna (*Yari nods and says "Mmmhmm"*) … and then the other one has 1.5 cups of water per tuna, per one tuna fruit (*Yari nods and says "Mmmhmm"*). So based on that … which one would you say is more tunaey.

Yari: (*responds instantly*) This one (*points to pitcher B*), the pitcher B.

TR: Why Pitcher B?

Yari: Because, umm, oh actually hold on sorry … (*raises hands in front of her and giggles*) Uhh, Mmm, it would still be, pitcher A … (*TR asks "Why" as Yari points to the "1.33 cups of water per tuna" under pitcher A*) Because you're using less cups per water, or per yeah, less cups per, per water, or per tuna.

Reflecting on her work from the Filling Bottles task prompted Yari to maintain the order of the units in the Agua de Tuna task (cups of water per tuna fruit), thus modifying her initial guess (tuna fruits per cups of water). Yet, when the witness researcher asked Yari if the "one point five cups per tuna" made sense, she confessed that she "wouldn't be able to explain" even though it did make sense to her. Leveraging that I knew Yari had firsthand experience with making Agua de Tuna, I took her focus away from the math in front of her by asking her to imagine this situation occurring in her own home with her mother. This triggered a turning point in Yari's confidence as she was able to instantly provide a response to my initial question ("which pitcher was more tunaey?"). At first, Yari pointed to pitcher B, but then quickly shifted to pitcher A as being the pitcher that was more tunaey. When asked to explain, she concluded (stumbling a bit over her words) that pitcher A would be less tunaey because it contained "less cups of water … per tuna."

This exchange is important as it highlights that it is possible for teacher-researchers to leverage a student's funds of knowledge in order to bring out the true potential in their math reasoning. In this case, it wasn't until Yari thought about the situation as an at-home experience that I was able to realize that she was (at least in this context) quantifying the tuna flavor as an association between cups of water and tuna fruits. That is, Yari was able to compare the tuna flavor across both pitchers by associating the cups of water in each pitcher with *one* tuna fruit. Conceiving of a ratio as an association between quantities is consistent with an *identical groups conception of ratio* (Heinz, 2000; Simon, 2006). This contrasts a *ratio as measure conception* (Simon & Blume, 1994), which requires one to conceive of a ratio as a multiplicative relationship that remains invariant. An important note is that Yari's final response (i.e., pitcher A was more tunaey because "you're using less cups of water … per tuna") matched her initial response, where she argued (based on "instinct") that pitcher A would be more tunaey because it contained less water. This suggests that students' intuition, connected to their funds of knowledge, can be a powerful tool in their mathematical ways of reasoning.

Discussion

This anti-deficit model of Yari's ratio-based reasoning, which was viable across future teaching sessions, showcases the powerful, mathematical sensemaking of a Chicana undergraduate student. This is especially significant given that, historically, deficit discourses have positioned Latin* students as academically inferior by (among other things) suppressing their cultural value (Valencia, 2011). One conjecture for why Yari did not leverage her experience of making Agua de tuna until I prompted her to do so is that she has been trained (via deficit discourses and traditional teaching modalities) to see mathematics as disconnected from her culture. Yet, as this model highlights, Yari's culture played a powerful role in bringing out her math reasoning.

There are two ways that an anti-deficit model differs from a traditional radical constructivist model. First, an anti-deficit model centers the sensemaking of students from historically marginalized groups (e.g., women, neurodiverse learners, students of color). When applied specifically to students of color, it challenges colorblind ideologies that assume uniformity in students' needs and experiences. Second, an anti-deficit model valorizes students' funds of knowledge in the sensemaking process. Rather than focusing primarily on students' engagement with math tasks to make sense of their math reasoning, teacher-researchers constructing anti-deficit models go one step further by leveraging students' culture and out-of-school experiences to make sense of (and/or bring out) their math reasoning (e.g., connecting Yari's initial response that pitcher A would be more tunaey because it contains less water to her home experience).

Circling back to the purpose of this paper, I have proposed an approach that radical constructivist researchers can leverage to challenge the status quo and deepen their commitment to equity; an approach that requires supplementing radical constructivism with an anti-deficit perspective to promote the construction of anti-deficit models, specifically with respect to students from historically marginalized groups. The benefit in utilizing this approach is that it has the potential to challenge deficit discourses that have historically positioned these students as academically and culturally inferior to students from the dominant group. I encourage researchers working within this paradigm to consider this approach when inquiring about how to better attend to equity-related issues. More broadly, and in alignment with the PMENA theme, I encourage math education researchers to continue discussing approaches to bridge cognition and equity work in order to promote a future where we work collaboratively across different paradigms to achieve our equity-related goals.

INCLUDING VOICES THAT MATTER: STUDENT PERSPECTIVES ON COMMUNITY IN ONE SOCIAL JUSTICE MATH CLASSROOM

Kathryn E. Roman
Portland State University
kroman@pdx.edu

Molly L. Robinson
Portland State University
molrob2@pdx.edu

Eva Thanheiser
Portland State University
evat@pdx.edu

Building classroom community with students is important to implementing social justice math lessons. This study investigated students' conceptions of community in a social justice high school math class. Data included two anonymous surveys that were analyzed using thematic analysis. The first finding showed three aspects of community in students' definitions: a group of people, sharing something in common, and group dynamics. The second finding showed that by Survey 2, more students felt comfortable speaking to their peers, and there was an increase in students believing the class was a community. These findings suggest that building community helps students feel more comfortable sharing their ideas, which can in turn help them feel more comfortable discussing sensitive topics (i.e., racism, sexism, in their math classes).

Keywords: Equity, Inclusion, and Diversity; High School Education; Social Justice.

Building community is an important aspect of implementing social justice mathematics (SJM) lessons (Bettez & Hytten, 2013; Conway IV et al., 2022; Thanheiser & Koestler, 2024). Not only is it important, but it "is also essential for SJM exploration that is rooted in and respects all people's humanity" (Conway IV et al., 2022, p. 36). Students have been trained to see mathematics as neutral (Gutiérrez et al., 2023; Thanheiser, 2023). Therefore, they might not feel comfortable talking about SJM topics (e.g., racism, sexism) in their mathematics classrooms. Being in a community offers students "connection, interdependence, and belonging" (Bettez & Hytten, 2013, p. 52). Hopefully, imbued with a sense of belonging, students feel they can share their ideas and thoughts in a space "intentionally built around principles of justice and anti-oppression" (Conway IV et al., 2022, p. 36). Given that students make up a majority of the classroom community, their perspectives matter (Wilkerson, 2021). Thus, we need to understand students' thoughts and feelings on building community, as well as whether they feel it has been built. Consequently, we explore students' conceptions of classroom community in a SJM high school class to in turn support teachers in building community in ways that can support discussions of SJM topics in their classrooms.

Literature Review

Researchers have offered approaches to build community in the classroom (e.g., Conway IV et al., 2022) that can be leveraged by teachers working within social justice curriculums. These approaches involve teachers (1) reflecting on their own biases (Conway IV et al., 2022a), (2) implementing activities (e.g., icebreakers) (Taylor et al., 2022), assigning math autobiographies (Conway IV et al., 2022), and (3) having participation structures in place (e.g., complex instruction, Featherstone et al., 2011) so that students can feel valued no matter how they participate. Yet, with these ways of building community, how does a teacher know that community was built in their classroom? Are they basing it on their own perceptions (e.g., Taylor et al., 2022), or are students' perceptions included? Id-Deen (2024) reminds us that we need to consistently gather feedback from the community to check in regarding their needs. As Wilkerson (2021) states, "A powerful, essential part of our mathematics community is our students…Their voice must be heard and they must be included in conversations, decision making and actions," (para 4). Thus, we need students' continuous feedback to know whether they believe community has been built in the classroom. Little research, however, shows what this looks like in practice (see Adamian, 2022 for exceptions). In this paper, we aim to better understand what is important to high school students in a SJM class when defining community and determining whether they believe community was built. Our hope is that through building community, the students feel safe to discuss sensitive topics because community creates a sense of belonging, and this belonging allows students to share their true feelings. We studied efforts to build community in one high school SJM math course. The research questions are as follows: (1) What definition of community do students have? (2) Did students feel community was built, why or why not?

Methods

Data was collected during the 2023-2024 school year at Forest High School (FHS, pseudonym) in the SJM class. FHS is a public high school located in the Pacific Northwest. The SJM class had a total of 30 students enrolled in the first semester. The class met every other day for 90 minutes. Mr. L (white man of Ashkenazi Central and Eastern Jewish descent, high school teacher) and Roman (white cisgender woman, graduate student) co-taught the course. The class consisted of predesigned TMfSJ lessons (PTMfSJLs, e.g., Berry III et al., 2020) as well as community builders (e.g., significant circles, Esteban-Guitart & Moll, 2014). During the first month of the class, approximately 45 minutes to an hour was dedicated to building community in each class period while the rest of the time was focused on the implementation of a PTMfSJL. After the first month, 20 to 30 minutes was spent on community building each class period.

Two anonymous community surveys were given during the first semester of the SJM class–one in the beginning of October (Survey 1, $n = 28$) and the other in the beginning of January (Survey 2, $n = 25$). There were two types of questions. The first type pulled from practical measures (Jackson et al., 2016), which are quick survey questions that gauge students' feedback on specific instructional strategies. Sample Likert scale phrases in the surveys included "I felt comfortable sharing my mathematical thinking" and "I felt comfortable sharing my views on race, racism, and society." The second type were short response questions aimed at gauging students' perceptions of community. Survey 1 had one short response question, "Do you feel this class is a community? Please explain." Since some of the students in Survey 1 said this depended on their definition of community, in Survey 2, the students were also asked to define community.

We used thematic analysis (Braun & Clarke, 2006) and bottom-up coding to analyze the students' definitions of community on MAXQDA. Roman read the students' definitions and created initial codes to capture what was included in their definitions (definitions could be assigned more than one code). For example, a student's definition of community was, "A group of people that share experiences and work through challenges." Roman's initial codes were, "1. Group of people. 2. Share experiences. 3. Work through challenges." She then read these initial codes to create initial themes. For example, anyone that mentioned working together or working through challenges was coded with the theme "working together." Initial themes were then collapsed into broader themes. For example, "working together", "comfortable with each other", and “getting along” were all collapsed into the broader theme, “Group Dynamics” to depict how members of the community worked with one another.

Results

Research Question 1: How Do Students Define Community?

In the second survey, 24 out of 25 students provided definitions for community. We found three themes: (1) a group of people, (2) sharing something in common (like a goal or interest, etc.), and (3) group dynamics (how the group worked together. The largest theme was “ a group of people (mentioned in 83% of definitions). For example, two students wrote “people together” while another student wrote “a group of people sharing a common interest.” The students also thought that community members must share something in common (mentioned in 58% of definitions), like ideas, beliefs, or goals. As an illustration, students wrote, “a group of people with a similar end goal” or “a group of people sharing something in common, like a location, ideas, and beliefs.” The last major theme was “group dynamics” (mentioned in 37.5% of definitions). For example, students wrote, “a group of people that live in the same place and have some of the same interest[s] by work[ing] together and supporting each other” or “a group of people that share experiences and work through challenges.” To them, working together and supporting each other was important for building community. This makes sense as the students worked on projects and community builders in groups. The way the class was run could have influenced their definitions.

Research Question 2: Did the Students Feel Community Was Built, Why or Why Not?

To answer this question, we compared the students’ responses (yes, no, and in between) in Survey 1 ($n = 28$) and Survey 2 ($n = 25$) (see Figure 1). The number of students who said yes to the class being a community increased from 11 students to 17 students (39.3% versus 68%) from the first to the second survey. Applying the themes from the students’ definitions (from RQ 1) (see Cobigo et al., 2016), students in both surveys tended to focus on sharing something in common, like taking the class, “yes because we all have something similar. We all take this class” (Survey 1); or being in the same place, “yes, we are all in the same class, in the same school, so technically we would be counted as a small community” (Survey 2). In Survey 1, three (out of 11) responses focused on group dynamics, like “we are all working towards the goal of learning social justice math and helping and uplifting each other when we need help.” Group dynamics were mentioned more in Survey 2, where 8 of the 17 “yes” responses shared feeling more comfortable discussing with one another and working together. A student shared,

> yes i feel this class is a community because there is never a time where we have to learn how to find an answer to something by ourselves, we will always work together to figure it out. it just makes us feel more comfortable about sharing ideas and asking questions.

Another student shared, “yes, i feel open to discussions with the whole group and i'm not afraid to show my ideas.” Thus, group dynamics seemed to play a bigger role in why the class was considered a community in Survey 2 versus Survey 1.

The number of students who had in between yes and no responses (e.g., “maybe”) decreased from six students to three students (21.4% versus 12%). Reasons for students’ uncertainty were linked to (1) how community was being defined, (2) sharing something in common, and (3) group dynamics. For example, a student wrote, “Maybe? It depends on how you define a community, because we're all just people that want a math credit for the most part” and another student wrote, “i feel like it's sorta a community but i would still feel judged by my answers or responses by the class.” In Survey 2, of the 3 responses, only one student explained, “Somewhat, we're all here to pass and graduate.” These highlight how the shared class setting and common goal–getting a math credit or trying to pass and graduate–did not automatically create a sense of safety in the learning process. The number of students who said “no” to the class being a community stayed the same ($n = 3$) in both surveys. Reasons included students feeling that (1) the class did not operate as a community and (2) sharing something in common did not make them a community. For instance, a student wrote, “nope, we're just here to get a grade, yes some of us are friends but we in a whole do not communicate or interact like a community” (Survey 1). Another student wrote “naw we're just kids trying to pass” (Survey 2). Thus, even though community was intentionally built in this class, it did not align with *all* the students' understandings of community.

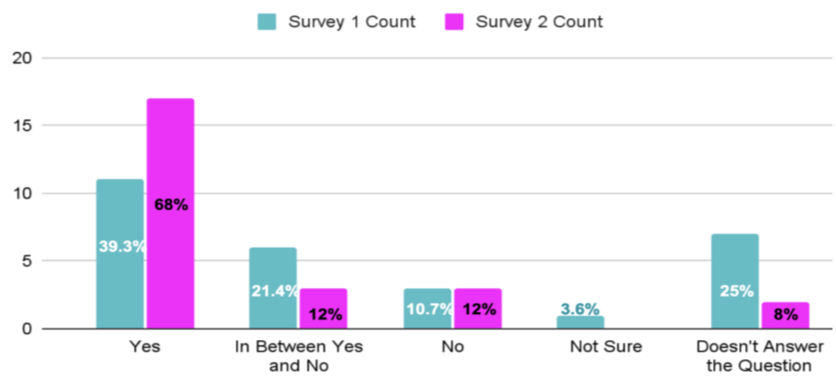

Figure 1: Survey 1 and Survey 2 Count of Whether the Class Was a Community

Discussion

Literature on social justice often talks about the importance of community for implementing SJM lessons (e.g., Thanheiser & Koestler, 2024) and ways to build community (e.g., Taylor et al., 2022), but often omits students’ perspectives from the discussion. In this study, we add to the literature by asking for students’ perspectives on community (RQ 1) and whether they believed community was built (RQ 2) in their SJM class. In response to RQ 1, the three aspects of community in students’ definitions were a group of people, sharing something in common, and group dynamics. In response to RQ 2, we found that the proportion of students who believed the class was a community increased from 39.3% to 68% from Survey 1 to Survey 2.

These results suggest that teachers who intentionally incorporate community building as part of their practice can help students feel a sense of community in their SJM classes. As illustrated by students’ responses to Surveys 1 and 2, this sense of community helped them feel more comfortable sharing their ideas. In Survey 1, students tended to worry about being judged and did not say much about group dynamics, whereas in Survey 2, group dynamics were mentioned more. A student said, “I like the community builders because I actually know the people in this class, my other classes I don't know anyone and don’t feel like I can share my opinion” (Survey

2). This suggests that intentionally building community can foster a safe space where students feel comfortable sharing their thoughts. This has implications for the way teachers encourage discussions around sensitive social justice math topics. If students do not feel comfortable about these topics, then the conversations may not be productive. Thus, intentionally building community may be one way for students to feel more comfortable speaking about these topics.

This shows the importance of intentionally building community and getting students' perspectives. They felt they could share their opinions in this class. If we truly want teachers to be able to discuss sensitive topics in their math classes, then we need students to feel more comfortable speaking about these topics as well. Intentionally building community and knowing what is important to students when it comes to building community is one way to do that.

PRESERVICE SECONDARY SCHOOL MATHEMATICS TEACHERS' PERCEPTIONS TOWARD STUDENTS WITH DISABILITIES: A PRELIMINARY INVESTIGATION

PERCEPCIONES DE FUTUROS DOCENTES MATEMÁTICOS DE SECUNDARIA HACIA ESTUDIANTES CON DISCAPACIDADES: UNA INVESTIGACIÓN PRELIMINAR

laura.vanzoest@wmich.edu

Better understanding preservice teachers' current perceptions toward students with disabilities will allow mathematics educators to create specific strategies for helping students to develop perceptions promoting inclusive classroom environments. To access these perceptions, we developed an online survey that asks respondents about their knowledge of disabilities, their experiences with people with disabilities, and decisions they would make based on classroom scenarios that involve students with disabilities. We gave this survey to 14 preservice secondary school teachers (PSTs). Key findings include five PSTs presented an inclusive perception toward students with disabilities, seven PSTs presented an ambiguous perception and the perceptions of two PSTs remained unknown. All but the latter two PSTs provided at least some evidence of their willingness to fully include students with disabilities in their mathematics classrooms.

Keywords: Equity, Inclusion and Diversity; Students with Disabilities; Teacher Beliefs; Preservice Teacher Education.

Purpose of the Study

History reflects a progression through four views about the participation of students with disabilities in classrooms: exclusion, segregation, integration, and inclusion (Sónia, 2012). Currently, the goal is classrooms with an inclusive environment for students (Radd et al., 2021), which means that students with and without disabilities are considered contributing members in the learning process. This requirement is what makes inclusion different from integration, as integration—the current norm—is satisfied merely by the presence of students with disabilities in the classroom without regard to the nature of their participation. Mathematics teachers, in their role as instructional leaders, affect the movement from integration to inclusion in their classrooms. Specifically, teachers' perceptions toward students with disabilities can affect, either positively or negatively, the creation of an inclusive environment in their mathematics classrooms. Better understanding teachers' perceptions is essential to being able to support them in making the transition from integration to inclusion, and being able to support preservice teachers to develop an inclusive perception at the beginning of their career will accelerate the change process. To move toward this understanding, our preliminary investigation used a classroom-scenario-based online survey to access preservice secondary school mathematics teachers' perceptions toward students with disabilities.

Theoretical Framework

Papadakis & Kalogiannakis (2020) defined teacher perceptions as "[t]he thoughts or mental images [that] teachers have about their professional activities and their students, which are shaped by their background knowledge and life experiences and influence their professional behavior" (p. 339). Following their definition, we use the phrase *mathematics teachers' perceptions toward students with disabilities* to mean "the thoughts or mental images that influence teachers' interactions toward students with disabilities" and assume that these perceptions are formed from teachers' background knowledge about disability and life experiences with people having a disability. The same definition applies to preservice teachers with respect to their future students.

To have a better understanding of teachers' perceptions toward students with disabilities, it is first important to understand their perceptions toward disabilities. This is why our framework (see Figure 1) addresses both types of perceptions. Perceptions toward disabilities focus on two things: (1) the medical, social, and revolutionary models of disability described in Tan et al. (2019; see Figure 2 below) as a way to categorize the conceptualizations teachers have of disability, and (2) which health conditions teachers recognize as disabilities. Our conceptualization of teachers' perceptions toward students with disabilities focuses on teachers' practice in the classroom around (1) their considerations toward students with disabilities in comparison to students without disabilities, and (2) their application of fairness, justice, equity, and human rights from the perspective of disability.

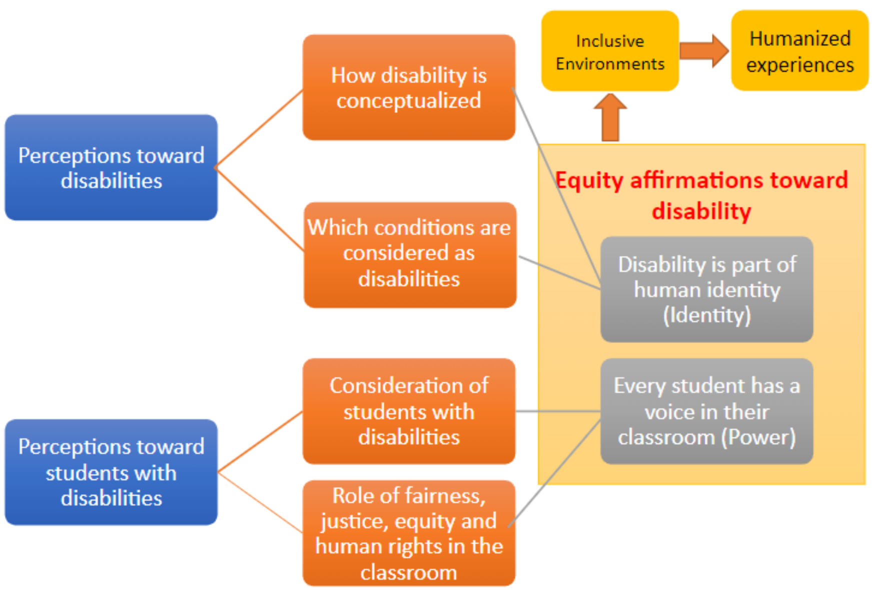

Figure 1: Conceptualization of Teachers' Perceptions toward Disabilities and Students with Disabilities (adapted from Romero Castro & Van Zoest, 2023)

We consider that teachers' perceptions toward disabilities or toward students with disabilities can be identified as inclusive if they promote inclusive environments in classrooms. Otherwise, they are identified as non-inclusive. The right side of Figure 1 illustrates two equity affirmations toward disability that promote inclusive environments and increase the possibility that students will have humanized experiences in their mathematics classrooms. We take the perspective that (1) in order to have an inclusive perception toward disability teachers need to embrace the fact that *disability can be part of human identity,* and (2) to have an inclusive perception toward students with disabilities they need to hold that *every student has a voice in the classroom* (for more details, see Romero Castro & Van Zoest, 2023). These two facts are considered affirmations of equity toward disability, and they are related to Gutiérrez's (2012) two dimensions of the critical axis of equity: identity and power. Particularly, alignment of these equity affirmations with the critical axis of equity is the necessary condition for inclusion toward disability, whereas the relationship between teaching practice and the dimensions in the dominant axis of equity—access and achievement—is a sufficient condition for integration (Romero Castro, 2023). This can be explained by considering that the active participation of students with and without disabilities in the learning process (which requires students' identities to be considered) is what makes an environment inclusive rather than integrative. On the other hand, access and achievement will guarantee that students are present for all classroom activities, which satisfies the definition of integration.

Methods

An anonymous classroom-scenario-based online survey was designed to assess the current perceptions of mathematics teachers. We gave this survey to 14 preservice teachers (PSTs) at the end of a secondary mathematics methods course at a mid-western U.S. university. Before accessing the survey, the PSTs were asked to accept the conditions of a consent form appearing on the first screen of the survey link; all 14 people enrolled in the course accepted. The survey was created using the software Qualtrics (2020) and has three components. The first component assessed which conditions PSTs considered as disabilities. Although other studies have asked preservice teachers to explain their concept of disability (e.g., Mason & Connor, 2022), for our purposes, it seemed more useful to draw on the existing legal documents in the United States that require the integration/inclusion of students with disabilities that belong to certain categories. Specifically, we drew on the categorization of disabilities from the Individuals with Disabilities Education Act of 2004 (as cited in Radd et al., 2021). The PSTs were provided with a list of 12 health conditions and asked to indicate whether each was or was not a disability, or if they were "unsure." The health conditions listed were cerebral palsy, blindness, hearing impairment, leprosy, panic disorder, autism, sleep-wake disorder, Tourette syndrome, spinal cord injury, Down syndrome, oppositional defiant disorder (ODD), and depression; leprosy and sleep-wake disorder are the only conditions on this list that are not considered disabilities in IDEA. For each of the conditions in the list, teachers were also asked to identify whether they have the condition, they have met someone inside/outside the school with the condition, or they have not had exposure to the condition. They also were provided with the opportunity to enter other disabilities and describe their exposure to them. Babik and Gardner (2021) established that exposure since childhood to people with disabilities is one of the factors that positively affect perceptions toward them.

The survey's second component asked the PSTs to describe the nature of their experiences with people with disabilities. There are two questions related to this: one focused on their interactions in their educational career (with teachers, school staff, classmates) and the other focused on their interactions with people outside of school. In each of these two questions, PSTs may choose if they have had only good experiences, at least one complicated experience, or no related experience in the respective environment. If they choose the second option, then they are encouraged to describe why it was complicated. In addition, they were asked to determine whether they felt “totally,” “enough” or “not” prepared to be the teacher of a student with a disability. All these questions help to understand PSTs’ backgrounds, which inform their conceptualization of disability and their perceptions toward students with disabilities in the classroom (see Figure 1).

The third component of the survey positioned the PSTs in two classroom scenarios and asked them to respond to mathematical contributions from students with disabilities during a classroom discussion. The first scenario involves Sam, a student with cerebral palsy who, after working individually on a geometric problem the teacher provided in class, publicly gives an incorrect answer. The second scenario involves Chris, a student with a mathematical learning disability who, after working with a group on an algebraic problem the teacher provided in class, shared the group’s correct answer. As described in Romero Castro & Van Zoest (2023), each scenario is followed by a series of three questions, with each question having three to four choices and the option to write one’s own response if it is not captured by one of the options. Question 1, “What first comes to your mind?” is intended to access the extent to which teachers embrace the complex nature of disabilities as being part of students’ human identities (Figure 1: Equity Affirmation #1). For this question, they are asked to write their response before selecting the choice that best fits their response. Question 2, “What would you do next?” is intended to access the extent to which students with and without disabilities have a voice in the classroom (Figure 1: Equity Affirmation #2). The response to Question 1 informs the response choices for Question 2. Question 3, “Why did you choose that response?” is designed to access their justifications for their answer in Question 2 through a view of the student’s identity.

For the analysis stage, responses to Question 1 were aligned to the models of disability’s conceptualization described in Tan and colleagues (2019). Figure 2 shows a brief description of each model and example choices for Question 1 to illustrate how the response options in the survey support identifying a respondent’s model based on their choices.

Model of disability	Description (Tan et al., 2019)	Example Response Choices for Question 1
Revolutionary	considers disability as part of a person’s humanity and not something to be fixed “posits that mathematics belongs to all students, assuming that all learners, without distinction, are creative thinkers and doers in their multifaceted everyday experience of mathematics” (p. 39)	(Scenario 1) I need to figure out what Sam is thinking because there are multiple ways they could have gotten that wrong answer. (Scenario 2) I need to figure out what Sam is thinking because there are some reasoning ways they could have answered.
Social	“points to the deficiencies within the environment that contributes to the construction of the disability or impairment” (p. 37) “addressing disability issues becomes more a matter of social change rather than individual fixing or even curing or correcting biological or	(Scenario 1) Maybe this problem is too hard for Sam, so I should modify it to support Sam to get the right answer. (Scenario 2) I wish I knew more about Chris’s mathematical learning disabilities so I would know how to help Chris more effectively.

	functional impairments" (p. 39)	
Medical	"locates the deficit, impairments, or disability solely on the individual" (p. 34) "the mathematics learning environment and socially acceptable classroom rules, expectations, and circumscribed ways of knowing and doing mathematics are thought of as adequate and are unquestioned" (p. 36)	(Scenario 1) That's a common answer, even a normal student might come up it because everyone comes to the class with their own conceptions or misconceptions. (Scenario 2) It feels risky to have Chris present the solutions because their mathematical learning disabilities prevent Chris from making sense of it.

Figure 2: Models of Disability and Their Manifestation in for Survey Response Choices

Based on the first equity affirmation we mentioned—*disability can be part of human identity*, the revolutionary model reflects an inclusive perception toward disability whereas the medical and social models reflect a non-inclusive perception. The analysis for the responses to the first question was set up to determine the respondent's perception toward disability in the following way:

- Inclusive when the revolutionary model is shown across both the written and selected responses to both scenarios.
- Non-inclusive when the medical or social models are shown across both the written and selected options respond to both scenarios.
- Ambiguous when the responses vary within or across scenarios.

Responses to Question 2 and Question 3 were analyzed to determine whether PSTs would consider people with disabilities for participating in class, from which it is possible to infer their perceptions toward students with disabilities (see Figure 1) in the following way:

- Inclusive when there is consistent evidence the respondent considered students with disabilities for class participation.
- Non-inclusive when there is consistent evidence the respondent would not consider students with disabilities for class participation.
- Ambiguous when there is inconsistent evidence about the respondent's consideration of students with disabilities for class participation.
- Unknown when there is no response to Questions 2 and 3 for both scenarios.

The survey responses were imported and organized into a Microsoft Excel spreadsheet by respondent number to support the analysis process.

Results & Discussion

Here we briefly discuss key findings for each of the three survey components. In the first component, cerebral palsy and blindness were the only health conditions identified by all 14 preservice teachers (PSTs) as disabilities, even though only five and nine of them, respectively, indicated past interactions with people having those disabilities. Autism and Down syndrome were identified as disabilities by 13 PSTs; one PST was unsure about Autism and said Down syndrome was not a disability. In general, the PSTs identified legal disabilities as disabilities, or were unsure. For example, depression is legally identified as a disability (ADA, 2018) and eight PSTs identified it as such, four were unsure, and only two said that it was not a disability. Interestingly, one of the two PSTs who said depression was not a disability identified themself as having depression and the other as knowing someone who did. Eight PSTs in total identified themselves as having one of the listed health conditions: one with hearing impairment, two with panic disorder, and five with depression[4]. In addition, one PST entered that they had post-traumatic stress disorder (PTSD). Regarding interaction with others, 13 PSTs reported exposure to someone with autism, 10 for Down syndrome, and 9 for hearing loss. Interestingly, although five PSTs in the class reported having depression, eight of their classmates reported not having been exposed to anyone with depression, highlighting the invisible nature of depression as a disability. In addition to the health conditions on the list, one PST each entered that they had exposure to someone with the following: attention-deficit/hyperactivity disorder (ADHD), obsessive-compulsive disorder (OCD), multiple sclerosis, muscular dystrophy, hip dysplasia, and epileptic seizures.

For the second component, seven PSTs (50% of the sample) declared they had all good experiences interacting with people with disabilities *within* school relationships, while the other 50% declared having had at least one complicated experience. Among the reasons given by the PSTs who declared to have at least one complicated experience, the lack of preparation or knowledge about disabilities was the most common. For example, PST 10 wrote, *It was one of my first times working with a student who had a disability [autism], and I felt ill-prepared in helping them.* A different reason is illustrated by PST 6: *How the teacher thought about the student was a negative.* This PST did not identify any contact with a particular disability in the first component of the survey, but their answer implies that they could identify a teaching practice with a non-inclusive perception toward the student with a disability. PST 13 distinguished among different types of disabilities: *Sometimes, students who have disabilities can (not often) be disruptive to the class (especially those with neurodivergent ones). Disabilities that are purely physical are usually handled well by myself, classmates, and teachers*.

Similarly, six of the PSTs declared they had all good experiences interacting with people with disabilities *outside* school relationships, seven declared at least one complicated experience, and one had no experience. PSTs described complicated experiences around family issues and fluency in daily conversations. For example, PST 13 wrote: *Being friends/family with someone who has a disability can be hard. Of course, I do not downplay the dignity of that person. However, loving them takes effort on their hard days* and PST 8 expressed: *Sometimes I struggle with navigating conversations with people and worry about what I might say, so I get worried about saying the wrong thing to someone with a disability*. In the same survey component, one of the PSTs declared to feel totally prepared to be a teacher of a student with a disability, while twelve of them felt somewhat prepared and one of them not really prepared.

The results of the third survey component are organized in Table 1. We first discuss the model of disability that the PSTs' responses mapped to for each scenario and their resulting

[4] It is important to clarify that PSTs were not allowed to select more than one choice in the determination or the exposure parts. This is a design feature that we will modify in future uses of the survey so that respondents will be able to indicate both their own experience and exposure to others.

inferred perception toward disabilities. We then discuss the PSTs' consideration of students with disabilities and their inferred perceptions toward students with disabilities.

In Scenario 1, ten PSTs responses mapped to the revolutionary model, none to the social, three to the medical, and one presented as ambiguous. In Scenario 2, five mapped to the revolutionary model, three to the social, three to the revolutionary, and three presented as ambiguous. Table 1 shows that of the ten PSTs that mapped to the revolutionary model in Scenario 1, four mapped to the revolutionary model in Scenario 2, two to the social, one to the medical, and three presented as ambiguous. These differences in models across the two scenarios could be affected by the differences between the scenarios: type of disability (physical or non-physical), evaluation of the student's contribution (correct or incorrect), and type of work (individual or group). Considering the results, we conclude that four PSTs presented an inclusive perception toward disability, two PSTs presented a non-inclusive perception, and eight PSTs presented as ambiguous. The fact that only four PSTs presented an inclusive perception toward disabilities suggests that there is much work to be done to prepare teachers to promote an inclusive classroom. Furthermore, even PSTs who have an inclusive perception may need

additional opportunities to better understand disabilities. For example, PST 13 wrote in the blank box for Question 1 in Scenario 1: *The first thing that comes to my mind, without even reading the numbers yet, relates [to Sam's] perspective to the problem. Without solving and analyzing the error, I would wonder if Sam's experience with wheelchairs informs the solution*. Since

Scenario 1 does not mention anything about Sam's experience with wheelchairs, PST 13 may have assumed that Sam uses a wheelchair because he has cerebral palsy. The reality is that above 50%-60% of children with cerebral palsy can walk independently (CDC, 2023).

Five PSTs' responses to the second and third questions provided evidence that they would consider further participation of the students with disabilities in the scenarios, and thus they were inferred to have an inclusive perception toward students with disabilities. Seven PSTs' responses to one of the scenarios provided evidence that they would consider further participation, but because they were missing responses to Questions 2 and 3 for the other scenario, they were coded Ambiguous. Two PSTs' perceptions toward students with disabilities remain unknown because they did not provide any responses to Questions 2 and 3. It is interesting to note that these two were the same PSTs who had non-inclusive perceptions toward disabilities.

To illustrate, for Scenario 1, nine PSTs chose *Ask Sam to explain their result* (seven of them *to better understand the root of [their] misconception* and two *to give other students a chance to notice whether they share Sam's argument*), and one PST chose *Ask someone else who had the same answer to share their thinking* to *promote discussion in the classroom.* PST 14 chose to create their own response: *Have Sam take me through step by step so I can understand their thinking and build from it*, and their reason behind their response was: *Sam is a person with a disability. He is more than the disability.* All these PSTs were willing to include Sam in the conversation and seemed to value Sam's contributions. For Scenario 2, five PSTs chose *Ask Chris to give their reasoning for their answer* (four of them *to promote discussion in the class* and one *to deepen Chris's mathematical reasoning*). In addition, PST 11 wrote: *I would first ask Chris to explain their reasoning and then solicit help from the group if he struggled* and chose as their reason *to deepen Chris's mathematical reasoning.* Four of these six (PSTs 4, 7, 11, and 13) demonstrated an inclusive perception both toward disabilities and toward students with disabilities. PST 5 demonstrated an inclusive perception towards students with disabilities and an ambiguous perception toward disabilities because they had one response that seems to reflect a medical model of disability. The fact that there was more missing data for Scenario 2, where the student was identified as having a mathematical learning disability, raises the question of whether PST 13 was correct in assuming that PSTs are more comfortable responding to students who have physical disabilities. However, Scenario 1 involved a student's own contribution and Scenario 2 involved a student representing their group's answer, which could also be a reason for the difference.

Conclusion

This preliminary investigation provides a glimpse into preservice secondary school mathematics teachers' perceptions toward disabilities and toward students with disabilities. Our results suggest that PSTs have a fair amount of experience with people with disabilities, and much of it has been positive. Furthermore, all but two PSTs provided at least some evidence of their willingness to fully include students with disabilities in their mathematics classrooms. Despite these encouraging signs, there is much work to be done to support teachers in achieving the goal of creating an inclusive environment in their mathematics classrooms. Better understanding PSTs' current perceptions toward students with disabilities will help teacher educators create specific strategies for helping them to develop perceptions promoting inclusive classroom environments from the beginning of their careers.

Having only two scenarios for PSTs to respond to meant that we could not clearly identify which aspects of the scenarios were responsible for the differences in the models of disability their responses reflected and inconsistencies between their consideration of students with disabilities as contributors of mathematics. Expanding the survey to additional scenarios would allow us to better identify nuances in their responses (e.g., physical vs. intellectual disability, individual vs. group work, accuracy of the contribution).

PROMOTING EQUITABLE SCHOOL-FAMILY COLLABORATION THROUGH A CULTURALLY RESPONSIVE MATH ROUTINE

Jennifer Suh
George Mason University
jsuh4@gmu.edu

Stephanie Calabrese
George Mason University
scalabr@gmu.edu

Keywords: Early Childhood Education; Equity, Inclusion and Diversity; Culturally Relevant Pedagogy; Professional Development

This exploratory, qualitative study looked at a mathematical routine, focused on family-provided photos, that elicited children's mathematical and general observations and inquiries and engaged caregivers in mathematical communications. As such, the study of this routine prioritizes family engagement in early mathematics learning through the theories of funds of knowledge (González et al., 2005) and parents as intellectual resources (Civil & Andrade, 2003). As intellectual resources, parents have knowledge and experiences that serve as funds of knowledge to strengthen children's development of positive mathematics outcomes and dispositions, both at home and in school. (Vélez-Ibañez & Greenberg, 1992; Moll, et al., 1992). Set in three kindergarten classrooms serving a diverse, multilingual community in the northeast United States, teacher interviews utilized photo elicitation to study ways in which implementation of this culturally responsive, family-inspired mathematics routine revealed parents' intellectual resources and family and children's mathematical funds of knowledge.

Research-Based Design

This study followed three project teachers after one year of PD and lesson enactment to explore how they were expanding on what they learned from the PD. The focus of the follow-up was to learn how teachers engaged families in mathematics, particularly by amplifying family voices and learning ways to elevate families as assets and intellectual resources. In framing our work on Funds of Knowledge and Parents as Intellectual Resources, we added a component of "Family Inspiration" to a Mathematizing the World Routine (MWR). The original MWR was a routine that teachers engaged in, during year one of our project, focused on developing students' observational and mathematical questioning skills related to some phenomenon, prompting students to notice, wonder, and pose mathematical questions Centered on this revised routine, our study focused on the following research question: What does the culturally responsive, family-inspired MWR reveal about family and children's math knowledge, assets and practices?

Findings

Photo elicitation interviews allowed us to revisit the routine enactment as well as related teacher-family communications. We asked teachers to select the most memorable photos in terms of math talk and family engagement. Recurring themes fell into three categories: 1) Linking family practices with math practices; 2) Making connections among diverse families, peers and educators; and 3) Increasing communication and participation of diverse families. The family-inspired MWR offers a unique integration of mathematical content and family engagement.

Korean Immigrant Parents' Ways of Providing Support for Mathematics Understanding at Home

Yewon Sung
California State University-San Bernardino
yewon.sung@csusb.edu

Asian parents are often described as tiger parents in the U.S. media which is a monolithic representation of them. However, it does not consider cultural differences among subgroups in Asian populations. Korean mathematical expressions differ from the U.S. curriculum, and some Korean immigrant parents directly support mathematics at home. This research explores Korean immigrant parental involvement in home math support during the ongoing COVID-19 pandemic and remote schooling. My analysis reveals how these parents utilize culturally relevant approaches to help their children understand U.S. mathematics to negotiate differences in curriculum, cultural artifacts, academic language, and mathematics identities.

Keywords: mathematical processes and practices; equity and justice; culturally relevant pedagogy

Parental Involvement in Education

The importance of parental involvement in children's learning has never been in doubt" (Sénéchal & LeFevre, 2002). This quote emphasizes the positive relationship between parental involvement and their children's learning. Parental involvement in education has three dimensions: involvement at school, involvement at home, and academic socialization (Wang & Sheikh-Khalil, 2014). Among these, home-based involvement happens at home and in local communities such as monitoring schoolwork and progress, supervising homework, setting time or location to do homework, and exploring local places, libraries, or museums. Academic socialization is communication with their children, sharing parental expectations about schoolwork and the importance of education, encouragement of educational goals, and making plans and preparations (Wang & Sheikh-Khalil, 2014).

Parental involvement at home fundamentally influences children's academic success (Jeynes, 2003). Hyde et al. (2006) examined mother and child interactions while working on pre-algebra equivalence problems, such as $3 + 4 + 5 = 3 +$___, and found children understand mathematical concepts better with parental support from home. Not only does it help in understanding concepts, but parental involvement at home also has advantages in shaping identities. According to Vukovic et al. (2013), parents help reduce mathematics anxiety, leading to progress in children's mathematics achievement in higher-order mathematics such as word problems and pre-algebra.

Korean Immigrant Parental Involvement in Education

Asian parents are often described as tiger parents in U.S. media, which presents a monolithic representation of them (Juang et al., 2013). Although there may be commonalities in Asian parenting, parental approaches also vary across subgroups. Specifically, Korean cultural customs, ideas, and lived experiences—such as the devastation of the Korean War leaving the country impoverished for over a generation, living under the North's nuclear threats, and having hostile superpowers close by—surely influence parenting in unique ways. Contrary to the common belief toward Asian parents in general, Kim et al. (2018) found that only 11 percent of Korean immigrant parents in their study provided academic support among the 141 participants. This suggests that a small portion of Korean immigrant parents directly interact with their children's education in the U.S.

Culturally Relevant Practice at Home. Some Korean immigrant parents face difficulties due to a lack of English proficiency when supporting their children's academic progress (E. Kim, 2002), as they are not familiar with the U.S. curriculum and content jargon. For example, in mathematics education, Korean immigrant families encounter differences in the U.S. mathematics curriculum, including cultural, historical, and political contexts, as well as different learning styles, content, mathematical word problems, and so on. However, there has been limited attention given to interactions between Korean-born parents and their American-born children (H. Kim, 2019). To address this gap, the study reported here specifically focuses on how first-generation Korean immigrant parents support their children's mathematical understanding at home by negotiating these differences. The data were collected during the middle of the pandemic in the summer of 2021, a period when such support was particularly salient.

This article employs the theory of *Culturally Relevant Practice* (Ladson-Billings, 1995) as a lens to examine the efforts of parents in negotiating differences and enhancing their children's understanding of U.S. mathematics. The study delves into the interactions of five Korean immigrant parents with elementary-aged children in the 4th, 5th, and 6th grades who are actively involved in their children's mathematics learning at home. Narrative inquiry is utilized to comprehend the diverse experiences of the five participants' families through observations and interview sessions. Due to the literature gap on Korean-American family education in the U.S., this paper specifically focuses on the observational data that highlight Korean families' mathematical interactions. The present article examines these interactions as the key methodology in this analysis. With this in mind, the research question for this study is as follows: *How do first-generation Korean immigrant parents support their elementary-aged children's understanding of mathematics across different cultures, languages, and identities?*

Methods

Narrative inquiry investigates the story itself and subjective experiences (Riessman, 1993), which also include collective narratives among people to discern authentic meaning and value in conversation. The narrative inquiry method aligns well with this study, as it emphasizes the parents and their children's collective narratives to discuss mathematical understanding.

Participants

I recruited five first-generation immigrant families with elementary-aged children via a Korean online community and Korean communities in the U.S. Since this study aims to explore mathematics support at home, participating parents must provide direct mathematics support at home. All participants' names are pseudonyms, chosen by the participants themselves. Except for Seong Chan's family, who stayed for 4 years, the other four families have resided in the U.S. for more than 10 years. Participating children were expected to enter 4th, 5th, and 6th grades, and the data collection period from June to August 2021. Seong Chan was the only father who taught math at home, and his wife Hyeon Ji also occasionally participated in the interview sessions. Participants had varying immigration years, ages, occupations, and numbers of children.

Data Collection and Analysis

The results reported here are derived from observations, which included authentic conversations between Korean immigrant parents and their children regarding mathematical understanding and how to navigate mathematical expressions within two different cultures, languages, and identities. Observation sessions occurred twice, with each session lasting 40 minutes. Follow-up interview sessions lasted about 20 minutes, resulting in a total observation time of 1 hour for each interaction. All sessions were transcribed using the Artificial Intelligence transcribing program, Naver Clova Note (https://clovanote.naver.com/). Each transcript underwent multiple checks, as the technology sometimes did not capture the correct narratives. Additionally, the transcripts were scrutinized for themes that participants highlighted on how to negotiate differences in culture, language, and curriculum. When a person used two languages, Korean and English, I translated the interview verbatim into English to aid the audience of this study. I inserted the translation in italicized fonts for the Korean parts. English-spoken parts were marked with bold fonts to indicate the code-switching from Korean.

Results

Korean immigrant parents and their children jointly 'negotiated' cultures, identities, and language differences in their interactions to enhance their mathematical understanding. Although the parents are not education experts, they endeavored to bridge differences in culture and language. Negotiation is the process by which two or more parties attempt to resolve perceived incompatible goals (Brett, 2000; Carnevale & Pruitt, 1992). Brett (2000) discussed intercultural negotiations involving cultural preferences, norms, priorities, and negotiation strategies. These communicative preferences meet in the middle of a negotiation, dealing with both similarities and differences.

In alignment with Ladson-Billings's culturally relevant practice (1995), I address *cultural negotiation for mathematics understanding*. This negotiation stems from interactions between Korean immigrant parents and their children, where mathematical meaning, concepts, and mathematics identities are jointly explored, revisited, revised, and negotiated in terms of different cultures, languages, and identities. This also provides insight into how immigrant parental involvement either strengthens or impedes children's learning when navigating various cultural, national, and generational differences during the learning process. Parents' immigration with changed social location influences their children, exposing them to two languages at home. If immigrant parents attempt to teach academic skills to their children, their learned curriculums would differ due to generational gaps and diverse cultural backgrounds. However, all participating parents made efforts to connect their learned curriculum with their children's U.S. mathematical concepts. Table 2 presents themes reflecting the differences parents observed and the ways they engaged in cultural negotiations to address disparities in curriculum, artifacts, academic language, and identities.

Table 2: Cultural Negotiation for Differences in Mathematics Understanding

Differences	Cultural Negotiation
Curriculum	Curriculum differences in Korea and the U.S.
Artifacts	Culturally relevant revision
Academic language	Cultural negotiation in language differences
Math identities	Sharing expectations

Discussion

This study explored how Korean immigrant parents support their elementary-aged children's mathematical interactions at home by addressing differences. In alignment with Ladson-Billings's culturally relevant practice (1995), I address *cultural negotiation for mathematics understanding* based on observations of Korean immigrant parental involvement in four ways: negotiation in curriculum, artifacts, languages, and identities during mathematical interactions. While not experts in culturally relevant pedagogy, they provided cultural revisions to enhance their children's mathematical understanding. Parents sought to connect their learned curriculum with the U.S. curriculum and endeavored to revise unfamiliar cultural terms (Ladson-Billings, 1995) in word problems to help their children grasp the mathematical meaning. Regarding languages, when a child made an error using a Korean expression, parents explained the U.S. way. For instance, when a child said, 'Twelfth One,' the parent corrected him by saying, 'One Twelfth.' Beyond fostering understanding, parents also shared their mathematics identities and values in problem-solving to yearn for children's academic success. Interestingly, their emphasis on the use of mental math varied, challenging common myths about Asian parents as a homogeneous population.

Although some Asians have been perceived as model minorities inherently good at mathematics, findings reveal that Korean immigrant parents and their children's narratives still need support in language and cultural differences in their mathematics schoolwork. This study uncovers Korean immigrant parents and their children putting effort into understanding U.S. mathematics, a challenging task. It is a winding road that must navigate many challenges, including cultural differences in mathematics terms and meaning, as well as the interweaving of parents' and children's mathematics curricula. This implies educators need to invite all students, regardless of immigrant backgrounds, cultures, identities, or linguistic assets. Furthermore, educators should conduct more professional development sessions to better understand students' backgrounds and incorporate them into their lessons. They should also invite parents to share their family narratives and culture.

Limitation

One limitation of this study is that it includes only narratives from five families. The observation data, along with my interpretation, may not be a direct representation. However, the follow-up interview session somehow covers the reasoning behind participating parents' approaches.

Conclusion

This study specifically uncovers Korean immigrant parents and their children's cultural negotiation to build mathematical meaning at home during the COVID-19 pandemic. It illustrates that language and culture are interrelated, influencing conceptual differences in mathematics. Immigrant families put in extra effort to understand U.S. mathematics. The study delves into Korean immigrant parents' and children's mathematical interactions, revealing their additional efforts. Future research is needed to understand how Korean immigrant students negotiate mathematical meaning in their classrooms.

THEORIZING REFUGEE YOUTHS MATHEMATICAL IDENTITIES AND EXPERIENCES: A CALL FOR ASSET-BASED PEDAGOGY FOR EQUITABLE MATHEMATICS INSTRUCTION

Emmanuel Chukwuebuka Umeh
University of Missouri, Columbia.
ecung6@missouri.edu

Keywords: Refugee youth, Urban and Rural Refugee, Mathematical experiences, Identity, Equitable mathematics instruction

This poster explores high school refugee students' mathematics learning experiences and identities using the Math-trivium framework (Umeh, 2023) and calls for support for Central Missouri high school teachers in adapting to asset-based pedagogical practices in mathematics to meet the academic needs of refugee youth. Central Missouri schools are seeing an increase in refugee students. The most recent available data shows that the percentage of Multilingual learners more than doubled (from 3.41% to 6.99% between 2009 and 2022 in Columbia Public Schools (CPS) (DESE, 2022), and the Democratic Republic of Congo, Afghanistan, Eritrea, Syria, Burma, and Sudan are the most common countries of nationality (RPC, 2023). While schools are expected to facilitate the reintegration of refugee youths into a new academic and social culture, they often lack the readiness to address these students' specific learning needs and identities (Hos, 2016). Thus, there is a need to provide adequate support for high school teachers to understand the refugee experiences and identity as assets for equitable mathematics instruction.

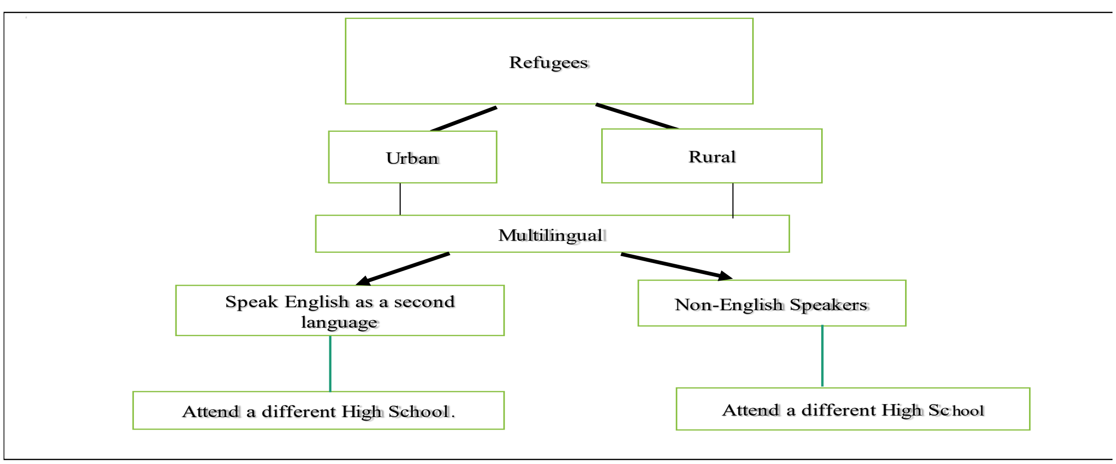

Figure 1: Shows an Identity Map of Refugee Youth.

Therefore, this poster explores the mathematical identities of refugee youth within the context of urban and rural refugees living in Central Missouri, United States of America. Although they have the same refugee status, their mathematics identities and experiences differ.

There is a need to prepare globally competent high school refugee teachers and mathematics teacher educators for more equitable mathematics instruction for refugee youths.

Acknowledgments

My sincere gratitude goes to the faculty members of the University of Missouri Columbia mathematics education program. It has been an honor to learn from their experience and expertise.

IDENTIFYING STORYLINES WITH INDIGENOUS AND NEWLY MIGRATED MATHEMATICS STUDENTS

David Wagner
University of New Brunswick
dwagner@unb.ca

Sacha Dewolfe
Mount Allison University
sdewolfe@mta.ca

In this methodological paper, we describe our approach to engaging middle school students in identifying storylines at work in their experiences of mathematics learning. Storylines are an important part of the theorization of positioning but they are underexplored. Our focus is on students who identify (or are identified) with groups that have often been marginalized, namely Indigenous students and students who are newly arrived migrants. It was important for us to garner the trust and also the interest of students while guiding them to conceptualize storylines so that they are the ones identifying the storylines that impact their experiences. In the presentation we will share more data.

Keywords: Equity, Inclusion, and Diversity; First Nations and Indigenous Cultures

Student experiences of mathematics learning have been investigated using the theorization of *positioning*. Indeed, it is important for educators to understand how students understand themselves as learners and how they understand their actions. Students are positioned by teachers, classmates, media, community, organizations, language constructs, and families, through current and historical practices. We are particularly interested in the positioning of students who identify (or are identified) with groups that have often been marginalized, namely Indigenous students and students who are newly arrived migrants.

A focus on storylines

Most research using theories of positioning focuses on the positioning (e.g., Drageset, 2024, Sengupta-Irving, 2021; Tait-McCutcheon & Loveridge, 2016). However, the tradition referred to as positioning theory sees a triad at work in human interaction, including the three elements of positioning, storyline and speech/communication act (e.g., Harré, 2012; Herbel-Eisenmann, 2015). A storyline is a story known to a participants in an interaction. The people in the interaction are associated with positions in the story, which guides the people's choices about how to interact. Storylines are important because they provide the repertoires for action for mathematics students. The storylines available (known) to students and their teachers make certain positions possible, and they exclude other positions from possibility.

As far as we know, the research that focuses on storylines in mathematics education research investigates common stories that appear in public discourse (e.g., Andersson et al., 2022; Chorney et al., 2016; Herbel-Eisenmann et al., 2016; Rodney et al., 2016)—namely news and entertainment media. In our research project we work with Indigenous and new migrant students and aim to identify the storylines at work in their mathematics learning environments. In this paper, we describe how we have gone about doing this, noting the principles we embrace, the challenges we experience, and results of our choices. This is a methodological paper.

We do not yet have detailed data sufficient to share in this paper, but we expect to have data to share for the conference. In this paper we describe our methodological choices and how they manifest in our interactions with participants. The research aim is to identify storylines, animated with accounts of student experiences. We will next share these with teachers and work with them to develop alternative pedagogies that build on student strengths and experiences. (We have some detailed data already including accounts of student experiences, but to honour our anonymity promises, we cannot yet publish any of the accounts of experiences because that would make it possible for some people to identify the students who told us of their experiences.)

First context: Conversations with Indigenous students

Our research project is situated on the traditional unceded and unsurrendered territory of Wolastoqiyik and Mi'kmaq peoples (often marked on maps as part of eastern Canada). Since colonization, the majority of people living here have been settlers, and there has been a recent surge in settlement with the general upswing in global human migration. Given the history of terrible experiences at the hands of settler people and colonizing institutions, it takes time and care to develop a relationship of trust with Indigenous students.

In the first context of our research project, Dave (the first author) worked with a teacher who, for more than a decade, has worked as a support teacher for the Indigenous students from a local Wolastoqiyik community. We note that this teacher's endorsement and collaboration accelerated the students' willingness to speak openly about their experiences (i.e., to trust). In other words, trust can be shared, to some extent, from an already trusted person. Of course, the teacher was willing to endorse and collaborate with us based on our past interactions (also a development of trust). We also drew on the teachers' knowledge of the students to decide on an approach to interaction, and thus decided to work for some time with a group of students (about 8 middle school students) in a series of six biweekly one-hour meetings. The group felt safe when they were all together, so dividing them up probably would have undermined that sense.

In the first interaction Dave briefly described to the students what we hoped for in the research, and taught the students a game he learned from a Mi'kmaq student in a previous research project. The game play would develop relationship, and the Indigenous source of the game showed students that Dave had interacted with other Indigenous students before, attentive to their cultural heritage. Once we started the interactions focused on identifying storylines, we needed to find a way for students to understand the concept of storyline. How to do that was not straightforward, given that Dave and others in a sister research project (with some of the same research team members, also with a similar focus on storylines associated with Indigenous and newly migrated students, but in Norway) have been finding it challenging how to describe a storyline, as discussed in Simensen et al. (2022). The theory work on positioning has not been very helpful, and the paucity and inconsistency of examples of identified storylines in research has led to questions about how to describe storylines and how to name them. Should they be full sentences? Can they be described with a few words like a theme? Those questions persist.

In the interactions, the approach that we settled into as productive (in terms of garnering quantity and quality sharing from the students) had Dave asking what has happened recently in math class or relating to the math they did in math class. After a student identified something that happened, then Dave probed with questions about what is "really happening" when things like that happen. Using the triad of positioning theorization, the happening is a communication act or a series of communication acts, and the description of what is really happening is the storyline. We discussed questions like "Why would [the person] do that?" Dave probed for other similar experiences. It was very productive to compare the happening to parallel happenings outside of school math. For example, when students talked about feelings of success or failure it was helpful to consider feelings of success or failure in other contexts—which tended to be sports contexts, probably because of the passions of the most readily vocal among the students. Or, when talking about feelings within interactions with people in math class, it was productive to consider how that was different from interactions among friends.

After this series of group conversations, the next step was for us to synthesize the stories and dialogue over the hours of interaction and bring them back to the students. The teacher arranged for each student to meet Dave individually, but it was hard to decide how to conduct those interviews. After Sacha and Dave discussed the deep knowledge emerging from the recorded interactions, Dave synthesized the foci with the following storylines:

1. We have to try hard to learn math.
2. Teachers respond to students differently based on the students' reputations.
3. Math is important.
4. The math we do in school is not interesting.
5. We are more worried about failure than attracted by success in math.
6. How I feel about my math performance depends on my expectations for myself.
7. Math teachers don't understand native people [i.e., Indigenous people].
8. Math should be done in silence.
9. Something about parents… <not sure what>

In the interviews with individual students Dave told them he made a list of storylines from the conversations we had had. He said he would read them one at a time, and ask for example stories that illustrate those storylines. For #9 he said that there was a lot of talk about parents but he could not identify a storyline succinctly. He asked each student if they could say what the storyline might be. The fourth of the students (the most shy among them) provided a storyline: "Parents expect you to do well." After this, Dave replaced #9 with the student-provided storyline. Also with the first few students it became clear that #5 and #6 were not like the others. Students said they were not sure about them. Emerging from those conversations, Dave learned that it was helpful to ask them if they thought the statement is true, or if they thought the statement is something people say or think. For #5 and #6 almost all the students said the statements were true (not surprisingly: these emerged from our earlier interactions) but that they were not statements that people think or say. Thus, we see that they are not storylines: they are not known stories. This reminds us that storylines do not have to be true to be well known. And their power is independent of their truth. The students provided rich accounts of the storylines, some of them repeated from earlier interactions. We look forward to reporting on the storylines illustrated by particular experiences. As noted, to protect anonymity we cannot do this yet.

Following the principle of OCAP (ownership, control, access, possession), "First Nations have control over data collection processes, (…) they own and control how this information can be used" (https://fnigc.ca/ocap-training/). Thus, for the learning from our interaction with the Wolastoqiyik students, they themselves and their community are the most important people to report to. Sacha (the second author) identified a knowledge keeper (a.k.a., Elder) from the students' community as a person to report to first, and the teacher endorsed this choice. Dave spent a couple hours with the knowledge keeper to report on what happened thus far in the research conversations, including the specific storylines discussed most recently in individual interviews. Dave did not tell the knowledge keeper about the experiences shared by students, but the knowledge keeper already knew the general nature of those experiences (knowledge keepers know things!). We invited the knowledge keeper to join the next gathering of the student research group. The knowledge keeper told the students of their own experiences as a student and as an adult dealing with Indigenous and settler peers and with "authorities". The students asked questions and told the knowledge keeper about some of their experiences in and related to school. That interaction reinforced our prediction—people tell different stories depending on whom they interact with. Dave closed by asking the students if they wanted to be kept in the loop—to be kept informed and to be given the opportunity to guide the future steps with the knowledge they generated and shared in our conversations. They said yes.

Second context: Conversations with new migrant students

The conversations with the Wolastoqiyik students informed our approach to newly migrated students. Again, the first challenge with addressing these students is garnering their interest and trust, but we did not have the benefit of the same kind of teacher ally with longstanding relationships because the students are newcomers. We also know that many newcomers are highly cautious about what they say about their experiences of migration because they are in the process of qualifying for residency status. Many of them come from situations that prompt them to be extremely careful of their information getting into the wrong hands.

Dave and a graduate student met with some classes to tell them about the research and invite participation in interviews. He said that we are interested in interviewing any students but especially interested in the experiences of newcomers. In the first session, he used the approach he had used with the Wolastoqiyik students—asking for examples of things that happen in math class, and following up with questions about what is really happening when these things happen—but the students seemed bewildered by this. The dynamics of being in a larger group of people and also some linguistic barriers probably impacted their ability to focus on questions that are unlike the questions they are accustomed to in school. For the subsequent groups, Dave switched to an approach informed by the interviews with the individual Wolastoqiyik students.

Dave said he would read some statements, and ask students to say if the statement is true, and then to say if they think others think the statement is true. He said that the interviews would go like this, but in the interviews the interviewer would also ask for examples of things that happen because of people thinking the given statement is true. He said that the interviewer would then go vice versa, and ask for accounts of things the students particularly liked or disliked in math learning. With the story of the liked or disliked thing, the student with the help of the interviewer would try to figure out what statements (storylines) people believed in order to get them to do the thing they were doing in that situation.

For this set of storylines, Dave mixed together some storylines from the Wolastoqiyik students and from the research contexts in the sister project described above. So, Dave would say, for example, "When I do math, I need to use my first language" (i.e., a version of a storyline from the sister project) and ask students to put up their hands if they thought it was true (fewer than half of the students said it was true). And then to put up their hands if they thought some people think it is true (almost all the students thought that some people think it is true). The students were laser focused on these questions, locking eyes with Dave in a way he has not experienced in a classroom before. The struggle to decide whether to put their hands up or not was evident on students' faces (even students who have been in Canada less than a month). In other words, the students were invested in these storylines. The students recognized importance of these storylines—the impact of these storylines on their experience of mathematics learning.

Acknowledgments

This research was supported by the Social Sciences and Humanities Research Council of Canada, as part of a grant entitled "Migration and Indigenous contexts of Mathematics Education (MIME): Changing storylines with strength-based pedagogies" (Principal Investigator: David Wagner).

This report presents a case study of one teacher's impactful implementation of a culturally affirming pre-calculus task, "Being Hispanic: Heritage or Self-Perception?" We observed a sustained engagement by the students and the teacher with the mathematics and the social context within the task. Through an analysis of the classroom discussions and the teacher's reflection on the lesson, we identified a new critical consciousness resource (CCR) called criticality of racialized labels. Our findings highlight the moments and ways in which this CCR was activated. We propose that synergy of the teacher's own resources and excellence, the culturally affirming curriculum, and an anti-deficit math workshop setting contribute to critically conscious engagement with mathematics. Such engagement promotes meaningful experiences for students and teachers thus supporting a more just and equitable mathematics education.

Keywords: Equity, Diversity, and Inclusion; Curriculum; Culturally Relevant Pedagogy; Precalculus

The question of what is meaningful to teachers and students while engaging with people and curriculum in mathematics classrooms is valuable for unpacking what the future of mathematics classrooms looks like. As culturally relevant (Ladson-Billings, 1995), responsive (Aguirre & Zavala, 2013), and affirming (Lozano, 2023) mathematics teaching practices continues to be a sought-after approach to creating more meaningful experiences for all students, in particular traditionally minoritized students, there is a need for growing our understanding of *why* and *how* these practices make an impact in the lives of students and teachers.

In this case study, we describe how critically conscious engagement with mathematics emerged and was sustained by a college instructor, Sarah, (Author 4), at a large public Hispanic Serving Institution (HSI) in the Southwestern U.S. By illustrating what the classroom experience was and how it impacted Sarah and possibly her students, we elucidate specific factors that contribute to shaping the critically conscious engagement in the classroom, and afterwards.

Our analysis centers around one Culturally Affirming (CulturA; Lozano, 2023) precalculus task implemented by Sarah during a weeklong summer bridge program. We analyze how the mathematics and the context of the "Being Hispanic: Heritage or Self-Perception?" (*Being Hispanic*) task, as well as its setting and implementation contributed to the emergence of critically conscious engagement. This window into a Culturally Affirming (CulturA; Lozano, 2023) mathematics classroom serves as a possible model for intentionally co-creating with students critically conscious mathematics learning experiences that transcend the walls of the classroom and the moments when a lesson was enacted.

Prior studies identified opportunities and challenges linked to implementations of mathematics curriculum promoting critically conscious mathematics engagement. Some prior work acknowledges potential “pitfalls” (Harper, 2019) in implementing Teaching Mathematics for Social Justice (TMSJ) curriculum (e.g., Bartell, 2013; Brantlinger, 2013). Others (e.g., Gutstein, 2016; 2003) portray the “promise” (Harper, 2019) of these curricula by highlighting how students were able to see themselves in the curriculum and use it to “read and write the world with mathematics” (Gutstein, 2003). These studies provide a starting point for our discussion of what an impactful implementation of CulturA curriculum entails, by identifying some key contributing factors arising in this implementation of the Being Hispanic task.

The purpose of this paper is to offer a proof-of-concept for how an impactful implementation of a culturally responsive mathematics curriculum can support the co-creation of critically conscious engagement by valuing, eliciting, and building upon students’ voices. This study also contributes to understanding the role curricula like CulturA can play in activating specific critical consciousness resources (CCRs; Witt, Lozano & Anhalt, in press), and the role these can have both within and beyond the classroom. We focus our investigation on the question: *How might a culturally responsive mathematics task engage students and teachers’ critical consciousness?*

Frameworks

CulturA

The task featured in this study was created through Project (blind for review) along with over 80 others designed to enhance relatability and connection through robust, authentic mathematics in the core precalculus curriculum (Lozano, 2023). We operationalize culturally responsive mathematics teaching (CRMT; del Rosario Zavala & Aguirre, 2023) through the implementation of CulturA curriculum. CulturA is a place-based, affirming curriculum mirroring the identities and strengths of the local area by, “…center[ing] cultures, peoples, and identities traditionally absent from standard curricular content, keeping an asset-based lens” (Lozano, 2023) and thus embodies the three strands of CRMT described by del Rosario Zavala and Aguirre (2023). By design, CulturA aims to center knowledges and identities through its tenet of affirming identity and strengths. It also promotes rigor and support by being authentic while also being mathematically robust. Finally, in being place-based, CulturA makes space for leveraging local students’ everyday experiences to enable power and participation.

Critical Consciousness Resources and Critically Conscious Engagement

Developing critical consciousness (CC) with students is one of the three core components of culturally relevant pedagogy (Ladson-Billings, 1995). This goal is vitally important to equipping future generations with the agency to initiate change in their lives and their communities, also in addition to its being associated with various positive well-being outcomes (Jemal, 2017). In this study, we take the perspective that ideas abstracted from our experiences, identities and backgrounds (see also Jemal, 2017; Watts, Diemer, & Voight, 2011; Freire, 1970) inform whether and how people critically engage in affecting change in the world around them. We define *critical consciousness resources* (CCR), “ideas that elevate a person’s awareness or sense of agency to ‘engage the world and others critically’ (Ladson-Billings, 1995, p. 162)” (Witt, Lozano, & Anhalt, in press). We are interested in moments when these CCRs are made public, collectively shaped, and possibly transformed. We describe these moments as critically conscious engagement in mathematics which can lead to increased awareness and agency in social issues. In general, the activation of CCRs stems from perceiving affordances and constraints of present situations (e.g., within CulturA tasks) that may relate to sociopolitical contexts. Over 10 different CCRs were identified previously, and Witt, Lozano, and Anhalt (in press) documented nine prospective mathematics teachers eliciting these resources while engaging with the CulturA curriculum. We hypothesized that investigating CCRs can reveal teachers' strengths and shape the student experience in specific ways. The present study identifies and examines one new CCR, critically of racialized labels, activated through engagement in the Being Hispanic task.

Methods

Data Context and Sources

The data from this study comes from a professional development project for university instructors with a focus on developing anti-deficit teaching with minoritized students (Adiredja, Civil, & Jarnutowski, 2024). One component of this project is a weeklong summer bridge program for local high school students in the Southwest U.S. to transition into the local university. Also inspired by Ladson-Billing's (1995) notion of culturally relevant pedagogy, students' voice and inquiry become the focus in the teaching as participants also engage in critical conversations about race, gender and mathematics.

Sarah was an instructor participant in the project and implemented five CulturA tasks in her pre-calculus section. She had six students in the section, all of whom identified as Hispanic. In the classroom, the teacher sat shoulder to shoulder in a circle with students, at times holding a portable whiteboard to write down and share ideas that were raised during the discussion. Students had on average 5-10 minutes to work on a task, then she would ask students for their thoughts and possible solutions or strategies.

Sarah voluntarily brought up the Being Hispanic task in a debrief discussion with Authors 2 and 3 as "the most interesting because [she] kept thinking about it." Figure 1 shows the entire task, but the first three of the seven questions are most relevant to this study. Her classroom implementation and a debrief/reflection interview occurred two weeks afterwards were video recorded. The transcripts for these two recordings are the main two data sources for this paper.

Being Hispanic: Heritage or Self-Perception?

People living the in United States (US) who acknowledge having Hispanic heritage may or may not self-identify as Hispanic. According to 2017 survey[2], the percentage of US adults with Hispanic heritage who self-identify as Hispanic, H, can be thought of as a function, f, of generation, g, where $g = 1$ means being "first-generation Hispanic," or being born in a Hispanic country, $g = 2$ means being "second generation Hispanic," or having parents who were foreign-born, and so on.

(a) What does the expression $f(3) = 77$ mean in every day terms?

(b) According to survey data, $f(1) > f(2)$. What does this expression tell us in everyday terms?

(c) Suppose f is an increasing function of generation. What would this mean in every day terms? What would it mean for f to be a decreasing function of generation? Do you expect f to be increasing, decreasing, or neither? Explain.

(d) Given the context of this problem, which of the following could be the domain of f? Identify all possible answers and explain.

(I) $[1, 4]$ **(II)** $[0, 10]$ **(III)** $\{1, 2, 3, 4, 5\}$

(IV) $[0, \infty)$ **(V)** $\{0, 1, 2, 3, 4\}$

(e) Tables 1 and 2 are based on survey data. One table shows values of f. The other shows the percentage of US adults with Hispanic heritage who self-identify as non-Hispanic, N, as a function of g. Which table is which? Identify each by filling in the name of the dependent variable.

g	1	2	3	4
	3	8	23	50

Table 1

g	1	2	3	4
	97	92	77	50

Table 2

(f) The function represented in Table 1 increases at an increasing rate. Why is this true? What does this mean in terms of generations and Hispanic self-perception?

Figure 1. "Being Hispanic: Heritage or Self-Perception?" [reprinted with permission from Lozano et al. 2021]

Analytic Approach

We began our analysis by identifying instances when the teacher (Sarah) identified with the task from the curriculum, or what we call "I-statements" (e.g., "I keep thinking about [the task]"). This approach was similar to that of Witt et al. (in press) but was adapted to better suit the nature of our current data sources. We coded for this type of statement (I statements) and parsed out those statements as they are related to issues of identity, power, access, and achievement (see also Gutierrez, 2009) and relative to the perceived level of agentic disposition they convey. These statements can offer insights into ways that teachers are provoked by or intrigued by the issues raised in the task, whether it is mathematically or socio-politically. In the current paper, this pointed us to the Sarah's implementation of the Being Hispanic task.

We then conducted a thematic analysis (Braun & Clarke, 2006) to identify sociopolitical theme(s) that were raised during the class and interview discussions. We examine the extent that these themes coalesced into a critical consciousness resource. We then returned to the full transcript of the recordings to identify times when this CCR was activated during the classroom implementation and reflection. We situated these moments in context to better understand what may have prompted these ideas to emerge. For more details about how to identify CCRs and their associated contexts see Witt et al (in press).

Findings

Criticality of Racialized Labels

The Being Hispanic task offered an opportunity for Sarah and the students to draw from their personal experience to make sense of the mathematics in the task and prompted a rich discussion about heritage. Our analysis revealed a broader theme related to the students and the teacher questioning, describing, and contrasting racial and ethnic identities. For example, one of the students, José, after realizing that the graph of f was decreasing in the task, questioned what people would identify as if they identified less with Hispanic. This moment in class also led to Sarah discussing the differences between Latina, Chicana, and Hispanic that came up when talking to a friend. We identify this broader theme as a critical consciousness resource called criticality of racialized labels.

This new CCR, criticality of racialized labels, was made explicit in the transcripts in five key moments across two interactional contexts (during Sarah's reflection interview and during Sarah's classroom implementation of the Being Hispanic Task). Three moments occurred during her interview reflection and two during implementation of the task. After sharing the details of these moments, we summarize the ways by which the CCR was activated as a way to operationalize critically conscious engagement.

Criticality of Racialized Labels in Sarah's Reflection

Moment 1. In the quote below, Sarah is recalling how José's question expanded the classroom discussion into one about how a decrease in people self-identifying as Hispanic suggests an assimilation of Hispanic identities occurring as generations go on.

> "I'm really trying to quote [José] as best as I can, [paraphrasing José]'but then you're correlating an ethnic identity, and replacing it with a nat–, like a country identity, which are not the same thing…what is then an American identity? Because it's not ethnic, but if it's not ethnic, is it kind of secretly white—in its ethnicity? And are you just kind of all melting into whiteness?'"

Moment 2. Seconds later Sarah described how her conversations in class became prominent in her conversations with friends. She continues,

> "....a friend was reading poetry by a leading Hispanic author, maybe poet?…[the author] identifies as Latina, or Chicana but not Hispanic, because it's the word that the community didn't make and I had never heard that before. So I keep having conversations as a result of that–what my students said, which was so, man, it was really cool."

Moment 3. Approximately 15 minutes later, Sarah was asked how she felt navigating sensitive topics with her students. She states,

> "…It was intimidating in the best way possible…seeing his–the gears turning and also the disappoint–like the sadness in his face of what it would mean then to lose cultural identity in

favor of white culture...I was like, Oh, this is a lot of feelings in this group. But also man, you said something really profound."

These moments show how this new CCR was evident when she recalled her students' words (Moment 1), when she describes how the conversation extended into her personal life (Moment 2), and when she reflected on how she felt about facilitating this conversation (Moment 3).

Criticality of Racialized Labels in Sarah's Implementation

Moment 4. During her implementation, as Author 4 and her students collectively interpreted what the Being Hispanic task must mean in everyday terms and the following exchanges took place.

> "Sarah (S): So, do we think it's going to be increasing or decreasing? What do you say?
> [inaudible from student]
> S: Well, no, in general, do you think people will [inaudible], generation-wise get away from it, the more or less you identify as Hispanic?"
> [multiple students respond, some say "More", some say "Less"]
> S: I don't know, it's it's completely subjective, what do you think?
> Student: Well, from (b), [inaudible] it's already less,
> S: Somebody picked up on context clues! So yeah, would that be a decreasing or increasing function?
> Student: Decreasing.
> S: Decreasing. So the further you get away, you identify less?
> [nods from students]
> José(J): [inaudible] Then what do you identify more as?
> S: What if you identify more?
> J: Well, what replaces it?
> S: Yeah! Yeah, what *do* you identify more as then?
> Student: American
> J: How does a genealogical background get replaced by a national [background]?
> S: Yeah, that's a really good question my friend.
> Student: What did he ask?
> J: So like Hispanic is like genealogical, [inaudible] but national is like a country?
> S: So an ethnic root versus a country identity. Well yeah, and then you also wonder at what point do you also lose track of your family as to what the heck the history of it was. How many generations does it take to be like, 'I don't know anymore!'"

This exchange initiated a broader discussion where other racial identities were discussed. José continued, *"But then like my question is, is the default that when you lose [said identity], you just become white?"*

Moment 5. Sarah then extended the conversation to how "hyphenated" identities (e.g., Mexican-American, Italian-American, African-American, etc.) may change over time and made a connection to what she knows regarding the term "Black."

> "Yeah, why is the default just white? I mean no one's ever asked me where I'm really from…despite the fact that my mom is-I'm actually first gen on one side, but no one's asked

> and you're very right, because I am white and so people won't ask…No one would call me English-American, I've never heard of one. But also, what happens with an African-American? … from what I've read and what I've been told, is they're reclaiming the word Black because, it does describe the answer that, you don't know, because you couldn't know because it was taken from you…"

These moments showcase how this CCR was initiated by José's engagement with the task (Moment 4) and as a result an opportunity for critically conscious engagement occurred in students and the teacher. These episodes also show how Sarah's affirming disposition and actions in the classroom allowed for her to inform her students of related ways in which racialized labels are critiqued (Moment 5).

Discussion

We argue that an impactful implementation of the CulturA task, Being Hispanic, supported the emergence of critically conscious engagement centered around the CCR, *criticality of racialized labels*. This engagement was initiated by a student, José, noticing and questioning the implications of what it means for self-identification as Hispanic to be a decreasing function of generation (see Figure 1). This prompts him to wonder whether this implies that people who are choosing to adopt a national identity, such as American, are then trending towards "becoming white." This supports a theme in Harper's (2019) qualitative metasynthesis of TMSJ research highlighting,

> "Four cases (Aguirre et al., 2013; Bartell, 2013; Turner & Font Strawhun, 2013; Turner et al., 2009) provided evidence that the students themselves focused on race and racism in relation to the social justice topic without direct prompting from the teacher…" (p. 286).

This is impactful because race and racism have the potential to emerge in many mathematics tasks coming from authentic contexts (e.g., Gutstein, 2003; Lozano 2023; Turner et al., 2022) and the ability to navigate these conversations in a safe and affirming way presents the potential for stronger relationships with students.

José's wondering and Sarah affirming his perspective enabled him to share with the rest of the class some of his background knowledge on the nuances between national and "genealogical" identities. This conversation appears to have been meaningful to Sarah in such a way that she felt comfortable discussing this idea with friends who then informed her more about the nuances between Hispanic, Latina, and Chicana identities. Thus, the critical consciousness engagement we describe extended through the walls of the classroom and instilled a sense of *critical awareness and agency* (Witt et al., in press) with respect to criticality of racialized labels.

When Sarah describes the conversation as, "intimidating in the best way possible," and "really cool" José's words as "poignant" and "profound," one could argue that the critically conscious engagement may have been supported by an *anti-deficit perspective* (Adiredja, 2019) that she embodies and is in accordance with CulturA's *affirming of identity and strengths* tenet (Lozano, 2023). This is evident in the way she frames the interaction in a positive light, focusing on student strengths and the value of this discussion. By acknowledging the care that one needs to take navigating conversations about race and ethnicity and the value of José's voice, Sarah is bringing an awareness of the sociopolitical context of mathematics spaces inhabited by historically minoritized students (Gutiérrez, 2013). In addition to this awareness, one could argue that critically conscious engagement afforded the opportunity for emotional connections to be made between the teacher and students which is a key aim of the curriculum.

Many might argue that our intuition leads us to believe that teaching can "feed one's soul." Teachers often reflect on how they learn just as much from their students as their students learn from them, but additionally in this case, we see how the CulturA curriculum coupled with the professional development setting accentuated the teacher's strengths as an affirming person, allowing her to leverage student thinking to co-construct an impactful space for learning. This was impactful to Sarah's self-reported learning about the nuances of Hispanic identities but also potentially impactful to her students who were encouraged to critically interpret the implications of the mathematics in the task. This vision for an experience that encourages an introspection that grows from thinking critically about mathematics is one that may be critically important for building positive dispositions towards one's mathematical and racial identity.

Our initial examination of this experience yielded *criticality of racialized labels*, being a salient theme in the teacher's experience. Extensions of this work may more carefully examine how this work may connect with other established framings of equity in mathematics education (e.g., Aguire, Mayfield-Ingram, and Martin; 2024). Given the prominence of Hispanic identity in the task and analysis above, future work may benefit from making stronger connections to a LatCrit framing (e.g., Rolón-Dow & Davison, 2021; Solórzano & Yosso, 2001). This case may be analyzed trough a *microaffirmations* (Rolón-Dow & Davison, 2021) lens or considered a counter-story (Solórzano & Yosso, 2001) to narratives regarding the lack of enthusiasm that marginalized students may experience when engaging with critical mathematics curriculum (e.g., Brantlinger, 2013).

Conclusion

Given the potential "pitfalls" (Harper, 2019) of teaching a critically conscious mathematics curriculum (e.g., Bartell, 2013; Brantlinger, 2013), we present this implementation of the CulturA task as a counter story to those that have encountered issues such as: problematic negotiation of mathematics and social justice goals (Bartell, 2013), and resistance from students in having racial and political discussions in class (Brantlinger, 2013). We presented how engagement with CulturA curriculum, the affirming implementation of it, and the flexible setting, served as resources for a new CCR to be activated and thus critically conscious engagement. Further examinations into similar curricula, settings, and implementations may center the critical potential of other mathematics tasks and the role that professional development fostering an anti-deficit perspective plays in supporting the development of personal connections between teachers, students, mathematics, and their lives.

HIDDEN STORIES: USING NARRATIVE INQUIRY TO INVESTIGATE THE EXPERIENCES OF WOMEN IN INQUIRY-BASED, PROOF-BASED COURSES

Elizabeth Wrightsman
Texas State University
ewrightsman@txstate.edu

Keywords: Research Methods, Gender, Undergraduate Education, Equity, Inclusion, and Diversity

While there is evidence to suggest that inquiry-based instruction leads to positive student outcomes (Freeman et al., 2014; Laursen et al., 2014), there have been several studies that state otherwise (Johnson et al., 2020; Reinholz et al., 2022). Thus, inquiry learning does not guarantee equitable student outcomes. Therefore, it is critical to identify the classroom conditions and aspects of inquiry that can impede or bolster equitable outcomes. Thus far, much of the research on student outcomes in inquiry classrooms focuses on achievement results (e.g., grades) or survey-based affective measures rather than students' lived experiences (Melhuish et al., 2022). Therefore, it is imperative to ascertain methods for delving deeper into the human experience within inquiry courses.

Purpose & Methodological Perspective

This poster demonstrates how narrative inquiry can help illuminate women's experiences in inquiry-based courses. Understanding women's experiences may reveal conditions and factors that detract from or support equitable outcomes. I answer the research question: *How might narrative inquiry provide insight into women's experiences in an inquiry-based, proof-based course?* Narrative inquiry has been gaining popularity within mathematics education research. Much of the mathematics education research incorporating narrative inquiry involves accentuating racialized, gendered, or religious identities (Allaire, 2018; McGee, 2011), possibly in hopes of revealing the stories of those whose voices generally go unheard. Narrative inquiry is a qualitative research methodology that focuses on studying and understanding the lived experiences of participants through the analysis of narratives or stories (Clandinin & Connelly, 2004). These narratives provide rich data that reveal how individuals perceive and make sense of their experiences, identities, and the social and cultural contexts in which they are situated. Hence, I employ narrative inquiry to gain insight into women's experiences in inquiry-based, proof-based courses.

Study Context

The participants are four undergraduate women across two inquiry-based proof-based courses taught in Fall 2023 and Spring 2024. Data collected includes two student interviews and weekly journal submissions. Additionally, weekly classroom observations were conducted to witness the classroom climate and assess the nature of the inquiry implemented.

Results

The four female participants' narratives varied considerably, yet each elucidated their experiences in their inquiry-based, proof-based course. Therefore, narrative inquiry is an appropriate methodology to answer the call by many (e.g., Adiredja, 2017) for additional research on equity issues in undergraduate education, particularly investigating perceptions of their inquiry learning experiences beyond survey results and achievement outcomes.

PLACE MATTERS: MAPPING CONSEQUENTIAL GEOGRAPHIES THROUGH PLACE INQUIRY AND SPATIAL METHODS IN BILINGUAL MATHEMATICS EDUCATION

Cathery Yeh	Lauren Rigby	Frances Lopez
University of Texas at Austin	University of Texas at Austin	University of Texas at Austin
Cathery.yeh@utexas.edu	laurenrigby@utexas.edu	mary.frances.lopez@utexas.edu

The spaces we inhabit provide the context in which we learn about ourselves and make sense of who we are; they shape our identities, our relationship with others, and our perspectives of the world. We introduce Mathematics Education Journey Mapping as a critical methodology to center teachers as co-designers in the educational design and research process. We first provide a socio-spatial analysis to mathematics education. Next, we introduce mathematics education journey mapping, a critical qualitative method adapted from Annamma's (2018) Education Journey Mapping. Finally, we analyze Mathematics Education Journey Maps from ten bilingual mathematics educators to highlight the "geography of opportunity" (Butler & Sinclair, 2020) within the context of language, mathematics, and identities and the physical and ideological sites of resistance that bilingual teachers and communities inhabit.

Keywords: Elementary School Education; Equity, Inclusion, and Diversity; Professional Development.

Introduction

The spaces we inhabit play an intricate part in our life experiences. They provide the context in which we learn about ourselves and make sense of who we are; they shape our identities, our relationship with others, and our perspectives of the world (e.g. Lefebvre, 1974). In this paper, we introduce mathematics education journey mapping as a critical methodology that centers bilingual teachers in the educational design and research process. We first provide a socio-spatial analysis to mathematics education. Next, we introduce Mathematics Education Journey Mapping, a critical qualitative method adapted from Annamma's (2018) Education Journey Mapping, to examine how location, locale, and sense of place shape one's mathematics experience as a learner and teacher. Finally, we analyze the Mathematics Education Journey Maps (MEJMs) of ten bilingual educators to showcase how place and space shape the "geography of opportunity" (Butler & Sinclair, 2020) for teacher and student experiences at the intersections of language, mathematics, and identities and the physical and ideological sites of oppression and resistance that bilingual teachers and their communities inhabit.

Theoretical Framework and Literature Review

Here, we draw on the definition of space by political geographer, John Agnew (1987), in which he describes it as spaces that people have made meaningful or have attached to in some way. Agnew's (1987) definition of space has three fundamental aspects: (1) a location - a specific fixed point in space where a place exists, (2) a locale - the material setting in which people conduct their lives at that location, and (3) a sense of place - the meaning attached to a particular location or locale. We build on Agnew's (1987) definition of space, alongside Soja's (2010) concept of "spatial justice" to highlight the connection between space, power, and resistance. Justice and injustice have spatial expressions or, what Soja (2010) has called, "consequential geography" (p.1). The concept of consequential geography highlights how justice and injustice shape - and are shaped by - the localized set of changing social, political, and historical conditions. Thus, the pursuit of educational justice requires a critical understanding and examination of space not as a background to our social lives but as active agents in shaping lived experiences and institutions, including mathematics education.

There has been a growing call for a spatial turn in mathematics education (Larnell & Bullock, 2018; Rubel & Nichole, 2020; Poling & Weiland, 2020). This body of work draws from scholarship in critical geography, urban education, and critical mathematics education to examine the role geography (space) have to generate, sustain, and disrupt inequalities. Larnell & Bullock (2018) offered a theoretical framework for thinking about urban mathematics education scholarship with an explicit focus on spatial logic in addition to the sociopolitical. Rubel and Nichole (2020) draw from frameworks of place, including indigenous ways of knowing, to include four thematic categories "geographies of human opportunity, mapping, human mobility, and land relations and obligations" (p. 6). Recent work on space highlights the potential to teach mathematics for spatial justice or using mathematics to identify power relations in and through space. For example, Rubel and colleagues (2016) investigated issues of social inequalities in New York City math classrooms by interrogating the structures of the lottery and paycheck loans. Poling & Weiland (2020) showcase the use of Common Online Data Analysis Platform (CODAP) and data from Public Use Microdata Areas (PUMA) to explore the "geographies of opportunities"that shape geographic, economic, and educational development across spatial and ideological boundaries, such as cities and suburbs. These studies highlight the potential in examining the arrangements of spatial geography and the distribution of social opportunity as well as levels of scale (e.g. classroom, school, state, etc.) in the scope of spatial consideration. Our project builds from this body of work that argues for considering the spatial dimension of mathematics education and extends the work to consider how the examination of space and the use of mapping can serve as a methodological and pedagogical tool for teachers to examine consequential geographies – the dynamic role that space plays in shaping justice and injustice – require critical examination since social processes and space influence each other (Annamma, 2018; Soja, 2010).

Research Approach

This project builds on an existing partnership in a dual language school in Texas. With funding from the Elementary and Secondary School Emergency Relief, Texas schools were encouraged to address educational inequities through tier three pull-out mathematics interventions consisting of drills of previous grade level skills to "catch up." School leaders noticed disproportionate representation of Black, Latinx, and refugee students from Afghanistan and Central America in the pull-out intervention—and the intervention was not leading to improved outcomes. Building on the belief that competence should be presumed for every student, the burden was on us - as educators and school leaders - to transgress and dismantle curriculum, pedagogy, and assessment practices that were leading to labeling, sorting, and separating of students across race, language, and class. The hope was to identify change within classrooms and also within the research process itself. Building from community engaged research (Warren et al., 2018), this project uses a co-design approach (Ishimaru et al., 2018), a participatory approach to designing solutions in which the school community are co-designers in the collaborative research inquiry and design for educational change. The project follows Ishimaru and colleagues' (2018) four stage co-design process for collaborative research inquiry: a) relationship building & theorizing; b) designing/developing tools to support new relationships and theories of change; c) enacting theories and practices in classrooms and schools; and d) analyzing and reflecting on our process for continued learning and innovation.

Partnership activities require careful attention to historicity, power, and relationality (Warren et al., 2019). The Mathematics Education Journey Mapping served as a tool for the second stage of the co-design process using mapping to collectively develop theories for change that leveraged the historical experiences and unique understandings that we each bring to the project. The research team consisted of three bilingual teachers (Monique, Anath, and Patty), the two school math coaches (Jorge and Elyse), school interventionist (Lydia), and four university researchers (Catalina, Lorie, Frankie, and Danica). Understanding the potential for mapping to stimulate participants' reflections about their identities across space and time, we adapted the techniques of Annamma's Education Journey Mapping to create a Mathematics Education Journey Mapping. Specifically, we wanted the codesign team of researchers and teachers to think critically individually and collectively about the ways in which mathematical opportunities, identities, and languages were shaped by space and place. We adapted the framework specific to mathematics teaching and learning with the following prompt:

> Use words, drawings, pictures to tell your personal journey of mathematics teaching and learning. Reflecting: What are four or more critical teaching and learning moments? Looking forward: What are your hopes and goals? Use different colors, images, the math tools, and resources to highlight experiences, show different feelings, and to share your story. These are just suggestions. Be as creative as you like. We will later share our journey / number line with each other.

After sharing the prompt visually, the first author read the prompt out loud and shared her own Math Education Journey Map (MEJM) understanding that identity exploration is a vulnerable process. We wanted to honor that vulnerability by opening up about our own process of identity formation as part of the process of mutual sense-making. After participants created their MEJMs, we each shared our narratives out loud to each other one-by-one. Participants had 15 minutes to work on their individual journey maps and group sharing lasted about 45 minutes.

Data Analysis

Primary data includes the video recorded session and its transcriptions as well as participants' drawn MEJMs. To analyze the data, we relied on Agnew's (1987) three fundamental aspects of space: location, the locale - the material setting at that particular location, and sense of place and alongside Soja's (2010) concept of spatial justice and followed the analytic procedures for mapping from Knigge and Cope's (2006), grounded visualization. To look for particular instances as well as general patterns in the MEJMs, we used Knigge and Cope's (2006) entry-level code categories for coding and solution driven theme-building – conditions, interactions, strategies and tactics, and consequences – to identify important connections within and between maps.

Findings

We organized the preliminary findings into three themes that aligned with the conceptual framework of space. Each theme connects to Agnew's (1987) three fundamental aspects of space: location, the material setting at that location, and sense of place, and Soja's (2010) concept of spatial justice- the connection between space, power, and resistance.

Although the prompt for the MEJMs focused on the participants' personal journey teaching and learning mathematics, math was only explicitly mentioned twice throughout the group sharing of MEJMs. Both mentions of math were in reference to math classes that served as crucial deciding points for future STEM careers. Instead, participants focused on aspects of language, identity, and culture while sharing their journey teaching and learning mathematics.

Findings 1: Systems of Power in Spaces

Throughout their MEJMs, participants identified the distribution of opportunity and the ways in which place not only contains patterns of (in)equality but shapes - and is shaped by - patterns of inequality and systems of power and domination. For instance, Lydia drew a number line in which 0 represented her birth (see Figure 1).

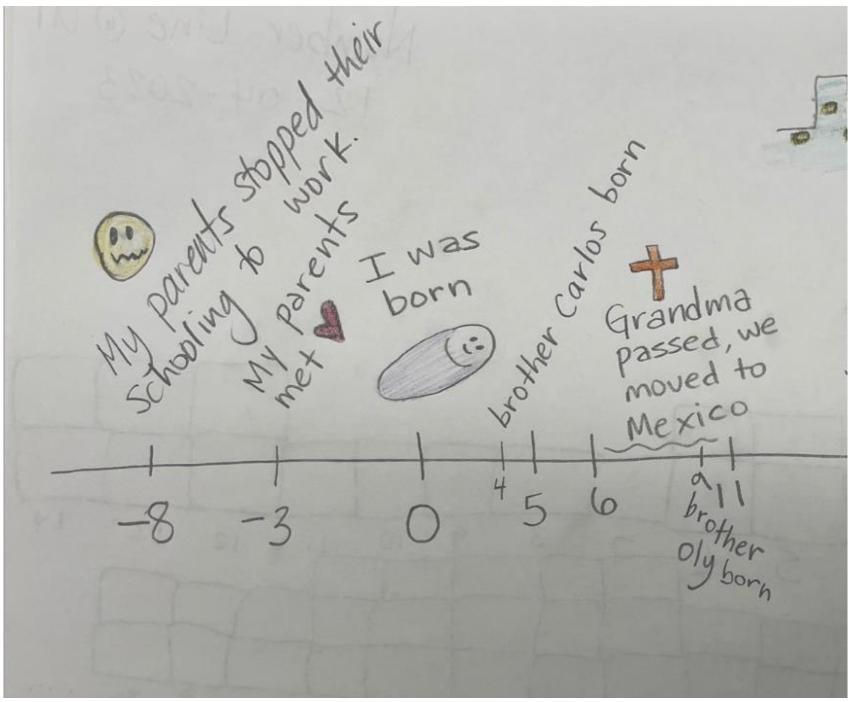

Figure 1: The start of Lydia's Mathematics Education Journey Map

Lydia starts her education journey map with her parents' educational journey:

> This is me, resembling Lydia, when she was born. I didn't put years; I decided to use integers on my timeline. So, I was born (which is 0 on the timeline) but eight years prior, my parents interrupted their schooling to start working and helping - helping their families. My mom is from a large family. They came from a larger home. So, she was always helping with the little ones. As soon as you could start working, she started working and then supporting the

family. My dad, his family migrated up north (to the U.S. to work). So from even before, like way before I was born, I think because they were not able to, you know, continue their education, I knew education – bilingual education and mathematics education - were important.

Lydia then continues to describe moving between the borders of Mexico and the U.S. throughout her K-12 schooling and how the movement between borders shape her bilingual and bicultural identity. Similarly, Anath discussed border crossing:

> I was born in the late 1900s. I did preschool and kindergarten in Mexico. That's where my family's from. Spanish was my first language. Then when I turned six, we moved to Texas and started first grade in the U.S. with basically no English. Back then, I mean, it's still the same now, but it's mostly sink or swim, right? You got it or you didn't. Yet, it really helped that I had Spanish, my first language, which was very well built and that helped me grasp on. Then, there was the pull-out when I was 8. It wasn't beneficial because it was like cat is gato. I already know this. That's also the start of the shift of speaking English only (in classrooms) because that's the only way you're allowed to learn. That's the only way you're gonna survive – English only. Then when I turned 10, that's when 9/11 happened. There was this huge shift again, towards people who don't speak English. Again, a force to speak English as much as you can, especially when you're crossing the borders, so they know that you belong here.

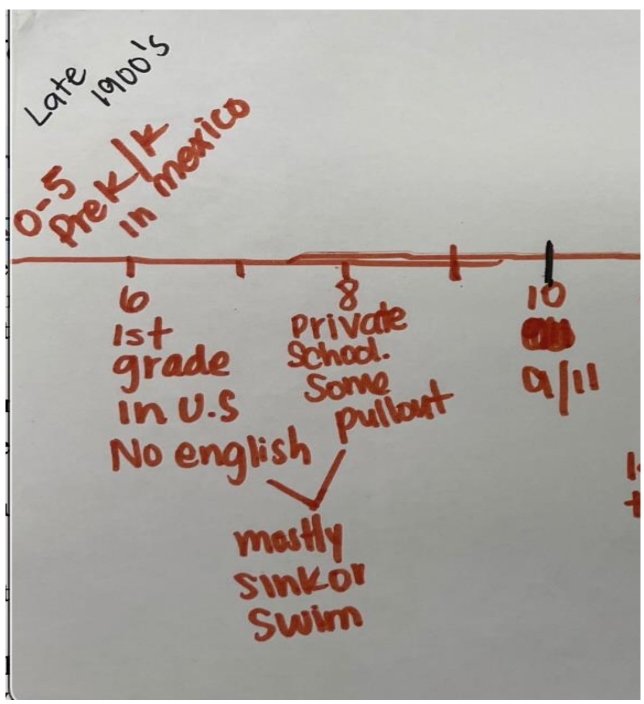

Figure 2: Anath's early school years on Mathematics Education Journey Map

Both Anath and Lydia described space as both physical and ideological (e.g. English hegemony; watered-down curriculum; and the role of compliance in mathematics classroom) and were naming the conditions and interactions within and across locations that perpetuated inequities and exclusion. Note how they both weaved and flowed between stories of their family, the classroom, to the state-national borders to highlight the ways which space is fluid and includes multiple levels of scale (e.g. classroom, school, state, nation). Soja (2005, 2010) describes the process of loosening of territorial boundaries created in terms of political power and cultural identity as processes of deterritorialization and reterritorialization, or debordering and re-bordering, as consequences of the globalization of capital, industry, and labor. This hybridization of spaces occurred throughout most of the teachers' stories in which they, their families, and their students are contending with an assortment of geopolitical, economic, cultural, and oppressive factors across state-sanctioned racialized borders separating countries, classrooms, and families.

Findings 2: Space as Sites of Resistance

A repeated theme across MEJMs was how educational spaces such as schools are not neutral. Boundary lines (e.g., city, state, nation) are traditionally thought of as political dimensions of maps. Yet, the teachers provided expansive notions of boundaries; they name out the boundaried aspects (e.g., English-only instruction; carceral schooling, compliance education) of mathematics education systems. Yet, they also used counter-cartographies to identify, tear down, and reimagine boundaries. Anath did this counter-cartography:

> I switched from psychology to education when I was 19. I thought I was going to teach in the English as a Second Language classroom. And then luckily, my cooperating teacher, she was like, why are you not teaching bilingual? You speak Spanish. And I was hesitant. I am glad she put me in a Spanish class. The class helped me reconnect with my Spanish and not be scared and hiding my Spanish, learning in Spanish and teaching other kids Spanish.

In this short description, Anath highlighted the collective nature of identification and disruption, naming a part of the re-boundarying in her mathematics educational journey that allowed her to honor herself. In mathematics education, where even access to one's native language is a privilege that is often withheld, most of the mathematics teachers' counter-cartographies demonstrated re-boundarying of their present, giving access to biliteracy and biculturalism for themselves and their students. Their responses challenge the neutrality in which mathematics education is often perceived as numbers only and decontextualizes from language and identities.

Findings 3: Space as Spatial, Historical, and Communal

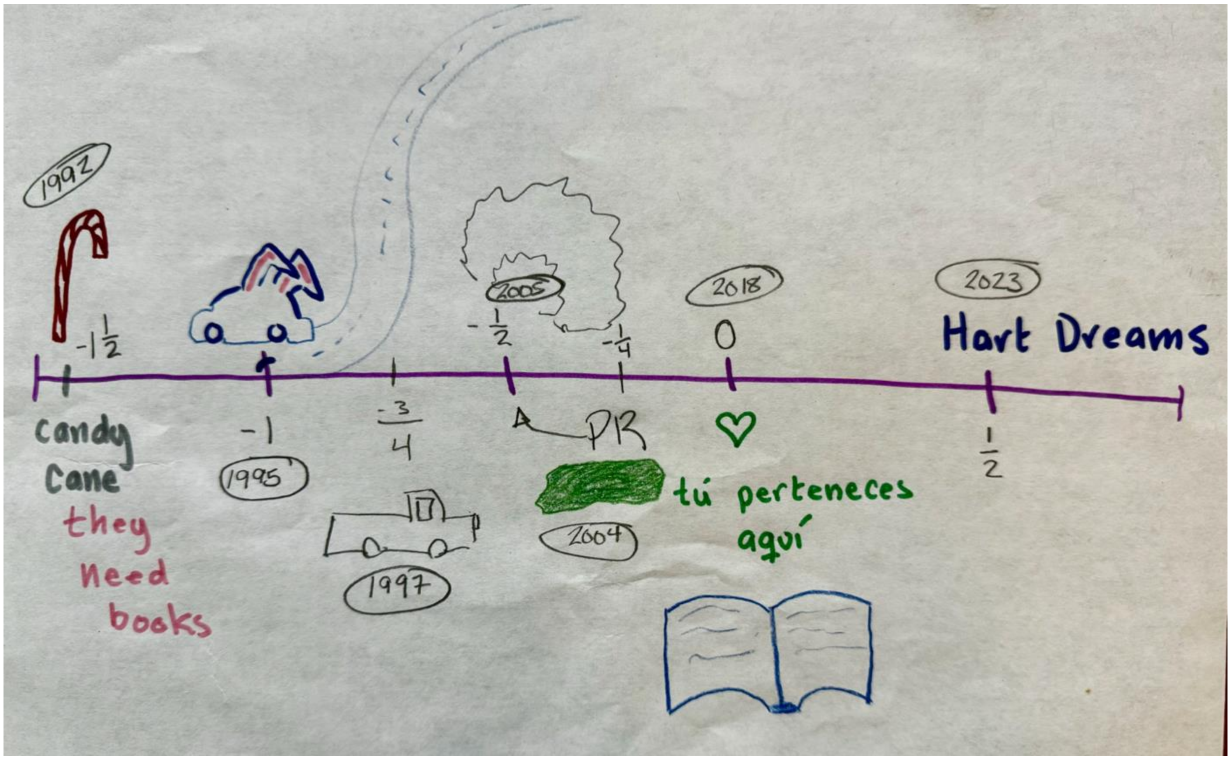

Figure 3: Frankie's Mathematics Education Journey Map

Frankie provides a timeline that marks 0 at "tú perteneces aquí." Below is their description of that moment.

> This is Race and Ethnic Relations (class). She's teaching us about the history of Texas. One of the first things she says in much more words —tú perteneces aquí— y en la manera en lo que lo hace, nos explica que la gente que vivió aquí… en este estado en lo que se conoce como tejas ahorita, la gente que ha vivido en México, siempre han viajado entre los dos libremente y siempre ha habido gente ahí, entonces la gente mexicana, o parte indígena, o latinoamericana, pertenecen aquí en estados unidos diga lo que diga la ley. That was probably the strongest moment that I knew that I have the right to be here. Now, do I have a right to be here? I don't know if I see that politically anymore. I feel like I have a responsibility to be here and to view my education differently. And to also when I speak with other people say that very same tú perteneces aquí, whenever I'm working with children or working with others.

Here, Frankie highlights the consequential geography of justice in which language justice is communal justice. Similar to Lefebvre (1996) arguments that all people, especially those from historically marginalized backgrounds, have a "right to the city," Frankie is calling on the right for linguistic justice in mathematics education.

Discussion

The project builds from a key premise that we - as an education community - arrive at better understandings and solutions to classroom and school-based inequities when those most impacted can influence key processes and decisions. Using the Mathematics Education Journey Map as a methodology allowed us to excavate individual and collective educational experiences in order to understand the particular historical experiences and unique understandings that the co-design team of teachers and researchers bring to the project. In this section, we briefly describe how these experiences can be utilized in the process of moving towards co-design professional learning spaces.

Attending educational justice as a personal endeavor, bilingual educators hold understandings of how dominant constructions of language within mathematics education perpetuate systems of oppression. Their personal experiences conveyed great cost and sacrifice to assimilate. Dominant narratives about newcomers, biliteracy, and English hegemony remain deeply pervasive in educational institutions, including mathematics education, that it can be difficult for even bilingual teachers to perceive its insidious effects. The bilingual teachers drew on their experiences to critique the centering of English as power and potentially challenge it in their own teaching.

Interactions within mathematics classrooms that reflected broader politics of transnationalism, immigration, and monoglossic language ideologies and policies emerged in the maps as a significant aspect of the material conditions of locations. The teachers described feelings of shame and othering and noted the immense power that teachers and schools had to impose a deviant identity upon them. Their MEJMs highlighted cultural tools such as standardized testing and remediation practices (e.g., labeling, separate classrooms) as stigmatizing. At the same time, they resisted these identities in the ways they authored their maps and stories. The mapping process of one's journey as students to teachers allowed participants to be understood as whole, resilient beings navigating difficult experiences and refusing to accept identities of deficiency. They authored their own identities by critiquing interactions that positioned bilingualism and multilingualism as less than and articulated the creation of safe spaces for themselves and their students. In doing so, they insisted upon their robust competencies, right to belonging, and their humanity.

The goal of the MEJMs was to provide a process for us to engage in discussion around theories of change. It was a space to identify our strengths, our goals, and our needs. These stories – our individual and collective stories – serve as a foundation to build together. As stated by Danica in explaining the last mark on her MEJM, "I just kind of put a pencil here because I feel like my story is not yet fully written." The struggle for spatial justice is not an individual endeavor but requires the exercise of collective power to reshape the process of ownership. The MEJMs as a critical methodological tool allowed individual and collective examination of the physical and political dimensions of educational experiences with the goal of learning through these mappings to restructure spaces of learning. Our next step is to bring in families into the co-design.

ASSIMILATING TO BELONG: A CRITICAL REVIEW OF SENSE OF BELONGING RESEARCH IN MATHEMATICS EDUCATION

Sabrina N. Zarza
Michigan State University
zarzasab@msu.edu

The purpose of this paper is to offer a critical review of the research surrounding sense of belonging to mathematics through a lens that exposes assimilatory perspectives and uplifts the fluidity and beauty of students' ways of being. Guided by Anzaldúa's (1999) concept of living and being in the Borderlands, as well as the mestiza consciousness this review resulted in identifying two types of sense of belonging research: work that aims to alter the student to fit the current constraints defining academic mathematics and work that considers how the system can be changed to best suit the student as they are. Implications from this review are discussed by envisioning what future sense of belonging to mathematics research might look like that would disrupt whiteness in mathematics education and offer space for healing.

Keywords: Systemic Change, Equity, Inclusion and Diversity

In a now frequently cited study that set out to understand member (under)representation in mathematics courses, degrees, and careers, Good, Rattan, and Dweck (2012) identified *sense of belonging to math* as a significant predictor to women's desire to pursue mathematics, academically and professionally. *Sense of belonging to math* was defined as "one's personal belief that one is an *accepted* [emphasis added] member of an academic community [mathematics] whose presence and contributions are valued" (p. 711). Although this study focuses on women, other sense of belonging studies echo the implications that the mathematics classroom can transform into a site for fostering belonging. In the literature on sense of belonging to mathematics, many researchers point to their studies to recommend changes within mathematics classrooms to encourage a greater sense of belonging for marginalized students which would in turn lead to greater representation in mathematics as an academic discipline (e.g., Barbieri & Miller-Cotto, 2021; Bjorklund, 2019; Jaworski & Walker, 2023; Rattan et al., 2012). So logically, starting from Good et al.'s (2012) definition, if we were able to increase a student's sense of belonging to mathematics, a feeling defined by *acceptance*, then we would see an increase in historically marginalized students pursuing mathematics courses, degrees, and careers. Academic mathematics however, is "rooted in appeals to White nationality and White benevolence" and "is a colonizing form of education" (Martin, 2015, p. 21). So, is acceptance truly what these students desire? Acceptance into the field that is used as a weapon (one of the many) to maintain and perpetuate white supremacy (Marchant et al., 2023)? Even if we were to accept this definition of sense of belonging, are there changes that can be made within the four walls of a classroom that can actually combat the oppressive intentions of academic mathematics?

In discussing belonging research, Rochelle Gutiérrez (2022) questions "when or how do we capture the complexity and contradictions in belonging research?" (p. 382). I believe part of the contradiction in belonging research is that either the goal of the work is to find ways to alter the students' perspective (see growth mindset) on mathematics or somehow alter an instructional component within the mathematics classroom that offers them a place of belonging to mathematics. Both goals still attempt to assimilate students as they want children to value a very specific definition of mathematics. This is not to claim instructional practices like cooperative learning, inquiry-based learning, or student-centered instruction are harmful to students, but rather, can these practices lead to a student feeling an increased sense of belonging to their mathematics classroom when the mathematics valued in this space has been curated by whiteness (Battey & Levya, 2016).

The purpose of this paper is to offer a critical review of the research surrounding sense of belonging to mathematics through a lens that exposes assimilatory perspectives and uplifts the fluidity and beauty of students' ways of being. This review is guided by Anzaldúa's (1999) concept of living and being in the Borderlands, as well as the *mestiza consciousness*. Drawing from her experience living between the Mexico-United States border, Anzaldúa theorizes, "an emotional Borderlands which can be found anywhere where there are different kinds of people coming together and occupying the same space or where there are spaces that are sort of hemmed in by these larger groups of people" (Urch et al., 1995, p. 77). She capitalizes Borderlands to distinguish this emotional state from the physical borderlands of the Mexico-United States border. I provide more detail about these concepts in my theoretical framework, but wish to note here that throughout this study, I refer to all students who do not feel they belong to mathematics, as living within the Borderlands. In doing so, I am aim to be inclusive to the diverse group that the racist, sexist, and ableist structures of white supremacy oppress, while also not essentializing the experience of marginalized people. I claim that students who do not feel a sense of belonging to academic mathematics do so for good reason. These students live within the Borderlands of places they are told they belong, navigating the push and pull between the varying worlds in which they experience and perceive mathematics.

Theoretical Framework

"If we have been gagged and disempowered by theories, we can also be loosened and empowered by theories" (Anzaldúa, 1990, p. xxvi).

Borderlands and Positionality

This review is guided by Gloria Anzaldúa's *Borderlands/La Frontera: The New Mestiza* (1999). In this work, inspired by her experience as a Chicana, lesbian, and activist, Anzaldúa examines the in-between spaces of the physical, cultural, and spiritual realms. Living on the Mexico-United States border, she describes a "border culture" where there are "two worlds merging to form a third country" (Anzaldúa, 1999, p. 3). In this borderland, that feels neither fully American nor fully Mexican, "is a vague and undetermined place created by the emotional residue of an unnatural boundary. It is in a constant state of transition" (p. 3). Existing in the in between is not a split 50/50 identity. Rather it is a fluid connection to the various cultures and lands that the borderland runs between. These lands are more than just a physical space, as they also represent something that is spiritual, cultural, and part of her identity. A capitalized, Borderlands, is used when referencing the spiritual, emotional, and cultural experience of being in-between spaces, identities, and categories (Anzaldúa & Keating, 2015).

Anzaldúa (1999) not only defines the Borderlands as a place of being but demands that its residents be seen as they are, in this place; no longer pushed or pulled into categories that are uncomfortable and demand an assimilation into a permanent identity. Referring to herself, and other Borderland people, Anzaldúa (1999) explains that we, “no longer feel that we need to beg entrance [into society], that we need always to make the first overture,” but rather “we ask to be met halfway,” on the *puente* (bridge) where acceptance and understanding reside (p. x). The existence of the *puente* resists the binary of us or them, in or out and instead allows for a middle ground that is not forcing labels or identities on anyone. *Mestiza consciousness* is understanding that the *puente* brings healing and that it is a place where transformation can occur and develop in a way that can have influence beyond the bridge. Anzaldúa further defines *mestiza consciousness* in *Borderlands/La Frontera: The New Mestiza* (1999),

> It is work that the soul performs. That focal point or fulcrum, that juncture where the *mestiza* stands, is where phenomena tend to collide. It is where the possibility of uniting all that is separate occurs. This assembly is not one where severed or separated pieces merely come together. Nor is it a balancing of opposing powers. In attempting to work a synthesis, the self has added a third element which is greater than the sum of its severed parts. That third element is a new consciousness–a mestiza consciousness…(p.85)

Through my experience, as a Chicana of indigenous descent in the field of mathematics, I fully accept and claim as fact that White supremacy is woven into the hierarchical structure of academic mathematics (Battey & Leyva, 2016; Martin, 2015; Martin, 2008; and many others). Those who do not fit the mold that academic mathematics serves live in the Borderlands, being pulled into assimilation to “succeed” in academic mathematics while simultaneously being pushed out because of their various identities that are positioned as “other.” This literature review is driven by the desire to not only recognize those experiencing and existing within these Borderlands but also to provide a path in future research for *mestiza consciousness*. This concept recognizes the pain that exists within the Borderlands but asserts that “its energy comes from continual creative motion that keeps breaking down the unitary aspect of each paradigm” (Anzaldúa, 1999, p. 85).

In my family, we often explain to people that “we didn’t cross the border, the border crossed us.” My ancestors are Genízaros, stripped of their tribal affiliation through enslavement and assimilation. As a result of generations of oppression and discrimination, assimilation became a means of survival. My sister and I were born into a lineage of borderland people but from the second we took our first breath we were pushed to find belonging within the United States culture of whiteness. Now, as a researcher in the field of mathematics education, one would assume my own sense of belonging to academic mathematics to be resoundingly positive. Although I have taught in the mathematics classroom and accomplished the highest academic achievements in this field as a student, I do not feel as though I belong to it. I do have an immensely strong connection to my identity as a mathematician, but so much of this connection stems from mathematical thought outside of academia and the relationships that mathematics has provided me. The mathematical thought that is behind every motion of my mother’s crochet hook connects to each stroke of hair color I painted on my client’s hair during my career as a hairstylist, which connects to each sprinkle of pepper and dash of allspice in my father’s secret family lasagna recipe. These are the types of mathematics that I identify with and feel as though I belong to and have a connection to, not logarithms and the rational root theorem. So, although I have fought through the battlefield of whiteness and stand on the other side of the border within the academic mathematics community, I do not feel as though I belong. I am alone amongst my peers in positioning my journey through mathematics as my healer, as something of beauty. I do not live on the borderlands my ancestors belong to, but I feel their embrace and wisdom forgiving me for abandoning our home. So, while I stand on the white side of the border, I have made a choice. Rather than ensuring I leave the door open for others in the Borderlands, I desire to help open other doors that lead to paths yet unknown. Paths that do not require distance from the body and home or a compromise to belonging.

Review of Research

Sense of belonging literature focuses on students who live within the Borderlands of belonging to their educational institution or to the STEM field as a whole. In reviewing the literature, there are two contradictory positions I found on how to increase a sense of belonging to mathematics. I will first review the most common theme in this literature, which is a focus on how to increase a sense of belonging within the current constraints of academic mathematics. This field of thought aims to alter the student to fit the system. As Gutierréz (2022) has pointed out, "when we study students and try to capture what prevents them from feeling they belong (and supports them to feel included), we are expressing our own desires that we want that for them" (p. 382). To put this more directly, this type of work approaches belonging by encouraging assimilation of Borderland inhabitants into the walls of academic mathematics without regard to where students already feel a sense of belonging. I will then review literature that takes a more critical approach to investigating a sense of belonging to mathematics and accepts Borderlands as a place of being for students, letting them exist how they are. This approach allows space for, and invites, a *mestiza consciousness* for students, instructors, and researchers in the field.

Assimilating to Belong

The following studies seek to understand a sense of belonging to mathematics without regard to how the narrow framing of what is valued in academic mathematics could be acting as a deterrent to those who do not seek assimilation into whiteness. This work envisions a future in this field without a *puente* (bridge) that could help embrace mathematical ways of knowing and being outside of what is defined as academic. That is, it assumes a permanence in this field which smothers the beauty, diversity, complexity, and spirituality that exist throughout mathematics.

Sense of belonging research has pointed to ethnicity/race as a predictor of sense of belonging in educational institutions and STEM as a field. Examining this connection, as early as middle school, Barbieri and Miller-Cotto (2021) look into the significance of a student's sense of belonging in relation to other self belief measures of self concept, importance, and entity view. In this study, they find that "not only is sense of belonging to mathematics a significant predictor of middle school students' learning, but it was the only significant predictor of the motivation and belief measures taken" (p. 7). These findings specifically call attention to underrepresented racial and ethnic minority students (URM), as these students "reported a markedly lower sense of belonging than non-URM students" (Barbieri & Miller-Cotto, 2021, p. 1). When investigating the cause for this racial gap in belonging, Morales-Chicas and Graham (2021) found that racial/ethnic makeup of a student's math class played a significant role in a student's sense of belonging. That is, "Latino and Black students in advanced math reported a greater sense of belonging in math when they perceived more similar racial/ethnic peers in class than in school"

(p. 9). These findings present major implications for districts that participate in math tracking that often results in Black and Latino students being underrepresented in advanced courses (Tyson, 2013).

Some sense of belonging studies focus on students of color who are succeeding academically in an effort to understand how to replicate their success. Strayhorn's (2008) study for example showed that there was a positive correlation between Latino college students earning a higher grade and their sense of belonging. But in a sample of 589 Latino and White students, descriptive statistics show that on average, Latino students receive lower grades in their courses than their White counterparts. To a similar result, Bjorklund (2019) found that "while more latinas/os are taking AP exams than in previous years, their passing rates have remained lower than other groups" (p. 109). So even when students of color are being 'pulled out of their Borderlands' and achieving some form of success, as defined by academic mathematics, they still remain othered in academia from their White counterparts. Furthermore, Bjorklund (2019) claims that the Latina/o participants in their study "leveraged their lack of sense of belonging to bolster their resilience and motivate themselves toward transformative resistance to succeed and prove others wrong" (p. 123). Although transformative resistance might seem like a positive step towards an equitable education for these Latino students, I wonder if we can create a system that allows students of color to succeed for themselves and their ancestors, rather than to prove their White counterparts wrong.

Results from a nine-country survey showed that school sense of belonging is a significant predictor of how students value advanced math courses (Smith et al., 2021). When surveying women in the United States, Thoman et al. (2014) found that women "feel pushed out of STEM when they feel a low sense of belonging" (p. 246). These results echo findings by Good et al. (2012), that show that a low sense of belonging for women in STEM predicts a decrease in desire to pursue math in the future. Women in math environments receive social messaging that women have a lower math ability than men, which further leads to low sense of belonging in math (Good et al., 2012). Rogers et al. (2021) attempts to investigate a more specific association with gender discrimination, school connectedness, and math/science achievement motivation. In a sample of 295 adolescent girls, they found that "gender discrimination was uniquely associated with girls' lower sense of school connectedness" (p.417) along with being a predictor of below average math achievement motivations (but not science).

Taking an intersectional approach, Rodriguez and Blaney (2021) investigate how Latina STEM majors develop their sense of belonging in academia. They find that "white and male classmates unjustly question the abilities and belonging of Latina students in STEM," and that their participants found other spaces on campus to feel supported (p. 452). In these studies, we see the struggle of Borderland women trying to live "between *los intersticios*, the space between the different worlds she inhabits" and being told this place cannot be home (Anzaldúa, 1999, p.32).

Belonging to Borderlands

In accepting the Borderlands as a place of being and a place of home, it is important to not examine how Borderland students succeed in mathematics in an effort to recruit into the field, but rather use this examination towards a futurity praxis, for "students and teachers to live out a future to which they want to belong" (Gutiérrez, 2022, p. 383). We need to highlight that when

Latina students pursue STEM degrees it is driven by their sense of belonging and commitment to their families and communities (Acevedo et al., 2021). Accepting those in the Borderlands also requires partnerships, *puentes.* In their study with Black women in college, Cook-Sather and Seay (2021), demonstrate how "pedagogical partnerships respect Black, female students' intellects; affirm their experiences and expertise; and make them feel they belong in conversations about teaching and learning" (p. 745). Positioning these women as experts of their own sense of belonging is key to acceptance in the field. Acevedo et al. (2021) also acknowledge changes required of the system to truly affect the sense of belonging to STEM. They recommend requiring an Ethnic Studies STEM course, "which confronts the issue of STEM reproducing white supremacy, whiteness and sexism" (p. 74).

Another way to accept Borderlands as a place of home is to recognize that the current system is not a place where Borderland people belong. I want to be clear that this is not to say that they do not belong because they *cannot* belong but rather that forcing a sense of belonging would be an act of assimilation and colonization. In examining how ableism affects students' sense of belonging in learning environments, Nieminen and Pesonen (2022) assert, "inclusive learning environment design cannot be a responsibility of individual teachers practicing 'pedagogies of care', as structural ableism needs to be challenged through systemic solutions from HE [Higher Education] institutions" (p. 2030). Furthermore, "while waiting for such radical changes, it might be more desirable – and safer – for disabled students not to belong to the learning environments" (p. 2031). In a similar argument, when investigating what effect Culturally Responsive Pedagogy might have for Australian students, researchers came to the conclusion that in order to actually improve sense of belonging, they would need to "conceptualize the role of education outside the desire to fit students into the mainstream culture of the school and its society" (Harrison & Skrebneva, 2020, p. 23). Stokes (2023) further highlights the problematic nature of most sense of belonging research as it represents "white supremacy as a normative construct for which people of color must adopt" (p. 30). Stokes continues by emphasizing a future that creates a new "us" which is in line with Anzaldúa's (1999) *mestiza consciousness*, where those in the Borderlands reject the pushing and pulling into systems in which they do not find belonging.

Envisioning a Future

This review of sense of belonging to mathematics research demonstrates the need to envision a future for mathematics education that centers students who are currently othered by academic mathematics and intentionally aim for a *mestiza consciousness* in this field. In order to actually address the member (under)representation in mathematics that Good et al. (2012) sought out to understand, we must emphasize "healing us," not "helping others," by targeting the whole system as opposed to just specific parts (Gutiérrez, 2022, p. 383).

Throughout this paper the word academic was placed in front of mathematics to emphasize that mathematics is so much more than what is valued as mathematical in academia. If we truly want students to find belonging in academic mathematics, we need to disrupt the hierarchy that whiteness has created in this field (Battey & Levya, 2016). As highlighted in the previous section researchers have begun this disruption, but we can build upon and continue this work by centering student perspectives. That is, rather than studying what negotiations or hurdles students must overcome in order to discover a sense of belonging to academic mathematics, instead respect youth as the experts of their own sense of belonging to guide us in defining this feeling.

Rather than research serving the current system it should serve Borderland students and bring their voice into the conversation. By engaging with students that live within the Borderlands of classroom mathematics and in examining sense of belonging while also rejecting a desire to recruit into a broken system, we can embrace a "relational understanding of knowing, existing, and healing that center values and ethics" (Gutiérrez, 2022, p. 381). Let us practice what we preach to our pre-service teachers and in professional developments and meet students where they are, on the *puente*.

We employed a dialogical self-approach to delve into the narratives of a group of seven women mathematics educators, including both graduates of the same doctoral program and their advisor. Through this lens, we gained insights into how we described ourselves, recounted personal experiences, and articulated our personal histories within the figured worlds. Three dialogical models emerged, including dialogues between past and present positions, dialogues between internal and external positions, and dialogues between self and societal norms. These models serve to offer insights into how intricate dynamics shape women mathematics educators' perceptions, interactions, and self-identities over time. By examining these dialogical interactions, we gain a deeper understanding of the multifaceted factors influencing the professional and personal development of women in mathematics education.

Keywords: Dialogical Self, Identity, Narratives, Women Mathematics Educator

Women mathematics educators often navigate the complex intersection of mathematics and education, experiencing a dynamic landscape where they simultaneously encounter both distance from and alignment with societal expectations (Zhou et al., 2023). On one hand, they are often stereotyped as extraordinary or exceptional, attributed to their significant involvement in mathematics. On the other hand, they also conform to societal expectations associated with the traditional female role as educators, nurturing individuals within society. This inherent contradiction shapes their professional journey, influencing their self-recognition. This study addresses the critical need to amplify the voices of women in mathematics education, highlighting the unique challenges and perspectives they bring. By examining these dialogical interactions, we gain a deeper understanding of the multifaceted factors influencing the professional and personal development of women in mathematics education, ultimately aiming to inform policies and practices that support their growth and retention in the field. Specifically, the following research question leads to the inquiry: *What dialogical models emerge to interpret the identity of women mathematics scholars over their life-long journey?*

Theoretical Perspectives

Building on Bakhtin's dialogism, Holland and colleagues (1998) articulated the dialogical self approach to elucidate individual identity through the act of authoring oneself within figured worlds (for an overview, see Holland et al., 1998). The concept of the dialogical self is characterized by its social nature, not merely involving interactions between an individual and external people but encompassing a multitude of voices within the self (Hermans, 2001). Hermans additionally (2013) articulates the dialogical self within educational settings, emphasizing that dialogues can occur between different positions within the self, emerge between internal and external positions, or take shape between two external positions of the self. Thus, the dialogical self-approach promotes internal and external discourse, providing educators with a lens for authoring figured worlds and narrating multiple, affordably accessible I-positions.

Akkerman and Meijer (2011) advocate for the adoption of a dialogical self-approach to investigate teacher identity, suggesting a threefold reconceptualization: viewing it as both unitary and multiple, continuous and discontinuous, and individual and social. So far, there are only a few studies in mathematics education which use a dialogical self approach as the analytic tool and theoretical framework to understand teachers' identity.

In Pipere and Micule (2014)'s exploration of three teachers' lifelong relationships with mathematics, emergent dialogical models in the teachers' mathematical identity, intertwined with perceptions of students' mathematical inclinations. This provides valuable insights for practical implementation of exploring mathematics educators' identity. Similarly, William (2011) delves into two mathematics teachers' narratives in the figured world of mathematics teaching and learning, and discovered that their cultural resources such as family, background, school, university, and teaching experiences, provide insight into how they author selves in the teaching mathematics. With the aim to explore the extent of reflexivity in shaping new identity spaces within mathematics, Solomon's (2012) study from the self-authored narratives of two undergraduate women in the figured world of mathematics, revealed the persistent challenge of altering the positioning of women in this field. Despite reflective efforts, the perception of mathematics as a gendered and predominantly masculine domain persists.

Drawing upon methodologies in the reviewed literature and responding to the call made by Lutovac and Kaasila (2018) for a more balanced psychosocial theoretical perspective in exploring identity in mathematics education that equally considers both individual and social dimensions, we have embraced the dialogical self approach to investigate the narratives the women mathematics educators.

Methods

In our study, ongoing monthly meetings of the group, spanning two semesters, have become a dynamic space for intentional narrative construction and self-authorship through carefully crafted prompts. First, we discuss the prompts, and then we spend 30-45 minutes writing our own narratives or stories to respond to them. Finally, we come back together to share our stories, which leads to an evolving inquiry in the group.

The prompts serve as catalysts for rich and dynamic internal and external dialogues. These prompts intricately weave dialogues within self and between self and others, fostering a holistic exploration of personal narratives. Internally, the prompts elicit dialogues within the individual, encouraging members to engage in reflective conversations with their past selves. As we delve into significant memories and episodes, these prompts facilitate an ongoing dialogue with the various I-positions that have shaped our identities across different life stages. Externally, the prompts spark dialogues among group members, creating a shared space for collective reflection and exploration. The prompts encourage open discussions, allowing us to share our diverse perspectives, experiences, and I-positions. Instead of taking on the role of critical friends as self-study (e.g., Hamilton & Pinnegar, 2000), the members primarily engage in active listening and understanding, fostering a strong sense of community and further promoting the group's collective narrative.

Fueled by these prompts, the monthly meetings provide a structured yet open platform for the group members to engage in a continuous process of self-reflection and narrative development. The individual narratives and recordings of group discussions serve as data sources for this exploration.

Findings from Interpretation of Dialogical Narratives

Exploring the question of what dialogical models emerged to interpret the identity of women mathematics scholars over their lifelong journey, we intentionally sought the dialogical voices from the narratives, who they talk to, what they talk of. Three dialogical models have emerged: Dialogues between Internal Past and Present Positions, Dialogues between Internal and External Positions, and Dialogues between Self and Societal Norms.

Dialogues between Internal Past and Present Positions

When addressing the prompts, we naturally initiated dialogues among our different I-positions, especially across the dimension of time. Engaging in a dialogue with our past selves from today's mathematics educator perspective can illuminate numerous challenging experiences, critical moments, and pivotal choices. Many past struggles can then be better explained and understood. Below is an example from Jill, sharing her nadir experience during her dissertation proposal defense with a reconciling perspective：

> I was not prepared for the high-stakes, high-pressure moment of my defense. I don’t remember any details about the meeting and any particular questions I was asked, but I sure do remember the feeling afterward - crushed, embarrassed, defensive, etc. I had passed, but with lots of critique and revisions and thinking to do… In hindsight, of course, I am grateful, but the memory is far from warm and fuzzy.

A different example from Hyunyi involves her revisiting herself as a 13-year-old girl to express her earlier thoughts on teaching and mathematics back then:

> When my mom asked me what I liked and what I wanted to be in the future. As a 13-year-old girl, this question made me think about experiences that had made me happy. I told my mom that my friends in the classroom asked me about their homework and test prep problems, and I felt happy when they thought my collaboration was helpful to them. I continued to explain to my mom that I want to be a literature or mathematics teacher. Since many of my classmates think math is more difficult than literature, I thought it might be better for me to become a math teacher as I would be able to help more people.

These dialogues explain the past challenges and perplexities and reconstruct experiences that align with current identities. By examining internal positions, past selves, and current selves, we aim to understand decision-making processes, such as the choice to pursue a PhD in mathematics education and a commitment to mathematics.

Dialogues between Internal and External Positions

As women mathematics educators recall experiences imprinted in their memories, dialogues emerge between themselves and others. In the example below, Brooke expresses surprise at being called a leader, a role beyond her own self-identification.

> I recall being at my 20-year high school reunion. I had just finished my PhD within the last year and was a lecturer at a Midwestern University. One of my classmate's husband was there, and he was 3 years older than me and the current high school principal. He said "you're a leader why don't you get things started." It surprised me because I did not see myself as a leader. I just saw myself as being me.

In another dialogical context, Ricki was questioned as a female pursuing mathematics.

> I received an interview for graduate school for mathematics. Upon entering the room for my interview, I was greeted with "Oh, you're female." The discovery of my femininity cast a shadow on the interview, disregarding the qualifications that I held. I didn't get into graduate school for mathematics; it left me feeling "not good enough" in mathematics.

The dialogues between internal and external positions confirm identity from others' perspectives. While some dialogues positively contribute to identity development, as seen in Bailey's example, others might negatively impact identity, as illustrated by Ryan's experience. Moreover, dialogues between internal and external positions indicate power inequity. These dialogues reflect not only how individuals perceive themselves internally but also how external factors, such as societal norms or institutional structures, may exert influence and contribute to power imbalances within personal narratives.

Dialogues between Self and Societal Norms

Dialogues between self and societal norms, such as being a woman or living in a specific culture, also emerged. In these dialogues, women mathematics educators author themselves in broader social contexts with collective identities, often grappling with struggles and uncertainty. Below are dialogues from Bima and Lindsay respectively, exploring aspects of culture, gender, and the intersection of both, shaping who they are.

> In the culture where I was raised, we do not usually say "no" when someone in a higher power asks you to do something. For example, when your senior colleagues interpret your ideas in a different way, I still cannot take a stance and say "that was not what I was thinking." But I have begun realizing that is not going to serve me well. I need to be more strategic and defend my ideas.
>
> Another noticing is that things that challenge all these women's identities - in one circumstance or another - is the desire to please others. We feel that tension from time to time, and it sounds like with age we are getting better at managing it, but it appears to be a challenge that can creep up on us again at times and interfere with our choices of how to divide our time between our personal and professional roles.

These narratives exemplify the complex interplay between individual identity construction and external societal influences. As we delve further into these dialogues, we gain valuable insights into the nuanced ways in which personal and social identities intertwine within the narratives of women mathematics educators.

Discussion

Using a dialogical self approach, we facilitate both internal and external discourses, exploring personal histories, narratives, and the development of evolving identities. Our findings indicate that exploring personal histories provides women educators with a deeper understanding of self within complex social relations. Encompassing both individual and social dimensions, the three identified dialogical models provide a foundation for future exploration of educators' identity. These models, in particular, inform designing interview questions, discussion prompts, or survey inquiries. By keeping these dialogical models in mind, researchers can create spaces for participants to respond authentically and author selves in the figured worlds.

ELEMENTARY PRESERVICE TEACHERS' ANGLE MEASURE APPROACHES GIVEN A CIRCULAR CONTEXT

Hanan Alyami
Purdue University in Fort Wayne
alyamih@pfw.edu

Curricular standards emphasize understanding angle measure as a fractional amount of a circle. However, learners struggle to connect angle measure to circular context. In this report, I explore 65 elementary preservice teachers' (PSTs') strategies as they engaged with a circular context. Thematic analysis of PSTs' drawings and written responses indicate that a little over a quarter of the PSTs utilized angle measure to complete the task. These findings suggest that despite the connection between angle measure and the circle concepts, such connection might not be spontaneous for learners. I conclude with implications and future considerations.

Keywords: Geometry and Spatial Reasoning, Measurement, Preservice Teacher Education.

Measurement is a critical mathematical domain for preservice teachers (PSTs) enrolled in teacher education programs (AMTE, 2017). Within this domain, the concept of angle and its measure are critical topics in school mathematics (Barabash, 2017; Thompson, 2008; Thompson et al., 2007). However, the concept is illusive, as learners (including PSTs) struggle with quantifying angle measure (Sinclair et al., 2017). Conventionally, angles are measured in relation to a circle centered at the angle's vertex. The angle is measured using its subtended arc as a specific, yet arbitrary, fractional amount of the circle's circumference. When measuring angles in degrees, the subtended arc is measured in units that are 1/360th of the circumference. This is known as the arc approach to angle measure (Moore, 2013), and is reflected in the *Common Core State Standards for Mathematics* (CCSSM), where angle measure is introduced in fourth grade:

> An angle is measured with reference to a circle with its center at the common endpoint of the rays, by considering the fraction of the circular arc between the points where the two rays intersect the circle. An angle that turns through 1/360 of a circle is called a "one-degree angle," and can be used to measure angles. (National Governors Association Center for Best Practices [NGA] & Council of Chief State School Officers [CCSSO], 2010, p. 31).

Despite the connection between the concepts of fractions, circles, and angle measure, researchers have reported that students do not relate angles to the circle context (Hardison, 2018; Hardison & Lee, 2019; Moore, 2013), and that students and teachers struggle with understanding angle and its measure (Crompton, 2017; Devichi & Munier, 2013; Keiser, 2004). However, while researchers have explored and reported PSTs' and in-service teachers' mathematical knowledge of various quantities (e.g., length, area, and volume), little is known about how PSTs and in-service teachers quantify angle measure (Smith & Barrett, 2017).

To provide PSTs with opportunities to develop a coherent understanding of mathematics (AMTE, 2017), as well as opportunities to use and connect mathematical representations (NCTM, 2014), it is important to explore PSTs' approaches to solve a problem situation that involve a circular context. In this report, I present a task that would provide PSTs with an opportunity to utilize angle measure given a circular context, summarize my analysis of their quantitative reasoning approaches (a construct I elaborate on in the following section), and provide insights on the implications of the findings.

Theoretical Framework

I build on principles of quantitative reasoning, which involves an individual's mental actions for "conceptualizing an *object* and an *attribute* of it so that the attribute has a unit of measure, and the attribute's measure entails a *proportional relationship*...with its unit" (Thompson, 2011, p. 37, emphasis added). Given this description, quantification involves coordinating three components: an object, its measurable attribute, and a quantification (measurement) process.

Given the conventional approach to angle measure described earlier, the angle is considered the object; its measurable attribute of openness is quantified as a multiplicative relationship between the angle's subtended arc and the circumference of the circle containing the arc. The arc approach to angle measure is beneficial, especially for the study of trigonometry (Moore, 2013, 2014), and inverse trigonometry (Paoletti, 2020). However, students have applied other approaches to angle measure, such as iteration and partitioning (Hardison, 2020; Mullins, 2020). For example, ninth-graders described a 1° angle by attending to the space between the angle's rays as the measurable attribute of angle, and utilized iteration (repeatedly producing 1° angle copies, where 360 copies would form a full circle) or partitioning (successively dividing a known angle into equiangular parts to produce a 1° angle) to quantify the attribute (Hardison, 2020).

The CCSSM's description of 1° angle as a *turn through 1/360 of a circle* suggests the amount of turn as a measurable attribute of angle. Clements and Burns (2000) have argued that understanding angle as a turn is important for students' ability to estimate angle measure. However, conceptualizing angle dynamically as a turn does not guarantee that the angle is viewed quantitatively as *an amount* of turn. Mitchelmore suggest that the difficulty in this conceptualization could be because, "young students do not *spontaneously* conceptualize turning (as found in rotation and hinging situations) in terms of angles" (1998, p. 278, emphasis added).

Since the quantification process being mental actions, where different individuals may have different quantification approaches for the same object, learners quantify angle measure using the length of the angle's subtended arc (Moore, 2013) or the space between the angle's rays (Hardison, 2020) as the angle's measurable attributes. Additionally, researchers reported that learners often spontaneously attend to other measurable attributes of angle (Crompton, 2017; Devichi & Munier, 2013; Keiser, 2004; Lehrer et al., 2012; Thompson, 2013). For example, students associate angle measure with the length of its rays (Keiser, 2004), or the linear distance between the angle's rays (Thompson, 2013). Additionally, students associate angle measure with the angle's orientation, where a change in the angle's orientation (e.g., from the horizontal) is conceptualized as causing a change in the angle's measure (Crompton, 2017; Devichi & Munier, 2013; Lehrer et al., 2012).

Approaches to angle measure that are different from the conventional arc approach indicate that learners may not spontaneously consider the angle's subtended arc as a measurable attribute of angle, suggesting a need for research that explores and acknowledges learners' spontaneous approaches to angle measure (Hardison, 2019, 2020). I address this need by exploring PSTs' spontaneous strategies to solve a problem situation that involves a circular context.

Methods

Participants and Context

The participants for this study are 65 PSTs who were enrolled in an elementary teacher preparation program at a Midwestern university in the United States. The PSTs were near the end of their program: They had already completed all the required mathematics for elementary school teachers courses and participated in this study as part of in-class activities in their elementary mathematics methods course.

Task

PSTs were given a task imbedded in an integrated science, technology, engineering, and mathematics (STEM) context, which involves designing a rocket. Through the design process, students learn that rockets need three fins to fly stably. Using rulers, tape measures, and waxed string to complete the task, the PSTs were given a table with two circles representing the body of two rockets from above to draw their fin placements (Figure 1). PSTs drew their representation of a rocket with three evenly spaced fins, and a second rocket with three randomly spaced fins.

<table>
<tr><th>Rocket 1
(with 3 evenly spaced fins)</th><th>Rocket 2
(with 3 randomly spaced fins)</th></tr>
<tr><td></td><td></td></tr>
<tr><td colspan="2">- What mathematical concept did you use to evenly space the fins?
- Using the previously mentioned concept, what was your strategy to evenly space the fins?</td></tr>
</table>

Figure 1. Placing Three Fins Around a Circular Rocket Model Task

While the task does not explicitly refer to angle measure, the circular context builds on the convention of measuring angles in relation to circles. The task aimed to discern the measurable attribute the PSTs would *spontaneously* attend to, and to answer the research questions: (1) What proportion of participating PSTs would associate the circular context to angle measure? (2) Given a circular context, what measurable attribute do PSTs (spontaneously) attend to?

Data and Analysis

The data for this report are PSTs' drawings and written responses to the previous task (Figure 1). I initially sorted the PSTs' drawings based on accuracy using a transparent template (Figure 2) to assess if PSTs' fins placement falls within an acceptable range (Zolfaghari, 2023).

Figure 2. Transparent Template of Acceptable Range for the Fins Placement

PSTs' drawings and written responses were then categorized using thematic analysis (Saldaña, 2013), with attention to the solution strategies and measurable attributes the PSTs attended to when completing the task. Specifically, some PSTs explicitly referred to using *angle measure* to complete the task, while other PSTs used *partitioning*. Additionally, since quantifying angle measure involves using the length of the angle's subtended arc (Moore, 2013) or the space between the angle's rays (Hardison, 2020) as the angle's measurable attribute, the initial categories were attending to *circumference* or *circle interior* as the measurable attribute. Table 1 shows the categories used to organize the data, which were not mutually exclusive. For example, a PST who operated on the circle's interior could have also utilized partitioning.

Table 1: Categorization of PSTs' Written Response to the Task

Category /Code	Accuracy		Solution Strategy		Measurable Attribute	
	Within acceptable range	**Outside acceptable range**	**Angle Measure**	**Partitioning**	**Circle's Interior**	**Circumference**
Description	Evenly spaced fins within an acceptable range based on the template in Figure 2.	Fins placed outside the acceptable range of the template in Figure 2.	Explicitly referring to angle measure in the response.	Breaking a whole into different parts. Breaking the circle into three $\frac{1}{3}$ fractions.	Attending to the interior of the circle to complete the task.	Attending to the circle's circumference to complete the task.
Examples						

Findings & Discussion

In this section, I highlight the frequency of PSTs' responses categories, and relate the findings to existing literature. Curriculum standards emphasize understanding angle measure as a fractional amount of a circle (NGA & CCSSO, 2010), suggesting a connection between fractions, circles, and angle measure concepts. Using and connecting these mathematical representations is considered an effective practice for learning and teaching mathematics (NCTM, 2014). However, only 26% of the PSTs connected the circular context to angle measure, suggesting that the connection between fractions, circles, and angle measure might not be spontaneous for learners (Hardison, 2020; Hardison & Lee, 2019; Moore, 2013).

Table 2. A Breakdown of Strategies and Measurable Attribute Applied by the PSTs

		65 Participating PSTs completed the task	
		Within Acceptable Range 57	**Outside Acceptable Range** 8
Solution Strategy	Angle Measure	16	1
	Partitioning	23	2
Measurable Attribute	Circle's Interior	43	7
	Circumference	14	1

While seventeen PSTs utilized angle measure to evenly space the three fins, only one explicitly referred to angle measure and used a string to evenly space the fins (circumference). The remaining PSTs who used angle measure operated on the circle's interior. Fifty-seven of the participating PSTs (88%) correctly spaced the three fins evenly around the circular rocket representation. Out of those fifty-seven PSTs, forty-three operated on the circle's interior, while fourteen used the circle circumference. Regardless of accuracy, fifty PSTs (77%) attended to the circle's interior as a measurable attribute, while fifteen PSTs (23%) utilized the circumference to complete the task. This suggests that understanding angle measure as a fractional amount of the circumference might not be supported (Moore, 2013; Thompson, 2008).

Conclusion

While measurement is a critical concept for (PSTs) enrolled in teacher education programs (AMTE, 2017), educators in such programs need to attend to and build on PSTs' existing and spontaneous approaches. Moore (2013) utilized the conventional approach to angle measure by emphasizing the relationship between the arc length subtending the angle and a benchmark associated with the circle containing the arc and is centered at the angle's vertex. Moore (2014) and Paoletti (2020) have demonstrated the benefit of the arc approach to angle measure for the study of trigonometry and inverse trigonometry, respectively. However, the arc approach was not spontaneous for participating PSTs, as most of them operated on the circle's interior. Although the fins would be placed physically around the circle (i.e., circumference), the PSTs partitioned the circle's interior as a solution strategy, reflecting that majority of the PSTs attend to the circle's interior as the measurable attribute given a circular context. This finding is not meant to describe PSTs' thinking as lacking. Instead, I would like to highlight PSTs' ability to successfully complete the task using various sophisticated strategies without needing to connect angle measure to the circular contexts (reflected in the few examples provided in Table 2). This finding suggests that understanding angle measure in relation to circles could be supported by building on PSTs' spontaneous attention to the circle's interior.

We report on a collaborative research study that coordinated two prominent theoretical perspectives (units coordination and spatial-numerical structuring) to build second-order models of students' geometric enumerations and measurement. We focus on one prospective elementary teacher, Jake, and his solution to a geometric enumeration task in two dimensions. This work contributes an in-depth explanatory account of Jake's reasoning in terms of his available units-coordinating actions and spatial-numerical structuring processes.

Keywords: Geometry and Spatial Reasoning; Number Concepts and Operations; Cognition; Learning Theory

Much research has investigated students' development of concepts and operations within geometric enumeration and measurement (e.g., Battista 2007; Barrett et al., 2017; Smith & Barrett, 2017). Spatial structuring, defined in the next section, is critical to students' spatial and geometric reasoning. Spatial structuring occurs via coordinations of mental actions such as iterating, partitioning, disembedding, and distributing—all mental actions involved in students' constructions and coordinations of numerical units (Hackenberg & Sevinc, 2024; Steffe, 1992)—as well as spatial mental actions such as rotating, translating, and reflecting. Meaningful measurement reasoning entails a *spatial-numerical linked structuring* (SNLS; Battista et al., 2018). Although units coordination and SNLS have similar constructivist roots and draw on a set of common mental actions, few studies (e.g., Antonides & Battista, 2022; Wheatley & Reynolds, 1996; Zwanch et al., 2023) to date have explicitly coordinated these perspectives.

In this paper, we coordinate the units coordination and SNLS perspectives to offer an in-depth theoretical account one case-study student's reasoning: Jake, a prospective elementary school teacher. We specifically focus on Jake's solution to a non-routine geometric enumeration task within an area context. Consistent with our constructivist epistemology (Beth & Piaget, 1966), we frame Jake's solution in terms of his available mental actions and their coordination. In summary, we seek to answer the following research question: *What spatial and numerical mental actions do students use and coordinate to solve non-routine area measurement problems?*

Theoretical Perspectives

Units coordination is a theory that explains students' capacities for constructing and coordinating multiple levels of quantitative units; for thorough overviews of the theory, see (Hackenberg & Sevinc, 2024; Ulrich, 2015, 2016). In brief, students at Stage 1 can reliably act on units of 1, through mental actions such as *iterating* and *partitioning*, to construct composite units (or two-level units)—collections of units conceptualized as units themselves. Students at Stage 2 can act on units of one using the mental act of *disembedding*, and they can actively iterate composite units to construct composites of composite units (three-level units). Student at *advanced* Stage 2 (Hackenberg & Sevinc, 2022; Tillema & Antonides, 2024) can also flexibly switch between different two-level units in their problem solving, such as switching between three twos and six ones as measures of the same quantity. Students at Stage 3 can bring three-level units into problem situations without needing to actively construct them.

We use the term *spatial structuring* in two senses. On one hand, spatial structuring refers to the mental process (a coordination of mental acts) of constructing a spatial organization or form for one or more objects (Battista & Clements, 1996). On the other hand, we refer to the "spatial structuring perspective" to refer to the body of research literature that frames students' spatial enumerations and measurement in terms of their structuring of spatial objects (e.g., Battista, 1999, 2007; Battista et al., 1998; Barrett et al., 2017; Clements et al., 2018; Cullen et al., 2018). Within this perspective, researchers have long investigated students' application of numerical concepts and strategies for enumerating spatial objects. Battista et al. (2018) introduced the term *spatial-numerical linked structuring* (SNLS) to capture reasoning that links spatial structuring and numerical structures; we view units coordination as a potentially powerful way of explicating students' SNLS.

Methodology

Jake was a student enrolled in the first author's content course focusing on geometry and measurement. Toward the start of the semester, we engaged Jake in one 45-minute semi-structured interview (Clement, 2000) in which we asked him to "think aloud" about his reasoning. We chose geometric enumeration tasks (including length, area, and volume) that we hypothesized would evoke SNLS and units-coordinating actions, without evoking procedural responses (e.g., finding area by multiplying L×W). We focus on Jake's solution to one enumeration task in an area context.

Pattern Tiles Task: (Part 1) How many green triangles would it take to cover Pattern 2 with no gaps or overlaps? (Part 2) How many green triangles would it take to cover the other patterns? [See Figure 1.]

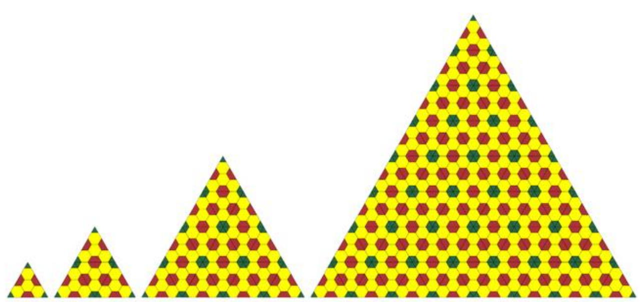

Figure 1: Image presented during the Pattern Tiles Task.

Using guidelines for networking theoretical perspectives (Kidron & Bikner-Ahsbahs, 2015; Prediger et al., 2008), we developed a plan for analyzing data and integrating our analyses. The four researchers split into the "spatial team" (Antonides and Battista) and the "numerical team"

(Zwanch and Norton). Each team developed a codebook consisting of mental actions suggested by existing research literature. Certain codes were common to both teams (e.g., unitizing, iterating, partitioning and subdividing), while other codes were particular to the spatial team (e.g., decomposing, rotating, transposing) or numerical team (e.g., disembedding). Codes appear in our Findings section as italicized mental actions. Each researcher first independently coded Jake's reasoning using their team's codebook, followed by team meetings to discuss and resolve discrepancies. We then engaged in a multi-stage process of collaboratively writing and integrating explanatory accounts of Jake's reasoning. For the Pattern Tiles Task specifically, Antonides wrote an initial analysis of Jake's reasoning from a spatial structuring perspective, then Zwanch wrote an analysis from the units coordinating perspective. Battista then wrote an integration of the two analyses, which Norton further developed and refined.

Findings

Data Excerpt. Jake was posed with Part 1 of the Pattern Tiles Task (triangles in Pattern 2). Three excerpts from his response are provided. The interviewer (Antonides) asked only clarifying questions aimed toward better understanding Jake's reasoning with minimal intentional influence.

> *Jake:* There's six triangles in each hexagon. … And also same with the trapezoid one, it's still a hexagon. It's two trapezoids, though. So, then that would be six triangles as well for each hexagon, as well as each trapezoid that's in there. So, but, some of them are cut off. So, there'd be 1, 7, because I counted those six. 10. 13. 16. Um. 22. Yeah. Um, 28. 34. 40. 43. [pause] 49. 52. 58. 64. 72. 76. Um. That'd be 82. 88. 91. 92, 93. 99. 105. 111. 117. 123. 129. [continues uttering number words inaudibly.] 144.

Analysis. We infer that Jake's solution of 144 green triangles was the product of his coordination of multiple spatial and numerical mental actions in an additive SNLS. To facilitate this SNLS, Jake seemed to treat each triangle, trapezoid, and hexagon as single entities (suggesting *unitization*) that he could *iterate*. Jake also established numerical relations between each shape by spatially *subdividing*, and numerically *partitioning*, each trapezoid into a unit of three triangles and each hexagon into a unit of six triangles. That is, each trapezoid and hexagon represented, for Jake, a two-level structure: one shape that can be subdivided into multiple congruent triangles. Moreover, Jake seemed to flexibly switch between two-level structures—six triangles to one hexagon, three triangles to one trapezoid, and two trapezoids to one hexagon—in his enumeration. This suggests Jake was operating at advanced Stage 2 of units coordination, though the image in Figure 1 may have provided material for facilitating Jake's switching between unit structures.

Data Excerpt. A moment later, Jake made comments relating Patterns 1 and 2.

> *Jake*: Pattern 2, the triangle is double the size of Pattern 1. … It just seems like the tip of Pattern 1 is like in the middle [of Pattern 2]. … So it, at first glance, it looks like it's double. [pause] But it also may not be because in here [Pattern 1], there's only four of the hexagons. And there's a lot more than eight in that [Pattern 2].
>
> *Int*: Okay. Yeah, what do you think is the relationship between Pattern 1 and Pattern 2?

Jake: There's four of Pattern 1 in Pattern 2. … 'Cause I can see the, the lines in it where you can break it up into the smaller Pattern 1 triangles.

Jake [a moment later]: I guess I could divide that [144] by four to find that answer. … Actually no, I think you might divide by three, because you still want to keep one of them. So, if you divide it by three, that essentially eliminates those three triangles. … No, you divide by four because then you're finding out how many is in each one.

Analysis. We infer that Jake's initial focus was not on the relative areas of each pattern, but rather on their relative heights, given his assertion that Pattern 2 is "double the size of Pattern 1." Jake spatially *subdivided* (numerically *partitioned*) the height of Pattern 2 into two parts, each equal to the height of Pattern 1. He quickly re-conceived the relation between Patterns 1 and 2, shifting his attention from length to area. He first did this by *disembedding* and *iterating* hexagons within each pattern, and using the number of hexagons as an indicator of the patterns' relative areas. Then, he *unitized* Pattern 1 and *partitioned*/*subdivided* Pattern 2 into parts that were each congruent to Pattern 1, articulating a four-to-one relationship between their areas.

Having constructed a multiplicative SNLS relating Patterns 1 and 2, Jake anticipated he could divide 144 by some number to find the number of green triangles needed to cover Pattern 1. However, he experienced uncertainty about the appropriate divisor: three or four. We infer Jake experienced a moment of transitioning between additive and multiplicative thinking: removing all but of Pattern 1 (divide by 3) versus finding the number of green triangles within one copy of Pattern 1. This kind of transitioning is characteristic of Stage 2 students since they need to build multiplicative structures in activity. Jake ultimately decided dividing by four made more sense, though he did not actually carry out the computation 144÷4.

Data Excerpt. Jake was then posed with Part 2 of the Pattern Tiles Task. He first used a highlighter to subdivide Pattern 3 into units of Pattern 1.

Jake: So, you just multiply 144 times four. Because this one [Pattern 2] has four [of Pattern 1] right here, and then this one [Pattern 3] has 16 [of Pattern 1]. So that's four times four is 16. … Same way I did Pattern 2 and made the individual triangles and realized that there's one, two, three, four, five, six, seven on that first row. [Counted silently] Five on this row, three, and then one.

Int: Is that 16?

Jake: I think. [Counted subdivisions within Pattern 3] Yes, it does. So, in my head, I'm thinking it's a multiple of four.

Analysis. We infer Jake constructed a multiplicative SNLS by spatially *subdividing* (numerically *partitioning*) Pattern 3 into units of size Pattern 1, with the aid of the image. He also said that he could subdivide Pattern 3 into units of Pattern 2, but he seemed to need to engage in the act of counting units of Pattern 1 within Pattern 3 to conclude a four-to-one relationship between Patterns 2 and 3—indicating Jake *may* not have constructed this multiplicative relationship prior to counting. After constructing this relationship, however, Jake was able to use it to determine the number of green triangles needed to cover Pattern 3. We infer Jake constructed Pattern 3 as a three-level unit structure through his spatial and numerical activity: a unit of 16 units (Pattern 1), each containing some number of green triangles.

Discussion and Conclusion

Jake applied and coordinated several spatial and numerical mental actions to solve each part of the Pattern Tiles Task. Both types of actions were critical to Jake's constructions and coordinations of units. Our findings underscore the importance of researchers attending to both spatial and numerical mental actions in building second-order models of students units coordinating activities, especially in tasks embedded within spatial contexts. Although this work has clear limitations—e.g., working with a single student, and presenting data on only a single task—we view this work as an important step toward future research that incorporates both spatial structuring and units coordinating perspectives. We suggest two potential avenues for future research. First, researchers could further examine and explicate the role of students' units coordinating structures in their SNLS (Battista et al., 2018). In particular, researchers could examine younger (e.g., Stage 0 and Stage 1) students' SNLS, particularly their spatial structuring and units coordinating actions. Second, researchers could extend our work focusing on length, area, and volume, to the context of angle measurement (e.g., see Hardison, 2024; Mullins, 2020).

SURFACE EXPLORER: INVESTIGATING 3D SOLIDS THROUGH LARGE-SCALE SURFACES IN VIRTUAL REALITY

Izge Bayyurt
University of Maine
izgebayyurt@gmail.com

Justin Dimmel
University of Maine
justin.dimmel@maine.edu

Keywords: Geometry and Measurement, Technology and Learning Environment Design, Mathematical Processes and Practices

Currently, most of the research projects in math education involving virtual reality (VR) have its users interact with smaller-than-human scale geometrical objects. These projects leverage the immersive/interactive nature of the VR environments to provide spatial alternatives to teaching 3D geometry through two-dimensional silhouettes (Palatnik & Abrahamson, 2022). While these initiatives are exciting, our goal has been to find ways VR allows its users to experience mathematical ideas that can't be replicated in another medium.

This pointed us towards the gap in the literature that involves exploration of geometric objects that are larger than what we can observe from a single vantage point. At these large scales, the defining features of geometric shapes will be lost to our senses. As an example, standing on top of a large rectangular prism is indiscernible from standing on top a large cube when the horizon extends far enough that the defining features of these solids- the shape of their faces- can't be known trivially. Our goal with this project is to find out how these macro-scale geometric objects could be used in an exploration task.

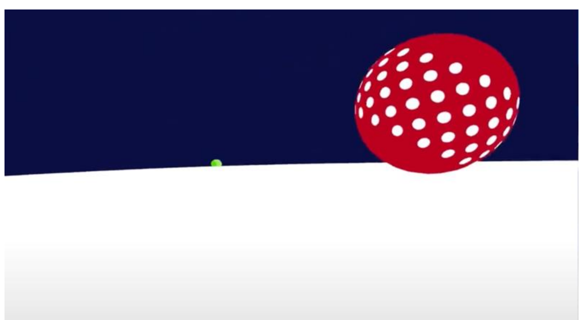

Figure 1: 2 rolling balls, green one disappearing off the horizon, red one is closer.

With these considerations in mind, we designed Surface Explorer as a playful experience that allows students from all backgrounds to engage with a mathematical task in a way that doesn't confront them with mathematics. The environment allows users to roll virtual balls on various surfaces to figure out the shape of the surface they are on. We argue that this novel experience enables students to make mathematical arguments using both mathematical and non-mathematical content knowledge through verbal and non-verbal language. Furthermore, the students' ways in orienting themselves in the space and describing what is happening around them provides information about how they think about 3D geometry outside of a classroom setting.

Through a more extensive study we aim to understand the potential value of investigating macro-scale geometries in classroom settings. We hope that investigating geometrical questions through a novel lens will create new learning opportunities for a wider range of students.

CHANGES IN STUDENTS' DESCRIPTIONS OF SPATIAL MOVEMENTS ON A GRID

Precision in language plays an important role in spatial thinking as well as computational thinking. We present results of a study where 26 first and 25 third graders provided verbal instructions for how a character should move along a path to reach a target on two occasions: at the beginning of a study and after playing a programming game with a peer for three, 20-minute sessions. Some of the students also analyzed worked examples of programs at the beginning of their sessions. Results suggest that analyzing worked examples of programs supported students in using more specific spatial language and articulating the number of movements.

Keywords: Geometry and Spatial Reasoning; Instructional Activities and Practices; Cognition; Computational Thinking

Language plays a key role in spatial thinking (e.g., Clements & Sarama, 2009; Hallowell, 2020; Owens, 2015). In line with the mathematical practice of attending to precision in language (National Governors Association Center for Best Practices & Council of Chief State School Officers, 2010), spatial tasks may involve students communicating and explaining specifics of direction, distance, and location using correct mathematical language (e.g., up, left, next to, etc.). This mathematical practice also plays a role in computational thinking practices that are aligned with programming (Wing, 2006). For example, a key computational thinking practice aligned with mathematics is algorithmic thinking. Algorithmic thinking involves being able to represent and make sense of steps of a process, whether it is interpreting equations in mathematics or programming a robot to complete a task in programming. Students might not realize the need for precision in their use and choice of language if they work alone to program characters to move; however, playing with a peer or analyzing worked examples of a program could help them see the need for precision in their language. The purpose of this study was to investigate how analyzing worked examples of programs and playing with a peer could support students in clearly explaining movements of a character on a grid as opposed to playing with a peer but without analyzing worked examples of programs.

Theoretical Frameworks: Computational and Spatial Thinking

Spatial Structuring, Orientation, and Language

Many early programming games for young students involve controlling movements of a robot or character on a grid (e.g., Coding Awbie™, ScratchJr, Code & Go® Robot Mouse). Programming movements typically requires students to input a direction and number of movements (and sometimes indicate a type of movement). However, to make sense of movements on a grid, students need to understand the columns and rows structuring of the grid (Clements & Sarama, 2009). Students who are developing their spatial structuring of arrays might double-count squares as they switch directions from counting along the column to a row (or vice versa; Battista et al., 1998). In programming, Kocabas et al. (2019) found that some first and third graders double-counted corner squares when programming a character to move on a grid, and they also found that sometimes students double-counted the character's initial square. Shumway et al. (2021) found similar results for kindergarteners who counted the initial grid space when programming a robot on a grid. To move a character on a grid, students need to have an external-based reference system for considering position and movement (Clements & Sarama, 2009). Such positioning may be particularly confusing because different games handle directional movements in contrasting ways (i.e., depending on the character's point of view versus the character's overall position). For example, to move the Code & Go® Robot Mouse to the left, a student would need to program it to turn until it is facing left and then program it to move forward. However, in Coding Awbie™, the student would only need to play a move left block (regardless of where the character Awbie is facing). Students must navigate these interpretations to create algorithms (the series of steps) for the program to execute.

Aside from making programs, students, especially if they are working in groups or talking to others, also need to be able to verbally explain how the character should move. In other words, they need to be able to communicate the algorithms they create or want to create. Typically, children's use of the words *up* and *down* develops early, followed by words such as *beside* and *over*, with horizontal directions *left* and *right* causing more difficulty (Clements & Sarama, 2009). Compared to adults, Lloyd (1991) found that 10-year-olds tended to rely on landmarks, when sufficient, instead of directional words when describing a route based on a simple map. In another route-describing task, six-year-olds relied on language such as *over there* or *forward* to describe movements, only rarely using specific directions, such as *right* (Blades & Medlicott, 1992). In the same study, eight-year-olds used left and right more often, but only used them correctly about a third of the time. Shumway et al. (2021) found that kindergarteners sometimes used *right* and *left* but more often used language such as *here*, *there*, and *forward* (often accompanied by gestures) when describing how to move a robot. Although Clements and Sarama (2009) suggest avoiding the use of words like "over" that are not specific enough in bi-directional spaces, there is little work suggesting what conditions help students take up more specific language.

Cohen and Emmons (2017) used the coding system developed by Cannon et al. (2007) to describe students' language about space in block-building tasks that included several categories such as spatial dimensions and features. Aspects of the framework that align well with describing movements on a grid include language related to *location and direction* and *continuous amounts*. Kocabas et al. (2022) used a modification of this framework in their work where students had to identify and fix discrepancies between a Lego manual and a Lego structure. They further categorized references within the language categories as specific versus generic. We build on this work by focusing on the location and direction aspects of spatial language in describing how a character should move on a grid within a programming study.

Worked Examples

Students need explicit experiences connecting mapping experiences with math (Clements & Sarama, 2009). One way to do this is through the analysis of worked examples. When students analyze worked examples, they can identify the important problem features and learn about solution steps (Booth et al., 2015; Durkin & Rittle-Johnson, 2012). Studying worked examples can promote effective problem-solving strategies and precise use of mathematical language when accompanied by opportunities for self-explanation or guided practice (Booth et al., 2013; Lang et al., 2014). Research has shown students' conceptual knowledge improves when analyzing worked examples, particularly for novice learners, and when those worked examples are incorrect (Durkin & Rittle-Johnson, 2012). This way, students can make sense of common errors in a particular incorrect worked example.

Current Study

Although there is extensive research on the use of worked examples in learning mathematical concepts, particularly in algebra (e.g., Booth et al., 2015), less is known about its role in developing students' mathematical practices and spatial language. In this study, using the context of the Coding Awbie™ programming game, we explored the role of analyzing worked examples of programs on students attending to precise mathematical language to explain movements on a grid. We focus on the following research questions: What is the role of analyzing worked examples of programs on students' explanations of Awbie's movements on a grid? What patterns arise in their explanations?

Method

Participants and Design

For this paper, we analyzed data from 26 first and 25 third graders who were from a US midwestern elementary school. The school's population included 45% economically disadvantaged students and 11% English Learners. In the study, students first took a pretest in the form of an individual interview. After the pretest interviews, students were randomly assigned to a play-group condition ($n = 27$) or an explain-group ($n = 24$) condition. Each condition lasted for six, 20-minute sessions during which students worked with partners to play a programming game where they controlled the character Awbie's movements on the iPad using tangible programming blocks. Students who were in the play-group condition played the Coding Awbie™ programming game in pairs for three sessions, took a midtest, and then in the next three sessions, they explained worked examples of programs, corrected incorrect worked examples, and played the programming game in pairs. Students in the explain-group condition started the first three sessions by explaining worked examples of programs and playing the programming game, then they took a midtest and participated in a presentation about programming applications, and for the last three sessions, they only played with the Coding Awbie™ programming game. After students completed their six sessions, they took a posttest, which followed the same procedure as the pretest (see Figure 1). For this paper, we focus on the pretest, first three sessions, and midtest, because changes from pretest to midtest reflect the difference between only playing the game (play-group condition) versus playing the game *and* analyzing worked examples (explain-group condition).

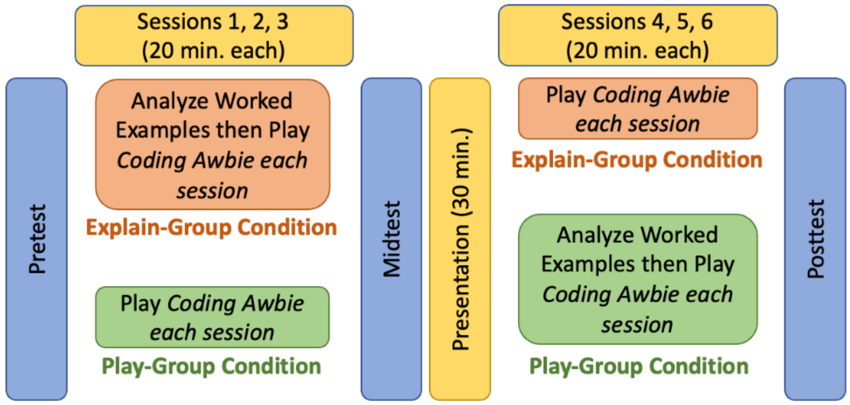

Figure 1: Study Design

Materials

In the individual pretest and midtest interviews (taken about a month apart), students responded to problems such as explaining Awbie's movement, debugging a program, and making a program. We focus on one of the problems that required students to explain how a character should move on a path (as an informal way of creating a program), which was given on the pretest and midtest (see Figure 2 below). The path was rotated 180º on the midtest so that students would not be able to use their explanations from the pretest.

Pretest Instructions: Awbie (point to character) can jump over flowers, bushes, or small rocks but not trees. Tell us a story about the movements Awbie made to get to the Red strawberry (point to it) using this highlighted path (point to path). We will tell your story to another student without showing the path and see if they can guess which strawberry you had Awbie get, so make sure your story only works for getting this *red* strawberry (point to it again).

Midtest Instructions: Tell me a story about how Awbie moves on the yellow path (point to path) to get to this strawberry (point to strawberry). Make sure you use enough details that I could figure out how Awbie moved, even if my eyes were closed.

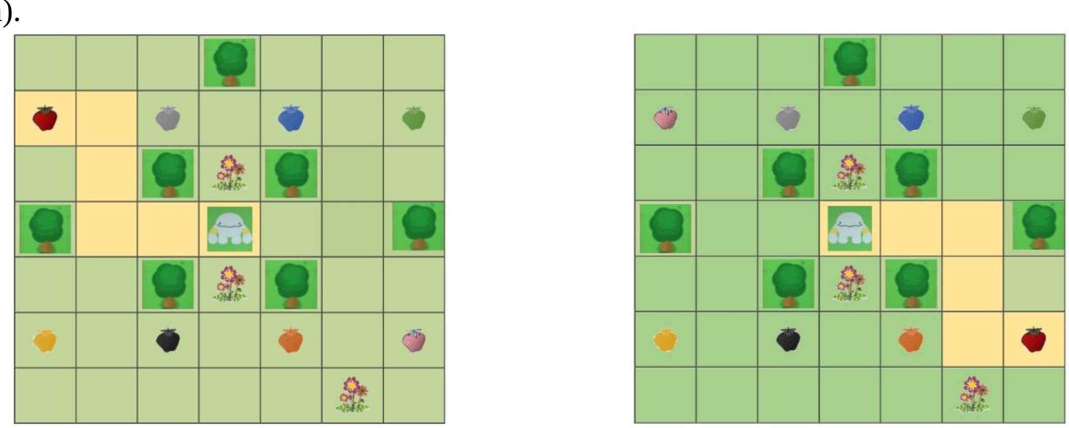

Figure 2: Explaining a Character's Movement Task on the Pretest and Midtest

In each of the three sessions when students in the explain-group condition analyzed worked examples, they analyzed one correct worked example of a program and one incorrect worked example of a program. During the second session, they also analyzed and completed one incomplete worked example of a program, for a total of seven worked examples across the three sessions. The worked examples showed scenes from the game and tangible programming blocks organized into a program to control Awbie's movements. As part of analyzing the worked examples, they also had to apply information from the worked example to a new program. The interviewer read the program to the students and then had the student pairs discuss their answers. Rather than giving feedback on their answers, the interviewer helped facilitate a conversation between the students, such as asking, "Do you agree with your partner? What do you think?" Figure 3 shows one of the worked examples of programs we used in the sessions. Importantly, in this incorrect worked example of a program, students were exposed to the directional words *down* and *left* and had to fix a double-counting error in the program (i.e., the correct program should be walk left (if no number is used, the default it 1), walk down 2, both of which are repeated 2 times).

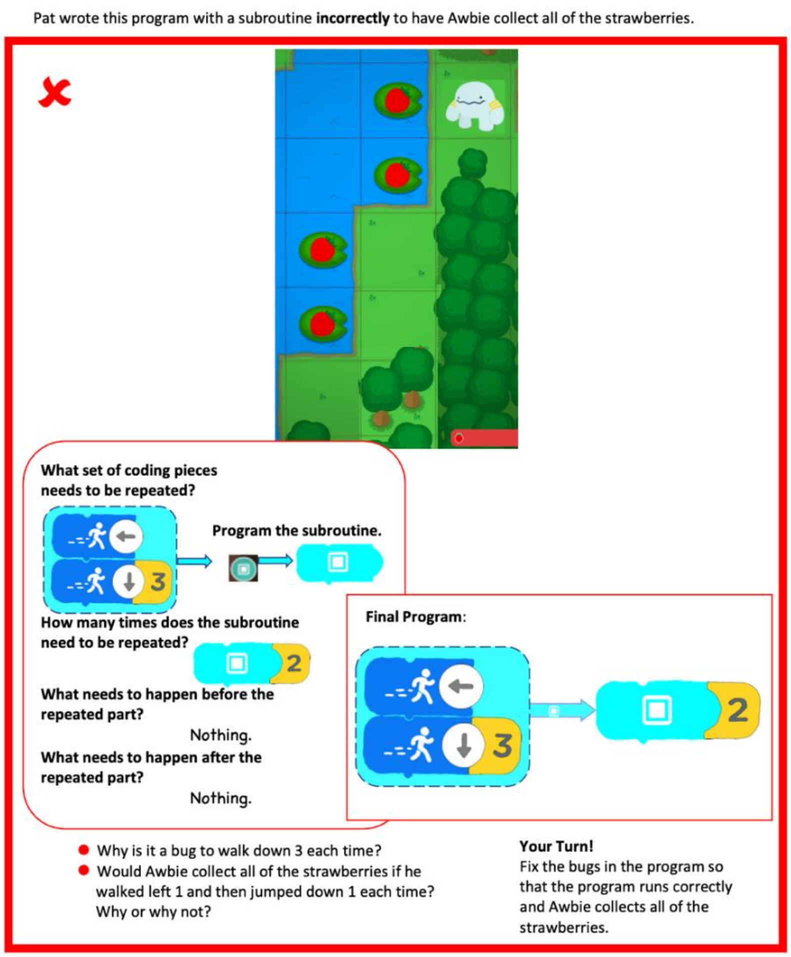

Figure 3: An Incorrect Worked Example of a Program in the Sessions

Analysis

We coded students' language by using a modified form of the framework described previously (Cannon et al., 2007) with the sub-category *specific* versus *generic* distinction used in Kocabas et al. (2022). Further, because our work involves situations where the character could move both up and down and left and right (i.e., specific language), in our sub-categories, we wanted to account for language that specified a horizontal movement but was not specific enough to describe which horizontal direction (e.g., "over"). We classified words that fell into this sub-category as semi-specific language. The location or direction category includes students' use of words indicating where Awbie is or would go. The number category includes students' descriptions of how far Awbie should move. The movement category includes descriptions of how Awbie should move (see Table 1 for examples). We ended up adding a descriptive sub-category for the location or direction category to better capture the meaning of some students' explanations. After coding the categories, we further tallied which words students used within the *location or direction* category.

Table 1: Spatial Language Examples by Sub-Category Codes

Spatial Language	Specific	Semi-specific	Generic	Descriptive
Location or Direction	right, left, up, down	sideways, next, over, straight	here, (over) there, on the trail, this way	easy, hard, long, short
Number	number words	another	a little bit	n/a
Movement	walk, run, jump	turn	move(s), go(es)	quickly

Results

Location or Direction Language

Overall, the play-group condition started out on the pretest using the directional word *up* more than students in the explain-group condition (74% of students versus 33% of students). If students improved on language related to the vertical dimension, we would expect them to use the word *down* on the midtest (recall that the path went down instead of up on the midtest). We found this to be the case with 93% of students in the play-group condition and 79% of students in the explain-group condition using *down* in their explanations. The explain-group saw greater growth in using specific terms for the vertical dimension than the play-group (46% more versus 19% more); however, the play-group also had less room to make gains since more used this language on the pretest. As an example of students' language changes, one first grader (ID: Duck4) in the explain-group condition explained the pretest path, "He has to walk *over here* and then go to *here*." On the posttest, he said, "Go two. Go two more *down*, then over."

The results for language related to horizontal movement, however, add more nuance. Typically, students who used the incorrect term (e.g., *right* instead of *left*) also self-corrected and used the correct term (see Table 2, e.g., *left & right* column); however, a couple of students did use the incorrect horizontal term exclusively (see Table 2, e.g., the *right* column percent is less than the *left & right* column percent for pretest). For example, one third grader (ID: Horse7) explained on the pretest, “He’s going to have to move twice to the right. Yes, twice to the right (points to the left).” Once again, the play-group condition used the correct term *left* more on the pretest than the explain-group condition. However, the play-group condition did not gain in the number of students using *right* in their midtest explanations; on the other hand, more students in the explain-group condition used *right* by the midtest and overall compared to students in the play-group condition. One third grader (ID: Horse5) from the explain-group condition had a dramatic change in explanation. On the pretest, she merely said, “He can walk.” On the midtest, she explained, “So he’s going to go over to the *right two times*. And then he’s going to go *down two times,* then over again to the *right* to get the strawberry. He will be walking.”

Other interesting patterns in terms of directional language included that students who did not use the specific terms *left* or *right* were most likely to use semi-specific terms *to the side*, *sideways,* or *over* on the midtest as well as *forward* and *straight* on either test. They also used non-specific terms *this/that way* and *over/right there*. Often, students mixed terms. For example, a first grader in the play-group condition explained on the midtest, “So he goes *this way* twice, *down* twice, and *over* one” using a non-specific, specific, and semi-specific term. On the pretest, two students (one from each condition: ID: Sheep5 and Sheep7) even described the movement as a *zigzag*, finding a way to characterize the set of movements. Another first grader (ID: Duck7) just called this “making a Z.”

Table 2: Percent of Students Using Specific Horizontal Direction Terms and Gain

	Pretest			**Midtest**			**Gain**		
Group	**Left**	Right	Left & Right	Left	**Right**	Left & Right	**Correct term**	Incorrect term	Left & Right
Play	**33%**	19%	37%	11%	**26%**	37%	**-7%**	-8%	+0%
Explain	**8%**	8%	13%	0%	**42%**	42%	**+34%**	-8%	+29%

Note. Bold indicates percent of students using the correct term to describe the direction on the path.

Number and Movement Language

In terms of students’ use of numbers to help describe the movements, there were similar trends as with the directional language. The play-group condition had more students designating the number of movements on the pretest than the explain-group condition (20% versus 13%). However, on the midtest, the play-group condition had fewer students designating the number of movements than the explain-group condition (48% versus 58%). This means that 45% of students in the explain-group condition improved in using numbers in their explanations compared to 28% of students in the play-group condition.

Although some students used numbers, they double-counted and stated an incorrect number of movements. For example, eight students double-counted a corner square. On the midtest, a third grader (ID: Goat5) said, "I think he would do one, two to this way (points to the right) and *one, two, three* down and then one across. Five students also double-counted the initial square. For example, the same third grader (ID: Goat5) on the pretest said, "So you would go *three* and then stop, and then turn and go two, and then turn and get to the strawberry." Another third grader (ID: Horse8) double-counted both the initial square and both corner squares, describing, "He can go from this by counting from one – it's like *one, two, three*. And then three, you can go down *one, two, three*, and then over one – over *two*." A third grader (ID: Rabbit5) explained the movements and revealed how some might consider double counting the initial square, "So he moved two, but he technically moved three because he's on the third one. But he would move two." Another first grader (ID: Goose8) explained the difficulty in a similar way, "Right, it's three, *but he's on the first one*. I think that's *go two…*"

Exclusively on the pretest, four students used individual movements to indicate the total distance to cover rather than using numbers. For example, one third grader (ID: Horse6) explained, " It would be left, left, up, up, left. And then he gets the strawberry." Another five students described how they needed to move two spaces on the horizontal and the vertical dimension but then used alternative words to indicate movement of one space on the final horizontal dimension. For example, one first grader (ID: Duck4) on the midtest said, "Go *two*. Go *two* more down, then over."

Discussion

As with prior research (Blades & Medlicott, 1992; Clements & Sarama, 2009), students in this study had an easier time using specific words to describe movements on the vertical dimension (i.e., up, down) than the horizontal dimension (i.e., left, right). However, by the midtest, the students in the explain-group condition used the term *right* more than found in prior research, suggesting that analyzing worked examples where designating direction is important might help them see a purpose in using more specific language themselves. Such modeling might be especially important if in their typical spatial tasks, students are working together with the same vantage point and are used to assuming others know what they are talking referring to and can see where they are pointing. They need more experience considering situations where others might do a similar task later. Focusing on specificity of language tasks such as these could serve as a helpful foundation for considering precision in language for other areas of mathematics. For example, the class could consider what they mean by *zigzag* and come up with a definition for how to indicate the size or dimensions of a *zigzag*. This could lead to students adopting horizontal and vertical language or coming up with a class-accepted precise definition for *zigzag*. In turn, such discussion could support inquiry around the definitions of shapes.

Interestingly, some students, even in the explain-group condition, double-counted after playing the programming game for three sessions. Students in the explain-group condition also analyzed a worked example that involved double-counting. It is possible that the double-counting needed to be more explicit, such as was the case when kindergarten students programmed a robot, Shumway et al. (2021), to encourage students to consider the implications of double-counting. For example, in a revised version, students could compare a worked example where a student made a program that involved double-counting versus a worked example where a student did not use double-counting and then could discuss which one works and why. Surprisingly, only third graders double-counted. One reason may be that first graders used numbers slightly less often. Yet, it is surprising that there was not even a single instance of a first grader double counting. The tension between seeing three spaces but only needing to move two spaces (because the character was on one of the three spaces) may be the reason that students double-counted the initial space. It is possible they were considering the initial space as where the character should be placed to start. Students might have also reverted to double counting the corner pieces if they were used to finding the area of arrays (where double counting the corner is needed to find the length of each side).

Overall, the students in the explain-group condition appear to have benefited from the opportunity to analyze worked examples beyond what the play-group condition got from only playing the game. These results provide additional evidence for the benefit of using worked examples to support students' learning of new concepts but also provide initial evidence for worked examples' potential for supporting students' precision in language use. Using worked examples to support mathematical practices is an area that needs to be explored further.

FORMAL AND INFORMAL PROOFS IN HIGH SCHOOL GEOMETRY

Óscar Chávez
Illinois State University
ochave2@ilstu.edu

Keywords: Reasoning and Proof, High School Education, Geometry and Spatial Reasoning

Are students who have been taught proofs more likely to respond to proof tasks correctly? In the study reported here, we describe differences in responses to proof items in tests used in a large-scale curriculum comparison study. The conceptual framework for this study was based on the proof schemes framework by Harel & Sowder (1998, 2007). In this framework, *proving* is "the process employed by an individual (or a community) to remove doubts about the truth of an assertion and includes two subprocesses: ascertaining (removing one's own doubts about the truth of an assertion) and persuading (removing others' doubts about the truth of an assertion).

The data reported here were collected as part of a longitudinal study in U.S. high schools, the COSMIC study (Grouws et al, 2013; Tarr et al, 2013; Chávez et al, 2015). This longitudinal study examined the impact of different content organizations on student learning. As part of a curriculum comparison study, we included items involving proofs in geometry (Chávez et al, 2011; Sears & Chávez, 2015). One of the items was designed to elicit an informal argument, for first-year high school students (n = 2508); the second was for students in the third year of high school (n = 1936) who had taken either a geometry course or an integrated course that included topics of proof in geometry. Given the longitudinal nature of the study, the students who took the second test had taken the first two years earlier.

For the first problem, of 2508 first-year students, 29% gave a complete correct answer, 25% a partially correct answer, 31% gave an incorrect response and 9% did not attempt the problem. For the second problem, of 1936 students, 12% did not attempt the problem and 56% gave an incorrect answer. Only 28 students, less than 2%, gave a complete correct answer.

As expected, first-year students did not attempt "formal" proofs. The answers given suggest that students relied on the pictorial representation and made reasonable assumptions that could be the basis of a correct proof. It is important to note that in their responses, students explained how they knew they had a correct answer. A vast majority of third-year students, more than half, did not give an incomplete or partially correct answer.

It seems that the third-year students were not reasoning about the question but instead trying to remember how proofs are supposed to be written. In contrast, more first-year students felt reasonably confident about figuring out an answer for the first problem precisely because it was an unfamiliar problem. Students with little or no instruction in formal proof are more likely to attempt an informal justification. Students who have been taught proofs seemed to have developed an external conviction proof scheme, relying either on the form of the proof (e.g., 2-column proofs) or on the authority of the teacher or textbook to determine what is a valid proof. This may explain why so many students did not write a correct or partially correct proof for the second problem.

Our results suggest that we should give students opportunities to explain how they know, focusing on the ascertaining process of the act of proving and helping them to make this process explicit. For many of the students in this study, writing a proof may have become a recall exercise not an opportunity to explain or justify.

INVESTIGATING PRESERVICE MATHEMATICS TEACHERS' SPATIAL REASONING IN PROBLEMATIZED TASKS

Lizhen Chen
Western Washington University
chenl24@wwu.edu

Keywords: Geometry and Spatial Reasoning, Preservice Teacher Education, Problem Solving

Learners engaged in reflective thinking often encounter a perplex, difficult, or hesitating situation and need to search for a solution that is not immediately apparent. Piaget (1960) described learners' struggles as a process of resolving disequilibrium and developing new understanding. Recently, Bjork and Bjork (2011) stated that tasks containing "desirable difficulties" can "optimize long-term retention and transfer" (p. 57). Little is known about individuals' internal struggles outside of whole-class discussion settings (Santagata, 2005). This study aims to use individual think-alouds and investigate how preservice elementary mathematics teachers' (PSTs) navigate cognitive struggles or uncertainties through problematized spatial tasks. The theoretical framework builds on Warshauer's (2015) categorization of learners' struggles and Park et al.'s (2022) phases of sensemaking amid uncertainties: (1) phenomena representation where learners interpret and represent the tasks and generate initial thoughts; (2) exploration where learners are engaged in problem solving by analyzing existing and new information and ideas, and generate explanations and reasoning; (3) application and evaluation where learners apply the generated reasoning to the represented phenomena, evaluate the potential solution(s), and possibly revise the initial thoughts.

This study is a part of a large study that explores the effects of technology and tangible manipulatives on PSTs' spatial reasoning. PSTs are enrolled in teacher preparation programs in a public university. Preliminary results report 13 elementary PSTs' spatial reasoning and learning struggles in eight 3D block building tasks. Using the think-alouds methods, PSTs' spatial reasoning processes were recorded. PSTs used multi-link cubes, virtual 3D Block Builder, or both to make 3D structures. All 3D block building tasks are problematized in ways that contain ambiguous or missing information and make multiple solutions possible. Data are coded into three phases of sensemaking. PSTs' certainties (e.g., confidence about an interpretation or a strategy) are coded along with uncertainties (e.g., confusion about some spatial vocabulary).

Results show that only two PSTs provided alternative 3D structures whereas the rest thought of only one 3D structure. In the *phenomena representation* phase, PSTs likely interpreted the problematized task hints as close-ended rather than open-ended. For example, task#2 only provided information about green and orange blocks in a three-block tower; PSTs considered the third block as either green or orange. In *exploration*, about one third of PSTs' spatial reasoning instances (104 in total) began with partial structures and then analyzed possible placements of other blocks. PST#6 built a two-block structure made of a green and a blue block before placing two other red blocks in task#5, which turned to be effective. In *application and evaluation*, some PSTs encountered an impasse when their initial ideas conflicted with given information; they tended to stick with their initial ideas without revisions when they applied their reasoning to build 3D block structures. These findings imply PSTs' early certainties about block quantity, colors, or spatial relationships in the phenomena representation phase could cause uncertainties in later phases. Investigating PSTs' certainties and uncertainties in mathematical sensemaking sheds light on instructional scaffolds that teacher educators could provide.

TOWARD DECOMPOSING THE CIRCLE: LEARNING TO JUSTIFY THE AREA FORMULA FOR A CIRCLE

Dana Cox

Jane-Jane Lo
Western Michigan University
Jane-Jane.Lo@wmich.edu

In this study, we studied the impact of a one-time unscripted interaction with an applet on Preservice Teachers' (PSTs') justification of area formula of a circle. After just one classroom exposure including individual exploration, PSTs improved their understanding of this formula. However, for most PSTs, this one experience was not enough to overcome the epistemic gap between justifying the formula as an approximation of the area and a true deductive argument.

Keywords: Technology, Geometry and Spatial Reasoning, Instructional Activities and Practice, Preservice Teacher Education

Background and Literature

Being able to give an informal derivation between the circumference and the area of a circle is a common middle-grades standard (CCSSO, 2010), yet the curved boundary lends challenge to students used to working with polygons. A growing number of online applets and DGS sketches utilize dragging actions to transform geometric figures and provide students with opportunities to explore and act on figures while forming and verifying conjectures about embedded mathematical concepts (Leung, 2011). Using Geogebra, Or (2012) developed one such applet based on the mathematical storyline depicted in Figure 1, to help students bridge the epistemic gap between interpreting the area formula of a circle as an approximation and an exact value.

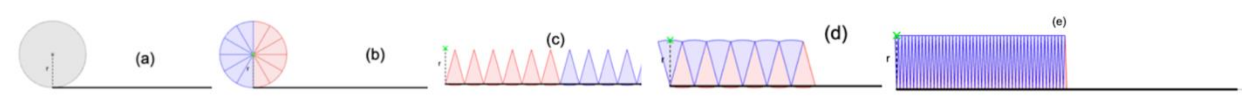

Figure 1: Illustrating the Storyline of Or (2013)'s Applet

Using a slider, the applet leads students through subdividing a circle into an increasing number of pieces. This subdivision is visible as a full circle (Figure 1b), an "unwrapped" circle (Figure 1c) and all positions in between. Once the circle has been unwrapped, continuing to drag the slider rearranges the sectors so that they form an approximation of a parallelogram (1d and 1e) that, if taken to infinity, would be a rectangle with dimensions r and πr. The area of which, we deduce, can be measured as πr^2.

In this study, we studied the impact of a one-time unscripted interaction with this applet on Preservice Teachers' (PST) ability to justify the area formula for a circle. After giving PSTs time to explore the applet in small groups, we brought the whole class together for a discussion of those experiences. Collecting data before and after this event, we asked, *to what degree does engagement with the applet change the way PSTs justify the formula, bridging the epistemic gap between interpreting the area formula of a circle as an approximation and an exact value?*

Methodology

This study was conducted in a Midwestern university. All participants (n=70) were enrolled in one of two sections of a course on geometry for preservice elementary teachers taught by Author 1. The data used in this study were collected at the end of a unit on measurement in which significant work had been done toward a deep understanding of linear and area measurement. This work included activity related to the meaning of perimeter and area in the context of simple and composed polygons. It was our hope that prior experience with decomposition of polygons would support their engagement with circles.

Instructional Sequence

Or (2012)'s applet, was chosen as the primary lesson delivery system to assist participants in applying the technique of decomposition to circles. Participants had used other pre-designed sketches in a unit on classifying special quadrilaterals. Like this experience, participants were asked to engage with applets in small groups prior to whole class discussion about that activity.

Following the applet experience, a whole-class discussion was facilitated by the instructor. During that discussion, the applet was projected at times on a pull-down screen and at times on a white board where PSTs could choose to draw, record predictions, or annotate images and locations where they found mathematical meaning. The goal was not to reteach or to make a demonstration, rather, to focus on specific interactions participants had with the applet and allow for reflection on the significance of those interactions.

Data Collection

Pre- and Post-test Data were collected to better understand how the applet is taken up by PSTs as a tool in justification. Prior to the applet exploration, PSTs were asked to write individual justifications for why the area of a circle could be found using a specified formula. We collected 69 hand-written justifications on blank white paper. Following the instructional sequence, we gave PSTs the same open-ended task of justifying the formula without specifically mandating or even suggesting the use of the applet as a tool. Specifically, PSTs were asked to submit work that "1) Shows that you understand the meaning of radius, diameter, circumference and area; and 2) Provides reasoning about the area formula for circles in your own words."

Data Analysis

We analyzed the pre-justifications first which generated the framework summarized in Table 1 along with our findings. We read through the set of all justifications looking for similarities and differences. Once an original set of categories were identified, we used an iterative process of reading through the data and refining the categories, such as with the category "dimensional analysis" which is described in more detail in a previous paper (Cox & Lo, 2019). When a response seemed to span two categories, we refined the categories when possible. However, when the category did not warrant subdivision, we placed each response according to the most sophisticated reasoning provided. We then applied this framework to the set of post-justifications and were able to use this data to refine the category of "decomposition." This refinement is summarized in Table 2 along with our findings.

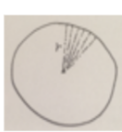
Findings

Exposure to the applet changed the way students thought about the formula for the area of a circle. These shifts are apparent in the type of attempted reasoning in the post-justifications compared to the pre-justifications (Table 1). Prior to exposure, 43.5% (n=30) PSTs sought to justify the symbolic formula through a process of symbolic deconstruction aimed at associating the dimensions of the circle with the symbols and operations within the general formula. We referred to this type of reasoning as *Dimensional Analysis.* In most cases, this meant finding meaning in the isolated terms r, r^2, and π. While r was always defined as the radius of the circle, there was more variation in the ways that PSTs found meaning in r^2 and π. Brandon was one who did reference *π*. He wrote, "*Because radius is half of a circle in order to get the full circle, you must square the radius. You then multiply by π because π is a measurement used in circles.*" Katie wrote, "*We do πr to find the distance around the entire circle. Then, you must multiply that number r again to account for all the area from the edge of the circle to the center of the circle.*" After exposure to the applet, only three PSTs used this type of reasoning.

Table 1: Categorization of Pre- and Post-Justifications of the Area Formula for a Circle

Strategy	Description	Pre	Post
Non-Justification	No attempt at justification.	17	1
Discrete Fact(s)	Brief attempt to connect measurements within the circle to the task of justifying the area formula, but the response doesn't exceed a true, discrete statement that does not support a justification.	9	6
Empirical	Proof by example (Harel & Sowder, 1998).	1	0
Dimensional Analysis	Symbolic deconstruction aimed at associating meaning with the symbols and operations within the general formula	29	3
Approximation	Comparison to the area of a square of length r or $2r$	6	1
Decomposition	Attempt to decompose the circle into equal parts and sum.	7	59
Total		**69**	**70**

Decomposition was not common prior to exposure. Figure 2 shows one of the most advanced examples from the pre-justifications. The drawing and the accompanying explanation showed some evidence of finding the area of the circle by first decomposing a circle into many tiny sections and then summing the area of these tiny sections.



I will cut a circle into a lot of pieces of triangles and get the area of one triangle and then add them together.

Figure 2. Justifying the area formula using decomposition pre-exposure.

Compared to the work submitted prior to the applet experience, the justifications submitted following the experience were more diverse and contained explicit reasoning about decomposition and limit. For example, Elizabeth made the following argument:

> *I made a circle and divided it into equal sections. Then, I arranged those parts in a formation that barely looks like a rectangle. However, after dividing the circle into very small sections, the shape looks more like a rectangle. The circle will transform into a perfect rectangle by dividing the circle into infinitely many times so we can't point out the lines of the sections.*

After exposure, most students chose to decompose the circle. Some were able to connect that action to the symbolic formula, still others showed a partial understanding of limit in this context, and a select few (like Elizabeth) provided a deductive argument based on limits and infinity. This diversity of sophistication led us to refine the category (Table 2).

At one end of the progression is *disconnected decomposition*. In these justifications, PSTs decomposed the circle, but made no attempt to link that imagery to the symbolic formula. Rather, the focus was on describing the "actions" on the screen. Tina wrote, "*unravel the circle so that it lays flat and the triangles are all sticking up, still split down the middle by color*." At the other end of the progression were ten PSTs who were able to articulate the concept of limit as Elizabeth did above.

Table 2: Progressive Reasoning for Strategies Incorporating Decomposition

Description	Pre	Post
Disconnected Decomposition: no attempt to link to the symbolic formula	4	3
Attempted Symbolism: made an unsuccessful attempt to link to the symbolic formula		7
Achieved Symbolism Connected the area formula symbolically with a decomposed circle.	1	33
Partial Limit Justification included the reasoning that more sectors yield a better approximation		6
Developed Limit Justifies the symbolic formula including reasoning about infinity.		10
Total	5	59

Discussion

Data from this study indicated that Or's applet is a tool that PSTs consider interesting and useful. Imagery was represented by many in sketches, screenshots, and narrated video segments. Even deeper, most utilized multiple images and the storyline of the applet was clearly present in the set of post-justifications. It was a tool for mathematical exploration and learning, but also became a tool for justification. Unfortunately, for most PSTs, this one experience was not enough to overcome the epistemic gap between approximation and deductive reasoning based on limits. However, 16 PSTs did write or talk about subdividing the circle into ever-smaller segments (Figure 1e) in their post-justification and of those, 10 approached a full justification. That suggests that more effort to draw PSTs attention to this part of the storyline is warranted.

There are two additional considerations for the PME-NA community. First, given the opportunity to explore differences between discrete and continuous data, *is this an important opportunity to build that connection?* Second, almost all participants showed conceptual growth, yet only few were able to walk across the epistemological bridge. *How important is it for elementary teachers to provide a full justification for this formula?* In these uncertain times, we feel more and more pressure to reduce the amount of content in preparation programs and discipline-specific professional development. We welcome the opportunity to talk about our future and conceptual priorities at the conference.

The study reported here is developing the curricular and pedagogical components of an approach to teaching qualitative change as it relates to deep creativity within elementary mathematics education. Through this work, the project aims to make three contributions to the fields of creativity, mathematics education, and the learning sciences: (1) new understandings about the development and multimodal expressions of children's qualitative mathematical thinking, (2) new insights about the benefits children experience from their engagement in activities that develop their understanding of qualitative difference as a foundational dimension of learning for radical change, and (3) evidence of the transformative role of deep creativity in elementary mathematics education. In this brief research report, we share preliminary findings of pilot research through a case study of a 5-year-old child named "Opal."

Keywords: Elementary School Education, Geometry and Spatial Reasoning, Design Experiments, Cognition.

Simply stated, *STEM needs creativity*. From equity to the economy to the environment, addressing major global issues demands both "deep creativity" and STEM knowledge and skills. Innovative solutions to address these large-scale problems can be derived through creative processes fundamental to scientific thinking (Cropley & Cropley, 2010). Regrettably, however, creativity is almost absent from mainstream approaches to STEM learning. If we do not resolve the disconnect between creativity, innovation, and the sciences, STEM graduates will be ill-equipped to tackle the most critical and persistent global issues. The *Stretchy Minds* project brings together researchers working at the intersection of mathematics education, creativity, and embodied and emergent design to resolve this conflict. Working in collaboration with elementary math teachers, this project is leveraging the unique affordances of qualitative mathematics to develop a theoretical model for cultivating deep creativity. The vision is that this model will be used to catalyze the enactment of new and much-needed approaches to building foundations for children's STEM creativity within elementary mathematics education. *Conceived with an eye toward this imagined future,* the purpose of this report is to share preliminary findings of pilot research through an exploratory case study of "Opal," a 5-year-old participant in the project.

Mathematics carries the intrinsic capacity to develop young learners' skills and abilities in creativity and innovation through their engagement with *qualitative* forms of mathematical thinking and reasoning. *Qualitative geometry* (Greenstein, 2014, 2018), in particular, has unique affordances for this endeavor because it involves the core concepts of deep creativity – including qualitative change and divergent thinking – *and* it is accessible to young learners (Greenstein, 2014; George, 2017; Piaget & Inhelder, 1956). Accordingly, we've proposed that qualitative geometry can offer a transformative space in which to introduce young children to the concepts of deep creativity in ways that are conceptually understandable, materially tangible, and aesthetically driven. Project findings will enable us to contribute to the expansion of the theoretical understanding and instructional practice of creativity in the space of elementary mathematics education, and in STEM education more broadly.

Our first research question focuses on the design of curricular tasks and the determination of pedagogical principles that engage and develop learners' embodied understandings of qualitative difference as it relates to deep creativity. The following two research questions are the focus of this proposal: *What ideas about qualitative difference are elicited and developed as a result of learners' systemic engagement in these curricular experiences? How are their understandings of qualitative difference enacted, expressed, and made visible through their engagement?*

Theoretical and Conceptual Framing

Creativity, Novelty, and Change. To conceptualize what we mean by *deep creativity*, we first define creativity not as an internal characteristic but as an active process for doing something *novel* and *appropriate* within a situated context (NACCCE, 1999; Sternberg & Lubart, 1999). Next, we propose that creativity is *deep* when it yields novel forms of change that have both quantitative and qualitative dimensions. These dimensions are defined in relation to the two types of change (Bergson, 1911; Deleuze, 1994; Deleuze, 1998):

- *Change-in-degree* (Δ_d) is a ***quantitative*** change, which is (only) incremental.
- *Change-in-kind* (Δ_k) is a ***qualitative*** change, which is wholly and genuinely novel.

At the Intersection of Embodied Creativity and Qualitative Geometry. Simultaneous to a renewed interest in embodiment and collaboration in creative work (e.g., Feldman & Benjamin, 2006), research suggests the promise of adopting an embodied and situated perspective on creativity – an *embodied creativity* as Malinin (2019) calls it. First, there is evidence that the features and qualities of the socio-material environment play a role in enhancing creative expertise (Malinin, 2016); insights into the roles they play can inform the pedagogical practices that lead to creativity. Second, an enactive approach to cognition (Thompson, 2007) has demonstrated that qualitatively novel ideas emerge via embodied actions, where doing *precedes* knowing. It's the doing that enacts meaning into being (Kerr & Frasca, 2021). Conceived from this perspective, this project is testing the conjecture that learning qualitative difference requires open-ended, exploratory, experimental, and emergent educational experiences.

Although mathematics is often viewed as the quantitative domain, it is also home to creative and qualitative processes. This is evident in the domain of topology, which is a non-metric, *qualitative* geometry. The "rubber sheet" conception of topology is useful for demonstrating its qualitative foundations. In general, any two curves are topologically equivalent if each can be bent and stretched, but neither glued nor broken, to produce the other. The property that determines their equivalence is the quality of connectedness that is invariant through the distortion of the rubber sheet. These elastic transformations produce curves that are equivalent precisely because they vary by (quantitative) *differences in degree*. A segment cannot be bent or stretched into a triangle because their connectedness is a (qualitative) *difference in kind*. We chose Speks magnetic toys as a medium for children's learning about qualitative difference, because one can imagine the topological concepts of connectedness and genus (i.e., the number of "holes" in a surface) embedded in them as loops formed by connecting their magnetic ends. The configurations of Speks toys in Figure 2 illustrate the two forms of change using "number of loops" as the criteria for equivalence (i.e., sameness in kind), and "size of loops" as the criteria for difference in degree. Shapes A, B, and C are different in kind, since they each contain a different number of loops. Shapes B and D are different in degree in that the loop in D is larger than the loop in B, and size is a matter of degree.

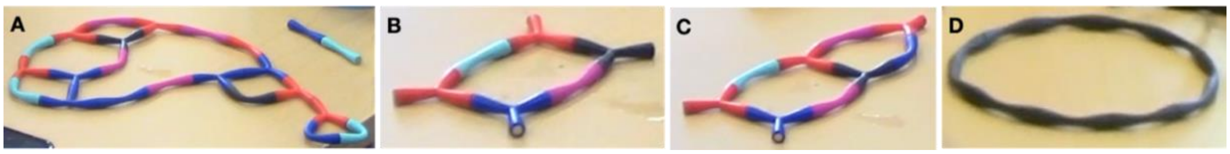

Figure 2: Configurations of Speks toys express differences in kind and degree.

Methods

This project is employing multi-phase design-based research (Brown, 1992; Collins, 1992; DBRC, 2003) to produce responsive curricular experiences that engage and develop learners' thinking about qualitative difference as it relates to deep creativity. Informing the design of those experiences are small-group teaching experiments (Cobb, 2000; Steffe & Thompson, 2000) that yield models of children's thinking (Thompson, 1982), and microethnographic methods (Nemirovsky et al., 2012) that characterize children's multimodal expressions (Edwards, 2009; Goodwin, 2014) of their thinking by tracing their moment-to-moment bodily and situated mathematical activity. Analyses of these expressions entail a grounded, bottom-up approach of constant comparisons (Glaser & Strauss, 1967) that generates inferential interpretations of the children's elicited understandings of qualitative difference.

Participants range in age from 5 to 10 years old. The age-related criterion is informed by research which finds that the development of children's spatial thinking begins as early as 3.5 years of age (Piaget & Inhelder, 1956). A related rationale is found in researchers' calls for deliberate creativity learning to begin in early childhood (Resnick, 2007; Yardley, 2011). Collected data includes video recordings of the children's small-group participation in design sprints; their drawings, magnetic toy structures, and other artifacts; and analytic memos (Strauss & Corbin, 1998) and field notes (Van Maanen, 1988) about the children's goal-oriented actions. Video recordings allow for in-depth analysis of the dynamic interplay between the children's whole-body movement, their material interactions, and their verbal explanations, conversations, and collaborations, as they relate to processes of deep creativity. A review of research that employed qualitative methods to analyze observational data of children's embodied expressions confirms the viability of this analytic approach (McCluskey et al., 2023).

Preliminary Findings

Our pilot study work is exploring whether we can support the development of children's understandings of deep creativity through game-based (Nguyen, 2020) learning activities we designed based on the following conjecture: Conceptual knowledge of difference-in-kind and difference-in-degree can emerge for the child in instrumented (Vérillon & Rabardel, 1995) fields of promoted sensorimotor interactions (Abrahamson & Sánchez-García, 2016; Abrahamson, & Trninic, 2014; Reed & Bril, 1996) with the cultural artifacts (Vygotsky, 1978) into which these target concepts are embedded (e.g., playing the game of *Sprouts* (see NRICH, n.d.) with Speks toys provided phenomenal grounding for the proto-conceptual learning of genus and connectedness). This conjecture about mathematical learning organizes the concepts of deep creativity as follows: In qualitative geometry, there is a property that defines the qualitative difference (or equivalence) of two shapes. That property can be considered a rule that determines whether two shapes are different or equivalent. By changing that rule, new shapes emerge as different or equivalent. These different shapes exhibit a truly *novel* distinction.

What new worlds arise when children come to understand that qualitative difference is a foundational dimension of learning for creative change? This is the question that framed the summer camp that provided the context for the second pilot study, which was held over 3 days with 8 children (3F, 5M) ages 5 to 10. Thirteen teacher-collaborators joined in to support and promote the children's agentive and exploratory play. Here we share some preliminary findings through an exploratory case study (Yin, 2014) of "Opal" (F), who was 5 years old at the time.

Opal was the youngest child at the camp; she was also the least verbal. A focal moment in Opal's activity elucidates her emergent thinking. At one point, we incorrectly inferred from her struggle to learn how to use the Speks toys to play Sprouts that the issue may be developmental. When we revised our approach to try and give her access to it, we learned from her responses that it was the scaffolding that we provided to Opal that was the source of the problem. Our approach was confusing Opal's already emergent ways of knowing about differences in kind and degree. For reasons that have to do with the rules of Sprouts, we had been promoting the use of "3-piece" Speks toys to form loops, and "2-piece" toys to enlarge or reduce the size of those loops. At the point at hand, Opal had already realized that a 3-piece could accomplish both tasks! At various points throughout her play, she used these 3-pieces to form loops and then make distinctions between shapes in terms of differences in kind based on *the number of loops* they possess. She also used those same 3-pieces to enlarge or reduce *the size of loops* and then make distinctions between shapes in terms of differences in degree. We had very little access to Opal's cognition through verbal expressions, but the enactive perspective (Thompson, 2007) revealed them via instrumental and embodied actions with Speks toys that provided evidence of her emergent cognitive structure (Varela et al., 1991) of qualitative difference.

A related conflict arose shortly thereafter when we sought to promote the use of "same" to name shapes that are alike in kind (i.e., topologically equivalent). In contrast, Opal enacted a more elaborate conception of same-ness, saying that two topologically equivalent shapes are actually *not* the same if they have "the same number" of loops, yet those loops and other features of a shape vary by degree. Thus, according to Opal's conception, two shapes are the same if and only if they are alike in kind *and also* alike in degree.

Conclusion

This case of Opal's experiences suggests the promise of this empirical exploration into developing the curricular and pedagogical components of an instructional approach to teaching qualitative change as it relates to deep creativity within elementary mathematics education. As this work continues, this project aims to make three contributions to the fields of creativity, mathematics education, and the learning sciences: (1) new understandings about the development and multimodal expressions of children's qualitative mathematical thinking, (2) new insights about the benefits children experience from their engagement in activities that develop their understanding of qualitative difference as a foundational dimension of learning for radical change, and (3) evidence of the transformative role of deep creativity in elementary mathematics education. In this brief research report, we share preliminary findings of pilot research through a case study of a 5-year-old child named "Opal."

KINDERGARTEN THINKING: CONNECTIONS BETWEEN FORMAL MATHEMATICS AND STUDENT'S FUNDS OF KNOWLEDGE IN 3D SHAPES

Alyssa Kasahara
University of Minnesota
Kasah010@umn.edu

Keywords: Elementary Education; Geometry and Spatial Reasoning; Equity, Inclusion, and Diversity; Classroom Discourse

Students come with a wealth of knowledge in elementary mathematical spaces. Moll and colleagues (1992) refer to this informal cultural knowledge as students' Funds of Knowledge (FoK). Each culture brings their own unique perspective, background knowledge, and experiences (Banks, 1993; Pradhan, 2020). However, there exists the expectation that students be fluent in dominant mathematics (Gutiérrez, 2017). In the elementary classroom, dominant mathematics is displayed through strict processes, structures, and algorithms, leaving little room for instructional variation and multiple ways of knowing (Atwater et al., 2013). This limited view of mathematics continues to perpetuate the inequities in the US education system (Ladson-Billings, 2006).

Scholars document students' development of geometry concepts when students have agency around their learning (Civil, 2002; Natalija et al., 2019; Ng & Sinclair, 2015; Ng & Ye, 2022). Nevertheless, there is little to no research observing and documenting what connections students make from their FoK to the formal mathematical content. Because Clements and colleagues (1999) show primary students continued struggle to identify shapes, this study investigates students' connection between the formal mathematics and their FoK in the elementary classroom setting, specifically in the three-dimensional (3D) shapes unit.

3D shapes are important to teach because they strengthen students' ability to identify and organize visual information (Tsamir et al., 2015). Two overarching questions guide this study: How do primary elementary students incorporate their informal mathematical home-culture knowledge into their geometric units? How do students make connections between their informal mathematical knowledge and the formal mathematical terminology in a geometry unit in 2D and 3D shapes? In this study, students participated in their usual 3D shapes unit. I audio and video recorded their daily lessons consisting of a fifteen-minute, whole group mini-lesson followed by practice opportunities through table work. During the table work, I recorded a small group of six students (one table) and conducted five-minute, one-on-one interviews with the same students. The interviews focused on what shapes students drew and where they might see those shapes at home. Additionally, I collected the written work from the entire class.

To analyze the data, I use Bloome and colleagues' (2005) discourse analysis. The data will be transcribed and evaluated for common themes found between interviews, small group work, and whole class discussions. Through this analysis, I anticipate identifying key ways students talk about geometric shapes informally. I will identify the home contexts that are particularly relevant for students. I anticipate that students will use their FoK to distinguish between 3D shapes. I also expect students to use their FoK to describe the attributes of shapes.

By documenting the common connections students make between formal mathematics in 3D shapes and students' FoK, educators will be able to help students more authentically engage 3D shapes in ways beyond the current dominant mathematics in the formal academics. The students will be able to see themselves, their culture and community in their learning.

In this study, we considered how two teachers' use of invariant properties of draggable geometric objects are related to their geometric reasoning. We used a Discernment of Invariance theory to look at these teachers' levels of invariant properties as a way to make sense of their reasoning. Our analysis suggests that these teachers' ability to discern invariant properties at an advanced level was a key aspect for making meaningful conjectures, justifying, and explaining them. However, such an ability seems necessary, but not sufficient to explain and justify a geometric phenomenon. We found that unpacking more level-1 invariant properties and making more invariants level-2 connections between them can offer a richer exploration. We also found that an invariant property can be described as a feature of change. Implications for professional development and teacher education are discussed.

Keywords: Geometry and Spatial Thinking; Reasoning in Dynamic Geometry Environment; Variance and Invariance; Technology

Purpose and Background

Research shows that teachers' ability to discern invariant properties is a necessary skill in developing rich and deep understanding of draggable geometric objects (e.g., Leung 2015; Nagar, Hegedus, & Orrill, 2022b; Sinclair, 2018; Sinclair, Pimm, & Skelin, 2012). Despite its importance, invariance is often not as readily apparent among teachers; and when teachers considered invariant properties, they associated them mainly with shape, measurement, location, and calculation (Nagar, Hegedus, & Orrill, 2022a). Leung, Baccaglini-Frank, & Mariotti (2013) developed a Discernment of Invariance theory distinguishing between two levels: *Invariant properties level-1* are invariant properties that a person might perceived, while *invariants level-2 connections* are possible logical connections between level-1 invariant properties. Most research is focused on examining how a person might discern invariance and what type of invariant properties are discerned. More research is needed to unpack possible connections between invariant properties as part of reasoning. Thus, in this study, we investigated the following question: *How do two teachers use invariant properties at two different levels (invariant properties level-1 and invariant level-2 connections) as part of their geometric reasoning?*

While Leung et al. (2013) focused on students' awareness of invariant properties and whether they succeeded or failed to express awareness of level -2 invariant properties, in this study, we focused on what invariant properties level-1 teachers might use as part of their reasoning; what connections they might make; the direction and frequency of such connections; and whether there are other types of invariant properties that a person might discuss compared to previous results (e.g., Nagar et al., 2022a).

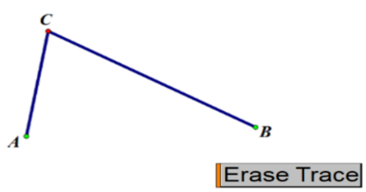
Theoretical Framework

Invariant properties are certain geometrical properties that remain unaltered when a transformation on the object is applied (Baccaglini-Frank, Mariotti, & Antonini, 2009; Hadas, Hershkowitz, & Schwarz, 2000; Laborde, 2005; Yerushalmy, Chazan, & Gordon, 1993). We consider a variable object as a draggable object under transformation, and the property that is 'an invariant satisfied' (i.e., remains unaltered) as an invariant property (Nagar et al., 2022b).

We drew on Leung et al.'s (2013) Discernment of Invariance theory to distinguish between two levels of discernment of invariant properties in a DGE. Discernment of invariant properties level-1 denotes to the awareness of invariant properties of a dynamic figure perceived under different dragging strategies; and discernment of invariant level-2 connections refers to the awareness of different types of control on level-1 invariant properties to imply logical relationship between them. We used a tablet based DGE, so the user could place one or more fingers to enact movement (by dragging an object). The use of dragging allows the user to "feel" the variation of the construction (Baccaglini-Frank & Mariotti, 2010) and to discern invariant properties (Nagar et al., 2022b; Sinclair et al., 2012), which can be help in unpacking the situation at hand.

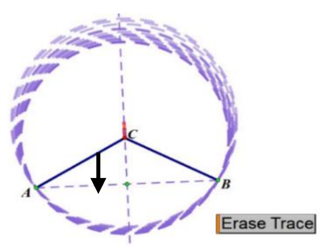
Data Sources and Method

(a) Activity 1



Participants could manipulate a draggable point (point C) connected to two fixed points A and B. Based on idea presented by Leung (2003). Point C could be dragged anywhere on the screen and leaves a colored trace.

(b) Possible Generalization



Generalizing that as long as point C (the center of the desired circle ("dashed circle") is being dragged along the perpendicular bisector of segment AB, it is possible to maintain a circle that changes its size.

Construction: Drawing three points, setting A and B to be fixed points, and constructing segments AC and BC.

Figure 1: Activity Used in the Study

The work reported here is part of a larger study where the primary data came from a set of two 45-minutes video recorded task-based interviews with six high school mathematics teachers: Four females - Amanda, Lisa, Diana and Susan; and two males - Andy and Mark (pseudonyms). Each interview focused on a set of four activities that were designed using the Sketchpad® Explorer (Jackiw, 1991). Figure 1 presents one of these activities. All interviews were videotaped and transcribed verbatim. We focus on Activity 1 Part 2 where participants were asked to think about ways to drag point C so that a circle passing through A and B with C as its center can exist; and then, if possible, to maintain such a circle.

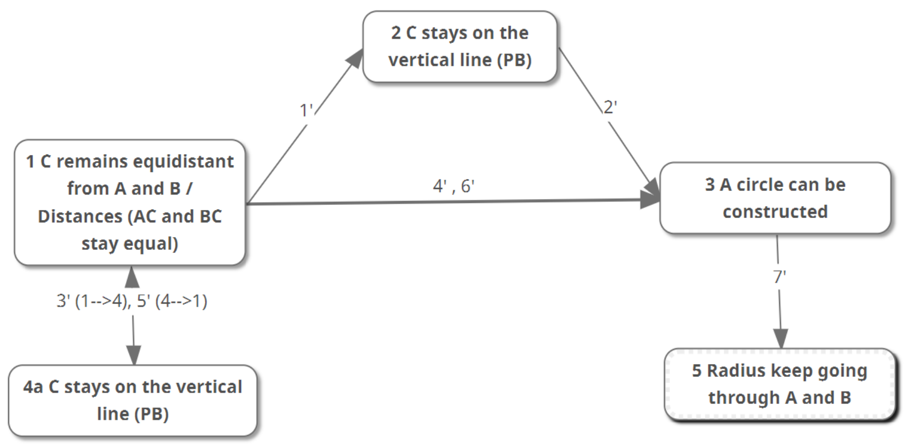
The analysis included two cycles of coding. In the first, we used *descriptive coding* (Miles, Huberman, & Saldaña, 2014) and created four spreadsheets to look at what participants said (verbally) and did (through actions). In the second cycle, we coded characteristics related to the two levels of invariants (invariant properties level-1and invariant level-2 connections). We also tracked the justifications and explanations provided by participants (if any), as well the direction and relative frequency of these connections. We then created *connection maps* (see below) to focus on both the invariant properties level -1 (represented by nodes) and invariant level-2 connections (represented by arrows). Connections map visually shows the logic relationships (level-2 connections) between the level-1 invariant properties. Lastly, we used a *pattern coding* method (Miles et al., 2014) to look for major themes and patterns.

Results

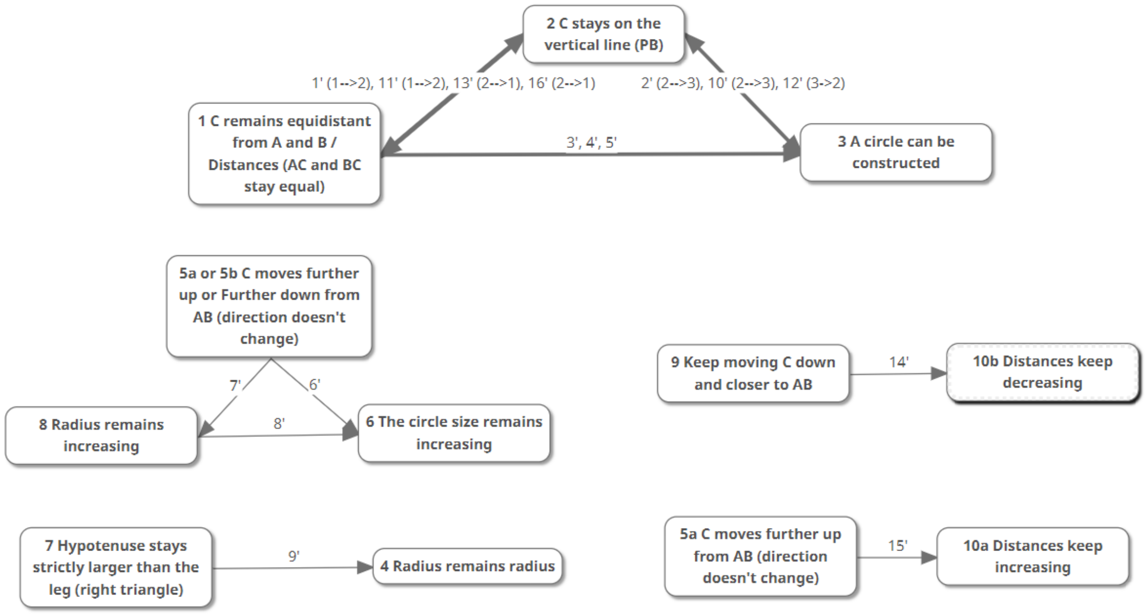
Invariant Properties Connections Maps

Table 3: Invariant Properties Connections Maps

Andy's use of invariant properties connections map



Mark’s use of invariant properties connections map



Note: A node represents the invariant property discerned (Level-1) and describes it.

The numbering inside the nodes is used to order the properties according to the participant's order of discernment.

An arrow between two nodes represents a connection between two invariant properties and its direction (Level-2).

A connection is a conditional/conjecture of the form "if ... then..." statement.

The prime numbering (e.g., 1', 2', etc.) indicates the order of the connections participant made. When a bidirectional arrow appears then the parenthesis indicates the direction of that connection – for example in Andy’s map the connection 3’(1→4) means that the participant made a statement (in his 3rd connection) saying that if the distances AC and BC stay equal (Node 1), then C remains on the vertical line (PB-perpendicular bisector) to AB (Node 4).

The thickness of an arrow indicates the relative frequency of the connection. The frequency can also be calculated by counting the prime numbers appearing on a single arrow – that is the number of times a connection was made.

Comparing between Andy’s and Mark’s Invariant Properties Connections Maps

In looking at both connections maps, it seems that both Andy and Mark were able to make important connections between key level-1 invariant properties to unpack the situation and to generalize that the perpendicular bisector of AB is a path that allows for the desired circles to be constructed. In addition, they both drew on the definition of a circle to make these connections. However, while Andy discerned only five invariant properties, Mark discussed twelve invariant properties. Mark offered advanced reasoning combining several big ideas in geometry such as: circle, right triangles, hypotenuse, perpendicular bisector, etc., and he also discussed several interesting invariant properties related to a feature of change.

While Andy made seven invariant level-2 connections, Mark made sixteen such connections and it seems that his reasoning was more coherent (using the same ideas more frequently). Mark was also able to generalize and formulate more connections between level-1 invariant properties and to unpack the situation in more depth. Lastly, although both participants were able to discern invariant properties at an advanced level (in both levels of invariant properties), still we saw that Andy did not justify all his conjectures even when was asked directly to try. Also, Mark did not provide justifications for his last two invariant level-2 connections (14' and 15').

Discussion and Conclusions

Our analysis shows that identifying different level-1 invariant properties and making invariant level-2 connections between them were key aspects in unpacking a dynamic geometric situation. Similar to Leung et al. (2013) who "were able to gain insight into explorations within DGE, analyzing in fine detail how discernment unfolds" (p. 458), we saw that both levels of invariant properties seem to be the basis for having the skills to make conjectures, state theorems, justify them, and make links to generalization. Thus, it is suggested that teachers might benefit from not only discerning multiple invariant properties, but also making and justifying possible connections between them. It also seems that if a person is able to unpack more level-1 invariant properties and make more connections between them (level-2), the exploration can be richer and deeper. We conclude that future research should focus on how to design opportunities in dynamic environments to support teachers in developing such skills.

We also found that some invariant level-2 connections were not justified. Maybe some connections are difficult to explain (e.g., Mark's connections 14' and 5'). Thus, it seems that the ability to identify level-1 invariant properties and make connections (level-2) is necessary, but not sufficient to explain and justify a geometric phenomenon. More research is needed to examine what challenges teachers might express in working with both levels of invariants, and how it is possible to overcome such challenges.

Lastly, Mark drew on an interesting idea - *an invariant feature of change* (e.g., describing a distance as changing in length but having a feature that remains the same – always increasing). He used this not only to explain a phenomenon about the size of the circle as increasing or decreasing, but also to experience the object has having different formations (continuous variation). Doing so, he offered a richer exploration and unpacked more sophisticated ideas. This adds to previous results (Nagar et al., 2022a) where we analyzed more than 150 descriptions and found four categories of invariant properties (Shape, Measurement, Location, and Calculation). So, in this paper, instead of just looking at something that stays constant like a circle (Shape) or distances (Measurement), it is possible to have a feature of change as invariant property. This might be an important aspect of geometric reasoning. Thus, the role of such invariant property (feature of change) in reasoning is worth further examination, as well as whether such an invariant property can be easily accessible to teachers or not.

Graphical representations are commonly used in everyday life and are important in STEM fields. Interpreting graphs entails understanding the underlying structures of graphs, including coordinate systems and reference frames. In this report, we characterize one student's constructions of coordinate systems. These constructions indicate two distinct types of reference frames not currently distinguished in the literature: (a) continuous and (b) ordered-discrete. Using data from a 10-session teaching experiment, we discuss the interplay of a student's perception of tasks, the reference frames she reasoned with, and differences in those reference frames. We consider how the interplay of the aforementioned items may have influenced the quantities she considered as well as the coordinate systems she constructed. We conclude with suggestions for research and teaching that support students' productive graphing activity.

Keywords: Geometry and Spatial Reasoning, Mathematical Representations, Cognition, Middle School Education

Graphs are a powerful way to visualize, explore, and communicate relationships between quantities. In STEM contexts, graphs can be used to mathematize spatial situations or represent relationships between covarying quantities (Paoletti et al., 2020; Glazer, 2011). In our view, students' meanings for graphs should depend on their meanings for coordinate systems, especially if their meanings for graphs are to be productive (Lee et al., 2020). Recent research has focused on differences in the underlying coordinate systems that students construct and how reasoning within these coordinate systems explains their graphing activity (Paoletti et al., 2018, 2022; Parr, 2023). In this report, we offer another contribution to this literature by characterizing two novel types of reference frames that underlie coordinate systems and by describing how students may use these reference frames to reason about quantities represented in coordinate systems. We begin with a theoretical background that defines two different types of coordinate systems and establishes a distinction between types of reference frames. We describe one student's use of both types of references frames within each coordinate system. We conclude with implications for teachers, curriculum designers, and researchers.

Theoretical Background: Two Types of Coordinate Systems and Reference Frames

Researchers (Lee, 2017; Lee et al., 2019, 2020) have distinguished between two kinds of coordinate systems (CSs): spatial and quantitative. Each type of CS is built by coordinating one or more reference frames. *Reference frames* (RFs), which are constructed to gauge relative extents of attributes in phenomena, consist of some orienting reference objects, directionality, and some anticipation of a measurement process that could be carried out (Lee et al., 2020; Joshua et al., 2015). When students consider quantities (Thompson, 2011), there must be at least one RF involved. We provide several examples of abstract quantities, using parentheticals to provide specific examples of situational quantities with explicit RFs: Distance (e.g., number of miles east a person is from school), time (e.g., number of minutes after passing a rest stop), and temperature (e.g., degrees Fahrenheit above 0).

A *spatial CS* involves the mental coordination of one or more RFs and a selection of units of measure which are imposed onto a physical space of interest. In this case, RFs are used to gauge the relative locations of objects within that space. In a spatial CS, locations in the space may be tagged with coordinates guided by these RFs and obtained through carrying out the anticipated measurement. For example, a student might organize the map in Figure 1a by constructing a spatial CS consisting of two RFs that imply the consideration of distinct distances from a reference object (like the star icon). The spatial CS could then be used to describe the X's (or any object's) location in terms of unique pairs of distances from the star icon.

A *quantitative CS* involves the mental coordination of one or more quantities which are activated upon assimilation of a situation, disembedded from it, and inserted into a new representational space through the coordination of their RFs. For example, a person may coordinate the relationship between the time and temperature throughout a day and represent this relationship via a graph in a quantitative CS. Within both spatial and quantitative CSs, locations within the CS are imbued with quantitative extents, which necessarily involve RFs.

In this paper, we add a fourth dimension to thinking within RFs: continuity. In addition to reference object, directionality, and some anticipated measurement process, we have found in our work with students that the notion of directionality and some anticipated measurement process could be established either discretely or continuously. Hence, we distinguish between two kinds of RFs that students indicated when reasoning in both types of CSs: *ordered-discrete RFs* and *continuous RFs*. A *continuous RF* involves understanding a continuum of an attribute's extents relative to the reference object and guides measuring activities that would lead to measurements as continuous quantities. An *ordered-discrete RF* involves segmenting an attribute's extents according to distinct, bounded regions that are arranged in some (implicit or explicit) sequence. Ordinal or directional language can be an indication of an established ordered-discrete RF and guides measuring activities that would lead to measurements in discrete units. For example, an individual who has established an ordered-discrete RF within a designed region might describe sub-regions in ordinal terms (e.g., second row or last circle from the center) or directional terms (e.g., left side or near the middle).

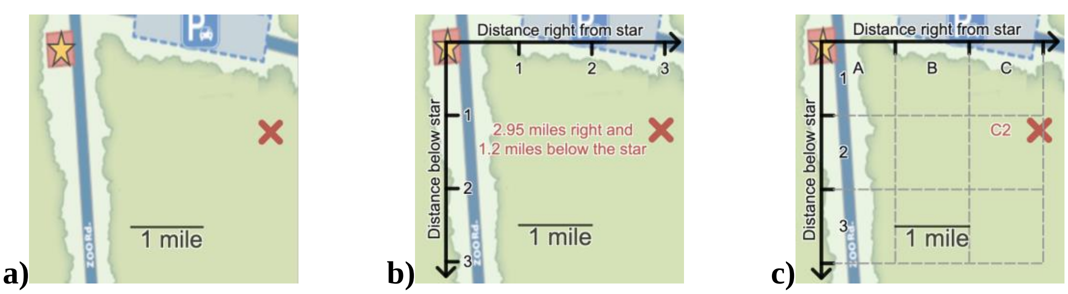

Figure 1: A map indicating: a) no CS, b) a spatial CS constituted by coordinating two continuous RFs c) a spatial CS constituted by a coordination of two ordered-discrete RFs.

We note an individual may understand an attribute as continuous and still construct an ordered-discrete RF; such a construction is dependent on the student's conceived context, goals, or current quantitative constraints in their reasoning. For example, Figure 1b shows how a spatial CS could be constituted by coordinating two continuous RFs. Figure 1c shows how a spatial CS could be constituted by coordinating two ordered-discrete RFs. In this report, we address the research question: *How does a student's construction of continuous and ordered-discrete RFs impact her reasoning in spatial and quantitative CSs?*

Methods

To address our RQ, we report on data from a teaching experiment (Steffe & Thompson, 2000) with three sixth-grade students: Nina (who self-identified as Latina), Tara (who self-identified as a White female), and Jacobi (who self-identified as an African American male). We focus this report on Nina's activity because she provided the strongest indications of the RFs of interest. The teaching experiment took place in a middle school whose population consisted of over 75% students of color. Participants were recruited based on teacher recommendation and student availability. Nina attended 10 teaching experiment sessions each lasting 35–40 minutes (Table 1). We video- and audio-recorded each session to capture utterances and gestures. Student activity on the Desmos platform was screen recorded, and we digitized all written work.

Table 1: Small Group Teaching Experiment Sequence

Session	Students Present	Task	Intended Student Goal
0	Nina	Pre-Interview	Various
1	Nina, Tara, Jacobi	X Marks the Spot – Guess Where	Construct and/or interpret spatial RFs and CSs to describe and/or identify locations in space
2	Nina, Tara	X Marks the Spot – Anywhere	
3		X Marks the Spot – Classmates' Descriptions	
4	Nina, Jacobi	X Marks the Spot – Anywhere	
5	Nina, Tara, Jacobi	North Pole Task	
6 7	Nina, Tara, Jacobi	Zoo Task	Interpret points in a quantitative CS
8	Nina, Tara, Jacobi	Kodiak Task	Interpret graphs in a quantitative CS

10	Nina, Tara	Post-Interview (Growing Fruit)	Various

Tasks

We describe Nina's activity across several tasks from Sessions 3, 4, and 10. In the *X Marks the Spot-Anywhere* and *-Classmates' Description* tasks (Sessions 2–4), students took on the roles of Describer and Guesser in Desmos. The Describer was prompted to mark an X on the map and then generate a description of the X's location. The Guesser used that description to mark an X on their own version of the map. Students had access to a set of digital overlays (e.g., vertical lines, horizontal lines, concentric circles anchored at the star icon) that could be activated to potentially support students' location descriptions. For example, in Figure 2, the 'Horizontal' and 'Vertical' overlays are activated. In the *Anywhere* variation of the task, a pair of students take turns as Describer and Guesser for each other. In the *Classmates' Descriptions* variation, the students worked together as Guessers, with hypothetical classmates as Describer. The hypothetical classmates' descriptions were researcher-authored and sequenced to progress from (what we then considered) less precise to more precise descriptions in both polar-like and Cartesian-like CSs. We had yet to distinguish between continuous and ordered-discrete RFs when we authored these descriptions. However, in retrospect, the descriptions that we considered less precise used language indicative of ordered-discrete RFs while the descriptions that we considered more precise used language indicative of continuous RFs. In Session 10 Nina and Tara completed a post-interview together wherein they attempted tasks individually, and the teacher-researcher (TR) facilitated discussion across their responses. The fourth task of the post-interview, *Growing Fruit,* asked students to describe a situation that would be reflected by a given graph representing the relationship between a hypothetical fruit's weight and calorie content, both of which changed over time (Figure 3a).

Analysis

Consistent with teaching experiment methodology, we analyzed the data via conceptual analysis, which entails "building models of what students actually know at some specific time and what they comprehend in specific situations" (Thompson, 2008, p. 45). We watched all videos and identified moments that offered insight into the CSs and RFs Nina constructed as she addressed each task. We then created models characterizing whether Nina was constructing quantitative or spatial CSs. As we described Nina's reasoning in each type of CS, we characterized continuous and ordered-discrete RFs as an important distinction in her reasoning; we had not considered this distinction prior to conducting this analysis.

Results

Nina used two distinct types of RFs, *ordered-discrete* and *continuous* to construct and interpret both spatial and quantitative CSs. Further, the RF Nina constructed influenced her reasoning in each CS. Because Nina constructed both types of RFs within both types of CSs, we present these types of reasoning in a two-by-two matrix and detail four examples from the teaching experiment that demonstrate each combination (Table 2).

Table 2: Task and activity in which Nina constructed a CS using each type of RF

	Ordered-discrete RFs	Continuous RFs
Spatial CS	Describing locations in *X-marks the Spot-Anywhere*	Interpreting locations in *X-marks the Spot Anywhere*
Quantitative CS	Interpreting a given graph in the *Growing Fruit task*	Interpreting a modified graph in the *Growing Fruit task*

Continuous Reference Frames in Spatial Coordinate Systems

In Session 3, Nina interpreted continuous RFs in a spatial CS when she followed a hypothetical classmate's description to mark an X in the *X Marks the Spot – Classmates'*

Descriptions task. Nina's interpretation of the following description shows her ability to construct continuous RFs in a spatial CS:

> Click the Star (1) and Circles (3) options. Imagine the star is like a clock with the line going straight up being 12 o'clock and the line going straight down being 6 o'clock. The X is 1.25 miles from the star [icon] halfway between 10 and 11 o'clock.

This description is intended to introduce a pseudo-polar, spatial CS in which the continuous RFs are the radial distance (explicitly in 'miles') from the star icon and angle measure (implicitly in 'hours') from the top vertical line. After reading the description, Tara moved the cursor to an approximately correct location. Nina grabbed a measuring device (a wax-covered string bent at a length equivalent to the '1 mile' key on the map), which she used to confirm Tara's approximation. Specifically, Nina placed one end of her measuring device at the center of the star overlay and oriented the other end halfway between the lines representing 10 and 11 o'clock, near where Tara had placed the cursor. Nina reasoned that if the string piece was one mile, then the X must be slightly beyond it. Hence, Nina reasoned about distance from the center as a continuous quantity (i.e., 1.25 miles is slightly more than 1 mile) while also attending to the clock description as a continuous quantity (i.e., a location halfway between 10 and 11 o'clock). Thus, Nina used continuous RFs to generate an exact location in a spatial CS.

Ordered-Discrete Reference Frames in Spatial Coordinate Systems

In Session 4, Nina primarily used ordered-discrete RFs. For example, in her third turn as Describer in the *Anywhere* variation of the task, Nina established a spatial CS using two ordered-discrete RFs to describe a region in which her X was located. Nina marked an X as in Figure 2a and provided the description "Use horizontal and vertical lines. The lines make squares so count from the left, go all the way to the bottom, and count 6. Then go up 2, the x is in the right corner." To Nina, the combination of the vertical and horizontal overlays created distinct 'squares' (discrete regions) that Jacobi could count (ordering language) to identify which region contained the X (Figure 2a). Reflecting the non-continuous nature of the RFs Nina was constructing, the relative size of these 'squares' was not relevant from her perspective; her description did not distinguish the partial boxes in the bottom-most row and left-most column from the other boxes in the grid. Hence, we infer she was reasoning about discrete, ordered, regions from the bottom left corner. Hence, Nina established a spatial CS to describe a region by coordinating two discrete ordered RFs (The number of boxes to the right starting from the left side of the map and the number of boxes vertically up from the bottom of the map).

a) b)

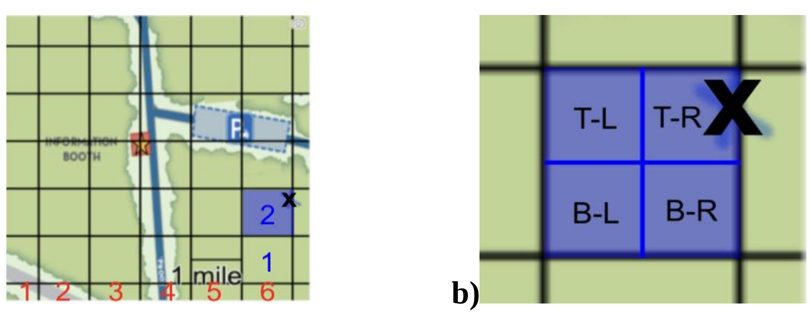

Figure 2. Representation of Nina's ordered-discrete reasoning in space in a) the first part and in b) the second part of the description

Nina’s use of ordered-discrete RFs influenced her activity in the spatial CS as it led her to using more than one set of ordered-discrete RFs as she described increasingly narrow regions in which points were located. That is, we infer that Nina’s addition of “x is in the right corner” was a second ordered-discrete RF she constructed within the first box she described. (We note Nina did not specify between top or bottom right corner, but we conjecture she meant top-right based on the X’s placement.) Our inference is based on her use of “right corner” as a location rather than a reference object (i.e., “in the right corner” as opposed to “1 cm from the right corner”). One possible way she could have done this is by mentally subdividing the ‘square’ into (at least) four discrete, ordered quadrants (i.e., top-left, top-right, bottom-left, bottom-right; Figure 2b). Thus, we infer that Nina could have coordinated two ordered-discrete RFs (left/right and top/bottom from the midpoint of the box) to describe a narrower region within a particular region of a spatial CS.

Reference Frames in Quantitative Coordinate Systems

In Session 10, Nina addressed the *Growing Fruit* task (Figure 3a). A normative explanation would include a description that at first the fruit gains weight while its calories remain the same and then the fruit’s weight and calories increase simultaneously. Based on Nina’s activity in Sessions 7-11, we anticipated Nina would use continuous RFs to interpret the given graph and produce a normative explanation. However, we infer that Nina initially reasoned about the quantities using an ordered-discrete RF and shifted to using a continuous RF when the TR added numbers to the horizontal axis. We provide evidence for each claim in the next two sections.

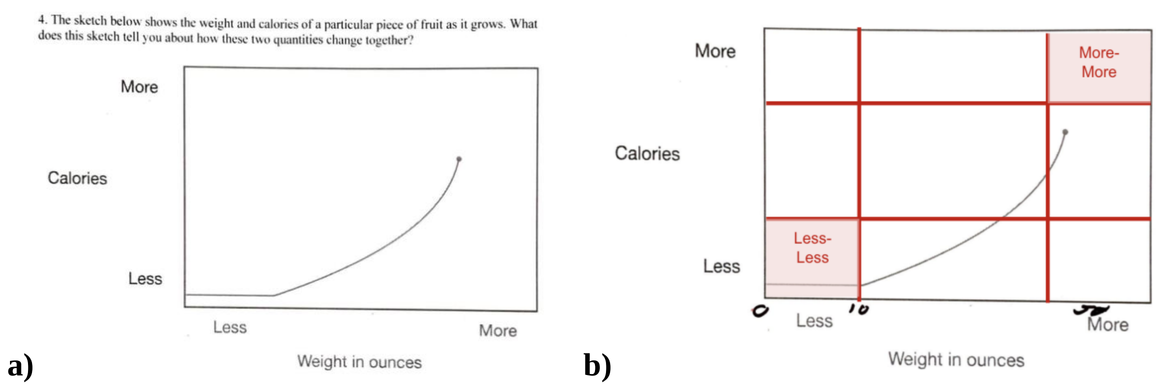

Figure 3: a) Growing Fruit Task as presented and b) a potential depiction of how ordered-discrete RFs could be coordinated to reason about the horizontal segment of the graph.

Ordered-discrete reference frames in quantitative coordinate systems. When initially interpreting the horizontal segment (and possibly the entire graph), Nina employed an ordered-discrete reference frame. Describing a situation that created this graph, Nina explained:

N: The fruit starts off, like, without any calories [*points to horizontal segment*] and doesn’t weigh a lot. And then while it grows [*traces curve*] it gains calories and … weighs more.
TR: Gains calories and weighs more?
N: Yeah.

TR: [*referring to the curved part of the graph*] So that's sort of what you [Tara] were saying, too. So, I think you're both in agreement. Now let me ask you [Nina] this question. If we start say, here [*gestures to the vertical intercept*] and just paying attention to this part [*tracing the horizontal portion of the graph*]. What's changing?
N: Nothing.

Considering Nina's argument, Tara disagreed with it. Tara traced the horizontal part of the graph saying, "Well as you go right the weight is getting bigger because it's getting closer to 'more' weight, I guess. But the calories would stay the exact same right here." Nina explicitly disagreed with Tara's argument stating, "I don't think here it's getting bigger [*traces horizontal segment*]. 'cause it's like [*pointing to "Less" markers on each axis*]...[3 second pause] For me it's like not getting bigger cause it's like still at less."

We interpret Nina as reasoning with ordered-discrete RFs as she interpreted the weight and calories of the fruit for the horizontal segment. In particular, she argued the horizontal segment was representing the quantities as both being in a static state of 'small' because the segment was close to the 'Less' label on each axis. Like her activity in *X Marks the Spot - Anywhere,* Nina was reasoning about ordered-discrete RFs on each axis by creating regions based on the 'Less' labels along each axis. We show one potential illustration of the resulting regions Nina may have been reasoning about in Figure 3b.

We note Nina's initial description of the curved segment ("while it grows it gains calories and … weighs more") could be indicative of reasoning with either ordered-discrete RFs or continuous RFs. If Nina understood that the curved graph spanned the (Less, Less) region and the (More, Medium) region, then she might have argued that the weight and calories both increased by some unknown amount as each moved into a higher-ordered region. If, however, Nina understood there to be a continuum of values beyond the (Less, Less) region, then she could have been using a continuous RF to reason about this part of the graph. As the TR was not aware of the distinction between the two types of RFs in the moment, he did not explore this possibility further. However, he did conjecture the 'Less' and 'More' labels on the axes, which were novel relative to quantitative CS used in previous sessions, may have been the catalyst for her reasoning about the straight segment. Hence, he opted to add numbers to the horizontal axis (0, 10, 50; seen in Figure 3b) to see if this change would lead Nina to a different interpretation.

Continuous Reference Frames in Quantitative Coordinate Systems. When the TR added the numbers to the horizontal axis, Nina immediately engaged in reasoning about the horizontal segment using a continuous RF in a quantitative CS and generated a normative interpretation of this part of the graph:

TR: But say if there were numbers here. Say this was like 0, 10, and like 50 [*writes in numbers on horizonal axis as shown in Figure 3b*]
N: Then it would get bigger
TR: Then you think it would-
N: It would weigh more
TR: You think it would weigh more?
N: Yeah
TR: And what about the calories? Would that be changing?

N: No [*shakes head*]

TR: No? Okay so it's sort of like this distinction between sort of like 'less' like we're in this less state-

N: Yeah

TR: -versus if there were numbers, you'd say they were changing? [*Nina nods head*]

When the TR added numbers to the horizontal axis, Nina immediately interpreted the horizontal segment as showing the weight increasing ("It would weigh more") as the calories remained constant. Thus, we infer Nina understood the horizontal axis as a continuous RF representing the weight of a hypothetical fruit. Furthermore, she agreed with the TR that the distinction between viewing the horizontal segment as representing a state of 'less-ness' versus viewing it as a record of change was based on the addition of the numbers. Hence, we infer the addition of numbers to the axes changed Nina's interpretation of the graph (and of the situation) as she shifted from using an ordered-discrete RF to using a continuous RF. Further, she exhibited reasoning compatible with a continuous RF on the next task in the post-interview, which asked her to construct a graph to represent the weight and calories of a novel fruit.

Discussion, Implications, Limitations, and Concluding Remarks

Addressing our RQ, we have shown how Nina used ordered-discrete and continuous RFs to reason within both spatial and quantitative CSs. Within a spatial CS, Nina's use of different RFs led to different strategies to mark or describe a location. With continuous RFs, Nina could identify an exact location, but she reasoned about increasingly narrow regions when using ordered-discrete RFs. In a quantitative CS, Nina's use of RFs impacted her interpretation of a situation represented graphically. When engaging with ordered-discrete RFs, Nina treated a segment of the graph as a single object, representing a static condition (i.e., Less-Less). However, with a minor alteration to the task, Nina considered the weight RF as continuous, thereby interpreting the segment as representing a record of change.

We note that Nina's construction of different RFs was influenced by her interpretation of and/or goals in the task. Although she was capable of reasoning with continuous RFs in both spatial and quantitative CSs, she opted to use ordered-discrete RFs when they satisfied the demands of a given task as she perceived it. We have observed other students who, like Nina, are capable of reasoning about continuous RFs in a spatial CS but opt to use ordered-discrete RFs to satisfy their perceived demands of a given task.

Implications for Curriculum and Instruction

We consider it likely that a continuous RF supersedes an ordered-discrete RF. Our hypothesis is that individuals who have constructed a continuous RF in a context would necessarily be able to construct an ordered-discrete RF in the same context, whereas an individual who constructs an ordered-discrete RF may not yet be able to construct a continuous RF in that context.

However, we emphasize that one type of RF is not inherently preferred; rather, their utility is determined by an activity's (or student's) context and goals. In spatial CSs, regions can be described using continuous RFs (e.g., Webb & Abels, 2011), but there may be instances in which ordered-discrete RFs are sufficient or even more appropriate. Although continuous RFs are more commonly used when constructing quantitative CSs, there are situations in which ordered-discrete RFs are useful. For instance, Webb and Abels (2011) describe using combination charts to describe the relationship between three quantities, such as cost of a number of pencils (represented along a horizontal axis), cost of a certain quantity of erasers (represented on the vertical axis), and total cost of n-pencils and m-erasers (represented in the cell (n, m)). Such a combination chart is an example of a quantitative coordinate system made up of two ordered-discrete RFs, in which number of pencils and number of erasers are discrete quantities.

It is important to be aware of the distinctions between these types of RFs, as their conflation can lead to unintended graphical interpretations. For instance, Figure 1c depicts a spatial coordinate system, but it is ambiguous whether each RF should be treated as continuous or ordered-discrete. On one hand, the vertical numeric labels suggest that students could describe the X's position using a continuum, but the use of letters as labels on the horizontal axis limits the ability to refer to non-discrete positions. Further, the positioning of the labels between tick marks rather than on tick marks may promote the creation of regions rather than a continuum. Depending on how an activity using a similar map is enacted, students may not conceive a distinction between the two types of RFs. Teachers and curriculum designers should be deliberate in crafting tasks and graphs such that students are prompted to engage with both types of RFs and explore the affordances and limitations of each in a variety of spatial and quantitative contexts.

Limitations and Concluding Remarks

This report is limited in that we only analyzed the activity of one student in a particular set of tasks. Future researchers may be interested in exploring how a wider range of students spontaneously construct and utilize both continuous and ordered-discrete RFs in quantitative and spatial CSs. Such research can support the field's understanding about how students reason about graphs and how such reasoning can be supported towards more normative graphing meanings. Understanding the ways in which students interpret and construct the fundamental components of graphs, such as RFs, is crucial to supporting students' developing meanings for graphs, which are ubiquitous in STEM contexts.

HOW PICTURE BOOKS PRESENT AREA AND PERIMETER

Jessica L. Postma
Western Michigan University
jessica.l.postma@wmich.edu

Elizabeth Gorton
Western Michigan University
elizabeth.s.gorton@wmich.edu

We conducted an analysis of children's literature centered on area and perimeter, using an adaptation of a framework for assessing the characteristics of picture books for learning mathematics. This paper focuses on the presence and absence of specific elementary and middle school Common Core State Standards related to area and perimeter within twelve picture books. We also consider whether the mathematics content is explained within each picture book. Findings reveal there are available picture books for teaching area and perimeter throughout elementary and middle school grades, except for sixth grade. We also found that most of the books presented the mathematics with explicit explanations, instead of implicitly. These findings could aid in teacher's selection and use of picture books when teaching mathematics.

Keywords: Elementary School Education, Geometry and Spatial Reasoning

Introduction

As educational practices evolve in these changing times, it is critical to envision the future of mathematics teaching. With traditional approaches being reevaluated, innovative teaching methods are becoming essential to meet the changing needs of students. Using picture books in mathematics instruction can meet those needs in the following ways.

Picture books enhance student engagement by immersing them in captivating stories, where interactions with characters and mathematical content make learning exciting (Skoumpourdi & Mpakopoulou, 2011). These books provide relatable contexts that allow students to apply their knowledge and see the relevance of mathematics in their daily lives (McAndrew et al., 2017). Lastly, picture books offer a promising way of teaching novel terms and associated properties of geometry specifically, by using both pictures and words. Further classroom discussion of these terms within the context of the books encourages students to make sense of and communicate with new mathematical language (Capraro & Capraro, 2006; McAndrew et al., 2017; Skoumpourdi & Mpakopoulou, 2011).

Despite these advantages, not all picture books related to mathematics are equally useful for teaching (Skoumpourdi & Mpakopoulou, 2011; Nurnberger-Haag et al., 2021). For example, how the mathematical content is presented influences the way a teacher incorporates the book in their teaching. If the mathematical content is only implied in the story, and not explained, the teacher would need to bring out the mathematics and help students build their understanding (Austin, 1998). However, if the mathematical content is explicit, there is danger it is being used to "tell" the mathematics, which can hinder cognitive engagement among students (Lobato et al., 2005). Thus, picture books' effectiveness in teaching mathematics must be assessed individually. However, there is limited research evaluating picture books for their effectiveness in teaching mathematics (Nurnberger-Haag et al., 2021), and most focus on the topic of shape (e.g., McAndrew et al., 2017; Skoumpourdi & Mpakopoulou, 2011). Our goal is to aid in broadening this field, by focusing on assessing picture books covering the concepts of area and perimeter, chosen due to students' common struggles in understanding these topics (Milinia & Amir, 2022). Using an adaptation of van den Heuvel-Panhuzen and Elia's (2012) f *Framework of Learning-Supportive Characteristics of Picturebooks for Learning Mathematics*, we intend to address the overarching question: How does the presentation of area and perimeter in picture books relate to their usability for teaching, based on the framework's learning-supportive characteristics? In this preliminary study, we focus on two questions: (1) Which elementary and middle school Common Core State Standards about area and perimeter are represented in picture books?; and (2) How are these concepts presented—implicitly or explicitly?

Theoretical Framework

In this study, we draw upon van den Heuvel-Panhuzen and Elia's (2012) *Framework of Learning-Supportive Characteristics of Picturebooks for Learning Mathematics* as a foundation. This framework identifies characteristics of picture books that contribute to the learning of mathematics by kindergartners. It consists of two main sections: (1) *Supply of mathematical content* identifies the mathematical content within a picture book; and (2) *Presentation of mathematical content* indicates how the mathematics is presented (e.g., explicitly or implicitly) and the characteristics that could prompt specific behaviors from children.

A. Supply of Mathematical Content		
A.1. Mathematical processes and dispositions		
A.2. Mathematical content domains The picturebook deals with CCSS.MATH.CONTENT… ***2nd grade*** **G.A.2:** Partition a rectangle into rows and columns of same-size squares and count to find the total number of them. ***3rd grade*** **G.A.2:** Partition shapes into parts with equal areas. Express the area of each part as a unit fraction of the whole. **MD.C.5:** Recognize area as an attribute of plane figures and understand concepts of area measurement. - **A:** A square with side length 1 unit, called "a unit square," is said to have "one square unit" of area, and can be used to measure area. - **B:** A plane figure which can be covered without gaps or overlaps by *n* unit squares is said to have an area of *n* square units. **MD.C.6:** Measure areas by counting unit squares (square cm, square m, square in, square ft, and improvised units). **MD.C.7:** Relate area to the operations of multiplication and addition.	- **A:** Find the area of a rectangle with whole-number side lengths by tiling it, and show that the area is the same as would be found by multiplying the side lengths. - **B:** Multiply side lengths to find areas of rectangles with whole-number side lengths in the context of solving real world and mathematical problems, and represent whole-number products as rectangular areas in mathematical reasoning. - **C:** Use tiling to show in a concrete case that the area of a rectangle with whole-number side lengths *a* and *b* + *c* is the sum of *a* × *b* and *a* × *c*. Use area models to represent the distributive property in mathematical reasoning. - **D:** Recognize area as additive. Find areas of rectilinear figures by decomposing them into non-overlapping rectangles and adding the areas of the non-overlapping parts, applying this technique to solve real world problems. **MD.D.8:** Solve real world and mathematical problems involving perimeters of polygons, including finding the perimeter given the side lengths, finding an unknown side length, and exhibiting rectangles with the same perimeter and different areas or with the same area and different perimeters.	***4th grade*** **MD.A.3:** Apply the area and perimeter formulas for rectangles in real world and mathematical problems. ***6th grade*** **G.A.1:** Find the area of right triangles, other triangles, special quadrilaterals, and polygons by composing into rectangles or decomposing into triangles and other shapes; apply these techniques in the context of solving real-world and mathematical problems. **G.A.4:** Represent three-dimensional figures using nets made up of rectangles and triangles, and use the nets to find the surface area of these figures. Apply these techniques in the context of solving real-world and mathematical problems. ***7th grade*** **G.B.4:** Know the formulas for the area and circumference of a circle and use them to solve problems; give an informal derivation of the relationship between the circumference and area of a circle. **G.B.6:** Solve real-world and mathematical problems involving area, volume and surface area of two- and three-dimensional objects composed of triangles, quadrilaterals, polygons, cubes, and right prisms.
B. Presentation of Mathematical Content		
B.1. Way of presenting The mathematical content… - is addressed *explicitly* (something mathematical is happening that is explained) or *implicitly* (something mathematical is happening that is not explained) - is *integrated* in the story (either explicitly or implicitly) or *isolated* from the story (e.g., there is a picture of somebody wearing a dress with a nice geometrical pattern, but the story does not mention the dress)		
B.2. Quality of presentation		

Figure 1: Mathematical Content Domains and Way of Presenting (Adapted from van den

Heuvel-Panhuzen & Elia, 2012)

We adapted van den Heuvel-Panhuzen and Elia's (2012) framework to apply to picture books focusing on area and perimeter across various grade-levels. The primary change was replacing A.2—*Mathematical content domain*—with the Common Core State Standards of Mathematics (CCSSM) related to area, perimeter, circumference, and surface area for elementary and middle school grades. Notably, kindergarten, first, fifth, and eighth grade have no standards on these topics. We defined each characteristic of the framework, except for the CCSSM, was defined using our interpretations of van den Heuvel-Panhuzen and Elia's (2012) explanations. Although other adaptations were made, they fall beyond the scope of this paper.

In this report, we will focus on characteristics A.2—*Mathematical content domains*—and how they were presented, implicitly or explicitly, within B.1—*Way of presenting*—as shown in Figure 1. Content presented *explicitly* means the mathematics was explained in the words or images, while an *implicit* presentation includes no explanations of the mathematics.

Methods

The picture books we analyzed were chosen based on their connection to area, perimeter, circumference, and surface area. These were found by searching Google and the Western Michigan University library database for the following keywords: children's book or picture book and area or perimeter or circumference. Once we identified a potential book, we read it and kept it if it was related to area and/or perimeter, resulting in twelve books (Figure 2).

Adler, D. A. (2012). *Perimeter, area, and volume: A monster book of dimensions.*	Neuschwander, C. (1997). *Sir Cumference and the first round table*.
Brucke, C. Y. (2009). *Wrappers wanted: A mathematical adventure in surface area*.	Neuschwander, C. (1998). *Sir Cumference and the dragon of Pi.*
Burns, M. (1997). *Spaghetti and meatballs for all!*	Neuschwander, C. (1999). *Sir Cumference and the Isle of Immeter.*
Gabriel, N. (2006). *Sam's sneakers squares.*	Pilegard, V. W. (2004). *The warlord's kites*.
Murphy, S. J. (2001). *Racing around.*	Pollack, P., & Belviso, M. (2002). *Chickens on the move*.
Murphy, S. J. (2002). *Bigger, better, best!*	Reisberg, J., & Hohn, D. (2006). *Zachary Zormer: Shape transformer: A math adventure*.

Figure 2: Picture Books Focusing on Area and Perimeter

We began by independently analyzing each picture book using the framework in Figure 2. We individually highlighted any characteristic in the framework present in the book and included significant notes about its presence or absence. We then met to ensure consistency, discussing any differences, and clarifying definitions until agreement was reached.

Findings

Figure 3 identifies the CCSSM about area and perimeter addressed in each picture book.

Most CCSSM standards in second, third, fourth, and seventh grade were addressed by multiple books; yet, no picture book focused on the third grade standards, **G.A.2** or **MD.C.7.C**, which refer to partitioning shapes to represent fractions and modeling the distributive property with area, respectively (see Figure 1). However, these standards teach other concepts through area, rather than area itself, which may explain their absence from the books in our study. We also found that no books in our collection covered the sixth grade standards, **G.A.1** or **G.A.4** (see Figure 1). While one book, *Sir Cumference and the First Round Table* cut apart shapes and moved portions around, it did not find area by decomposing shapes as in **G.A.1**. Similarly, *Wrappers Wanted* described finding surface area by adding the area of each face of a box, but the idea of nets was not utilized as in **G.A.4**. Thus, none of the sixth grade standards were fully covered within any of the picture books analyzed.

When considering the *way of presenting*, *Spaghetti and Meatballs for All!* and *Chicken's on the Move* presented mathematics implicitly, as opposed to the other ten books which did so explicitly. For example, in *Spaghetti and Meatballs for All!*, the characters consider how many chairs fit around different configurations of tables. This implies the relationship between area and perimeter without explaining the mathematical concepts or using mathematical language.

Figure 3: CCSSM for Area & Perimeter Addressed in Picture Books

Discussion and Conclusion

Our findings reveal there are picture books available for teaching a range of CCSSM related to area and perimeter throughout elementary and middle school grades. However, a gap exists in the representation of the sixth grade standards as seen by the absence of coverage for **G.A.1** and **G.A.4**, which describe decomposing shapes to find area and using nets to find surface area. Both standards involve manipulating and visualizing spatial elements, ultimately enhancing students' ability to understand and solve complex spatial problems (Davis et al., 2015). Thus, picture books focusing on these standards would provide much needed resources for teachers.

Ten of the twelve picture books explicitly incorporated mathematics content. Teachers may find it convenient to include these books in lesson plans as they require minimal interpretation on the teacher's part. However, it is crucial to use picture books as part of an integrated approach that enhances students' understanding of mathematical concepts (Austin, Thompson, & Beckman, 2005). Presenting mathematics implicitly requires students to actively engage with the material and draw connections between the story or illustrations and the mathematical concepts, fostering a deeper understanding of the mathematical content (Austin, 1998). Therefore, increasing the availability of picture books that implicitly present mathematics related to area and perimeter would benefit both elementary and middle school students and teachers.

By assessing these twelve picture books based on the CCSSM for area and perimeter, teachers can identify which ones may be beneficial for teaching their intended standard(s). We recognize we may have missed relevant books, which could be a limitation of our study. For example, books that present mathematics implicitly may not use the terms area and perimeter, so they may not have come up in our search. Our framework directs teachers' attention to specific learning-supportive characteristics (e.g., *way of presenting*) that may influence how picture books are used in their classroom. Looking forward, we anticipate this framework serving as a guide for categorizing the usability of picture books for teaching mathematical content, aiding educators in making informed decisions tailored to their classrooms' needs.

A THIRD-GRADER'S DISTINCTION BETWEEN QUALITATIVE AND QUANTITATIVE TIME

Amy Smith
Stetson University
asmith92@stetson.edu

This paper explores how nine-year-old Loren described the duration of common experiences through qualitative perceptions and quantitative measurement. After organizing four "everyday" activities from shortest to longest duration (sleeping at night, watching a movie, eating lunch, brushing teeth), Loren justified their ordering through contrasting the paradox of how each experience felt against a quantified length of each duration. These distinctions demonstrate the complexity of temporal and durational reasoning and evidence potential conceptions that elementary-age children may have when reasoning about time—a consideration that mathematics teachers and researchers have often overlooked.

Keywords: measurement, elementary school education, problem-solving

When reflecting on the duration of common activities, elementary-age children draw on numerous aspects of their lived experiences (Smith, 2021). Many of these attributes are quantifiable in and of themselves, such as knowing that you have a long way to walk (distance) so it will take a while or building a Lego with 500 pieces (500 being a larger quantity) taking longer than a mini-figure (with only three pieces to construct). However, some aspects of experience are not measurable in the same, mathematical sense, such as having the long walk be on a hot (or cold) day which will make it *feel* like it is taking longer or having a knowledgeable sibling help build the Lego so it will not take as long (but a less-practiced sibling may cause it to take even longer). These less well-defined attributes of experience are not considered when formal time teaching and learning are established in early elementary school (see Common Core State Standards Initiative, n.d.); yet, they are commonly, informally prevalent in durational experiences throughout an individual's life, and thus, should be explored. The present case exemplifies one such child's attempt to articulate this mathematical paradox.

Theoretical Framework

Young children develop an intuitive sense of duration based on their perceptions of succession—the sequence in which events occur, and duration—the intervals of and between events (Piaget, 1969). These perceptions develop through conclusions made as they reflect on their lived experiences. Children who reason intuitively, for example, may consider duration as a result of their efforts, believing that *because* more work was done, the duration was necessarily longer (Piaget, 1969; Smith, 2021). A child reasoning in such a manner might conclude that *because* they drew lots of lines, the duration was long. As they grow and through experience, children's conceptions of time develop from intuitive—based purely on observations—to operational—based on the relationships abstracted from their observations (Long & Kamii, 2001; Piaget, 1969). When reasoning operationally, children recognize the reciprocal relationship of succession and duration (Piaget, 1969). When the previous child, for instance, can reason that they were able to draw a lot of lines because they took more time to complete it *and* that taking more time allowed them to draw more lines, they would demonstrate an operationalization of durational reasoning. This reasoning is necessary for durational measurement (Kamii & Russell, 2010, 2012; Piaget, 1969).

Flaherty and Meer (1994) posited a general theory of lived time, where the retention and recollection of durational events are defined by an individual's engagement, attention, emotional connection, and habituality of the event. In other words, how an individual might measure the duration of their experiences is impacted by how they processed the experience in the first place. Events that are common or less engaging might be perceived as taking more (or less) time than the actual, measured duration. This processing can lead to uneven durational perceptions, such as time feeling like it is "flying by" (temporal compression) or "dragging on" (protracted duration; Flaherty & Meer, 1994), which can impact durational measurement and reasoning (Smith, 2021).

Qualitative durational reasoning corresponds with Piaget's gross quantification (1952), where asymmetrical relations engender the difference between two quantities. Such comparison allows for the distinction of more (longer), less (shorter), or the same. *Quantitative durational reasoning* utilizes numbers as the units of measure (Russell, 2008). This occurs when an individual can distinguish space measurement from time measurement (i.e., can account for the duration of an event disparate from their perception of the event). This durational measure is no more or less cognitively demanding than qualitative reasoning because both require the individual to reflect on, and abstract, the durational relationships they experience (Piaget, 1969). Rather, these are two distinct ways that individuals might reflect on their durational conceptions.

Methodology

The case presented (Yin, 2003) came from a larger study that explored how elementary-aged children (age 4-11) organize the duration of common experiences (Smith, 2020, 2021). Each participant was asked to organize four activities: brushing teeth, eating lunch, watching a movie, sleeping at night, from the shortest to longest duration. Then, the interviewer inquired into the child's reasoning. This case illustrated markedly different reasoning from other participants.

Participant and Data Collection

The data presented come from an interview with nine-year-old Loren[1]. Loren was a third grader from a large suburban city in the Midwestern United States. The interview was video recorded to capture Loren's words and actions. During the interview, Loren was given four cards with images and words of the four activities and asked to put the activities in order from what took the least amount of time to the most amount of time, then discuss their reasoning.

Data Analysis

With the distinct nature of Loren's responses, I used a phenomenological lens during analysis (Creswell, 2013; Hycner, 1999) to understand as much as possible about Loren's reasoning. Following Wolcott's (1994) three-part analytic framework, I worked to create "data out of experience" (p. 13), by first incorporating all of Loren's words, actions, wait times, and inflections into a *descriptive* transcript. From my *analysis*, I distinguished Loren's quantitative durational reasoning from their qualitative perceptions of the durations. Reflecting on Loren's

[1] Gender neutral pseudonyms were used as gender identity was not the central to the research focus.

data as a whole, I returned to existing theories to better *interpret* how Loren conceived of duration as a measurable attribute of their lived experience.

Findings: Description and Analysis

When initially asked to organize the four activities, Loren placed the "sleeping at night" card on the far-left side of the table, indicating the shortest duration. They then placed "brushing teeth" at the far-right side, indicating the longest duration. This process was similar to how individuals bound the duration of their experiences, finding the upper and lower durational limits, then constructing the unit within (Smith, 2021). Interestingly, Loren's placement of these cards (longest/shortest), was backward/opposite of all other participants interviewed. Loren then placed the "watching a movie" card after sleeping at night, indicating that to them, watching a movie took longer than sleeping at night. Finally, they placed "eating lunch" between watching and movie and brushing teeth.

Sleeping at Night

Loren began describing how they considered the duration of each activity with what they conceived of as the shortest duration—sleeping at night. Loren explained, "When I fall asleep and I know that's like 12 hours, I wake up [swiped hand through air] and it feels like it's 30 seconds." This description was one of Loren's clearest examples of their qualitative reasoning distinct from quantitative reasoning. Qualitatively, and paradoxically, Loren explained that they *knew* the duration of their experience as one quantity (12 hours) despite that it *felt* like a different, much shorter quantity (30 seconds). Quantitatively, Loren attributed the duration of their sleep through two different standardized units of measure: 12 *hours* versus 30 *seconds*. I inferred that their motioning of swiping their hand through the air was an iconic gesture (McNeill, 1992) of the comparison between these two units, symbolizing their acknowledgement that 30 seconds is a quantifiably different durational amount than 12 hours. Remembering that Loren placed this activity as the shortest of the four, it seems that their qualitative durational reasoning guided their overall consideration of the durational organization.

Watching a Movie

After justifying their placement for sleeping at night, Loren immediately went on to explain, "I feel like movies are short, but when you look at the time, it's already like, if you started watching at 3:30 it's already 5:54 and I just feel like watching a movie is fun, and something that I enjoy." Similar to sleeping at night, Loren seemed to openly distinguish between their qualitative perceptions of the duration and the quantitative measurement—even providing a somewhat reasonable approximation of the duration of a typical movie (around 2.5 hours). Multiple times, Loren reflected specifically on how the duration felt, noting that it felt "short" and was "fun"/enjoyable. These perceptions were countered by Loren's hypothetical description of looking at a clock to note the start and end times of the movie (quantitative measurement).

Eating Lunch

Loren placed the eating lunch event last when organizing the events. Unlike the previous two experiences, Loren's reflection on the duration of eating lunch was less defined both quantitatively and qualitatively. Loren stated, "Eating my lunch, I usually don't eat that much, um, I have a salad and eggs, but I chose eating my lunch here [pointed to placement] because I feel like it's just, um, [hesitated three seconds] uh, I don't know." Initially, it seemed that Loren reflected on the quantity of food as related to the measure of the duration. This reflection on gross quantity as a proxy for durational length has been evidenced by other children (Smith, 2021), though never with explicit relation to qualitative durational reasoning. Loren did go on to state that they *felt* like it belonged in the placement it was but was unable or unwilling to elaborate on why this experience felt the duration it did, either qualitatively or quantitatively.

Brushing Teeth

Brushing teeth was the second event placed during Loren's initial organization and bound the "upper limit" (longest duration) of Loren's established durational timeline. Loren explained, "Brushing my teeth, I feel like it's two minutes, but when I go downstairs my dad will say, what are you doing, I told you to brush your teeth, you've only been up there for 30 seconds [laughed]." This explanation echoed Loren's previous descriptions in the use of measurable, quantitative durations based on established time units (two minutes, 30 seconds). However, Loren's qualitative explanation that brushing their teeth *felt* like two minutes but was, in fact, much less than that (30 seconds), yet was situated as the longest duration of the four events, highlights the impact that qualitative reasoning had on Loren's overall durational reasoning. I see Loren's last response, a laugh, as a critical piece of evidence of this durational paradox. Loren seemed aware that the quantitative duration of this event did not align with their qualitative experience of the event. Yet, even with this awareness, Loren maintained the order of the events as they were originally situated, from shortest (sleeping at night) to longest (brushing their teeth).

Discussion: Interpretation

The data presented highlight Loren's diverse durational reasoning. Quantitatively, Loren demonstrated understandings of various standard durational units—seconds versus minutes versus hours—and provided verbal evidence and non-verbal cues of an awareness of the relationship between these units (that seconds are a smaller duration than hours, etc.). Additionally, Loren quantitatively bound events (starting a movie at 3:30 and ending it at 5:54), providing evidence of unitizing duration (Piaget, 1969; Smith, 2021). Qualitatively, Loren explicitly stated that each of the four events "felt" a specific way. Some of these "feelings" provided context for their numerical quantification (12 hours of sleep feels like 30 seconds) while others provided evidence of Loren's appreciation for the paradoxical nature of duration and temporal events ("time always goes slow on something you don't enjoy").

Loren's ability to distinguish between the qualitative nature of the duration of their experiences and the quantified measurement of these durations aligned with various established durational and temporal conceptions. Specifically, Loren's descriptions provided evidence of four temporal and durational conceptions: 1) how engagement/enjoyment can impact perceived durations (Flaherty & Meer, 1994; Smith, 2021); 2) the correlation between gross quantity and durational measurement (Piaget, 1969; Smith, 2021); 3) how an individual's actions can impact the duration of their experiences (Piaget, 1969; Smith, 2021); and 4) how parents can impact children's perceptions of durations (Piaget, 1969).

Implications

When considering Loren's durational understandings, it is important to consider implications this may have both in formal schooling and in life. Clearly, Loren has a much richer bank of conceptions to their durational reasoning than established state and national standards consider. As they are currently situated, standards for time teaching and learning focus solely on analog and digital clock reading and hypothetical elapsed time calculations (CCSSI, n.d.). There are no math standards nor expectations for durational reasoning nor is there any consideration of how qualitative perceptions of time might impact or coordinate with quantified, standardized time (hours, minutes, seconds). Instead, time teaching and learning is siloed to elementary classroom clock reading, yet time-related concepts span the K-12 curriculum (e.g., time as an independent variable, Thompson, 2012, or scientific uses of time, Tasar, 2010). Shifting out of the elementary classroom, temporal and durational reasoning is an essential "life skill" in our Western society. Time management and scheduling are critical skills that rely heavily on durational reasoning, both quantitatively ("clock time"; Earnest, 2018) and qualitatively ("event time"; Earnest, 2018). To support students like Loren, we need to appreciate the complexity of time and consider how children's perceptions of this abstract, invisible quantity (Earnest, 2019) might impact their durational measurement.

GEOMETRY REPRESENTATIONS ON STANDARDIZED TEST

Waldemar Stepnowski
Temple University
wstepnowski@temple.edu

Keywords: Geometry and Spatial Reasoning, Mathematical Representations, Assessment

Teachers, students, and designers of exams must make choices in how they represent a mathematical object so that it helps them attain their goal. To be able to make choices in the use of geometry representations, teachers, students, and test designers need to know which representations are available, how to use them, and what are some benefits of using one over another. In this study, I analyze the geometry representation on state, national, and international exams at the secondary level in order to see what is deemed necessary as students leave high school and prepare for college and/or a career.

Besides the above, there are a few more reasons why studying representations is valuable. First, we all want students to solve problems with a high degree of accuracy and efficiency, and representations help us manage mathematical information. Students who coordinate different mathematical representations well solve mathematical problem better than those who do not (Gagatsis & Shiakalli, 2004). Second, to solve problems students need to use aids or tools like representations to reduce the complexity of a problem. We use representations as a kind of external memory, where we can offload some of the information from our working memory (Scaife & Rogers, 1996). Third, in the digital age, there are also practical reasons to study geometry representations. We are beginning to develop digital textbooks, online environments, etc., where the choice of representations is important (Presmeg et al., 2016).

Methods

I have examined standardized test given at the end of secondary school. Some of the exams are designed and administered at the state level like New York's Regents. Some are more regional/national like the PAARC and Smarter Balanced. Some exams like the SAT are national and designed as college readiness exams. Finally, some are international like PISA.
The unit of analysis is one question/problem from the exams. I searched for a minimum of 10 questions from each test, which were downloaded from the agencies that administered and/or designed the exams. If there were fewer than 10 questions, I looked at a related website that had a recent exam. If an exam had more than 10 question, I used no more than 20, selecting those that most resembled Euclidean geometry.

Results

From the preliminary result, many exams have typical problems with diagrams, but some avoided using diagram. There were few problems using real-world physical language on many of the exams, but the PISA math assessment contained multiple examples of this type with very complex diagram. On some exams the meta-language was quite complex, e.g., refute a claim is an abstract level higher than actually solving a problem. Calculator buttons were used to enter an answer such as a ration instead of selecting an answer as in multiple choice questions or writing the answer.

HIGH SCHOOL STUDENTS' FIGURATIVE AND OPERATIVE THOUGHT WHEN REASONING ABOUT DISTANCES

Irma E. Stevens
University of Rhode Island
irma.stevens@uri.du

Hamilton L. Hardison
Texas State University
HHardison@txstate.edu

Amanda Brown
University of Michigan
amilewsk@umich.edu

In this report, we share analysis of 55 students' interview responses to a "suspension of sense-making" story problem involving how far two people live from one another. The prompt occasioned different ways of reasoning. Some students reasoned about lines; others about triangles; and still others about circles. Students' differing responses indicate across-student variation in spatial organization and the quantitative roles of distance in those spatial organizations. We describe students' mental operations of reasoning about points as varying and static and relate it to research on students' meanings for a circle as representing all points an equal distance away from a center point. Overall, this study provides a quantitative reasoning lens to better understand how students make sense of a well-studied problem.

Keywords: Geometry & Spatial Reasoning, Mathematical Representations, Cognition

Over the past several decades, researchers have described the importance of students' quantitative reasoning (Thompson & Carlson, 2017). Research has also shown that school mathematics can constrain what students might consider when responding to certain problems (Palm, 2008). In this study, we report on high school students' responses to a question about the distance between two places (Figure 1). One productive response involves students constructing circles. An individual's spontaneous consideration of a circular path when tasked with identifying locations that are a specified distance from a fixed point is an indication of what Hardison et al. (2017) referred to as an operative conception of a circle; such a conception involves a smooth radial operativity if the individual anticipates a rotating segment of constant radial length around one fixed endpoint while the other endpoint traces out a circular path. However, there exist responses contraindicating students considering circles with this problem, and thus, we sought to answer the question: "What ways of reasoning do students indicate when considering distances between objects? What are the figurative and operative aspects of these ways of reasoning, and how do they relate to the realistic nature of students' responses?"

Bruce and Alice go to the same school. Bruce lives at a distance of 17 kilometers from the school and Alice lives at 8 kilometers. How far do Bruce and Alice live from each other?

Figure 1: *The School Problem* (adapted from Treffers & de Moor, 1990)

In this report, we first review existing literature around *The School Problem*, the word problem used in this study (Figure 1), highlighting reported findings on students' reasoning. We then consider this problem and prior findings in relation to the Piagetian constructs of figurative and operative thought (Piaget, 1970; Thompson et al. 2024); we specifically build upon Hardison et al.'s (2017) definitions and examples of figurative and operative conceptions of circles. We then report on the ways of reasoning indicated by 55 high school students who answered this problem. We focus on distinguishing figurative and operative aspects of the imagery indicated by students' responses and compare this analysis to previous findings on the realisticness of responses to this problem.

Literature Review

In this literature review, we report on findings on the *School Problem* and situate those findings within the literature on quantitative and covariational reasoning. We conclude the literature review with a focus on figurative and operative thought.

Problem Solving

The context of the study reported on here developed from a larger interest in understanding students' realistic mathematical sense-making (Reusser & Stebler, 1997). Researchers have reported on students' suspension of sense-making (Schoenfeld, 1991) when solving word problems (e.g., Palm, 2008), noting that students rely more on procedural mathematics than conceptual applications to solve these word problems. Researchers have also reported that students' suspension of sense-making increases over time as they develop more experience in problem solving and modeling in school (Mellone et al., 2017).

Verschaffel and colleagues explored this suspension of sense-making through word problems designed to have different responses depending on the extent to which students are attending to the realistic nature of the problem. One of these problems was used in this study (Figure 1) (from Verschaffel et al. (1997), as worded in the English-translated Treffers & de Moor (1990)). Verschaffel et al. classified it as a "problematic" item because the underlying mathematical modelling assumptions are problematic from a realistic point of view. According to the authors, there are two non-realistic answers and one realistic answer to this problem. The two non-realistic answers they provide are 9 km (i.e., 17−8) and 25 km (i.e., 17+8). The realistic answer is "you cannot know how far Saskia [*Alice in our study*] and Bruno [*Bruce in our study*] live from one another" (p. 344). Verschaffel et al. (1994) conducted a study with 75 students (aged 10–11), and only 3% of students provided a realistic answer to this problem. In Verschaffel et al. (1997), out of 332 pre-service teachers from three different institutes for elementary school teacher training in Flanders, 48% gave realistic reactions. This 48% includes responses with realistic answers and other responses researchers indicated as including "activation of real-world knowledge" (p. 345) (e.g., gave an indication that more than two answers were possible). In both studies, few details were provided into specifics of the "non-realistic" and "realistic" reasoning the participants engaged to determine their solutions. In this study, we use the ideas of quantitative reasoning and figurative and operative thought to understand students' ways of reasoning when solving this problem.

Distances and Quantitative and Covariational Reasoning

The *School Problem* can be interpreted in terms of quantities and their relationships. Quantities are measurable attributes an individual conceives in a situation, and, over several decades, researchers employing principles of quantitative reasoning have provided insights into the quantities students construct and quantitative operations students enact (Thompson & Carlson, 2017). This subfield has offered explanatory models for students' construction and interpretation of various representations (e.g., graphs, tables, geometric shapes).

For example, Carlson et al. (2002) elaborated differences in students' reasoning about the relationship between volume and height of water in a bottle as it is filled. Some students engaged in directional covariational reasoning by stating that the water's height increases as the volume of water added to the bottle increases. Here, students consider height and volume as quantities and reason about them changing in tandem via quantitative operations (e.g., addition, subtraction of quantities or states of quantities).

Previous research on the *School Problem* has not taken up this focus on quantitative reasoning. In this study, we do, and we specifically identify three quantities are of interest (from our perspectives): the distance Bruce lives from the school, the distance Alice lives from the school, and the distance Bruce and Alice live from each other.

Figurative and Operative Thought

Beyond quantities and quantitative reasoning, the Piagetian constructs of figurative and operative thought are relevant for the present study; these are two complementary aspects of thought. Piaget (1970) defined the figurative aspect of thought as "an imitation of states taken as momentary and static" (p. 14). In Piaget's view, figurative thought serves important cognitive functions involving, for example, perception and mental imagery. In contrast, the operative aspect of thought "deals not with states but with transformations from one state to another…it includes actions themselves, which transform objects of states" (p. 14). In Piaget's work, operative thought necessarily entails reversibility and is at the level of interiorization. Reversibility can be considered as follows: if an initial state is subjected to an operation, *A,* then an inverse operation, *B*, can be subsequently enacted to revert to the initial state. To say that operative thought is at the level of interiorization means that the operations can be carried out in the mind without being enacted physically. We emphasize that the figurative-operative distinction characterizes complementary aspects of thought in that the latter cannot exist without the former; operations require some (figurative) state on which to operate. However, Piaget (1970) clearly stated his interest in understanding operative aspects of thought in particular remarking, "...to my way of thinking the essential aspect of thought is its operative and not its figurative aspect" (p. 15).

For example, in Lee et al., (2018), the authors describe a student, Lydia, who conceived a slope of a given graph as "rising" three, which perturbed her when the researcher rotated the given graph counterclockwise 90 degrees. She struggled to conclude if the slope value should stay positive or become negative, given that the graph was no longer "rising." Moore et al. (2019) described this reasoning as figurative because her meanings for increasing and decreasing values were constrained by orientation.

In Moore et al. (2019), emergent shape thinking is provided as an example of operative thought. Emergent shape thinking involves covariational reasoning with quantities (e.g., reasoning with volume and height in the bottle problem) and transforming figurative entailments constructed from that reasoning (e.g., identifying amounts of change in volume for a change in height) into a quantitatively equivalent representation (e.g., a coordinate system).

Hardison et al. (2017) introduced the idea of figurative and operative circle concepts and reported on reasoning associated with an individual reasoning with figurative circle concepts. In the present study, we identify figurative and operative aspects of student thinking as indicated by their responses to the *School Problem* (Figure 1), specifically attending to the construct of an operative circle construct. The next section details this construct.

Conceptual Framework

In 2017, Hardison et al. considered figurative and operative aspects of thought in the context of one prospective teacher's thinking about circles. Specifically, they offered definitions for *figurative circle concept* and an *operative circle concept* (Figure 2). A *figurative circle concept* "consists of an individual's ability to recognize or re-present a circle as a static form." A figurative circle concept functions as a mental template for producing or assimilating a circle. An individual can bring forth an image of a circle in visualized imagination or recognize circle models (e.g., a hula hoop) as being circular in shape. In contrast, an *operative circle concept* entails an individual's mental image of a segment of fixed length rotating around a fixed endpoint while the other endpoint traces out a circular path. We emphasize that this smooth radial operativity is one of several operative possibilities for circles. In their 2017 work, Hardison et al. did not consider other forms of operativity for circles, and we will not either in this report because they were not identified within our given dataset.

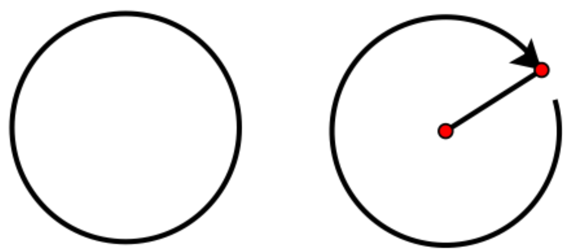

Figure 2: (left) Figurative circle concept and (right) smooth radial operative circle concept

We extend the work of Hardison et al. (2017) by noting that the smooth radial variety of an operative circle concept entails the following two aspects: Constructible and Quantitative (Figure 3). The constructible aspect of an operative circle concept involves an individual's anticipation that a circular arc will necessarily result when one considers a set of locations that are a fixed distance away from a fixed point (Figure 3 top). In contrast, the quantitative aspect of an operative circle concept involves an individual's anticipation that, when starting with a path known to be circular, all points along the path are necessarily the same distance from a particular (center) point (Figure 3 bottom). The distinction between these two aspects of an operative circle concept lies in what is taken as (a) the initial state and (b) the resultant state. In the constructible aspect, the initial state involves a fixed distance from a fixed point, and the resultant state is a (subset of) a circular path. In the quantitative aspect, the initial and resultant states are reversed. Common to both constructible and quantitative aspects is a mental rotational motion of a radial segment that enables transitioning between initial and resultant states in each case.

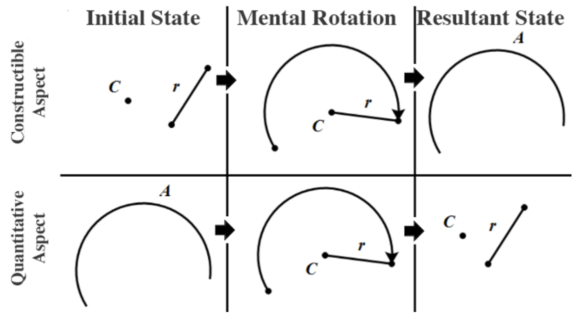

Figure 3: Reversibility of an Operative Circle Concept: Constructible (top) and Quantitative (bottom) Aspects

To demonstrate these concepts, Hardison et al. (2017) reported on a 12-session, semester-long teaching experiment (Steffe & Thompson, 2000) with a prospective secondary mathematics teacher (Lydia) at a large institution in the southeastern U.S. Lydia was working on the two tasks in Figure 4: *Going Around Gainesville* and *Where Did They Go?* For *Going Around Gainesville*, students were tasked with creating a graph relating the car's total distance travelled and its distance from Gainesville during the trip (Figure 4 top left). For *Where Did They Go?*, students were tasked with constructing a path representing the same relationship between distances from two points (A and B) in the given graph.

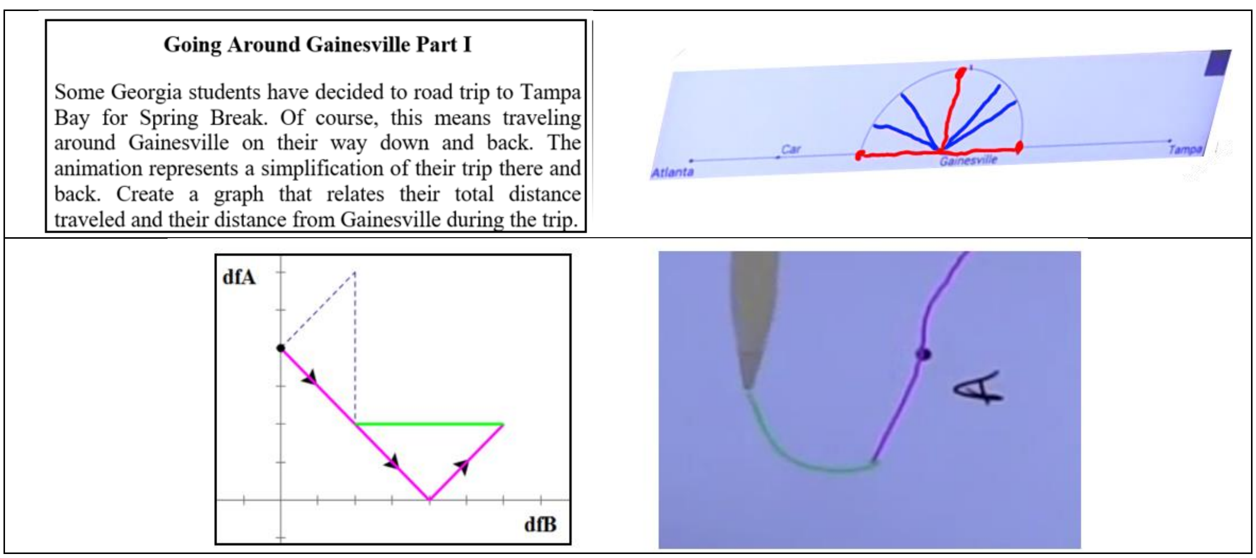

Figure 4: *Going Around Gainesville* Task and Lydia's work (top) and *Where Did They Go Task?* and Lydia's diagram (bottom)

In *Going Around Gainesville*, Lydia recognized the (semi-)circular portion of the road and drew red and blue line segments emanating from Gainesville and extending to the semi-circular portion (Figure 4, top right). She identified the distances represented by the red segments as "the same…because that's the radius length." Thus, Lydia recognized the static form of the a (semi-

)circle in this situation which is evidence of at least a figurative circle concept. The same was not true for the blue lines where she thought "at some points in the circle we're going to be closer to Gainesville". Thus, the quantitative aspect of an operative circle concept is contraindicated since Lydia's recognition of a semicircular path did not entail her immediate anticipation of equal radial distances from the center (i.e., Gainesville).

In *Where Did They Go?*, after drawing portions of a road map (Figure 4, bottom right) to appropriately account for the pink portions of the provided graph (Figure 4, bottom left), Lydia considered drawing a curved green path, which she called a "loop" in the road, to account for the green horizontal segment in the graph. She rejected her "loop" because she recognized from the graph that the distance from City A was "not supposed to change" and, according to Lydia, the loop had "changing distances." Thus, although Lydia recognized the need for a path that was a fixed distance from City A, this did not immediately evoke for Lydia a circular arc. In summary, Lydia's initial reasoning on this task contraindicated an operative circle concept precisely because Lydia's observable activities were contrary to the constructive aspect of operativity.

We expand on Hardison et al.'s (2017) work with Lydia in two ways. First, we identify examples of students who indicated operative circle concepts. Second, we discuss how other students' reasoning and diagrams seemed to contraindicate an operative circle concept.

Methods and Analysis

The study included 55 high school students from three settings: 17 enrolled in a 90-day English-speaking, island-based semester-program with a place-based curriculum, and 38 in a regular high school setting (16 with placed-based tasks). Each student participated in a 30-minute clinical interview, which included responding to three story problems, the third of which was the *School Problem* (Figure 1). The individual interviews occurred via video-conferencing software, and there was an audio recording and an image recorded of students' final written solution. Students were encouraged to think aloud. Video records were transcribed using natural language processing software (NLP) and then refined by a research assistant.

Analysis began with two rounds of coding: the first replicated Verschaffel et al.'s (1994) coding scheme, categorizing student work according to realistic reasoning (No answer, Expected Answer, Technical Error (e.g., subtraction miscalculation), Realistic Answer), and the second involved open coding to identify differences in students' approaches and strategies. In this second round, approaches were distinguished in terms of: (i) how many configurations of the locations of the houses and school the student considered (ii) how many configurations the locations of the houses/school the student thought were possible, (iii) whether students identified the minimum or maximum distances possible, and (iv) the various diagrams the students used. This second round of analysis inspired further consideration regarding how students' configurations foregrounded figurative and operative thought, given the variety of student responses and diagrams. Thus, a third round of analysis attended to students' figurative and operative thought—with students' solutions grouped by type of diagram and ways students within in each diagram type category described their images of the situation (i.e., more than a mental picture [see Thompson, 1996]).

Results

In this section, we discuss the responses from the 55 high school students. Recall that for the *School Problem* that an awareness of multiple solutions indicates realistic reactions. From the first round of analysis using the Verschaffel framework, we identified that 31 (~56%) of the students provided a realistic reaction. However, in the subsequent analysis of student responses, we identified that these realistic responses varied in the extent of potential alternatives. For example, 12 (~22%) students identified the maximum and minimum distances Bruce and Alice could live from each other by rearranging the order of the locations on a straight line, but this indicated awareness of only two potential Bruce-Alice distances. Two others indicated different configurations were possible, but not necessarily all values between 9 and 25; that is, the number of configurations of buildings was more than two, but the number of possible Bruce-Alice distances was still finite. Only five students clearly identified a range of values (two others indicated a range but did not provide numerical bounds). The remaining realistic responses indicated a multitude of configurations, but not necessarily a continuous range of Bruce-Alice distances. A summary of these considerations, including non-realistic responses (i.e., one configuration considered; no others), is in Table 1 (left). This distinction is relevant to figurative/operative thought because an activated operative circle concept would necessarily result in the consideration of two circles with each delineating the possible locations for each house, thus representing all possible configurations simultaneously.

Table 1 (right) summarizes the results from the second round of analysis, and the remainder of the results are from the third round of analysis which highlights the figurative and operative nature of select students' reasoning as indicated by the representations they drew. It is important to note that two students interpreted the distances as along paths and not as the crow flies and seven (different) students did not physically draw diagrams when working on the problem, so their results are excluded from Table 1 (right). It is also important to note that several students drew more than one diagram (e.g., triangle and circle), and so their work is counted more than once in Table 1 (right) unless they drew multiple cases of the same diagram (e.g., straight line segment switching whether the school is on the left or the middle of the segment).

Table 1: (left) Diagram Configurations Considered and (right) Student Diagrams

Consideration	# Students
One configuration considered; no indication others are possible	24
One configuration considered; indication others are possible	6
Multiple configurations considered; no indication others are possible	13
Multiple configurations considered; indication others are possible	5
Range of possible configurations	7

Diagram/Configuration Count	# Students
Straight Line Segment	34
Multiple Line Segment Cases	3
Triangle	9
Circles	3

Operative Circle Conception

Seven (~13%) students identified a range of possible configurations for the locations of Alice's and Bruce's houses respective to the school. Three of these students drew diagrams with circles (one of whom also drew a triangle). Two others drew multiple line segment cases (one of whom also drew a triangle) and the remaining two did not draw diagrams. For those who drew circles, the school was the center for two circles, each of which had a radius length corresponding to the given distances Bruce and Alice were from the school. Student A stated, "We don't actually know how far Bruce and Alice live from each other". He then noted a range of potential solutions: "At the least, they live nine kilometers away. At the most. I think it's, um, yeah, at the most it's 25 kilometers away." Student B wrote that Alice and Bruce "could be anywhere", providing several options around the perimeter of the circles. Student C, similarly, noted that the distance would be "at least nine". These three student responses demonstrate an operative circle construction. Like Lydia from Hardison et al. (2017), these students began with an initial state involving a fixed distance from a fixed point (i.e., the school) and a goal to construct a continuous path maintaining that distance from the fixed point. But unlike Lydia who did not demonstrate an operative circle concept, these students produced representations suggestive of a mental radial rotation resulting in circular paths (Figure 4).

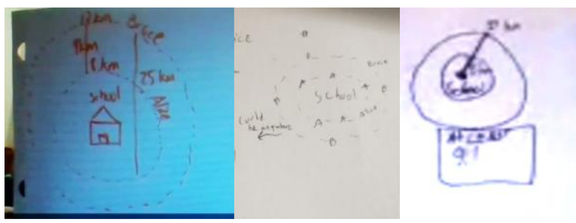

Figure 4: Student diagrams of circles for Student A, Student B, and Student C

Figurative/Operative Results Amongst Various Diagrams and Configurations

Most students created diagrams that were not circles. For instance, 24 students (44%) considered a single configuration of the buildings. Of these, 16 students considered a single straight-line configuration of the homes and school, answering either the sum or difference of the given distances (see Figure 5a). Four constructed triangle diagrams (two of which were right triangles), and the remaining four did not draw diagrams. Given that an operative circle concept necessarily involves considering multiple locations, we infer the 44% of students who considered only a single configuration likely did not leverage an operative circle concept in their solution strategy. If so, these students did not assimilate the *School Problem* to an operative circle concept or were yet to construct such a concept.

Instead, these students indicated relying on operations on static locations. For example, one student described the problem as "your classic triangle problem," which is, due to the static locations involved, evidence against an activated operative circle. These students considered the three buildings as three vertices of a triangle and solved for the unknown distance. For example, in Figure 5d, Student D used the Pythagorean Theorem to calculate the hypotenuse as 17.

However, not all students who only drew straight line diagrams or triangles only considered a single configuration. Eleven of the 34 students who only drew straight line segments considered multiple configurations of them. Three of the six students who only drew triangles considered multiple configurations of them. The remaining three students who drew triangle diagrams also drew other diagrams, indicating they considered multiple configurations. These students, along with one of the three students who drew multiple line segments, are examples of the 24 total students (43%) who were aware that multiple configurations of the buildings were possible, but who did not provide a range of values as their solution to the problem. Thus, an awareness of multiple configurations is not only insufficient for the construction of a circle but also in providing a range of potential distances as the solution to this problem.

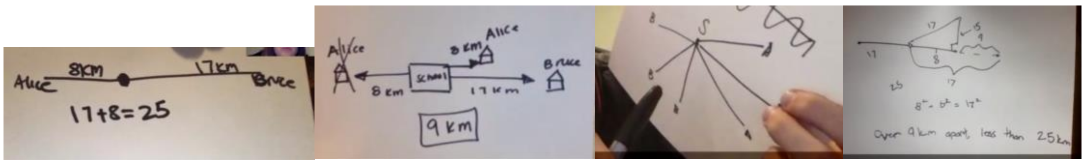

Figure 5: Student diagrams of a (a) line segment, one configuration (b) line segments, multiple configurations, (c) multiple line segments and (d) triangle

Conclusions

Verschaffel and colleagues' research on the suspension of sense-making on the *School Problem* has provided initial insights into the realisticness with which students solve the problem. This realisticness involves considering more than one configuration of the locations of two houses, each a fixed distance from the school. In this report, we have connected that consideration to operative and figurative circle concepts. In particular, we have expanded on Hardison et al.'s (2017) initial characterization of figurative/operative circle concepts by proposing the constructive and quantitative aspects involved. These aspects provided novel insights into students' quantitative reasoning on the *School Problem*. For instance, although 56% of students provided what Verschaffel would classify as realistic responses, only 12% of students identified a range of response, and 3 of the 7 of them did so with indications of enacting operative circle concepts. We also noted that 44% of students only considered a single configuration of buildings, which given our definition of an operative circle concept as including a variation, entails contraindications they were engaging in operative thought. These results imply a need to understand the relationship between students' realistic responses and the nature of their quantitative reasoning, particularly with regards to figurative and operative thought.

Acknowledgments

The authors wish to thank Mr. Michael Mackey for his generous support which made the data collection phase of this research possible. The views expressed herein are solely those of the authors and do not necessarily reflect the views of the donor. We also thank Kevin Moore for continued discussions on figurative and operative thought developing from Lydia's data.

TRANSFORMATIONAL REASONING WITH ADINKRA SYMBOLS: A LESSON PLAY ON SYMMETRIES

Matthew Tsutsui
Portland State University
mtsutsui@pdx.edu

Steven Boyce
Portland State University
sboyce@pdx.edu

We investigate prospective geometry teachers' (PSTs) transformational reasoning when analyzing symbols and construct a lesson play based on the results. The primary symbols used are Adinkra, prominent icons in Ghanaian culture. We find that the PSTs exhibited formal and informal reasoning about transformational relationships about the symbols, exercising precision in describing some features but not others. This paper contributes a lesson play which may help teacher educators apply similar activities focusing on non-Western cultural symbols and support student development of transformational reasoning.

Keywords: Geometry and Spatial Reasoning, Teacher Educators, Culturally Relevant Pedagogy

Introduction

Transformational reasoning can refer to (at least) two related but distinct forms of reasoning. First, there is reasoning about geometric transformations. One might evoke this type of transformational reasoning to justify that the opposite angles of a parallelogram are congruent, via an argument about rotating the parallelogram 180 degrees about its center and finding the coincidence of the preimage and image. Transformational proofs in geometry use the existence and properties of transformations such as rotations, reflections, translations, and dilations in deductive reasoning (GeT: A Pencil (2022; St. Goar & Lai (2022). The Common Core State Standards (2010) advocate for students to provide justifications involving transformations for defining congruence and similarity.

Secondly, transformational reasoning can also refer broadly to dynamic mental imagery (both with or without perceptual referents). Building on Piaget's extensive works (e.g., 1970), Simon (1996) defined this second form of transformational reasoning as the mental or physical enactment of an operation or a set of operations on an object or set of objects that allows one to envision the transformations that these objects undergo and the set of results of these operations. Central to transformational reasoning is the ability to consider, not a static state, but a dynamic process by which a new state or continuum of states are generated. (p. 201)

In this report, we describe an activity for prospective secondary geometry teachers (PSTs) which utilized both forms of transformational reasoning about *Adinkra*, symbols rooted in Ghanaian culture (Babbitt et al., 2015). We created a *lesson play* (Zazkis et al., 2009) to extend the activity to deepen connections to secondary geometry teaching.

Theoretical Background

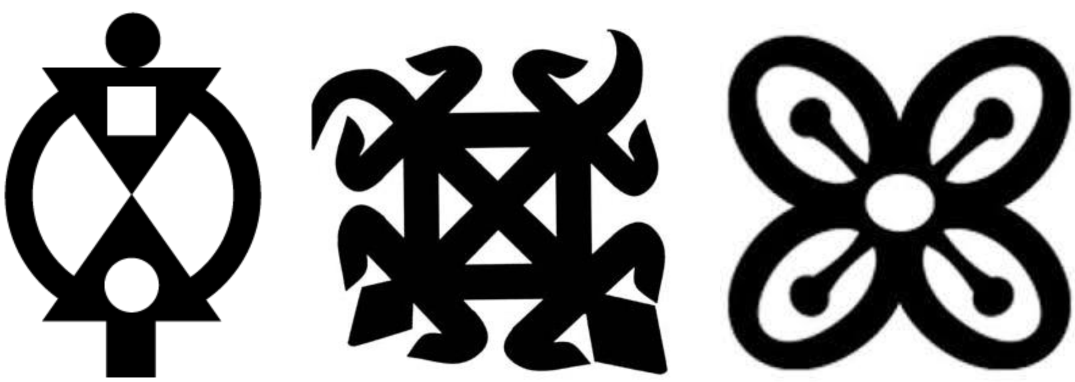
The research in this proposal fits broadly within the umbrella of design research in that it networks multiple theoretical perspectives to inform the design and refinement of instructional materials (Swan, 2014). This includes applying a radical constructivist lens (Glasersfeld, 1995) for modeling students' transformational reasoning as the product of their mental actions as well as a socio-cultural lens for understanding students' learning about the meanings of Adinkra as both a window into another culture and a mirror into their own (Gutiérrez, 2008). This report uses activities from a lesson study (Cerbin & Kopp, 2006) to investigate the transformational reasoning of PSTs, which also included objectives for learning about Adinkra. The creation of the lesson play itself can be considered the product of duoethnographic research, with its focus on simulating and fostering salient aspects of our observations of PSTs interacting in classrooms over the course of iterations of instructional design (Zazkis & Koichu, 2015).

Methods

The methods we used in the lesson study were qualitative, as we analyzed video-recordings of classroom observations as well as (primarily text-based) written artifacts. Our coding approaches fit within the grounded theory tradition (Corbin & Strauss, 1990), as we used the constant comparative method and axial coding to identify and code themes in the data as part of a larger analysis team (Boyce et al., 2023).

Participants and Activities

The participants in this study are 15 PSTs from a college geometry course. The PSTs finished a unit on transformations and symmetries prior to the lesson on Adinkra. We analyzed the students' responses from two lesson activities. The first activity involved students' observations during class about the three Adinkra symbols Boa Me Na Me Mmoa Wo, Funtummiereku Denyenmireku, and Bese Saka (see http://www.adinkra.org and Figure 1). They provided individual, written observations about the symbols' symmetries and features in small groups via Geogebra classroom. In the second activity, which followed the class as a homework assignment, students were asked to create their own symbol, and then identify transformations within another student's symbol. IRB approval was granted for analyzing artifacts from students' work. Pseudonyms are used in the analysis section of this report to protect student privacy.



Figures 1A, 1B, and 1C. Adinkra Symbols Boa Me Na Me Mmoa Wo, Funtummiereku Denkyemiereku, and Bese Saka

Analysis of Data

We analyzed each of the PSTs' written responses to investigate the qualities of their transformational reasoning. After compiling responses across both activities, we categorized sections of their responses based on which transformations they described, and then we analyzed their transformational reasoning by categories: *reflection, rotation, translation, and dilation*. After analyzing the responses in these categories, we took note of a central theme: the degree of precision in students' transformational reasoning.

Creating the Lesson Play

Zazkis et al. (2009) defines *lesson play* as "imagined interaction related to a particular student's difficulty" (pg. 43). These interactions usually take the form of a pre-written script before teaching instruction. The key difference between a lesson plan and lesson play to Zazkis and colleagues is the spotlight remains on students' mathematical topics which emerge from interaction rather than guided notes for teaching instruction. In research, lesson plays can be used to investigate a teacher's interaction with a student or group of students (e.g., Dooley & Grimes, 2023), and sometimes lesson play script writing can be delegated as a task for a group of prospective student teachers (e.g., Zazkis & Zazkis, 2016). We construct our lesson play to be used for these purposes as well by using a virtual duoethnography approach (Zazkis & Koichu, 2015). This type of lesson play creation involves characters which typify the writers' experiences with students learning the particular topic. After finishing the analysis, two student characters were drafted by the first author to reflect the themes in our participants' transformational reasoning. The second author then reviewed the lesson play to suggest revisions to reflect his teaching experiences.

Analysis of Student Reasoning About Transformations

Rotations and Reflections

The most frequent type of symmetries PSTs identified were rotational and reflection symmetries. Some students connected the presence of reflectional symmetry with 180 degree rotational symmetry when referring to Boa Me Na Me Mmoa Wo (Figure 1A):

> Saul: There is "near" reflective symmetry horizontally and vertically, the exception being the negative/positive space of the square and circle. In this way there is also rotational symmetry (180 deg)

It appears that some students may have conflated reflections and rotations. Although it is possible in some cases–such as Kip below–students were using the term "reflect (around a point)" to refer to a 180-degree rotation.

> Kip: two triangles that are reflecting around the vertex that is touching…

Dilations and Translations

Some students also reasoned about dilations and translations. Of the five students who described dilations, two seemed to only consider the scale factor as relevant, neglecting or omitting identification of the center of dilation. This was the only time a student described a dilation with a scale factor less than one; the rest of the students who stated dilation relationships started with the smallest shape and described the larger, similar ones as the scaled up images.

As for translational relationships, six students identified them in symbols where a regular shape appeared to them to be "copied and pasted" in different locations. One PST even identified a star that seemed to be "created" from copied and translated triangles.

Role of Precision

A common theme across PSTs' writing about transformations and symmetry patterns regards the structure of precision in their articulations. We posit that PSTs may view their transformational reasoning *within* the symbol and their transformational reasoning *of* the symbol (within the plane) as having different standards for precision. The figures they were transforming were not explicitly embedded within a coordinate system, and most students did not add labels for points or lines to identify with transformations. PSTs instead mostly described reflectional symmetry via sketching lines of reflection or using descriptors such as horizontal or vertical. For rotations and dilations, PSTs did not usually identify a center.

A main struggle emerged with identifying symmetries in symbols like Bese Saka (Fig. 1C). By this we mean those symbols also had four congruent subshapes attached to a common center shape. At least a couple PSTs identified diagonal lines of symmetry or extra rotational symmetries (one incorrectly said this is demonstrated via a 45-degree rotation rather than a 90-degree one). However, even then, students ignored the details of the center shape. Bese Saka has an oval which would disrupt this symmetry; the student-created symbols "like" Bese Saka involved hexagons in the center, which do not have 90-degree rotational symmetry.

Lesson Play Construction

We wrote a lesson play following the analysis to assist teachers in navigating dialogue with students about the concept of transformations. This lesson play draws inspiration from our interactions with the PSTs in a college geometry course; however, it is tailored to include a broader audience of teachers introducing the concept of transformations for the first time with students.

Hypothetical characters for the lesson play, Art and Bo, were based on PSTs who reflect familiarity with communicating transformational reasoning in different ways. Specifically, Art communicates his transformational reasoning with drawings, gestures, and verbalized visual imagery. Bo communicates her transformational reasoning with specific terms and values (e.g., "center of rotation"). It seemed common for students to have a general concept of transformational relationships and symmetries but either omit necessary mathematical details explaining their reasoning or fail to visualize the complete image of a transformation.

In our presentation, we will present and get feedback about this script.

Discussion and Next Steps

Our analysis of the Adinkra activities gave insight to how this particular group of PSTs in our lesson study reasoned in their descriptions of symbols' properties and meanings. After analyzing the data of PSTs engagement with the two activities, we described ways in which they reasoned both formally and informally about transformations. We then wrote a lesson play to capture some identified PSTs' strengths and struggles and provide a resource for instructors.

The analysis results provide two key research takeaways we will explain in further detail in the presentation. The first is findings consistent with St. Goar and Lai's (2022) study with PSTs: even college students in mathematics or education tracks did not fully understand that transformations map every point on the plane. It was common for students to imagine transformations affecting only parts of a figure and not others to argue the existence of symmetries. The second takeaway is evidence of students exercising transformational reasoning through analyzing figures, both existing symbols like Adinkra and student-created ones. A few

PSTs even imagined how a figure could have been 'created' through copying and transforming parts of a figure.

The lesson play is another contribution. Teacher educators can have PSTs in a workshop or course create or edit an existing lesson play script around a specific math topic. This activity can serve as a conceptual analysis (Thompson, 2008) of a math topic; that is, a means of detailed thinking from a student's perspective on how to make sense of a concept mentally. Creating a lesson play might also unveil a teacher's implicit biases: what characters do they create? What details about them matter? Who are the authoritative voices? Researchers can test the generalizability of this script by seeing how well the student characters in it (Art and Bo, in our case) represent the thinking of other high schoolers or PSTs when working with transformations.

We presented our lesson play to another group of PSTs in the same undergraduate geometry course. We gave these PSTs the same symmetry task with the same Adinkra symbol, Bese Saka, as provided in the lesson play and determine if they encounter the same hurdles as characters Art and Bo. We also gave the PSTs a chance to engage with the lesson script after and modify it themselves. For the presentation, we will report our findings from this activity in the presentation along with the original lesson play script.

STUDENTS’ MISCONCEPTIONS IN DEFINING AND REPRESENTING TRIANGLES

Victoria Wiest
California State University, Fresno
wiest_victoria@mail.fresnostate.edu

Dr. Yaomingxin Lu
California State University, Fresno
yaomingxinlu@mail.fresnostate.edu

Keywords: Geometry and Spatial Reasoning, Cognition

We are interested in the following questions: 1) What misconceptions do students have about defining and representing triangles? 2) How do students resolve these misconceptions over time?

A mix of middle-school and high-school students participated in our study, including 10 seventh graders, 8 eighth graders, 5 tenth graders, and 5 eleventh graders. All participants attended the same school in a mountainous area of the California Central Valley. In each interview, participants were asked to do the following tasks: (1) define a triangle and (2) split up a rectangle, hexagon, and a star into triangles.

The students’ definitions of a triangle were scored (out of 3 points) based on if they mentioned: (1 point) three sides, (1 point) three vertices/three angles/closed, and (1 point) planar/polygon. We deemed a students’ attempt of splitting up a shape as successful if: (1) the shape was completely split up into triangles, (2) the edges of the triangles were straight, and (3) the triangles were closed.

Our results suggest that the high school students perform better on both tasks, but the differences are less significant than we originally expected. Due to the small sample size and the limited details the students gave as reasoning, we cannot draw any substantial conclusions at this time.

Instead, we see this study as a jumping off point to further explore findings that piqued our interest. For example, six out of the 28 participants did not split the inner pentagon of the star into triangles. Three out of the six participants mentioned above successfully split up the hexagon into triangles. Since a pentagon and hexagon are structurally similar shapes, we are curious about this inconsistency and want to further explore whether it is due to the students’ limited geometrical understandings or merely due to inattention.

During several interviews, we noticed that the participants interpreted our “simple” tasks as an insult of their intelligence. We believe we may be able to resolve this issue by asking participants to complete a longer and more challenging test with our original tasks included in the assessment. This way participants will feel mentally stimulated, and we will be able to better assess their geometric knowledge.

We are also interested in if there is a statistically significant correlation between the teachers’ geometric knowledge and their students’ geometric knowledge. Hence, in our future research, we have plans to assess the teachers the same way we do the students.

Based on conversations with other educators and working with students one-on-one, it seems that geometry often falls between the cracks in K-12 classrooms, which we believe is a great disservice to students. Furthermore, we believe that even small gaps in a student’s geometric understanding have a lasting impact on their mathematical performance. So, we hope our research sheds light on how fundamental geometric concepts, such as the definition of a triangle, relate to more involved geometric tasks, such as splitting shapes into triangles.

IMPROVING PRESERVICE SECONDARY TEACHERS' KNOWLEDGE OF SOLVING ALGEBRAIC EQUATIONS

Comfort Temitope Aje
Purdue University
caje@purdue.edu

Keywords: Preservice Teachers, Secondary Teachers' Knowledge, Algebraic Equations

Algebraic equation solving is a fundamental skill within the secondary education mathematics curriculum, playing a pivotal role in shaping students' mathematical reasoning and problem-solving abilities as well as serving as a foundation where more complex mathematical concepts can be built (Mamba et al., 2017; Salani & Jojo, 2023). Mastering algebraic concepts is essential for academic success and equipping students with critical thinking skills applicable to various real-world scenarios (Mamba et al. 2017; Sandoval et al., 2023). The competence of preservice secondary teachers in imparting this knowledge is crucial, influencing the quality of instruction and the development of students' mathematical proficiency (Kennedy & Ebuwa, 2022, Kleickmann et al., 2013, Sam et al., 2023, McCrory et al., 2012). Van Dooren et al. (2002) focused on underscoring the relevance of preservice teachers' proficiency in discerning and guiding students through problem-solving processes, particularly in the context of algebraic reasoning. Therefore, secondary mathematics preservice teachers are required to possess mathematical content knowledge which will help them to teach effectively in the classroom (Daniel, 2015). This study aims to explore how preservice teachers' pedagogical content knowledge relates to their ability to effectively teach and create meaningful learning opportunities for secondary school students in solving algebraic equations.

The Mathematical Knowledge for Teaching (MKT) framework, developed by Ball et al. (2008), expands on Shulman's (1986) concept of Pedagogical Content Knowledge (Nolan et al., 2015). MKT can be referred to as mathematical knowledge required by teachers to teach mathematics in the classroom (Nolan et al., 2015). The MKT framework addresses PCK and Subject Matter Knowledge (SMK), which are two important domains of teacher knowledge described by Schulman (1986). The MKT framework emphasizes the significance of teachers' adaptive expertise in problem-solving, encouraging flexibility in selecting appropriate strategies and recognizing the diverse ways students may approach algebraic tasks (Van Dooren et al., 2003).

This study comprehensively reviews the existing literature on preservice secondary teachers' knowledge of solving algebraic equations. The PRISMA principles were followed in this review (Liberati et al., 2009). ERIC and Google Scholar are selected as online databases to find relevant articles. There are inclusion and exclusion criteria along with the justification. The ERIC and Google Scholar databases were searched using the following keywords with connectors "AND" "OR" words: ("pedagogical content knowledge" or PCK) AND ("teacher candidates" or "preservice teachers" or "student teachers" or "pre-service teachers") AND ("secondary school" or "high school" or" secondary education") AND "solving algebraic equations" AND ("math education" or "mathematics education") OR algebra while in Google Scholar the same search terms are used without quotation and parenthesis. The search terms produced a total number of

184 articles (ERIC 157 and Google Scholar 27). To narrow down these numbers using the inclusion and exclusion criteria produced a dataset of 15 research publications, which served as the basis for the current contribution. The preliminary findings align with these datasets, highlighting that preservice teachers' pedagogical content knowledge is crucial for effectively teaching algebraic equations and promoting meaningful learning opportunities for secondary school students.

PRACTICING MIDDLE GRADES TEACHERS UNDERSTANDING OF REFERENT UNIT

Rachael Eriksen Brown

Referent unit is foundational knowledge for rational numbers and quantity. This exploratory study examined how sixteen practicing teachers reasoned about a mathematical situation during an interview requiring the use of referent unit. Half of the teachers correctly reasoned with referent unit and a quarter made a referent unit error. This error may have been connected to a previous interview question as opposed to indicating a misunderstanding about referent unit. However, attending to details, particularly language, is important. Considerations for professional development and preservice education are discussed.

Keywords: Teacher Knowledge, Rational Numbers & Proportional Reasoning, Rational Numbers

The importance of referent unit for both students and teachers for understanding fractions has been established (e.g. Hackenberg, 2007, Izsák, 2008; Steffe & Olive, 2010). Focusing on teacher understanding of referent unit; Izsák, Tillema, and Tunc-Pekkan (2008) showed data from Ms. Reese's lessons on addition and subtraction of fractions on number lines and a student's interpretation of these lessons. These researchers suggested teachers need to focus on particular details such as language. Ms. Reese tended to refer to fractions as "amounts," and this added to a misunderstanding of referent unit for at least one of her students. Armstrong and Bezuk (1995) documented challenges middle school teachers faced as they explored multiplication and division of fractions in a PD setting. One challenge was identifying the referent unit for each number in a fraction number sentence. Orrill, Izsak, Jacobson and de Araujo (2010) focused on teachers using drawn representations to solve fraction problems, and one of their findings indicates that the teacher often "resisted thinking in terms of nested levels of units" (p. 339). For example, one teacher struggled to correctly explain why $2/3 \div 1/4 = 8/3$ using drawings. In her representation, she drew a rectangle and divided it into thirds. After shading two-thirds, she discarded one-third, stating that the problem only concerned 2/3. She further divided the remaining thirds into four pieces and claimed that these eight pieces represented the numerator of the answer, while the thirds served as the denominator. However, her interpretation of fourths in the answer was incorrect as she "eliminated crucial units that the answer referred" (p. 339) from her representation. These studies highlight the importance of referent unit to teachers' own understanding as well as their support of their students' understanding.

In this study, our research question was how do practicing teachers reason about a question requiring the use of referent unit?

Theoretical Framework

In this exploratory study investigating practicing teachers understanding of referent unit, we define referent unit as the unit of measure (Olive & Çağlayan, 2008) or how a quantity is measured (Epstein, Orrill & Brown, 2023). The knowledge of referent unit is foundational knowledge, and we view the knowledge of teachers through the lens of the Knowledge Quartet (Rowland & Turner, 2007; Orrill, Brown, Thapa, & Nti-Asante, 2022). As Rowland et al. (2005) state: the Knowledge Quartet "is about raising awareness; it is not about being judgmental. Whilst we see certain kinds of knowledge to be desirable for elementary mathematics teaching, we are convinced of the futility of asserting what a beginning teacher, or a more experienced one for that matter, ought to know." (p. 257). Thus, the intent of this study is to become aware of how some practicing teachers found the answer to a question involving referent units.

Methods

As part of a larger study, we interviewed 16 practicing teachers from two different states on the east coast of the United States. Eight of the teachers were currently working in public schools and eight were currently working in a private, religiously affiliated school. Two identified as male; the average years of teaching math was a little over 15. Three participants identified as Hispanic and 14 identified as White/Caucasian (with 1 indicating both). Half the teachers had facilitated professional development themselves with two of them being related to mathematics education. Half also had a master's degree with two in mathematics education. One teacher indicated they had non-math related accommodations at some point in their educational process.

The interviews were conducted via Zoom using a Google jamboard to share items and see any markings the participant made while solving the mathematical problem shared with them. Eleven situations were shared with two to six questions asked for a total of 36 questions asked. The interviewer asked clarifying questions about their solution. The interviews lasted about an hour. All interviews were recorded and transcribed. The transcript was used to determine if a teacher's response was correct and to note how the teacher solved the problem. One participant experienced technological issues so was unable to write on the jamboard during the interview.

For this exploratory study, we considered one of the subitems in the interview requiring the teachers to find the size of part of a rectangular area (see Figure 1). This was the fifth question asked regarding the Garden situation. All of the garden questions were designed to address a teacher's understanding of referent unit. This particular item was selected because teachers were familiar with the context and were applying their knowledge of referent unit to find the answer.

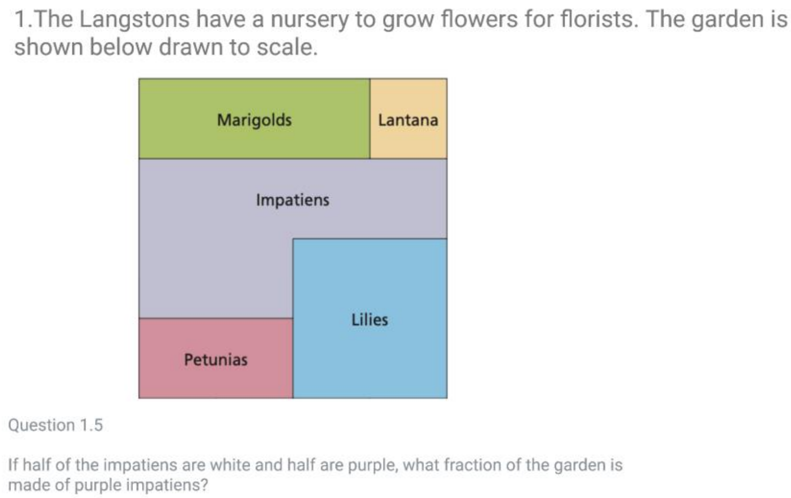

Figure 1: Math problem from interview

Three researchers coded the response for correct reasoning with 100% agreement. Then one researcher went back through transcripts and images from jamboards to detail how the teachers approached the question. These descriptions were shared with the other two researchers to see if there were any disagreements and to discuss the analysis.

Results

Of the 16 teachers interviewed, eight correctly reasoned three sixteenths of the garden was purple impatiens. In their explanation of how they found their answers, half the teachers used sixteenths and the other half used eighths.

For the sixteenths, one teacher explained their reasoning this way (representative of how the other 3 solved the problem): "so I like counted in basically in their 16 little lantanas, right? So if I break it all up, it's four by four. So it's 16". This teacher described how they broke up the entire garden into sixteen pieces (and sketched that on the jamboard as well). The teacher went on to explain the impatiens were 6/16 of the garden so the purple impatiens would be 3/16. One teacher who reasoned this way simplified 6/16 to 3/8 but then interestingly decided taking half of 6/16 was easier.

For the eighths, the teachers found all the impatiens to be 3/8 of the garden. For example, one teacher said: "I think that the lilies is a quarter, and that's the same. And then this is half of a quarter, which is an eight. So I've got two eighths plus one eighth. So I'm saying that impatiens make up three eighths of the garden". Once they knew the whole area of the impatiens, the teachers found half of 3/8 with three teachers writing a numeric representation of either ½ * 3/8 or 3/8 * ½.

For the remaining eight teachers who did not reason correctly, one teacher looked at the five colors of the garden and concluded 1/5. Another teacher estimated their answer, while another teacher just generically described the steps they would take which may or may not have been correct reasoning (thus not coded as correctly reasoned). Of the remaining five teachers, one teacher made a calculation error, one made both a referent unit and calculation error and three made a referent unit error. For the calculation errors, if the teacher did not realize the unreasonableness of their answer than we did not code as correctly reasoned even if they correctly described the area of the impatiens and needing to find half. The referent unit errors were based on not attending to the whole in the question (the whole garden). One teacher used the area of impatiens as the referent unit, and another identified the area of impatiens as ¾. Two used the area of the lily as the referent unit, based on the previous interview question that asked if the Lilies section is one acre of land, what fraction of an acre are the Impatiens? One of these teachers also miscalculated.

Discussion

Given the small sample size, this exploratory study highlights a few ways in which teachers may apply their understanding of a referent unit to a specific garden problem. Half the teachers correctly reasoned both about referent unit and arithmetically. Another quarter of the teachers made a referent unit error. This referent unit error may have been connected to the previous question in the interview and may not reflect a misunderstanding. However, if a teacher does not attend to the details around language, this may have a negative impact on their students, similar to the findings of Izsák et al. (2008).

Looking at the erroneous thinking, there is lots of potential to support teachers to correctly reason by modifying the question to emphasize the whole garden, asking if an answer is reasonable, or asking for more detail in the situation. The intent of the interview was to see what knowledge teachers already had about referent unit prior to a professional development experience that would focus on referent unit. Future research should examine how these teachers continue to use referent unit reasoning in the professional development experience.

Acknowledgments

We would like to thank the teachers for their willingness to participate in the study. This material is based upon work supported by NSF DRK12 2201127 & 2331772. BROADENING & CONNECTING MATHEMATICS: EXPLORING HOW ELEMENTARY TEACHERS CONCEPTUALIZE THE BIG IDEAS

Marjorie M. Hahn

The new California Mathematics Framework provides a roadmap for organizing mathematical knowledge around broader, integrated concepts ("big ideas"), with equity as a focus (CDE, 2023). This study involved collaborating with a local school district to select and train eight elementary teacher leader fellows in professional development (PD) focused on big ideas instruction and examining their conceptualization of the big ideas in mathematics after PD. Analysis of interviews with the eight teachers revealed they employed real-world analogies, education-specific schemas, and distinct content examples to understand and explain the big ideas. These methods allowed them to perceive the big ideas as central and interconnected within their mathematics instruction, encompassing a range of concepts wider in scope than traditional standards. We discuss implications for teacher learning around mathematics content.

Keywords: Mathematical Knowledge for Teaching, Professional Development, Elementary School Education

Purpose of Study

Critical to envisioning a just future for mathematics education is addressing the persistent inequities in students' access to meaningful opportunities to learn. While numerous initiatives focus on supporting teachers through the adoption of inclusive and dialogic pedagogies (Smith & Stein, 2018; Joseph et al., 2019) and/or culturally relevant curricula (Gutstein, 2007), an underlying concern remains: Could the very nature of the mathematical canon contribute to the perpetuation of these inequities? Our study investigates mathematical knowledge, emphasizing overarching, unified ideas over fragmented, smaller concepts, as this shift facilitates the enactment of equitable pedagogy (Boaler & Staples, 2008; Cabana et al., 2014).

The evolving landscape of mathematics education, notably marked by the adoption of the National Council of Teachers of Mathematics (NCTM) standards in the 1980s and the Common Core State Standards in the 2010s, has heralded calls for a coherent teaching approach. Despite these aspirations, the predominance of state standards emphasizing a disaggregated list of skills and procedures has persisted, influencing both assessment and instruction. The new California Mathematics Framework delineates a visionary shift towards organizing mathematical knowledge and practices around foundational "big ideas," with equity as a focus (California Department of Education [CDE], 2023). Our study directly engages with this transformative moment, responding to the critical need for empowering teachers and administrators to navigate and implement this innovative framework. Researchers partnered with a local school district to support elementary teachers in engaging with a big ideas approach in their mathematics teaching, thereby advancing equitable mathematics instruction for all students (CDE, 2023). This paper explores these teachers' emergent understandings of the big ideas. In particular, we ask: After a professional development (PD) focused on big ideas instruction, how do elementary teachers conceptualize the big ideas of mathematics for their grade level?

Theoretical Perspectives

Our study is informed by two related yet distinct theoretical perspectives on mathematics content. First, we discuss what we mean by the term "big ideas" as it relates to mathematics teaching and learning. Second, given that our focus here is on teachers' conceptions of big ideas, we draw on Ball and colleagues' (2008) notion of "mathematical knowledge for teaching" to theorize teachers' interactions with and perceptions of the big ideas.

Big Ideas in Mathematics

Too often, students view mathematics as an abstract, arbitrary, and disconnected set of rules. In the big ideas approach, however, students engage with the essential concepts in mathematics, which are composed of smaller, connected ideas. We adopt Charles's (2005) definition of a big idea as "a statement of an idea that is central to the learning of mathematics, one that links numerous mathematical understandings into a coherent whole" (p. 10). This focus on the "coherent whole" enables teachers and students to grapple with the "essential mathematical meaning" of the idea (Charles, 2005, p. 10). Although the big ideas approach overlaps with similarly minded pedagogies (e.g., conceptual teaching, reform-oriented instruction), it explicitly relates to mathematics content and curriculum. As such, teaching to the big ideas necessitates a focus on a smaller set of essential mathematics concepts that coherently link numerous ideas.

The National Research Council (1999) recommended this approach over two decades ago: "Superficial coverage of all topics in a subject area must be replaced with in-depth coverage of fewer topics that allows key concepts in the discipline to be understood" (Bransford et al., 2000, p. 20). Students who work "in-depth" forge connections between mathematical ideas. This approach builds on research that has shown that teachers who organize content around big ideas and teach with an equity focus bring about higher and more equitable achievement (Boaler & Staples, 2008; Cabana et al., 2014).

Mathematical Knowledge for Teaching

To implement this approach, teachers need to be able to construct their own meanings of the big ideas, growing both their subject matter knowledge and their pedagogical content knowledge (Koellner et al., 2007). In their work on mathematical knowledge for teaching, Ball and colleagues (2008) specify three types of subject matter knowledge that mathematics teachers need: common content knowledge (CCK), specialized content knowledge (SCK), and horizon content knowledge (HCK). CCK refers to mathematics knowledge and skills that are used in non-teaching settings. In contrast, SCK refers to mathematical knowledge and skills unique to teaching, involving the "unpacking of mathematics" (Ball et al., 2008, p. 400). Further, HCK is teachers' awareness of how mathematics concepts are "related over the span of mathematics included in the curriculum" (Ball et al., 2008, p. 403).

We contend that when teachers engage with and make sense of the big ideas of mathematics, they are simultaneously building all three types of subject matter knowledge (CCK, SCK, and HCK). As they grapple with the big ideas on math tasks as learners themselves, they build CCK, while as they analyze their curriculum to unpack what comprises each big idea and where the big ideas live, they build SCK and HCK, respectively. Accordingly, we view teachers' emergent conceptions of the big ideas of mathematics as amalgamations of all three types of subject matter knowledge. In examining how teachers make sense of the big ideas, we take up Ball and colleagues' (2008) call for supporting and empowering teachers to understand how mathematical knowledge is generated and structured.

Methods

This qualitative study uses a multiple-case design with eight participants (Yin, 2016). The case study methodology enabled us to provide an in-depth and nuanced exploration of teacher conceptualization of big ideas for a small number of participants.

Setting and Participants

In spring 2021, research team members met with administrators from a local school district in Northern California to understand their needs and discuss possible ways of supporting them during the pandemic, given prior work together. One-third of the elementary schools in this district are classified as Title I, and 37.4 percent of students received Free and Reduced-Price Meals (FARM) in the 2019-2020 school year.

The administrators and research team members co-constructed a teacher leadership fellowship to leverage the research team's expertise to develop teacher leaders who could support their colleagues with math instruction. In the 2021-2022 school year, the research team and administrators worked together to recruit site-based teams of two to three elementary teachers who applied to become "mathematics teacher leader fellows." The teachers admitted to the fellowship also consented to participate in this study. Our purposeful sample of teachers included sufficient variability in teaching experience and grade levels taught (Table 1).

Table 1: Participant Characteristics

Participant*	School*	Grades	Years Teaching
Amber	Tabitha Elementary	4/5 Combo	24
Sam	Pinewood Elementary	3	9
Stephanie	Pinewood Elementary	3	22
Denise	Jackson Elementary	5/6 Combo	6
Erin	Jackson Elementary	3/4 Combo	5
Nicole	Golden Sierra Elementary	2	13
Elizabeth	Golden Sierra Elementary	2	15
Heather	Golden Sierra Elementary	2	20

**All names are pseudonyms.*

Professional Development Context

The teachers participated in five professional learning days (PD) in the spring and summer of 2022. In these sessions, teachers worked in small groups on mathematics tasks and participated in mathematics discussions of these tasks and the big ideas embedded within them. Additionally, they examined the big ideas in their grade level and collaborated with grade-level colleagues to construct unit and year-long plans for the 2022-2023 school year.

Data Collection

The data collected for this paper are part of a larger data corpus. Here, we focus on two semi-structured Zoom interviews with eight teacher participants (n = 16 interviews). These interviews took place after the PD during the school year: in Oct/Nov 2022 ("Int2") and in Apr/May 2023 ("Int3"). In both interviews, interviewers asked teachers role-playing questions (Patton, 2002) to ascertain their conceptualization of the big ideas, e.g., "How would you explain 'big ideas in math' to a colleague who was not familiar with the term?"

Data Analysis

Our data analysis centered on teachers' responses to questions about the big ideas during the mid-year and end-year interviews. A team of five researchers engaged in a collaborative process of codebook development, refinement, and application. The analytic process included multiple rounds of coding, memo-writing, and discussions about emerging themes (Saldaña, 2009).

Codebook Development. The codebook was created through inductive analysis. Our team initially coded a subset of transcripts, then engaged in discussions to compare coding approaches and resolved disagreements regarding the definitions and criteria for inclusion or exclusion (Campbell et al., 2013). We then developed a second iteration of our codebook that expanded it from three codes to six, all under the domain "Conception of Big Ideas," with a definition and example quotes from the data (Creswell, 2013). We applied this codebook to the interview excerpts related to big ideas. Using Dedoose, the researchers eliminated one undersaturated code and determined the final codebook to be applied to all 16 interviews (Table 2).

Table 2: Code Descriptions

Code	Description
Analogy	Draws parallels or constructs similes and metaphors that liken big ideas to universally comprehensible or visually representational objects, such as umbrellas, webs, and circles.
Schema	Refers to a structure that helps organize and interpret big ideas based on common attributes, experiences, or concepts – particularly using educational terms, e.g., essential questions, enduring understandings, guiding questions, key points, units, frameworks, etc.
Open Tasks	Refers to big ideas as open tasks utilized in instruction.
Active Pedagogies	Refers to big ideas as student-centered instruction and other active learning pedagogies, e.g., changing environment and questioning; describing how students engage with the content and each other in the classroom, how they enact big ideas in the classroom through particular practices.
Specific Content	Statements in which teachers refer to a specific idea in their grade-level mathematics content, e.g., equivalence.

Thematic & Content Analysis. To examine the data (n = 72 excerpts) for emerging themes, we exported the Dedoose quotes grouped by code to Google Sheets. This extraction allowed us to re-code the interview excerpts with pattern coding (Saldaña, 2013). Through this process, we continued to memo on emerging themes, descriptive notes, and representative quotes. Once our final themes were decided (Table 3), we conducted content analysis (Patton, 2002) to provide a quasi-quantification of the number of teachers aligned with each theme.

Results

Teachers drew on various conceptual tools and content examples when asked how they would explain the big ideas of math to a colleague unfamiliar with the term. Table 3 shows the three most common themes in teachers' responses. To differentiate between analogy and schema, we draw upon Parsons and Davies (2022), who articulate that reasoning by analogy is a comparison of two concepts at the same concrete level of abstraction, whereas mapping a more general schema may help learn the abstract sense of an idea. Half of the teachers used real-world analogies to illustrate how they conceptualize the big ideas in mathematics, while all teachers drew on education-specific schema to articulate their conceptualization. Additionally, all teachers shared examples of specific grade-level content to explain the big ideas further. In this section, we delve into these three findings, then close by how these come together in describing teachers' emergent conceptualization of big ideas in mathematics.

Table 3: Themes and Representative Quotes from Interviews

Themes	Representative Quotes
Analogy used to conceptualize big ideas. (4 / 8 teachers)	
Concretized big ideas by using analogies to connect to something visual.	"I see the **visual of the web** in my mind and how all of these big ideas really connect to each other to form the standards that my students will learn in third grade" (Erin_Int2)
Illustrated the centrality and connectedness of big ideas using analogies.	"And so to me, a big idea is this **umbrella** of one idea that has a bunch of ideas within it. All of these little things that we go through that all tie back to that and intertwine with each other." (Amber_Int2)
Schema used to conceptualize big ideas. (8 / 8 teachers)	
Built on prior knowledge through a professional lens.	"In the old days, when you looked at state testing, you wanted to know what your **power standards** were. I kind of likened the bigger circles to the power standards." (Elizabeth_Int3)

Situated big ideas as broader in grain size.	"My current understanding is a lot of super smart people looked at the standards and distilled it down to some **monster conceptual** topics that I feel vertically align throughout the grade levels, are foundational and integrated." (Elizabeth_Int2)
Specific mathematics content referenced in relation to big ideas. (8 / 8 teachers)	
Referred to specific math topics as big ideas.	"For third grade, big ideas are multiplication, division, fractions, time down to the minute, area and perimeter." (Sam_Int2)
Discussed connections between topics.	"I would explain it as an understanding of how to process math, like learning about patterns in place value or understanding what 100 is, is kind of a general descriptor of what you might think or connect to." (Heather_Int2)

Analogy Used to Conceptualize Big Ideas

Four of the eight teachers utilized analogies (e.g., umbrella, web, tree, brainstem) to help them concretize this abstract concept into a familiar visualization, many of which specifically highlighted the centrality of big ideas and their connectedness. One participant explained:

> And when we look at some of these main ideas, these big things that all kind of go together, I think of it as an umbrella. Everything is underneath, and it's, there's so many things that are connected with each other. A big web, I mean, that's just like a big web, and you can make the connections between different concepts and different reasonings and activities. And to me, the big ideas is the idea that everything's connected. So, it's not just these small little bits of things and then you go, and you're done. (Amber_Int3)

In this description of the big ideas, Amber emphasized two everyday visuals: an "umbrella" and a "big web," while also attending to the specificity those two analogies brought to her conceptualization – connectedness and centrality. In this excerpt, she stated some iteration of "connect" three times. To her, this analogy was also based on the resemblance of everything being "underneath" the umbrella, eliciting a visual focal point for the big ideas to reside under.

Schema Used to Conceptualize Big Ideas

Expanding beyond a visual analogy, all eight teachers used a schema with teacher-facing language to discuss how they conceptualized a big idea (Table 3). Participants built on prior knowledge through a professional lens, referencing backward planning, units, frameworks, and red checks. As participants drew on other educational terminology, they conceptualized big ideas as broader in grain size than other units of content. For example, one participant noted: "If you take your long plan for math, and you have your standards, you have all these standards, your standards are then grouped" (Sam_Int2). Here, Sam not only drew on her prior work with standards to think about big ideas but emphasized that big ideas are bigger than standards; they are groups of standards.

Specific Mathematics Content Referenced in Relation to Big Ideas

In addition to drawing on the conceptual tools of analogy and schema, all teachers referenced mathematical content to explain the big ideas. Teachers identified specific topics, such as “fractions” (Erin_Int3), as big ideas at their grade level. Further, some teachers demonstrated an appreciation for the depth of these topics. A notable example includes Amber’s discussion of fraction multiplication:

> If one of the big ideas was understanding fraction multiplication, visually, that's not one thing. That's not one activity, and you're done. There's so much underneath that, so much within that that it just comes off of it. It's not one thing. A big idea is just not one great idea. It's a bunch of things that make up this whole big topic with all these different appendices. (Amber_Int2)

Amber’s nuanced understanding of depth mirrors the analogies (e.g., umbrella) frequently employed by teachers to describe their grasp of big ideas. Our analysis also showed that teachers' discourse demonstrated a more generalized understanding of mathematical content. For example, conventional topics such as addition and subtraction were conceptualized in broader terms like “groupings of things” or “composing and decomposing numbers” (Heather_ Int3). Rather than emphasizing content as standards, they discussed broader concepts.

Another emergent pattern pertains to the interconnectedness of specific pieces of content. For instance, Amber highlighted how the big ideas encapsulated a holistic view that interlinked “multiplication, factors, and number sense” (Int3), illustrating the content's connected nature within her teaching practice. Similarly, Heather discussed how the big ideas allowed her to draw connections between addition and subtraction properties, along with number sense, to support her students in utilizing number lines and hundreds charts—underscoring how big ideas facilitate a deeper understanding and teaching of mathematical concepts, enabling teachers to link specific classroom strategies with the foundational concepts their students are exploring.

Teachers’ Emergent Conceptualizations of Big Ideas

Taken together, our findings uncovered three key takeaways about teachers' emergent understandings of big ideas: the centrality and connectedness of big ideas using analogies, the big ideas as broader in grain size, and the connections between topics. The centrality and connectedness of big ideas, illuminated through the use of analogies such as webs and umbrellas, enabled teachers to grasp how individual concepts are not isolated but rather part of a larger, interconnected framework. This visualization process helped teachers conceptualize the curriculum not as a series of discrete lessons but as a cohesive narrative where each concept contributes to the understanding of a central, larger idea. Addressing the big ideas as broader in grain size, teachers acknowledged that these encompass larger conceptual domains compared to the more finely partitioned content typically encountered in standard curricula. Lastly, the connections between topics as part of the big ideas were further emphasized. Teachers recognized that effectively teaching to the big ideas involves drawing explicit connections between seemingly disparate topics, thereby unveiling the cohesive structure of mathematical knowledge. These articulations of the big ideas demonstrate that teacher participants employed a variety of conceptual tools to both comprehend and conceptualize the big ideas.

Discussion

Our results show that teacher participants drew on various real-world and education-specific conceptual tools to understand and explain the big ideas. Further, teachers utilized examples of specific grade-level content to support them in describing the big ideas. Through these tools, teachers saw the big ideas as central to their content, composed of multiple connected ideas, and broader in grain size than the standards with which they were used to working. Our findings highlight several main points, with implications for related research and professional learning.

Tools for Conceptualization

First, we found that conceptualization tools–schemas and analogies–were pivotal in helping teachers make sense of big ideas. Analogies help by linking new concepts to familiar ones, facilitating the application of known knowledge to new ideas (Parsons & Davies, 2022). This cognitive strategy enhances learners' ability to abstract, generalize, and transfer knowledge across different contexts, which is crucial in education. Our study supports existing literature indicating that individuals connect new information to prior knowledge when learning new concepts (Bransford et al., 2000). For instance, participants used the analogy of a web, relying on their understanding of a spider web or a graphic organizer, to grasp the interconnected nature of essential mathematics concepts. Here, our data highlighted the effectiveness of using analogies to connect new abstract concepts with familiar understandings.

Schemas, on the other hand, act as the cognitive structures that organize and interpret information, playing a crucial role in the way new knowledge is integrated into existing cognitive frameworks (Gick & Holyoak, 1983). As "mediators" of knowledge transfer, schemas enable individuals to categorize and store new information efficiently, facilitating easier retrieval and application in future learning situations (Gick & Holyoak, 1983, p. 2). Our findings showed that teachers used existing schemas to make sense of big ideas within their professional knowledge. Teachers assimilated new pedagogical approaches by mapping them onto familiar educational constructs such as standards, units, and frameworks. Therefore, providing teachers adequate time and support is crucial to linking big ideas with prior knowledge and tangible concepts during their learning journey.

Second, teachers drew on specific content examples as another tool to support their learning and uptake of some of the big ideas at their grade levels. Interviews showed that teachers offered deep, conceptual descriptions of topics such as addition and subtraction, pointing to their “unpacking of mathematics” (Ball et al., 2008, p. 400). This approach transforms abstract mathematical concepts into accessible knowledge for students, requiring a dynamic interplay between common content knowledge (CCK) and specialized content knowledge (SCK) as teachers master and teach the subject matter (Ball et al., 2008). Likewise, incorporating horizon content knowledge (HCK) into this discourse reveals a forward-thinking aspect of teachers' engagement with big ideas. By acknowledging the interconnectedness of mathematical concepts across different grade levels and curricular structures, teachers are aware of the "span of mathematics included in the curriculum" (Ball et al., 2008, p. 403). This awareness aligns with the complex nature of mathematical content knowledge (MKT), which includes multiple forms of knowledge about mathematics, students, curriculum, and pedagogy. This study demonstrates the utility of MKT in theorizing teachers' interactions with and perceptions of big ideas.

Implications for Policy and Practice

The new California Mathematics Framework advocates for moving away from lists of discrete and disconnected skills and procedures (CDE, 2023). This shift is challenging for teachers, administrators, and professional developers because state standards have driven assessment and instruction for decades. Additionally, viewing mathematics as a list of procedures aligns with dominant discourses that mathematics is a fixed body of knowledge to be practiced, further complicating the shift (Louie, 2017).

As teachers in our study conceptualized the big ideas in mathematics education—a central component of the new framework—they highlighted elements of centrality, connectedness, and broad grain size. Teachers recognized that effectively teaching to the big ideas involves drawing explicit connections between seemingly disparate topics, thereby unveiling the cohesive structure of mathematical knowledge. This approach challenges the traditional compartmentalization of mathematical topics, advocating instead for a curriculum that mirrors the inherent connectedness of mathematical concepts. Viewing mathematics content as a set of fewer, connected, and conceptual big ideas has the potential to make mathematics activity more expansive and inclusive (Louie, 2017; CDE, 2023). Importantly, this approach supports teachers in developing mathematical knowledge for teaching (MKT), particularly horizon content knowledge (HCK), as it emphasizes connections across grade levels and units (Ball et al., 2008).

Our findings indicate areas for growth in how teachers develop a deep, conceptual, and connected understanding of the big ideas at their grade levels, particularly at the elementary level. Traditionally, teacher training has emphasized common content knowledge (CCK) more heavily than specialized content knowledge (SCK). Our results suggest the benefits of engaging teachers in grade-level teams to develop their SCK related to the big ideas and to build HCK through connections to other grades. This underscores the necessity of ongoing conceptual work to aid teachers and administrators in navigating this pedagogical shift. Future research should explore how teachers and school administrators adapt their practices to incorporate big ideas, including and beyond the new California Mathematics Framework. This inquiry could reveal insights into the systemic adoption of the framework and its impact on mathematics education, contributing to a more equitable and effective system for all learners.

FACTORING QUADRATICS: HOW SECONDARY TEACHERS VIEW AND FOSTER PROCEDURAL FLUENCY

Casey Hawthorne
Furman University
casey.hawthorne@furman.edu

Erin Prins
Furman University
priner2@furman.edu

While researchers have characterized what procedural fluency of numerical computation entails at the elementary level as well as identified instructional methods that support its development, secondary teachers do not have access to the same resources. To support these teachers, we must first understand how they perceive and attempt to foster procedural fluency. To do so, we interviewed eight experienced secondary teachers about how they teach factoring of quadratics and their associated goals. Results indicate that teachers lack an in-depth understanding of procedural fluency associated with factoring. While some teachers hope students develop more conceptual understanding, they ultimately teach rote algorithms that lack meaningful insight into the process. We outline what methods teachers use to teach factoring and provide a framework highlighting three different ways teachers approach the teaching of procedural knowledge.

Keywords: Algebra and Algebraic Thinking, High School Education, Mathematical Knowledge for Teaching

The relationship between the role of conceptual and procedural understanding in mathematics education has long been explored and argued (Rittle-Johnson, et al., 2015). This debate was at the center of the heated math wars in the 1990s (Schoenfeld, 2004) and continues today as states like California rewrite their mathematics curriculum. Researchers, often critical of the elevated attention to procedures in classrooms, have advocated for an emphasis on conceptual understanding, making this the focus of the reform movement. However, as Kilpatrick et al. (2001) explained, pitting one against the other creates a false dichotomy. Procedural and conceptual understanding are not separate, competing forms of knowledge, but are interwoven competencies that support each other. As such, rather than characterizing one as more or less valuable than the other, a more productive approach is to describe ways in which different manifestations of each are robust or not (Star, 2005).

Nevertheless, researchers continue to emphasize conceptual understanding, paying less attention to procedural fluency (Bay-Williams, 2020). The one exception has been at the elementary level where a significant effort has been made to explicitly characterize what procedural fluency of numerical computation entails as well as identify instructional methods that support its development (Bay-Williams & San Giovanni, 2021). This has led to a robust understanding of the types of strategies and reasoning involved in this critical mathematical understanding, previously only known by vague terms such as “number sense.” Such details have begun to appear in our standards and curriculum documents (CCSS, 2010), providing guidance for teachers to shift away from teaching rote algorithms and now target robust procedural knowledge. In addition, math educators have collectively developed various activities that support its development as well as numerous tools (rekenreck, number lines, area models, etc) that promote such ways of thinking. Such findings mean that what was once viewed as an innate quality in only a few students can now be developed in all students (Bay-Williams & San Giovanni, 2021).

Notably, in light of these advances, instruction in the US still tends to predominantly emphasize rote procedures. While we know that at the elementary level teachers' lack of mathematical knowledge is a contributing factor (Ma, 2010), there are limited studies that explore how teachers understand and attempt to foster procedural fluency at the secondary level. There have been multiple theoretical pieces characterizing the relationship between procedural and conceptual knowledge as well as empirical studies exploring how different instructional foci support student learning, but we do not have a strong understanding of what procedural fluency looks like for different secondary topics or what teachers' perspectives of procedural fluency is. Establishing such views is critical, enabling the field to develop targeted ways to better support teachers in engaging in more conceptually connected instruction of different procedures. The aim of this study was to fill this void. To do so we focused on the topic, quadratic factoring, to explore the question, *What understandings and perceptions of procedural fluency shape secondary teachers' instruction of factoring quadratics*?

Conceptions of Procedural Knowledge

Both procedural skills and conceptual understanding have long been valued components of mathematics education, but have historically been viewed as separate entities. Notably, when Hiebert and Lefevre (1986) first introduced and defined the terms procedural and conceptual knowledge, while they explored relationships between the two and acknowledged that it is hard to imagine students developing one without the other, they still positioned them as different types of reasoning, defining procedural knowledge as a familiarity with syntactic manipulation and conceptual knowledge as a deep, connected understanding. Fundamentally, they characterized all learning with meaning as conceptual, aligning with Skemp's (1978) notion of robust relational understanding and all procedural knowledge as rote, equivalent to the more superficial instrumental understanding. Critical of such an association, Star (2005) argued that knowledge type and quality should be treated as independent dimensions, challenging the field to conceptualize deep procedural knowledge and make it an instructional goal.

Today, scholars agree that robust procedural fluency should be an instructional goal, but there is debate over how best to foster it. NCTM (2014) advocates for instruction that extensively develops conceptual knowledge before procedural knowledge. However, Rittle-Johnson, et al. (2015), after a comprehensive analysis of multiple empirical studies, found no evidence for fostering one type of knowledge prior to the other. Instead, they concluded that the two serve to support each other and should be developed simultaneously.

More recently, in an effort to formalize this work, Fan and Bokhove (2014) offered a framework characterizing instructional foci that foster procedural fluency at three different levels (see Figure 1). In the first level, the focus is on rote practice with the goal of developing an instrumental understanding to consistently and correctly carry out the steps. The second level is characterized by a relational understanding of why the algorithm works and how it can be modified to accommodate different situations. The final level inherently involves familiarity with different algorithms as it consists of the ability to judge and compare the efficiency of different algorithms. Level 3 also includes the ability to construct or generalize new algorithms.

In addition to highlighting the type of student thinking associated with each level, Fan and Bokhove (2014) also highlight how the nature of the algorithms taught shape the level of thinking. While certain algorithms make the foundational ideas driving the algorithm quite accessible, others mask these underlying concepts making it difficult or impossible to unpack them. Drawing on Kilpatrick et al. (2001), they propose five different features (certainty, reliability, transparency, efficiency, and generalizability) to analyze the quality of algorithms themselves, which they see as aligning with the different levels of their proposed framework. Specifically, they argue that algorithms that only focus on the certainty that given steps are fixed and unambiguous correspond to level 1. Procedures that provide transparency for why they work as well as the reliability to consistently obtain correct answers characterize level 2 thinking. Finally, algorithms that allow for efficiency and generalizability are associated with the top level.

Level of Thought	Fluency with Algorithms	Features
Level 1: Knowledge and Skills	• Reproducing steps of a procedure	Certainty
Level 2: Understanding and Comprehension	• Describing why a procedure works • Applying procedure in a complex situation	Reliability Transparency
Level 3: Evaluation and Construction	• Comparing different algorithms • Judging efficiency of an algorithm • Constructing new algorithms (strategies) • Generalizing	Efficiency Generalizability

Note. Recreation of image created by Bay-Williams (2020) based on Fan & Bokhove (2014) framework including algorithm features.

Figure 1: Procedural Fluency Framework with Corresponding Bloom's Taxonomy

While this framework provides a theoretical lens to categorize procedural knowledge in general, it lacks details about what these different categories entail for different content areas. As noted, one exception where such details have been developed has been at the elementary level, where Bay-Williams and colleagues (2021) have developed an in-depth characterization of fluency with numerical operations. In addition, they articulate how fluency goes beyond simply speed and accuracy, identifying different strategies which illustrate flexibility as well as provide a broader view of efficiency that incorporates appropriateness. While such work offers a powerful resource to support teachers at the elementary level, we have a limited understanding of procedural fluency at the secondary level. One example is Durkin et al. (2017), who worked with algebra teachers to explore if instruction that focused on comparing different solution methods of symbolic algebraic equations would support students in developing procedural knowledge. They found students developed more robust procedural knowledge in classrooms where teachers used the curricular materials more, but also found that most teachers did not engage students in these activities and struggled, in particular, to facilitate conversations around different methods. Such results hold promise, but indicate that more work is needed exploring how teachers understand and attempt to foster procedural fluency.

Factoring

Factoring provides a productive context to explore teachers' perceptions of procedural fluency as there are multiple different and well-known ways to approach this topic. However, to analyze these different approaches, we first define the conceptual understandings associated with factoring. We see two interrelated concepts that are critical to understanding factoring. First, students must recognize that the factoring process serves to transform algebraic expressions from an additive to a multiplicative structure. They must understand that the two forms are equivalent expressions, but that the different structures elevate different characteristics. However, in most cases this process cannot be determined directly. Instead, it requires carrying out the distributive property and observing patterns to be able to reverse the process. Such pattern recognition characterizes the second conceptual component. While often taught as rote rules, the ability to effectively identify and generalize useful forms involves the mathematical practice *Looking for and Using Structure* (CCSS, 2010). As teachers know, fostering this practice is challenging, as the ability to strategically decompose algebraic expressions relies on a combination of goals and student understanding and thus cannot be taught as a rule.

Features of Quadratic Factoring Algorithms

With these underlying conceptual ideas in mind, we apply the Fan and Bokhove framework to the different quadratic factoring methods that have emerged. Considering which features each algorithm possesses, highlights the levels of thinking they afford.

Slide, divide, bottoms up-level 1. A well-known algorithm that focuses on certainty, without transparency is Slide, Divide, Bottoms Up, also known as Slip Slide (Steckroth, 2015). However, while it provides a sequence of easy-to-follow steps to factor all nonmonic quadratics, most are not only unjustified, but mathematically incorrect. So illogical are the different steps that the only way to know how to carry out the algorithm is by following the steps outlined in the name (see Figure 2). Since the underlying rationale is hidden, this algorithm allows for only a level 1 level of thinking. Moreover, it encourages students to treat algebraic expressions as a collection of disconnected symbols that can be moved and manipulated as isolated characters, serving to undermine the development of any structural sense.

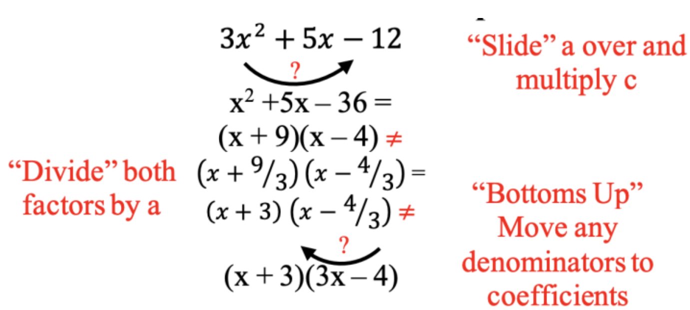

Figure 2: Outline of steps involved in Slide, Divide, Bottoms-up

AC method-level 1+. Another systematic approach that provides a consistent and reliable algorithm for all cases is the AC Method. This method relies on creating a 4-term expression, which can be factored using grouping, by splitting up the linear term into two factors of the product AC that add together to form b (see Figure 3). However, while each step follows correctly from the previous and the grouping provides a clear connection between factoring and distributing, there is no transparent reason for why the factors of AC should lead to 4 terms that can be reliably grouped. Moreover, to avoid challenges associated with grouping, teachers often use a 2x2 Box. Each of the 4 terms are placed in a separate box and the GCD from each row and column is factored out. In contrast to grouping, this avoids conceptualizing the binomial (x + 3) as a single algebraic entity, a key component of structural reasoning (Musgrave, et al., 2023) and again encourages students to treat each symbol as an isolated object, rather than a meaningful expression. As such, this method has attributes of level 2, offering some insight into how the multiplicative structure is formed, but still lacks full transparency, leaving it at the lower level 1.

AC = -36

9(-4) = -36

Grouping

$$3x^2 + 5x - 12 =$$
$$3x^2 + 9x - 4x - 12 =$$
$$3x(x + 3) - 4(x + 3) =$$
$$(3x - 4)(x + 3)$$

Box

	x	3
3x	$3x^2$	9x
-4	-4x	-12

Figure 3: Symbolic and Box approaches to the AC Method of Factoring

Guess and check-level 2. As noted above, conceptually understanding factoring requires seeing the connection to the distributive property which inherently involves pattern recognition to reverse the process. Such a method is often referred to as guess and check. While the pattern for monic quadratics is reliably the same, this is not the case for quadratics when the leading coefficient is not 1. Such a method can definitely be characterized as transparent and at times efficient, However, when applied to numbers with multiple factors, this method loses efficiency.

Scaling-level 3. One algorithm that is not only consistent and transparent, but also generalizable is a scaling method (see Figure 4) offered by Cuoco (2009) as part of the CME project. This algorithm uses substitution to transform all quadratics into a monic quadratic. Such a method provides a systemic approach that allows students to use the general pattern of looking for two factors of the constant term that add to the linear term.

$$3x^2 + 5x - 12$$
$$\frac{1}{3}(9x^2 + 15x - 36) = \frac{1}{3}((3x)^2 + 5(3x) - 36)$$
$$\frac{1}{3}(u^2 + 5u - 36)$$
$$\frac{1}{3}(u + 9)(u - 4)$$
$$\frac{1}{3}(3x + 9)(3x - 4)$$
$$(x + 3)(3x - 4)$$

Multiply expression by leading coefficient to scale up by a factor of a.

Create a monic quadratic by substituting u = ax

Divide expression by a

Figure 4: Scaling method which transforms quadratics to a monic form

Methods

To explore how teachers view and foster procedural fluency associated with quadratic factoring, we conducted and videotaped one-hour individual semi-structured interviews (Ginsburg, 1997) with eight high school teachers (1 male, 7 female; all white). Overall, the teachers possessed a wealth of experience and expertise, with four to 34 years in the classroom and an average of 17 years teaching. All but one had a graduate degree, with the majority studying specifically mathematics education, and had experience teaching multiple grades and classes. To ensure a diversity of perspectives, teachers were selected from seven different schools across two different states. The schools represented a wide range of student populations in terms of their socioeconomics (30%-88% poverty rates) as well as prior achievement (27%-65% meeting minimal proficiency levels on state algebra test). In particular, two schools were among the top performing in the state and two were among the lowest in the state.

Interview questions focused on identifying what methods the teachers have taught and currently teach in different classes as well as different questions aimed at eliciting their instructional motivation for choosing these. In addition, we asked the teachers about their instructional goals associated with factoring, their familiarity and understanding of different factoring methods, and ways they differentiated instruction including the use of different tools (i.e. algebra tiles). We began our analysis by identifying statements that referenced the methods they teach, the rationale behind those methods, and their understanding of the conceptual value of factoring. This led to several codes marking the overall conceptual understandings of factoring teachers possessed which we refined through multiple iterations of analysis. Ultimately, we found three categories that were representative of how teachers understand procedural fluency and their teaching of factoring.

Results

We organize our results around two major findings. First, we outline the actual methods that teachers instruct in class (see Table 1), separated by the tracked level assigned to students (see Prins & Hawthorne (2024), for more information about how tracking shaped teachers' instruction of factoring). Because some used more than one method, totals add to more than the number of participants. We then outline the different goals that teachers communicated about factoring. Together these methods and associated goals provide insight into the approach these teachers use to foster procedural fluency.

Table 1: Factoring Methods Used by Teachers for Different Levels

	Level 1			Level 2	Level 3	
		AC Method				
	Slide Divide	Grouping	Box Method	Guess & Check	Scaling	Calculator
High Track	1	2	0	6	0	0
Low Track	2	2	5	1	0	1

As the above table illustrates, the majority of the teachers use the Guess and Check method in their honors classes, while teaching the Box-AC method for their lower tracked students. Thus, teachers implement more conceptually grounded methods with their higher tracked students, but teach rote algorithms with limited to no transparency to their lower tracked students. Notably, when asked why they teach guess and check in honors, only one teacher made reference to the conceptual value of such a method. All others, even when probed multiple times, explained that they taught it for efficiency reasons, as they saw it as the best way to quickly arrive at the answer. Conversely, the teachers collectively taught the lower tracked students methods void of meaning, explaining that they saw the consistent steps of the Box-AC and Slide-Divide methods as the easiest to follow. Looking through these results through the Fan & Bokhove (2014) framework, such methods ensured that only students deemed advanced had access to more robust procedural fluency, but to support efficiency, not conceptual understanding. Ultimately, these teachers picked these methods not to foster procedural fluency grounded in flexibility or sensemaking, but rather out of a desire for speed in the higher tracks and a deficit perspective towards students in the lower tracks.

Probing deeper into the motivations behind such choices, we found that the majority of teachers saw factoring as simply a tool used to produce an answer, rather than a conceptual topic. As a result, they teach their students rote algorithms which allow students to arrive at a factored form, but without having to struggle with the deeper mathematics that are at play. Moreover, when asked, the teachers were unable to provide justification for these different methods and in most cases were unaware. However, results provide nuance to the teachers' understanding of factoring which led to three distinct categories that characterize the different ways in which teachers viewed factoring: conceptual value, general value, and performance value (see Table 2).

Table 2: Characterization of Instructional Value Associated with Procedures

Categories	Teachers	Characterization
Conceptual value	1	Articulated conceptual value in factoring and taught methods that aim to foster such understanding
General value	3	Alluded to vague notions of conceptual value (logical and reasoning, graphical and symbolic, multiplying and dividing), and focused on speed and answers
Performance value	4	Saw no conceptual value in factoring and taught methods that solely got an answer

Conceptual value

The first category, conceptual value, consisted of a single teacher who was able to speak to the conceptual value of factoring and as a consequence taught methods that aimed to foster such understanding. Throughout the interview, her responses indicated that she wanted students to understand the basis of different factoring forms and intentionally pushed back against methods that did not allow students to see the conceptual foundation associated with factoring. When asked about these other methods, she said, "kids don't understand the concept of what factoring is… they get caught up in learning this trick and memorizing it verses teaching them that factoring is just the reverse of multiplication." It is important to note that because of these beliefs, she teaches the guess and check and grouping methods to all students, regardless of track, and was the only teacher to do so. When asked why she preferred teaching guess and check, she emphasized that this method supports students in "understand[ing] the concept" and "it sticks with them longer." While her description of the underlying concepts was not necessarily robust, her appreciation of such understanding was significant enough to strive to support all students to engage in the thoughtful understanding of factoring.

General value

The second category, general value, was composed of three teachers who, when prompted, alluded to vague notions of a conceptual value in factoring. These notions included logic and reasoning skills, understanding graphical and symbolic relationships, or multiplying and dividing. As one teacher explained, "Understanding that factors are things you multiply to get this, and now we can do this with expressions the same way we do it with numbers." In particular, they predominantly focused on applications when describing the value of factoring (as opposed to thinking), citing that factoring is needed for finding zeros, and simplifying rational expressions. While these teachers were able to identify instructional goals that went beyond simply getting answers, these were vague without clear methods to foster such goals. Consequently, without more explicit understanding of the value of factoring, their instruction was characterized by a focus on speed and answers. All teachers in this category opted for methods they saw as producing answers quickly for their honors classes, and taught their lower tracked either the Box-AC method or Slide-Divide, believing these would be the easiest to produce correct answers. A quote from one teacher summed up how teachers' vague notion of conceptual understanding shaped their teaching of procedural fluency, "It is definitely a good thing to use sound methods, I don't know if that means that it is more advantageous to another." Despite her seeing value in using more conceptual methods, she ultimately opts for an algorithm that is less mathematical and easier for students.

Performance value

The last category was representative of 4 teachers who did not see any conceptual understanding in factoring and therefore teach factoring methods they believe will most easily produce correct answers. When asked about what they see as the value of factoring, these teachers cited needing to know how to factor for future math classes, application problems and solving for zeros. Representative of this category was one teacher who said, "The whole point [of factoring] is can you see some function and find out features of that function... most of the things we want to know is what can we solve this function for, which relates to the x-intercepts, so factoring is just simply a way to do that." Due to a lack of more in-depth goals, teachers in this category focused on getting to the answer most accurately and with the least amount of struggle for students. For the lower track, these teachers used the Box-AC method or Slide-Divide, with the exception of one teacher who had eliminated factoring from her instruction to exclusively teach the use of the quadratic formula as this had proven to be the easiest for students to get to an answer. While these methods do not foster a robust procedural knowledge, their instruction makes sense given their understanding and perspective. If teachers do not see any value in the process of factoring, then there is limited justification for using more challenging methods that lead to more student pushback and possibly lower accuracy.

Discussion

We found that teachers lack an in-depth understanding of procedural fluency associated with factoring, with half of the teachers teaching mathematically superficial and incomprehensible methods that serve to only produce answers. In addition, another group of teachers wanted students to develop a more robust procedural fluency, but were unable to articulate what this would entail. Without clear goals, these teachers eventually focused on speed and ease as well. However, there was one teacher using more conceptually grounded methods to instill a more meaningful understanding in all her students.

Notably, all of the teachers we interviewed had tried a variety of different methods, suggesting they had autonomy for their instruction of factoring. Furthermore, none of them spoke of stresses associated with testing, curricular demands, or department or administrative pressure. While this might be because most of the participants were highly experienced and taught in states without an end of the year exam past Algebra I, such independence distinguishes secondary teachers from their K-8 colleagues. Instead, what shaped their instruction was a narrow view of procedural fluency of factoring with a sole focus on answers combined with beliefs about their students. These teachers had each invested significant amounts of time learning multiple factoring algorithm along with different scaffolds to help students easily and reliably carry them out. So focused on simplifying the process that issues of productive struggle, mathematical practices, or possible messages about mathematics were overlooked. Even questions about why such algorithms worked were not considered, as teachers were not only unable to explain various steps of these algorithms, but had clearly never thought about this.

As noted earlier, the field has limited insight into how secondary teachers perceive and teach procedures. These results fill that void, highlighting that teachers need guidance in what procedural fluency entails and how to foster it. Moreover, they need support in understanding how different algorithms (and tools) aid or hinder procedural fluency.

The study of teachers' knowledge and competence in integrating mathematical modeling has gained recent attention, particularly in German research (Greefrath et al., 2022). Such knowledge and competence have been explored by academics with the purpose of, on the one hand, designing teacher training strategies and, on the other hand, measuring the impact of these strategies. The present study explored eight educators' testimonies and how they implement modeling in their classrooms to address the research question: *What pedagogical approaches do practitioner teachers use to design and apply mathematical modeling tasks that integrate virtual simulations?*

Methodology. This study conducted eight semi-structured interviews. Data sources encompassed video recordings, transcripts, activity handouts, and researchers' notes. The constant comparison method (Merriam & Tisdell, 2015) was employed for data analysis, involving open coding to identify main themes across all activities and interviews. Additionally, we utilized Kaiser and Sriraman's (2006) classification of modeling perspectives to categorize the pedagogical approaches described by the teachers. Our focus on simulations serves as a compelling example of the purposes of the whole project. The themes we will discuss are: (1) simulation promotes a change of beliefs about chance, and (2) simulations through embodied modeling generate empathy.

Conclusions. Overall, our findings underscore the importance of teachers' specialized knowledge in designing effective simulation-based activities that cater to their students' diverse needs and contexts. Teachers can create transformative learning experiences that promote critical thinking, problem-solving, and socio-cultural awareness by recognizing and leveraging the power of simulations in mathematics classrooms. A limitation of this study corresponds to the number of participants and tasks included. However, we identified differences with the perspective on teacher knowledge described by Gerber et al. (2023), which are based on work done mainly by European authors, primarily German. In this sense, our results add to the efforts of Cordero et al. (2022) to seek alternative perspectives to the dominant demands of Europe.

ELEMENTARY PRESERVICE TEACHERS' MATHEMATICAL MEANINGS FOR TEACHING FRACTIONS

Hyunjeong Lee
Indiana University
hle5@iu.edu

Keywords: Mathematical Knowledge for Teaching, Pre-Service Teacher Education, Algebraic Thinking.

Introduction

Students' stages of units coordination are closely related to constructing schemes for fractional knowledge (Hackenberg, 2013). While students learn fractions in their elementary school, there are many middle school students who have difficulty coordinating multiple levels of units (Zwanch & Wilkins, 2021). Furthermore, some Pre-Service Teachers (PSTs) have not reached to stage 3 of units coordination (Jacobson & Izsák, 2014; Son & Lee, 2016). Although there are many studies about students' stages of units coordination (e.g., Hackenberg, 2007; Hackenberg & Lee, 2015; Hackenberg & Sevinc, 2024; Hackenberg & Tillema, 2009; Steffe, 1992, 2003), little is known about teachers' stages of units coordination (e.g. Izsák et al., 2012).

Teachers' mathematical meanings for teaching fractions may give more context to teachers' understanding and their scheme related to teaching. While there are studies about teachers' mathematical knowledge for teaching fractions (Copur-Gencturk, 2021; Izsák et al., 2012; Olanoff et al., 2014; Veloo & Puteh, 2017), little is known about teachers' mathematical meaning for teaching fractions (Thompson, 2013). This study examines how PSTs' capacity for units coordination is related to how they construct fraction schemes and create mathematical meanings for teaching fractions with two research questions: (1) Which cognitive processes might PSTs go through? What modifications to their fractional reasoning schemes might be noticed? and (2) How are PSTs' unit coordination stages related to the development of their Mathematical Meanings for Teaching Fractions?

Methodology

I intend to initiate the data collection by administering a written task to eight elementary PSTs, aiming to select four (out of the 8) candidates for the subsequent 10-episode teaching experiment and post-test. The data collection will involve two distinct phases. Initially, I will enlist 8 PSTs for a written task focusing on units coordination and fractions for the pre-test by using instrument by Norton et al (2015). Subsequently, I aim to conduct 10 episodes to delve into fractional knowledge. The initial five episodes will concentrate on their first-order knowledge, engaging participants in fraction-related problems accompanied by 45-minute discussions. The latter five episodes will center on the PSTs' second-order knowledge, involving their interpretation of elementary students' problem-solving videos related to fractions. Following the 10 episodes, the 4 selected PSTs will undertake a post-test similar to the pre-test, again performing written tasks on units coordination and fractions while recording videos.

This theoretical analysis examines the diverse designs and intentions behind mathematics teacher educators (MTEs)' diagnostic interview assignments for elementary preservice teachers (PSTs). It underscores the necessity for PSTs to develop integrated specialized content knowledge and pedagogical skills. The study establishes a framework to assess alignment between MTEs' design goals and actual practices. Through cross-institutional collaboration, common phases of diagnostic interviews were identified, focusing on evaluating PSTs' abilities to analyze student thinking and apply pedagogical strategies. The analysis emphasizes the importance of intentional design tailored to PSTs' needs, prompting educators to review interview design and rubrics for effective course planning.

Keywords: Instructional Activities and Practices; Mathematical Knowledge for Teaching; Preservice Teacher Education; Elementary School Education

Effective mathematics teachers evaluate and reflect on both the mathematics content and teaching methods they use in the classroom to support the learning of a diverse student population (Association of Mathematics Teacher Educators [AMTE], 2017). To learn how to enact that reflective practice, well-prepared elementary preservice teachers need opportunities to build a cohesive understanding of specialized mathematics content knowledge (SCK) and how to apply that knowledge through effective pedagogical practices (Ball et al., 2008; Li & Howe, 2021; National Council of Teachers of Mathematics [NCTM], 2014). However, preservice teachers (PSTs) in the U.S. experience a wide variance in the number of opportunities to learn how to teach mathematics effectively in their teacher training due to differences in program and course structures (Bertolone-Smith et al., 2023; Cochran-Smith et al., 2015). Mathematics teacher educators (MTEs) with limited time to prepare their PSTs, must design methods courses in innovative ways and scaffold instruction so that their PSTs build an integrated knowledge base of mathematics content and pedagogy (Harr et al., 2014; Saclarides et al., 2022).

Diagnostic interviews are one type of assignment often used by MTEs in math methods courses to create integrated opportunities for PSTs to develop various types of knowledge and practices necessary for their future career, while assessing PSTs' competencies for teaching.

However, MTEs' designs and goals for diagnostic interviews are diverse. The purpose of this theoretical analysis is to understand the diversity and intentionality of MTEs' designs and goals for diagnostic interviews and create a framework for them to reflect on and self-evaluate the alignment of these two elements.

Theoretical Framework

There are two core elements to teaching mathematics that all PSTs must know: 1) Specialized Math Content Knowledge (SCK); and 2) Pedagogical Content Knowledge (PCK). These two elements are the foundation of the theoretical framework for the theoretical inquiry presented in this analysis.

Mathematics teachers should elicit students' mathematical thinking and use it as evidence to inform their instruction (Forzani, 2014; NCTM, 2014). To enact this practice effectively, teachers need a strong foundation in domains of SCK (Ball et al., 2008). These domains include being able to notice and understand students' mathematical thinking; evaluate the accurate, flexibility, and fluency of students' mathematical strategies; as well as the differences between conceptual understanding of a topic and procedural strategies to apply that conceptual understanding (Bahr & de Garcia, 2010; Ball et al., 2008; Jacobs et al., 2010). Teachers also need a strong foundation in the domains of PCK. These domains include knowledge of the content, curriculum, students, and teaching practices (Ball et al., 2008). Pedagogical practices for teacher noticing focus on interpreting students' knowledge of the math content, where that knowledge falls within the curriculum and using evidence to adjust instruction as needed to support student learning (Jacobs et al., 2010; NCTM, 2014). Additional pedagogical curriculum teaching practices that support mathematics learning important to our theoretical framework include establishing goals, purposeful task design for reasoning and problem solving, using representations, posing purposeful questions, building understanding and using evidence of student thinking for curriculum planning (Litster et al., 2020; NCTM, 2014).

Analysis of the Issues

This theoretical analysis is one component of a cross-institutional study that examines how PSTs in elementary mathematical content and methods preparation courses develop and use SCK and PCK for teaching. During 2023, representatives from eleven universities met and discussed activities in their programs that integrate specialized math content and pedagogical methods. One common activity across multiple institutions was the use of a diagnostic interview given to K-12 students in a clinical setting. However, the interview at each university was unique in design. Through an iterative qualitative process, the group identified and refined five common phases of the interview process that may showcase evidence of PSTs' SCK and PCK from the theoretical framework (see Table 1). Then, each researcher reviewed their own design using a self-evaluation model that identified the tasks they require in each phase of the interview, whether the design allows the teacher educator to strongly evaluate, partially evaluate or not evaluate PSTs SCK and PCK from Table 1 for that phase, as well as any factors that contributed to the intentionality of that design. This analysis will first present potential evidence of SCK and PCK at each phase from our analysis in Table 1 and then present findings from the diverse MTE interview designs and intentionality behind those designs.

It is important to note that the potential tasks and knowledge that can be evaluated in this table is a compilation of information from all university interviews; there was not a single interview that encompassed every aspect of the table. The knowledge that can be evaluated is based on the design of the individual interview and the purpose behind the interview design

Table 1: Diagnostic Clinical Interview Phases and Knowledge Types

Interview Phase	Specialized Math Knowledge	Pedagogical Knowledge
Preparing Interview -choosing tasks -solving tasks/answer key -narrating background -establishing trajectory -adapting question	-open/closed quality of math tasks -accuracy/strategies for solving the task/problem - mathematical decomposition of the learning goal	-trajectory/ standard alignment -appropriate for student/goal -quality of task - common misconceptions -reasoning/problem solving - purposeful question design
Implementing the Interview -asking questions -adapting questions -requiring representations -taking notes/ transcript	-adaptability for follow-up questions -cognitive demand -accuracy of questions and responses to students -teacher noticing: attend to math	-adaptability -pose questions -productive struggle -representations -teacher noticing: attending to student thinking
Evaluating Student Thinking -concepts/procedures -math accuracy/fluency -flexible strategy/represent -strengths vs areas need	-common vs specialized "acceptable" strategies. -noticing math strengths/weaknesses -difference between procedures and concepts	-use evidence of student thinking -teacher noticing: interpreting student thinking
Informing Instruction -identify objectives -develop individual plan -develop class lesson plan	-Math in new lesson/individualized plan is accurate (math aligns with next step)	-appropriate math progression -teacher noticing: deciding how to respond based on student thinking -differentiation
Self-Reflection -reflecting (Multiple Stages)	-reflection on personal math understanding	-reflection for personal professional growth

In order to more closely evaluate the purpose of the interview design and how that design influences what PST knowledge can and cannot be measured, we used a collective self-study. Each researcher reviewed their own design using a self-evaluation model that identified the tasks they require in each phase of the interview and whether the design allows the teacher educator to strongly evaluate, partially evaluate or not evaluate PSTs' knowledge from Table 1 for that phase. Researchers justified any rationale to support their design choice such as point in the program, content vs. methods course, or access to children. Finally, they identified any formal evidence collected to evaluate PST knowledge.

Results showed that the needs identified by the teacher educator for their PSTs influenced the design. Results also showed areas of self-evaluations indicating a strong evaluation of PSTs' knowledge or skills were directly tied to lines in the assignment grading rubrics. A few examples organized by interview phase are shared below.

Time, type of course, and PSTs' mathematical and pedagogical abilities played a part in preparation design. For example, one researcher noted in their self-evaluation that due to time constraints they did not feel PSTs in their math methods course were ready to design their own questions in the preparation phase; as a result, they provided appropriate questions to choose from. This led to no strong areas of math or pedagogical knowledge evaluation, and there were no items on the rubric relating to preparation of the interview. In a second example, a researcher noted in their self-evaluation that one goal of the interview in their content course was to consider a variety of student strategies to solve math problems; as a result, they provided specific questions that allowed for a variety of strategies. Although nothing in the preparation phase was evaluated on the rubric, a major component of the rubric was "rich descriptions of how the student solved the problem" which ties directly into the purpose of the preparation design. In a final example, a researcher noted that their partner schools were concerned about PSTs' ability to align math content to the standards and solve the mathematics themselves; as a result, they required students to design three questions that align to a standard and solve the problems. The rubric for this design has points for alignment to the standard as well as accurate solution strategy and representation.

Two key aspects of implementation design focused on teacher noticing of student thinking and adaptability based on student responses. All self-evaluations indicated a strong ability to evaluate teacher noticing and ability to evaluate accuracy of student responses or strategies. Although many of the interviews required a copy of notes or a transcript, rubric items to evaluate these two areas of implementation were done concurrently with phase 3 (evaluation of student thinking). Adaptability was another common area with high evaluative potential (partially or strongly). A few interviews with strong potential for adaptability required PSTs to preplan potential misconceptions and follow-up questions (scaffolds or higher-order) based on student responses to help facilitate adaptations and measure adaptability.

Across all self-evaluations, results showed the evaluation phase is the keystone of the interview design and purpose. Researchers indicated the ability of their design to help PSTs notice and interpret student strength in accuracy, fluency or flexibility of mathematics. Additionally, PSTs were required to use evidence from their interview to support their interpretations across all interview designs. This did look slightly different across rubrics for grade alignment. For example: Rubric 1: "The profile contains rich descriptions of how the student solved the problem, with ample relevant and revealing evidence of their thinking. Key mathematical details from the student's thinking are attended to and interpreted in a way that creates reasonable models of the student's understanding." Rubric 2: "Describe the student's specific math strengths and weaknesses relating to accuracy, fluency, and flexibility. Support with evidence from notes."

The key aspects for design when planning next steps relied on when and where the interview was taking place as well as the similarity in interview topics. For example, one researcher who had all the PSTs do the same interview with students of the same grade level, had groups of PSTs co-create a lesson plan based on evidence from the interviews. The purpose was on using information about multiple students to plan for instruction. In another interview where PSTs' interviews covered a variety of math topics and grade levels, the next steps focused on the individual child's needs and scaffolds.

As this analysis has shown there is diversity in the intentionality of interview designs across institutions. There are many factors that can influence design such as timing, PSTs' knowledge, type of math preparation course, access to children, or other needs of the community.

Implications for Practice

In conclusion, this study supports our collective development and refinement of elementary math methods course assignments that seek to integrate content and pedagogy. Working across institutions will allow us to develop adaptable assignments that can be used in diverse contexts, and will support our collective efforts to improve elementary math teacher preparation.

As shown in this theoretical analysis, there is not one correct way of designing a diagnostic clinical interview. However, the design should be intentional for preparing, implementing, and evaluating the interview to meet the needs of PSTs at that institution. As societal shifts change the needs of PSTs entering the teaching profession, this analysis presents one way MTEs can review and analyze the intentionality of an interview design or rubric in their mathematics preparation courses or analyze a public interview design they may want to adopt for use to ensure it meets the needs of their unique population.

EXPLORING PRESERVICE TEACHERS' UNDERSTANDING OF FRACTIONS FROM A COMMOGNITIVE LENS

Jinqing Liu

Merav Weingarden
Tel-Aviv University
merav.weingarden@gmail.com

Fraction is one of the most challenging mathematical topics to learn and teach. Teachers often lack a profound understanding of fractions, which may lead to students working with fractions procedurally. In this paper, by drawing upon the commognitive framework, we offer an in-depth examination of two preservice elementary teachers' (PSTs') fraction understanding. We show how two PSTs who solve the same comparing fraction task, follow similar steps, and get the same correct answer, participate differently in the discourse about fractions. This different participation was identified by the extent to which the PSTs individualized the standard routine of comparing fractions, which we conceptualized in this paper. We discuss the affordances of the commognitive discursive lens on PSTs' understanding of fractions and highlight the study's contribution to teacher educators and teacher preparation programs.

Keywords: Preservice Teacher Education, Teacher Educators, Classroom Discourse, Learning Theory, Rational Numbers.

Fractions are widely recognized as one of the most challenging mathematical topics for both learning and teaching across K-12 education (Liu & Jacobson, 2022; OECD, 2014; Siegle, 2017). Despite the importance of teachers supporting students in developing a deep understanding of fractions and providing opportunities to explore underlying concepts, studies reveal that many teachers, especially prospective teachers (PSTs), often lack this foundational knowledge (Olanoff et al., 2014). While PSTs can often correctly solve fraction problems using established procedures, they frequently overlook the conceptual meanings and mathematical connections behind these procedures. This gap significantly limits their ability to effectively teach fractions in a way that fosters true understanding among all students in the future.

To address this challenge and enhance PSTs' proficiency in teaching fractions for understanding, the first author conducted a research project aimed at improving PSTs' teaching knowledge toward teaching fractions for understanding (Liu, 2021). This current study serves as a follow-up, focusing on a subset of data from the larger project and conducting a detailed analysis using a commognitive theoretical lens. Through this focused approach, we aim to uncover fresh insights into how PSTs conceptualize and understand fractions.

Specifically, our study examines how two PSTs individualize a standard routine for comparing fractions, known as the common denominator strategy. Our research questions guide this exploration: How do these PSTs individualize the standard routine for comparing fractions? Additionally, what are the differences in their de-ritualization processes?

Theoretical background

A Commognitive Theoretical Perspective

From a commognitive theoretical perspective, mathematical thinking is viewed as a discourse, a form of communication (Sfard, 2008). Learning within this framework is seen as a transformation in discourse—specifically in how learners talk about and interact with mathematical objects. According to commognition, any discourse can be characterized by four key elements: the use of specialized terms, visual tools, endorsed narratives, and discursive routines—patterns of actions performed in discourse (Steiner, 2018).

The evolution of learners' routines can be understood as a process of discourse development, where learners personalize established routines (Lavie et al., 2019). Initially, they *repeat* shared routines in society. Over time, they *individualize* the shared routines– “into independent, agentive implementers of those routines"(Lavie et al., 2019, p. 156). This gradual shift from ritual to explorative engagement is termed de-ritualization (Lavie et al., 2019).

Lavie et al. (2019) identified six key desirable characteristics of routine: flexibility, bondedness, applicability, performer's agency, objectification, and substantiation. They distinguish between ritual and explorative actions for each characteristic to describe learners' participation in discourse. This study specifically investigates how PSTs demonstrate bondedness, substantiation, and objectification within their mathematical discourse.

Bondedness refers to the interconnectedness of steps where the output of one step feeds into the next (explorative). When a performer precisely follows an expert's procedure but lacks awareness of these step relations, it results in disjointed steps (ritual).

Substantiation involves justifying or explaining a routine through reasoning. Ritual performances often focus on detailing the actual actions taken (object-level) for substantiation. In contrast, explorative performers base their justification on the meta-rules accepted by the community (meta-level).

Objectification encompasses reification, alienation, and saming. Reification occurs when participants shift from discussing processes to nouns (e.g., from "multiply 3 and 8 to get 24" to "24 is the common denominator"). Alienation involves excluding human agents from the discourse (e.g., from "I multiply 3 by 4 to get 12" to "12 is the product of 3 and 4"). Saming refers to treating seemingly different concepts as identical (e.g., "2/3 could be rewritten as 16/24"). More explorative objectification is indicated by increased reification, alienation, and saming in discourse.

A Standard Common Denominator Routine

In this study, we define and standardize a commonly used strategy for comparing fractions, known as the common denominator strategy, referred to as the CD routine. The CD routine addresses a mathematical challenge: the inability to directly compare or order fractions with unlike denominators and unlike numerators (Fractions_udun) in their symbolic form because a fraction's value depends on both its numerator and denominator. Thus, by applying the CD routine, we can standardize one variable (the denominator) by converting Fractions_udun to their equivalent forms with a common denominator (Fractions_cd) and then order the Fractions_cd by comparing their numerators.

This CD routine represents the culmination of historical development and expert consensus in fraction comparison strategies, typically codified in textbooks, curriculum standards, and educational guidelines. It comprises three essential subroutines: finding a common denominator, converting fractions to their equivalents using this common denominator, and listing them in order (referred to as finding, converting, and listing).

The first subroutine is finding a common denominator among the given fractions' denominators. A common denominator is a common multiple of these denominators, and while numerous numbers can serve as a common denominator, the least common multiple is often chosen for efficiency. Methods such as factor trees and listing multiples are commonly used to determine this common denominator.

Once the common denominator is established, the following subroutine is to convert each fraction to an equivalent form using this common denominator. This conversion follows a meta-rule: multiplying both the numerator and denominator by a nonzero number preserves the fraction's original proportion. This principle stems from the mathematical property that multiplying any number by one leaves its value unchanged.

By executing these subroutines—finding the common denominator and converting fractions—we transition from comparing Fractions_udun to comparing Fractions_cd. The third subroutine involves listing fractions in order, where the order of Fractions_cd is established by sorting their numerators. This is based on the understanding that a fraction a/b can be interpreted as the product of its numerator a and the reciprocal of its denominator (a * 1/b).

By the above conceptualizations, we could then examine how PSTs individualize the CD routine for comparing fractions, suggesting a better understanding of how they participate in the fraction discourse.

Methods

The setting, participants, and data source

This study draws data from a larger project aimed at enhancing PSTs' proficiency in fractions through an intervention. The focus of this study is on two participants: Hannah, a junior who completed required mathematics content courses on numbers and operations, as well as geometry; and Oprah, a senior who completed the same content courses along with a mathematics method course. Hannah and Oprah were chosen based on their positions within the teacher preparation program—Oprah being two years senior than Hannah. This educational difference potentially provided Oprah with more opportunities to develop a more explorative discourse, which in turn could increase variations in how they personalized and adapted the CD routine for fraction comparison. This selection is aligned with the purpose of this study.

As part of the intervention, PSTs were assigned the task of ordering fractions (2/3, 3/4, and 3/8) using various strategies, documenting their thought processes through written and verbal explanations (similar to a think-aloud activity) both before and after the intervention (pre- and post-test). The PSTs' responses, including their use of the CD routine, were recorded on video and transcribed for detailed analysis. This study specifically aims to explore how PSTs individualize the CD routine differently. Therefore, our focus is solely on analyzing the initial data from Hannah and Oprah: their respective pre-test excerpts.

Data analysis

We started the data analysis by consolidating each participant's written responses and verbal transcripts from the pre-test excerpts into cohesive documents. When verbal communication was ambiguous, we referred to video recordings to capture non-verbal cues. Each excerpt was systematically divided into lines based on the PSTs' speech patterns and narratives. Through regular meetings and discussions, we identified the specific subroutines within the CD routine that each PST utilized—namely, finding the common denominator, converting fractions, and listing them in order. To answer the research question, our analysis focused on pinpointing the characteristics of these subroutines, particularly examining bondedness, substantiation, and objectification. Subsequently, employing a comparative perspective, we assessed to what degree the characteristics of their routines leaned towards ritual or explorative practices. Since we view learning as a progression from ritual to explorative, our approach focuses on comparatively situating each PST's discourse along this continuum rather than categorically labeling any PST's discourse as strictly ritual or explorative.

Findings

As depicted in Figure 1, both PSTs compared 2/3, 3/4, and 3/8 using the three subroutines of the CD routine outlined earlier. Initially, they identified the common denominator 24 for the fractions 2/3, 3/4, and 3/8 (subroutine 1). Subsequently, they converted each fraction to its equivalent form (e.g., 2/3 to 16/24) (subroutine 2) and then established the order of the fractions (e.g., stating 2/3 as the second largest) (subroutine 3).

Our analysis revealed that while both PSTs followed these subroutines and achieved consistent outcomes, their discourse surrounding the process differed, indicating variations in their individualization processes and suggesting different levels of engagement in the discourse on fractions. In the following sections, we provide a detailed description of how each PST performed the three subroutines. Additionally, we delve into how they personalized each subroutine by examining variations in three key characteristics: bondedness, substantiation, and objectification.

	Oprah	**Hannah**
Written response		Finding	“And a multiple of 3, 4, and 8 is 24.”	"So, instead, I'm going to use 24"
Converting	e.g., “So, a new fraction is 16/24.”	“So, 2 times 8 becomes 16, and 24.”
Listing	"Our second largest is that (circled 2/3) because then we have 16 over twenty-fourths."	“Then the next lowest, the middle one, is going to be the 16/24.”

Figure 1. PSTs’ Written Responses and Indication for The Performed Routines

Subroutine 1: Finding the common denominator 24

Oprah: Oprah initiated the task by clearly connecting the subroutine of finding the common denominator with the broader goal of ordering fractions. She expressed, "You can solve it (the given task) by getting common denominators for all of them," indicating a direct alignment with the macro task. Oprah further detailed her approach by considering 24 as a common multiple of 3, 4, and 8. She justified her choice of 24 by explaining that it is divisible by each of these denominators, noting that they are factors of 24 ("a multiple of 3, 4, and 8 is 24, 24 is divisible by all of these numbers.").

Hannah: Hannah's initiation to the task was more procedural-focused. She stated her intent to "find a common denominator" without explicitly linking it to the larger task of comparing fractions. She then elaborated on the steps she took to arrive at 24, mentioning specific calculations ("between 3 and 4…is 12 to me… I also have to include 8… So, instead, I'm going to use 24").

The Characteristics of PSTs' Individualization of Subroutine 1

The descriptions above show that both PSTs identified the common denominator 24, yet they differed in their approach to bondedness, substantiation, and objectification. Regarding bondedness, which pertains to the awareness of connections between steps, Oprah integrated subroutine 1 of finding the CD with the overarching goal of comparing fractions. In contrast, Hannah focused solely on the procedural steps for finding the CD, highlighting a less integrated approach compared to Oprah's more explorative bondedness.

In terms of substantiation, which concerns how the procedure was justified, Oprah supported why 24 was chosen as the common denominator using meta-rules endorsed by the mathematics community. These included the concept of a common denominator as a multiple of denominators and its divisibility by each individual denominator. In contrast, Hannah detailed the calculations to explain why 24 was selected as the CD, focusing more on the process than the conceptual rationale behind it. Thus, Oprah's approach demonstrated more explorative substantiation compared to Hannah's.

Regarding objectification, Hannah's discourse involves more references to herself performing the procedures to find the common denominator. She uses phrases like "I'm going to use..." or "I'm going to do..." which place greater emphasis on her actions and decision-making processes rather than on the properties of the resulting object (24). In contrast, Oprah's discourse treated 24 as an abstract concept with inherent properties, discussing its divisibility without explicitly tying it to the procedural steps undertaken. This distinction suggests that Oprah's discourse was more objectified, focusing on the abstract properties of 24 itself, whereas Hannah's discourse was more human-centered and process-oriented, reflecting a more ritualistic approach.

Subroutine 2: Converting to equivalent fractions

Similar to subroutine 1 of finding the common denominator, subroutine 2 also concluded with both PSTs achieving the same outcome – three fractions with a common denominator of 24 that are equivalent to the three given fractions, respectively (16/24, 18/24, 9/24. See the written responses row in Figure 1). However, upon examining their discourse comprehensively, several differences in their discourse of this subroutine become evident.

Oprah: Oprah began by meta-discursively describing the actions required to maintain equivalence between two fractions. She stated: "What you have to do to the bottom, you have to do to the top." She applied this meta-rule to convert 2/3 to 16/24 and justified this approach by aiming "to make it proportionate." Oprah consistently followed this procedure of multiplying both the numerator and denominator by the same number for the other two fractions, resulting in three equivalent fractions.

Hannah: Hannah initiated this subroutine with a clear arithmetic objective – "to make all these [three fractions] out of 24." She then detailed the operational procedures while working with the fractions. Starting with 2/3, she first aimed "to get to 24 from 3." Hannah explained that achieving 24 from 3 required multiplying 3 by 8. After identifying this factor of 8, she proceeded to multiply both the numerator and the denominator of 2/3 by 8, resulting in 16/24 ("So I'm going to do the same thing on the top. So, 2 times 8 becomes 16."). Hannah followed a similar process for 3/4 and 3/8, obtaining 18/24 and 9/24, respectively.

The Characteristics of PSTs' Individualization of Subroutine 2

Similar to the first subroutine, Oprah's approach in subroutine 2 demonstrates both bondedness and substantiation. When revealing the equivalent fractions, Oprah seamlessly integrated the output of each procedural step into the next, such as increasing the denominator eight times, followed by increasing the numerator eight times to convert 2/3 into 16/24. Such kinds of interconnectedness reflect an explorative bondedness. Moreover, Oprah substantiated her actions by first establishing meta-rules ("what you have to do to the bottom, you have to do to the top") and then illustrating this rule through specific examples, like converting 2/3 to 16/24. She articulated this as creating "a six more relationship," emphasizing the systematic approach of multiplying both the numerator and denominator by the same number to maintain proportionality, which adds to the explorative substantiation in her discourse.

In contrast, Hannah's approach to subroutine 2 is characterized more by ritual substantiation. While she also applied the meta-rule of "doing the same thing on the top and the bottom," Hannah primarily focused on detailing the procedural steps without justifying them with broader meta-rules or conceptual explanations. For instance, she methodically described steps like setting 24 as the new denominator, dividing this new denominator by the old denominator (24 ÷ 3 = 8), multiplying this outcome (8) by the old numerator (2), and obtaining the new numerator (16). However, Hannah did not delve into the rationale behind these steps or the mathematical principles supporting her actions, illustrating a ritualistic approach to substantiation.

Regarding bondedness, Hannah connected her steps using transitional phrases like "So," indicating her awareness of the sequential relationship between actions. However, her discourse was characterized by a loose structure where individual steps appeared somewhat disconnected, lacking the cohesive flow observed in Oprah's approach. This mixture of goal-oriented phrases and rigidly performed steps suggests a relatively more ritual bondedness in Hannah's routine.

In terms of objectification, both Oprah's and Hannah's discourse employed human actors and emphasized the process (such as "You have to …" and "you would" in Oprah, and "I am going to …" and "You have to…" in Hannah), indicating ritual objectification. However, Oprah's discourse is a slightly more objectified exploratively regarding how she communicated about the number used to multiply. Oprah named it as "times of relationship" (e.g., eight times more relationship), while Hannah called it as a number itself.

In summary, while both PSTs achieved the same outcomes in subroutine 2, their discursive approaches differed significantly in terms of bondedness and substantiation and slightly different in terms of objectification. Oprah's discourse exhibited explorative bondedness and substantiation by integrating procedural steps with meta-rules and conceptual reasoning, whereas Hannah's discourse leaned towards ritualistic substantiation and bondedness, emphasizing detailed processes without the same depth of conceptual justification.

Subroutine 3: Listing the fractions in order As a result of the preceding routines, both PSTs obtained the same converted fractions: 16/24, 18/24, and 9/24. These fractions served as the starting point for the third subroutine.

Oprah: Oprah structured her approach by ranking the fractions based on the quantity of "twenty-fourths" each possessed. She asserted that 18/24 was the largest because it represented "eighteen of the twenty-fourths," identifying it as equivalent to three-fourths. She then identified 2/3 and 16/24 as the second largest by noting they both represented "sixteen over twenty-fourths." Finally, she designated 3/8 and 9/24 as the smallest due to having "the least amount of twenty-fourths."

Hannah: Hannah's method began with a focus on comparing the numerators directly. She determined that 3/8 was the smallest fraction by noting, "So we have 16, 18, and 9... So, the smallest one is going to be 9 out of 24, or the original fraction we were given is three-eighths." Hannah repeated this process with the other two fractions and got the correct fraction order.

The Characteristics of PSTs' Individualization of Subroutine 3

Both Oprah and Hannah demonstrated strong bondedness in their discourse by explaining how they determined the order of the fractions based on the results of subroutine 2, which provided fractions with a common denominator. Hannah emphasized the process by stating, "We can just compare the numerators," while Oprah provided a more detailed explanation. Oprah substantiated her process by describing how each fraction's numerator related to the total twenty-fourths, such as 18/24 having "eighteen of the twenty-fourths" and 9/24 having "nine of the twenty-fourths," thereby facilitating their comparison based on their numerators. This detailed substantiation made Oprah's discourse more explicit than Hannah's, which primarily focused on the method of comparing numerators, reflecting a higher level of explorative bondedness and substantiation in Oprah’s discourse.

In terms of objectification, both Oprah's and Hannah's discourse employed human actors and emphasized the process (such as "I have …" and "our second largest" in Oprah, and "so we have…" and "We were given…" in Hannah), indicating ritual objectification. However, Oprah's discourse demonstrated a relatively more objectified approach in how she communicated about fractions compared to Hannah. For instance, Hannah primarily referred to the numerator as an object ("we can just compare the numerators"), whereas Oprah discussed the fractions themselves as objects ("amount of twenty-fourth") and contextualized the numerator within the fractions (e.g., "our second largest is that [circled 16/24] because then we have sixteen over twenty-fourths". Meanwhile, while both Oprah and Hannah samed equivalent fractions, Oprah’s saming was much more straightforward (Oprah: "eighteen of the twenty-fourth…which was three-fourths" vs. Hannah: "nine out of twenty-four. Or the original fraction we were given is three-eights).

In summary, while both PSTs successfully completed the third subroutine with consistent outcomes, their discursive approaches varied in terms of bondedness, substantiation, and objectification. Oprah's discourse demonstrated deeper substantiation, stronger bondedness, and more objectified language compared to Hannah's, which was more process-oriented and human-centered.

Summary and Discussion

Based on the examination of each PST's individualization of the CD routine, with particular attention to routine characteristics, we present two different prototypes for individualizing the CD routine, which also reflect varied participation in the discourse on fractions. These cases are intriguing because despite following the standard routine, both PSTs exhibit notable similarities and differences.

Both Hannah and Oprah correctly identified the common denominator of 24, converted the fractions accordingly, and ordered them, adhering to the three subroutines typical in such comparisons. As Lavie et al. (2019, p. 156) observe, "Since the source of an individual's routines is in what other, more experienced performers are doing, we all end up acting in similar, compatible ways." Hence, it's expected that Hannah and Oprah follow the routine similarly.

However, upon closer examination of their discourse characteristics, we observed that Hannah and Oprah individualized the CD routine of comparing fractions in distinct ways, indicating varying degrees of de-ritualization from ritual to explorative characteristics. Generally speaking, Oprah's engagement in the discourse exhibits more explorative elements compared to Hannah's, particularly evident in how they approached substantiation, objectification, and bondedness. This study demonstrates that beyond mere correctness, there exists ample opportunity for further exploration and improvement (Liu & Zhuang, 2013). This study also expands upon our prior understanding of PSTs' fractional knowledge (Olanoff et al., 2014) and offers valuable insights into improving PSTs' proficiency with fractions.

The commognitive theory, which offers a unique perspective on learners' discourse as a reflection of their mathematical understanding, provided insights into the PSTs' potential learning processes and their individualization of standard routines. In the realm of teacher education, this analysis and its insights into how PSTs engage differently in the discourse about fractions can assist teacher educators in identifying specific areas for improvement. For instance, there could be a focus on supporting Hannah in justifying her procedures using meta-rules.

Our findings underscore the value of analyzing PSTs' discourse through a commognitive lens, offering a practical framework for examining how they individualize common mathematical routines. This approach provides an operationalized tool for understanding their learning and growth in mathematical pedagogy.

MANIFESTATIONS OF MATH ANXIETY IN MIDDLE AND HIGH SCHOOL MATH TEACHERS

J. P. Mannix
Ball State University
jpmannix@bsu.edu

Math anxiety can affect students and teachers in many ways, including student performance and instructional practices. Math anxiety has been well documented in elementary teachers, but little research has occurred on math anxiety at the middle and secondary levels. This study analyzed the ways in which math anxiety can manifest in middle and high school math teachers. Using phenomenological analysis methods on interviews with 11 teachers, findings from this study revealed that middle and high school math teachers with math anxiety see their anxiety manifest in three different ways: (1) in specific mathematical subjects; (2) when doing math in front of others; and (3) as a fear of new or unknown mathematics. These results demonstrate

Keywords: Affect, emotion, beliefs, and attitudes; teacher beliefs

Math anxiety, which researchers have long defined as feelings of fear or discomfort when dealing with mathematics (Ashcraft, 2002; Maloney & Beilock, 2012), can greatly impact student learning. This is true whether it is the student who is anxious (e.g., Sorvo et al., 2017) or the teacher (Beilock et al., 2010). Studies have shown that elementary teachers commonly have math anxiety (Hembree, 1990) and that it can impact their teaching practices (Hadley & Dorward, 2011). Research has also shown a negative correlation between math anxiety and attitudes about mathematics in elementary teachers (Çatlıoğlu et al., 2014; Jackson, 2015). However, little is known about math anxiety in middle and high school mathematics teachers.

A recent doctoral study (Mannix, 2022) demonstrated the presence of math anxiety in middle and high school math teachers. This study further uncovered a curious phenomenon in that secondary math teachers (which, for the purposes of this study, those teaching middle or high school) do not seem to experience math anxiety in the same ways as students or elementary teachers. Specifically, SMTs do not seem to feel math anxiety as a fear of mathematics itself. In fact, many of the participants from Mannix's (2022) study described pleasant, even joyful, feelings toward mathematics. This curious finding begs the question, in what ways does math anxiety manifest in middle and high school math teachers? Note, this brief report will examine this question as it manifests generally, not specifically in their teaching practices.

Methods

This study is part of a larger research project on the experiences of secondary math teachers with math anxiety. The larger study consisted of a survey that used convenience sampling to recruit participants with experience teaching at the middle and high school level, defined as grades five through 12. In this survey, participants responded to questions about their teaching experiences and their anxieties about math and teaching math. The current study focused on a set of interviews with 11 middle and high school math teachers who identified themselves as having some amount of math anxiety. Some information about each of the participants can be found in

Table 1. Transcripts from the interviews were analyzed using descriptive phenomenology, as outlined by Giorgi (Vagle, 2018).

Table 1: Participant Information

Pseudonym	Years Teaching	Degrees Held	Teaching Experience
Autumn	34	BA Math Ed; MS Math	High School
Brittany	7	BA Psychology; MA Math Ed	Elementary and Middle School
Charlie	17	BA English; MA Education	Elementary and Middle School
Daisy	33	BS Education; MA Education	Middle School
Georgia	16	BA Elementary Ed (Math Add-on); MA Education (Math Add-on)	Middle and High School
Hannah	2	BS Math; MS Math	High School and College
Michelle	11	BA Math Ed; MA Math; PhD Math Ed	High School and College
Oliver	5	BS Math	High School
Rachel	7	AA English; BA Math Ed; MS Math; MA Education	High School
Sarah	30	BA Math Ed; MA Education	High School
Whitney	4	BS Math; MA Math Ed	High School

Findings

The teachers in this study shared many interesting experiences and observations about their math anxieties. Notably, it seems that their math anxiety manifests in three different ways. For some, their math anxiety manifests within or around a particular subject, like geometry or statistics. For others, their anxiety manifests in front of other people. Finally, several of the teachers explained that their math anxiety manifests when confronted with new or unknown mathematics.

Math Anxiety in Particular Subjects

Each of the teachers in this study cited an anxiety with a particular branch of mathematics or a specific math course. For many, those anxieties stemmed from negative experiences in math classes at one level or another. For example, Georgia enjoyed math until she got to geometry, which she said was "frustrating in a bad way and made math lose its excitement" in her eyes. Similarly, Charlie shared an experience that would make anyone turn away from mathematics. He explained that, when he struggled in his high school AP calculus course, his teacher told him that he "may have hit his [mathematical] limit." This insidious comment made Charlie feel as though he had gone as high as he could with mathematics and that he wouldn't be able to understand the material in any further math courses. While he wouldn't consider it a traumatic experience, he does feel that it altered his trajectory and stunted his mathematical journey, causing him to refuse to take math courses in his undergraduate career.

Several of the teachers cited an anxiety with statistics. Specifically, Autumn said she doesn't like statistics because "it is often about making decisions that don't always make sense and may not seem logical," though she admitted that she didn't take a statistics course until graduate school, which might explain her anxieties around and biases against the subject. Rachel, on the other hand, did not care for the overlap between statistics and probability and found the multiple types of probability to be very confusing, causing her to feel anxious around any sort of statistical topic.

Brittany and Hannah shared an aversion to higher-level mathematics. Brittany explained that she was most anxious with courses like linear algebra and calculus because she feels she "lacks a foundation in those areas." Hannah, on the other hand, pursued a PhD in mathematics, but she had to leave the program after failing one of her qualifying examinations. "I had all of these dreams revolving around math, and I felt like they all shattered. So my relationship with math is definitely different." Hannah went on to say that she enjoys teaching math at the high school level, but she doesn't think she'll ever revisit the doctoral level mathematics that she had been doing.

One teacher, Whitney, said she felt most anxious not in a particular course but with a particular type of problem. For Whitney, multiple choice math problems cause her the most anxiety, particularly those with an answer choice of "answer not here." These problems, she says, cause her to second guess herself, so she prefers problems that are open ended as they allow her to share her thinking.

Math Anixety in Front of Others

For six of the participants in this study, their math anxiety affected them greatly when they were tasked with doing mathematics in front of people. Charlie and Georgia both felt anxious in front of their peers who taught higher-level math classes than they do or who have been teaching the courses for much longer than they have. Charlie shared that he "feels like he doesn't know what he is doing" when in these situtations, while Georgia said she knows she's smart enough to do and teach the math that her colleagues can do and teach, she just "doesn't have the knowledge right now," in the moment like they do, which makes her feel anxious and lesser than her peers.

Similarly, Daisy said she feels most anxious when being observed or when she knows someone might look over her work.

Oliver said he felt anxious when students would ask him for help with advanced math problems, like those they faced in math competitions. These problems are generally geared toward problem solving and tend to be critical-thinking heavy, and this teacher explained, "If I feel in the moment that I can't help with that question, I'm a little bit anxious…I don't feel as confident on those [types of problems]." Similarly, Whitney said she used to get anxious when students would ask about why certain topics or structures worked the way they do, but she said this has gone away with time and practice. For Michelle, that anxiety has not gone away. She said she can feel anxious when standing at the board in front of students, "even if I'm prepared or over prepared, I get that anxious feeling… I think that comes from the fact that I really do strive to let the students create discourse and conversation." She went on to explain that it was letting go of the control in a mathematical space, where there are so many different solution strategies, that made her anxious. "It's not just black and white, like everybody thinks." This ambiguity, mixed with having to make judgment calls on whether or not a specific strategy will always work, still cause her to feel anxious when in front of students.

Math Anxiety with New or Unknown Mathematics

Two of the teachers, Georgia and Autumn, emphasized moments when their math anxiety manifests as a fear of the unknown. Material they are unfamiliar with (as a teacher or student), in topics ranging from geometry to statistics to calculus and beyond, can cause them to feel anxious. Specifically, Georgia said she was most anxious when "performing math [she] doesn't know yet," and Autumn explained that she was most anxious when she had to tackle a problem with which she was unfamiliar or one that required her to combine skills and content areas in new ways. Similarly, any topic that requires her to memorize things can cause her anxiety as she struggles with memorization. "I like math because I am a problem solver. I'm not a good memorizer." It's the problem solving aspect of mathematics that she likes and is largely why she decided to be a math teacher. In general, though, the teachers said they feel least anxious with math they have taught previously, since they have had time to get used to it and figure out the ins and outs of the material.

Conclusion

While there has been a great deal of research in math anxiety throughout the years, only recently have researchers turned their attentions to math anxiety in middle and high school math teachers. This study examined how math anxiety manifests in 11 teachers of middle and high school mathematics and found that there were three primary manifestations: (1) in particular subjects; (2) in front of others; and (3) in new or unknown mathematics. These findings indicate a very real presence of math anxiety in secondary teachers and suggest that additional research is needed to further explore this phenomenon. Are there other ways in which math anxiety can manifest for secondary teachers? What effects, if any, does math anxiety have on math teachers' instructional strategies or pedagogical beliefs and attitudes? What impact does a secondary teachers' math anxiety have on their students' learning? Additionally, what supports would help these teachers overcome their math anxiety? These are all questions that should be addressed by future research.

COMPARING PRE-SERVICE ELEMENTARY TEACHER'S BELIEFS ABOUT OPERATIONS WITH THEIR FACILITY FOR SOLVING WORD PROBLEMS

Bryan J. Moseley Ph.D
Chaminade University of Honolulu
bryan.moseley@chaminade.edu

Keywords: Teacher Beliefs; Teacher Knowledge

Research has shown that typical undergraduates have difficulty solving compare word problems (Heagarty, Mayer, & Green, 1992; Haegarty, Mayer, & Green, 1995) in which a central term such as "more" is indicated but the problem is most easily solved with its inverse operation, such as subtraction. This study examined 1) if pre-service teachers also make these errors, 2) if there are differences in these errors before and after receiving instruction and 3) if these errors are related to beliefs preservice teachers hold about operations (addition, subtraction, multiplication and division) and 4) if these beliefs are influenced by their preservice training.

Method

Ten participants (one male and nine female) were given pre and post instruction think aloud problem-solving interviews and 22 item surveys asking how much they agreed or disagreed with true and false statements about operations such as "if you the see the word 'more' then that means you should always use addition." The identical survey items were repeated pre and post while the interview problems were each given a different cover story to make them seem less familiar but retain the same mathematical relations. The interviews were retrospective think aloud interviews in which participants reasoned with problems ranging from start unknown, change unknown, result unknown or compare word problems and explained their reasoning upon completion (Van den Haak, de Jong, & Schellens, 2003).

Results

Results indicate that participants were successful both pre (93.75%) and post (85.25%) instruction solving the range of word problems but scored slightly lower on the post after seeming to become more complacent when a compare problem came directly after a typical result unknown item.

Despite being able to solve these problems, survey data indicated that pre and post data demonstrated distributions of faulty beliefs about operations overall and keywords more specifically at the posttest. Qualitative comparison of the pre-and post-survey data suggests that pre-service teachers still hold patterns of misconceptions about operations that are influenced by instruction to shift but remain part of their mathematical knowledge. In many cases increased support for true statements would be offset by greater support for false ones and vice versa.

Discussion/Conclusion

Results indicate that although pre-service teachers can successfully manipulate word problems, they frequently still have misconceptions in their understandings for the underlying operations. These misconceptions may not simply increase or decrease but vary in their support for believing true or false statements about the operations making them complex and difficult to address.

AN EXAMINATION OF IN-SERVICE TEACHERS' RESPONSES TO A FRACTION DIVISION PROBLEM

İbrahim Burak Ölmez
MEF University
olmezi@mef.edu.tr

Michael Lawson
Kansas State University
mlawson1@ksu.edu

The purpose of this study was to investigate 236 U.S. in-service elementary and middle grades teachers' responses to a measurement fraction division problem including their strategies and types of errors. Using an inductive content analysis approach, one main result was that relatively high number of teachers (218 out of 236 teachers; 92.4%) responded to the problem correctly. A second main result was that a greater percentage of teachers had the quantitative meanings of measurement division, indicating flexibility with referent units, in comparison to those teachers and preservice teachers in past research. Regarding informal strategies, teachers relied on the common denominator and decimal strategies; however, strategies such as repeated subtraction, unit rate, or dividing numerators and denominators were not present. We discuss implications for improving teachers' knowledge of fraction division.

Keywords: Mathematical Representations; Rational Numbers; Teacher Knowledge

Part of teaching students mathematical concepts entails the teacher knowing and understanding the concepts themselves (National Council of Teachers of Mathematics [NCTM], 2000). However, U.S. teachers have performed poorly on content-based assessments in comparison to their international counterparts from top performing countries (e.g., Center for Research in Mathematics & Science Education, 2010). Further, the concept of fractions has been identified as one of the "most cognitively challenging" topics in school mathematics for both teachers and their students (Lamon, 2007, p. 629).

According to recent curriculum standards such as the Common Core State Standards for Mathematics (CCSS-M; National Governors Association Center for Best Practices & Council of Chief State School Officers, 2010), teachers and their students need to have both conceptual and procedural understandings of fractions. This includes knowing how to compute with fractions and explaining why computations work when fractions are situated within problem contexts. Much of the existing research on teachers' reasoning about fractions, however, has reported that in-service and pre-service teachers struggled with reasoning about fractions despite their facility with fraction computation based on memorized rules and procedures (Jansen & Hohensee, 2016; Ma, 1999). Additionally, in an extensive review of past research on preservice teachers' understanding of fractions by Olanoff and colleagues (2014), most preservice teachers were found to have a hard time reasoning about fractions in terms of quantities, indicating preservice teachers' limited conceptual understandings about fractions.

For improving teachers' conceptual understanding of fractions, studies show that understanding and reasoning about referent units is critical (Izsák, 2008; Izsák et al., 2019; Lee, 2017; Lee, Brown, & Orrill, 2011; Philipp & Hawthorne, 2015). As an example, Izsák et al. (2019) administered a novel fractions survey to a national sample of 990 U.S. in-service middle grades teachers and found that teachers' proficiency with referent units were linked to their performance with the remaining components of reasoning about fractions. On the other hand, Izsák and colleagues (2019) found that only 30% of the teachers in the national sample demonstrated proficiency in referent units. One key characteristic of referent units is flexibility with referent units, defined as "a teacher's ability to keep track of the unit to which a fraction refers … and to shift their relative understanding of the quantities as the referent unit changes" (Lee et al., 2011, p. 204). In the present study, we investigated U.S. teachers' flexibility with referent units in a fraction division situation, to better understand their strategies and types of errors.

Conceptual Framework

Starting in the 1980s, researchers attempted to identify what teachers need to know for examining mathematical knowledge of teachers. Based on this line of research, teachers need to have both content knowledge (CK) and knowledge unique to teaching, called as pedagogical content knowledge (PCK; Shulman, 1986). PCK includes understanding students' particular difficulties and facilities on a topic, identifying their potential misconceptions, and being familiar with particular representations that are helpful for students to learn specific topics. For example, PCK about fraction division implies knowing why the invert-and-multiply algorithm works, being aware of students' potential misconceptions about this algorithm (e.g., inverting the dividend instead of the divisor), and selecting specific visual models to uncover and support students' understanding (e.g., double number lines, area models). Ball and colleagues (2008) articulated and expanded the body of knowledge that Shulman (1986) introduced as *mathematical knowledge for teaching* (MKT).

By drawing from both frameworks, based on what teachers need to know for teaching mathematics to their students, we refer to this construct as *specialized content knowledge* that includes teachers' understanding of mathematics unique to teaching. In the context of the present study, the key characteristic of *specialized content knowledge* is flexibility with referent units. Because conceptual understanding is a main strand for proficiency in mathematics and the ability to represent problem situations is an important indicator of such understanding (Kilpatrick et al., 2001), using visual models such as number lines, length and area models are strongly recommended in fraction instruction to support students' learning (CCSS-M, 2010). On the other hand, most teachers use drawings for the purpose of illustrating final answers, instead of supporting early understanding (Izsák, 2008).

Referent units are units when numbers are embedded in problem situations, and they are necessary for conceptual understanding of fractions (Philipp & Hawthorne, 2015). For the problem "Julia's cat eats 1/3 cups of cat food each day. If she has 1/2 cups of cat food, for how many days can she feed her cat?", it is possible to obtain the answer by using the invert-and-multiply algorithm. On the other hand, a teacher who has conceptual understanding of fractions is expected to keep track of the referent unit and think accordingly as the referent unit changes (i.e., flexibility with referent units). In terms of the measurement meaning of division, the teacher may interpret this situation as how many groups of 1/3 are in 1/2. While the referent units for 1/2 and 1/3 are the same one whole, the referent unit for the quotient is 1/2 of the whole. Lee et al. (2011) documented the need for teachers to have flexibility with referent units to interpret drawings appropriately in a way that makes sense to them and their students. Thus, we assume that teachers' showing flexibility with referent units would support their students' conceptual understanding of fractions, especially in fraction multiplication and division problem situations.

Literature Review

Existing research on understanding of fraction multiplication and division have reported that teachers (e.g., Copur-Gencturk, 2021; Izsák, 2008; Izsák et al., 2019; Webel & DeLeeuw, 2016) and preservice teachers (e.g., Baek et al., 2017; Tobias, 2013) struggled with identifying the units appropriately. For example, Baek et al. (2017) examined 85 preservice elementary and middle grades teachers' understanding of referent units through their valid and invalid pictorial strategies to the Paycheck problem shown as follows:

> Emily receives her paycheck for the month. She spends 1/6 of it on food. She then spends 3/5 of what remains on her house payment. She spends 1/3 of what is then left for her other bills. Finally, she spends 1/4 of the remaining money for entertainment. This activity leaves her with $150, that she puts into savings. What was her original take-home pay? (p. 4)

Based on preservice teachers' responses to this problem, Baek and colleagues reported that most had trouble keeping track of the referent units in each step of the Paycheck problem. As an example for fraction division situations, Jansen and Hohensee (2016) examined how 17 preservice teachers' conceptions of partitive division with fractions were connected and flexible when solving a partitive division problem. As a result of interviews conducted with these preservice teachers, Jansen and Hohensee found that they demonstrated inflexible conceptions of partitive division with fractions. In a recent study, Copur-Gencturk (2021) examined 303 U.S. in-service elementary mathematics teachers' responses to a fraction division problem and found that only 14% of the teachers used the referent units correctly.

In addition to those difficulties, several studies have documented that in-service and preservice teachers had trouble showing flexibility with referent units in fraction multiplication and division situations (e.g., Baek et al., 2017; Copur-Gencturk & Olmez, 2022; Izsák, 2008; Lee, 2017; Lee et al., 2011; Webel & DeLeeuw, 2016). In one such study, Son and Lee (2016) analyzed 60 preservice primary and middle grades teachers' written responses to a fraction multiplication problem and found that while 40% were able to identify and draw the problem correctly, only 30% of preservice teachers treated the underlying concept of fractions as "finding portions of portions", an indication of flexibility with referent units, and others applied a standard algorithm without considering referent units. In another study, Lee and colleagues (2011) interviewed 12 in-service middle grades teachers and analyzed their responses to eight multiple-choice items that required using drawings. Lee and colleagues reported that teachers relied on referent units correctly in only 25% of the problems, indicating teachers' difficulty of making the referent units explicit. Specifically, in one item, Lee and colleagues asked teachers to identify the number line that shows 1/5 x 1/4 (Figure 1). While Figure 1a demonstrates 1/4 – 1/5 = 1/20 with each number's referring to the same referent unit, which was one whole, Figure 1b is the correct number line representing 1/5 x 1/4, where the referent unit for 1/5 is the 1/4 of the whole and the referent unit for 1/4 is the whole. Lee and colleagues reported that only four of the 12 teachers were able to identify the referent units correctly in this problem.

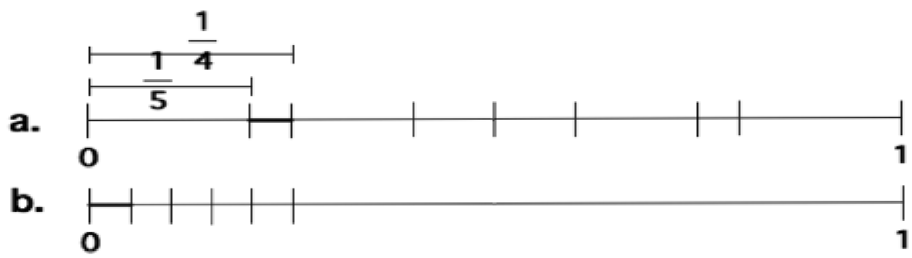

Figure 1: a) Number line for 1/4 – 1/5; b) Number line for 1/5 x 1/4 = 1/20 (Lee et al. 2011, p. 209)

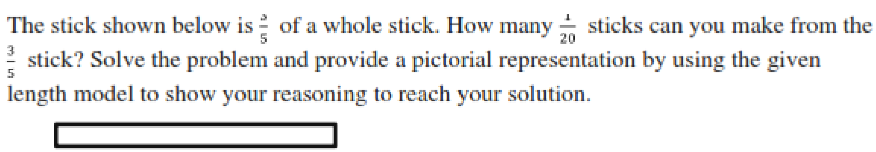
In a recent study, Lee (2017) examined 111 U.S. preservice elementary teachers' written solutions to the stick problem using a length model in Figure 2. Lee found that while 52 preservice teachers (47%) gave a correct response to this problem, only 13 of those 52 preservice teachers (11.7% of the sample) reasoned through drawings, indicating flexibility with referent units. Eight preservice teachers relied on informal strategies of common denominator (or making equivalent fractions) and decimal strategies (Son & Crespo, 2009), whereas the remaining 31 preservice teachers gave a correct response using the invert and multiply strategy.



The stick shown below is $\frac{3}{5}$ of a whole stick. How many $\frac{1}{20}$ sticks can you make from the $\frac{3}{5}$ stick? Solve the problem and provide a pictorial representation by using the given length model to show your reasoning to reach your solution.

Figure 2: Stick problem (Lee, 2017, p. 335)

By building off the work of Lee (2017), the present study investigated in-service teachers' flexibility with referent units in the Stick problem and has two major contributions to the field. First, most studies that examined in-service and preservice teachers' flexibility with referent units were based on fraction multiplication situations rather than fraction division situations (e.g., Baek et al., 2017; Webel & DeLeeuw, 2016). Second, most studies examining in-service teachers' flexibility with referent units were conducted with either a small number of teachers (e.g., Izsák, 2008; Lee et al., 2011) or used an area model (e.g., Copur-Gencturk & Olmez, 2022). Given that Lee's (2017) study focused on preservice teachers who were taking the same methods course at the same institution, our study relied on 236 U.S. in-service elementary and middle grades teachers in the U.S with a wide range of backgrounds, giving us the opportunity to contribute a broader description of in-service teachers in terms of their strategies and types of errors.

The research questions guiding our study were as follows:

1. To what extent do teachers solve a measurement fraction division problem correctly?
2. What strategies and types of errors do teachers demonstrate in solving a measurement fraction division problem?

Methods

Participants

The sample of this study consisted of 236 in-service elementary and middle grades mathematics teachers in Grades 1–8 (i.e., children ages 6 to 14) from 48 states in the U.S. We collected data during Spring and Summer 2020 using an educational research company that provided contact information of teachers and partner professional development organizations. Teachers received an invitation email with an online screening survey that started with general questions about the teacher's educational background and teachers who were currently teaching mathematics in grades 1-8 were eligible to participate. In addition to providing information about their educational background, teachers answered the Stick problem by uploading their responses including drawings and descriptions. Participants were 80.5% female and 72% were White. The participants also had an average of 9.2 years of mathematics teaching experience, with a standard deviation of 8.04 years.

Fraction Division Problem and Coding of Teachers' Responses

We used the Stick problem to capture teachers' flexibility with referent units (see Figure 2). The stick problem was a measurement fraction division problem asking teachers to come up with a solution and a drawing that represents how they reached the solution. We coded teachers' responses to the Stick problem independently by following the categories in Lee's (2017) study and our agreement was over 90%. We discussed any disagreements and resolved them.

Specifically, based on Lee's (2017) coding scheme, we classified teachers' correct responses into three categories: (1) *computing based on algorithms without quantitative reasoning*, (2) *reasoning through computations not tied explicitly to quantities*, and (3) *reasoning with quantities*. For the category of *computing based on algorithms without quantitative reasoning*, teachers' solution was computationally correct, but did not include any reasoning about quantities. Teachers in this category used either a formal strategy (invert and multiply strategy) or cross-multiplication but indicated no flexibility with referent units. They also might have not produced any drawing, their drawings might have been incorrect, or their drawings might have only shown the final answer. For the category of *reasoning through computations not tied explicitly to quantities*, teachers' solution was based on computations not tied explicitly to quantities. Teachers in this category used an informal strategy (common denominator strategy; repeated subtraction strategy; decimal strategy; unit rate strategy; and strategy of dividing numerators and denominators; Son & Crespo, 2009), but indicated no flexibility with referent units. They also might have not produced any drawing, their drawings might have been incorrect, or their drawings might have only shown the final answer. For the category of *reasoning with quantities*, teachers' solution was based on reasoning with quantities. As opposed to previous categories, teachers in this category focused on drawings before using formal or informal strategies, identified referent units, and demonstrated flexibility with referent units. Their drawings also indicated appropriate use of mental operations such as partitioning, iterating, and disembedding. Specifically, teachers obtained three parts through partitioning, added two more fifths to make a whole stick (i.e., the referent unit), then obtained 20 pieces from the whole stick through partitioning and counted the number of twentieths corresponding to the 3/5 stick.

Regarding incorrect responses, based on Isiksal and Cakiroglu's (2011) coding scheme, we classified their incorrect responses into five categories: (1) *algorithmically based mistakes*, (2) *intuitively based mistakes*, (3) *mistakes based on formal knowledge of fraction operations*, (4) *misunderstanding of the symbolism of a fraction*, and (5) *misunderstanding of the problems*. In a fraction division operation, *algorithmically based mistakes* included misapplication of basic operational rules such as inverting the first term instead of the second term (e.g., $\frac{7}{8} \div \frac{1}{3} = \frac{8}{7} \bullet \frac{1}{3}$). *Intuitively based mistakes* consisted of inappropriate application of the properties of whole number operations to fractions such as thinking that one could get a smaller number when dividing 7/8 by 1/3 because dividing a whole number by another whole number results in a smaller number. *Mistakes based on formal knowledge of fraction operations* were based on lack of knowledge about the properties of fraction operations such as thinking that a given problem was a fraction multiplication problem ($\frac{7}{8} \bullet \frac{1}{3}$) instead of a fraction division problem ($\frac{7}{8} \div \frac{1}{3}$). *Misunderstanding the symbolism of a fraction* was based on limited understanding of the notation of fractions such as considering 7 as denominator and 8 as numerator for 7/8. Lastly, *misunderstanding the problem* results from limited understanding of the problem due to lack of mathematical knowledge or language.

Data Analysis

We used an inductive content analysis approach for analyzing teacher responses to the Stick problem (Grbich, 2007). First, we created an Excel spreadsheet of the raw data of teachers' responses, including images and descriptions. Then, we made initial coding of a subsample of the data to ensure reliability in our analysis and finalized coding schemes with examples. We then identified each response as correct or incorrect and coded all data based on the finalized coding schemes. This process was done for all data individually and we met to discuss discrepancies in coding. Our coding scheme allowed us to examine how teachers solved the problem and we report percentages of teachers who demonstrated flexibility with referent units and/or used certain strategies (formal and informal) for the correct solutions, along with certain errors for the incorrect solutions.

Results

Based on teachers' responses to the Stick problem, while relatively high number of teachers (218 out of 236 teachers; 92.4%) provided correct solutions, 18 teachers (7.6%) provided incorrect solutions. Regarding the correct solutions of the 218 teachers, 93 teachers (39.4%) demonstrated reasoning with quantities through drawing (i.e., flexibility with referent units); 106 teachers (44.9%) showed reasoning through computations, although they were not tied explicitly to quantities; and 19 teachers (8.1%) showed reasoning based only on computations.

The 93 teachers who showed reasoning with quantities (i.e., flexibility with referent units) focused on the drawing before computing any formal or informal strategy, obtained three parts through partitioning, added two more parts to make a whole stick, obtained 20 pieces through partitioning each part into 4 pieces (totally 20 pieces), and counted the number of pieces that align with the 3/5 stick (Figure 3).

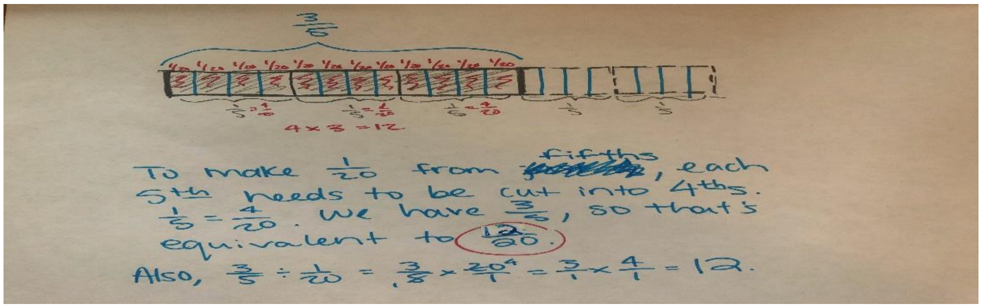


Figure 3: Example of teacher solution based on reasoning with quantities

The 106 teachers who showed reasoning through computations not tied explicitly to quantities used informal strategies for solving the Stick problem (Figure 4). In particular, while almost all of those teachers (103 teachers) used the common denominator strategy, by making equivalent fractions between 3/5 and 1/20, the remaining three teachers relied on decimal strategy by performing the division operation as a result of converting the given fractions into decimals. On the other hand, the strategies of repeated subtraction, unit rate, and dividing numerators and denominators were not present.

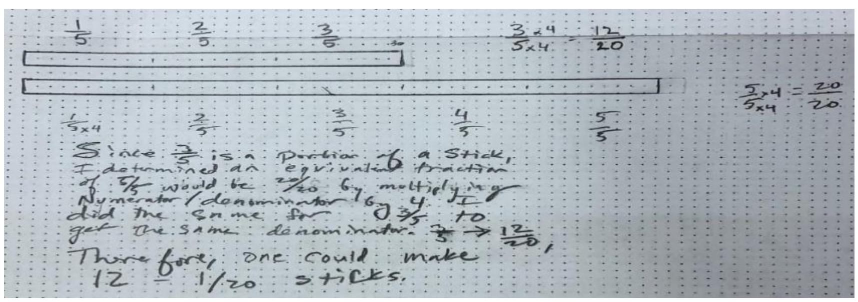

Figure 4: Example of teacher solution based on the common denominator strategy

The 19 teachers who showed reasoning based only on computations, 18 of them relied on the invert and multiply strategy and converted the fraction division expression into multiplication and only one teacher used the cross-multiplication by multiplying the numbers across each side of the equation (Figure 5).

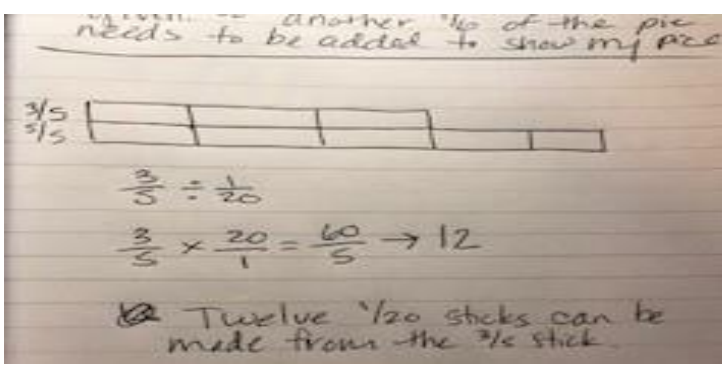

Figure 5: Example of teacher solution based on the invert and multiply strategy

Regarding the incorrect solutions of the 18 teachers, 11 teachers showed *misunderstanding of the problems*, indicating limited understanding of the problem due to lack of mathematical knowledge or language. These teachers interpreted 1/5 of the given stick as “20 pieces” and stated that the answer is “60 1/20 pieces” or partitioned 1/5 of the given stick into 5 pieces instead of 4 pieces. Three teachers showed *mistakes based on formal knowledge of fraction operations*, indicating a lack of knowledge about the properties of fraction operations. These teachers appeared to consider the Stick problem as a fraction multiplication problem by multiplying 3/5 by 1/20 instead of fraction division problem. One teacher showed *misunderstanding the symbolism of a fraction* by multiplying the numerator and denominator with different numbers to make an equivalent fraction. Three teachers made incomplete drawings and wrote that they have no idea about how to solve the problem. Lastly, none of the teachers made *algorithmically based mistakes* and *intuitively based mistakes*.

Discussion

The purpose of the present study was to examine U.S. in-service elementary and middle grades teachers’ responses to a measurement fraction division problem using a length model including their strategies and types of errors. One main result was that a relatively high number of teachers responded to the problem correctly. While only 47% of the preservice teachers (52 out of 111 preservice teachers) provided correct solutions for the Stick problem in Lee’s (2017) study, the percentage of the in-service teachers with correct solutions was 92.4% (218 out of 236 teachers) in our study. A second main result of the present study was that a greater percentage of teachers had the quantitative meanings of measurement division, indicating flexibility with referent units, in comparison to those teachers and preservice teachers in past research (e.g., Authors, 2022; Baek et al., 2017; Copur-Gencturk, 2021; Lee, 2017; Lee et al., 2011; Son & Lee, 2016). While only 11.7% of the preservice teachers (13 out of 111 preservice teachers) in Lee’s (2017) study showed flexibility with referent units through reasoning with quantities, the percentage of the in-service teachers who demonstrated flexibility with referent units was 39.4% (93 out of 236 teachers).

Furthermore, our results reveal that in-service teachers in our study outperformed preservice teachers in Lee’s (2017) study in terms of the use of strategies and types of errors. In particular, while 44.9% of the in-service teachers (106 out of 236 teachers) in our study showed reasoning through computations although they were not tied explicitly to quantities, the percentage of the preservice teachers who reasoned through computations not tied explicitly to quantities in Lee’s (2017) study was only 7.2% (8 out of 111 preservice teachers). Those in-service teachers relied on common denominator and decimal strategies as informal strategies, but not on repeated subtraction, unit rate, and dividing numerators and denominators. This result suggests that like preservice teachers, in-service teachers in the U.S. may have insufficient experience of providing alternative strategies for solving fraction division problems. Thus, professional development programs should emphasize teachers using a variety of informal strategies in classroom instruction.

In terms of types of errors, only 7.6% of the in-service teachers (18 out of 236 teachers) in our study responded to the problem incorrectly. Most of those teachers’ errors were based on mistakes resulting from misunderstanding of the problem based on Isiksal and Cakiroglu's (2011) framework. As opposed to our study, 53% of the preservice teachers (59 out of 111 preservice teachers) in Lee's (2017) study responded to the problem incorrectly and most of their errors were related to mistakes resulting from *misunderstanding of the problem*, *mistakes based on formal knowledge of fraction operations*, and *algorithmically based mistakes*.

Despite a better positive picture in terms of a greater percentage of in-service teachers who demonstrated flexibility with referent units compared to prior studies, teachers should be supported in teacher education and professional development programs to improve their flexibility with referent units. These supports include awareness of different visual models, such as length, area, and set, emphasis on making drawings in classroom settings, and encouragement for identifying the referent units in the drawings. Future studies should focus on examining in-service teachers' flexibility with referent units in partitive fraction division or fraction multiplication problem situations.

In this paper, we present Epistemic Network Analysis of 32 teachers knowledge resources used to solve two different tasks. Using Drijver's (2018) framework about ways technology can be used for learning, we argue that using technology supports teachers to activate more knowledge resources and to use them in connected ways. We propose that this may offer insight into the design of professional development aimed at supporting teachers in the development of connected knowledge.

Keywords: Technology, Teacher knowledge, Rational Numbers and Proportional Reasoning

Purpose

In this paper, we address two research questions:

- What knowledge resources do teachers use to solve two proportional reasoning tasks?
- Are those knowledge resources connected in ways that seems to support Skills Practice, Conceptual Understanding, or some combination of both?

We argue that technology provides a different experience than static tasks for teachers as they engage with mathematics, thus allows a different kind of thinking. Further, we suggest that using technology to think about mathematics opens opportunities for teachers to develop more connected understandings of the mathematics they teach. We end with a discussion of the implications of this work.

Perspectives

We draw from two perspectives to make our case for the value of technology in supporting teacher conceptual understanding. First, we use a Knowledge in Pieces (KiP) lens to contemplate cognition and how it can be conceived of in teacher learning. Then, we draw from Drijvers' work on technology in mathematics education to situate the ways in which we use technology.

Knowledge in Pieces

Knowledge in pieces is a theory of conceptual change that considers knowledge to be comprised of fine-grained resources (diSessa, 1988, 2018; diSessa, et al., 2016). In KiP, learning can be viewed as creating new knowledge resources, refining existing knowledge resources, and/or creating connections between and among knowledge resources. For this paper, we are particularly interested in the connections participating teachers were making between their knowledge resources.

To make knowledge resources visible and to focus on interactions between knowledge resources, we rely on Epistemic Network Analysis (ENA; Shaffer et al., 2009). ENA is a quantitative ethnography (Shaffer, 2017) method that, in our case, allows knowledge resources to act as nodes and for lines between nodes to indicate the relative frequency of the co-occurrence of the knowledge resources. A co-occurrence, for us, is any instance in which more than one knowledge resource is used to solve a single task. We consider co-occurrences to be proxies for connections between knowledge resources.

Technology in Mathematics Education

In their conceptualization of the uses of technology in mathematics education, Drijvers and his colleagues (e.g., Drijvers, 2015, 2018) have developed a heuristic for technology use in mathematics education. They posit that the ways in which we think about technology in mathematics education should be driven by the function of the technology rather than the form of the technology. Thus, they conceive of technology as either helping us Do math or Learn math. And, in the case of technology that helps us Learn math, there is technology that helps with Skills Practice and technology that helps with Conceptual Development. It is this kind of technology that is the focus of this paper. By using KiP, we are able to think about knowledge as a series of fine-grained understandings that can be grouped in myriad ways. By using the Drijvers framework, we have a language for characterizing the ways in which the knowledge resources are interacting.

Methods

The data reported here comes from a pair of interviews conducted with a convenience sample 32 middle grades teachers from four states. The first interview was a think aloud protocol in which the participants responded to a set of tasks using a LiveScribe pen to capture and coordinate their voices and inscriptions. The second interview was a face-to-face interview with similar mathematics tasks, however some of the tasks used dynamic sketches on an iPad. The live interviews were recorded with two video cameras: one focused on the participants' faces and one on anything they wrote or at which they pointed.

For this analysis, we focused on two tasks: the Santa Task (Figure 2) and the Bears Task (Figure 3). For the Santa Task, which was based on a task from de Bock, Van Dooren, Janssens, & Verschaffel, 2002), we provided scaffolded prompts to support teachers in thinking about the situation. These included:

- Ms. Yarbrough's class had two favorite answers. About 40% of her class chose 18 ml and about 40% chose 54 ml. What might the students who were wrong been thinking about? Is that something you see commonly with your own students?
- One of Ms. Yarbrough's students drew rectangles around the images. Do you think this is a helpful strategy for a student? Why or why not?

For the Bears Task, we asked the teachers:

- Describe what is happening as you drag the slider. How is the image changing? When we started, the two figures were similar. Where you have ended, are they still similar?
- How would you characterize the growth as you move the slider? Is there anything in the relationship of the bears to each other that stays the same? How would you describe how many times larger the new bear is than the original? How would you describe the scale factor of the new bear to the original?

- What is the ratio of the bear's belly to the frame? Does that ratio stay the same as the bear change size?

These tasks were selected for this analysis because they engaged the teachers with similar mathematics, though Santa was done on paper and Bears was an interactive app.

Data were coded using an emergent coding scheme (Weiland et al, 2021) in which each code was a knowledge resource. We used ENA for the data analysis (Shaffer et al., 2009), which meant that each utterance was coded using a binary system (present/not present). In this case, an utterance was the answer to a single task. Once coding was done, the ENA webtool created the maps of participants' use of knowledge resources. For these maps (Figure 2a & b), the nodes indicate the knowledge resources being used by the participants. The size of the node is relative to its frequency in the dataset. The lines connecting knowledge resources indicate that those pairs of knowledge resources occurred together within an utterance. The thickness of the line indicates the relative frequency of the co-occurrence.

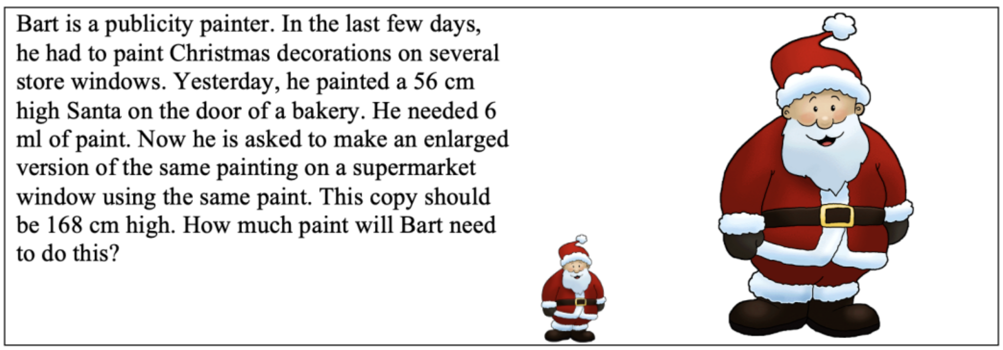

Figure 1. The Santa Task (based on de Bock, Van Dooren, Janssens, & Verschaffel, 2002)

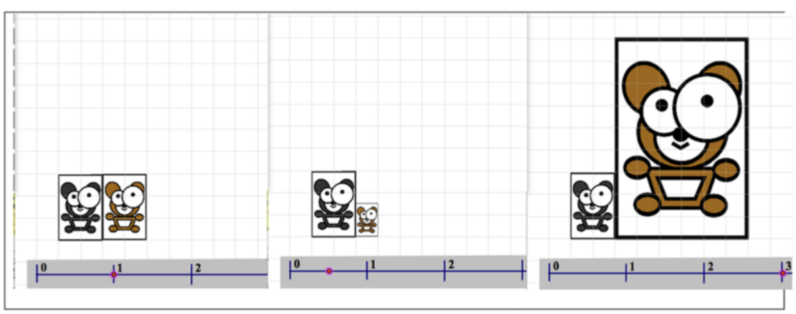

Figure 2. The Bears Task

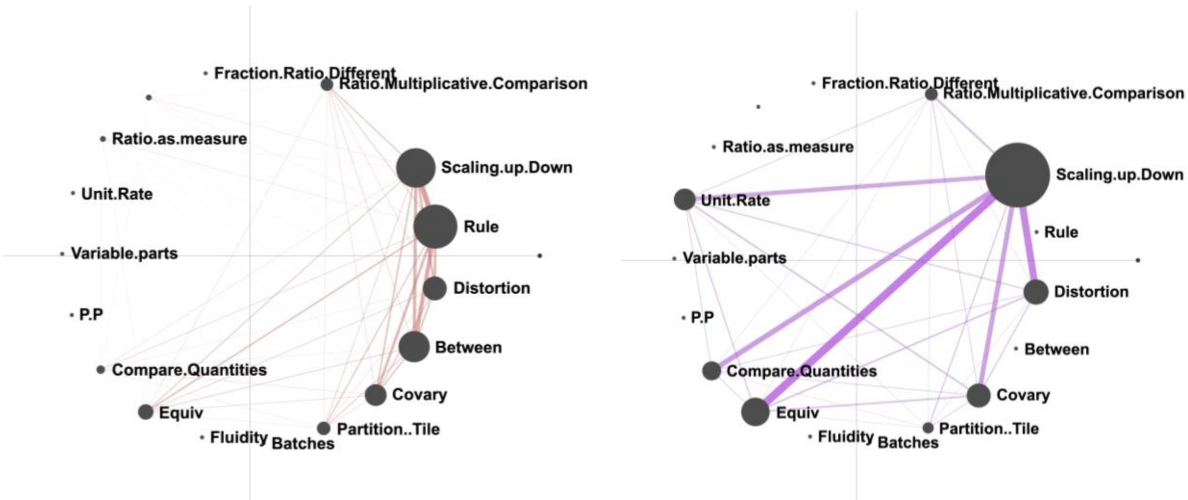
Results

As shown in the ENA graphs (Figure 3a & b), the teachers relied heavily on Rules (mostly cross multiplication) and Scaling Up and Down to solve the Santa Task. Because they jumped to these two procedures, most of the teachers missed that the relationship between height and amount of paint is not a proportional one. The proportional relationship is between the area of the big Santa and the area of the small Santa (for a full qualitative analysis of the answers given, see

Brown et al., 2020). There were few connections made between knowledge resources, meaning that teachers often went straight to an algorithm and did not invoke other proportional knowledge resources. Most interestingly, most of the resources they did use were focused on answer finding, which is more related to Skills Practice than Conceptual Understanding (Drijvers, 2018). We argue that the only structures they attended to in connected ways were Covariation (e.g., the numerator and denominator change together) and the Between Measure Space relationship (e.g., attending to the relationship of one quantity, such as height, to the other, such as width), both of which were used less than the two skills.



(a) (b)

Figure 3. ENA results for the static Santa Task (a) and dynamic Bears Task (b)

In contrast, on the Bears Task, these same teachers did not rely on Rules at all. Further, there is much more interaction between knowledge resources., overall. While we still see a reliance on procedures with most of these interactions, we do see more variety in approaches. This suggests that there is something about the dynamic representation that both cues more knowledge resources and promotes more interaction between those resources.

Discussion and Conclusions

Given that learning in the KiP framework can happen through development of new resources, refinement of existing resources, or making new connections between resources, we posit that using technology-based tasks is a way to engage teachers in learning. Further, we suggest that doing this may support the development of connections between knowledge resources, which is potentially useful for supporting teacher learning. Consistent with Drijvers (2018) framework, the technology-based task seemed to offer more opportunity for Conceptual Understanding than did the static task. To this end, we propose that developing professional development that is designed to take advantage of technology in ways that supports the development of conceptual understanding may be fruitful for support teachers in better connecting their already-existing mathematics knowledge resources.

The implications of this are pragmatic. Too often, professional development is focused on building new knowledge without regard to the knowledge teachers already have. Because they are adult learners, often with degrees beyond a bachelors, teachers need professional development that caters to them. As shown in Figure 3, the teachers in our sample all had knowledge resources important for understanding proportional relationships. However, they needed the Bears task to activate some of them and to activate more than one in an utterance.

SECONDARY PRE-SERVICE TEACHERS' MATHEMATICAL PROBLEM SOLVING KNOWLEDGE FOR TEACHING

Brooklynn R. Willett

Christine M. Phelps-Gregory
Central Michigan University
phelp1cm@cmich.edu

Keywords: Geometry and Spatial Reasoning, Mathematical Knowledge for Teaching, Preservice Teacher Education, Problem-Solving

There are urgent calls for teaching methods which foster students' problem solving in mathematics (NCTM, 2000; NGA, 2010). To do this, teachers and pre-service teachers (PTs) need the knowledge and skills to successfully teach for problem solving. This base of knowledge and skills is called *Mathematical Problem Solving Knowledge for Teaching* (MPSKT); that is, the knowledge needed to help students develop mathematical problem solving proficiency (Ball et al., 2008; Chapman, 2015). MPSKT consists of six subcomponents: knowledge of problem solving, problems, problem posing, students as problem solvers, and instructional practices, as well as affective factors and beliefs (Chapman, 2015). While some research has investigated the MPSKT of teachers and PTs (Chapman, 2016; 2017; Clivaz et al., 2023; Owens, 2023; Owens & Nolan, 2021a; 2021b; Piñiero et al., 2021), very little of this work has holistically examined the MPSKT of secondary PTs. This is an unfortunate limitation as secondary PTs are vital to our goal of fostering problem solving skills in all students.

Purpose, Methods, and Analysis

This poster presents details of a qualitative pilot study on secondary PTs' problem solving proficiency, MPSKT, and the relationships between them. PTs (n=4), who had recently completed a geometry methods course which focused on how to teach secondary geometry topics with student-centered approaches, took part in two interviews. The first was a task-based interview that assessed problem solving proficiency using think aloud protocols (Cowan, 2019). The second was a semi-structured interview examining each of the six subcomponents of MPSKT. Analysis focused on describing the problem solving proficiency and MPSKT of each PT as well as identifying any relationships that emerged between MPSKT and problem solving proficiency. A future study will build on this work with a larger sample.

Results and Implications

PTs' overall MPSKT was grounded in their personal experiences as students but lacked skills we would expect of experienced teachers. For example, when discussing their knowledge of beliefs and affective factors, PTs focused primarily on either the emotional needs of students or beliefs about the nature of mathematics, but never on both (as we would expect from experienced teachers). PTs typically held very little knowledge of problem posing. In addition, a complex interplay between PTs' problem solving proficiency and MPSKT emerged. PTs with weaker problem solving proficiency tended to demonstrate weaker MPSKT. However, higher problem solving proficiency did not necessarily predict comprehensive MPSKT in all six subcomponents, suggesting teacher educators may need to deliberately teach MPSKT. As we envision the future of mathematics education, we will need to better understand secondary PTs' MPSKT and our role, as teacher educators, in helping them further develop their knowledge and skills to ensure all students develop rich problem solving proficiency.

Keywords: Assessment, mathematical knowledge for teaching, Rational Numbers

In this poster, we discuss the development and validity argument for the Mathematical Knowledge for Teaching (MKT) of fractions measure (MKT-Fractions). Ball et al. (2005; 2008) defined MKT as including specialized content knowledge (SCK) and pedagogical content knowledge (PCK) for teaching mathematics. PCK includes knowledge of content and students (KCS) and knowledge of content and students (KCT). Whereas SCK involves understanding the different valid, and invalid, approaches to engaging in certain procedures or approaches, PCK involve understanding children's mathematical reasoning (KCS) and appropriate pedagogy to scaffold students' reasoning (KCT) (Ball et al., 2006; 2008).

We surveyed 103 undergraduate students from two Midwestern U.S. universities to evaluate an updated version of the MKT-Fractions measure (University A=49.5%; University B=50.5%). Prior versions of the measure included only KCS items, while this updated measure includes 18 multiple-choice items assessing: KCS (n=8), SCK (n=5), and KCT (n=5). Prior versions of the MKT-Fractions measure have collected validity evidence on test content, response processes, reliability and internal structure (Zolfaghari et al., 2021; 2022). In this paper, we used Rasch modeling to collect data on reliability and internal structure.

Rasch analysis began with a Principal Component Analysis (PCA), which provided support for unidimensionality across all KCS, KCT, and SCK items (λ=2.28, disattenuated correlation = 1.00). Item fit, another indicator of unidimensionality, suggested good model fit with an average mean square for item infit ($MNSQ$ =.99, Z=.00) and outfit ($MNSQ$=.98, Z=.00). The samples' model fit was also supported with person infit ($MNSQ$= 1.00, Z=.00) and outfit ($MNSQ$ = .98, Z=.00). Item and person reliability provided additional validity evidence. Item reliability was .96 with an item separation index of 5.09, indicating the measure's consistency in distinguishing between item difficulties. Person reliability was 0.64, with a person separation index of 1.33. Pragmatically, the statistics suggest participants can be categorized into two different levels (Boone et al., 2014). Analyses of prior versions of the MKT measure suggest the lower person reliability is primarily due to our sample being limited to undergraduate students, as in-service teachers typically score higher on PCK (Zolfaghari et al., 2021, 2024).

Examination of validity evidence for internal structure and reliability indicates that the MKT-Fractions measure is sufficient for evaluating teachers' mathematical knowledge for fractions. The results from this study show that the majority of PSTs demonstrated above-average knowledge in teaching fractions, as evidenced by the MKT-Fractions scores (M = .41, SD = .99), where 0.00 represents the average level of knowledge. This result is not surprising, given all of the participants had completed at least one mathematics methods coursework and grades 3-6 field experience. Both the mean scores and lower person reliability suggest a need for a more diverse sample, including experienced in-service teachers and more novice preservice teachers.

Maral Karimi
University of Central Florida
Maral.Karimi@ucf.edu

Farshid Safi
University of Central Florida
Farshid.Safi@ucf.edu

Mathematics educators universally agree that mathematical proofs stand as the core of mathematics, highlighting a significant consensus on their importance. Despite this agreement, research consistently shows that both students and teachers encounter substantial difficulties in teaching and learning proofs. These challenges underscore a critical gap in educational practices and comprehension. This study wants to bring the attention about the importance of studying the proof in standards and practices which directly affects teacher preparation programs.

Keywords: Reasoning and Proof, Standards, Teaching Practices.

There has been extensive research on mathematical proofs in school mathematics. Students are not only expected to learn but also to construct various types of proofs, including proof by contradiction, proof by induction, pictorial proofs, paragraph proofs, flowchart proofs, and two-column proofs. Despite the emphasis on its role and importance in school mathematics, research shows that no matter what grade they are in, students encounter difficulties when involved in proof-related activities (Weber, 2001; Knuth et al., 2002). This problem is universal and not limited to school students; even college-level mathematics major students struggle when working on proving mathematical statements (Zazkis, Weber & Mejia-Ramos, 2014). However, this doesn't mean students are incapable of building proofs. According to Lester (1975), students in all grades can understand and even construct proofs despite facing obstacles and difficulties.

According to Usiskin (1987), a root problem is how students are introduced to proof in school mathematics. It seems teachers are not adequately prepared, lacking exposure to proving tasks, which hinders their ability to teach proofs effectively and engage students in proof-related activities. A significant issue is the absence of explicit experiences to enhance content and pedagogical teaching knowledge (Abbaspour, 2022). It was for this reason that the researchers of this study tried to examine the standards and teaching practices to investigate if the expectations the mathematics education community has of students are consistent with the standards and practices defined for teachers to be prepared to help students learn mathematical proofs. For this purpose, this study analyzes the role of proof in NCTM's Principles and Standards for School Mathematics (2000) and Common Core State Standards for Mathematics (NCTM, 2010), Principles to Actions (NCTM, 2014), Catalyzing Change in High School Mathematics (NCTM, 2018), Standards for the Preparation of Secondary Mathematics Teachers (NCTM, 2020), and AMTE's Standards for Preparing Teachers of Mathematics (2017).

Standards and Teaching Practices

The Common Core State Standards for Mathematics mention proof primarily in high school geometry, without significant expansion. "Principles to Action" focus on reasoning and problem-solving but lack explicit proof instruction, missing guidance for teachers. "Catalyzing Change in

High School Mathematics" broadens proof application across disciplines, detailing the creation and validation of proofs. The "Standards for the Preparation of Secondary Mathematics Teachers" highlight the importance of reasoning and proof construction but lack detailed preparation standards, suggesting Linear Algebra for proof engagement. The "Standards for Preparing Teachers of Mathematics" emphasize mathematical arguments and reasoning, offering general course guidance but insufficient preparation standards for effective proof teaching.

Conclusion

It can be seen that the Standards go in depth with details when it comes to expectations for students regarding learning proofs. However, when reviewing the standards and preparations for teachers to teach proofs efficiently, there is a huge gap, which seems to be one of the underlying problems behind students' difficulties and teachers' obstacles in teaching and learning proofs. This study aims to highlight the importance of studying proof standards and practices, which directly affect teacher preparation programs.

ANALYSIS OF A GRADE 4 STUDENT'S MATHEMATICAL REASONING IN A MATHEMATICAL LOGIC TASK

Nathalie Bisaillon	Sarah Dufour	Doris Jeannotte
Université de Montréal	Université de Montréal	UQAM
nathalie.bisaillon@umontreal.ca	sarah.dufour.3@umontreal.ca	jeannotte.doris@uqam.ca

Recent studies underscore the importance of teaching logic in elementary education, stressing its crucial link to reasoning. This study aims to analyze students' mathematical activity during logic tasks, employing Toulmin's (2003) theoretical framework to explore how students adapt to the specific rules of a logic game. The results provide diverse problem-solving strategies used by students, alongside the challenges they faced while reasoning. The discussion encompasses the challenges and the potential of such tasks to develop mathematical reasoning skills and the necessity of nurturing this skill in educational practices.

Keywords: Reasoning and proof, elementary school education, problem-solving

Introduction

In this project, we experiment a sequence of mathematical logic tasks, progressively integrating language and mathematical concepts, with two groups of 4th graders in primary school to explore how logic tasks could foster the development of mathematical reasoning. This angle is interesting given that mathematical reasoning lies at the heart of the mathematical activity (Mason et al., 2010). Moreover, its significance is reflected in various curriculums and institutional documentation (e.g., Common Core State Standards Initiative, 2024), highlighting its pivotal role in shaping educational practices. Yet recent and increasingly convergent research underscores the importance of teaching logic in elementary school: "logical thinking is not a natural talent [...], but a skill that can be trained, like say muscles are trained at the gym" (Adkhamjonovna, 2022, p. 915). The aim of this study is to describe and analyze the mathematical reasoning of elementary school students as they solve a logic game task.

Theoretical framework

The concept of mathematical reasoning is often used intuitively, without definition or characterization (Yackel & Hanna, 2003). Given the context of logic games established in this research, Toulmin's (2003) model helps us to describe the potential of mathematical reasoning for this type of task. Indeed, this model sheds light on the argumentative, logical and persuasive aspects of mathematical reasoning, offering a deeper understanding of the cognitive process involved. It emphasizes the importance of context and therefore can be used to understand how students adapt their reasoning to the game specific rules. The model enables the highlighting of reasoning steps and their analysis, facilitating the study of what Knipping (2003) calls chain of reasoning. Toulmin's model emphasizes three main elements: data, warrant, and claim. Starting from data and an often implicit warrant, it is possible to formulate a claim. Substantiating a claim requires offering evidence which constitutes the data. It is also necessary to convince oneself, that is to accept as valid or plausible the connection between the data and the claim. This is the role of the warrant, it supports the inference from the data to the claim (Toulmin 2003).

Three other elements may appear in a reasoning step: the backing, the qualifier and the rebuttal. The backing supports the warrant and consists of elements that have a certain consensus in a given community, upon which one can rely. The qualifier refers to the epistemic value of the claim, determining its truth value or plausibility. One way to decide about the status of this epistemic value is to use a rebuttal. A rebuttal is a statement that, if proven true, leads to the rebuttal of the claim, admitting it to be false.

Method

To achieve our goal, we selected one logic task and undertook a descriptive case study (Yin, 2018). The logic task examined in this paper was part of a larger project conducted over an entire year in two 4th grade classes (9- and 10-year-olds). Researchers visited the classrooms once or twice a month to introduce new types of tasks, which were then piloted by the teachers in the following weeks. The researchers interviewed six students to study their mathematical activity in greater depth. All activities were filmed. We chose this task firstly because it was used during the initial interview. Secondly, the task is a strictly visual mathematical logic game[2], minimizing the influence of reading skills and prior mathematical knowledge. Thirdly, the order in which the clues are presented does not strictly lead to a deductive chain, allowing for different types of claims and various reasoning steps.

The objective of this logic puzzle is to place all nine geometric pieces within a 3x3 grid, following the provided visual clues (See Figure 1). Each clue offers information related to the placement of pieces. While several strategies are possible, we opted to encourage students to interpret the clues sequentially, noting their resolutions as they progress (by temporarily positioning pieces in the grid).

Figure 1: Logic puzzle used in this research (Lyons and Sabinin, 2015)

A qualitative analysis helps us examine the meaning of the material collected through Toulmin's (2003) framework. Firstly, we looked at the task in terms of its potential to foster students' mathematical reasoning. Second, we construct an analysis grid for the task, highlighting the elements of potential reasoning steps in this type of task for each of the puzzle's clues. Third, we studied the nature of the task according to two criteria: explicit/implicit and positive/negative information. We determined a list of possible inferred claims that can come from the data and warrant; and analyzed their qualifier (or epistemic value). Secondly, we studied the mathematical activity of the six students who solved this task using the same framework.

[2] https://apps.defimath.ca/gym-logique/

Results

Task Analysis Results

Based on Toulmin's (2003) model, we can say that it is the combination of multiple clues that provides enough information to generate the data and warrants necessary to infer all the claims to solve the puzzle. Furthermore, the mathematical reasoning that takes place relies on some shared ground (backing), i.e. the common knowledge (the name of the geometric piece, the color, the position) and to the "graphic" elements established by the task itself (the grid is 3x3, the waving pattern indicating the place of a piece (e.g., Clue 1), the X indicating the impossibility of placing a piece).To carry out our analysis, we processed the indices one after the other, since it was the strategy that has been valued in class. We present in table 1 a summary of the analysis of the first four clues.

Table 1: Analysis of the first four clues

Clues	Data	Inferred claims (qualifier)	Chains of reasoning
	*Any form* Blue Top left Corner	Blue circle is top left (P) Blue square is top left (P) Blue triangle is top left (P) One blue piece is top left (T)	
	Circle Red *Bottom line, center or right corner*	Red circle is center of bottom line (P) Red circle is bottom right corner (P) Red circle is bottom center or right (T)	
	Square Blue *Center or Bottom line, 2nd or 3rd column*	Blue square is center (P) Blue square is center of bottom line (P) Blue square is center 3rd column (P) Blue square is bottom right corner (P) Blue square is in one of the four right bottom places (T)	With Clue 1: Blue square is top left (F)
	Triangle *Any color* NOT 1st nor 2nd column. *3rd column*	Red triangle is top right corner (P) Red triangle is center 3rd column (P) Red triangle is bottom right corner (P) Blue triangle is top right corner (P) Etc.	With Clue 1: Blue triangle is top left (F) Blue circle is top left (T) With Clue 2: Red circle is bottom right corner (F) With Clue 3: Blue square is in the right column (F) Blue square is center (T)

		There is no circle nor square in the last column (T)	

Legend: italic (multiple possibilities), blue (implicit data), red (negative data), P (plausible), F (false), T (true)

The first thing we can notice from table 1 is that Clues 1 and 2 are independent and do not provide enough information to place a piece. We must process all clues up to the fourth one before being able to place a first piece with certainty, i.e. to infer a true positive statement about one singular piece. However, this true statement was first inferred as plausible while processing Clue 1. To validate that claim, Clue 4 must be combined with Clue 1 and Clue 3. Clue 4 also refutes inferred plausible claims from Clues 1, 2 and 3. Those refutations will be useful later to eliminate possibilities and solve the puzzle. Moreover, Clue 4 is the first one with negative information. For all those reasons, we can hypothesize that Clue 4 could be an obstacle to the resolution of this puzzle.

Analysis of students' mathematical activity

We analyzed the mathematical activity of the students by comparing their traces and discourses for each clue. Two strategies were observed for Clue 1. Four students placed all blue pieces in the top-left square, resulting in three plausible claims. Two students opted to place only the blue circle, inferring the claim "the blue circle goes in the top-left corner" and considering it true. Presumably, they initially scanned all the clues before processing them one by one. For Clue 2, all students positioned the red circle between the two bottom-right squares (See Figure 2). For Clue 3, all students place the blue square at the intersection of the four bottom-right squares (See Figure 2). Regarding Clue 4, students place a pile of triangles either at the top of the right-hand column or next to it (See Figure 2), except for E6, who stated, "we don't know yet." E6 seemed unable to infer that the triangles must be in the last column from the data and warrant for this clue.

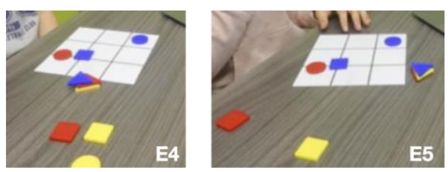

Figure 2: Traces of students E4 and E5 after processing Clues 1 to 4.

Our previous analysis of the task suggests that Clue 4 could lead to a chain of reasoning; it changes the epistemic value of the claims made in Clues 1, 2 and 3 from probable to true. We now know the place of the red circle and, consequently, the place of the blue square. However, none of the students relocate these pieces at first, thereby failing to alter the epistemic value of the previously inferred claims. This analysis confirms that Clue 4 certainly represents a turning point in this puzzle. Contrary to Clue 1, they cannot manage the consequences of this clue by relying solely on their traces. Indeed, for Clue 4, they seem to remain in a state of uncertainty. They are unable to make a definitive placement for the red circle and the blue square. Certainly, this chain of reasoning represents complex reasoning. It requires the student to manage several elements that can change status (e.g., the claim becomes a refutation for a previous reasoning step).

Discussion and Conclusion

This project aims to describe the mathematical reasoning of primary school students through their engagement in logic tasks. In both analysis (the task and the students' mathematical reasoning), Clue 4 appeared as an obstacle. Firstly, Clue 4 provokes a particularly complex chain of reasoning. The claims inferred from this clue can be used to validate or refute previously established claims with plausible status. This is reminiscent of Knipping's (2008) proposal around local and global arguments. She suggests that, starting from local arguments, it is possible to restructure the whole reasoning. That's what is at stake here. The processing of Clue 4 is local but enables a restructuring of previous reasoning steps. This type of reasoning chain is complex and represents advanced reasoning. The student participants seem not to be able to change the epistemic value of previously established claims, keeping their already produced traces. The change in epistemic value is based on an argument that must be accepted as true by the student. They must be convinced. It is the argumentative aspect, among others, that students must be able to use when constructing proofs, for example. However, even in a highly controlled environment, students have difficulty relying on these established facts as true. This environment is controlled, e.i. their choices are restricted by the task. A very narrow set of claims is possible, and the backing is rather clear and circumscribed. This is different from an open-ended task, where students rely on a broader set of mathematical facts to formulate a conjecture with no alternative if it turns out to be false. Our analysis also highlights the challenge of managing these traces. Students must decide what information to collect, how to collect it, and how to use these traces to guide their reasoning.

THE MODELS OF TEACHING AND LEARNING MATHEMATICAL PROVING AND MATHEMATICAL PROOFS: A MULTIDISCIPLINARY PERSPECTIVE IN PK-20

Meveryn Chau
The College of William and Mary
ychua01@wm.edu

The models of teaching and learning mathematical proving and mathematical proofs are narrowly focused on the mathematics discipline. Scholars in mathematics education theorized the formal-embodied-symbolic triad as a basis of understanding teaching and learning mathematical proving and mathematical proofs. This paper, in contrast, adopts a multidisciplinary perspective of the teaching and learning of mathematical proving and mathematical proofs. By proposing a novel model of teaching and learning, this paper aims to improve the extant state of the teaching and learning mathematical proving and mathematical proofs in a PK-20 context.

Keywords: Proof; Reasoning; Modeling

Mathematical proving and mathematical proofs are the heart of mathematics; yet it is seldom the focus of students. Students in contrast view mathematics as discrete branches of mathematical knowledge that one usually picks up starting from Algebra 1 classes to Advanced Placement examinations (e.g., Calculus BC). From the teaching and learning perspective, the scholarly work on teaching and learning mathematical proving and mathematical proofs are bifurcated into teaching (by teachers) and learning (by students) perspectives. This thinking and way of doing things is outdated with the leveraging of generative artificial intelligence in learning mathematical proving and mathematical proofs.

Objectives

By adopting a practitioner-scholar perspective, this paper puts forth a novel theoretical framework of the teaching and learning of mathematical proving and mathematical proofs that incorporates insights from computer science, economics, epidemiology, mathematics, physics, psychology, and statistics. This model incorporates a diversity of approaches and emphasized the applications of mathematical proving and mathematical proofs beyond the discipline of mathematics.

Theoretical Framework

Discussion on the teaching and learning of mathematical proving and mathematical proofs tend to originate from the mathematics discipline (Stylianides et al., 2024; Tall et al., 2012). This paper goes beyond this narrow focus and examines mathematical proving and mathematical proofs from a multi-disciplinary perspective: computer science, economics, engineering, epidemiology, mathematics, physics, political science, psychology, and statistics (e.g., Brauer et al., 2019; Franklin, 1983; Gersting, 2007).

Coming from the perspective of mathematical thinking, Tall et al. (2012) adopts a learner-centered approach and posits that mathematical proving and mathematical proofs should be examined from three categories: formal, embodied and symbolic. Scholars in non-mathematics discipline tend to adopt an applied perspective by focusing on using mathematical proving and mathematical proofs to explain a real-life phenomenon. The theoretical framework is multi-level and its focus starts from fundamental forces from neuron level to humans, classrooms, schools, families, and to the large geographical areas (e.g., regions); thereby overcoming narrow dualism of teaching (by teachers) and learning (by students).

Methods

This paper adopts a review of the theories of the teaching and learning of mathematical proving and mathematical proofs in computer science, economics, engineering, epidemiology, mathematics, physics, psychology, and statistics by reviewing the top five journals of each field from 2010 to 2024. The first step is a title search, and the keywords include terms such as "proofs" and "mathematical proving," The second step is to review the abstracts and the third step is to read the shortlisted articles in-depth and to tease out the models of teaching and learning mathematical proving and mathematical proofs.

This paper adopts a practitioner-scholar perspective, and it will review the five most commonly use mathematics textbook in computer science, economics, engineering, epidemiology, mathematics, physics, political science, psychology, and statistics (e.g., Pipes & Harvill, 2014). It will also review mathematical proving and mathematical proofs courses in PK-20 sectors in California, Florida, Massachusetts, New York, and Texas.

Results

The preliminary results show that there are fundamental models that can explain real-life phenomena that students can relate to. These models can be a good starting point for courses that would incorporate theory-based and evidence-based methods of teaching and learning mathematical proving and mathematical proofs. The model focuses on fundamental forces from the neuron level to large geographical areas (e.g., regions); thereby overcoming narrow dualism of teaching (by teachers) and learning (by students). In the age of generative artificial intelligence, my model centers on self-learning and continual learning of mathematical proving and mathematical proofs under highly trained mentors.

Discussion

This paper goes beyond the conventional way of teaching and learning mathematical proving and mathematical proofs. By examining how non-mathematics disciplines use mathematical proving and mathematical proofs to examine real-world phenomena, this paper's model provides an alternative way of teaching and learning mathematical proving and mathematical proofs in PK20.

Situated within efforts to understand the complex interplay among learners, teachers, and tasks in mathematical modeling education, we examine how contingent scaffolding moves influence the modeling process. Using mixed methods, we coordinated qualitative frameworks for scaffolding and modeling competencies through their application to task-based cognitive interviews with undergraduate STEM majors. A mixed logistic regression model with participant random effect analyzed the temporally-linked frequencies of codes. The model sustains claims about the compatibility of the frameworks and predicts moves eliciting competencies.

Keywords: modeling, advanced mathematical thinking, cognition, mathematical representations

In any didactic situation, there is a triadic interaction among the learner, the teacher, and the task environment (Brousseau, 1997; Koichu & Harel, 2007). Understanding how the teacher influences the interaction between learner and task environment is a major research objective in mathematics education. In learning environments that focus on developing mathematical modeling skills, learners are assumed to enter with real-world knowledge (and therefore assumptions) that may not afford the intended mathematics (Cai et al., 2014). A number of studies have shown that educators may respond to the learners' work in ways that amount to consistent negative feedback or diminish learner autonomy in decision-making while modeling (Verschaffel et al., 2020). Additionally, support which may, on the surface, seem adaptive to error is not always contingent to a learner's in the moment needs (Wischgoll et al., 2015). For these reasons, educators have sought means for scaffolding learners' modeling processes that maintain cognitive demand, endorse and extend their autonomous ways of reasoning, and do not inadvertently teach the idea that there is a "school math" entirely distinct from "real math" (see Nunes et al., 1985; Watson, 2008). Our study is situated within the broader agenda to understand which kinds of scaffolding moves are effective in supporting modelers as they learn to construct and validate meaningful models of real-world scenarios. In particular, the aim of this study was to investigate the influence of facilitators' micro interventions on undergraduate STEM majors' modeling processes.

Literature Review

Mathematical modeling is a cognitive process.

Cognitive perspectives on mathematical modeling conceive it as a process of transforming a question about the real world into a mathematically well-posed problem (Kaiser, 2017). For example, one way the question *How rapidly will a disease spread through a community?* can be answered is by using the equation $\frac{dS}{dt} = \tau SH$ as a model of the scenario. Using an equation as a model means the modeler constructs quantitative meanings for the variables $\boldsymbol{S}$ and $\boldsymbol{H}$ which represent the number of sick people and healthy people at time $\boldsymbol{t}$, respectively. This sub-process is known as *mathematizing*. Another important sub-process of modeling is *validating*. This is done by adopting (implied or explicit) assumptions about how the world works and evaluating the adequacy of the resulting representation against those assumptions. Assuming that having the disease does not confer immunity to it is consistent with the model in the example. In general, modelers decide which real-world conditions and assumptions are important (or not) to incorporate into their model as mathematical properties, parameters, and relationships (Schwarzkopf, 2007; Zbiek & Conner, 2006). This sub-process is known as *simplifying & structuring*. Mathematical modeling cycles (MMCs) provide a descriptive framework that organizes the cognitive sub-processes as a set of phases connecting stages of model construction (Blum & Leiß, 2007). Table 1 shows Blum and Leiß (2007)'s cycle for the stages a modeler passes through and the sub-processes that connect those stages.

Table 4 Modeling competencies from (Blum & Leiß, 2007)

Sub-Processes	Definition	Connects Stages
Understanding	Forming an initial idea about what the problem is asking for	real world → situation model
Simplifying & Structuring	Identify (un)important real-world entities and relationships	situation model → real model
Mathematizing	Represent idealized version of the real-world problem using mathematical conventions	real model → mathematical model
Working Mathematically	Analyze or solve mathematical problem	mathematical model → mathematical results
Interpreting	Re-contextualize mathematical results	mathematical results → real results
Validating	Verify results against constraints	real results → real situation

Many studies have investigated the sub-processes and their manifestations across grade levels and content areas (Cevikbas et al., 2021), the characteristics of tasks that evoke them (Bock et al., 2015; Maaß, 2010), and the challenges learners face in carrying them out (Galbraith & Stillman, 2006; Klock & Siller, 2020). Importantly, many studies have found modeling does not proceed linearly through the sub-processes (Ärlebäck & Bergsten, 2010; Borromeo Ferri, 2007; Czocher, 2016, 2018). Despite the low predictive power of MMC's, they remain powerful descriptive models of desirable learner engagement with modeling tasks. There are robust analytic frameworks of observational indicators for which sub-process the modeler is engaged with that are applicable across content areas and grade bands (Czocher, 2016; Maaß, 2006). Within *working mathematically*, for example, learners are seen to exhibit procedural and conceptual mathematics knowledge whereas during *simplifying* and *validating*, learners are seen to articulate and justify assumptions they make and may not draw overtly on mathematical knowledge at all. Because carrying out the sub-processes successfully is critical to constructing a viable mathematical model, they are styled as *modeling competencies* (Maaß, 2006). Modeling competencies are learning objectives in their own right and a major goal of research in modeling is understanding how a teacher, who is using modeling problems to teach mathematics (or to teach modeling), can scaffold and thereby promote learners' modeling competencies.

Scaffolding in mathematical modeling ought to be contingent.

Scaffolding a learner as they develop and validate a model has two goals. The local goal is helping the modeler arrive at a viable model for a particular problem. The global goal is promoting competencies that can be used in other problems. Both are challenging because facilitators need to focus on learners' current knowledge and understanding as it is expressed within a given sub-process of the MMC (Blum & Borromeo Ferri, 2009; Doerr, 2006; Schukajlow et al., 2015; Stender & Kaiser, 2015; Wischgoll et al., 2015). The high-level idea is that because the nature of a learner's engagement in modeling changes across modeling competencies, there are likely to be differing (and specific) moves a facilitator can make that would support each sub-process. Providing hints towards a normatively correct mathematical representation when the learner is mulling over which variables are important to include robs her of the modeling experience and does little to cultivate competencies. Investigating this conjecture calls for a view of scaffolding suitable for studying learners' productions and their relations to facilitator moves at a within-task grain size, rather than broader views that take into account classroom-level organization or cross-lesson supports (Anghileri, 2006). For these reasons, the active trend in modeling research is to adopt a Vygotskian view of scaffolding as an interactive process between a teacher and a learner that gives support to the learner as she works on a task she might not otherwise be able to accomplish (van de Pol et al., 2010, p. 274).

Building on the scaffolding means and intentions framework (van de Pol et al., 2010; van de Pol et al., 2015), Stender and Kaiser (2015) assumed that scaffolding the modeling process may be productive under three conditions: the learner has disengaged (and therefore requires motivation to re-engage in the problem), the learner asks a question, or the learner has been working unproductively for an appreciable time and does not realize it. The latter case presents the most challenging aspect of designing and evaluating scaffolding moves. Effective in-the-moment scaffolding is *contingent*, meaning that the proffered support increases facilitator control when the learner is struggling and decreases control when the learner is succeeding. In some studies, contingency is conceived as being along three-point ordinal scale (van de Pol et al., 2015). Çakmak Gürel (2023) examined the interplay between teachers' participation structures and their scaffolding methods and found that the level of support could vary according to modeling competency. These findings did not directly relate level of support to modeling competency, instead showing that scaffolding method is mediated by the teachers' preferred form of engagement in the classroom. Additionally, modeling tasks can be quite open and learners' engagement in the modeling process is idiosyncratic, based in part on their highly individual previous knowledge and experiences (Borromeo Ferri, 2006; Stillman, 2000). Thus, contingency for scaffolding modeling processes means adapting support to be responsive to the particularities of a learner's constructed knowledge and how it manifests during the modeling process, not only attending to the accuracy of learners' intermediate productions – requiring the facilitator to engage in diagnostic activities before intervening (Kaiser & Stender, 2013).

To address the research need for analyzing contingent support, Stender (2016) developed a framework to capture contingent interventions in learners' modeling processes that are responsive to a learner's current conceptual and (partially formed) mathematical models of the real world scenario, anticipate the specific cognitive needs of the learner, and are calibrated to provide minimal in-the-moment support such that the learner will retain control of their modeling process (excerpt in Table 2). We focus on the "B3 Codes", which classify the contingent moves. Stender and Kaiser (2015) found that requesting leaners to summarize the work they'd done thus far (code B3.1 Work Status) enabled them to continue working independently or aided the facilitator in diagnosing their work to proffer further supports, regardless of how far along the learners were in model development. Stender and Kaiser (2015) also found some expected associations between scaffolding moves and particular modeling competencies. Thus, some scaffolding moves could be competency-general while others may be capable of promoting specific competencies. Stender and Kaiser (2015) also cautioned that it was not always possible for them to determine success of an intervention because there wasn't sufficient information in the students' work. They focused on only on the few minutes before and after the facilitators' intervention into a few focal groups' work and on normative correctness of the students' models. In this study, we used task-based cognitive interviews to generate facilitator-learner interactions that could be analyzed for the extent that scaffolding moves promote modeling competencies. This maximized the amount of information available to the facilitator for informing which moves to attempt and to the analysis for examining the impact of the proffered support. We address the research question: *Which modeling competencies were more frequently elicited by which kinds of scaffolding moves?*

Table 5 Scaffolding moves (Stender & Kaiser, 2015), fitted with instances from this study.

Code Name	Description	Rule to use	Example
B3.1 Work status	Learner asked to describe current work status or what they are currently working on	Can be a direct question or implicit; Intended to orient facilitator to the learner's reasoning	Can you summarize what you have done here, so far? Can you share what you're thinking about?
B3.6 Prompt to include real-world aspects	Learner asked or encouraged to include a certain aspect	Learner asked to add an aspect to the model. Can be used to increase complexity or to draw attention to specific variable or quantity	Are there any factors that negatively influence the number of current infections?
B3.10 Request reason or explanation	Interviewer requests a reason, explanation, or justification	The reason can be about assumptions made, refer to algebra steps, or to the whole modeling process	Why did you choose multiplication here? What leads you to think that way?

Methods

We used explanatory sequential mixed methods (Creswell, 2014). We deductively coded task-based interviews according to the modeling competencies framework for participants' modeling processes and the contingent scaffolding framework for interviewer moves. The quantitative analysis used mixed logistic regression model with a participant random effect.

Data Collection

Twenty four undergraduate STEM majors at a large southern university were recruited from differential equations courses or courses listing it as a pre-requisite to participate in a set of 10 hour-long task based interviews conducted over zoom. Each participant worked on between four and eleven modeling tasks across the sessions. The modeling tasks had well-defined goals and ill-defined answers (Yeo, 2007) and were designed based on canonical problems from differential equations featuring feedback loops. We studied participants' model construction (*simplifying & structuring, mathematizing*), interpretations of models (*interpreting*), and justifications of model adequacy (*validating*) and ignored *understanding* and *working mathematically*. The tasks were given as written statements so the *understanding* competency is primarily indicated by "reading the problem statement" (Czocher, 2016), and occurs without contingent scaffolding. Additionally, many of the resulting differential equations models cannot be solved analytically, so we did not ask for their solutions (also, contingent support would be highly tailored to the mathematical content instead of participants' modeling needs).

The tasks were sequenced so that later tasks presented scenarios whose mathematical structures subsumed the structures of earlier tasks. The first 4 tasks included embedded scaffolding (sub-tasks) oriented towards learners' quantitative reasoning to aid them in constructing or transferring quantitative structures to the task scenario (Moore et al., 2022; Thompson, 2011). The remaining tasks did not include embedded scaffolding and featured only contingent scaffolding provided by the interviewer. Not every participant saw all tasks, depending on how "far" they got through the trajectory, which was based on their capacity to work autonomously on the tasks. A lead interviewer and a witness from the research team were present during each interview (Steffe & Thompson, 2000). The interviewer intervened in the participants' modeling process if the participant requested help, if it seemed that the participant got stuck, or to generate and test conjectures about the participants' ways of reasoning about the mathematical or real-world aspects of the task. The probing questions were designed to focus on aspects of quantities and quantitative reasoning, but overall interviewer turns were formulated so they could map to the scaffolding moves framework. The alignment between interviewer moves and the scaffolding framework was achieved through several rounds of pilot interviews and subsequent analysis, not reported here. In this paper, we consider only the tasks without embedded scaffolding to isolate the influence of contingent scaffolding. The dataset for this study comprised 51 hour-long modeling sessions.

Table 6 Summary of interview tasks

Task Name	Intended Canonical Model	n	Median Task Time
Tropical Fish	Contaminated tank	18	1:10:11
Tuberculosis	Two compartment disease transmission	17	0:47:07
Ebola	Three compartment disease transmission	11	0:53:03
Bobcats & Rabbits	Two-species predator prey	2	1:04:44
Diffusion	Fick's first law (one dimension)	2	0:20:18
Kidneys	Dialysis across a one-dimensional membrane	1	0:42:26

Data Analysis

Qualitative analysis proceeded with deductive coding procedures based on pre-defined, published codes for engagement in modeling processes (MMC codes) and contingent scaffolding moves (B3 codes). Participant engagement and interviewer moves were coded separately. To code for participant engagement, we viewed the videos in MaxQDA and assigned an MMC code if an indicator for that code could be observed in the participant's speech or writing. The MMC codes were not mutually exclusive; a participant's actions at a given time could indicate both *interpreting* and *validating*, for example. Start and stop times for the codes were determined independently of the start and stop times for other codes. Because much of the modeling process takes place in the mind of the modeler, when a modeler "really starts" to make assumptions is not accessible information. Thus, we assigned a timestamp to the earliest moment there was verbal or written evidence of an indicator for the code. To code interviewer moves, the recordings were segmented into durations of 30s and each segment was assigned each intervention code the segment evidenced. In this way, the scaffolding moves codebook produced time series corresponding to if the code is "on" or "off" during each 30s segment. Pilot studies (not reported here) adapted the scaffolding moves codebook to the research setting. We then mapped each instance of a scaffolding move to the MMC by identifying which stage of model construction the intervention referenced (situation model, real model, mathematical model, mathematical results, real results). For example, the move "Let's work on just the susceptible and infectious. And we'll pick back up the removed later" was coded as B3.23 Narrowing scope because the interviewer suggested the participant to ignore the removed population. Because the move referred to the distinct populations identified by the learner (susceptible, infectious, recovered), we inferred it to refer to the Real Model stage of the MMC. In this way, we obtained a description of the move and its modeling-stage referent.

Due to the complexity of the codebooks, total duration of the 51 sessions, and planned quantitative models, our primary concerns about reliability were the chance of missing codable segments and consistent application of the codebooks across participants and tasks. Thus, two analysts independently coded each event. To mitigate coder drift, six pairs of analysts were formed from four research team members and rotated. Pairs met regularly to reconcile codebook application and resolve disagreements based solely on code definitions. Since neither codebook was mutually exclusive, multiple codes could be added to the same data segment if warranted. Remaining disagreements were considered by the whole group and resolved by consensus.

To investigate the impact of the contingent scaffolding moves (B3 codes) on the modeling competencies (MMC phases), at each instance of a B3 and for each MMC phase, we determined if the competency was observed during the subsequent two-minute window. If the competency was observed at least once in the window, we said the B3 move was taken up by the participant. Combining the results across tasks and participants, we estimated the probability of uptake for each competency and set of B3 codes.

As seen in Table 4, the number of instances observed varied considerably by competency. As expected, *understanding* (233) and *working mathematically* (261) competencies were rarely elicited, and so were excluded from analysis. However, *validating* was observed nearly twice as often as *interpreting*. To account for variation, we estimated a base probability under the null or no effect model where the null assumption is that MMC codes are uniformly distributed across the sessions. Under the null model, we let X_k be the number of instances of MMC code k in a given two-minute window. Then X_k follows a binomial distribution with size equal to the total number of instances of code k and probability equal to 2 divided by the total combined time of the sessions. The base probability is $p_{b_k} = P(X_k > 0)$. We then normalized the probability of uptake, by computing an odds ratio:

$$\text{OR} = \frac{(p/(1-p)}{(p_{b_k}/(1-p_{b_k})}.$$

If the uptake probability equals the expected value under the null model, then $OR = 1$, and indicates the contingent scaffolding move is not associated with an increased uptake of competency k. On the other hand, $OR > 1$ indicates that the contingent scaffolding move promotes competency k.

Initial investigations indicated that the proportion of uptake depended on the modeling stages referred to. Hence, we used the analysis of B3 code instances in terms of model construction stage to collapse to four broad categories: Real (scaffolding move refers to situation and/or real model), Math (scaffolding move refers to mathematical model), Both (scaffolding move refers to both Real and Math), and Neither (scaffolding move refers to neither Math nor Real). Only 15 instances of intervention codes referring only to math result, 14 referring only to real result, and 9 referring to both were observed. We excluded the low counts. Instances of B3.10 Request Reason or Explanation could fall into distinct secondary categories, depending on the stage referred to by the specific move at that time in the interview.

Results and Interpretations

Figure 1 shows variation in the odds of uptake of each competency following interviewer moves referring to the stages of model construction. To fully characterize the differences observed in Figure 1, for each competency we fit a mixed logistic regression model with a participant random effect, $\boldsymbol{u_i}$, to account for dependence (Agresti, 2012):

$$\log\left(\frac{p}{1-p}\right) = \beta_0 + \beta_1 \text{Real} + \beta_2 \text{Math} + \beta_3 \text{Both} + u_i$$

Results of the models are shown in the Relationship with Stage Referred to column of Table 4. "$A < B$" indicates that the Odds of uptake for that competency is significantly less for stage A than B. "$A = B$" indicates no significant difference.

Figure 3 Odds ratio of uptake of modeling competency by stage of scaffolding move referred to.

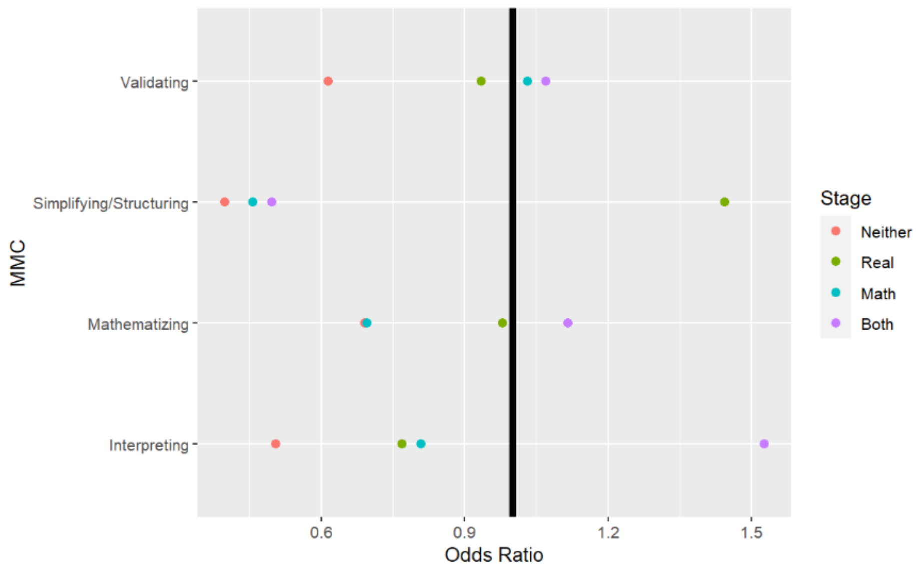

Table 7 Summary of competencies, relationship with stages referred to, and log odds for three of the contingent scaffolding moves from Table 2

Competency	Count	Relationship Stage Referred to	B3.1	B3.6	B3.10
Simplifying & Structuring	1218	Neither = Math = Both < Real	-0.289	0.027	-0.100
Mathematizing	929	Neither = Math < Real = Both	0.391	0.943	-.656
Interpreting	787	Neither< Real = Math < Both	0.208	0.408	0.192
Validating	1428	Neither< Real = Math = Both	0.552	-0.139	-0.101

As expected, contingent scaffolding moves referring to the Real stages were much more likely to elicit *simplifying/structuring* than those referring to other stages. Specifically, the odds are 1.4 times expectations under the null model. Scaffolding moves classified as Real and Both had the greatest odds of eliciting *mathematizing*, which is sensible because the mathematizing competency bridges thinking about real-world conditions and assumptions to reasoning about mathematical properties and parameters (Zbiek & Conner, 2006) it also, according to the MMC, ought to follow chronologically from thinking about real-world conditions and assumptions. Additionally, the odds of eliciting the *interpreting* competency are greatest when a move refers to Both (Math and Real) stages of model construction. This makes sense theoretically because *interpreting* competency, like *mathematizing*, bridges real-world and mathematical knowledge. Finally, a wide range of scaffolding moves can elicit *validating* – as long as the move refers to either Real or Math or Both -- corroborating claims in previous work that validating arises throughout the modeling process in response to multiple knowledge sources (Czocher, 2018; Ishibashi & Uegatani, 2022).

Due to space constraints, we discuss only three of the 48 B3 Codes. The log odds (Table 4) show increased rates of *mathematizing, interpreting,* and *validating* followed a request for the participant to summarize their current work (B3.1 Work Status), relative to the base rates of occurrence for these competencies, while it is not an effective move for eliciting *simplifying & structuring*. Because *mathematizing* and *interpreting* are likely to follow B3.6 Prompt to Include Aspects (of the real world), moves which primarily refer to Real stages of model construction, it seems that prompting learners to attend to their ideas about how the world works leads to competencies associated with increasing model complexity and scope. We are not surprised to see a positive association between B3.10 Request Reason or Explanation and *interpreting*, because asking a learner their rationale for a modeling decision would often necessitate interpreting situationally relevant meanings. However, its negative association with *validating*, which shares aspects of justifying and explaining (Czocher et al., 2018) was surprising. We had anticipated that B3.10 would increase elicitation of *validating*.

Finally, there were several scaffolding moves for which the odds of eliciting any of the four focal competencies were less than the base rate predicted by the null model. The move 3.11p Math Procedure was one such example. In contrast, the move B3.14 Suggestion for Action, Related to Content (focus on directing attention to variables and quantities) elicited all four focal competencies more than expected. Thus, it seems attending to the role of quantities and quantitative reasoning promotes modeling competencies.

Conclusions

We conclude that the logistic regression model adequately captures expected relationships between contingent scaffolding moves, their referents relative to the MMC, and elicitation of modeling competencies. We view it as an initial model capable of sustaining claims about (a) the compatibility of the analytic frameworks and (b) predicting which moves are capable of eliciting which modeling competencies. Importantly, the regression model quantifies variation and differences across competencies, scaffolding moves, and the likelihoods of their interactions. This is a promising advance for work seeking to understand the impact of modeling-forward learning environments on learners' modeling competencies. The approach retains the nuance of the critical aspects of contingent scaffolding, as articulated by the scaffolding moves framework, while offering a vision of the larger cross-participant and cross-task patterns. One limitation is that presently, it is unclear the extent to which the random effect model adequately accounts for the person-dependence of each competency. Future iterations would improve on this uncertainty. In the end, the holy grail is a model capable of informing facilitators which contingent scaffolding moves are most and least likely to promote which competencies so they may focus on developing powerful moves. Due to the large number of codes, we clumped them according to the stage they referred to. Future iterations can examine individual moves to understand which perform similarly with respect to competency elicitation and distill move types into strategies.

STRATEGY COMPARISON AS A PRECURSOR TO STRATEGY ADOPTION IN THE CONTEXT OF INTEGER MULTIPLICATION

Carlos Alejandro de Alba

Our study explored how fifth-grade students compare and adopt integer-multiplication strategies. They solved ten problems before instruction and answered seven reflective questions to reveal new strategies. Responses were analyzed across four dimensions: Focusing, Judging, Comparing, and Adopting. The findings show students' intuitive grasp of negative numbers and their willingness to engage with strategies. Teachers can support adoption and enhance understanding by attending to students' focus, judgment, and comparison processes.

Keywords: Algebra and Algebraic Thinking, Number Concepts and Operations, Elementary Education

Perspectives and Theoretical Framework

Comparing and discussing solution methods is recognized as an effective learning strategy in mathematics (Rittle-Johnson & Star, 2007; 2009; Silver et al., 2005). The National Council of Teachers of Mathematics Standards also endorses this practice (NCTM, 1989; 2000). However, concerns exist regarding potential overreliance on teacher guidance versus student-led thinking (Richland et al., 2007; Rittle-Johnson & Star, 2007). Effective implementation of comparing and discussing solution methods often involves presenting two examples with instructional support (Rittle-Johnson & Star, 2009). Our study builds on this research, focusing on integer multiplication and strategy adoption.

Previous work by Rittle-Johnson & Star (2007; 2009) explored how comparisons affect procedural knowledge, flexibility, and conceptual knowledge. They found that students who compared examples were more likely to transfer methods to novel tasks, enhancing conceptual knowledge and flexibility (Rittle-Johnson & Star, 2007; Rittle-Johnson, Star, & Durkin, 2020). Comparing correct and incorrect methods helped students identify important characteristics and differentiate usefulness in various situations (Rittle-Johnson & Star, 2007). Students who compared strategies focused more on methods for solving rather than final solutions, thus attending to the key similarities and differences between methods, which influenced subsequent judgment (Rittle-Johnson & Star, 2007).

Research in cognitive science suggests that exposure to novel transfer problems prompts adaptation (Paas & Van Merrienboer, 1994; Rittle-Johnson & Star, 2009). Analyzing examples with unfamiliar solution strategies and answering similar problems aids in studying the adoption process. Researchers must assess the extent to which learners change strategies to accommodate task differences (Lamb et al., 2023). Providing opportunities for students to explore multiple strategies may enhance learning. Identifying how students focus and judge examples during comparison tasks can offer insights into adopted strategies for future problems.

Our study aims to understand how students compare strategies and their subsequent use in tasks, particularly in the context of integer multiplication. Carpenter and Wessman-Enzinger

(2018) highlighted the inventive nature of students' pre-instructional strategies in early integer multiplication, making it a valuable domain for comparison and adoption research. We explore how focusing, judging, and comparing influence strategy adoption through two main research questions: How do students attend to the strategies and descriptions of others and to what extent is that attention influenced by similarities to their own reasoning? Additionally, to what level and in what ways do students adopt the strategies of other students in the domain of integer multiplication?

Methods

Seven fifth graders from two different schools were interviewed for our study. We share the results of our interview with one student, Nico, because of the variations in adoption he exhibited. Throughout the interview, Nico was asked to answer open number multiplication problems (e.g., $\square$ x -3 = -18) before being asked to explain his strategy (adapted from Bishop et al., 2018; Lamb et al., 2018). The unknown and the distribution of negatives varied across all problems (e.g., -4 x 3 = $\square$, 5 x $\square$ = -20, $\square$ x -3 = 9). Interspersed throughout the interview were opportunities for the students to reflect on sample strategies that we provided to them. We developed these strategies by adapting the strategies of students from our own pilots and from the strategies described by Carpenter and Wessman-Enzinger (2018). Each of these strategies included the name of a fictionalized student and a brief description of their work, written in first person natural language. For clarity, the interviewed students will continue to be referred to as the students and those whose strategies we introduced will henceforth be referred to as the Sample(s). After a student had completed two or three tasks, we presented the student with a Sample's strategy for answering the most recent question(s). Once a student had read a Sample's description aloud, they were asked to describe how the Sample was thinking and how it was similar to or different from their own reasoning. The student was then asked to rate the Sample's strategy on a modified scale (Rittle-Johnson, Star, & Durkin, 2012) with the following options: *Very good way; OK to do, but not a very good way; Not OK to do; Not sure if this is OK to do.* Student responses were analyzed on three a priori dimensions – Focusing, Judging, and Comparing (adapted from Rittle-Johnson & Star, 2007) and the induced adoption dimension (see Table 1 below). Researchers also took note of the multiplication strategies, following Carpenter & Wessman–Enzinger's (2018) framework, which were used to identify changes over the course of the interviews.

Table 1: Dimensions and Codes

Dimension	Code	Description. Students...
Focusing	On the Method	Focus on how a Sample reasons
	On the Answer	Focus mostly on the result of the Sample's work
Judging	Efficiency	Judge clarity or speed
	Confidence	Judge a Sample's certainty and/or confidence
	Accuracy	Judge correct or incorrect use of a rule

Comparing	Between Samples	Compare two Samples to one another
	To Own Work	Compare one or both Samples to their own work
Adopting	Authentic Adoption	Use a Sample's strategy
	Quasi-Adoption	Use a strategy that is modified from a Sample
	Lack of Evidence of Adoption	Use a strategy that is not from a Sample

Results

From Nico's written work, explanations, and use of provided materials, we found that he aligned closely with many of our dimensions and codes. Although all our codes are presented in Table 1, the following results and discussion only include the dimensions and codes that fit Nico's responses. Nico focused predominantly on Sample methods, not their answers, and judged those methods on matters of confidence and accuracy. For question nine (-2 x □ = 6), he had episodes of judging methods based on a Sample's confidence and accuracy. Sample Sofia had identified a counter movement technique that yielded not only the correct answer but also the same answer that Nico had found. However, Sample Sofia also conveyed a lack of confidence in her strategy when she shared, "Wait, is it six? Can you do that? But they're negatives. Hmmmm, I'm not positive." Nico thus chose to assess Sample Sofia's work as *OK to do, but not a very good way* because "she isn't sure, and you should always try to be sure." This response suggests that uncertainty was important to Nico in judging the worth of a strategy. The act of gauging clarity and confidence may be a result of classroom practices and teacher feedback. For this same problem, Nico judged accuracy when he noted that Sample Louis' methods were flawed because he had "treated negative numbers as subtraction, which would be okay if this was adding." Sample Louis had answered the problem by filling the box with 8 and justifying his choice by saying that 8 - 2 was 6. Throughout the interview, Nico noted that treating a negative as subtraction was inaccurate. This identification seemed to affect how he assessed Sample strategies.

The Sample responses to question five (□ x -3 = -18) sparked an episode in which Nico compared the Samples to each other and to his own work. His response that Sample Fatima and Sample Gabriel "thought the same way as me…[but] I think that Gabriel did a miscalculation" seemed to double down on his choice to focus and judge the method primarily over the answer. Comparing them to one another presented the idea that Gabriel's "strategy was good…but result wasn't." Nevertheless, Nico marked both methods as *very good way*, implying that the miscalculation did not affect the quality of the strategy. Earlier in the interview, Nico had used the same methods of repeated addition that were used by both Samples and comparing his work to theirs seemed to serve as a method of validation.

The path to adopting a strategy seems to relate to a chain of focus, judgment, and comparison. What Nico attended to and how he did so ultimately informed the degree to which he made sense of and replicated the strategy in novel tasks. When answering problems four (5 x □ = -20) and five, Nico explicitly named Sample Abbi as influential to his thought process. Sample Abbi used the language of groups in her descriptions, particularly when working with negatives which she described as groups of negatives. Nico suggested that Abbi would have read problem four as "five groups of negative four" and problem five would similarly be read as "how many groups of negative three would you need to get negative eighteen." Nico's work on questions one through three suggested that he was relying on multiplication facts and making attempts to induce a rule for how to work with negatives, a rule of which he was uncertain. In being exposed to Sample Abbi's work, Nico was able to identify a legitimate strategy that was based on existing techniques with which he was comfortable, thus adopting authentically.

Discussion and Implications

The results of this study illustrate some of the features found in the work of Rittle-Johnson & Star (2007; 2009) and the strategy adoption that may follow. We hypothesize that Nico attended to the reasoning of other students because he was looking to identify familiar patterns as well as a justification of his own intuition. His tendency to judge accuracy suggested that he was looking to uncover and understand methods that were seemingly familiar. At a pre-instructional stage, he was hesitant to completely discount or support a solution or a strategy, but he was comfortable judging the elements of a strategy. His judgment, however, was not just a matter of accuracy, but also a matter of the Sample's confidence, which affected his perception of their work and his willingness to adopt that strategy.

When comparing, the decision to weigh one element of a strategy more than another may have been due to comfort with procedural multiplication skills (such as repeated addition), fact memorization, or could have resulted from comfort with strategies used throughout a Sample's method. In line with the findings of Rittle-Johnson & Star (2009), Nico benefited from viewing two Samples at once as he was able to compare methods more deeply than if he had seen them one at a time. Attempting to uncover the mathematical thinking of the Samples seemed to suggest that Nico was prepared to go beyond the rules of integer multiplication, looking for potential traces of the underlying relationships between integers under multiplication.

The decision to adopt a strategy was the result of many considerations for Nico, such as whether he felt like he could reproduce the strategy in a similar setting. However, the decision to adopt, or not, could also have been based on the need for, or lack of, a strategy. Adoption is informed by all three of the a priori dimensions but is perhaps most influenced by the comparison stage. In some sense, adoption is built upon the constructivist concepts of accommodation and assimilation, in which decisions are made based on whether and how to accept new environmental stimuli into an existing conceptual understanding. In the comparison stage, students get an opportunity to identify how their work aligns with that of others. By identifying the varying degrees of similarities and differences, Nico had the potential to create a new understanding that combines the most salient and perceived accurate elements of each strategy. This process is iterative as it continues to occur with exposure to every new Sample as well as with the ideas that arise when a student attempts to reason through a problem themselves.

Nico held some intuition of negative numbers and was willing to attempt to reason through integer multiplication before and after exposure to Sample strategies. There are rich opportunities for growth if instructors better understand what students are coming into the classroom knowing and thinking. Attending to how a student focuses, judges, and compares their strategies to others may reveal what they are comfortable accepting as mathematical fact as well as the content knowledge and intuition they already possess. Furthermore, interpreting how those factors result in their level of adoption may inform how to enact teaching practices so that all students have the opportunity to authentically adopt rich strategies. Future work on this project might benefit from tracing the process of adoption across multiple mathematical topics in a classroom setting. We may also wish to explore other factors that contribute to flexibility and the willingness to adopt strategies, such as mathematics maturity and mathematics anxiety.

A thorough understanding of the intuitions and thought processes of students is vital to the future of mathematics education. Students come to the classroom with vast arrays of prior knowledge and experiences. The ways in which they employ those in the classroom is of particular interest when considering how they might try to incorporate new strategies into their own problem-solving schemes. We envision a future that highlights student thinking and the teaching methods that might nurture student learning.

PLAYFUL MATH: WHEN STUDENT AUTHORING GENERATES NOVEL MATHEMATICS

Amy Ellis
University of Georgia
amyellis@uga.edu

Dru Horne
University of Georgia
dhorne8@uga.edu

Anna Bloodworth
University of Georgia
anna.bloodworth@uga.edu

We propose the construct of playful math to support instances of student authoring. Authoring positions students as authors of mathematics in an environment in which students and teachers meet as epistemological equals. By emphasizing student agency and autonomy, playful math encourages students to explore self-selected goals as they design novel problems for one another or for their teachers. We introduce two types of novel mathematics that emerged from student authoring, Unfamiliar Problem and Catalyst, and share one example of each to envision a mathematics education future that celebrates student authoring.

Keywords: Algebra and Algebraic Thinking, Cognition, Problem-Based Learning.

Supporting students to develop and solve their own problems can enhance creativity, understanding, and positive attitudes towards mathematics (Kaur & Rosli, 2021; Kontorovich et al., 2012). Problem posing is seldom considered in relation to creating new mathematics, but some researchers have written about the experience of learning new ideas from their students' activity. For instance, Norton and Flanagan (2022) described how the ideas they developed about nested number sequences and logarithms as maps between multiplicative worlds were informed by their research on children's mathematics, and Ellis (2022) noted that her participants' mathematics "served as a source of novel mathematics for me as a researcher, as it could also do for teachers" (p. 24). We propose that student authoring of mathematics can create opportunities for both students and their instructors to experience new ideas, and that one way to foster authoring is through playful math. By *authoring of mathematics*, we refer to students producing something original (Cheng et al., 2022), using their mathematical voices to "enquire, interrogate, and reflect upon what is being learned" (Povey et al., 1999, p. 243). This use of authoring draws on Povey et al.'s (1999) notion of author/ity, in which teachers and students consider themselves to be members of a knowledge-making community where they "meet as epistemological equals" (p. 234). This perspective positions students as creators, not just doers, of mathematics.

Playful math describes the activities and features of an instructional environment that can facilitate mathematical play (Ellis et al., 2022). This can include task features, instructional moves, and engagement with artifacts. In playful math, students have agency to explore self-selected goals and to author novel problems. We present two examples of student authoring that introduced new mathematics both for the students and for us. We distinguish two types of new mathematics that can emerge from these contexts, Unfamiliar Problem and Catalyst.

Problem Posing and Mathematical Play

Problem-posing tasks are ones that "require teachers or students to generate new problems and questions based either on given situations or on mathematical expressions or diagrams" (Cai et al., 2020, p. 2). Problem posing can counteract the belief that there is one right way to do mathematics, as there is no one "right" question to ask (Palmér & van Bommel, 2020). It can also promote a sense of agency (Brown & Walter, 2004) and can improve motivation and creativity (Kontorovich et al., 2012). We have developed playful math environments as a vehicle for fostering student agency and author/ity. When students experience author/ity, they author problems that raise new mathematics not only for them, but also for us as teacher-researchers.

Defining and Designing for Mathematical Play

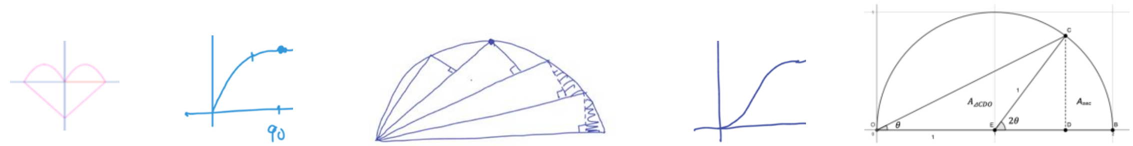
We define mathematical play to include (a) agency in exploration, (b) self-selection of goals, (c) immersion, and (d) enjoyment (Ellis et al., 2022). *Agency in exploration* means that students choose whether and how to participate (Huizinga, 1955) and how to accomplish their goals (Jasien & Horn, 2018). *Self-selection of goals* acknowledges that a learner's agency in determining goals (or sub-goals) is crucial for play (Dewey, 1916/1966). The final two traits are *immersion* and *enjoyment.* Mathematical play is imaginative and creative (Featherstone, 2000), and most accounts of students' mathematical play mention enjoyment (e.g., Sukstrienwong, 2018). Mathematical play can support experimentation, reflection, and persistence (Barab et al., 2010; Gresalfi et al., 2018), and it can provide a productive route for exploring and conjecturing (Mason, 2019; Williams-Pierce, 2019). Given these benefits, we set out to see if we could encourage mathematical play for secondary and undergraduate students.

We have established playful math five design principles to encourage (but not guarantee) mathematical play. They are (1) enable free exploration within constraints; (2) engender anticipation within the task; (3) provide a method for intrinsic feedback; (4) offer meaningful challenge while still being feasible; and (5) allow the student to act as both designer and player. As an example, we draw on an activity in which students investigate growing shapes, graphing a shape's area compared to its length as it sweeps left to right. To playify the task, we created the Guess My Shape game, in which students create secret shapes of their choice (design principles 1 and 5), construct graphs comparing length and area (principles 2, 4, and 5), and challenge each other to determine the shape based on the graph alone (or vice versa; principles 2, 3, and 4). Our principles are consistent with several features of problem-posing tasks, but the open nature of the Guess My Shape game offers greater agency than typical tasks to support author/ity and enable students to author problems reflecting their own mathematical interests.

Data Examples: Sector Areas and Vertical Line Segments

Unfamiliar Problem: Determining Areas in a Semicircle

In the following example, Phyllis and Ryan (secondary pre-service teachers) decided to create a heart shape (Figure 2a). They imagined a line segment on the x-axis that swept counterclockwise, rotating 360° to sweep out the shape. The task for the other students was to graph the area swept as a function of the angle swept by the line segment. Phyllis and Ryan reasoned that the initial part of the graph, from 0° to 90°, would increase at a decreasing rate (Figure 2b). However, when the other students encountered the challenge, they thought that the area would first increase at an increasing rate from 0° to the peak of the semi-circle, and then increase at a decreasing rate from the peak to 90°. To determine this, they created equiangular partitions and reasoned perceptually about the rates of change (Figure 2c), deciding that the area should be "bigger and then smaller" (Figure 2d).



(a) (b) (c) (d) (e)

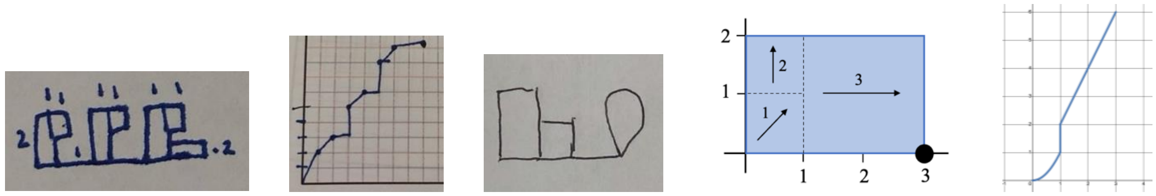
Figure 2: Heart shape (a), Phyllis and Ryan's graph (b), partitioning the semi-circle (c), Meredith and Toby's graph (d), and a semicircle with radius 1 (e)

When the groups compared their solutions, they resolved the discrepancy by redrawing a more precise version of Figure 2c with smaller partitions. They concluded that the area indeed increased at a decreasing rate throughout the semi-circle, but they acknowledged that this decision was based on a perceptual judgement. The students' disagreement led us to realize that we did not know how to directly compute the area of these equiangular portions. We wondered how to find the area between two non-radii chords without computing a double integral in polar coordinates. Thus, the students' authoring led to a novel Unfamiliar Problem for us. An Unfamiliar Problem is a problem addressing a new mathematical idea or challenge for the problem-solver, in this case, us as the teacher-researchers. Certainly, the mathematical ideas in the problem are not novel, but we experienced them as unfamiliar in that we were not aware of a solution method. We solved the problem by drawing a semicircle whose radius is 1 (Figure 2e). Denote by A the area covered by $\angle COB$, which can be decomposed as the sum of the area of triangle $\varDelta COE$, denoted by $A_{\varDelta COE}$, and the area of the sector corresponding to $\angle CEB$, denoted by A_{sec}. If we take OE as the base of $\varDelta COE$, the length of the height is $\overline{CD}$, which is $\sin(2\theta)$. So, we find $A_{\varDelta COE} = \frac{1}{2}(1)\sin(2\theta)$ and $A_{sec} = \frac{1}{2}r^2\alpha = \frac{1}{2}(1)^2(2\theta) = \theta$, hence $A = \frac{1}{2}\sin(2\theta) + \theta$. This function does indeed increase at a decreasing rate from 0 to $\frac{\pi}{2}$.

Unfamiliar problems can emerge when students have the freedom to explore directions of their own interest. They introduce genuine problem-solving experiences for one another and, in this case, also for us as teacher-researchers. Even though the mathematics was not novel from the perspective of the field, we found the problem to be interesting and worth exploring. Unfamiliar problems create problem-*solving* experiences, rather than problem-*posing* experiences.

Catalyst: Vertical Line Segments

The second example comes from teaching sessions with three middle-school students, Artemis, Apollo, and Francis, who had limited familiarity with graphing or linear functions. In this example, the students decided to create a Guess My Shape challenge for the teacher-researcher (TR), inventing a shape that they called "waves" (Figure 3a). The students graphed the first "wave" correctly, but beginning with the second "wave", they made an iconic translation of the vertical section of their shape directly into the graph, in which the vertical segment represented an increase of 2 square units with no change in the horizontal distance of the graph. They repeated this iconic translation for the final "wave."



(a) (b) (c) (d) (e)

Figure 4: The wave drawing (a), the associated area-length graph (b), TR1's graph (c), up-down square task (d), graph of up-down square task (e)

The vertical line segments created a perturbation for the TR, who wondered how to represent an increase in area without gaining any horizontal length. She proposed a solution in the moment by setting up a new convention of a "bubble", in which there is only one point on the line of horizontal sweeping that nevertheless generates an amount of area (in this case, 2 square units, Figure 3c). This task also resulted in establishing a new convention that any area generated in future tasks should be attached to the line of sweeping, to avoid the difference between the rectangular area in the first "wave" of Figure 3a with that seen in Figure 3c.

The bubble was a spontaneous response to a puzzling situation, but it led us to wonder whether we could create a swept shape that would produce a legitimate vertical segment for its area / length graph. In this case, the students' authoring resulted in an Unfamiliar Problem for themselves, as they tackled the challenge of creating the graph, but it also created a Catalyst for us, in that it provoked a new question: What if an area / length graph *could* have a vertical line segment? What shapes could produce such a segment? A Catalyst is a situation that challenges or reveals an ambiguity about an accepted (or implicit) convention or rule. It can thus engender problem-posing activity, such as the creation of novel sweeping shapes.

We continued to wonder about this question and reasoned that the x-axis quantity would need to stop growing as the area continued to grow. This led to the shape in Figure 3d. In this shape, the square first grows both in length and height, producing area at a constantly changing rate of change (a quadratic graph). Once the square reaches 1 square unit, it then grows up to produce an additional square unit, but without sweeping additional horizontal length, resulting in a vertical line segment. The rectangle then sweeps to the right, producing an additional 4 square units of area at a constant rate (producing a linear graph, Figure 3e). In the graph, the x-axis quantity is the horizontal distance traveled by the dot. We also realized that once the dot stopped moving horizontally, the area could grow up and down multiple times. In creating this problem, we reflected on the fact that the shape of the graph and the trace of the graph are different. This realization led to further problem posing, creating related tasks that incorporated both linear and quadratic growth in the vertical line segments, which can only be distinguished by considering the graph's trace.

Discussion

In both examples, the students experienced Unfamiliar Problems through authoring. However, the novel mathematics that we experienced as teacher-researchers differed. With the semicircle, we experienced an Unfamiliar Problem that required us to devise a solution method we had not previously encountered. The mathematical ideas were not new, but we were challenged to solve a novel (to us) problem. In contrast, the vertical line segment acted as a Catalyst to challenge us to imagine new mathematics. By asking “What if an area / length graph has a vertical line segment?”, we introduced new questions for ourselves, such as “Are there sweeping shapes that could produce such a graph, and if so, what would they look like?” This led to a novel set of problems inspired by up-down square, as well as a consideration of the ways in which two graphs can look identical even as their traces differ.

Student authoring can raise unique challenges for teachers, who may be faced with navigating unfamiliar ideas or puzzling situations while interacting with their students. We acknowledge that this can be difficult. However, we envision author/ity environments in which it is allowable for teachers and students to occasionally shift roles, in which teachers experiencing puzzlement or new learning can be normalized and celebrated, and in which we see our students' activity as sources of new learning for us, just as our instruction can be for them.

INVESTIGATING CARTESIAN COORDINATE SYSTEM IN HIGH SCHOOL

Semra Guven

Gülseren Karagöz Akar
Boğaziçi University
gulseren.akar@boun.edu.tr

This large-scale study investigated high school students' reasoning of spatial and quantitative Cartesian coordinate system, meanings of a point and graphing. By integrating related frameworks, data from 229 students across different grade levels were analyzed through nine open-ended questions. Results revealed that students had critical difficulty in conceiving axes as frames of reference to represent quantities as horizontal and vertical directed distances from the origin in coordinating quantities. A significant number of students carried non-normative meanings for points in terms of multiplicative objects, and relatedly had difficulties in envisioning the graph as emergent trace of multiplicative objects. We discuss the implications of the results for learning, teaching, and curriculum development.

Keywords: Cartesian Coordinate System, Graphing, Multiplicative Object, High School Students

Coordinate systems are one of the most commonly used representational tools in learning and doing mathematics, and in science, technology, mathematics, and engineering (Paoletti et al., 2016; Roth et al., 1999). Cartesian coordinate system (CCS) enables representing attributes of two or more quantities on axes, where uniting their orthogonal projection results in forming a *multiplicative object* in mind. This allows students to conceive and represent the relationship between quantities' values and magnitudes (Thompson et al., 2017), which contributes to the development of covariational reasoning and reasoning about graphs (Moore et al., 2013). CCS also lays the foundations for function and rate of change ideas (Thompson et al., 2017) as well as to reason about ratios and proportional relationships, number systems, geometry, algebra, functions, vectors, and matrix quantities (CCSM, 2010). Therefore, forming a solid understanding of CCS and closely related concepts such as meanings for point and graphing is of great significance, particularly at the high school level.

Despite their significance in mathematics, the construction of coordinate systems receives little instructional time, and is taken for granted by researchers, teachers, and curriculum developers (Lee, 2017). Yet, constructing a coordinate system (Lee, 2020) and plotting a point at the quantitative level is non-trivial (Frank, 2016). Students from middle school to undergraduate level face several difficulties in constructing and interpreting graphs (Moore & Thompson, 2015). Despite demonstrating an understanding of quantitative relationships, preservice teachers struggled in clinical interviews when confronted with unconventional aspects of coordinate systems, such as conceptualizing y as the horizontal and x as the vertical axis. Researchers (e.g., Frank, 2017; Stevens & Moore, 2017; Thompson & Carlson, 2017) suggest that part of these challenges arise from an inability to conceive points as multiplicative objects.

While not exhaustive, the reported difficulties above highlight the need for research on students' meanings of CCS, especially on a large scale and at the high school level. It is in this regard that we investigated the following research questions: 1) How do high school students reason about Cartesian coordinate system and graphs within spatial and quantitative CCS? 2)

What are high school students’ meanings of a point in terms of multiplicative object, point on a graph, and outputs of a function?

Bringing together frameworks related to CCS, this study extends the literature by investigating high school students’ reasonings of CCS in a more comprehensive way through investigating their construction of spatial and quantitative CS, reasoning of a point in terms of multiplicative object, and graphing in spatial and quantitative CS, which are all components of robust and coherent understanding of CCS. Results shed light on high school students’ weaknesses and strengths, hence imparting implications for learning and teaching mathematics at various academic levels.

Conceptual Framework

We used the literature on CCS (e.g., Battista, 2007; Demir, 2012; Knuth, 2000; Lee et al., 2019; Moon, 2019) the framework on the use of multiplicative object (Tasova, 2021), and the framework for reasoning about graphing in spatial and quantitative Cartesian coordinate systems (Paoletti et al., 2018) in juxtaposition to each other, as these ideas relatedly and collectively might provide a more comprehensive picture of high school students’ reasoning about the CCS.

In this study, we define a coordinate system as “a mental system of coordinated measurements [of quantities] obtained through coordinating multiple frames of reference” and a *frame of reference* as “a mental structure through which an individual situates a quantity where the structure is constructed through the process of committing to a reference point, a unit measure, directionality of measure comparison” (Lee et al., 2019, p.82). A quantity is a measurable quality of an object that emerges when conceptualizing a situation by considering the measurable attribute of the object (Thompson, 1994).There are two types of coordinate systems based on their intended uses: spatial and quantitative CS (Lee et al., 2020).

A *spatial CCS* can be constructed by overlaying a reference point and two orthogonal lines passing through reference point onto physical or imagined space. Then quantities are produced by measuring attributes of the space using frames of reference and coordinating such measurements to represent attributes of the objects in the space or situation. For instance, a spatial CCS can be laid onto a Ferris Wheel such that the axle is located at the origin. Then the location of the car at a specific moment is described by Cartesian coordinates found by orthogonal distance from the origin. Constructing *quantitative CCS*, entails extracting quantities from the space a situation or phenomenon occurs and projecting them onto new space. In quantitative CCS, quantities are overlaid onto two orthogonal number lines and a point is formed by uniting their orthogonal projections forming a multiplicative object in the context of graphing (Tasova & Moore, 2020). For instance, in the Ferris Wheel example, height of the car from the ground and time can be extracted from the problem situation and their varying magnitudes are represented on number lines, e.g. time by the horizontal and distance from the ground by the vertical axis. By Cartesian product of distance and time {time x distance}, a two-dimensional CS is constructed which is different than the space containing the problem situation (Foerster, 2005).

Method

In this study phenomenography was used to identify and categorize student’s meanings of CCS as phenomenographic study mainly aims to identify various ways in which people experience, interpret, understand, perceive, or conceptualize a certain phenomenon (Orgill, 2012). In phenomenography, collecting data through open-ended questionnaire is advantageous when the number of participants is relatively high (Han & Ellis, 2019). The study took place in the Spring semester in 2021-22 academic year at a private high school in Istanbul which requires high performance at the national high school entrance exam, indicating high potential and capability in learning and doing mathematics. The sample consisted of 229 volunteer students from grade level 9 to 12 who had former experience with graphing, modeling, and forming various types of functions such as linear, quadratic, and exponential. Therefore, students' such lived experiences (i.e., the phenomenon) provided a rich information base for the study. Students worked on the hardcopies of the inventory in 70-80 min. within their two back-to-back classes. Students had access to computers, tablets, or phones to explore the simulations in some of the questions. Since the study aimed to explore students' reasoning skills with quantities, questions mostly did not include numerical values. Therefore, we provided them with scissors, wire, and papers to use as straight edge as optional tools to use in questions.

Inventory was developed in light of the existing research (e.g., David et al., 2019; Lee et al., 2020; Sencindiver, 2020; Tasova, 2021). After taking expert opinion from four mathematics educators who conducted research on students' understanding of CCS, opinions of three high school mathematics teachers teaching at the same school where the study took place were taken about the content and language of the inventory. Next, we conducted a pilot study with two high school students and revised the inventory again. This way, content's appropriateness of the and the inventory's language were ensured. The final version consists of nine open-ended questions with question 6 through 8 including sub-questions.

In this paper, in lieu of space we report on Q1, highlighting prominent findings on students' construction of CCS. In Q1, students' construction of CCS, more specifically, how students leverage their ways of spatial coordination to coordinate quantitatively was explored. In the problem, two ants (represented by points) move haphazardly in tubes that can be rotated and moved in a dynamic geometry environment. The question was "Can you describe mathematically the locations of the two ants with a single point that moves along with the ants?".

In the analysis, students' responses were categorized using coded analysis mainly based on the frameworks as shown in Table 1. In order to obtain reliable and consistent results, the authors analyzed, reviewed, and discussed each item in the inventory regularly.

Table 1: Table of Specification for the Analysis

Goal	Questions	Analysis
Students' meanings of a point in Cartesian coordinate system as a multiplicative object	Q2, Q3, Q4, Q5, Q7	Framework for representing a multiplicative object in the context of graphing (Tasova & Moore, 2020; Tasova, 2021)
Students' graphing in Cartesian coordinate system	Q6a, Q6b, Q8a (in spatial CS)	Framework for reasoning about graph in spatial Cartesian coordinate system (Paoletti, Lee & Hardison, 2018)
	Q8b, Q9 (in quantitative CS)	

In coded analysis of Q1, students' spatial and quantitative coordination was investigated according to their uses of frames of reference (Joshua et al. 2015). Students established either a spatial or quantitative CS; they gave no answer or incorrect answer.

Results

As depicted in Table 2, results showed that unfortunately 86% of the students couldn't generate a solution for Q1. Only 5% of the students constructed a quantitative CS by spatially orienting the tubes and using them as axes to represent distances with respect to the reference point origin. These students were aware of the quantities to describe location of a point mathematically and how to measure and represent them using a CCS (Figure 1a). On the other hand, 9% of the students formed a spatial CS by laying a CCS onto the figure and assigned coordinates of the points accordingly. These students failed to describe location of the two ants as one single point that moves along with the ants. Instead, they relied on conventional tasks such as finding mid-point and connecting two points by line (Figure 1b). They didn't seem to conceptualize axes as tools to represent the directed distances from the origin and coupling these quantities to represent the location of a point.

Table 2: Frequency and Percentages for Question 1

Responses for Question 1	
Quantitative CS	12 (5%)
Spatial CS	20 (9%)
No Answer	129 (56%)
Incorrect	68 (30%)
Total	229 (100%)

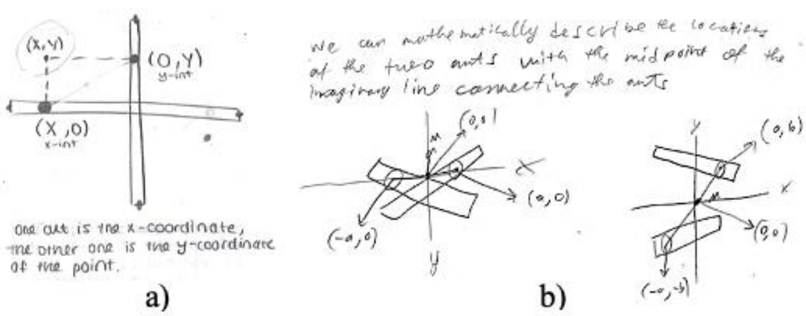

Figure1: a) Quantitative Cartesian CS b) Spatial Cartesian CS

Discussion and Conclusion

Results from Q1 support that constructing a coordinate system by organizing multiple frames of reference is a non-trivial task for high school students even when they have high capability in learning and doing mathematics (Drimalla et al., 2020; Lee et al., 2020). Results showed that students exhibited critical difficulty in conceiving axes as frame of references to represent the horizontal and vertical distance from the origin, thus failed to envision point as union of orthogonal projections of quantities represented on axes. Instead, they relied on procedural tasks that they were familiar from their mathematics classes such as finding mid-point or drawing graphs to depict distance traveled by time. As suggested by Karagöz Akar et al. (2022), results highlighted conceptualizing a point, for instance (*a*, *b*), as combination of directed lengths between origin and (*a*, 0) and origin and (0, *b*) rather than combination of just two labels. Future studies might investigate students' construction and understanding of coordinate systems further through design-based research studies. Finally, although this study provided a picture of 229 students' understanding of CCS, point and graphing in CCS, their meanings might be elaborated more in depth through clinical interviews.

Acknowledgement

This study is a part of the first author's master thesis, which was completed under the supervision of Dr. Gülseren Karagöz Akar at Boğaziçi University, Turkey.

STRENGTHENING SMALL GROUP LEARNING ENVIRONMENTS

Jill V Hamm
University of North Carolina-Chapel Hill
jhamm@email.unc.edu

Daniel J Heck
Horizon Research, Inc.
dheck@horizon-research.com

Keywords: Classroom Discourse, Instructional Activities/Practices, Middle School Education

Background and conceptual framing. PEARL (Peers Engaged as Resources for Learning) research project studied an integrated understanding of effective small group learning environments, drawing on conceptual frameworks addressing demanding and groupworthy tasks (Lotan, 2003; Stein et al., 1996), productive mathematics discourse (Sztajn, Heck, & Malzahn, 2021), and peer cultures of effort and achievement (Hamm et al., 2012). Small group environments offer opportunity to address goals in *Principles to Actions* (NCTM, 2014) and *Common Core State Standards for Mathematics* (NGA, 2010).

Research Question. In what ways do resource lessons providing teacher and student supports and a teacher professional learning program enhance high school Math 1 students' experience of small group learning environments?

Research Design and Findings. The research team combines expertise in mathematics instruction for conceptual understanding and adolescent classroom peer processes. In this naturalistic study, three high school teachers taught four lessons on algebra and statistics topics intended for group work in their Math 1 courses during a baseline year. They engaged in two-day professional learning (PL) program in the following summer focused on high-functioning groupwork and were introduced to re-designed versions of the lessons that incorporated teacher and student supports for engaging with the task, in math discourse, and with peers as partners in learning. During the subsequent year, the teachers taught the re-designed lessons in comparable classes. Following each lesson (at baseline and post-PL), the students individually completed a survey to report on their experience working in small groups. The survey included scales for task, discourse, and peer interaction, as well as a single item on group collaborative focus. Surveys from 328 students in 46 groups in 4 lessons across the 3 classrooms were analyzed using 3-level (students in groups in classrooms) HLM to compare results from the baseline and post-PL. Students' self-report of their groupwork experiences indicated a significant, positive difference in their attention to demands of the task ($M = 4.32$, $SD = .79$ pre vs. $M = 4.51$, $SD = .69$ post; treatment coeff = .23 $p \leq .01$), and group focus ($M = 4.11$, $SD = 1.03$ pre vs. $M = 4.39$, $SD = .77$ post; treatment coeff = .27, $p \leq .01$;). Comparisons of student-rated group discourse and peer interaction were not significantly different pre- versus post-PL. Qualitative evidence from audiorecordings of these students engaged in groupwork will be presented, that provides corroborating illustrations of interaction sequences within groups that demonstrate greater engagement with task demands and stronger collaborative group focus post-PL using the enhanced resource lessons.

Conclusion. The project aims to build stronger theoretical and practical framing of small group learning environments to inform teachers' professional practice. Situated authentically in classrooms, the study attends to mathematics content, student learners, and the learning context. Initial findings reveal opportunities and challenges for teachers to produce and maintain balance within and across three dimensions of small groupwork to deliver on the promise of peer-to-peer learning.

Acknowledgments

This research is funded by the National Science Foundation (NSF) to Hamm [1432143] and Heck [1432084]. The findings reported here do not necessarily reflect the opinions of the NSF. Hamm and Heck are married and Heck is employed by and co-owns Horizon Research, Inc. UNC reviewed these arrangements, concluding that the possible benefit to Hamm or Heck is not likely to affect participant safety or the scientific quality of the study.

TOWARDS A DYNAMIC NARRATIVE: UNDERSTANDING A CALCULUS STUDENT'S DECISION MAKING ALONGSIDE HER EVOLVING MATH IDENTITY

Siqi Huang
University of California, Berkeley
shuang123@berkeley.edu

This paper juxtaposes Schoenfeld's (2010) decision making theory with the literature on math identity to investigate the ways in which a Calculus student's decision making and math identity co-evolved. Through a detailed analysis of the student's identity stories, goals, orientations, resources, and decisions over the course of a semester, this study illuminates the complex process through which she transitioned from pursuing deep understanding as an aspiring math major to dropping Calculus and admiring math only from afar. Notably, the student's evolving math identity stories were closely connected to her consequential decision making. The findings suggest a plausible mechanism for the co-evolution of students' math identity and decision making, extending Schoenfeld's theory across temporal dimensions.

Keywords: Calculus; Equity, Inclusion, and Diversity; Affect, Emotion, Beliefs, and Attitudes

High attrition rates in STEM fields significantly impact students, families, communities, and the nation (Lee & Ferrare, 2019). Calculus exacerbates this issue by eroding students' confidence (Bressoud et al., 2015) and disproportionately "filtering" students based on gender, race, ethnicity, socio-economic status, and first-generation college status (Seymour & Hunter, 2019). This study examines a Latina Calculus student's recalibration of her math identity alongside her decision making, linking the literature on identity with Schoenfeld's (2010) theory to expand both.

Scholars have varied views on math identity (Langer-Osuna & Esmonde, 2017). This study adopts a narrative approach to foreground historically marginalized students' narrativization of their math-related selfhoods. Gee (2000) defines identity as "being recognized as a 'certain kind of person' in a given context" (p. 99), while Sfard and Prusak (2005) view it as "reifying, endorsable, and significant" (p. 16) stories. Martin (2000) underscores the role of community and institutional forces, framing identity as beliefs about self and math. Prior research suggests that identity can change across time by analyzing students of different age groups (Nasir, 2002) or by focusing on micro-level positioning moves (Langer-Osuna, 2011). This study expands on these approaches by linking identity narratives with decision making mechanisms (explained below) and tracking their co-evolution over time.

Schoenfeld's (2010) theory models how individuals make decisions in the moment: Decisions are shaped by three factors: resources, goals, and orientations. Resources include all elements (e.g., knowledge) available to individuals during decision making, goals encompass both conscious and unconscious aims, and orientations cover "beliefs, dispositions, values, tastes, and preferences" (p. 29). Given the theory's focus on short time frames, there is a lack of studies examining how individuals' goals, orientations, and resources evolve and shape decision making over extended periods. This paper addresses this gap by offering an explicit mechanism for implementing Schoenfeld's theory across temporal dimensions.

Methods

From over 1,511 students enrolled in a first-semester Calculus course for STEM majors at a prestigious U.S. university in Fall 2023, 57 participated in the larger Calculus Learning Experience study. The course included large lectures and smaller discussion sections, with 80%-90% of students having taken Calculus in high school, yet 36.7% either dropped out or received failing grades (C-, D, F, NP). This paper focuses on Grace, a second-year Latina student who demonstrated significant changes in major selection, career path, and approach to learning math within a semester, reflective of the students who failed the course.

The primary data for this case study include video recordings of three 50-minute interviews, observations of lectures and discussions, field notes from 13 informal tutoring sessions, and Grace's written artifacts and survey responses. Interviews involved open-ended questions and problem solving tasks designed to elicit conceptual understanding and deep contemplation of Calculus concepts. Data analysis followed five phases: 1) conducting a holistic review of recordings, interactions, and notes to develop an overview of Grace's major decisions and math identity trajectory; 2) transcribing recordings to detail Grace's self-narratives and utterances during problem solving; 3) developing a conceptual framework grounded in Schoenfeld's theory and the referenced math identity studies; 4) chronologically organizing data to identify emerging themes; and 5) conducting a comprehensive review of all data to ensure accuracy and thoroughness in the analysis and revising the conceptual framework accordingly (see Figure 1).

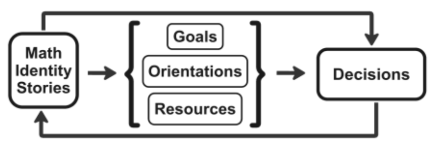

Figure 1: Conceptual framework connecting mathematical identity and decision making

Results

Weeks 1-4: An Aspiring Math Major Who Proactively Sought Deep Understanding

Math Identity Stories. Grace noted that she did not have a solid math foundation in high school but transformed from a state of confusion to "thoroughly enjoy[ing] math" through the Pre-Calculus course she took at the university (Interview, week 14). Although none of her family members pursued STEM-related fields (Field Note, week 2), Grace aspired to double major in math and philosophy (Field Notes, weeks 1 & 3). Her confidence was palpable. She stated, "My relationship with math, before I took this [Calculus] class, was really good. I think I understood, like, all the foundational aspects of math before going into Calculus" (Interview, week 14). She elaborated, "This [Calculus] class is pushing me more towards math because I really enjoy it… I came to understand why there's Pre-Calculus in the first place… I don't think there's a challenging part [about the course] because it all makes sense" (Interview, week 4).

Goals. Grace succinctly summarized her goal: "To understand Calculus!" (Survey, week 1).

Orientations. Grace perceived math as interconnected, logical, and coherent, believing it makes sense and prioritizing understanding in learning (Field Notes, weeks 1-4).

Resources. Grace leveraged her Pre-Calculus foundation, consulted textbooks, actively participated in discussions, derived meaningful insights from lectures, and regularly engaged in in-depth conversations about Calculus with the author (Field Note, week 2; Interview, week 4).

Decisions. Grace actively engaged in the course, sought deeper math understandings, and assisted peers with challenging concepts (Discussion Observations, weeks 2-4). She demonstrated a strong commitment to understanding by posing questions such as “What if…?”, “Why must…?”, “Why don’t you…?”, “Without…, how would you…?” (Field Notes, weeks 1-4).

Weeks 5-9: A Disheartened, Resilient Math Learner Who Adapted Learning Strategies

Math Identity Stories. Grace faced increasing challenges in the course, noting the accelerated pace and her need for more time to understand concepts (Interview, week 14). Her relationship with and confidence in math declined significantly after the first midterm (Figure 2).

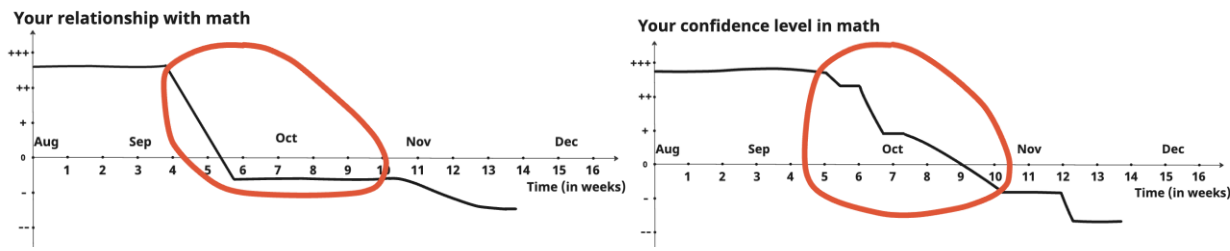

Figure 2: Grace’s drawing of her relationship with and confidence in math (Interview 3)

Despite growing frustrations, Grace persisted. During problem-solving, she encouraged herself with affirmations like “That’s hard. It’s okay, I got this.” or “I don’t wanna give up. OK, let me think.” ((Field Notes, weeks 5 & 7; Interview, week 9). When receiving low scores, she reassured herself, saying, “At least I’m learning,” or “It’s okay. The class is about learning, right?” (Field Note, week 6-9). She remained hopeful: “After the midterm, my relationship with math stabilized because I changed my learning strategies, and then I was like, okay, maybe I could do this” (Interview, week 14). She continued to find joy in math (Field Note, week 9).

Goals. Grace prioritized a deep understanding of Calculus (Interview, week 9; Field Notes, weeks 5, 7, 8) and planned to persist in the course by “toughing it out” (Interview, week 9).

Orientations. Grace recognized the substantial effort required for understanding Calculus concepts and derived satisfaction from achieving conceptual clarity (Interview, week 9). Her resilience was evident in her perseverance through challenges (Field Notes, weeks 5-9).

Resources. Grace supplemented the instructor’s lectures with Youtube tutorials, engaged in challenging problems during discussions, practiced additional textbook exercises, and engaged in in-depth mathematical conversations with the author (Interview 2; Field Note 6 & 8).

Decisions. Grace adjusted her learning strategies and sought deeper conceptual understanding in this phase (Field Notes, weeks 8 & 9; Interview, week 9). She reflected:

> After the first midterm, I realized I needed to change something. I started watching Youtube tutorials and re-watching lecture recordings… I tried to do the homework more before the quizzes because I learned that’s what you need to do in order to do well on the quiz. I also increased my study time and did additional problems from the textbook. (Interview, week 14)

Grace consistently posed insightful questions to deepen her understanding, such as “How would you see a horizontal asymptote without a graph?”, “Why does the derivative of the sine inverse function not have any trigonometric expressions in it?”, and “What if a non-continuous function has a zero? Will the theorem still apply?" (Field Notes, weeks 6, 7, 9).

Weeks 10-14: A Mathematics Admirer from Afar Who Dropped Calculus

Math Identity Stories. Grace's informal calculations of her potential course grade threatened her established identity as an "A+" student, instilling a fear of failure and a sense of alienation in the course (Field Notes, weeks 11 & 12). Grace's parents' advice to prioritize her mental health and withdraw from Calculus negatively impacted her confidence in math (Interview, week 14). Reflecting on her experience, Grace revealed that while law school had been a distant consideration, Calculus unexpectedly propelled her towards a career in law and humanities (Interview, week 14). Notably, Grace maintained a genuine appreciation of math after withdrawal:

> The course was challenging but it was definitely a growing experience… I just think I needed more time to process it in order to really do well on exams, and I didn't have that time. But yeah, math is an interesting field. It's delicate, complicated, and beautiful. I don't think I'll ever not like math… So math is like, my soulmate, I guess? (Interview 3, week 14)

Goals. Grace's primary objective was to "just pass the class" (Field Notes, weeks 11 & 12). Additionally, she emphasized the need to "focus on other things" (Interview, week 14).

Orientations. Grace continued to appreciate the beauty of math, believing that everyone, including herself, can excel through hard work (Field Notes, weeks 10-12; Interview, week 14).

Resources. In addition to the resources used in the previous phase, Grace sought emotional support from friends, input from family, and advice from the author (Interview, week 14).

Decisions. Grace reconsidered her career paths, asked fewer questions aiming for a deeper conceptual understanding, and dropped the course. There was a noticeable decrease in Grace's enthusiasm and instances of seeking deep understanding (Field Notes, weeks 11-13). Figure 3 summarizes the evolution of Grace's math identity and decision making over the semester.

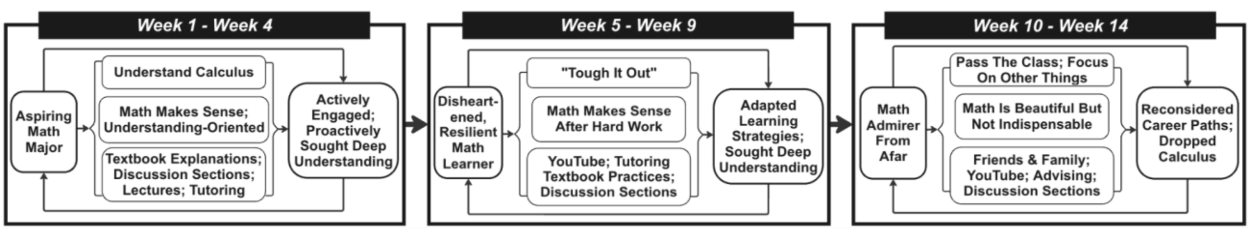

Figure 3: The evolution of Grace's mathematical identity and decision making

Discussion

This paper documents how Grace's math identity and decision making co-evolved over time. Notably, Grace's evolving math identity stories were closely connected to the decisions she made. Her active engagement in the course and proactive pursuit of deep understanding were congruent with her identity as a math major, holding potential benefits for her aspirations. As a resilient learner, Grace's adaptation of learning strategies and quest for deeper understanding were her natural responses to unsatisfactory feedback. The dissonance between her established identity as an "A+" student and the emerging narrative of failing in the course contributed to Grace's reconsideration of career pathways. Considering her new future self-image where math was no longer indispensable, it was understandable that Grace asked fewer questions aiming for a deeper conceptual understanding. Dropping Calculus allowed her more time and energy to focus on things that mattered to her new career trajectory while safeguarding her GPA.

Examining students' co-evolving identity narratives alongside their goals, orientations, resources, and decisions yields valuable insights into how they navigate learning challenges. These theoretical linkages are particularly crucial given the lack of connections between math identity literature and decision-making studies. Furthermore, since decision-making theories have yet to extend to temporal dimensions (A. Schoenfeld, personal communication, June 2, 2024), this study paves the way for more in-depth investigations into the evolution of decision making over time, as well as the identity-related factors influencing these changes.

TRANSFORMATIONS OF SEMIOTIC REPRESENTATIONS IN MODELING: THE CASE OF LIV

Sindura Kularajan
Utah State University
sindura.kularajan@usu.edu

Jennifer A. Czocher
Texas State University
czocher.1@txstate.edu

Students' use of representations yields insights into their learning of mathematical concepts. Thus, utilizing students' representations can reveal how they construct mathematical models for dynamic situations. In this brief research report, we investigate an undergraduate STEM major's use of multiple representations while modeling an exponential growth scenario. Through constructing second-order accounts of Liv's modeling activities, we demonstrate the ways in which she used multiple representations to arrive at a symbolic representation that predicts the growth of a yeast colony.

Keywords: Cognition, Representations, Mathematical Modeling

Mathematical modeling (hereafter, modeling) is the process of constructing mathematical structures to mathematically represent a situation. Scholars within the cognitive modeling perspective (see Kaiser, 2017) have extensively studied the process of modelers representing activities, with explicit attention on *mathematizing* (e.g., Suh et al., 2017; de Almeida, 2018). Yet, the difficulty in examining students' modeling process and helping them advance continues to be a significant challenge (Cevikbas et al., 2021). Particularly arduous is the task of guiding modelers towards constructing mathematical equations that establish relationships among conceived quantities symbolically (Jankvist & Niss, 2020)—a predictive component of a model. Fundamentally, modeling is the process of re-presenting a modeler's conception of the scenario through representations (Lesh et al., 2003). Therefore, the cognitive process involved in modeling can be investigated via the different representations a modeler uses (Duval, 2006). In particular, a modeler's representations and transformations of those representations over time are fertile ground for guiding modelers towards constructing expressions for situations. In this preliminary study, we report on one undergraduate's use of multiple representations to construct a symbolic representation for an exponential growth scenario.

Theoretical Framing and Background

Duval (2006) proposed looking at semiotic representations as a means for analyzing students' cognition as they engage in mathematical activities. This is because "mathematical processing always involves substituting some semiotic representations for another" (p. 107), and therefore the analysis of mathematical activities can be afforded through the transformations of representations. Duval distinguishes semiotic representations from mental representations. While mental representations are in the mind of the learner, semiotic representations are externalized mental representations that are observable by an outsider. In this study we consider semiotic representations as the objectifications (Radford, 2013) of mathematical thinking. Within this perspective, a sign can be verbal or non-verbal, and its role is to represent something else (Pierce 1998, Colapietro, 1993). Pierce (1998), defined *sign* as a triadic relationship among an object (signified), representamen (signifier) and interpretant (the effect it has on an individual whether it is the utterer or the interpretant).

Examples of non-verbal registers include graphs, symbols, equations, and tables. These are often referred to as the types of representations. Whether a representation is verbal or not is determined by the mode of production, such as written, spoken, or gestured (Goldin, 2020). A mathematical object can be represented via multiple semiotic representations. For example, an exponential growth can be represented via the symbolic form $y = e^x$, or through a graph that depicts how y changes with respect to x.

Duval (2006) posits two types of transformations of semiotic representations: treatment and conversion. While *treatments* are transformations of representations that happen within the same register, *conversions* are transformations of representations that entail converting to a different register but the same mathematical object (pp. 112-113). For example, a student who used an exponential function to model the growth of a continuously compounding bank account, may choose to work mathematically within the function to evaluate the amount of money in the account after 5 years. In contrast, the student may choose to create a table that coordinates the amount of money in the bank account with number of years, to represent her perception of the scenario. Despite the use of multiple representations, the underlying mathematical object—exponential function—remains the same. Duval (1999) calls the ability to use multiple representations to reason mathematically about the same object as *coordination*. Dreyfus (1991) posited that students' ability to use more than one representation, connecting and integrating representations can be taken as an indication of advancement in their learning process. More recently, Fonger (2019) defined representational fluency as "the ability to create, interpret, translate between, and connect multiple representations" (p.1). Scholars have investigated students' construction of mathematical ideas (Fonger, 2019; Selling, 2016) through the representations students produced and the evolution of those representations. However, research is still scarce on students' transformations of semiotic representations while constructing a mathematical model for a situation. In this report, we explore *how did an undergraduate STEM major used multiple semiotic representations to construct an exponential growth model*?

Methods

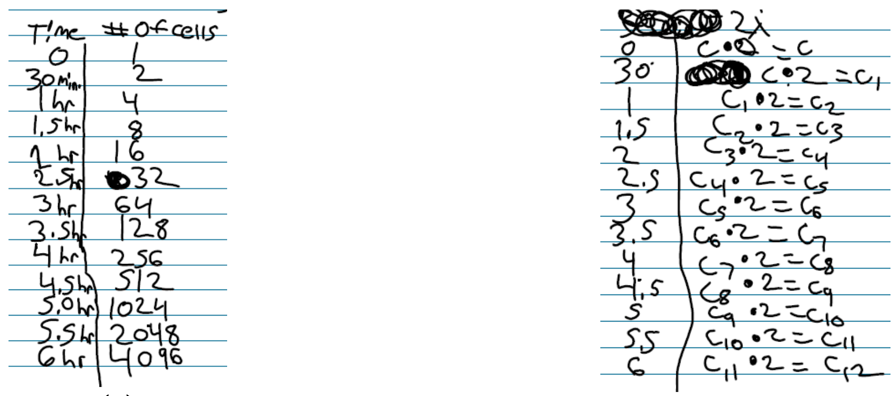
For this preliminary analysis we draw on one undergraduate STEM major's—Liv (pseudonym)—work on the Baker's Yeast task. The Baker's Yeast task was an exponential growth modeling task in which a colony of yeast cells reproduces every 30 minutes. Liv was tasked with constructing an expression for the number of cells present in the bowl at any given time. The data was collected through a 1-hour clinical interview (Goldin, 2012). Data was analyzed through constructing second-order accounts (Steffe & Thompson, 2000) of Liv's mathematizing activities. Explicit attention was paid to Liv's written semiotic representations and their transformations, while utilizing her spoken and gestured representations primarily as an explanatory source.

Findings

We present three phases of Liv's work which were pivotal in helping her construct a general symbolic representation of the number of cells present in the bowl.

Construction of Source Representation

Liv represented the scenario using a table where she coordinated the values of time and number of cells (Figure 1). Liv wrote $30\text{min} + 2 \cdot x$ to represent the number of cells after a particular time. She defined x to signify the number of cells. She decided that the equation did not require 30min, and scratched it out. Liv expressed frustration that she did not know "how to figure this out," referring to the construction of an expression that would give the number of cells in terms of time. Liv further expressed, "for me the easiest is to draw chart, but I don't know there is some faster way [referring to a formula]."



(a) (b)

Figure 1: Liv's Source Table (a) and Treatment of Table (b)

***Treatment* of Source representation to Determine a Symbolic Representation**

To help Liv transform her table into a symbolic representation, the interviewer asked Liv what the reproduction would look like if there were c cells present in the bowl initially. Liv constructed the chart in Figure 1(b), where she wrote the number of cells at time t in terms of the number of cells present at time $t-1$. On her calculator, Liv checked the values of 2^4 and 2^5 to see if they aligned with the number of cells at $t = 2$ hours and $t = 2.5$ hours as depicted in her table in Figure 1(a). In doing so, we interpret that Liv was implicitly considering $C_4 = C_3 \cdot 2 = C_2 \cdot 2 \cdot 2 = C_1 \cdot 2 \cdot 2 \cdot 2 = C \cdot 2 \cdot 2 \cdot 2 \cdot 2$. After confirming that the numbers do align, Liv first wrote C^{X+1} to represent the number of cells. Unable to explicitly state what C or X in her expression represented, Liv wanted to determine a way to include "number of half hours" in her expression. To accomplish this, Liv considered a specific case of $t = 10$ hours and posited that there would be 20 half hours. She then modified her symbolic representation to be 2^X, where X was the number of half hours. She then wrote that $1 \cdot 2^X$ would be the number of cells if there were 1 cell initially.

***Conversion* of Source Representation to Determine a Symbolic Representation**

To determine a more general expression, Liv considered a specific case: 5 cells were present initially. Liv wrote $5^{2 \cdot 20}$, where 20 in her expression signified the number of half hours and 2 signified the cells doubling. Upon request, Liv compared her model for the number of cells present when starting with 5 cells — $5^{2 \cdot 20}$—to her model when starting with 1 cell—2^X. She compared the values of 2^{20} and $1^{2 \cdot 20}$, and realized that they did not have equal outputs.

Upon suggestion by the interviewer, Liv drew diagrams for when there was initially one cell (Figure 2(a)) and 5 cells (Figure 2(b)) in the bowl. After drawing the diagram, Liv reasoned: "each individual cell [when starting with 5 cells] will follow the same pattern as if it were just starting out with just one cell." She further stated that in Figure 2(b), 5 copies of the process in Figure 2(a) were taking place. Through her reasonings, we interpret that Liv was comparing the number of cells present in the scenario as depicted in Figure 2(b) to the number of cells present in the scenario depicted in Figure 2(a), at each time step. She referred back to her table in Figure 1(a) and said that there would be $5 \cdot 4096 = 20{,}480$ cells at the end of 6 hours.

Consequently, she modified the number of cells present in the bowl at $t = 10$ hours as $5 \cdot 2^{20}$ (Figure 2(c)). Liv generalized this expression by nominalizing what each of the numbers in her expression signified: 5 signified the number of cells, 2 signified the process of cells doubling, and 20 signified the number of half hours (see Figure 2(c)). She checked her model by considering a known case of $t = 6$ hours and got $20{,}480$ yeast cells, where she simultaneously moved between her representations in figures 1(a) and 2(c). Liv produced 3 types of written semiotic representations (table, diagram, symbolic) in which the treatment and conversion of her source representation (Figure 1(a)) aided her in constructing a symbolic representation for the Baker's yeast scenario (see Figure 2(a)).

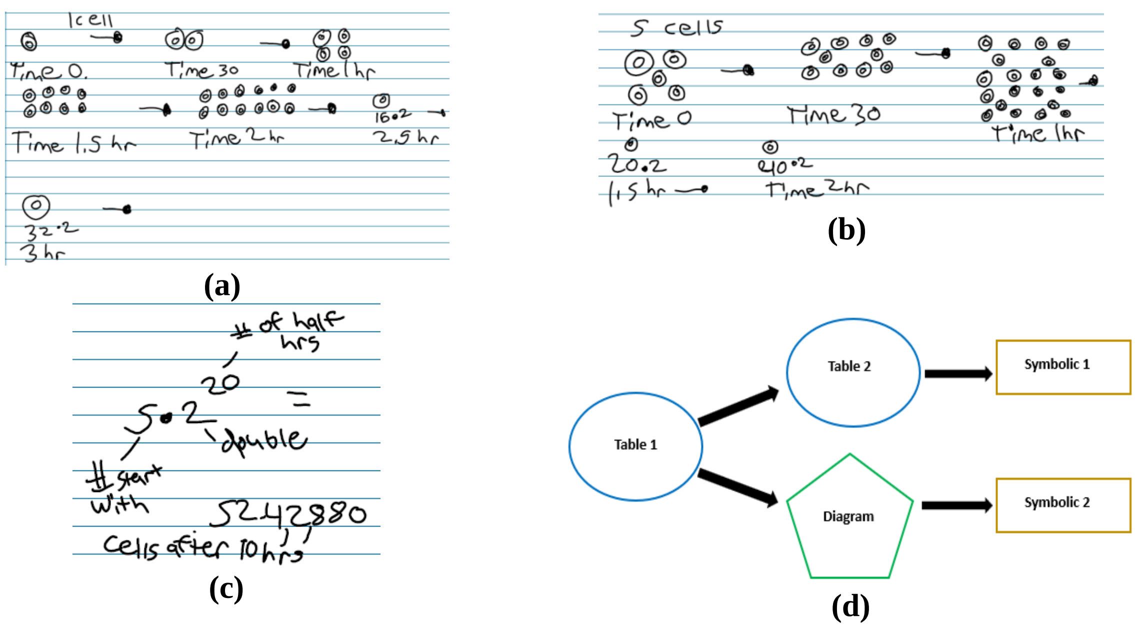


Figure 2: Liv's diagram for cells populating (a, b), symbolic representation (c), and network of types of representations (d).

Discussion

Students' reasonings, as they engage in modeling activities, are ongoing. However, students transforming from one representation to another can be taken as pivotal moments in their cognitive processes. This is because, during these shifts, students are either reorganizing their already existing conceptual structures or developing new ones. Therefore, these shifts can be seen as sensitive points to learning. Our findings suggest that students' representations can be leveraged to not only trace the evolution of their model through the inscriptions they make (Czocher & Hardison, 2019), but also in guiding them towards the modeling goal educators have for them. Students' *learning* of modeling and students' creations, interpretations, and coordination of multiple representations while *doing* modeling are interconnected (Dreyfus, 1991). Therefore, our study instigates a conversation within the modeling education community to answer questions such as how can a modeler's representations be leveraged to articulate what that modeler has learned during model construction? —a research problem yet to be solved. While our analysis attended to the transformations of representations, the focus of analysis was not on the mental operations that aided those transformations. Future research can network theories (Radford, 2008) of representations together with other compatible theories to capture the complexities and intricacies of model construction.

THE USE OF TAPE DIAGRAMS: A SCOPING REVIEW

Yue Ma
University of Delaware
yuemajoy@udel.edu

Tape diagrams, which are also known as strip diagrams, bar models, bar diagrams, length models, model-drawing strategy, percentage bars, and model methods, may be a powerful tool for developing students' conceptual understanding and problem solving abilities in mathematics. Murata (2008) observes that students in Japan and Singapore outperformed U.S. students in the Trends in International Mathematics and Science Study (TIMSS) in 2003, and associates this finding with a systematic and consistent curricular emphasis on tape diagrams across grades, unlike the U.S.'s inconsistent usage. She and Timothy (2022) argue that mathematical word problems across grade levels can be solved using tape diagrams. Empirical studies have also shown that tape diagrams have the potential to improve students' problem-solving skills in the context of algebraic word problems involving both whole numbers and fractions (e.g., Ng et al., 2009), addition and subtraction problems involving whole numbers (e.g., Osman et al., 2018), algebra word problems involving whole numbers (e.g., Baysal et al., 2022), fraction and percentage problems (e.g., Dennis et al., 2016; Sharp et al., 2017).

In the above-mentioned studies, none of the studies focused on lower-achieving students. The participants in these studies were students with learning disabilities, average-ability students, above average-ability students, and randomly selected students. Of these studies, some studies randomly recruited their participants (e.g., de Koning et al., 2022). One study focused on students with mathematics difficulty (i.e., Morin et al., 2017). One study focused on higher-achieving students and average-achieving students (i.e., Ng et al., 2009). One study focused on higher-achieving students (i.e., Maglicco et al., 2016), and one study focused on average-achieving students (i.e., Mahoney, 2012). Two studies applied different scales of criteria. The synthesis of the participants in these studies revealed that there is no study focused on lower-achieving students. Lower-achieving students constitute a significant proportion of U.S. students and should be researched and offered support. Therefore, the focus on lower-achieving students might be one study area of using tape diagrams.

In the above-mentioned studies, few studies used tape diagrams as the sole intervention. Of these studies, eight studies used tape diagram drawing with step-by-step instructions on problem solving (e.g., Green, 2009; Preston, 2016; Dennis et al., 2016). Four studies did not have any information about the intervention (i.e., Putrawangsa et al., 2021; Osman et al., 2018; Van Galen et al., 2013; Madani et al., 2018). Two studies included some information about the intervention (i.e., Shah et al., 2021; Baysal et al., 2022). The synthesis of the intervention showed that tape diagrams might not be the sole intervention. Other types of interventions are always accompanied with tape diagrams. More studies can be conducted on students' understanding of tape diagrams and how students develop tape diagrams as an effective tool to solve problems.

Of these works, most of the studies focused on students' correct problem solving (e.g., Preston, 2006; Mahoney, 2012; Maglicco, 2016; Putrawangsa et al., 2012). Only three studies described students' obstacles while using tape diagrams to solve problems (i.e., Baysal et al., 2022; Green, 2009; Madani et al., 2018). By learning students' obstacles in using tape diagrams, more effective instructions can be developed to support students' learning. Further exploration on "what do students notice and wonder about while they are using tape diagrams and how are the things that they notice and wonder about related to the errors they make?" can be done.

En respuesta a las iniciativas globales que abogan por la integración de problemas reales en la educación matemática para estimular el desarrollo de conocimientos y habilidades matemáticas, así como reflexiones sobre los desafíos ambientales, este estudio se centró en analizar el conocimiento matemático que emerge cuando un grupo de estudiantes universitarios aborda una actividad (MEA) en el contexto de la escasez de agua. El marco teórico fue la Perspectiva de modelos y modelación. El análisis cualitativo permitió concluir que la MEA propició que los estudiantes profundizaran en el contexto e incorporaran sus experiencias personales en el proceso de modelación. Además, exhibieron el uso de sus conocimientos como razones, porcentajes, proporciones, variación, razón de cambio constante, y estimación para describir y predecir la escasez de agua en el lago de Chapala.

Palabras clave: Modelación, función, representaciones matemáticas

Introducción

De acuerdo con la UNESCO & MGIEP (2017) se requiere ampliar los esfuerzos educativos para introducir en la educación matemática problemáticas reales para apoyar el desarrollo de conocimiento, habilidades matemáticas y la reflexión de los estudiantes hacia los retos ambientales del mundo. En este artículo se reportan los resultados de una investigación que se enfocó en describir el conocimiento matemático relacionado con el concepto función que emerge cuando un grupo de estudiantes de nivel universitario resuelven una situación-problema cercana a la vida real. La situación-problema fue creada en el contexto de la escasez del agua, tópico importante en los Objetivos de Desarrollo Sostenible. La pregunta de investigación fue ¿qué conocimiento matemático relacionado con funciones exhiben los estudiantes universitarios al construir modelos para resolver una situación problema cercana a la vida real?

Marco Teórico

Este estudio se basó en la Perspectiva de Modelos y Modelación (MMP, por sus siglas en inglés), la cual plantea que el proceso de desarrollo de conocimiento matemático puede describirse como un proceso no lineal de desarrollo de modelos que se modifican de manera continua durante la interacción de un individuo o estudiante con sus compañeros o maestro para resolver una situación problemática (Ärlebäck & Doerr, 2015; Lesh, 2010).

Dentro de esta perspectiva, un modelo se define como un sistema formado por elementos, relaciones, reglas y operaciones que pueden utilizarse para dar sentido, explicar, predecir o describir otro sistema (Doerr & English, 2003; Lesh & Doerr, 2003). De acuerdo con Lesh y Doerr (2003) cuando los estudiantes construyen modelos, sus ideas se expresan a través de una variedad de medios de representación, en los cuales los significados matemáticos están distribuidos (Figura 1). La elaboración de modelos implica que los estudiantes sigan múltiples iteraciones donde expresan, prueban y validan el modelo (Lesh & Lehrer, 2003). Estas iteraciones implican "la comprensión de la situación problemática, el desarrollo de un modelo matemático como solución al problema planteado, la expresión del modelo a través de alguna forma de representación como tablas, gráficos y ecuaciones, la comprobación de la utilidad del modelo y la revisión/refinamiento del modelo si es necesario" (Sevinc, 2021, p. 80).

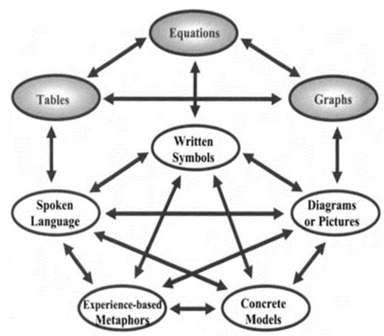

Figura 1: Medios de representación que pueden ser utilizados en un modelo. Esquema tomado de Lesh y Doerr (2003, p. 12)

La MMP propone que se utilicen Actividades Provocadoras de Modelos (MEAs, por sus siglas en inglés Model Eliciting Activities) para propiciar el aprendizaje de las matemáticas. Las MEAs son actividades diseñadas para conocer las concepciones e ideas matemáticas iniciales de los alumnos mientras desarrollan sus habilidades como solucionadores de situaciones problemáticas reales y significativas (Doerr, 2016). Resolver MEAs implica que los estudiantes puedan construir maneras útiles de interpretar la naturaleza de los datos, las metas y posibles trayectorias de solución de la situación problema; estas actividades demandan procesos de matematización que apoyen la toma de decisiones de un cliente a través la creación de modelos compartibles y reutilizables (Ärlebäck & Doerr, 2018; Sevinc & Lesh, 2018).

Metodología

La investigación fue de tipo cualitativo. Participaron 12 estudiantes que cursaban los últimos semestres de una licenciatura en matemáticas, quienes fueron organizados en cuatro equipos (A, B, C, D), cada uno conformado por tres integrantes. De acuerdo con el profesor del curso, esta fue la primera vez que los estudiantes participaban en la resolución de una MEA.

La MEA titulada "El día cero" fue construida con base en los seis principios de diseño descritos por Lesh et al. (2003). El contexto aborda uno de los problemas medioambientales relacionados con la escasez de agua, específicamente el decrecimiento del volumen de agua del

Lago de Chapala del estado de Jalisco. En la MEA se solicita a los estudiantes que ayuden a Sonia a describir la disminución de agua del Lago de Chapala y predecir el desabasto a la Zona Conurbada de Guadalajara (ZCG) con el paso de los años. En la nota periodística los estudiantes pueden identificar información como la siguiente: la población total de la ZCG según el Censo de Población y vivienda en 2010, la capacidad total del Lago de Chapala, así como el porcentaje de agua en el Lago hasta el 28 de febrero de 2023. La actividad se llevó a cabo en dos sesiones, cada una de aproximadamente 60 minutos. En la primera sesión los estudiantes escribieron la carta y la leyeron a todo el grupo. En la segunda, en una discusión plenaria, explicaron con detalle su carta. Para ello realizaron dibujos, tablas y gráficas en el pizarrón. La toma de datos fue a través de la recolección de las cartas escritas, audios de la sesión grupal, y fotos de las contribuciones en el pizarrón durante la sesión plenaria. Tres de los autores de este reporte apoyaron al investigador principal en la recolección de datos, transcribieron y codificaron la información en: a) conocimiento matemático asociado al concepto de función utilizado en la construcción de los modelos y b) uso de representaciones (Figura1). Finalmente, analizaron y discutieron en grupo los hallazgos y redactaron el reporte.

Resultados y Discusión

A continuación, se hace una descripción de los modelos construidos por los estudiantes y los conocimientos matemáticos subyacentes. Los modelos se denominaron de acuerdo con la idea principal utilizada en las cartas. Durante el proceso de creación de modelos, todos los equipos discutieron el fenómeno y reflexionaron sobre el cúmulo de variables que lo afectaban. Sin embargo, ante la solicitud de la MEA de escribir una carta para ayudar a Sonia, tomaron decisiones que les permitieron construir respuestas.

Modelo: el volumen del lago cambia

El equipo A sugirió medir el volumen de agua del lago de Chapala. Propuso atar un objeto pesado a una cuerda, sumergir el peso al lago y determinar la profundidad del lago. Con base en ello, sugirió calcular el volumen del lago y seguir este procedimiento cada año para predecir la disminución del nivel de agua. El equipo explicó que podrían partir de la hipótesis de un lago con forma semiesférica para hacer más fáciles los cálculos. Considerando las representaciones mencionadas por Lesh y Doerr (2003), el equipo A utilizó principalmente: lenguaje hablado, diagramas o dibujos y modelos concretos. El conocimiento matemático distribuido en estas representaciones fue: longitud, volumen y razón de cambio (volumen/año).

Modelos: el desabasto de agua puede ser en tres años

El equipo B sugirió calcular el gasto del agua del lago de Chapala mediante el uso de los datos incluidos en la nota periodística. Obtuvo el volumen porcentual del agua del lago y supuso un consumo constante de 8.27% cada tres meses. Este planteamiento de una razón de cambio constante de consumo de agua permitió al equipo crear su modelo y estimar cuándo podría ocurrir el día cero, sin necesidad de conocer el volumen preciso del agua del lago. Predijo que en tres años se acabaría el agua del lago bajo las condiciones iniciales planteadas.

Considerando las representaciones mencionadas por Lesh y Doerr (2003), el equipo B utilizó: lenguaje hablado y símbolos escritos. El conocimiento matemático distribuido en estas representaciones fue: porcentajes, razones, proporciones y estimación, todos ellos asociados a una función lineal ya que se partió de la idea inicial de un consumo constante de agua.

Modelo: muchas variables y poca información

El equipo C comentó que había poca información en el problema y para describir el fenómeno influían diversas variables como la cantidad de agua utilizada por los habitantes y las empresas, la influencia del crecimiento poblacional y de la cantidad de empresas, y el historial del uso del agua en el transcurso de los años. En la sesión plenaria el equipo construyó un histograma para explicar cómo podría comportarse la disminución de agua del lago de Chapala cada año. Además, argumentó que la fecha en la cual llegaría el día cero dependía del consumo por los habitantes y del consumo por las empresas, el cual es mayor.

El equipo consideró que debido a que no tenían muchos datos en el problema y la disminución del agua podía deberse a muchas variables, no podía construir y proponer un modelo matemático preciso. Requerían de más información por la gran cantidad de variables que influían en un fenómeno como este. Esta percepción de falta de información es común que emerja al resolver problemas abiertos (Vargas-Alejo et al., 2018a; Vargas-Alejo et al., 2018b). Algunos estudiantes enfocan su discusión en la diversa cantidad de variables que hay alrededor de un fenómeno y la dificultad de construir algún modelo ante esa situación.

Considerando las representaciones mencionadas por Lesh y Doerr (2003), el equipo C utilizó: lenguaje hablado y gráficas. Algunos de los objetos matemáticos distribuidos en estas representaciones fueron: razones y porcentajes.

Modelo: el desabasto del lago puede ser en 60 años

El equipo D hizo suposiciones con base en la información de la nota periodística y datos que investigaron en internet, por decisión propia, para describir la disminución de agua del Lago de Chapala y predecir el desabasto a la ZCG. Estimaron que había un decrecimiento constante que equivalía al 1% por año, desde el año 2010 hasta el 2023. Con este dato, propusieron un modelo lineal y predijeron que bajo estas condiciones iniciales planteadas podríamos tener agua por un periodo de 60 años más. El uso de porcentajes obtenidos en su búsqueda en internet y en la nota periodística, así como el planteamiento de la hipótesis de una razón de cambio constante para estimar el desabasto de agua, permitió al equipo construir su modelo y estimar cuándo podría ocurrir el "día cero" para el Lago de Chapala, que definió como el momento en el que quedara del 5 al 8% de agua en el lago.

Considerando las representaciones mencionadas por Lesh y Doerr (2003), el equipo D utilizó: lenguaje hablado, símbolos escritos y gráficas. El conocimiento matemático distribuido en estas representaciones fue: variables, variación, proporciones, razón de cambio (porcentaje de desabasto / año), función lineal y estimación.

Conclusiones

El conocimiento matemático exhibido por los estudiantes al construir sus modelos para describir la disminución de agua del Lago de Chapala y predecir el desabasto a la ZCG puede resumirse en lo siguiente. El equipo A usó longitud, volumen y razón de cambio (volumen / año), mientras que el equipo C utilizó razones y porcentajes para describir el comportamiento del fenómeno. Ninguno de los equipos A y B predijeron una fecha de desabasto. Los equipos B y D usaron razones, porcentajes, proporciones, variación y razón de cambio constante para estimar una solución. Los equipos consideraron la necesidad de describir el desabasto con base en alguna tasa de cambio, conocimiento asociado al concepto de función. Tal como señala Lesh y Doerr (2003) las experiencias personales, así como académicas influyeron en el proceso de modelación y, por lo tanto, en las reflexiones sobre la problemática.

La MEA, diseñada bajo los seis principios de Lesh et al. (2003), permitió que los estudiantes se enfrentaran a la construcción de un modelo, una experiencia novedosa para ellos. Los estudiantes matematizaron, es decir, tomaron decisiones para reducir variables y relacionarlas, estimaron una respuesta que funcionara bajo ciertas condiciones; finalmente, documentaron y auto evaluaron su modelo. La MEA posibilitó que los estudiantes conectaran conocimientos matemáticos con la situación planteada, desarrollaran y discutieran sus habilidades de modelación y reflexionaran sobre temas de sostenibilidad, respondiendo así a las necesidades planteadas por la UNESCO y MGIEP (2017) para ampliar los esfuerzos educativos frente a los retos ambientales del mundo que estamos viviendo.

Agradecimientos

INFERENTIAL KNOWLEDGE: THE GLUE THAT HOLDS THE STEPS IN A PROCEDURE TOGETHER

In mathematics education, knowledge is often divided into conceptual knowledge and procedural knowledge. These two knowledge types are sometimes seen as competing for teachers' attention and curricular focus. Similarly, there exists a perceived dichotomy between proof-based mathematics and procedure-based mathematics. In this context, learning procedures, which include computations and calculations, is frequently viewed as learning how to execute them to obtain answers. However, from our perspective, procedures should be understood as a sequence of inferences. Thus, we propose the construct of inferential knowledge *as an alternative to the traditional conceptual-procedural divide. We present* inferential decomposition *as a technique to deconstruct the knowledge required in understanding a procedure inferentially. We advocate for using inferential knowledge to integrate sensemaking and explanation within procedures.*

Keywords: Algebra and Algebraic Thinking, Reasoning and Proof, High School Education, Undergraduate Education

Deductive inference-making is paramount to mathematics. However, in some sub-disciplines of school mathematics, the core inferential basis is sometimes hidden behind routines and algorithms. We address this by introducing an *inferential knowledge* framework that serves a dual purpose of highlighting the inferences within procedures and also deconstructing the types of knowledge underlying an understanding of the validity of these inferences. Our inferential knowledge approach: 1) sheds light onto decades-long debates about procedural knowledge versus conceptual knowledge, 2) highlights a viable opportunity for incorporating sensemaking into learning already standardized procedures, and 3) provides potential avenues for smoothing the transition from calculation-centric mathematics (where inferences are often below the surface) to proof-centric mathematics (where inferences are more transparent).

Inferences Hidden in Procedures: Two Examples

To help illustrate the fundamental perspective driving this work, that inferences underlie procedures, we discuss two typical procedure-centric examples: The first is in the context of introductory calculus, specifically "implicit differentiation"[3].

Example 1: The Ladder Problem and Implicit Differentiation

Consider the procedure of implicit differentiation. Figure 1, below, displays an example of a fairly common introductory calculus problem whose standard solution utilizes such a procedure.

---

[3] We refer to the described method for solving this problem as "implicit differentiation" for convenience, even though it may not technically qualify as such (Mirin & Zazkis, 2020).

A 3-meter ladder is sliding down a vertical wall. The top of the ladder is sliding down the wall at 0.1 m/s. Using y to represent the height of the ladder's top from the floor, and x to represent the distance of the ladder's bottom from the wall (both in meters), we have the equation $x^2+y^2=9$. Find the speed of the bottom of the ladder

Figure 1: *The Ladder Problem*

A student is likely to procedurally take $\frac{d}{dt}$ of both sides of

1. $x^2 + y^2 = 9$,

substitute in the given information, perform some manipulations, and then arrive at the answer. Mirin and Zazkis (2020) propose a way of conceptualizing this implicit differentiation procedure in a way that coheres with typical introductory calculus material: viewing the equation (1) as an equality of functions (of *t*), we use the fact that sameness of function implies sameness of derivative to infer that the derivative (with respect to t) of the function represented by the left hand side is the same as the derivative of the function represented by the right hand side. This then implies that:

2. $\frac{d}{dt}(x^2 + y^2) = \frac{d}{dt}(9)$.

While there are more steps (inferences) to solve this particular problem, here we focus on the very first step in transitioning from equation (1) to equation (2). We note that understanding why a procedure is valid encompasses other mathematical understandings. In the context of the ladder problem, Mirin and Zazkis (2020) propose that understanding why implicit differentiation is valid is tantamount to viewing the procedure as an inference from function equality to derivative equality (from equation (1) to (2)), and the authors consider the conceptualizations involved in understanding such an inference. Understanding equation (1) as a statement of function equality acts as a warrant for writing (2), a statement of derivative equality, which in turn acts as a warrant for performing the differentiation procedure. While there might be other productive ways of understanding (1) and (2) besides function and derivative equality (e.g. using a calculus grounded in differentials, as in Ely, 2021), our central point here is that underlying this common procedure of differentiating both sides of an equation is an inference from equation (1) to (2). Our broad point is that deductive inferences, such as the one shown above, are omnipresent in procedures but are often left tacit outside proof centered contexts.

Example 2: The Number Line Problem and Solving Inequalities

We now consider another example to guide our discussion: a typical secondary school algebra problem, which we hereafter refer to as the number line problem.
